
Discussion Points:

- The top of a coupling (Regular Coupling, Measurement Port or Pumping Port) is the reference point for describing nominal depths and nominal lengths. Actual positions of packer seals and zone lengths are determined with respect to the appropriate reference positions.
- Packer Position Example: A packer with a nominal depth of 50 ft. (15.2m), will have a nominal packer seal position of 51.3 to 54.3 ft. (15.59 to 16.49m)
- Zone Length Example: A zone whose upper packer is at 50 ft. (15.2m) and bottom packer is at 70 ft. (21.3m) will have a nominal zone length of 15 ft. (4.6m) and an actual zone length (between packer seals) of 15.0+1.3+0.7 = 17.0ft. (4.6 + 0.39 + 0.2 = 5.19m)
- Information on the position of Measurement Port Valve and MOSDAX Transducer sensor, used for detailed calculation of piezometric level measurements, are described separately.

TABLE 4
MW-16-01WB As-Built Packer and Port Summary

Port No.	Zone No.	Measurement Port Depth (m)	Pumping Port Depth (m)	Magnetic Collar Depth (m)	Depth to top of Packer (m)	Top of Zone (m)	Bottom of Zone (m)
1	QA1	114.9			113.4	114.7	120.1
2	Zone 1	110.3		110.9	108.8	110.1	113.8
3	QA2	90.5			89.0	90.3	109.2
4	Zone 2	85.9		86.5	84.4	85.7	89.4
5	QA3	74.6			73.1	74.4	84.8
6	Zone 3	71.6		72.2	70.1	71.4	73.5
7	Zone 4	67.0		67.6	65.5	66.8	70.5
8	QA4	64.0			62.5	63.8	65.9
	Riser		62.5	61.3	30.5	31.8	62.9

Note 1: All depth measurements in meters below ground surface.
Note 2: All depth measurements use 'Nominal' casing lengths.
Note 3: Not corrected for borehole angle, deviation or borehole temperature effects.
Note 4: All Westbay Port depth measurements to upper edge of coupling item.
Note 5: Depths for top and bottom of zone based on packer seal position.

1	W020110			W0205	Measurement Port	8911			114.88
0	W0203								117.92

Depths are with respect to ground surface.

* Component positions are referenced to the top of the subject Westbay System coupling.

* Packer positions are referenced to the top Westbay System coupling on the packer.

Monitoring zone dimensions are determined as described on the attached "Dimensions of Packer Seals and Monitoring Zones".

The position of a MOSDAX Transducer in a Measurement Port is illustrated in the attached "MOSDAX Transducer Position".

This information may be used in calculating piezometric levels.

Polynomial Gage Factors (MPa) **A:** -2.4733E-09 **B:** -0.00050601 **C:** 4.7755

Pressure is calculated with the following equations:

Linear: $P(MPa) = C.F.(Li-Lc) - [Tk(Ti-Tc)] + [0.00010(Bi-Bc)]$

Polynomial: $P(MPa) = A(Lc)^2 + BLc + C + Tk(Tc-Ti) - [0.00010(Bc-Bi)]$

	Date (dd/mm/yy)	VW Readout Pos. B (Li)	Temp °C (Ti)	Baro (Bi)
Shipped Zero Readings:	6-May-15	9046	21.7	1018.6

Li, Lc = initial (at installation) and current readings
Ti, Tc = initial (at installation) and current temperature, in °C
Bi, Bc = initial (at installation) and current barometric pressure readings, in millibars
B units = B scale output of VW 2102, VW 2104, VW 2106 and DT 2011 readouts
B units = Hz^2 / 1000 ie: 1700Hz = 2890 B units

Borehole: MW14-01A (BH5, CFD-0402)
Borehole Angle: 90 [degrees]
Test Number: 1
Start of Test Interval: 137.25 [mbgs]
End of Test Interval: 148 [mbgs]
Test Type: constant rate injection
Packer System: hydraulic
Date: 12-Aug-14

Steady State Equation: $T = \frac{Q * \ln(R_i/R_{ew})}{2*(pi)*H}$ (Thiem, 1906)[1]

Flow Rate			
injection flow rate (Q)	3.82	[L/min]	collected in field
injection flow rate (Q)	6.4E-05	[m^3/s]	calculated
Water Level			
[pressure transducer data used to estimate static WL]			
pressure transducer depth[2]	138.3	[mbgs]	in pressure transducer holder below single packer
pipe stickup	3.00	[mags]	collected in field
pressure head	196.74	[psi]	pressure transducer reading, psi absolute
atmospheric pressure	12.81	[psi]	assumed
pressure head	129.32	[vertical m H2O]	corrected for atmospheric pressure
Water Level 1 (pressure transducer)	9.02	[vertical mbgs]	calculated
[if pressure transducer data not available]			
pipe stickup	0.33	[mags]	collected in field
depth to water	149.26	[mbtp]	Estimated from the closest static WL at MW14-01B on 8-Sept-2014 at 12:55 PM.
Water Level 2 (manual)	148.93	[vertical mbgs]	calculated
Excess Pressure Head (based on surface readings)[3]			
friction losses (hose to swivel)[4]	0.03	[m]	computed from http://www.tasonline.co.za/toolbox/pipe/velfirc.htm
friction losses (packer mandrel)[5]	0.27	[m]	IPI hydraulic packer manual or from Darcy-Weisbach equation (pneumatic packer)
most reliable static water level measurement	manual	transducer/manual	transducer (water level 1) or manual (water level 2)
analog pressure gauge height above ground	1.80	[vertical mags]	collected in field
analog pressure gauge reading	50.0	[psi]	collected in field
Exess Pressure Head (most reliable static WL)	185.6	[m]	H, calculated: static WL plus injection pressure, relative to ground surface
Excess Pressure Head Check (based on pressure transducer readings only)			
stabilized pressure[6]	263.52	[psi]	pressure transducer reading, psi absolute
differential pressure[7]	67	[psi]	difference between injection pressure and static WL pressure
Excess Pressure Head (transducer readings)	46.9	[m]	H, calculated - convert differential pressure to m H2O
Other Data			
radius of wellbore (R_w)	0.048	[m]	1/2 of the ID of open HQ borehole
length of test interval	10.8	[m]	collected in field
skin	0	[-]	assumed
effective wellbore radius (R_{ew})	0.048	[m]	$R_w$exp(Skin)
radius of influence (R_i)	10.8	[m]	assumed (equivalent to length of test interval)
$\ln(R_i/R_{ew})$	5.4	[-]	calculated
Is packer test interval in the unsaturated zone	TRUE	[TRUE/FALSE]	tests in the unsaturated zone are not considered reliable
Flow velocity in open borehole	0.0088	[m/s]	flow rate divided by cross-sectional area
Reynold's number	528.0	[-]	flow velocity x borehole diameter / kinematic viscosity of H2O (at approx. 4°C)
Is flow laminar (Reynold's No. <2040) or turbulent (>2040)	Laminar	[TRUE/FALSE]	results based on turbulent flow should be considered very approximate
Calculated Result			
Transmissivity -- T	3.0E-07	[m^2/s]	Thiem equation; uses excess pressure head based on most reliable of surface (manual) or transducer readings
Hydraulic Conductivity -- K	2.7E-08	[m/s]	equivalent to T divided by test interval

mbtp = metres below top of pipe, mags = metres above ground surface, mbgs = metres below ground surface

1. Thiem, G., 1906. Hydrologische Methoden; Gebhardt, Leipzig.
2. For hydraulic packer, transducer positioned 43" below bottom of packer in gauge holder; for pneumatic packer it is located just below stuffing box.
3. Data from analog pressure gauge read at surface used to guide test during injection and to confirm pressure transducer data
4. Computed from http://www.tasonline.co.za/toolbox/pipe/velfirc.htm assuming rubber lined pipe, 5 m length, ID 19 mm
5. IPI hydraulic packer manual or Darcy-Weisbach equation as provided in http://www.pipeflow.com/pipe-pressure-drop-calculations/pipe-friction-loss for the pneumatic packer.
6. Estimated stabilized pressure at end of injection period
7. Differential pressure eliminates absolute gauge effect, does not need to be corrected for atmospheric

Borehole: MW14-02B (BH-09, CFD-0418)
Borehole Angle: 90 [degrees]
Test Number: 2
Start of Test Interval: 102.50 [mbgs]
End of Test Interval: 125 [mbgs]
Test Type: constant rate injection
Packer System: pneumatic
Date: 21-Aug-14

Steady State Equation: $T = \frac{Q * \ln(R_i/R_{ew})}{2*(pi)*H}$ (Thiem, 1906)[1]

Flow Rate			
injection flow rate (Q)	4.13	[L/min]	collected in field
injection flow rate (Q)	6.9E-05	[m^3/s]	calculated
Water Level			
[pressure transducer data used to estimate static WL]			
pressure transducer depth[2]	-	[mbgs]	in pressure transducer holder below single packer
pipe stickup	2.93	[mags]	collected in field
pressure head	-	[psi]	pressure transducer reading, psi absolute
atmospheric pressure	-	[psi]	assumed
pressure head	#VALUE!	[vertical m H2O]	corrected for atmospheric pressure
Water Level 1 (pressure transducer)	#VALUE!	[vertical mbgs]	calculated
[if pressure transducer data not available]			
pipe stickup	1.27	[mags]	collected in field
depth to water	13.60	[mbtp]	Static WL in MW14-02B on 26-Aug-2014 at 20:00
Water Level 2 (manual)	12.33	[vertical mbgs]	calculated
Excess Pressure Head (based on surface readings)[3]			
friction losses (hose to swivel)[4]	0.04	[m]	computed from http://www.tasonline.co.za/toolbox/pipe/velfirc.htm
friction losses (packer mandrel)[5]	0.01	[m]	IPI hydraulic packer manual or from Darcy-Weisbach equation (pneumatic packer)
most reliable static water level measurement	manual	transducer/manual	transducer (water level 1) or manual (water level 2)
analog pressure gauge height above ground	1.83	[vertical mags]	collected in field
analog pressure gauge reading	30.0	[psi]	collected in field
Exess Pressure Head (most reliable static WL)	35.2	[m]	H, calculated: static WL plus injection pressure, relative to ground surface
Excess Pressure Head Check (based on pressure transducer readings only)			
stabilized pressure[6]	-	[psi]	pressure transducer reading, psi absolute
differential pressure[7]	#VALUE!	[psi]	difference between injection pressure and static WL pressure
Excess Pressure Head (transducer readings)	#VALUE!	[m]	H, calculated - convert differential pressure to m H2O
Other Data			
radius of wellbore (R_w)	0.048	[m]	1/2 of the ID of open HQ borehole
length of test interval	22.5	[m]	collected in field
skin	0	[-]	assumed
effective wellbore radius (R_{ew})	0.048	[m]	$R_w$exp(Skin)
radius of influence (R_i)	22.5	[m]	assumed (equivalent to length of test interval)
$\ln(R_i/R_{ew})$	6.2	[-]	calculated
Is packer test interval in the unsaturated zone	FALSE	[TRUE/FALSE]	tests in the unsaturated zone are not considered reliable
Flow velocity in open borehole	0.0095	[m/s]	flow rate divided by cross-sectional area
Reynold's number	569.9	[-]	flow velocity x borehole diameter / kinematic viscosity of H2O (at approx. 4°C)
Is flow laminar (Reynold's No. <2040) or turbulent (>2040)	Laminar	[TRUE/FALSE]	results based on turbulent flow should be considered very approximate
Calculated Result			
Transmissivity -- T	1.9E-06	[m^2/s]	Thiem equation; uses excess pressure head based on most reliable of surface (manual) or transducer readings
Hydraulic Conductivity -- K	8.5E-08	[m/s]	equivalent to T divided by test interval

mbtp = metres below top of pipe, mags = metres above ground surface, mbgs = metres below ground surface

1. Thiem, G., 1906. Hydrologische Methoden; Gebhardt, Leipzig.
2. For hydraulic packer, transducer positioned 43" below bottom of packer in gauge holder; for pneumatic packer it is located just below stuffing box.
3. Data from analog pressure gauge read at surface used to guide test during injection and to confirm pressure transducer data
4. Computed from http://www.tasonline.co.za/toolbox/pipe/velfirc.htm assuming rubber lined pipe, 5 m length, ID 19 mm
5. IPI hydraulic packer manual or Darcy-Weisbach equation as provided in http://www.pipeflow.com/pipe-pressure-drop-calculations/pipe-friction-loss for the pneumatic packer.
6. Estimated stabilized pressure at end of injection period
7. Differential pressure eliminates absolute gauge effect, does not need to be corrected for atmospheric

pipe stickup	0.97	[mags]	collected in field
depth to water	133.64	[mbtp]	Static WL in MW14-03B on 13-Oct-2014 at 15:41
Water Level 2 (manual)	132.67	[vertical mbgs]	calculated
Excess Pressure Head (based on surface readings)[3]			
friction losses (hose to swivel)[4]	1.47	[m]	computed from http://www.tasonline.co.za/toolbox/pipe/velfirc.htm
friction losses (packer mandrel)[5]	0.44	[m]	IPI hydraulic packer manual or from Darcy-Weisbach equation (pneumatic packer)
most reliable static water level measurement	manual	transducer/manual	transducer (water level 1) or manual (water level 2)
analog pressure gauge height above ground	1.52	[vertical mags]	collected in field
analog pressure gauge reading	1.0	[psi]	collected in field
Exess Pressure Head (most reliable static WL)	133.0	[m]	H, calculated: static WL plus injection pressure, relative to ground surface
Excess Pressure Head Check (based on pressure transducer readings only)			
stabilized pressure[6]	-	[psi]	pressure transducer reading, psi absolute
differential pressure[7]	#VALUE!	[psi]	difference between injection pressure and static WL pressure
Excess Pressure Head (transducer readings)	#VALUE!	[m]	H, calculated - convert differential pressure to m H2O
Other Data			
radius of wellbore (R_w)	0.048	[m]	1/2 of the ID of open HQ borehole
length of test interval	22.5	[m]	collected in field
skin	0	[-]	assumed
effective wellbore radius (R_{ew})	0.048	[m]	$R_w$exp(Skin)
radius of influence (R_i)	22.5	[m]	assumed (equivalent to length of test interval)
$\ln(R_i/R_{ew})$	6.2	[-]	calculated
Is packer test interval in the unsaturated zone?	TRUE	[TRUE/FALSE]	tests in the unsaturated zone are not considered reliable
Flow velocity in open borehole	0.0691	[m/s]	flow rate divided by cross-sectional area
Reynold's number	4144.7	[-]	flow velocity x borehole diameter / kinematic viscosity of H2O (at approx. 4°C)
Is flow laminar (Reynold's No. <2040) or turbulent (>2040)	Turbulent	[TRUE/FALSE]	results based on turbulent flow should be considered very approximate
Calculated Result			
Transmissivity -- T	3.7E-06	[m^2/s]	Thiem equation; uses excess pressure head based on most reliable of surface (manual) or transducer readings
Hydraulic Conductivity -- K	1.6E-07	[m/s]	equivalent to T divided by test interval

mbtp = metres below top of pipe, mags = metres above ground surface, mbgs = metres below ground surface

1. Thiem, G., 1906. Hydrologische Methoden; Gebhardt, Leipzig.
2. For hydraulic packer, transducer positioned 43" below bottom of packer in gauge holder; for pneumatic packer it is located just below stuffing box.
3. Data from analog pressure gauge read at surface used to guide test during injection and to confirm pressure transducer data
4. Computed from http://www.tasonline.co.za/toolbox/pipe/velfirc.htm assuming rubber lined pipe, 5 m length, ID 19 mm
5. IPI hydraulic packer manual or Darcy-Weisbach equation as provided in http://www.pipeflow.com/pipe-pressure-drop-calculations/pipe-friction-loss for the pneumatic packer.
6. Estimated stabilized pressure at end of injection period
7. Differential pressure eliminates absolute gauge effect, does not need to be corrected for atmospheric

Notes:

highlighted cells indicate period of test used for stabilized P and Q readings.

Borehole: MW14-04T (BH-06, CFD-0439)
Borehole Angle: 90 [degrees]
Test Number: 6
Start of Test Interval: 281.25 [mbgs]
End of Test Interval: 301 [mbgs]
Test Type: constant rate injection
Packer System: hydraulic
Date: 11-Sep-14

Steady State Equation: $T = \frac{Q * \ln(R_i/R_{ew})}{2*(pi)*H}$ (Thiem, 1906)[1]

Flow Rate			
injection flow rate (Q)	0.12	[L/min]	collected in field
injection flow rate (Q)	2.1E-06	[m^3/s]	calculated
Water Level			
[pressure transducer data used to estimate static WL]			
pressure transducer depth[2]	-	[mbgs]	in pressure transducer holder below single packer
pipe stickup	2.50	[mags]	collected in field
pressure head	-	[psi]	pressure transducer reading, psi absolute
atmospheric pressure	-	[psi]	assumed
pressure head	#VALUE!	[vertical m H2O]	corrected for atmospheric pressure
Water Level 1 (pressure transducer)	#VALUE!	[vertical mbgs]	calculated
[if pressure transducer data not available]			
pipe stickup	-	[mags]	collected in field
depth to water	-	[mbtp]	Static WL in MW14-02B on 26-Aug-2014 at 20:00
Water Level 2 (manual)	#VALUE!	[vertical mbgs]	calculated
Excess Pressure Head (based on surface readings)[3]			
friction losses (hose to swivel)[4]	0.00	[m]	computed from http://www.tasonline.co.za/toolbox/pipe/velfirc.htm
friction losses (packer mandrel)[5]	0.01	[m]	IPI hydraulic packer manual or from Darcy-Weisbach equation (pneumatic packer)
most reliable static water level measurement	manual	transducer/manual	transducer (water level 1) or manual (water level 2)
analog pressure gauge height above ground	2.00	[vertical mags]	collected in field
analog pressure gauge reading	70.0	[psi]	collected in field
Exess Pressure Head (most reliable static WL)	#VALUE!	[m]	H, calculated: static WL plus injection pressure, relative to ground surface
Excess Pressure Head Check (based on pressure transducer readings only)			
stabilized pressure[6]	-	[psi]	pressure transducer reading, psi absolute
differential pressure[7]	#VALUE!	[psi]	difference between injection pressure and static WL pressure
Excess Pressure Head (transducer readings)	#VALUE!	[m]	H, calculated - convert differential pressure to m H2O
Other Data			
radius of wellbore (R_w)	0.048	[m]	1/2 of the ID of open HQ borehole
length of test interval	19.8	[m]	collected in field
skin	0	[-]	assumed
effective wellbore radius (R_{ew})	0.048	[m]	$R_w$exp(Skin)
radius of influence (R_i)	19.8	[m]	assumed (equivalent to length of test interval)
$\ln(R_i/R_{ew})$	6.0	[-]	calculated
Is packer test interval in the unsaturated zone	#VALUE!	[TRUE/FALSE]	tests in the unsaturated zone are not considered reliable
Flow velocity in open borehole	0.0003	[m/s]	flow rate divided by cross-sectional area
Reynold's number	17.1	[-]	flow velocity x borehole diameter / kinematic viscosity of H2O (at approx. 4°C)
Is flow laminar (Reynold's No. <2040) or turbulent (>2040)	Laminar	[TRUE/FALSE]	results based on turbulent flow should be considered very approximate
Calculated Result			
Transmissivity -- T	#VALUE!	[m^2/s]	Thiem equation; uses excess pressure head based on most reliable of surface (manual) or transducer readings
Hydraulic Conductivity -- K	#VALUE!	[m/s]	equivalent to T divided by test interval

mbtp = metres below top of pipe, mags = metres above ground surface, mbgs = metres below ground surface

1. Thiem, G., 1906. Hydrologische Methoden; Gebhardt, Leipzig.
2. For hydraulic packer, transducer positioned 43" below bottom of packer in gauge holder; for pneumatic packer it is located just below stuffing box.
3. Data from analog pressure gauge read at surface used to guide test during injection and to confirm pressure transducer data
4. Computed from http://www.tasonline.co.za/toolbox/pipe/velfirc.htm assuming rubber lined pipe, 5 m length, ID 19 mm
5. IPI hydraulic packer manual or Darcy-Weisbach equation as provided in http://www.pipeflow.com/pipe-pressure-drop-calculations/pipe-friction-loss for the pneumatic packer.
6. Estimated stabilized pressure at end of injection period
7. Differential pressure eliminates absolute gauge effect, does not need to be corrected for atmospheric

Borehole: MW14-05A (BH-11A, CFD-0444)
Borehole Angle: 90 [degrees]
Test Number: 1
Start of Test Interval: 111.30 [mbgs]
End of Test Interval: 140.0 [mbgs]
Test Type: constant rate injection
Packer System: hydraulic
Date: 14-Sep-14

Steady State Equation: $T = \frac{Q * \ln (R_i/R_{ew})}{2*(pi)*H}$ (Thiem, 1906)[1]

Flow Rate			
injection flow rate (Q)	0.28	[L/min]	collected in field
injection flow rate (Q)	4.7E-06	[m^3/s]	calculated
Water Level			
[pressure transducer data used to estimate static WL]			
pressure transducer depth[2]	-	[mbgs]	in pressure transducer holder below single packer
pipe stickup	2.38	[mags]	collected in field
pressure head	-	[psi]	pressure transducer reading, psi absolute
atmospheric pressure	-	[psi]	assumed
pressure head	#VALUE!	[vertical m H2O]	corrected for atmospheric pressure
Water Level 1 (pressure transducer)	#VALUE!	[vertical mbgs]	calculated
[if pressure transducer data not available]			
pipe stickup	1.11	[mags]	collected in field
depth to water	133.20	[mbtp]	Static WL in MW14-05A on 11-Oct-14 at 15:45
Water Level 2 (manual)	132.09	[vertical mbgs]	calculated
Excess Pressure Head (based on surface readings)[3]			
friction losses (hose to swivel)[4]	0.00	[m]	computed from http://www.tasonline.co.za/toolbox/pipe/velfirc.htm
friction losses (packer mandrel)[5]	0.02	[m]	IPI hydraulic packer manual or from Darcy-Weisbach equation (pneumatic packer)
most reliable static water level measurement	manual	transducer/manual	transducer (water level 1) or manual (water level 2)
analog pressure gauge height above ground	2.07	[vertical mags]	collected in field
analog pressure gauge reading	52.5	[psi]	collected in field
Exess Pressure Head (most reliable static WL)	171.0	[m]	H, calculated: static WL plus injection pressure, relative to ground surface
Excess Pressure Head Check (based on pressure transducer readings only)			
stabilized pressure[6]	-	[psi]	pressure transducer reading, psi absolute
differential pressure[7]	#VALUE!	[psi]	difference between injection pressure and static WL pressure
Excess Pressure Head (transducer readings)	#VALUE!	[m]	H, calculated - convert differential pressure to m H2O
Other Data			
radius of wellbore (R_w)	0.048	[m]	1/2 of the ID of open HQ borehole
length of test interval	28.7	[m]	collected in field
skin	0	[-]	assumed
effective wellbore radius (R_{ew})	0.048	[m]	$R_w$exp(Skin)
radius of influence (R_i)	28.7	[m]	assumed (equivalent to length of test interval)
ln(R_i/R_{ew})	6.4	[-]	calculated
Is packer test interval in the unsaturated zone	TRUE	[TRUE/FALSE]	tests in the unsaturated zone are not considered reliable
Flow velocity in open borehole	0.0007	[m/s]	flow rate divided by cross-sectional area
Reynold's number	39.10	[-]	flow velocity x borehole diameter / kinematic viscosity of H2O (at approx. 4°C)
Is flow laminar (Reynold's No. <2040) or turbulent (>2040)	Laminar	[TRUE/FALSE]	results based on turbulent flow should be considered very approximate
Calculated Result			
Transmissivity -- T	2.8E-08	[m^2/s]	Thiem equation; uses excess pressure head based on most reliable of surface (manual) or transducer readings
Hydraulic Conductivity -- K	9.8E-10	[m/s]	equivalent to T divided by test interval

mbtp = metres below top of pipe, mags = metres above ground surface, mbgs = metres below ground surface

1. Thiem, G., 1906. Hydrologische Methoden; Gebhardt, Leipzig.
2. For hydraulic packer, transducer positioned 43" below bottom of packer in gauge holder; for pneumatic packer it is located just below stuffing box.
3. Data from analog pressure gauge read at surface used to guide test during injection and to confirm pressure transducer data
4. Computed from http://www.tasonline.co.za/toolbox/pipe/velfirc.htm assuming rubber lined pipe, 5 m length, ID 19 mm
5. IPI hydraulic packer manual or Darcy-Weisbach equation as provided in http://www.pipeflow.com/pipe-pressure-drop-calculations/pipe-friction-loss for the pneumatic packer.
6. Estimated stabilized pressure at end of injection period
7. Differential pressure eliminates absolute gauge effect, does not need to be corrected for atmospheric

radius of influence (R_i)	19.3	[m]	assumed (equivalent to length of test interval)
$\ln(R_i/R_{ew})$	6.0	[-]	calculated
Is packer test interval in the unsaturated zone	FALSE	[TRUE/FALSE]	tests in the unsaturated zone are not considered reliable
Flow velocity in open borehole	0.0007	[m/s]	flow rate divided by cross-sectional area
Reynold's number	41.45	[-]	flow velocity x borehole diameter / kinematic viscosity of H2O (at approx. 4°C)
Is flow laminar (Reynold's No. <2040) or turbulent (>2040)	Laminar	[TRUE/FALSE]	results based on turbulent flow should be considered very approximate
Calculated Result			
Transmissivity -- T	2.8E-08	[m^2/s]	Thiem equation; uses excess pressure head based on most reliable of surface (manual) or transducer readings
Hydraulic Conductivity -- K	1.5E-09	[m/s]	equivalent to T divided by test interval

mbtp = metres below top of pipe, mags = metres above ground surface, mbgs = metres below ground surface

1. Thiem, G., 1906. Hydrologische Methoden; Gebhardt, Leipzig.
2. For hydraulic packer, transducer positioned 43" below bottom of packer in gauge holder; for pneumatic packer it is located just below stuffing box.
3. Data from analog pressure gauge read at surface used to guide test during injection and to confirm pressure transducer data
4. Computed from http://www.tasonline.co.za/toolbox/pipe/velfirc.htm assuming rubber lined pipe, 5 m length, ID 19 mm
5. IPI hydraulic packer manual or Darcy-Weisbach equation as provided in http://www.pipeflow.com/pipe-pressure-drop-calculations/pipe-friction-loss for the pneumatic packer.
6. Estimated stabilized pressure at end of injection period
7. Differential pressure eliminates absolute gauge effect, does not need to be corrected for atmospheric

4.4 Ground Temperature

The thermistor string was downloaded approximately five (5) weeks after installation which provided sufficient time for the cement to set and cool, and the sensors to equilibrate to ground conditions. The thermistor data displayed temperature stabilization useful for determining permafrost thickness for the final planning of the MW16-01WB installation. Permafrost thickness is on the order of 67 metres, with temperatures below 0°C between 0.5 and 67 metres below ground surface. Figure 10 demonstrates sensor temperature stabilization over the course of several weeks after installation.

Notes:
Samples and sample data with RED text are not considered to be representative of formation water (See Appendix 5-D for further discussion).

1. Reportable detection limits (RDL) presented are the lowest detection limit for a given parameter. Note that the detection limit may have been raised by the analytical laboratory for some analytical results (e.g., due to matrix interference). See Table 3-8 in the main report for further details regarding reportable detection limits between 2014 and 2019.

2. Duplicate sample JH42-08 (Lab ID: UN0655) was collected on 04-Oct-2018 and not 05-Oct-2018 (dummy date for blind duplicate sampling) as indicated in the laboratory Certificate of Analysis.

Notes:
Samples and sample data with RED text are not considered to be representative of formation water (See Appendix 5-D for further discussion).

1. Reportable detection limits (RDL) presented are the lowest detection limit for a given parameter. Note that the detection limit may have been raised by the analytical laboratory for some analytical results (e.g., due to matrix interference). See Table 3-8 in the main report for further details regarding reportable detection limits between 2014 and 2019.

2. Duplicate sample JH42-08 (Lab ID: UN0655) was collected on 04-Oct-2018 and not 05-Oct-2018 (dummy date for blind duplicate sampling) as indicated in the laboratory Certificate of Analysis.

Notes:

Samples and sample data with RED text are not considered to be representative of formation water (See Appendix 5-D for further discussion).

1. Reportable detection limits (RDL) presented are the lowest detection limit for a given parameter. Note that the detection limit may have been raised by the analytical laboratory for some analytical results (e.g., due to matrix interference). See Table 3-8 in the main report for further details regarding reportable detection limits between 2014 and 2019.

2. Duplicate sample JH42-08 (Lab ID: UN0655) was collected on 04-Oct-2018 and not 05-Oct-2018 (dummy date for blind duplicate sampling) as indicated in the laboratory Certificate of Analysis.

Notes:

Samples and sample data with RED text are not considered to be representative of formation water (See Appendix 5-D for further discussion).

1. Reportable detection limits (RDL) presented are the lowest detection limit for a given parameter. Note that the detection limit may have been raised by the analytical laboratory for some analytical results (e.g., due to matrix interference). See Table 3-8 in the main report for further details regarding reportable detection limits between 2014 and 2019.

2. Duplicate sample JH42-08 (Lab ID: UN0655) was collected on 04-Oct-2018 and not 05-Oct-2018 (dummy date for blind duplicate sampling) as indicated in the laboratory Certificate of Analysis.

Notes:

Samples and sample data with RED text are not considered to be representative of formation water (See Appendix 5-D for further discussion).

1. Reportable detection limits (RDL) presented are the lowest detection limit for a given parameter. Note that the detection limit may have been raised by the analytical laboratory for some analytical results (e.g., due to matrix interference). See Table 3-8 in the main report for further details regarding reportable detection limits between 2014 and 2019.

2. Duplicate sample JH42-08 (Lab ID: UN0655) was collected on 04-Oct-2018 and not 05-Oct-2018 (dummy date for blind duplicate sampling) as indicated in the laboratory Certificate of Analysis.

Notes:

Samples and sample data with RED text are not considered to be representative of formation water (See Appendix 5-D for further discussion).

1. Reportable detection limits (RDL) presented are the lowest detection limit for a given parameter. Note that the detection limit may have been raised by the analytical laboratory for some analytical results (e.g., due to matrix interference). See Table 3-8 in the main report for further details regarding reportable detection limits between 2014 and 2019.

2. Duplicate sample JH42-08 (Lab ID: UN0655) was collected on 04-Oct-2018 and not 05-Oct-2018 (dummy date for blind duplicate sampling) as indicated in the laboratory Certificate of Analysis.

Appendix 5-B: Groundwater Quality Summary Statistics

Notes:

1. Where analytical results are below the reportable detection limit (<RDL), the RDL values are used in the statistical calculations.
2. Analytical results for the following samples have been excluded from the statistical calculations: MW14-03A (12-Oct-2014), MW14-03B (06-Oct-2014), MW14-05A (02-Oct-2014), MW14-05B (03-Oct-2014, 24-Jun-2015, 14-Jul-2015, 09-Aug-2015, 08-Sep-2015), and MW15-06WB (21-Jun-2015). See Appendix 5-D for further discussion.
3. Analytical results for dissolved organic carbon and total organic carbon for all samples collected at Westbay monitoring wells (MW15-01WB to MW15-06WB, and MW16-01WB) have been excluded from the statistical calculations. See Appendix 5-D for further discussion.
4. SD = Standard Deviation

Notes:

1. Where analytical results are below the reportable detection limit (<RDL), the RDL values are used in the statistical calculations.
2. Analytical results for the following samples have been excluded from the statistical calculations: MW14-03A (12-Oct-2014), MW14-03B (06-Oct-2014), MW14-05A (02-Oct-2014), MW14-05B (03-Oct-2014, 24-Jun-2015, 14-Jul-2015, 09-Aug-2015, 08-Sep-2015), and MW15-06WB (21-Jun-2015). See Appendix 5-D for further discussion.
3. Analytical results for dissolved organic carbon and total organic carbon for all samples collected at Westbay monitoring wells (MW15-01WB to MW15-06WB, and MW16-01WB) have been excluded from the statistical calculations. See Appendix 5-D for further discussion.
4. SD = Standard Deviati

Notes:

1. Where analytical results are below the reportable detection limit (<RDL), the RDL values are used in the statistical calculations.
2. Analytical results for the following samples have been excluded from the statistical calculations: MW14-03A (12-Oct-2014), MW14-03B (06-Oct-2014), MW14-05A (02-Oct-2014), MW14-05B (03-Oct-2014, 24-Jun-2015, 14-Jul-2015, 09-Aug-2015, 08-Sep-2015), and MW15-06WB (21-Jun-2015). See Appendix 5-D for further discussion.
3. Analytical results for dissolved organic carbon and total organic carbon for all samples collected at Westbay monitoring wells (MW15-01WB to MW15-06WB, and MW16-01WB) have been excluded from the statistical calculations. See Appendix 5-D for further discussion.
4. SD = Standard Deviati

Notes:
1. Where analytical results are below the reportable detection limit (<RDL), the RDL values are used in the statistical calculations.
2. Analytical results for the following samples have been excluded from the statistical calculations: MW14-03A (12-Oct-2014), MW14-03B (06-Oct-2014), MW14-05A (02-Oct-2014), MW14-05B (03-Oct-2014, 24-Jun-2015, 14-Jul-2015, 09-Aug-2015, 08-Sep-2015), and MW15-06WB (21-Jun-2015). See Appendix 5-D for further discussion.
3. Analytical results for dissolved organic carbon and total organic carbon for all samples collected at Westbay monitoring wells (MW15-01WB to MW15-06WB, and MW16-01WB) have been excluded from the statistical calculations. See Appendix 5-D for further discussion.
4. SD = Standard Deviati

TECHNICAL MEMORANDUM

To:	**Jennie Gjertsen (Newmont Goldcorp)**	**Date:**	**December 15, 2021**
From:	**Elliott Skierszkan (UBC), Jordi Helsen (Lorax)**	**Project #:**	**A362-4**
Subject:	**Coffee Gold – Isotopic Analyses in Support of Baseline Hydrogeological Assessment 2019 Update**		

1. Introduction and Objective

The following memorandum, prepared by Lorax Environmental Services Ltd. (Lorax), presents results of groundwater and surface water characterization within the Coffee Gold Project (the Project) by use of isotopic analyses of hydrogen, oxygen, and carbon. The Project is located within the Whitehorse Mining District, Canada, 130 kilometers (km) south of Dawson City, Yukon. The objective is to provide a better understanding of groundwater flow and ages across the Project area. This memorandum complements the Coffee Gold Baseline Hydrogeological Assessment (Lorax, 2017) and the Coffee Baseline Hydrogeological Assessment 2019 Update (Lorax, 2021).

2. Background - Isotopes of Hydrogen, Oxygen, and Carbon as Hydrological Tracers

2.1 Stable Isotopes for Tracing Groundwater Provenance

There are multiple stable isotopes of oxygen (^{18}O, ^{17}O, ^{16}O) and hydrogen (^{2}H and ^{1}H). The ratios of these isotopes in water are altered during phase transfer such as evaporation, condensation, and freezing. Preferential partitioning of isotopes between phases (*e.g.*, water and vapour) is defined as isotope fractionation.

The delta notation (δ) is used to describe the stable isotope composition of water samples by normalizing the ratio (R) of heavy to light isotopes in samples relative to that of an international standard:

$$\delta = \frac{R_{sample} - R_{standard}}{R_{standard}} \times 1000 \qquad (1)$$

The $^{18}O/^{16}O$ ratio is typically used for oxygen, and $^{2}H/^{1}H$ for hydrogen. Delta values are expressed in per-mil (‰) units relative to the VSMOW standard (Vienna Standard Mean Ocean Water).

Water stable isotope ratios vary in precipitation and can therefore be used to trace groundwater sources and recharge history. In a general sense, $\delta^{18}O$ and $\delta^{2}H$ values decrease for precipitation occurring under colder conditions. For example, precipitation falling at higher altitude (colder temperatures) in a given region tends to have lower $\delta^{18}O$ and $\delta^{2}H$ values. Similarly, precipitation occurring during the colder winter months and falling as snow tends to have lower $^{18}O/^{16}O$ and $^{2}H/^{1}H$ ratios than precipitation occurring during the warmer summer months. These seasonal

pulses are most evident in surface water and shallow groundwater systems because mixing of recharge through advection-dispersion mutes this signal in deeper groundwater.

In deeper groundwater systems with residence times of thousands to tens of thousands of years, variations in $\delta^{18}O$ and $\delta^{2}H$ values can be used to indicate water that recharged during periods of colder climatic conditions, such as the Pleistocene glacial period.

The slope of $\delta^{2}H$ versus $\delta^{18}O$ in precipitation is also useful as a hydrological tracer. The slope can vary depending on the air humidity during the primary evaporation of a vapour mass in a source region (*e.g.*, the oceans), as well as any evaporation that occurs between the formation of rain or snow in a cloud and the transfer of that water into aquifers (*i.e.*, groundwater recharge). At the local scale, a local meteoric water line (LMWL) can be defined for a given region, which describes the slope of $\delta^{2}H$ against $\delta^{18}O$ data in local precipitation. Deviations of the slope in groundwater data relative to the LMWL can indicate evaporation that occurred between precipitation and recharge.

To aid in the interpretation of $\delta^{18}O$ and $\delta^{2}H$ values in groundwater samples from the Project site, a LMWL was developed by combining rain and snow isotope data available in the literature from the nearby cities of Dawson City and Mayo, Yukon (Lapp, 2015; IAEA, 2020). These cities are located 130 km north and 180 km east of the Project area, respectively, and the isotopic compositions of their precipitation follow very similar meteoric water line trends, supporting the use of pooled precipitation isotope data (n = 85 samples) from these cities to generate a LMWL applicable to the Project site (Figure 1). In addition, average $\delta^{18}O$ and $\delta^{2}H$ values for precipitation at the Project site were estimated using rain and snow isotope compositions at Mayo and accounting for the change in elevation between Mayo (504 metres above sea level (m asl) and the Project area (430 to ~1,300 masl). For these calculations, an elevation gradient of 0.28 ‰ for $\delta^{18}O$ per 100 m elevation gain was assumed, which has been deemed appropriate for the Yukon climate (Poage and Chamberlain, 2001). Further details describing the development of a LMWL and estimation of the isotopic composition of precipitation at the Project site are provided in Appendix A.

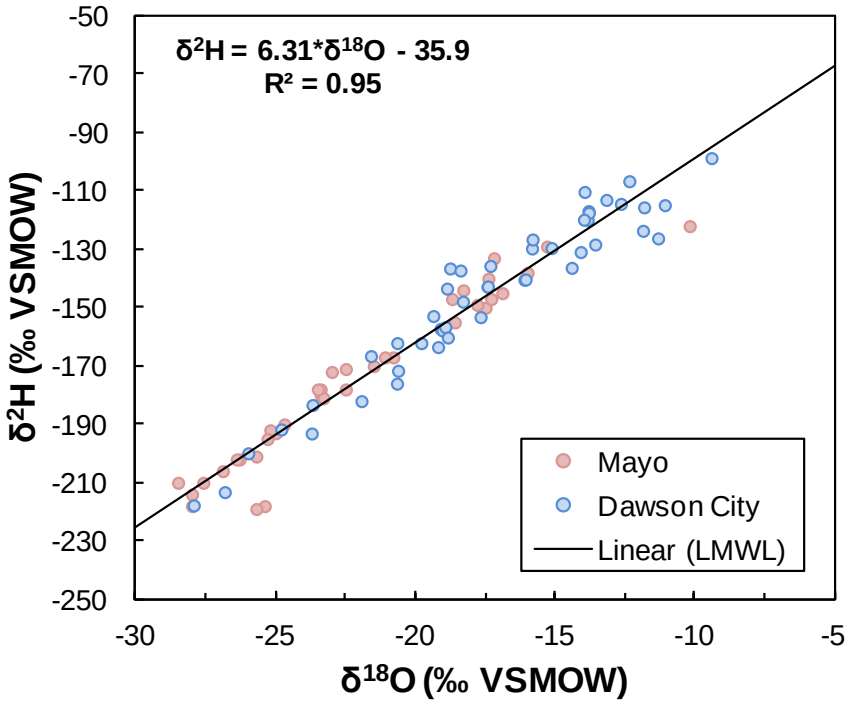

Figure 1: A local meteoric water line (LMWL) was developed for the Project site by pooling previously published isotope data for precipitation in the nearby cities of Dawson (Lapp, 2015) and Mayo, Yukon (IAEA, 2020).

2.2 Radioisotopes as Tracers of Groundwater Age

2.2.1 Overview

Tritium (^{3}H) and radiocarbon (^{14}C) are radioactive isotopes that decay at known rates through time and can therefore be used to estimate groundwater age (*i.e.*, mean residence time) assuming their concentrations at the time of recharge are known (Clark and Fritz, 1997). Both radioisotopes are naturally produced in the upper atmosphere and enter groundwater during precipitation and recharge events. These radioisotopes were also emitted by anthropogenic activity in massive quantities (*i.e.*, exceeding natural production) during Cold-War era nuclear weapons testing. Atmospheric ^{14}C concentrations were further impacted by humans since the industrial revolution because of combustion of fossil fuels that has released ^{14}C-free CO_2 into the atmosphere.

Tritium enters the hydrological cycle because it is incorporated into water molecules. Tritium data are expressed in tritium units (TU), where one TU corresponds to one ^{3}H atom per 10^{18} H atoms. The half-life of 12.32 years makes tritium a good qualitative tracer of relatively young (<70 years old) groundwater ages.

The half-life of radiocarbon is 5,730 years and it is therefore useful to determine the age of groundwater that is thousands of years old. Radiocarbon enters the hydrological cycle by uptake

of atmospheric $^{14}CO_2$ by biomass which enters the soil as organic matter. ^{14}C then enters groundwater through biodegradation of organic matter and release of this ^{14}C-bearing biomass into soil porewater as dissolved inorganic carbon (DIC). Raw radiocarbon data are expressed in units of percent modern carbon (pMC). A radiocarbon content of 100 pMC corresponds to the amount of radioactivity of ^{14}C equivalent to that of atmospheric CO_2 in 1890 (since that time, the ^{14}C content of atmospheric CO_2 has been altered by thermonuclear bomb testing and global anthropogenic combustion of fossil fuels). Older waters have lower pMC values due to radioactive decay.

Estimating groundwater age based on ^{14}C measurements requires corrections for dissolution of carbonate minerals from aquifer rocks and mineralization of ancient organic matter, which can generate ^{14}C-free DIC because many of these materials were formed hundreds of thousands to millions of years ago and thus all the radiocarbon has decayed in the time since their formation. Uncorrected radiocarbon dating of groundwater would therefore bias groundwater ages towards older values if ^{14}C dilution were not accounted for. In this memorandum, radiocarbon age corrections are based on the method of Pearson and Hanshaw (1970). Further details describing the method and radiocarbon age corrections employed in this memorandum are provided in Appendix B.

Hydrodynamic mixing creates uncertainty as to a water sample's absolute age for ages determined with both ^{3}H and ^{14}C radioisotopes. For example, groundwater mixing can contribute water to a well from different flow paths with a wide range of ages, meaning that the overall radioisotope age represents an average value of all the water sources contributing to that sample.

2.2.2 Mass Fractions of Young and Paleo Groundwater

Jasechko (2016a) proposes a method to estimate the fractions of young and paleo groundwaters (F_{young} and F_{paleo}, respectively) in a given groundwater sample on the basis of ^{3}H and ^{14}C measurements in samples. In this method, young groundwater is defined as groundwater that recharged between 1953 (*i.e.*, before the onset of large-scale thermonuclear bomb testing) and the time of sampling (*i.e.*, 2019). Paleo groundwater refers to groundwater that recharged prior to the end of the last major glaciation on Earth, approximately 11,700 years before present (BP; where present is defined as the year AD 1950). Further details describing the calculations involved in this method are presented in Appendix B.

It is important to note that there is substantial inherent uncertainty with calculated F_{young} and F_{paleo} values, therefore the results are interpreted as a qualitative assessment of the fraction of young and paleo groundwaters in a given sample, respectively (Jasechko, 2016a; Jasechko et al., 2017).

3. Isotope Samples and Data Collection

3.1 Surface Water, Aufeis and Groundwater Sampling

Isotope sampling was conducted between September 2014 and August 2019, and included samples of aufeis, surface water, and groundwater. Aufeis (*i.e.*, frozen groundwater seepage that accumulates within and adjacent to local creeks and streams at the Project site) is pervasive throughout the winter and melts during the freshet but can persist into the early summer. Surface water samples were collected at a total of eight locations in Latte, Halfway and YT-24 Creeks, while aufeis was sampled at three stations along Latte and Halfway Creeks. Groundwater was sampled from 15 monitoring wells in the Project area.

Stable isotope and tritium samples were typically collected in 1 L high-density polyethylene (HDPE) bottles between 2014 and 2019. Radiocarbon samples were collected in 1 L HDPE bottles in 2014 and 2015, and in 0.25 L amber glass bottles with a septum in August 2019. Radiocarbon samples collected in August 2019 were field filtered (0.45-micron), preserved with $ZnCl_2$ (1.25 grams per 250 mL sample), and kept cool until delivery to the UW-EIL.

3.2 Laboratory Analyses

Isotope samples collected in 2014 and 2015 were submitted to the Brigham Young University Laboratory of Isotope Geochemistry (BYU-LIG) in Provo, Utah, while samples collected in 2016, 2017 and 2019 were submitted to the University of Waterloo - Environmental Isotope Laboratory (UW-EIL) in Waterloo, Ontario. Stable isotope and radioisotope analyses and the corresponding precisions are presented in Table 1. Certificates of analysis for stable isotope and radioisotope samples provided by BYU-LIG and UW-EIL are presented in Appendix C.

Isotope samples sent to the BYU-LIG were analyzed for δ^2H, $\delta^{18}O$, and $\delta^{13}C$ using mass spectrometry, while ^3H samples were analyzed by electrolytic tritium enrichment followed by ultra-low level liquid scintillation spectrometry. The ^{14}C samples were precipitated as $BaCO_3$ at the BYU-LIG and splits of extracted CO_2 were analyzed using accelerator mass spectrometry (AMS) at the University of Georgia.

Samples sent to the UW-EIL were analyzed for δ^2H and $\delta^{18}O$ using a liquid water isotope analyzer, while the ^3H samples were enriched by electrolysis and then analyzed by liquid scintillation counting. For radiocarbon analysis, the sample was extracted under vacuum using H_3PO_4 to convert dissolved inorganic carbon (DIC) to CO_2, which was reduced to graphite and analyzed for ^{14}C by AMS. A subsample was analyzed for $\delta^{13}C$-DIC via dual inlet isotope ratio mass spectrometry (DI-IRMS). The AMS analysis was conducted at DirectAMS in Bothell, Washington.

Table 1:
Stable isotope and radioisotope parameters and precision (2014-2019)

Parameter	Units	BYU-LIG	UW-EIL
		2014-2015	2016-2019
$\delta^{2}H$	‰ VSMOW	1.0	0.8
$\delta^{13}C$	‰ VPDB	0.04 or 0.1 [1]	0.2
$\delta^{18}O$	‰ VSMOW	0.20 or 0.40 [2]	0.2
^{3}H	TU	0.3	0.8
^{14}C	pMC	0.07 - 0.20 [3]	0.040 - 0.26 [3]

Notes:
BYU-LIG = Brigham Young University Laboratory of Isotope Geochemistry, pMC = percent modern carbon, TU = tritium units, UW-EIL = University of Waterloo-Environmental Isotope Laboratory, VPDB = Vienna Pee Dee Belemnite, VSMOW = Vienna Standard Mean Ocean Water
1. Precision of $\delta^{13}C$ analyzed at BYU-LIG was 0.04 ‰ for samples collected between June and September 2015 and 0.1 ‰ for samples collected between September 2014 and April 2015.
2. Precision of $\delta^{18}O$ analyzed at BYU-LIG was 0.2 ‰ for samples collected between May and October 2015 and 0.4 ‰ for samples collected between September 2014 and April 2015.
3. Precision of radiocarbon counts vary by sample; consequently, a range is presented.

3.3 Sample Quality Assurance and Quality Control

A quality assurance/quality control (QA/QC) program was implemented to evaluate the quality of the isotope analyses. Six field duplicate samples collected in 2014 and 2015 were submitted for isotope analyses to the BYU-LIG, while six field duplicate samples collected in 2019 were submitted to the UW-EIL. In addition, internal reproducibility checks (*i.e.*, re-analysis) were completed at the UW-EIL on 26 samples collected in 2016 and 2017, and 14 samples collected in 2019. Isotope analytical results for field duplicate samples are presented in Appendix D (Table 1), while the results of the internal laboratory re-analysis of isotope samples are provided in Appendix D (Table 2).

Overall, the QA/QC analysis of isotope samples indicates reliable stable isotope ($\delta^{2}H$, $\delta^{18}O$) and radioisotope (^{3}H, ^{14}C) results for the interpretation of groundwater provenance and groundwater age tracing. The relatively large number of sampling locations, synoptic sampling at many locations, in addition to the general consistency of the data between sampling events, has yielded a robust isotopic data set. Some early inconsistencies with 2014 and 2015 $\delta^{13}C$ and ^{14}C data existed which were addressed with improved sampling protocols in 2019 that yielded satisfactory QA/QC results. Further details are provided in Appendix D.

4. Results and Discussion

This section discusses groundwater, surface water and aufeis isotope data collected as outlined in Section 3. The discussion covers stable isotope and radioisotope data. Stable isotope and radioisotope data for aufeis, surface water and groundwater samples are presented in Appendix D (Table 3).

4.1 Water Stable Isotopes

The stable isotope compositions of groundwater, surface water, and aufeis samples collected in the Project area generally plot along an array of similar slopes to the LMWL (Figure 2). The data plot slightly above the LMWL, which may reflect a slight difference in the source of water vapour that generates precipitation in the Project area in comparison to precipitation in Dawson City and Mayo.

Overall, groundwaters collected from the Project site are isotopically heavier than the estimated value for mean annual precipitation and plot closer to the isotopic composition of rain-dominated precipitation (May to October) than that of snow-dominated precipitation falling between November and April (Figure 2). This observation suggests that groundwater recharge at the Project site is more heavily driven by infiltration of rain than by snowmelt, and is consistent with a greater proportion of annual precipitation falling as rain (~70 %) and a smaller contribution from snow (~30 %) at an elevation of 975 m asl (Lorax, 2019). Similar results have been obtained in a groundwater stable isotope study in the nearby Ogilvie River Watershed, north of Dawson City, Yukon (Baranova, 2017). Surface waters are shifted towards an isotopically heavier range of values in comparison to groundwater. This may simply reflect surface water samples that were predominantly collected between late April and October, when their water budget included greater input from summer precipitation, which is expected to be isotopically heavier than the mean annual precipitation and groundwater discharge (Figure 2).

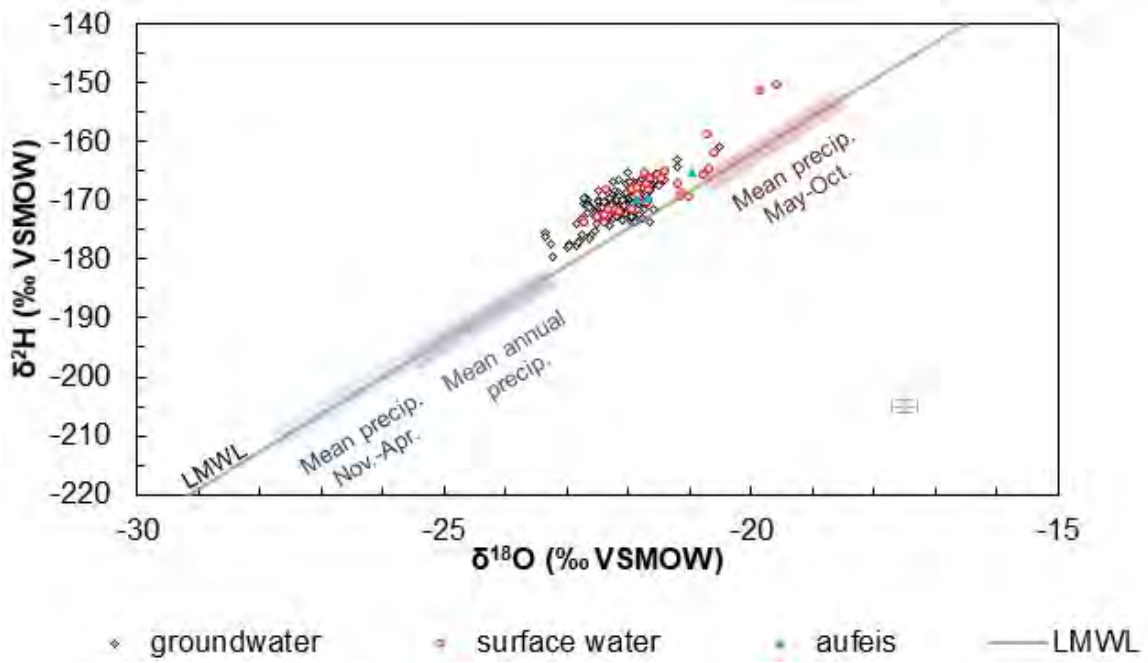

Figure 2: Isotopic composition of groundwater, surface water, and aufeis at the Project site. The LMWL was developed by combining precipitation isotope data from in Dawson City and Mayo (Lapp, 2015; IAEA, 2020). The range of estimated isotopic compositions for annual precipitation, rain-dominated precipitation (May-Oct.), and snow-dominated precipitation (Nov.-Apr.) are defined by purple, red, and blue shading, respectively. These ranges were calculated using isotope and precipitation data from Mayo (IAEA, 2020) and correcting for elevations encountered at the Project site (details in Appendix A).

There is considerable overlap in the stable isotope composition of groundwater at most monitoring wells, except for MW15-03WB (Figure 3). The water sampled at this location consistently has lower $\delta^{18}O$ and $\delta^{2}H$ values in comparison to other monitoring wells. This isotopically lighter signature at MW15-03WB is indicative of a colder recharge environment, which could be due to higher elevation precipitation or precipitation that fell during colder geological periods. For example, during the late-Pleistocene (50,000 to 20,000 years ago), $\delta^{18}O$ in precipitation was likely ~1 to 2 ‰ lower than during the Holocene (11,700 years ago to present time) due to a colder climate in extratropical areas (Jasechko, 2016b). In contrast, MW15-03AZ, which is screened in the active zone in the Halfway Creek valley, is characterized by isotopically heavier water, which indicates greater contribution of summer precipitation in the active zone flow system.

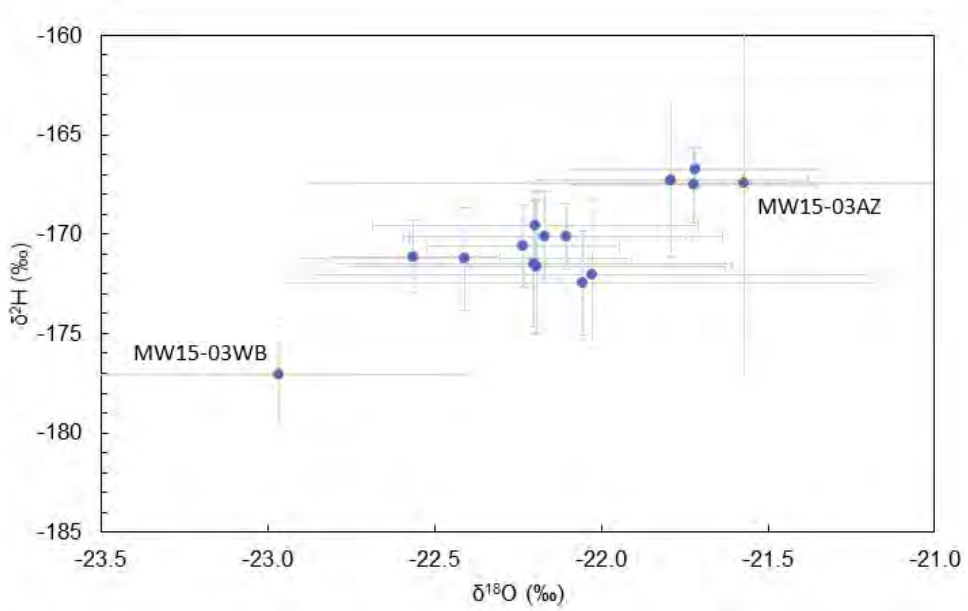

Figure 3: Mean stable isotope composition of groundwater at each monitoring well in the Project area (2014-2019). Error bars are ± 2 standard deviations.

4.2 Tritium and Radiocarbon

The Pearson and Hanshaw (1970) method for correcting radiocarbon age relies on assumptions of $\delta^{13}C$ of the recharge environment, which depends on factors including soil vegetation type and soil porewater pH (at the time of recharge). These factors cannot truly be known, and as a result $\delta^{13}C$ is commonly estimated (Clark and Fritz, 1997). For the interpretation of radiocarbon ages presented in this memorandum, a groundwater recharge pH of 7.0 and a soil $\delta^{13}C$ value of -23 ‰ (typical of C3-plant based ecosystems; Clark and Fritz, 1997) are assumed, which correspond to a $\delta^{13}C_{recharge}$ value of -17.3 ‰ (Table 2). It is worth mentioning that under a slightly lower soil pH (*e.g.*, pH 6.0), $\delta^{13}C$ of recharge under these conditions would change to -21.5 ‰, and the reported radiocarbon ages would be offset by approximately 1,000 to 2,000 years. The uncertainty inherent in this method should be considered when interpreting the calculated ^{14}C ages (Table 2).

Calculations of F_{young} and F_{paleo} are prone to large uncertainties given the large range in possible ^{3}H and ^{14}C concentrations since 1953 and over the last 60,000 years, respectively, as well as assumptions that must be made regarding $\delta^{13}C$ of recharge and DIC concentrations. Therefore, the results are interpreted using mean fractions of young and paleo waters in a qualitative manner.

Tritium and radioisotope data indicate that the majority of groundwater in high-elevation and sub-permafrost monitoring wells is at least 70 years old and may be thousands of years in age (Table 2). This includes groundwater from high-elevation monitoring wells in granite (MW14-05A, MW14-05B, MW16-01WB, MW15-05WB) and sub-permafrost north-facing terrain in gneiss (MW15-06WB, MW15-01WB). All these wells have little to no tritium and F_{young} values $\leq$0.1,

indicating that they are predominantly composed of water older than ~70 years (Figure 4, Figure 5). Calculated radiocarbon ages for these wells range from 6,500 to 22,400 years and F_{paleo} values range from 0.5 to 1, suggesting much longer residence times for sub-permafrost groundwater at high elevations at the Project site (Figure 6, Figure 7). The long groundwater residence times beneath permafrost in granite are supported by observations of low bedrock hydraulic conductivity at MW14-05A and MW14-05B which is $\leq 1x10^{-9}$ m/s and very slow well recharge rates observed during groundwater sampling.

In contrast, a large component of young groundwater with ages on the order of a few decades predominates along south-facing slopes above Latte Creek where permafrost is sparse (*i.e.*, MW14-02A, MW14-02B). Groundwater at MW14-02B and MW14-02A is tritiated (*i.e.*, contains tritium, with 5.4 and 7.2 TU, respectively) and has F_{young} values greater than 0.6 (Table 2:). A more active groundwater circulation pattern at these locations is consistent with higher hydraulic conductivity in the vicinity of MW14-02B, which ranges from $1x10^{-7}$ to $5x10^{-9}$ m/s. There is nevertheless a component of older groundwater that also appears to contribute to the water sampled at these locations, given calculated radiocarbon ages greater than 8,000 years and F_{paleo} values of 0.7 (Table 2). Groundwater mixing can account for this combination of young and old groundwater at MW14-02A and MW14-02B. The younger groundwater system in this area also appears in valley wells in Latte Creek at MW15-02AZ and MW15-02WB, which are tritiated (9.4 and 6.6 TU, respectively) and have F_{young} values of 1.0 and 0.7, respectively. These results indicate that permafrost-free and more rapid groundwater circulation on the south-facing slope above Latte Creek may be a major input to groundwater contributions in the Latte Creek valley.

Along the Halfway Creek valley, groundwater in overburden at MW15-03AZ is likely on the order of a few decades old, based on an elevated tritium content (7.9 TU) which is indicative of more rapid groundwater circulation. However, a large range in groundwater ages is apparent in bedrock groundwater along Halfway Creek. MW15-04WB contains elevated tritium (6 TU) indicating it is mostly comprised of water several decades in age. In contrast, groundwater at MW15-03WB is tritium-free (< 0.8 TU), has a calculated radiocarbon age of 13,500 years, and an F_{paleo} value of 1.0, suggesting that it is likely several thousand years old (Table 2). Groundwater at MW15-03WB also has the lowest $\delta^{18}O$ value (Figure 3), which could be consistent with paleo-groundwater that recharged during the Pleistocene when meteoric $\delta^{18}O$ values were approximately 1 to 2 ‰ lower than present-day (Jasechko, 2016b). MW15-03WB is artesian and is installed in a valley bottom, and its location is along an inferred lineament (Huscroft, 2002) which may act as a conduit for long-residence time flow with upwelling groundwater (based on strong upward hydraulic gradients measured by MW15-03T). The unique $\delta^{18}O$ value is consistent with distinct groundwater quality at MW15-03WB, given its end-member major ion composition for the Project site, as well as elevated salinity and SO_4 concentrations in relation to other bedrock wells, and low dissolved uranium concentrations compared to other wells screened in gneiss and located upstream along Halfway Creek.

Table 2:
Isotopic composition of 2019 groundwater samples.

Station	Sample Date	$\delta^{18}O$	$\delta^{2}H$	$\delta^{13}C$	^{14}C	*q* [1]	^{14}C age [2]	^{3}H [3]	F_{young} [4]			F_{paleo} [5]

Notes:
Max = maximum, Min = minimum, pMC = percent modern carbon, TU = tritium units, VPBD = Vienna Pee Dee Belemnite, VSMOW = Vienna Standard Mean Ocean Water
1. Radiocarbon dilution factor (q) used to correct ^{14}C ages, based on Pearson and Hanshaw (1970); assumes $\delta^{13}C_{recharge}$ = -17.3 ‰ and $\delta^{13}C_{carbonates}$ = 0.28 ‰ (see Section 2.2).
2. ^{14}C age determined using the Pearson and Hanshaw (1970) correction for carbonate mineral dissolution (see Section 2.2).
3. ^{3}H results reported below the detection limit of 0.8 TU were assumed to be equal to 0 TU for F_{young} calculations.
4. F_{young} input parameters: 1) $^{3}H_{post\text{-}1953}$ (TU) calculated using 10-year moving average of combined Anchorage and Ottawa ^{3}H precipitation records from International Atomic Energy Agency Global Network of Isotopes in Precipitation (mean 9.25 TU, minimum 2.56 TU, maximum 87.6 TU); and 2) $^{3}H_{pre\text{-}1953,}$ assumed to be 0 (all ^{3}H older than 1953 has decayed to below detection limit). Based on Jasechko (2016a) and Jasechko et al., (2017) (See Appendix B).
5. F_{paleo} input parameters: ^{14}C of atmosphere taken using 30-point moving average of ^{14}C compilations of Reimer et al. (2020) and Hua et al. (2013), decay-corrected to 2019, and corrected for carbonate mineral dissolution using *q* for each well. Based on Jasechko (2016a) (See Appendix B).
6. MW15-02AZ was frozen in 2019; 2015 data used instead.

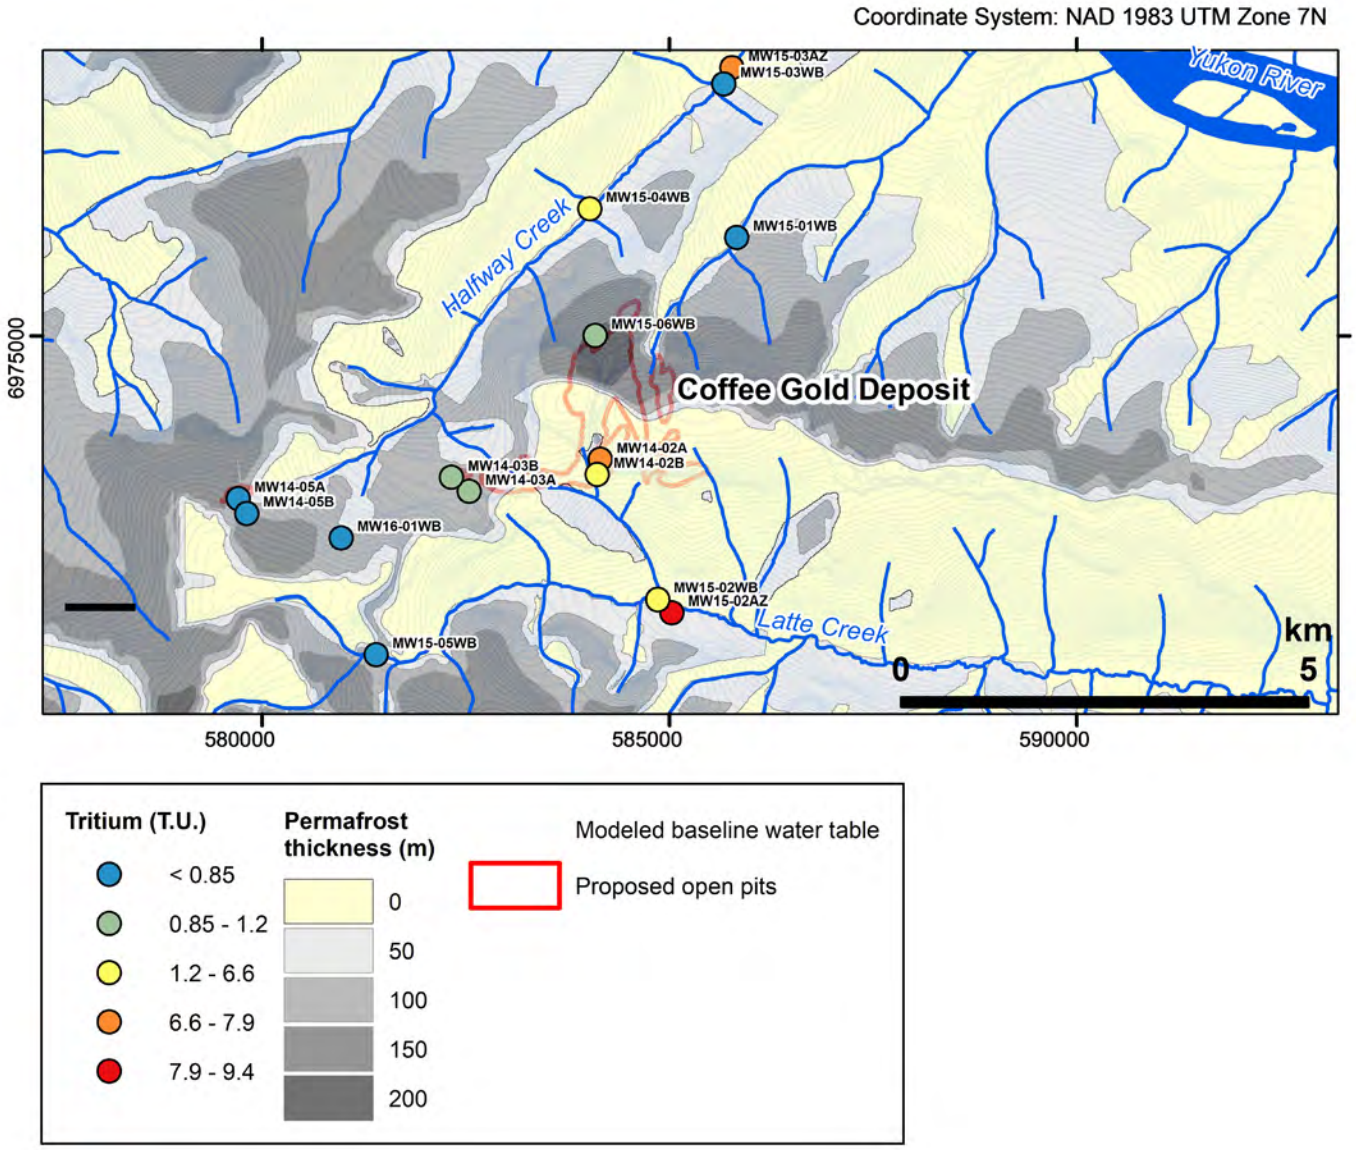

Figure 4: Tritium concentrations in groundwater across the Project site. Based on ^{3}H values in Table 2. Higher tritium concentrations indicate a greater component of young groundwater.

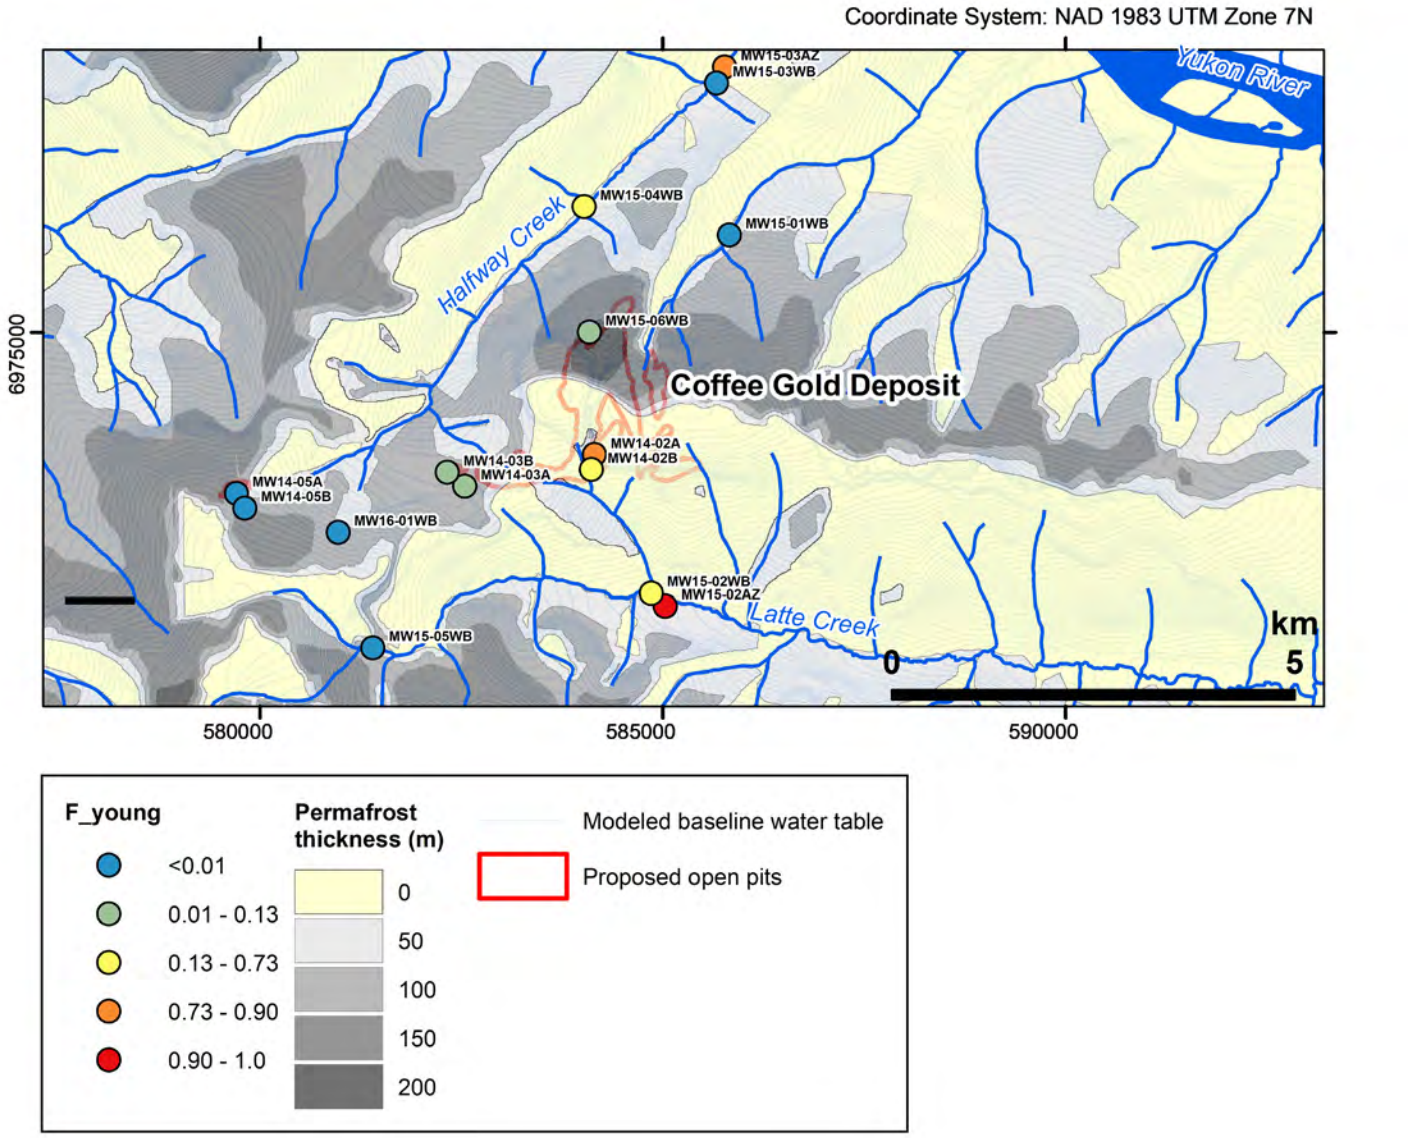

Figure 5: Fraction of groundwater recharged between 1953 and 2019 across the Project site. Based on F_{young} mean values calculated from tritium in Table 2.

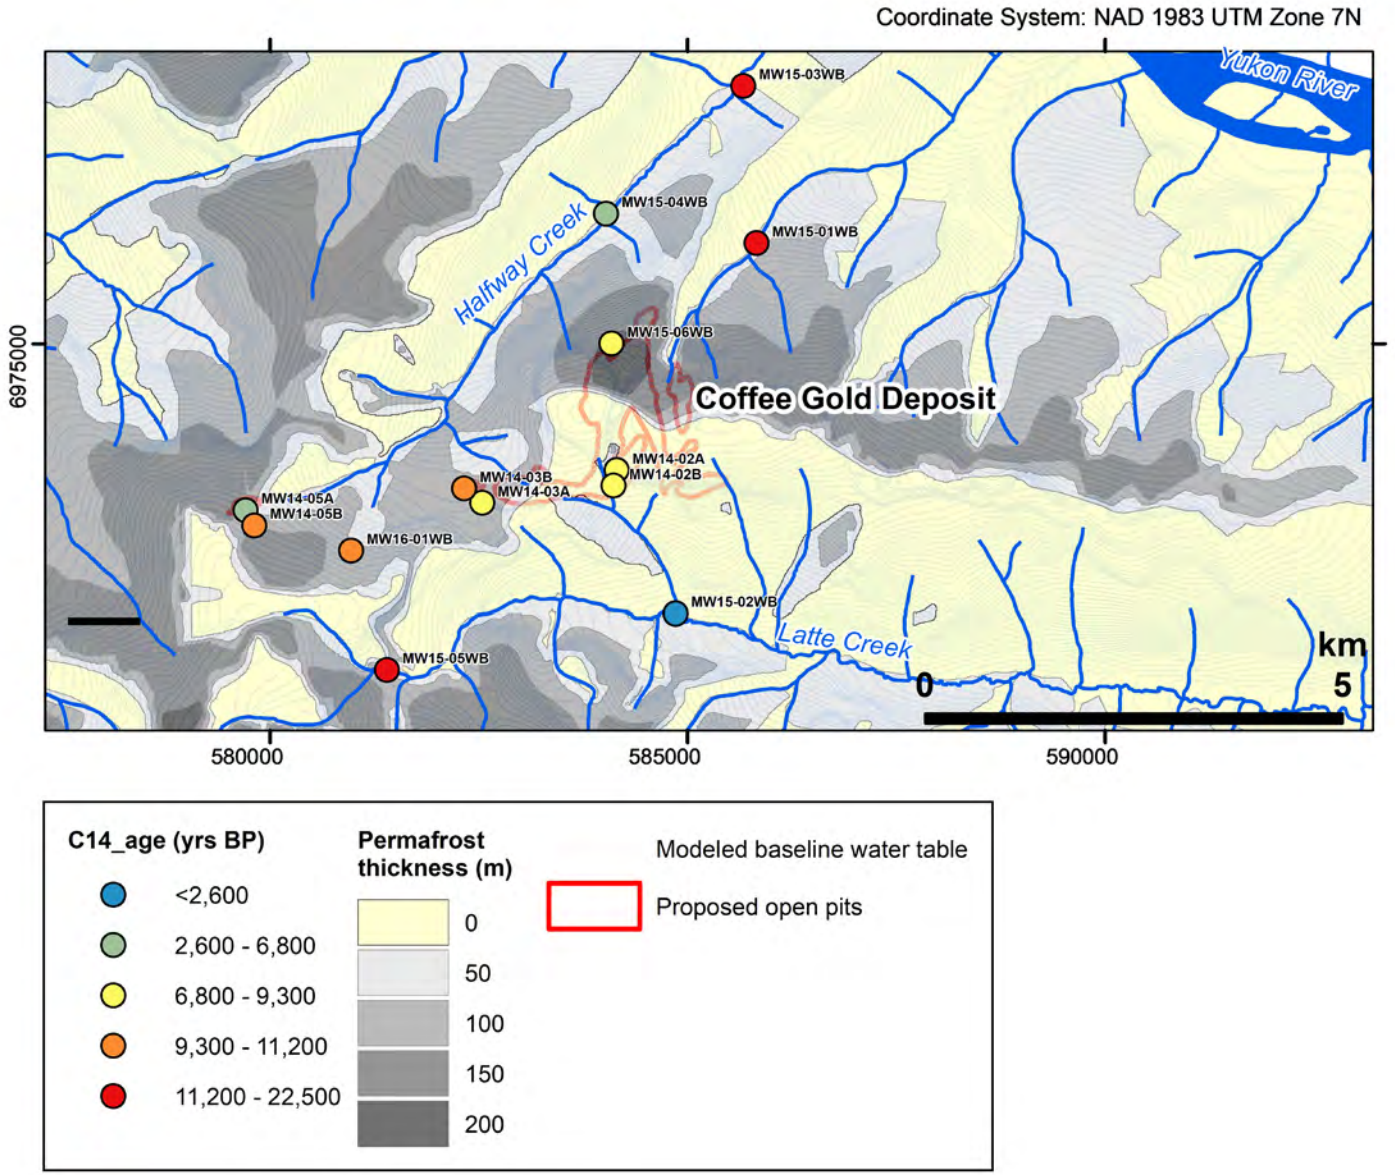

Figure 6: Groundwater ages determined from ^{14}C analyses across the Project site. Based on ^{14}C ages in Table 2.

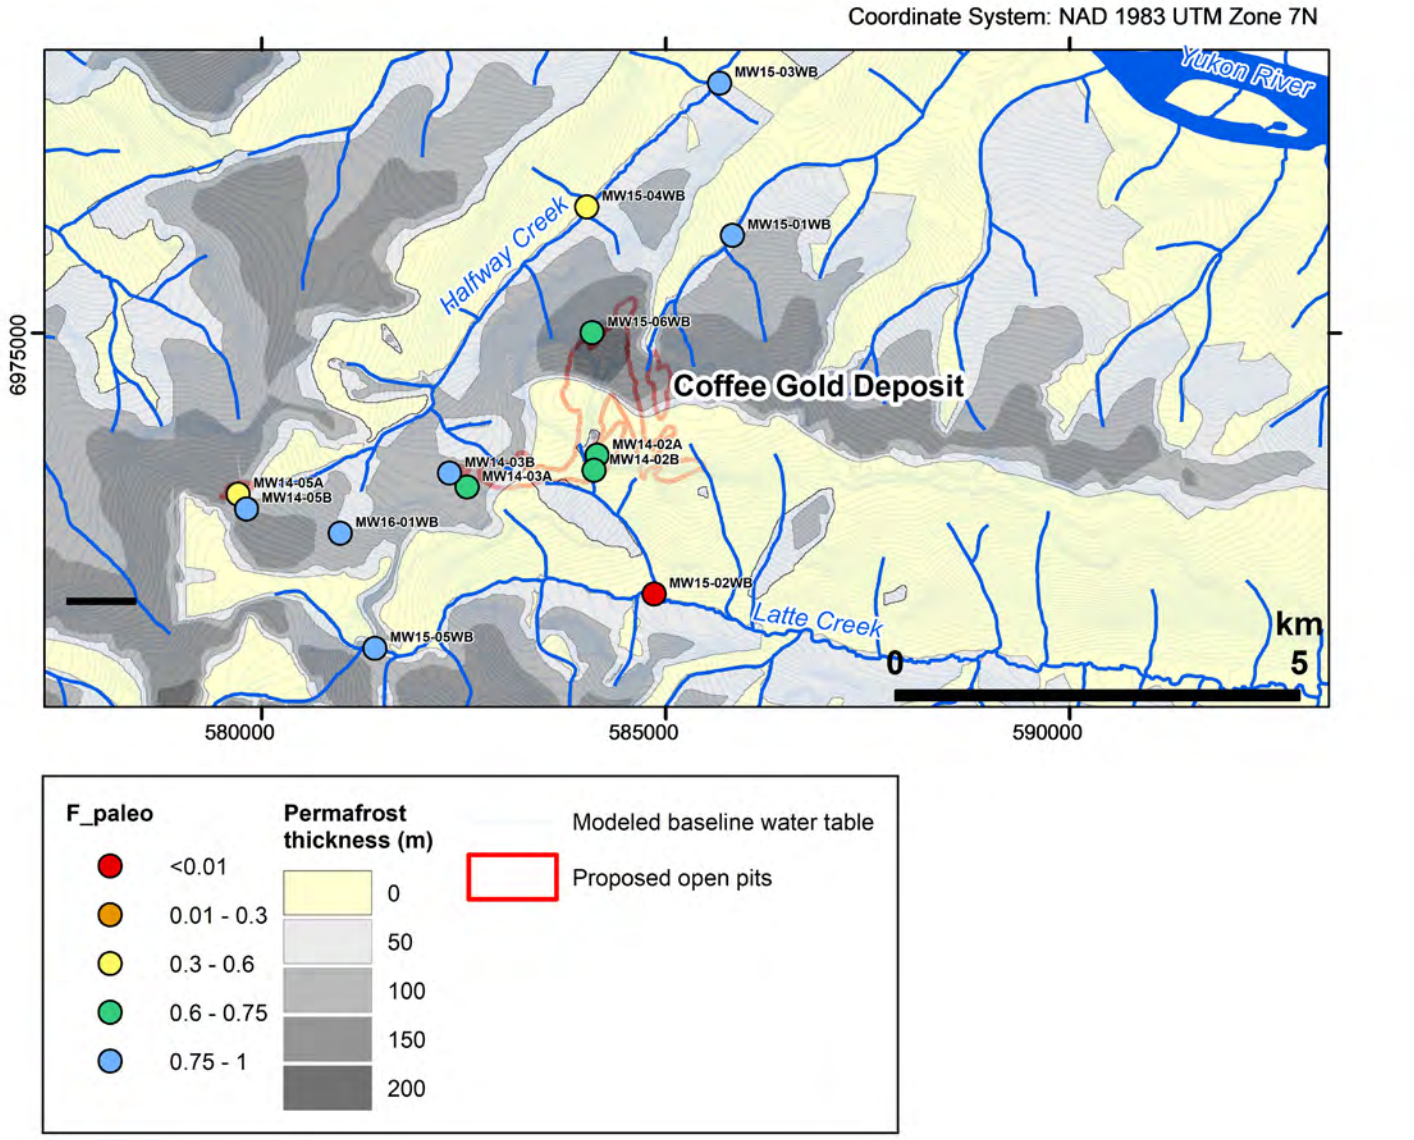

Figure 7: Fraction of groundwater recharged prior to 11,700 years before present across the Project site. Based on F_{paleo} mean values calculated from ^{14}C in Table 2. Note that there are no wells with F_{paleo} values between 0.01 and 0.3.

5. Conclusions

Stable isotope compositions of groundwaters collected at the Project site are isotopically heavier than the estimated composition for mean annual precipitation, and closer to the isotopic composition of rain-dominated precipitation (May-October) than that of snow-dominated precipitation (November-April). This suggests that groundwater recharge is more heavily driven by infiltration of rain than by snowmelt, which is consistent with a greater proportion of annual precipitation occurring as rain (~70 % at an elevation of 975 m asl) in the Project area (Lorax, 2019).

Isotopic analyses of carbon and hydrogen suggest that permafrost exerts a strong control on groundwater residence times. At high elevations and beneath permafrost, ^{3}H and ^{14}C data suggest that groundwater is predominantly greater than 70 years in age and could be thousands of years old. In contrast, along south-facing slopes where permafrost coverage is limited, such as Latte Creek around MW14-02A and MW14-02B, ^{3}H data suggest a more active groundwater circulation pattern with a large component of young groundwater with residence times on the order of decades.

Valley bottoms include a mixture of old and young groundwaters that converge in discharge areas. Shallow monitoring well installations completed in overburden (MW15-02AZ and MW15-03AZ) are characterized by young (decades-old or less) groundwater based on elevated tritium contents. Deeper Westbay installations MW15-02WB and MW15-04WB are also tritiated, indicating decades-old or less groundwater ages; however, MW15-04WB also includes a component of groundwater thousands of years in age based on its radiocarbon age. Valley bedrock installation MW15-03WB screens groundwater that is likely thousands of years in age based on its ^{3}H, ^{14}C, and $\delta^{18}O$ signatures, and is distinct in both isotopic and geochemical composition from other groundwater sampled in Halfway Creek and across the Project.

6. Closure

We trust that this memorandum meets your requirements at this time. Please contact us should you have any questions or concerns, or require additional information in support of this work.

APPENDIX A: METHODOLOGY FOR ESTIMATION OF $\delta^{18}O$ AND $\delta^{2}H$ OF LOCAL PRECIPITATION

Appendix A: Methodology for Estimation of $\delta^{18}O$ and $\delta^{2}H$ of Local Precipitation

1. Development of the Local Meteoric Water Line

A local meteoric water line (LMWL) for the Project site was estimated from previously published precipitation isotope data at Dawson City and Mayo, Yukon (Lapp, 2015; IAEA 2020). These cities are located at 130 km north and 180 km east of the Project site, respectively, and the isotopic compositions of their precipitation follow very similar meteoric water line (MWL) trends, supporting the use of the pooled precipitation isotope data (n = 85 samples) from these cities to generate a LMWL applicable to the Project site (Figure 1). Because there is no effect due to a change in altitude on the slope of the LMWL (Baranova, 2017), precipitation in the Project area should fall along a slope of ~6.3.

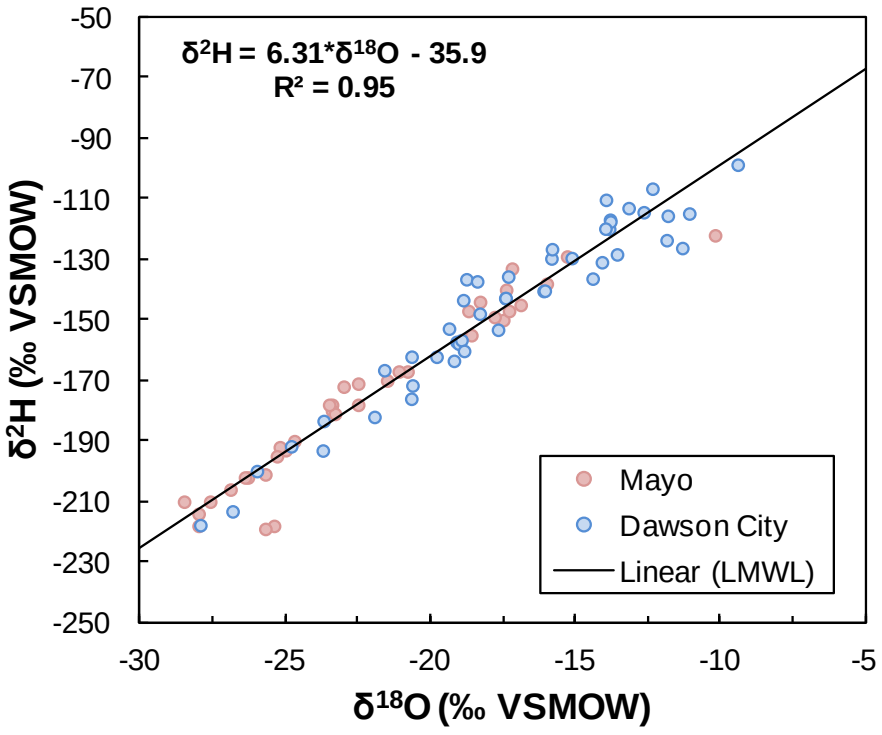

Figure 1: **A local meteoric water line (LMWL) was developed for the Project site by pooling previously published isotope data for precipitation in the nearby cities of Dawson (Lapp, 2015) and Mayo, Yukon (IAEA, 2020).**

1.1 Estimation of the Isotopic Composition of Groundwater Recharge

Precipitation isotope data from Mayo (IAEA, 2020) were used to extrapolate the isotopic composition of precipitation that occurs primarily as rain and snow at the Project site by applying corrections to account for the difference in elevation between the two sites.

The seasonal variability in the isotopic composition of precipitation at Mayo ranges from –10 to –30 ‰ for $\delta^{18}O$, and –122 to –229 ‰ for $\delta^{2}H$ (IAEA, 2020). The mean isotopic composition of precipitation at Mayo, weighted by precipitation depth, was calculated for each month, and is shown in Figure 2. The mean monthly isotopic composition in Mayoprecipitation ranges from –17 to –26 ‰ for $\delta^{18}O$, and –143 to –213 ‰ for $\delta^{2}H$ (Figure 2).

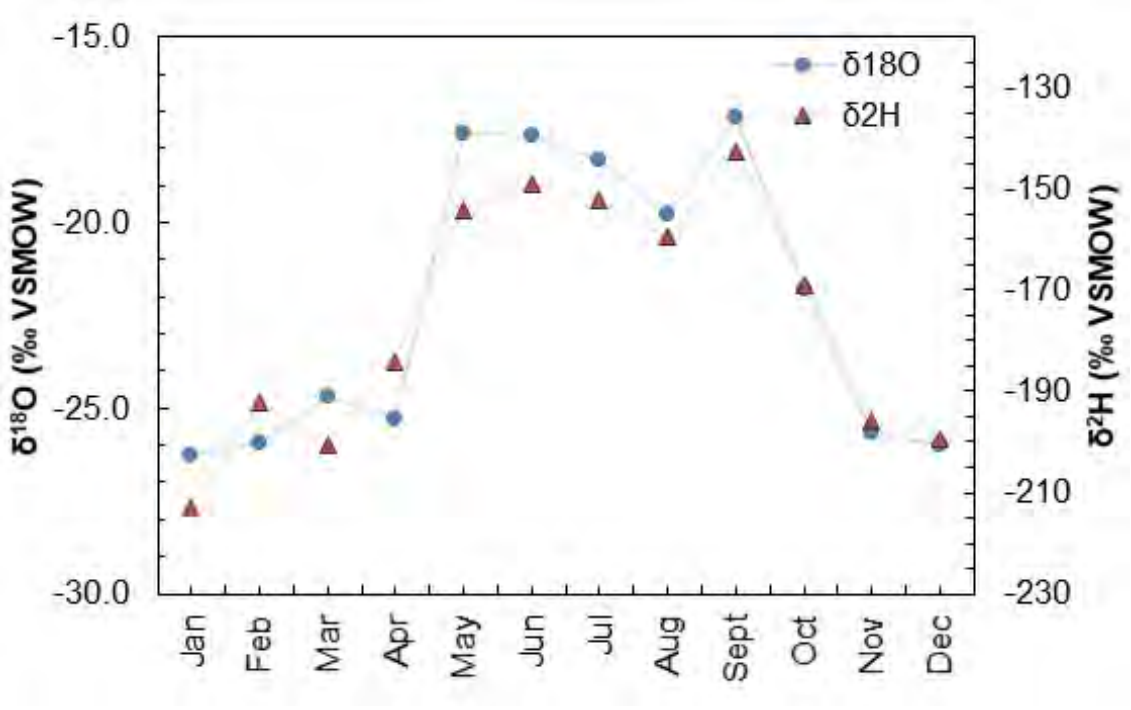

Figure 2: Depth-weighted mean isotopic composition of precipitation at Mayo, Yukon by month. Data from IAEA (2020).

The mean annual $\delta^{18}O$ and $\delta^{2}H$ values of precipitation in Mayo, weighted by precipitation depth, were calculated and are –24 ‰ and –186 ‰, respectively (Table 1). Since precipitation occurs primarily as snow between November and April, and rain for the balance of the year (*i.e.*, May to October), the depth-weighted mean monthly precipitation data from Mayo were used to estimate end-member isotopic compositions for snowmelt and rainfall, using the average of the monthly mean values for each time period (Table 1). These values were then used to calculate corresponding mean isotopic compositions for annual precipitation, snow-dominated and rain-dominated precipitation for the Project area using an elevation gradient of -0.28 ‰ for $\delta^{18}O$ per 100 m of elevation gain (Poage and Chamberlain, 2001) and a corresponding value of –1.76 ‰

per 100 m for $\delta^{2}H$ (calculated from the $\delta^{18}O$ elevation gradient and using the slope of 6.3 from the Mayo MWL, since the slope does not change with altitude (Baranova, 2017)). The isotopic composition of precipitation at the Project site was calculated based on the range of elevations present at the site (*i.e.,* 430 to 1,300 m asl). The estimated mean isotopic compositions of snow-dominated and rain-dominated precipitation, as well as the annual precipitation for the Project site are shown in Table 1.

Table 1:
Mean isotopic composition of annual precipitation, snow-dominated precipitation, and rain-dominated precipitation in the Project area estimated using precipitation depth-weighted monitoring data from Mayo (IAEA, 2020).

Location	Elevation	Mean Annual Precipitation		Mean Precipitation (Nov.-Apr.)		Mean Precipitation (May-Oct.)	
	m asl	$\delta^{18}O$	$\delta^{2}H$	$\delta^{18}O$	$\delta^{2}H$	$\delta^{18}O$	$\delta^{2}H$
Mayo	504	-24	-186	-26	-198	-19	-155
Project Site (Coffee Camp)	430	-23	-185	-25	-196	-19	-153
Project Site (ridgetop)	1,300	-26	-200	-28	-212	-21	-169

Notes:
m asl = metres above sea level
1. All $\delta^{18}O$ and $\delta^{2}H$ values expressed in ‰ VSMOW.
2. The estimated mean isotopic composition of precipitation, snow and rain for the Project site are based on Mayo precipitation data (IAEA, 2020) which have been corrected for elevation using an assumed elevation gradient of -0.28 ‰ for $\delta^{18}O$ per 100 metres of elevation gain (Poage and Chamberlain, 2001) and a calculated gradient for $\delta^{2}H$ of -1.76 ‰ per 100 metres of elevation gain (calculated from the $\delta^{18}O$ elevation gradient and the slope of the Mayo meteoric water line (6.3), since the slope does not change with altitude (Baranova, 2017)).

The estimated mean isotopic compositions for annual precipitation, snow-dominated precipitation (November to April), and rain-dominated precipitation (May to October) shown in Table 1 were used to define corresponding ranges of compositions across the Project site from the lowest to the highest elevation (*i.e.*, 430 to 1300 m asl). The range of compositions corresponding to each precipitation class (annual, May-Oct., Nov.-Apr.) is defined by an isotopically heavy end-member (*i.e.*, mean composition at 430 m asl) and an isotopically light end-member (*i.e.*, mean composition at 1300 m asl). These estimated ranges of isotopic compositions for mean annual precipitation, rain-dominated precipitation (May to October), and snow-dominated precipitation were then plotted on the LMWL that was developed for the Project site, along with the isotopic compositions of groundwater, surface water and aufeis as shown in Figure 3. This was done to facilitate interpretation of the isotopic data.

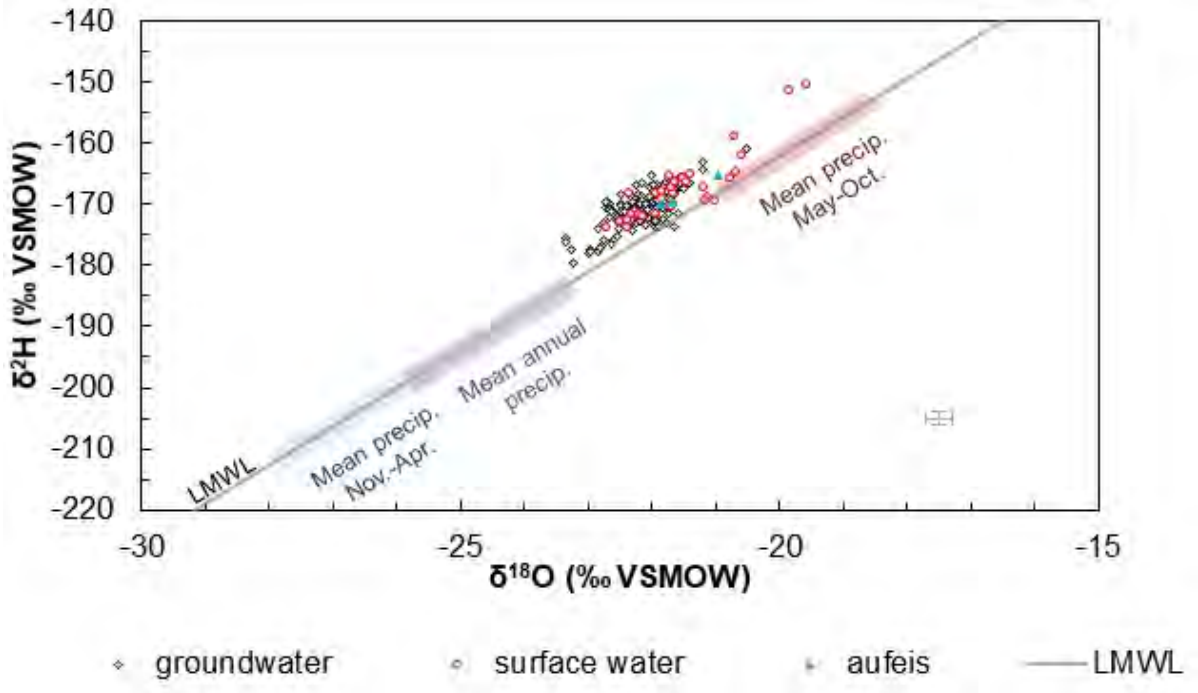

Figure 3: Isotopic composition of groundwater, surface water, and aufeis at the Project site. The LMWL was developed by combining precipitation isotope data from Dawson City and Mayo (Lapp, 2015; IAEA, 2020). The range of estimated mean isotopic compositions for annual precipitation, rain-dominated precipitation (May-Oct.), and snow-dominated precipitation (Nov.-Apr.) are defined by purple, red, and blue shading, respectively. These ranges were calculated using isotope and precipitation data from Mayo (IAEA, 2020) and correcting for elevations encountered at the Project site.

APPENDIX B: GROUNDWATER AGES METHODOLOGY

Appendix B: Groundwater Ages Methodology

1. Methodology for Radiocarbon Age Corrections

Estimating groundwater age based on ^{14}C measurements requires corrections for dissolution of carbonate minerals from aquifer rocks and mineralization of ancient organic matter, which can generate ^{14}C-free DIC because many of these materials were formed hundreds of thousands to millions of years ago and thus all the radiocarbon has decayed in the time since their formation. Uncorrected radiocarbon dating of groundwater would therefore bias groundwater ages towards older values if ^{14}C dilution were not accounted for.

In this memorandum, radiocarbon age corrections are based on the method of Pearson and Hanshaw (1970):

$$Apparent\ ^{14}C\ age = -8267 * \ln\left(\frac{a_C^{14}{}_t}{q \times a_C^{14}{}_{initial}}\right) \quad (1)$$

where, $a_C^{14}{}_t$ is the ^{14}C activity (pMC) at the time of sampling, $a_C^{14}{}_{initial}$ is 100 pMC, and q is a radiocarbon dilution factor.

The radiocarbon dilution factor (q) accounts for input of ^{14}C-free DIC from carbonate mineral dissolution and ancient organic matter degradation and is calculated using the carbon stable isotopes ^{13}C and ^{12}C, which provide a means to estimate the quantity of carbonate-mineral dissolution in groundwater. Biodegradation of ancient organic matter can be assumed negligible in the Project area where fossil fuels (*e.g.*, coal, oil) are not present in the rock. Thus, q is determined using the equation:

$$q = \frac{\delta^{13}C_{DIC} - \delta^{13}C_{carbonates}}{\delta^{13}C_{recharge} - \delta^{13}C_{carbonates}} \quad (2)$$

In this equation, the subscripts DIC, carbonates, and recharge relate to the measured $\delta^{13}C$ in the DIC component of a sample, of carbonate minerals, and of recharging groundwater, respectively. $\delta^{13}C_{DIC}$ was measured directly, while $\delta^{13}C_{carbonates}$ was computed as the average of a database of 51 carbonate-mineral $^{13}C/^{12}C$ analyses from the Project site (MacWilliam, 2018), which corresponds to +0.28 ‰ (relative to the Pee Dee Belemnite standard). The $\delta^{13}C$ value of groundwater recharge is unknown but is commonly estimated based on assumptions of soil pH and soil $\delta^{13}C$ values (Clark and Fritz, 1997). In this memorandum, a groundwater recharge pH of 7.0 (typical of the Project area) and a soil organic carbon $\delta^{13}C$ value of -23 ‰ (typical of plant

ecosystems using the C_3 carbon dioxide metabolic pathway; Clark and Fritz, 1997) are assumed, which correspond to a $\delta^{13}C_{recharge}$ value of -17.3 ‰.

2. Methodology for Groundwater Age Determination

The age of groundwater was determined using a method based on Jasechko (2016a). In this method, the fractions of young and paleo water in a sample are calculated from ^{3}H and ^{14}C data, respectively. Where F_{young} and F_{paleo} are defined as follows:

- F_{young} is the fraction of a groundwater sample that was recharged between 1953 and the time of sampling (*i.e.*, 2019). The year 1953 is selected to distinguish young water because it predates widespread Cold War-era thermonuclear bomb testing, which released orders of magnitude higher ^{3}H into the atmosphere.
- F_{paleo} is the fraction of a groundwater sample that was recharged prior to 11,700 years before present (BP). Present is defined as the year AD 1950 to follow conventions established by the radiocarbon isotope community: AD 1950 was the year that ^{14}C emerged as a tracer of artefact ages and it also predates large-scale thermonuclear bomb testing, which at its peak doubled the ^{14}C concentrations in the atmosphere. 11,700 years BP is used to separate paleo-groundwaters from younger (*i.e.*, Holocene) groundwaters because it marks the Pleistocene-Holocene transition and the end of the last major glaciation on Earth, which was a major driver of groundwater recharge.

2.1 Determination of F_{young} Using ^{3}H Data

F_{young} is calculated using the equation:

$$F_{young} = (^{3}H_{sample} - {}^{3}H_{pre\text{-}1953}) / (^{3}H_{post\text{-}1953} - {}^{3}H_{pre\text{-}1953}) \quad (3)$$

Where $^{3}H_{sample}$ is the measured ^{3}H concentration in a sample, $^{3}H_{pre\text{-}1953}$ is the tritium concentration in precipitation prior to 1953, decay-corrected to the year of sampling (2019), and $^{3}H_{post\text{-}1953}$ is the tritium concentration in precipitation between 1953 and the year of sampling. $^{3}H_{pre\text{-}1953}$ was estimated using the global relationship between latitude and ^{3}H of Jasechko et al. (2017):

$$^{3}H_{pre\text{-}1953,uncorr} = 0.0014*10^{-3}(latitude)^2 + 0.0236*10^{-2} + 2.4 \quad (4)$$

which yields 9.4 tritium units (TU) at the Coffee site latitude of 62.9°N. Accounting for radioactive decay of ^{3}H (using the ^{3}H half-life of 12.32 years), this value in 2019 is 0.23 TU, which is below the laboratory detection limit of 0.8 TU. Therefore, it can be assumed that for a sample collected in 2019, $^{3}H_{pre\text{-}1953} \approx 0$, such that F_{young} can be approximated as:

$$F_{young} = (^{3}H_{sample}) / (^{3}H_{post\text{-}1953}) \quad (5)$$

$^{3}H_{post\text{-}1953}$ must be estimated based on long-term ^{3}H records of precipitation, available from the International Atomic Energy Agency's Global Network of Isotopes in Precipitation (IAEA, 2020).

The nearest stations for which continuous data are available are Anchorage, Alaska and Ottawa, Ontario, for which records are available for the periods 1966-2019 and 1953-2019, respectively (Figure 1). As shown in Figure 1, there are differences in ^{3}H concentrations between these locations. Assuming that precipitation at the Coffee site consist of a mixture of storm events driven by Pacific and continental weather patterns, the average ^{3}H data from Anchorage and Ottawa were combined to create a ^{3}H record for use at the Project site. $^{3}H_{post\text{-}1953}$ was calculated using a 10-year moving average over this dataset, to account for hydrodynamic dispersion that occurs in groundwater systems (Jasechko et al., 2017). Decay-correcting this 10-year moving average ^{3}H concentration in precipitation to 2019 gives a $^{3}H_{post\text{-}1953}$ value of 9.25 TU. Thus, F_{young} can be approximated by:

$$F_{young} \approx (^{3}H_{sample}) / 9.25 \qquad (6)$$

The uncertainty with respects to F_{young} can be bracketed by assuming maximum and minimum 10-year moving average values of $^{3}H_{post\text{-}1953}$, and decay-correcting these values to 2019, which yields maximum and minimum $^{3}H_{post\text{-}1953}$ values of 2.56 and 87.6 TU, respectively. Due to the very large variations in ^{3}H since 1953, F_{young} uncertainties tend to be large (Jasechko *et al.*, 2017).

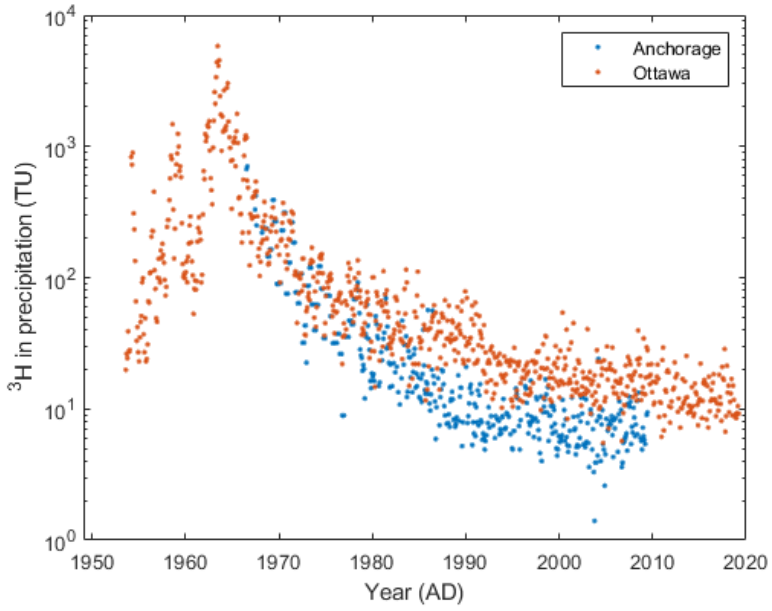

Figure 1: Tritium concentrations in rain and snow in Ottawa, Ontario and Anchorage, Alaska since 1953 (data from the International Atomic Energy Agency's Global Network of Isotopes in Precipitation). The peak in 1962 corresponds to maximum ^{3}H released during Cold-War era thermonuclear bomb testing. As of 2020, ^{3}H concentrations in rain and snow have returned to pre-nuclear bomb values as ^{3}H released into the atmosphere from nuclear bomb testing has undergone radioactive decay.

2.2 Determination of F_{paleo} Using ^{14}C Data

2.2.1 Overview

F_{paleo} is computed from ^{14}C data in a sample and requires several additional inputs that include re-constructed and decay-corrected ^{14}C data in the atmosphere from records spanning the last ~60,000 years, and $\delta^{13}C$ data to account for dissolution of radiocarbon-free carbonate minerals that contribute ^{14}C-free dissolved inorganic carbon (DIC) into groundwater, in addition to the ^{14}C-bearing groundwater that originates from recharge containing DIC sourced from the dissolution of atmospheric CO_2. The mass fraction, F_{paleo}, of a groundwater that recharged prior to 11,700 years BP corresponds to:

$$F_{paleo} = 1 - F_{Holocene} \quad (7)$$

where $F_{Holocene}$ is the mass fraction of a groundwater that recharged after 11,700 years BP (*i.e.*, during the Holocene). $F_{Holocene}$ is given by the equation (Jasechko, 2016a):

$$F_{Holocene} = ([DIC]_{sample}{}^{14}C_{sample} - [DIC]_{paleo}{}^{14}C_{paleo}) / ([DIC]_{Holocene}{}^{14}C_{Holocene} - [DIC]_{paleo}{}^{14}C_{paleo}) \quad (8)$$

where [DIC] is the concentration of dissolved inorganic carbon, ^{14}C is the radiocarbon concentration (in units of percent Modern Carbon, pMC), and the subscripts sample, paleo, Holocene pertain to the respective DIC and radiocarbon concentrations in the sample, in the atmosphere prior to the Holocene, and in the atmosphere during the Holocene, respectively. Paleo and Holocene ^{14}C values must also be decay-corrected to the year of sample analysis using the ^{14}C half-life of 5,730 years.

Groundwater ^{14}C concentrations also require correction for dissolution of carbonate minerals that formed millions of years ago, which contribute DIC without ^{14}C (because all ^{14}C from carbonate minerals has decayed in the time since their formation). The correction applied herein uses a radiocarbon dilution factor, *q*, that accounts for the amount of DIC sourced from carbonate mineral dissolution rather than from atmospheric CO_2, as per the method of Pearson and Hanshaw (1970) outlined in Section 1 of this appendix.

As per recommendations by Jasechko (2016a), equation (8) can be simplified by assuming that $[DIC]_{sample} \approx [DIC]_{Holocene} \approx [DIC]_{paleo}$ and that $q_{sample} \approx q_{Holocene} \approx q_{paleo}$. Thus equation (6) reduces to:

$$F_{Holocene} = (^{14}C_{sample} - {}^{14}C_{paleo}) / (^{14}C_{Holocene} - {}^{14}C_{paleo}) \quad (9)$$

$^{14}C_{paleo}$ and $^{14}C_{Holocene}$ must be estimated from ^{14}C records for the last ~60,000 years, decay-corrected to the year of sampling (*i.e.*, 2019) and accounting for dissolution of ^{14}C-free carbonate minerals using the equation:

$$^{14}C_{decay\text{-}corrected} = q_t\,^{14}C_{precip(t)}\, e^{[\lambda \times \Delta t]} \quad (10)$$

where $^{14}C_{precip(t)}$ is the ^{14}C activity in precipitation at a time t, λ is the ^{14}C decay constant (1.209×10^{-4} years), and Δt is the time (in years) elapsed between the recharge event and the year the sample ^{14}C analysis was completed. q is the dilution factor and is assumed to be time-invariant (Jasechko, 2016a).

2.2.2 Estimating the ^{14}C activity of DIC during the Holocene and Pleistocene

The ^{14}C activity of precipitation during the Holocene and Pleistocene was estimated from a database of ^{14}C determinations in the atmosphere from ~60,000 years BP to AD 1950 (Reimer et al., 2020) and from AD 1950 to 2010 (Hua et al., 2013). These databases were combined and ^{14}C activities were re-expressed in units of pMC (Figure 2). A 30-sample moving average was calculated as shown in Figure 2. Decay-corrections and corrections for carbonate-mineral dissolution were computed individually for each monitoring well, as each well sample had its own value of q from measurements of $\delta^{13}C$. Thus, decay-corrected and carbonate-mineral-dissolution-corrected ^{14}C activities were computed at each well for the entire Holocene and Pleistocene periods using a 30-point moving average over the Hua et al. (2013) and Reimer et al (2020) datasets. The average of the 30-point moving average over the Holocene and Pleistocene were taken as $^{14}C_{Holocene}$ and $^{14}C_{Pleistocene}$, respectively. There is a large range in minimum and maximum ^{14}C activities during these periods (range of <100 pMC to >160 pMC) as shown in Figure 2. Therefore, calculations of F_{paleo} also have substantial inherent uncertainty, as with F_{young}.

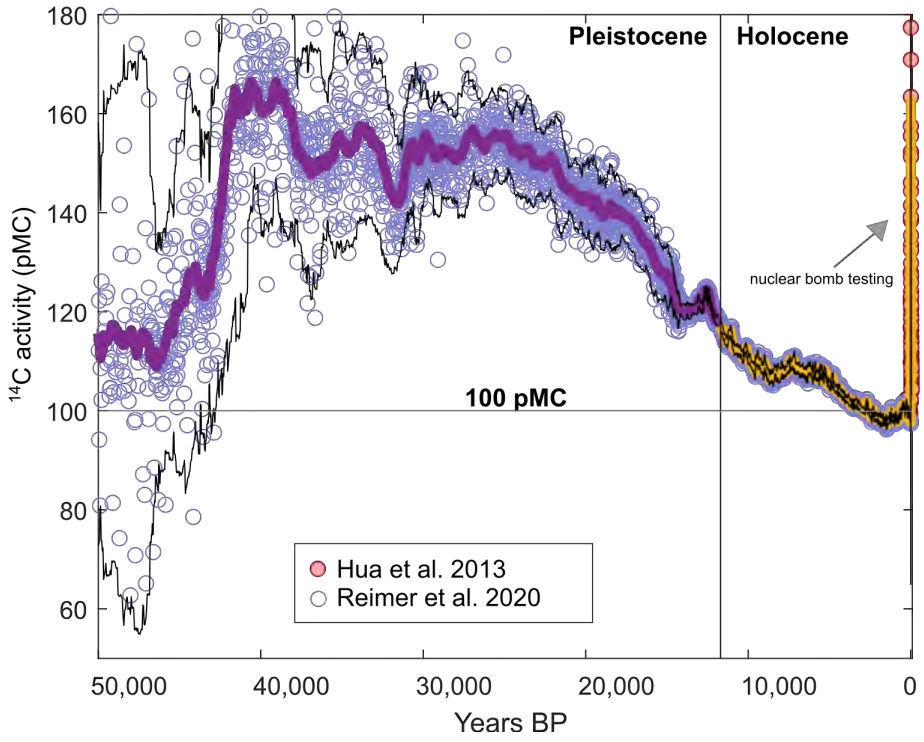

Figure 2: **Reconstructed ^{14}C activity of the atmosphere over the last 50,000 years, based on data from Reimer et al. (2020) (purple circles with white fill) and Hua *et al.* (2013) (red-filled circles). The thick line represents a moving average of ^{14}C (averaged over each 30 measurements available) over the Pleistocene (purple) and Holocene (yellow). One standard deviation around the moving averages is shown by the thin black line. The large increase in ^{14}C due to thermonuclear weapon detonations since the mid-20th Century is visible at the extreme right-hand side of the graph.**

NOTES:

$\delta^{18}O_{VSMOW\ (sample)} = [(^{18}O/^{16}O)_{sample} - (^{18}O/^{16}O)_{VSMOW} / (^{18}O/^{16}O)_{VSMOW}] * 1000$

$\delta D_{VSMOW(sample)} = [(^{2}H/^{1}H)_{sample} - (^{12}H/^{1}H)_{VSMOW} / (^{2}H/^{1}H)_{VSMOW}] * 1000$

$\delta^{13}C_{VPDB\ (sample)} = [(^{13}C/^{12}C)_{sample} - (^{13}C/^{12}C)_{VPDB} / (^{13}C/^{12}C)_{VPDB}] * 1000$

$\delta^{18}O_{VSMOW\ (sample)}$, $\delta D_{VSMOW\ (sample)}$ and $\delta^{13}C_{VPDB\ (sample)}$ are the measured "delta" values for the given sample. $(^{18}O/^{16}O)_{sample}$, $(^{2}H/^{1}H)_{sample}$ and $(^{13}C/^{12}C)_{sample}$ are raw isotope ratios, and $(^{18}O/^{16}O)_{VSMOW}$ $(^{2}H/^{1}H)_{VSMOW}$ are the defined isotope ratios for hydrogen and oxygen of the VSMOW international standard. VPDB values for carbon are produced by analysis with reference gases calibrated to NBS-19.

Values are normalized to the VSMOW/SLAP scale (Coplen, 1988; Nelson, 2000; Nelson and Detlman, 2001); however, uncertainties in normalization are not included in error estimates.

NOTES:

Pretreatment: Carbon was extracted from the water sample as barium carbonate precipitate. Carbon dioxide was recovered from the carbonate in a high-vacuum system for processing into benzene and isotopic analysis.

Comments: Percent modern carbon was calculated according to Stuvier, M. and Polach, HA, 1997, Discussion of ^{14}C data: Radiocarbon 19:355-63 by comparison against the activities of 4990C NBS oxalic acid and a total process blank. Based upon a Libby half life of 5568 years for ^{14}C.

David G. Tingey
Research Professor

APPENDIX D: ISOTOPE DATA AND QUALITY ASSURANCE/ QUALITY CONTROL

Appendix D: Isotope Data and Quality Assurance/ Quality Control

Six field duplicate samples collected in 2014 and 2015 were submitted for isotope analyses to the Brigham Young University Laboratory of Isotope Geochemistry (BYU-LIG), while six duplicate samples collected in 2019 were submitted to the University of Waterloo - Environmental Isotope Laboratory (UW-EIL). In addition, internal reproducibility checks on 2016 and 2017 samples were completed at the UW-EIL which included re-analysis of 26 stable isotope samples. In 2019, the UW-EIL re-analyzed 12 samples submitted for stable isotope analyses, as well as one sample for tritium and $\delta^{13}C$ analyses. Isotope analytical results for field duplicate samples are presented and compared in Table 1. The results of the internal re-analysis (*i.e.*, reproducibility checks) of samples submitted to the UW-EIL for stable isotope, tritium, and $\delta^{13}C$ analyses are provided in Table 2. The stable isotope and radioisotope data for groundwater, surface water and aufeis samples are tabulated in Table 3.

Field duplicate sample results were within 2.8 ‰ for $\delta^{2}H$ and 0.5 ‰ for $\delta^{18}O$ for samples submitted to BYU-LIG. Three duplicate pairs were characterized by a difference in $\delta^{2}H$ values (2.1 to 2.8 ‰) that slightly exceeded two times the precision (*i.e.*, 2.0 ‰), while two sample pairs had a difference in $\delta^{18}O$ values (0.44 and 0.48 ‰) slightly exceeding two times the precision (*i.e.*, 0.4 ‰).

In contrast, field duplicate results were within 0.71 ‰ for $\delta^{2}H$ and 0.18 ‰ for $\delta^{18}O$ (*i.e.*, within the precision of 0.8 ‰ for $\delta^{2}H$ and 0.2 ‰ for $\delta^{18}O$) for samples submitted to the UW-EIL. The internal replicate analyses conducted at the UW-EIL were within 1.36 ‰ for $\delta^{2}H$ and 0.37 ‰ for $\delta^{18}O$ (*i.e.*, within two times precisions of 0.8 and 0.2 ‰, respectively).

For tritium, $\delta^{13}C$, and radiocarbon analyses, duplicates samples were analyzed at the BYU-LIG and UW-EIL. The duplicate sample pair analyzed at BYU-LIG was characterized by results that were within 0.5 TU for ^{3}H (*i.e.*, less than two times the precision of 0.3 ‰); however, there were discrepancies of 1.2 ‰ for $\delta^{13}C$ values and 10.4 pMC for ^{14}C values, which are anomalously high relative to the precisions of 0.1 ‰ and 0.1 pMC, respectively. The cause of this difference is not known but it may involve CO_2 degassing following sampling (CO_2 degassing induces isotope fractionation) or post-sampling microbial oxidation of dissolved organic carbon. Following the initial sample analyses at BYU, improved sampling methods in 2019 included minimizing sample headspace and hold time, and addition of $ZnCl_2$ as an anti-microbial agent, which appear to have improved sample reproducibility for the latest analyses conducted at UW as $\delta^{13}C$ values were within 0.54 ‰ and ^{14}C data were within 0.15 pMC. Therefore, the 2019 radiocarbon analyses are given greater consideration when interpreting groundwater ages in this report.

Field duplicate sample results were within 1.3 TU for ^{3}H, 0.54 ‰ for $\delta^{13}C$, and 0.15 pMC for ^{14}C for the two duplicate pairs analyzed at the UW-EIL. Duplicate results for tritium were less than two times precision (*i.e.*, 1.6 TU), while ^{14}C results were within the precision of both sample results; only $\delta^{13}C$ values were slightly above two times precision (*i.e.*, 0.4 ‰). Internal replicate analyses conducted at the UW-EIL were within 0.39 ‰ for $\delta^{13}C$ (*i.e.*, within two times precision of 0.2 ‰), while the result and repeat analysis for tritium were both below the detection limit (< 0.8 TU).

Three samples analyzed for O and H stable isotopes and tritium at MW15-03WB (23-Sep-16), MW14-02A (5-Oct-17), and MW14-02B (5-Oct-17) showed results inconsistent with the larger dataset. The $\delta^{2}H$ and $\delta^{18}O$ values in these samples were substantially higher than those of all other samples collected at these locations, and outside the range of isotopic composition of precipitation measured at Dawson and Mayo (IAEA, 2020, Lapp, 2015). These analyses have been flagged as suspect. The source of error in these samples is uncertain but the internal laboratory replicate of the MW15-03WB (23-Sep-16) sample gave reproducible results. Regardless of the cause for these anomalous values, these samples were not considered in data interpretations made in this report.

Overall, the quality assurance and quality control (QA/QC) analysis of isotope samples indicates reliable stable isotope ($\delta^{2}H$, $\delta^{18}O$) and radioisotope (^{3}H, ^{14}C) results for the interpretation of groundwater provenance and groundwater age tracing. The relatively large number of sampling locations, synoptic sampling at many locations, in addition to the general consistency of the data between sampling events, has yielded a robust isotopic data set. Some early inconsistencies with 2014 and 2015 $\delta^{13}C$ and ^{14}C data existed which were addressed with improved sampling protocols in 2019 that yielded satisfactory QA/QC results.

Notes:
BYU-LIG = Brigham Young University Laboratory of Isotope Geochemistry, UW-EIL = University of Waterloo-Environmental Isotope Laboratory
pMC = percent modern carbon, TU = tritium units, VPDB = Vienna Pee Dee Belemnite, VSMOW = Vienna Standard Mean Ocean Water
insuf = insufficient carbon for analysis in duplicate sample D-1 (23-Aug-2019)

2.1 red shading and text indicates that the difference between the primary sample and duplicate sample results is greater than 2 times the precision as referenced in Table 1 in the memorandum.

Notes
BYU-LIG = Brigham Young University Laboratory of Isotope Geochemistry, DUP = duplicate sample, GW = groundwater, PS = primary sample, SW = surface water, UW-EIL = University of Waterloo-Environmental Isotope Laboratory
pMC = percent modern carbon, TU = tritium units, VPDB = Vienna Pee Dee Belemnite, VSMOW = Vienna Standard Mean Ocean Water
1. ^{14}C age determined using the Pearson and Hanshaw (1970) correction for carbonate mineral dissolution; assumes groundwater recharge pH of 7.0 and a soil $\delta^{13}C$ value of -23 ‰, which corresponds to a $\delta^{13}C_{recharge}$ value of of -17.3 ‰, as well as a $\delta^{13}C_{carbonates}$ value 0.28 ‰ (see Section 2.2 of this memorandum). Negative ^{14}C ages for HC-2.5 (24-Oct-2014, 3-Apr-2015) and MW14-02B (28-Sept-2014) are a result of the radiocarbon dilution factor correction and could be due to uncertain quality of $\delta^{13}C$ or ^{14}C values associated with these samples; these results are not considered in the data interpetation.
2. Samples and sample data with **RED** text and numbers are not considered to be representative of formation water (See Appendix 5-D of Lorax (2017).
3. Samples and sample data with **BLUE** text and numbers showed results that were inconsistent with the larger data set. These analyses have been flagged as suspect and were not considered in data interpretations made in the report (see Section 3.3 of this memorandum).
4. The sample date for MW14-05A (Lab ID 12346) is 23-Jun-2015, as shown above. Note that it is incorrectly referenced as 23-Jun-16 in the BYU-LIG certificate of analysis (Appendix C).

1.3	March 12, 2017	Updated to address First Nation reviewer comments and include additional lab data.	Pat Tobler Lyndsay Doetzel

EXECUTIVE SUMMARY

Fisheries and aquatic baseline studies for the proposed Coffee Gold Project were conducted from 2013 to 2016; some additional data was collected for other projects prior to 2013. Baseline studies undertaken to date have included the compilation of existing information, fish habitat assessments, sampling for fish (summer, fall and winter), environmental DNA (eDNA), benthic invertebrates, periphyton and stream sediments.

The study area includes a 332 km^2 area around the Mine (Mine study area; including portions of the Yukon River, Coffee, Latte, Halfway, Independence and YT-24 creeks) and a 125 km long corridor along the Northern Access Route (NAR study area; which crosses the Yukon and Stewart rivers as well as several smaller watersheds).

A total of 14 species of fish can be found within the streams adjacent to or downstream of the Project infrastructure including two species of salmon and 12 species of resident freshwater fish species. The majority of these species are found only in the Yukon and Stewart rivers with three of these species documented in the small/medium sized streams downstream of proposed mine. These species include slimy sculpin (*Cottus cognatus*), Arctic grayling (*Thymallus arcticus*), and juvenile Chinook salmon *(Oncorhynchus tshawytscha*). These three species were also the most common species encountered along the NAR. Baseline studies have not found Chinook spawning within the study areas; however, chum salmon (*Oncorhynchus keta*) spawning has been confirmed in groundwater fed side channels of the Yukon River in the study area, and in similar habitats in the Stewart River downstream of the NAR study area. Among the tributary creeks, the highest species diversity and abundance of fish have been documented in Coffee and Independence creeks, which are the two largest creeks in the Mine study area.

Coffee, Independence (and occasionally Halfway) creeks are used by juvenile Chinook as non-natal rearing habitat, and Coffee Creek provides confirmed overwintering habitat for this species. Arctic grayling use the creeks in the Mine study area primarily for summer rearing; eDNA data from March 2016 confirmed Arctic grayling overwintering in Coffee Creek and the Yukon River but not in any other streams within the Mine study area. It is common for Arctic grayling to use different streams for important life history periods such as spawning, summer rearing and overwintering. Moderate densities of Arctic grayling have been documented in the lower reaches of Latte Creek during the summer months; however, overwintering habitat for fish within this stream appears poor and eDNA samples collected in this creek in March 2016 tested negative for both Arctic grayling and juvenile Chinook salmon. Slimy sculpin are year round residents in Coffee Creek, the lower portion of Independence Creeks and the Yukon River.

The headwater streams within the Mine footprint are small, steep, have poor habitat and with are located significant distances from documented fish bearing locations. Lower down in the watersheds, these streams eventually provide fish habitat or flow into areas that are used by fish. Along the NAR, fish presence is typically associated with the larger streams that are crossed with likelihood of fish presence decreasing with distance from mainstem habitat.

Benthic invertebrate sampling indicated that mean total abundance was variable throughout the Mine study area, with the highest abundance in Independence Creek, followed by YT-24, Coffee, Latte and Halfway creeks. Primary production (as indicated through periphyton sampling) was very low for all sampling stations, which is typical of northern, nutrient poor aquatic habitats. Chlorophyll-a concentrations were lowest in samples collected farthest upstream in each of the watersheds, and increased in downstream locations, as stream flows and nutrient inputs increased.

Baseline tissue metal concentrations within the Mine study area were analyzed in fish (Arctic grayling, slimy sculpin and juvenile Chinook salmon) and benthic invertebrate tissues, as well as in sediment samples collected from the creeks in the Mine study area. Concentrations of estimated methylmercury in all slimy sculpin, Arctic grayling and juvenile Chinook salmon tissues exceeded the CCME residue guidelines for the protection of wildlife consumers of aquatic biota (CCME 2000a). Baseline concentrations of selenium in slimy sculpin exceeded the United States Environmental Protection Agency guideline for whole-body selenium (EPA 2015) at a small number of samples from Coffee and Independence creeks, and samples from Arctic grayling and slimy sculpin from all areas exceeded the BC guideline for selenium.

Analysis of baseline benthic invertebrate tissue metals concentrations conducted in March and August 2016 indicated that estimated methylmercury concentrations in all benthic invertebrate tissue samples (54% of total mercury) did not exceeded the CCME guideline set for the protection of piscivorous wildlife (0.033 µg/g ww; CCME 2000a) at any sample stations in the Project area; the highest concentration was found in the sample collected from Coffee Creek (CF2.7) in March 2016 (0.0226 µg/g ww). Uranium concentrations in benthic invertebrate tissues were higher in samples collected in March when compared with August data; this correlated to when uranium concentrations in water are at their annual peak during late winter low flows, resulting in increased proportions of groundwater contributions to surface water.

Analyses of sediment baseline metals concentrations collected throughout the Mine study area indicate that arsenic and chromium are consistently present at concentrations that exceed the CCME interim Freshwater Sediment Quality Guidelines (CCME 2000b). Concentrations of copper, cadmium and mercury were found to exceed the applicable guidelines in only a small number of samples, all of which were located in the Coffee Creek watershed.

ACKNOWLEDGEMENTS

Jennie Gjertsen managed this project on behalf of the Goldcorp Inc. and Allison Rippin-Armstrong managed the earlier portion of the project on behalf of Kaminak. Tom Bokenfohr (Goldcorp) provided GIS data used in this report. Ryan Fetterley and Jasmin Dobson from Goldcorp provided exceptional logistical support to ensure our field crews could complete the work in an efficient and effective matter. Ken Nordin of Laberge Environmental Services provided value insight and knowledge of streams within the Local study area.

EDI would like to highlight the exceptional assistance provided by Goldcorp's Environmental Monitors. Robert Farr and Kim Joseph provided navigation, local insight and field assistance for the road accessible portions of fieldwork. Evan Warren, Andrew Taylor and Derek Scheffen provided local insight and assistance for components that were based from the mine.

AUTHORSHIP

This report was prepared by EDI Environmental Dynamics Inc. Staff who contributed to this project include:

Pat Tobler B.Sc., R.P.Bio.....Author, Senior Review

Ben Schonewille, B.Sc., R.P.Bio .....Section Author

Ben Snow, B.Sc., R.P.Bio .....Section Author

Lyndsay Doetzel, M.Sc., R.P.Bio.....Section Author

Matt Power, A.Sc.T. .....GIS Mapping and Database Management

Jared Hobbs (M.Sc., R.P.Bio.) of Hemmera Envirochem Inc. produced the eDNA report included in Appendix A and led the eDNA sampling component of the field program.

Members of the EDI field crew for the 2016 fieldwork included the following EDI personnel: Ben Schonewille, Ben Snow, Josh Taylor, Dawn Hansen, Joel MacFabe, Jake Duncan and Pat Tobler.

1 INTRODUCTION

1.1 PROJECT DETAILS

The Coffee Gold Project (Coffee Project; the Project) is a proposed gold mine in west-central Yukon, located 130 km south of Dawson City. Gold was initially discovered at Coffee Creek in 2010, and exploration activities have been ongoing since then. Baseline environmental studies began in 2010 and were expanded in the following years in anticipation of future regulatory requirements.

The proposed Project will consist of an open pit gold mine and heap leach facility. The projected mine life is ten years with an 18 month construction period. The feasibility study proposes four open pits mined by conventional shovel and truck methods. The mine and associated activities will generally be located on a relatively high elevation ridge top, and will not extend into the lower elevations where the larger streams are located. The mine footprint does include the upper part of some headwater watershed (including Halfway Creek, YT-24 and unnamed tributaries to Latte Creek). Most prominently, the main proposed Waste Rock Storage Facility (WRSF) will be positioned in the upper Halfway Creek watershed.

The Project will be accessed by road from Dawson City via a 214 km single-lane, gravel road with pull outs. The initial part of this route, from the highway to Sulphur Creek utilizes a government-maintained gravel road. Beyond Sulphur Creek, the Northern Access Route (NAR) mainly follows existing placer mine roads which will be upgraded to provide all season access to supply vehicles. Approximately 30 km of new road will be constructed (Figure 1). Electricity will be generated onsite by diesel-powered generators. The majority of mine staff will access the site by air.

The Coffee Project is located on Crown land within the Traditional Territory of the Tr'ondëk Hwëch'in and the asserted traditional territory of the White River First Nation. A portion of Goldcorp's claim block is located in the Traditional Territory of the Selkirk First Nation and the proposed road also overlaps with the Traditional Territory of the First Nation of the Na-cho Nyak Dun.

The proposed Project will require an Executive Committee Screening from the Yukon Environmental and Socio-economic Assessment Board (YESAB), a Type A Water Licence issued by the Yukon Water Board and a Quartz Mining License issued by the Yukon Government, among other permits and licences.

1.2 PURPOSE AND SCOPE OF REPORT

This report provides an update to the Coffee Project fish and aquatic resource baseline for the mine. Palmer Environmental Consulting Group collected baseline data around the mine in 2014 and 2015 (PECG 2017) and along the access road in 2015 (PECG 2016). EDI collected additional baseline data in 2016 around the mine and NAR. This report synthesizes the 2016 results with all previous fish and aquatic resource data collected in the study areas from 2000 to 2015 and includes the Mine study area (Figure 2) and the Northern Access Road (NAR) study area (Figure 3). This report is intended to support the effects assessment for the Project and the preparation of the YESAB Project Proposal. This report includes:

- A summary of data collection methods and existing knowledge (prior to 2016) for fish and aquatic resources within the study areas including fish and fish habitat, benthic invertebrates, periphyton and stream sediments;
- Methods and results for 2016 Mine study area field studies include:
    - winter fish and fish habitat sampling including environmental DNA;
    - benthic invertebrate tissue sampling, March and August for metals;
    - whole-body fish tissue sampling for metals, March, July and August;
    - chlorophyll-a sampling in August;
    - fish and fish habitat investigations (July and August);
    - stream gradient modelling and analysis for small streams within the Project footprint, and;
    - spawning surveys for Chinook salmon.
- Methods and results for 2016 NAR study area field studies include:
    - fish and fish habitat investigations at stream crossings along the NAR;
    - fish sampling and fish habitat characterization at proposed barge landings;
    - fish and fish habitat investigations at back channel of Stewart River;
    - spawning surveys for chum salmon in the Yukon and Stewart rivers.
- A synthesis of the results from all fish and aquatic resources studies to date, and an updated discussion on fish use of streams within the study areas with an emphasis on the stream in the Mine study area.

1.3 INFORMATION SOURCES

Available information sources for fish and aquatic resources within the study areas include scientific studies conducted between 2000 and 2016 (Table 1), as well as Traditional Knowledge. Preliminary fisheries and aquatic assessments associated with the Coffee Project were conducted in 2013 (ACG 2014), and were followed by two years of fish and aquatic baseline data collection for the Project in 2014 and 2015 by Palmer Environmental Consulting Group (PECG 2017) and data collection by EDI Environmental Dynamics in 2016 (this report).

Additional data that is not associated with either Project was collected on Coffee Creek in 2010, 2001 and 2000 (Laberge and White Mountain 2010; Laberge and White Mountain 2002; White Mountain 2001). Traditional Knowledge was also incorporated and was sourced from a database of such information compiled by the Kaminak Gold Corporation.

Table 1. Summary of available information sources for aquatic resources in the study areas.

Year	Data Summary	Agency	Report References
2016	Winter: fish and fish habitat assessments, environmental DNA (eDNA) sampling for Arctic grayling and Chinook salmon and benthic invertebrate sampling for analysis of baseline metal levels. Summer/fall: salmon spawning surveys, stream assessments along NAR, fish sampling/habitat assessments around mine, chlorophyll-a sampling, metals analysis of invertebrates and fish tissue.	EDI Environmental Dynamics (EDI)	This report
2014, 2015	Fish and aquatic resources baseline report for the Coffee Project, including data on fish and fish habitat, benthic invertebrates, periphyton and stream sediments. Includes fish tissue sampling data and salmon spawning surveys.	Palmer Environmental Consulting Group (PECG)	PECG 2017
2015	Fish and aquatic resources baseline report for the mine access route (NAR) focusing on collection of fish and habitat data at proposed stream crossings.	Palmer Environmental Consulting Group (PECG)	PECG 2016

1.4 WATERSHED SUMMARY AND FISH SPECIES OVERVIEW

The Mine study area includes 32 km of the Yukon River as well as five smaller watersheds, all of which are tributaries of the Yukon River and generally flow in a northerly direction (Figure 2). These include:

- Coffee Creek watershed to the east;
- Latte Creek watershed to the south, which flows into Coffee Creek;
- Independence Creek watershed to the west, including the Kona Tributary; and,
- Halfway Creek and YT-24 watersheds to the north.

The NAR study area includes portions of the Yukon and Stewart Rivers and several smaller watersheds including (Figure 3):

- Indian River;
- Maisy May Creek;
- Barker Creek; and
- Ballarat Creek.

There are headwater tributaries of Latte Creek, Halfway Creek and YT-24 Creek which lie in close proximity to, or overlap with, with the planned Mine footprint (Figure 2). One tributary to Independence Creek, the 'Kona Tributary', is also near the planned Project footprint. In addition to these watersheds, two watersheds outside of the study area were sampled during 2014 to 2016 studies (Los Angeles and Isaac creeks; reference streams). Within the study areas, the Yukon and Stewart rivers provide overwintering, migration and rearing habitat for many fish species. Chum salmon spawning activity has been previously documented in the Yukon River in the study area (ACG 2014; PECG 2017) and in the Stewart River downstream of the NAR study area (Rivest Pers. Comm. 2016). In contrast, the smaller watersheds within the study areas support simpler fish communities, which include Chinook salmon (*Oncorhynchus tshawytscha*), Arctic grayling (*Thymallus arcticus*), and slimy sculpin (*Cottus cognatus*). Further information on relevant life history of key species found in the study areas (slimy sculpin, Chinook salmon, chum salmon [*Oncorhynchus keta*], and Arctic grayling) is described in the following sections.

Slimy sculpin are a small fish species commonly found in streams and lakes throughout the Yukon. This species is widespread and common in a variety of habitats although it is most common in streams with moderate to swift currents and coarse gravel/cobble substrate (McPhail 2007, McPhail and Lindsey 1970). Slimy sculpin diets include a wide variety of invertebrate prey items with chironomid larvae being a primary item taken; larger individuals may also feed upon the eggs of other fish species (McPhail 2007). They are bottom-oriented species and are known to have relatively small home ranges; they do not conduct any substantial migrations for any part of their life history (i.e. spawning, rearing, and feeding) and exhibit a high

degree of site fidelity (Gray et al. 2004). For this reason, the presence of slimy sculpin in Yukon watersheds is a good indicator of suitable overwintering habitat for other fish species. This species can also be a useful indicator species for bioaccumulation of metals at intermediate trophic levels in aquatic ecosystems, as they consume various benthic invertebrate species and are themselves prey items for larger fish species.

Chinook salmon are an anadromous fish species and the largest salmon species in the Yukon. This species is known to be an important fish for First Nations and recreational fishers in the Yukon River. As indicated by Traditional Knowledge (TH 2012), the Yukon River in the vicinity of Coffee Creek has long been an important salmon fishing location for First Nations. There is general acknowledgement that the Chinook salmon returns in the Yukon River are not as strong as historical.

In the Yukon River watershed, Chinook spawn from late July to late August in clear, fast flowing streams and rivers, where large and clean cobble substrates are present. Eggs are deposited in stream gravels and hatch in late fall or early winter as alevins. Chinook alevins remain in the gravels through the duration of the winter, and live off stored energy reserves during this time before emerging as fry in late spring (May/June). Juvenile Chinook salmon rear in freshwater streams for up to one year after emerging from the stream gravels. Juvenile Chinook salmon are known to migrate many kilometers as juveniles in order to find high quality rearing habitat; this can include use of both natal and non-natal streams. Juvenile Chinook salmon generally leave rearing habitats in the early spring in the year after emergence, spend 3 to 5 years in the ocean, and return to spawn in the Yukon River watershed as 4 to 6 year olds.

Chum salmon spawning has been documented in the Yukon River mainstem slough and side channel habitats from the White River to Tatchun Creek (near Carmacks) and appear to use similar habitats in the Stewart River. Chum salmon also migrate through the study areas of the Yukon and Stewart rivers to reach spawning areas further upstream. In the Yukon River watershed, chum spawning occurs from September to November and is almost exclusively associated with areas of upwelling groundwater discharge. As with Chinook salmon, the eggs hatch as alevins during the winter and remain in the gravel until emergence during the spring (May/June). However, unlike Chinook, chum fry head directly downstream to the ocean and do not reside in freshwater for any considerable period of time. Chum salmon from the Yukon River watershed typically spend 3 to 4 years in the ocean before returning as adults to spawn.

Arctic grayling are an important recreational fish species in the Yukon River watershed, and are also a traditional food source for local First Nations. This species can be found in a wide variety of habitats ranging from large lakes to small headwater streams. A common life history strategy involves seasonal migrations between overwintering, spawning and summer rearing habitats with the largest individuals often being found the furthest upstream during the summer months (McPhail 2007). As such, this species is typically the most widespread in terms of distribution in Yukon watersheds. Spawning occurs during the spring shortly after ice-out and takes place in flowing water over substrates dominated by gravels. Small juveniles are typically found along the margins of the spawning streams although sub-adults and adults are often found in streams which do not provide spawning habitat. Food items taken by grayling include a wide variety of aquatic and terrestrial insects and they may also feed upon small fish and/or eggs (McPhail 2007, McPhail and Lindsey 1970).

1.5 BASELINE SAMPLING STATION CONCORDANCE

Aquatic sampling stations established during the 2014/2015 baseline studies (within the Mine study area) were given the form "AQ##", where the hashtags represented a numerical station designation. An alternate set of sample station codes were developed as a component of the Coffee Project water quality baseline data collection program; these were used during recent aquatics sampling programs as sampling was conducted in areas not visited as part of the 2014/2015 program. Going forward, EDI has developed the following station designation codes that allow for easy determination of station location, and allow for the addition of new stations, if and where needed:

1. Each station ID designation begins with a two or three letter code for each stream in the Mine study area. Three letter codes are used for unnamed tributaries to named streams; LCC therefore corresponds to Latte Creek Tributary C.

2. Following the stream letter code is a numeric designation that represents the straight line distance (kilometres) of a sampling station from its major confluence.

3. For stations in the Yukon River, the same naming convention was used although distances were measured in a straight line from the Coffee Creek confluence. A 'U' was used to indicate a station upstream of Coffee Creek and a 'D' for stations downstream. To assist in rectifying previous sampling stations with the new system, a table of concordance is shown below (Table 2).

4. Discrete sampling locations within the same station are designated as sites (e.g. station CF2.3 sediment sampling sites 1, 2 and 3).

Table 2. Concordance table of Coffee Project fisheries and aquatic field sampling station identifiers.

Stream	2014/2015 Aquatic Baseline Station Name (PECG 2017)	Water Quality and Hydrology Station (Lorax 2016)	2016 Station Name (this report)

[1] While this site was labeled LC0.5, the actual distance of this site from the mouth of Latte Creek is ~50 m.

2 METHODS

2.1 TRADITIONAL KNOWLEDGE AND EXISTING INFORMATION SOURCES

Traditional Knowledge (TK) and current land use data provide information on fish species that are known to use the study areas and speak to fish species of interest to First Nations and local Yukon residents. This includes TK information shared by the Tr'ondëk Hwëch'in and White River First Nations, as well as a local trapping concession holder (Bates et. al. 2014, TH 2012, DRPC 2013; Interview 14, Pers. Comm. 2016). Prior to the initiation of the aquatic baseline studies for the Coffee Project, aquatic assessments in/near the Mine study area were conducted in Coffee Creek and the Yukon River in 2000 (White Mountain 2001), 2001 (Laberge and White Mountain 2002) and 2010 (Laberge and White Mountain 2012). The Fisheries and Oceans Canada Fisheries Information Summary System (FISS; DFO 2016) contains general data on fish presence in the Yukon River, including data records prior to the Coffee Project baseline studies.

Fish and fish habitat data were also collected just upstream of the mouth of Coffee Creek in July 2000 and 2001 and August 2010. Data collection included in-situ water quality parameters, stream discharge and velocity measurements, and general habitat attributes (e.g., channel width, substrate composition, cover, and stream morphology). Surface water quality samples were collected and analysed for metals concentrations, total dissolved solids (TDS) and total suspended solids (TSS). Benthic invertebrate sampling was conducted at the site at the mouth of Coffee Creek in 2001 and 2010 and fish sampling was conducted in all three sampling years (2000, 2001 and 2010). Sampling methods included minnow trapping in all years and, backpack electrofishing (2010 and 2001), gill netting (2001) and beach seining (2000 and 2001). Aerial surveys to attempt to locate Chinook salmon spawning were conducted in Coffee Creek 2000 and 2001.

2.2 SAMPLING AREAS AND RATIONALE

Aquatic resources sampling included fish sampling, habitat assessment (summer and overwintering), sediment and periphyton sampling, benthic invertebrate community composition via CABIN methods, and fish and benthic invertebrate tissue analysis for total metals. These activities were carried out in a number of streams in the Mine study area:

- Latte, Halfway and YT-24 creeks directly drain the Mine Site, and are those that are predicted to be most affected by project activities. These streams are considered 'near' to project activities.
- Latte Creek flows into Coffee Creek. Therefore, while Coffee Creek is downstream of the Project area, the reaches that are downstream of the Latte confluence are considered 'far' from Project activities.
- Independence, Los Angeles, and Coffee Creek upstream of the Latte Creek confluence were studies as part of the baseline program to act as 'reference' sites.

2.3 2013 TO 2015 BASELINE STUDIES

2.3.1 MINE AREA

The preliminary baseline studies for the Coffee Project began in 2013. Fish and fish habitat assessments were conducted at 10 stations (Figure 4), including Independence, Halfway and Coffee creeks. Fish habitat data collection included in-situ water quality measurements, stream discharge measurements and general observations of fish habitat suitability. Fish sampling was conducted using minnow traps. Aerial surveys to attempt to document spawning salmon were conducted in July, August, September and October 2013, and included the south bank of the Yukon River and the lower portions of Independence Creek (in July only; ACG 2014). Surveys focused on likely chum salmon spawning habitats in the Yukon River (i.e. side channel areas and sloughs), and included the portion of the river extending from approximately 500 m downstream of the confluence of Ballarat Creek to approximately 1 km downstream of the confluence of Independence Creek (ACG 2014).

More in depth aquatic baseline studies for the Coffee Project were completed in 2014 and 2015. The 2014 and 2015 baseline field sampling program included sampling at 18 fish community sampling stations, 17 fish habitat stations, and 12 benthic invertebrate, periphyton and sediment stations (PECG 2017; Figure 4). Sampling was conducted by Palmer Environmental Consulting Group (PECG) in August and October, 2014, and in March, June, July, and September, 2015. Winter sampling in March 2015 focused on documenting under-ice water flow in Latte and Coffee Creeks; however, no fish sampling was conducted.

Fish habitat was characterized by PECG at each fish sampling station in the study area. Data collected included in situ water quality parameters and an assessment of habitat quality and quantity based on general habitat attributes (e.g., channel width, gradient, substrate composition, cover, and stream morphology). Various station-specific fish sampling methods included backpack electrofishing, minnow trapping, fyke net trapping, and angling. In addition to summer fish habitat surveys, winter fish habitat surveys as well as salmon and Arctic grayling spawning surveys were completed. Fish samples were obtained from watersheds in the Mine study area and reference areas to analyze fish age, diet, and tissue metal concentrations[2].

Sediment samples were collected by PECG at stations throughout the Mine study area and were analyzed for nutrients, pH and metal concentrations. Periphyton sampling included analysis for chlorophyll-a and periphyton cell density. Benthic invertebrate field sampling was completed using the Canadian Aquatic Biomonitoring Network (CABIN) protocols (NWRI 2008), and were analyzed using the Reference Condition Approach (RCA).

[2] Metal analysis for fish was performed on whole slimy sculpin (except for head) and pieces of muscle tissue from the dorso-lateral area from Arctic grayling.

2.3.2 NORTHERN ACCESS ROUTE

In 2015, PECG completed stream assessments at 66 potential watercourse crossings along the Northern Access Route (PECG 2016). Streams were assessed for fish habitat, existence of downstream barriers to fish passage, and in some cases were sampled for fish. Since the completion of the work, a portion of the NAR has been realigned to avoid the Black Hills Creek watershed.

Included in the 66 watercourse crossings were the proposed barge crossings of Yukon and Stewart rivers. In these locations Chinook spawning surveys were completed and a general characterization of habitat was completed at the proposed barge landings.

Additional investigation was completed at a side/back channel of the Stewart River where the proposed road footprint will encroach on the high water mark. A description of the habitat, minnow trapping and water quality data was collected.

2.4 2016 BASELINE STUDIES

Baseline fish and aquatic resource studies conducted 2016 included fish and fish habitat assessments, sampling for environmental DNA (eDNA), winter fish habitat assessments, chlorophyll-a sampling, and fish and benthic invertebrate tissue sampling to assess baseline metal concentrations. A stream gradient modelling exercise was conducted to assess stream gradients in headwater tributaries of creeks in the vicinity of the Mine footprint. The methods for each of these components are summarized in the following subsections.

2.4.1 ENVIRONMENTAL DNA SAMPLING

The eDNA sampling conducted during March 2016 involved the collection of both water and sediment samples with the goal of supplementing conventional fish sampling results for Coffee, Latte, Halfway and Independence creek watersheds. Water-based eDNA samples provide an indication of winter habitat utilization whereas the sediment samples can potentially provide a longer term indication of habitat use. This is particularly important given that portions of the watersheds that were sampled may only contain the target species for some portions of the year. The eDNA field sampling effort was conducted for the Coffee Gold Project on March 1 and 2, 2016 and included 14 stations sampled for water and 12 stations sampled for sediment (Table 3; Figure 5). Detailed methods of the eDNA component of this project are described in APPENDIX A.

Table 3. Summary of eDNA sampling stations at the Coffee Gold Project, March 2016.

2.4.2 WINTER FISH HABITAT ASSESSMENT/SAMPLING

Winter fish habitat assessments and fish sampling were conducted from March 3 to 5, 2016 at seven stations (Table 4; Figure 6). Aerial video was also collected for Halfway, Coffee and Latte creeks on March 5, to provide additional data on winter fish habitat conditions in these streams. At stations where the stream channel was ice covered, an ice chisel (spud) was used to penetrate through the ice to allow for the assessment of under ice fish habitat conditions and fish sampling.

Table 4. Summary fish habitat assessment and fish sampling stations in the Coffee Project Mine study area, March 2016.

Station Name	Stream	UTM Co-ordinates (Zone 7)		Fish Sampling	
		Easting	Northing	Minnow Trapping	Underwater Camera

ID1.9	Independence Creek	579414	6983296	✓	✓
HF6.3	Halfway Creek	584040	6976554	✓	

Qualitative fish habitat data collection included station photos, descriptions of stream channel morphology and notes on observed under ice water flow and the presence of observed woody debris. Quantitative fish habitat data collection included measurements of ice thickness, water depth and the collection of in-situ water quality parameters (temperature, pH, dissolved oxygen and specific conductivity). In-situ water quality data was collected in the near vicinity of fish sampling sites, to provide context to fish capture and observation data.

Fish sampling included under ice minnow trapping and the use of an underwater video camera to attempt to visually document the presence of fish at sampling stations. At stations with numerous suitable locations to sample for fish, multiple minnow traps were set at various sites within the station in order to increase sampling effort at accessible micro-habitats (e.g. ice covered pools). At each station, 0.25 inch mesh (0.6 cm), gee-type minnow traps were baited with Yukon River salmon roe and were deployed in stream margin, slow water habitats. Traps were set to soak overnight, with soak times ranging from 17 to 25 hours. Under ice video was collected in pools at all minnow trapping stations except for LC1.6 and HF6.3, where a lack of suitable pool habitat prevented investigation with the camera. Observations were completed using one of two Aqua-Vu high definition underwater cameras (models AV 760c and AV Micro Plus with DVR). Both cameras were suspended below the ice to allow for easy rotation and movement in the water column. The duration of viewing ranged from 10 to 30 minutes, depending on the observed conditions at each station. The AV Micro Plus camera was used to record video data, while the AV 760c camera was used to

view the video data in real-time via a small attached display screen. Field staff watched the video data in real-time for the presence of fish, and recorded data was reviewed again in the office to ensure that all objects of interest were identified.

All captured fish were identified to species and measured. Fork lengths were measured for species with forked tails; total lengths were measured for fish with non-forked tails (i.e. sculpin). Incidental mortalities and those fish that were retained were also weighed.

High definition aerial video of Halfway, Coffee and Latte creeks was collected from a helicopter, which was flown at a low and slow speed over the creeks. Video data was collected with the goal of documenting any indications of winter groundwater flow (open water, ice free leads), as well as aufeis formation and general ice coverage extent. The surveyed portions of the creeks included:

- The entire channel of Halfway Creek from the confluence of the Yukon River upstream to its headwaters, including Tributary B;
- YT-24 Creek from to confluence with the Yukon River upstream to its headwaters;
- Coffee Creek from the confluence with the Yukon River, upstream to station CF10.0; and,
- Latte Creek Tributary C.

2.4.3 SUMMER FISH AND FISH HABITAT ASSESSMENTS (MINE)

Fish and fish habitat investigations were conducted in streams within the Coffee Project Mine study area in July and August 2016 to provide additional insight into fish presence and distribution. Sampled streams included Halfway and YT-24 as well as two small tributaries to the Latte Creek (Tributaries B and C; Table 5). Fish sampling was also completed in Latte, Coffee and Independence Creek to gain more information on fish use of the area and obtain additional tissue samples. Most sampling stations that were established and sampled during 2014 to 2015 summer baseline studies were revisited and sampled for fish, new sites were also established (Figure 7).

Fish habitat was characterized at representative locations in each stream using the methods described in the Resources Inventory Standards Committee (RISC) the Fish and Fish Habitat Inventory: Site Card Field Guide for the British Columbia government (BC MOE 2008). At each location where site cards were used to assess fish habitat (Table 5), a minimum of 100 m linear metres of stream channel was surveyed. At additional locations where fish sampling was conducted, fish habitat was characterized with detailed field including information on water depths, relative instream cover and channel morphology and bed material.

Electrofishing was the primary fish sampling method used to assess the presence of fish in Halfway and YT-24 Creek and Latte Creek Tributary C (Table 5). Latte Creek Tributary B was dry and was not sampled. Electrofishing was conducted using a Smith Root LR-24 electrofisher set at 60 or 70 Hz with a voltage setting ranging from 350 to 600 volts, depending on the in-situ specific conductivity at each site (i.e. higher volts were used at stations with lower conductivity). Electrofishing sampling effort ranged from 105 to 2,084 seconds with the goal of sampling at least 100 m of linear stream channel.

Minnow traps were deployed to increase fish sampling efforts at stations where water depths were sufficiently deep and stream velocities were not excessive. At each station, 0.25 inch mesh (0.6 cm), gee-type minnow traps were baited with Yukon River salmon roe and were deployed along stream margin, slow water habitats. Trap set depths were recorded and traps were set to soak overnight, with soak times ranging from 13.8 to 29.8 hours. At stations with numerous suitable locations to sample for fish, multiple minnow traps were set at various sites within the station in order to increase sampling effort. At all fish sampling stations, in-situ water quality parameters (temperature, dissolved oxygen, specific conductivity and pH) and photos were collected.

2.4.4 CHINOOK SALMON SPAWNING SURVEYS

Chinook spawning surveys were completed in areas where Traditional Knowledge indicated past presence and where habitat appeared to be suitable for Chinook spawning (Coffee and Independence Creek). Aerial surveys were completed by helicopter on Coffee Creek on August 18th, 2016 between 11:05 and 11:35 hrs and on Independence Creek on August 20th, 2016 between 13:27 and 14:11 hrs. Both streams were surveyed from the Yukon River upstream to a point where the stream was thought to be too small for adult Chinook (Independence was surveyed for 16 km and Coffee for 13 km; Figure 8). Observers were located in the front and backseats and the pilot positioned them over the river, flying sideways with the best possible vantage point at approximately 40-45 m above ground level. Surveys were completed in an upstream manner, from the mouth towards its headwaters. Observers wore polarized glasses to reduce glare. Weather was sunny and light conditions were considered very good. Tannins in both streams reduced the visibility in very deep pools, but the river could be seen to a depth of ~1m.

2.4.5 FISH TISSUE METALS ANALYSIS

Fish tissues for metals analysis were collected and analyzed by PECG in 2014 and 2015 and by EDI in 2016 (Table 6). Before the 2016 sampling it was determined that uranium is a contaminant of concern in the Project area; concentrations of uranium in water are predicted to increase and in some cases exceed the CCME guideline for the protection of freshwater aquatic life. Uranium is stored preferentially in mineralized tissues, including bone. Therefore, previous years sampling which focussed on muscle tissues are believed to have underestimated the uranium concentration in tissues. Fish tissue sampling in 2016 was conducted using whole body samples (Table 6). Aging structures could not be collected from samples collected for analysis of the whole body samples to avoid sample contamination. However age/length relationships were developed by PECG (2017) and these relationships can be used together with length data collected in 2016 to estimate age.

Fish were collected for tissue sampling during winter and summer fish and fish habitat assessments, from March 3 and 4, and August 20-23, 2016. Sampling attempted to capture 10 of each slimy sculpin and Arctic grayling from each sampling location; juvenile Chinook salmon were only retained when incidental mortalities of individuals occurred during sampling. All captured fish were identified to species and measured. Fork lengths were measured for species with forked tails; total lengths were measured for fish with non-forked tails (i.e. sculpin). Incidental mortalities and those fish that were retained were also weighed. Retained individuals from both species were rinsed with creek water from each station to remove any sediment or organics debris, and were preserved on-site via freezing. The target tissue size for total metals and percent moisture analyses was 5.0 g, however the lab indicated they would be able to work with as little as 2.0 grams if necessary. Individual retained fish of the same species from the same sample site with weights of less than one gram were pooled together to achieve a minimum target sample mass of one gram. Whole body samples were sent for analysis to Maxxam Analytics in Burnaby, B.C.

Maxxam conducted analyzed tissue samples for both percent moisture and metals concentrations. For percent moisture the lab collected a subsample from the homogenized tissue samples. The subsamples were placed on a tared pan and weighed on a two decimal point balance. The samples were then placed in a forced-air oven at 105 ± 5°C to dry, generally overnight. The samples were dried to a constant weight (removed and allow to cool, weigh sample, return to oven for 30 minutes, remove and cool, reweigh, repeat as needed), and the final weight recorded. The percent moisture was then calculated.

Maxxam analytics analyzed metal concentrations in fish tissue samples by first weighing and then digesting samples using a mixture of hydrogen peroxide and hydrochloric acid at 95°C for two hours. Samples were then filtered and analyzed using inductively coupled plasma mass spectrometry (ICP/MS). There were 31 total metals analyzed with detection limits as presented in Table 7.

2.4.6 BENTHIC INVERTEBRATE SAMPLING FOR TISSUE METALS ANALYSIS

Benthic invertebrate sampling for tissue metals analysis in the Mine study area and reference sites was conducted on March 3 and 4, and August 20 to 23, 2016 (Figure 9). The goal of this sampling was to collect benthic invertebrate samples of sufficient mass to allow for analysis of metals concentrations in benthic invertebrate tissues; sampling was not intended to assess benthic invertebrate abundance or distribution. Prior to March 2016, no metals analysis had been conducted on benthic invertebrate tissues; however, benthic invertebrate samples had been collected and submitted for taxonomic analysis to assess community composition and overall benthic invertebrate abundance/diversity (PECG 2017).

Tissue metals concentrations assist with the comprehensive understanding of station-specific metal bioaccumulation between sediments, benthic invertebrates and fish populations. Benthic invertebrate sampling was conducted via kick netting, and focused on riffle habitats (Table 8) which had the following characteristics:

- For winter sampling: sufficient area of riffle habitat that could be cleared of ice, or was ice free, at the time of sampling;
- Sufficient amount of stream flow to allow for dislodged benthic invertebrates to be washed into the kick net; and,
- Sufficient stream bed material to be easily agitated by kicking.

At each of the stations sampled, kick netting was conducted using a 250 micron mesh with a detachable collection cup. The final samples were all composites made of three or more net kicks. The opening of the net faced upstream and the bottom of the net was rested on the stream bed; the field sampler walked backward while moving in a zig-zag motion upstream through the sampling area. Benthic invertebrates were dislodged from the stream bed by vigorous kicking for a period of 20 to 40 minutes; the amount of sampling effort at each site was proportional to the available area of suitable habitat. In-situ water quality parameters including water temperature, pH, specific conductivity and dissolved oxygen concentration were collected at each sample site. More than one replicate was collected when benthic invertebrate abundance allowed (Table 8).

All collected sample material from each site was washed from the collection cup using stream water from each site. Samples were placed in large, clean Ziploc bags and all washings were retained. At the completion of each day's sampling, collected sample material was sorted and invertebrates were separated from stream sediments and organic debris. All observed macroscopic invertebrates were removed from each sample and were then preserved by freezing. All samples were weighed, and individually packaged in sterile, labelled WhirlPak containers, and were kept frozen until they were delivered under chain of custody (COC) documentation to Maxxam Analytical for analyses including percent moisture and total metals concentrations in benthic invertebrate tissues. The target tissue size for total metals and percent moisture analyses was 5.0 g, however the lab indicated they would be able to work with as little as 2.0 grams if necessary.

Maxxam conducted analyzed tissue samples for both percent moisture and metals concentrations. For percent moisture the lab collected a subsample from the homogenized tissue samples. The subsamples were placed on a tared pan and weighed on a two decimal point balance. The samples were then placed in a forced-air oven at 105 ± 5°C to dry, generally overnight. The samples were dried to a constant weight (removed and allow to cool, weigh sample, return to oven for 30 minutes, remove and cool, reweigh, repeat as needed), and the final weight recorded. The percent moisture was then calculated.

Maxxam analytics analyzed metal concentrations in fish tissue samples by first weighing and then digesting samples using a mixture of hydrogen peroxide and hydrochloric acid at 95°C for two hours. Samples were then filtered and analyzed using inductively coupled plasma mass spectrometry (ICP/MS). There were 31 total metals analyzed with detection limits as presented in Table 7.

Table 8. Summary of 2016 benthic invertebrate sampling in the Mine study area.

Station Name/Site Name	Stream	Sampling Date	Number of replicates collected	Sample weight (g) [1]
CF2.7	Coffee Creek	4/5 March 2016	6	1.3, 3.4, 2.5, 2.2, 1.3, 2.0

LaC4.8	Los Angeles Creek	20-Aug-16	2	2.2, 2.9

[1] Sample weights less than 2.0 g were analysed by the lab, but detection limits were raised, as necessary, see Maxxam COA, Appendix E, for detailed detection limits.

2.4.7 CHLOROPHYLL–A

Chlorophyll-a sampling was conducted in late summer when communities were expected to have reached maximum density and diversity. Sampling sites were selected with an attempt to standardize, where possible, water depth, velocity, gradient, substrate, and sunlight exposure (Figure 9; Table 9).

Six rocks were randomly selected and sampled at each chlorophyll-a sample site using a 10 cm (4") diameter template and scrub brush. Each rock represented one replicate, resulting in a total of six replicates collected

per site. Algae scrubbed from within the template area were washed into a 500 mL laboratory-supplied bottle; sample volume from each rock was approximately 50 mL. Each replicate was then filtered through a 0.45 µm filter within 12 hours of sample collection. The sample filters were separately preserved, as recommended by the analytical laboratory performing the analysis, and labelled with the site name, date, and area sampled. Sample filters were kept frozen and dark until they were transferred to the laboratory under chain of custody documentation.

Samples were sent to Maxxam Analytics in Burnaby, BC where they were filtered, ground, and extracted using 90% acetone and analyzed on a spectrophotometer. Results were presented as mass/area (µg/cm² or mg/cm²) as the lab was provided with the known volume sampled per area of substrate sampled at each site.

Upon receipt of data results from the laboratory, summary statistics for each site including minimum, maximum and mean values were calculated from the six replicates collected at each site. Mean values from each site were used to perform a between site comparison.

Table 9. Summary of 2016 chlorophyll-a sampling in the Mine study area.

2.4.8 STREAM GRADIENT MODELLING

Modelling of stream gradients was completed to provide additional context to the fish bearing potential of focal streams in the vicinity of the Project infrastructure, particularly those streams that intersect the proposed mine infrastructure. Although stream gradient alone cannot be used to indicate whether streams are fish bearing, analysis of stream gradient properties can be a useful tool in determining the likelihood of fish presence (BC MOF 1998).

The stream gradient modelling involved the use of LIDAR imagery (2 m resolution digital elevation model) with stream gradients measured at 100 m intervals along the streams of interest. A watercourse layer was produced digitally using the LIDAR imagery and provided to EDI for the purposes of this modelling. Stream gradient measurement data points where then color coded according to the stream gradient ranges, with hotter colors (reds) indicating steep gradients and cooler colors (greens) indicating shallow gradients (stream gradients found in Table 10).

2.4.9 NORTHERN ACCESS ROUTE

Fish and fish habitat assessments were completed along the NAR in 2016. Many crossings that were assessed in 2015 were revisited in order to collect additional information and where applicable, update the fish bearing status of each crossing. At each crossing, an assessment of channel characteristics was made to determine if the drainage should be considered a stream. A stream was defined as having flow on a perennial or seasonal basis having a continuous channel bed that was scoured by water and contains deposits of alluvium[3]. If it was determined to be a stream, a Fish Habitat Site Card (BC MOE 2008) was completed and investigations were made to determine if the stream was fish bearing, potentially fish bearing or non-fish bearing. Investigations included fish sampling (electrofishing and/or minnow trapping), assessment of habitat quality and evaluation of downstream barriers to fish passage and closely followed methods outlined in BC MOF (1998).

2.4.9.1 Barge Landing Investigations

Proposed barge landings on the Stewart and Yukon rivers were visited and sampled for fish during 2016. Visual observations were made to describe the fish habitat present in these areas. Fish sampling was conducted primarily using beach seining with minnow trapping also conducted at the proposed north Yukon River barge landing site. In some cases, the beach seining sites were located upstream or downstream of the proposed landing sites due to the presence of vertical banks which were not conducive to fish sampling. A total of six beach seining hauls were completed at proposed barge landing sites (three hauls on

[3] This definition is consistent with Forest Practices Code of British Columbia (1998); no such definition of stream in the Yukon could be found. A key consideration is that fish species found in Yukon would not use habitats that do not meet this definition of stream (unless it is a lake or open water wetland).

the Yukon River and three on the Stewart River) and minnow traps were set at two stations on the Yukon River (Figure 10).

The beach seine used was 10 m in length, 2 m deep and constructed of 5 mm mesh. Information collected for each beach seine haul included in-situ water quality, water clarity and seine haul dimensions (length, width, depth). Minnow traps were baited with Yukon River origin salmon roe and left to sit for approximately 24 hours. All fish captured were identified to species and subsample of 10 individuals per species measured to fork length.

2.4.9.2 Stewart River Back Channel Investigations

A back channel on the Stewart River which will be encroached upon by the Northern Access Route was visited on two occasions during 2016: July 14 and October 25. During the July visit, the area downstream of the back channel (Figure 10) was sampled for fish using a beach seine and in-situ water quality parameters were collected. During the October visit, the back channel was visited to collect water quality parameters and determine the potential for fish overwintering.

2.4.9.3 Chum Salmon Spawning Surveys

Aerial surveys were completed by helicopter on the Yukon and Stewart rivers on October 24 and 25, 2016. The Yukon River was surveyed from Britannia Creek (21 km upstream of Coffee Creek) downstream to Dan Man Creek, a river distance of approximately 35 km (Figure 11). The Stewart River was surveyed from 6 km upstream of Maisy May Creek, downstream below the proposed barge landings near Barker Creek to a point 8 kilometers downstream of Brewer Creek for a total river distance of approximately 26 km (Figure 11).

Observers were located in the front and backseats and the pilot positioned them over the river, flying sideways with the best possible vantage point at approximately 40-45 m above ground level. Surveys were completed in an upstream manner with both observers wearing polarized glasses to reduce glare. Air temperatures during the survey were relatively cold (-20°C) which resulted in freezing conditions on both rivers, particularly the Stewart River where the ice conditions limited the ability to see spawning chum. All open water areas within river channel were surveyed, although an emphasis was placed on side channel habitats where groundwater discharge areas were present (known preferred spawning areas for chum salmon on large Yukon rivers).

3 RESULTS – MINE STUDY AREA

The results from all fish and aquatic resource data collected in the Mine study area are synthesized in the following sections. Where results are detailed by date and are not otherwise referenced, the following reference sources apply:

- This report (2016 data);
- PECG 2017 (2014 and 2015 data);
- PECG 2016 (2015 NAR specific data);
- ACG 2014 (2013 data);
- Laberge and White Mountain 2010 and 2002 (2012 and 2001 data, respectively);
- White Mountain (2000 data); and,
- Traditional Knowledge.

3.1 BIOPHYSICAL CHARACTERISTICS OF STREAMS (OVERVIEW)

The biophysical characteristics of the creeks in the Mine study area that were measured from 2014 and 2016 are summarized in Table 10. Other than recent mining exploration for the Project, the watersheds associated with the Mine study area have not been subject to development and as such the streams/watersheds are in an unaltered state. Fish habitat quality varies between and within watersheds, with the most complex and high quality habitat being located in Coffee and Independence creeks. These low gradient streams have moderate size (mean channel widths range of 12 to 25 m; Table 10) with riffle-pool morphologies and primarily a gravel dominated bed. Deep pools (>1 m) are also found in Coffee and Independence creeks. Latte, Halfway and YT-24 creeks have substantially smaller channel widths, no deep pools (>1 m) and higher gradients, especially at sampling stations further upstream in the watersheds. Additional information on biophysical characteristics on streams around the Mine can be found in PECG (2017), APPENDIX B and in sections 3.4 and 5 of this report.

Table 10. Summary of biophysical characteristics of small watersheds associated with Coffee Project, data from PECG 2017 and from 2016 field studies.

Stream Name (Sampling Station)	Mean Channel Width (m)	Mean Channel Gradient (%)	Deep Pools (>1m)	Substrate Type		Total Stream Cover

YT-24 Creek (YT5.0)	1.87	11	N	boulder	cobble	Moderate

3.2 WINTER ICE COVERAGE EXTENT

Aerial video of Coffee, Latte, YT-24, Halfway and Latte Tributary C creeks that was collected in March 2016 showed that that majority of these watercourses were generally completely ice covered at the time of the overflights. Coffee Creek was the only creek where open water was observed. Varying amounts of aufeis formation (evidenced by snow free ice cover, and blue or brown tinged ice cover) were observed in all

creeks, particularly in the lower reaches of YT-24 and Halfway creeks. Ice coverage extent is detailed for each stream in the following sections.

3.2.1 COFFEE CREEK

The aerial video collected on Coffee Creek included the full length of the creek within the Mine study area; this included filming the creek from the confluence with the Yukon River to a linear distance of approximately 11 km upstream. Small, discontinuous areas of open water were observed in several areas in the lower 5 km of the creek (linear distance). This included a number of open water areas in the vicinity of the confluence with the Yukon River, as well as station CF2.7 (Photo 1), where several minnow traps were set in these areas of open water. A narrow area of open water was observed approximately 5 km upstream of the confluence with the Yukon River (Photo 2). Several small and discontinuous areas of 'overflow' or aufeis were observed in Coffee Creek, most notably in two straight and partially confined sections of the creek located approximately 4 km and 6.5 km (Photo 3) upstream of the Yukon River confluence. A small area of open water was also observed in the vicinity of sampling station CF10.0. The remainder of the surface of Coffee Creek was fully ice covered, including all areas upstream of the Latte Creek confluence.

Photo 1. Aerial view of site Coffee Creek sampling station CF2.7, showing winter open water leads; March 15, 2016. Photo blur due to motion of helicopter.

Photo 2. Aerial view of winter open water lead on Coffee Creek approximately 5 km upstream from the Yukon River confluence; March 15, 2016. Photo blur due to motion of helicopter.

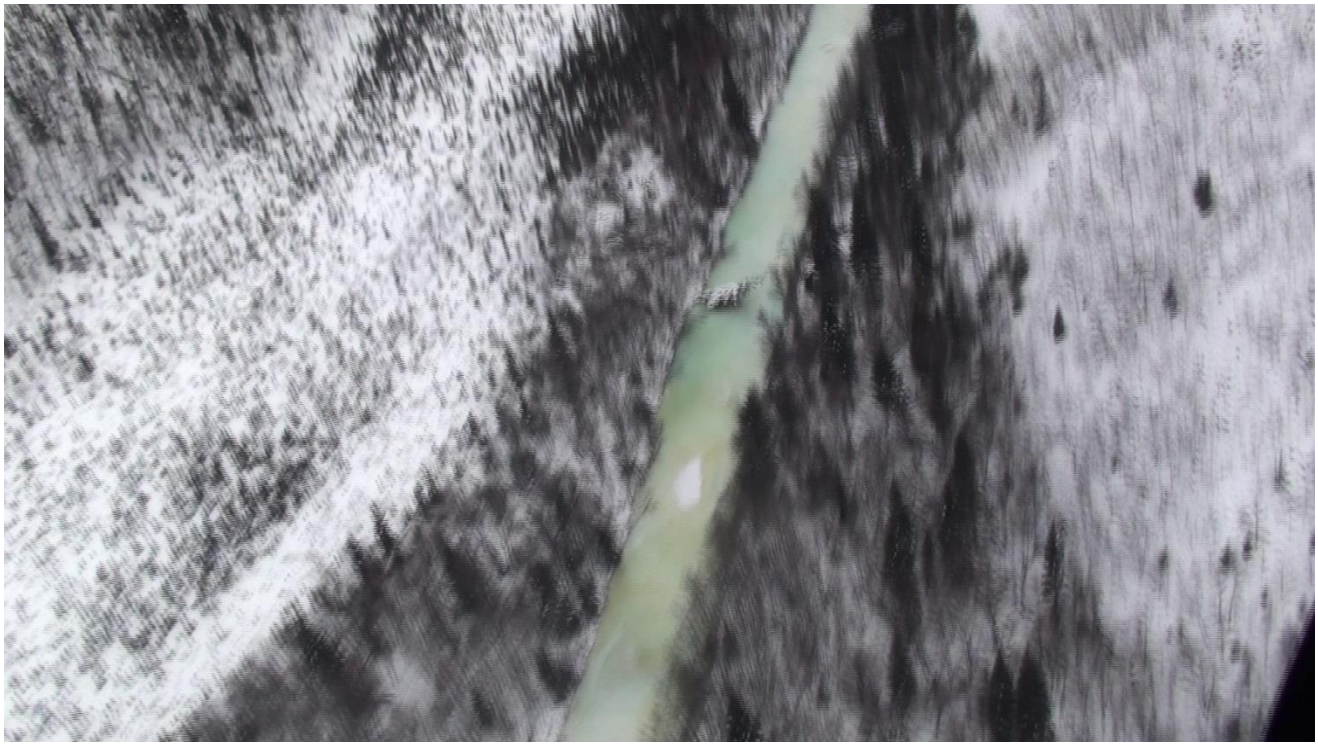

Photo 3. Aerial view of aufeis on Coffee Creek, approximately 5 km upstream of the confluence with the Yukon River.

3.2.2 LATTE CREEK

The aerial video collected on Latte Creek included filming from the confluence with the Coffee Creek to the confluence with Latte Creek Tributary C. No open water areas were observed, and the channel was fully ice covered. Discontinuous aufeis was observed throughout the creek (Photo 4).

Photo 4. Aerial view of aufeis on Latte Creek.

3.2.3 LATTE CREEK TRIBUTARY C

The aerial video collected on Latte Creek Tributary C included filming from the confluence with the Latte Creek to the headwaters of the tributary. No open water areas were observed, and the small channel width was fully ice covered. A small area of 'overflow' or aufeis was observed approximately 600 m upstream of the confluence with Latte Creek (Photo 5).

Photo 5. Aerial view of aufeis area on Latte Creek Tributary C, approximately 600 m upstream of the Latte Creek confluence; March 15, 2016.

3.2.4 YT-24 CREEK

The aerial video collected on YT-24 Creek included filming from the confluence with the Yukon River to the headwaters of the creek. Much of the lower 3 km of the creek channel is heavily forested along the stream banks, and the creek channel was difficult to observe from the air in this portion of the creek. No open water areas were observed, and the small channel width was fully ice covered. A substantial area of aufeis was observed approximately 3 km upstream of the confluence with the Yukon River (Photo 6), and it appeared that the area of aufeis extended beyond the banks of the creek channel.

Photo 6. Aerial view of aufeis formation on YT-24 Creek, approximately 3 km upstream of the Yukon River confluence; March 15, 2016.

3.2.5 HALFWAY CREEK

The aerial video collected on Halfway Creek included filming from the confluence with the Yukon River to the headwaters of the creek. No open water areas were observed, and the channel was fully ice covered. Discontinuous aufeis was observed throughout the Halfway Creek mainstem (Photo 7), but was not observed in smaller first order tributaries.

Photo 7. **Aerial view of aufeis formation on Halfway Creek, approximately 2 km upstream of the confluence with the Yukon River; March 15, 2016.**

3.3 STREAM GRADIENT MODELLING

The 2016 modelling of gradients in the small streams in the vicinity of the Project infrastructure indicates that portions of these streams have gradients that can be prohibitive to fish migration and use. Considering stream gradients independently of other variables, the British Columbia Fish Stream Identification Guidebook (BC MOF 1998) indicates that stream gradients greater than 20% for 100 m or greater can be considered barriers to all fish species.

Due to identified interactions with the Mine footprint, the primary focal streams for the gradient modelling included Latte Creek tributaries B and C and the upper portion of the YT-24 and Halfway Creek watersheds (Figure 12). On Latte Creek Tributary C, modelled stream gradients are commonly within the range of 8 to 16% and higher in the watershed there are sections with gradients in excess of 17% and some gradients over 20%.

The stream gradient modelling indicates that upper Halfway Creek has a number of high gradient sections which likely preclude fish presence in this portion of the watershed. The upper portion of YT-24 Creek has a relatively steep gradient, almost exclusively in excess of 12%. A field verified gradient barrier of 30% has also been documented by PECG (2017) near an area where the modelled gradient data shows an area of greater than 20%.

3.4 FISH DISTRIBUTION

Chinook salmon (juvenile), Arctic grayling, slimy sculpin and chum salmon have been captured or documented in Mine study area sampling stations during sampling conducted in 2000, 2001, 2010, 2013, 2014, 2015 and 2016 (Table 11; APPENDIX C). More detailed information is described for each stream in the following subsections.

Table 11. Summary of fish species documented in the Mine study area during baseline studies.

Station	Location	Years Sampled	Documented Fish Species	Season of Fish Capture or Observation

Fish species codes: CM =Adult chum salmon, CH = Chinook salmon (juvenile), CCG = slimy sculpin, GR = Arctic grayling, AL = Arctic Lamprey, LSU = longnose sucker, BB = burbot, RW = round whitefish.

[1] Round whitefish were added to the fish species at this site during fish tissue sampling during 2016.

[2]Arctic grayling were observed but not captured at this site.

[3]Slimy sculpin were captured in the lower 50 m of the creek, which was back flooded by the Yukon River at the time of sampling.

3.4.1 YUKON RIVER

Traditional Knowledge (TK) and Current Land Use information provides information on fish species that can be found in the Yukon River and speaks to fish species of interest to First Nations and local Yukon residents. TK identifies whitefish (various species), burbot (*Lota lota*), northern pike (*Esox Lucius*), Arctic grayling and Chinook and chum salmon in the Yukon River within the study areas (Bates et. al. 2014, TH 2012, DRPC 2013; Interview 14, Pers. Comm. 2016). This species assemblage is supported by fish sampling during 2016 and is supplemented by the information in the Yukon FISS database of fish species that have been documented in the Yukon River and could potentially be present in the study areas (Table 12).

Table 12. Documented Yukon River fish species that may potentially occur in the study areas (data from DFO 2016).

Category	Common Name[1]	Scientific Name
Salmon species	Chinook salmon *	*Oncorhynchus tshawytscha*
	chum salmon *	*Oncorhynchus keta*
Freshwater fish species	Arctic grayling *	*Thymallus arcticus*
	broad whitefish	*Coregonus nasus*
	lake whitefish	*Coregonus clupeaformis*
	burbot *	*Lota lota*
	inconnu	*Stenodus leucichthys*
	northern pike *	*Esox lucius*
	least cisco	*Coregonus sardinella*
	longnose sucker *	*Catostomus catostomus*
	lake chub *	*Couesius plumbeus*
	slimy sculpin *	*Cottus cognatus*
	round whitefish	*Prosopium cylindraceum*
	Arctic lamprey	*Lethenteron camtschaticum*

[1] Species denoted with an '*' were documented in the Yukon River during 2016 sampling associated with barge landing assessments or spawning assessments. Refer to Section 4.2 for additional information.

Aerial surveys to attempt to document Chinook salmon spawning in the Yukon River within the study areas in July and August 2013 (ACG 2014) and July 2015 (PECG 2017) did not document any spawning activity. Aerial surveys to attempt to document chum spawning salmon in the Yukon River were conducted in September and October 2013 (ACG 2014), 2014 (PECG 2017) and 2016 (this report). Spawning was documented in groundwater fed side channels in both 2013 and 2016. Additional details are provided in Section 4.2.1.

3.4.2 COFFEE CREEK

Juvenile Chinook salmon, Arctic grayling, and slimy sculpin have been documented in Coffee Creek throughout the Mine study area. Juvenile Chinook salmon were captured downstream of the confluence with Latte Creek via minnow trapping (in 2000, 2001, 2010, 2014, 2015 and winter 2016) and electrofishing (2001 and 2010; Table 13). Arctic grayling were captured via angling, electrofishing, beach seining and to a lesser extent, via fyke netting. Upstream of the Latte Creek confluence, sampling during 2016 documented both slimy sculpin and Arctic grayling. Slimy sculpin were captured throughout Coffee Creek via electrofishing, minnow trapping and beach seining. Tr'ondëk Hwëch'in TK indicates that Chinook salmon used to spawn up Coffee Creek (TH 2012); however, recent aerial surveys to attempt to locate Chinook salmon spawning in Coffee Creek in 2000 (sampling month not specified), July 2001, August 2014, July 2015, August 2015 and August 2016 did not report any evidence of spawning. An aerial for chum salmon spawning in October 2014 also did not report any observed spawning activity for this species in Coffee Creek.

Table 13. Baseline fish sampling and capture data in Coffee Creek from 2014 to 2016, ordered by sampling site from downstream to upstream-most site (open water season only).

Sampling Site	Sample Date	Sampling Methods	Total Sampling Effort	Fish Captured
CF3.9	Aug 2014	Minnow Trapping	243.3 trap hours	Chinook salmon (122 juveniles), Slimy sculpin (3)
CF3.9	Aug 2014	Electrofishing	1,457 seconds	Slimy sculpin (24), Chinook salmon (10 juveniles)
CF3.9	Aug 2014	Angling	2 hours	Arctic grayling (1)
CF3.9	Aug 2014	Fyke Net	53.8 trap hours	Arctic grayling (6), Chinook salmon (3 juveniles)
CF3.9	Oct 2014	Minnow Trapping	126.3 trap hours	Chinook salmon (25 juveniles), Slimy sculpin (1)
CF3.9	June 2015	Angling	3.8 hours	Arctic grayling (6)
CF3.9	June 2015	Minnow Trapping	121.25 trap hours	Slimy sculpin (3)
CF3.9	July 2015	Angling	2.5 hours	Arctic grayling (12)
CF3.9	July 2015	Minnow Trapping	132.9 trap hours	Chinook salmon (8 juveniles)
CF3.9	July 2015	Fyke Net	23.1 trap hours	Chinook salmon (1 juvenile)
CF3.9	July 2016	Electrofishing	5,324 seconds	Chinook salmon (3 juveniles), Slimy sculpin (144)
CF3.9	July 2016	Angling	1.3 hours	None
CF5.7	Aug 2014	Minnow Trapping	237.5 trap hours	Chinook salmon (72 juveniles) Slimy sculpin (1)
CF5.7	Oct 2014	Minnow Trapping	125 trap hours	Chinook salmon (30 juveniles) Slimy sculpin (2)
CF5.7	June 2015	Angling	3 hours	Arctic grayling (2)
CF5.7	June 2015	Minnow Trapping	112.5 trap hours	Slimy sculpin (2)
CF5.7	July 2015	Angling	1.5 hours	Arctic grayling (7)
CF5.7	July 2015	Minnow Trapping	99.6 trap hours	Chinook salmon (2 juveniles), Slimy sculpin (1)
CF5.7	July 2015	Fyke Net	26 trap hours	None
CF8.0	Aug, 2014	Minnow Trapping	271.7 trap hours	Chinook salmon (62 juveniles), Slimy sculpin (4)
CF8.0	Oct 2014	Minnow Trapping	125 trap hours	Chinook salmon (16 juveniles), Slimy sculpin (3)
CF8.0	July 2015	Minnow Trapping	123.8 trap hours	Arctic grayling (1), Chinook salmon (14 juveniles), Slimy sculpin (4)
CF8.0	July 2015	Fyke Net	23.92 trap hours	None
CF8.0	Aug 2014	Fyke Net	46.6 trap hours	Arctic grayling (3) Slimy sculpin (3)
CF8.0	Aug, 2014	Electrofishing	1,118 seconds	Slimy sculpin (31)
CF8.0	July 2015	Electrofishing	942 seconds	Slimy sculpin (6)
CF8.0	July 2015	Fyke Net	23.9 trap hours	None
CF8.0	July 2015	Angling	3.8 hours	Arctic grayling (20)
CF10.0	July 2016	Electrofishing	4,616	Arctic grayling (9), Slimy sculpin (34)
CF10.0	July 2016	Angling	0.5 hours	Arctic grayling (3)

3.4.3 LATTE CREEK

In Latte Creek, Arctic grayling and slimy sculpin were documented in 2014, 2015 and 2016 (grayling only; Table 14). Slimy sculpin were captured only at the most downstream station (LC0.5), near the confluence with Coffee Creek (within 50 m). Further upstream, Arctic grayling were captured in moderate numbers at station LC2.7, with an approximate population estimate of 6 Arctic grayling/100 m² in 2014, and 10 Arctic grayling/100 m² in 2015 (±2 grayling, 90% confidence intervals for both years; PECG 2017). No fish were captured upstream of station LC2.7 (including at stations LC9.9, LC10.4 and LC11.8); however, one adult Arctic grayling was observed at station LC9.9 during the summer of 2015. None were captured or observed during 2016.

Table 14. Baseline fish sampling and capture data in Latte Creek from 2013 to 2016, ordered by sampling site from downstream to upstream-most site (open water period only).

Sampling Site	Sample Date	Sampling Methods	Total Sampling Effort	Fish Captured
LC0.5	July 2015	Minnow Trapping	240 trap hours	Slimy sculpin (1)
LC0.5	June 2015	Electrofishing	1,839 seconds	Arctic grayling (5) Slimy sculpin (3)
LC0.5	July 2015	Electrofishing	1,309 seconds	Arctic grayling (1) Slimy sculpin (1)
LC0.5	Sept 2015	Electrofishing	1,100 seconds	Arctic grayling (1) Slimy sculpin (1)
LC0.5	Oct 2014	Fyke Netting	25.8 trap hours	Slimy sculpin (7) Arctic grayling (1)
LC0.5	Sept 2015	Minnow Trapping	110.4 trap hours	None
LC2.7	Aug 2014	Minnow Trapping	118.4 trap hours	None
LC2.7	Aug 2014	Electrofishing	2,898 seconds	Arctic grayling (20)
LC2.7	June 2015	Electrofishing	1,278 seconds	Arctic grayling (11)
LC2.7	July 2015	Electrofishing	3,151 seconds	Arctic grayling (39)
LC2.7	July 2016	Electrofishing	3,108 seconds	Arctic grayling (7)
LC9.9	June 2015	Electrofishing	870 seconds	None
LC9.9	July 2015	Electrofishing	854 seconds	None
LC9.9	July 2016	Minnow Trapping	216 trap hours	None
LC10.4	Aug 2014	Minnow Trapping	58 trap hours	No fish captured
LC11.8	Aug 2014	Minnow Trapping	55 trap hours	No fish captured
LC11.8	June 2015	Electrofishing	768 seconds	No fish captured
LC11.8	July 2015	Electrofishing	835 seconds	No fish captured

3.4.4 LATTE CREEK TRIBUTARY B

Latte Creek Tributary B was visited in July 2016. This tributary was dewatered at its confluence with Latte Creek at the time of the field visit and had no potential to support fish of any kind. Small areas of

discontinuous pooled water were present in the lower 100 m of the watercourse, potentially from recent precipitation. Considerable amounts of terrestrial vegetation were present in this seasonal drainage and alluvial bed material was discontinuous (Photo 8). Further upstream the dry drainage narrowed and two hard barriers were documented with drops of 0.5 and 0.6 m, respectively. Gradients of 16 and 21% were measured in this portion of the watercourse. This is not a stream, rather a seasonal seepage area.

Photo 8. Latte Creek Tributary B lacking continuous channel and alluvial material.

3.4.5 LATTE CREEK TRIBUTARY C

This small tributary was not sampled for fish previous to 2016. Minnow trapping and electrofishing was completed in the lower 300 m of the stream in July 2016, no fish were captured (Table 15).

The lower 15 m of this stream is influenced by back flooding from Latte Creek (Photo 9). A 1 m high cascade over organics is present 15 m upstream of the mouth (Photo 10). Between this drop and 100 m from the mouth the channel is often poorly defined with a discontinuous alluvial bed (Photo 11). Upstream of the first 100 m, channel banks and alluvial bed material re-establish; however, the channel is narrow (~0.6 m channel width) with maximum residual pool depths of 0.13 m and numerous (non-permanent) drops over organic material up to 0.65 m (Photo 12). The average stream gradient of Tributary C between 100 m and

200 m from the confluence with Latte Creek was 13.5%. Moving upstream in the watershed gradients increase and the channel becomes narrower.

Table 15. Baseline fish sampling and capture data in Latte Creek Tributary C, ordered by sampling site from downstream to upstream-most site.

Sampling Site	Sample Date	Sampling Methods	Total Sampling Effort	Fish Captured
LCC0.0	July 2016	Minnow Trapping	69.5 trap hours	None
LCC0.0	July 2016	Electrofishing	105 seconds	None
LCC0.2	July 2016	Minnow Trapping	57.1 trap hours	None
LCC0.2	July 2016	Electrofishing	509 seconds	None
LCC0.3	July 2016	Electrofishing	114 seconds	None

Photo 9. Downstream view of lower 15 m of Latte Tributary C. Note Latte Creek in the background and cascade at the lower portion of the photo.

Photo 10. One metre high cascade located 15 m upstream from the mouth of the stream.

Photo 11. Poorly defined channel in the lower 100 m of the Latte Creek Tributary C.

Photo 12. Upstream view of Latte Creek Tributary C in in the section 100-300 m upstream of the mouth.

3.4.6 HALFWAY CREEK

Halfway Creek has been sampled from 2013 to 2016 via a combination of minnow trapping and electrofishing (Table 16). Sampling near the confluence with the Yukon (HF0.0) resulted in the capture of one Arctic grayling in 2014 and 2015 and twenty slimy sculpin in 2016 (sculpin were captured in an area backwatered by the Yukon River). In the lower part of Halfway Creek, upstream of the mouth (HF0.2), no fish were captured in July 2016 or four sampling events in 2013, but twenty juvenile Chinook salmon and one Arctic grayling were captured in August 2016 in the lower 350 m of the stream. No fish were captured from 350-800 m of the mouth during the same sampling event.

Upstream of station HF0.2, the stream gradient of Halfway Creek begins to increase, the stream channel narrows and a number of small drops are present, including a 1.05 m drop over a large log jam at station HF0.9 (Photo 13). The water drops onto a log before dropping to the streambed, the plunge pool at the bottom of the drop has a depth of 0.4 m. This obstruction exceeds the jumping ability of adult Arctic grayling and juvenile Chinook salmon (Parker 2000). Electrofishing conducted in July 2016 immediately downstream and upstream of this drop did not capture any fish.

In the middle reaches of Halfway Creek (HF6.3) the stream channel gradient increases to an average of 10%, the channel narrows to approximately 2 m and residual pool depths are 0.17 m or less. Fish habitat is limited by fast flow and lack of deep pool habitat. Similar gradients and habitat extend up to stations HF8.8 and HF9.3. A field verified channel gradient of 21.3% over a distance of 100 m was documented in July

2016 in the headwaters of Halfway Creek at station HFA0.1. Fish sampling at station HF6.3, HF8.8, HF9.3 and HFA0.1 has included 3,205 seconds of electrofishing and 228 minnow trap hours (Table 16, not including winter sampling) and no fish have been captured at any of these sites.

Table 16. Baseline fish sampling and capture data in Halfway Creek from 2013 to 2016, ordered by sampling site from downstream to upstream-most site (open water season only).

Sampling Site	Sample Date	Sampling Methods	Total Sampling Effort	Fish Captured
HF0.0	August 2014	Electrofishing	653 seconds	1 Arctic grayling
HF0.0	June and July 2015	Electrofishing	1,421 seconds	1 Arctic grayling
HF0.0	August 2016	Electrofishing	97 seconds	20 slimy sculpin (in area backwatered by Yukon River)
HF0.2	July, August, September, October 2013	Minnow Trapping	185.2 trap hours	None
HF0.2	July 2016	Electrofishing	829 seconds	None
HF0.2	July 2016	Minnow Trapping	128.3 trap hours	None
HF0.2	August 2016	Electrofishing	2,084 seconds (600 m lineal length)	20 juvenile Chinook salmon, 1 Arctic grayling (all fish captured in the lower 350 m of stream)
HF0.9	July 2016	Electrofishing	287 seconds (210 of which upstream of falls)	None
HF6.3	July, August, September, October 2013	Minnow Trapping	175.9 trap hours	None
HF6.3	July 2016	Electrofishing	211 seconds	None
HF6.3	August 2016	Electrofishing	1,107 seconds	None
HF8.8	July 2016	Electrofishing	201 seconds	None
HF9.3	August 2014	Minnow Trapping	52.2 trap hours	None
HF9.3	June and July 2015	Electrofishing	1,741 seconds	None
HFA0.1	July 2016	Electrofishing	156 seconds	None

Photo 13. Field crew member standing downstream of a 1.05 m drop on Halfway Creek at station HF0.9, July 2016.

3.4.7 YT-24

Slimy sculpin are the only fish species that have been captured in YT-24 Creek. Five slimy sculpin were captured within 50 m of the Yukon River in 2015, which was back-flooded into the creek at the time of sampling (at station YT0.0; Table 17). In August 2016, twenty slimy sculpin were captured at this same sampling station; back-flooding by the Yukon River was also occurring during this sampling event. No fish were captured at the mouth of YT-24 in August 2014 or July 2016.

Upstream of the stream mouth, no fish have been captured by electrofishing and minnow trapping conducted in the lower reaches of the YT-24 (YT0.2, YT0.6, YT0.9 and YT1.3). Similarly, no fish were captured in the upper portion of YT-24 (YT4.6 and YT5.0) in any of the sampling conducted in 2014, 2015 or 2016 (Table 17).

A number of small drops in the stream channel are present a short distance upstream of the confluence with the Yukon River, including a 0.75 drop over a log jam approximately 100 m upstream of the mouth of the creek (Photo 14), a 0.7 m drop approximately 600 m upstream of the creek mouth as well as additional smaller drops. These drops are not permanent features, but likely limit the extent of fish use in the watershed.

In the upper reaches of YT-24 Creek (YT4.6), the average stream gradient increases to 9%, there is minimal instream cover and residual pool depths are 0.18 m on average. Fish habitat quality is poor. Electrofishing at this location in July 2016, and at stations YT5.0 in 2014, 2015 and August 2016 did not capture any fish. A barrier to fish passage (30% gradient over 7.4 m) was documented upstream of station YT5.0 by PECG

(2017; Figure 12). This barrier prevents access for all fish to the portion of YT-24 near the mine infrastructure.

Table 17. Baseline fish sampling and capture data in YT-24 from 2014 to 2016, ordered by sampling site from downstream to upstream-most site.

Sampling Site	Sample Date	Sampling Methods	Total Sampling Effort	Fish Captured
YT0.0	August 2014, June and July 2015, July 2016	Electrofishing	1,918 seconds	25 slimy sculpin
YT0.2	July and August 2016	Electrofishing	2,172 seconds	None
YT0.2	July 2016	Minnow Trapping	125.8 trap hours	None
YT0.6	July 2016	Electrofishing	259 seconds	None
YT0.9	July 2016	Electrofishing	276 seconds	None
YT1.3	July 2016	Electrofishing	209 seconds	None
YT4.6	July 2016	Electrofishing	331 seconds	None
YT5.0	August 2014	Minnow Trapping	48.8 trap hours	None
YT5.0	June and July 2015, August 2016	Electrofishing	2,306 seconds	None
YT5.9	July 2016	Electrofishing	171 seconds	None

Photo 14. View of a 0.75 m drop in YT-24 Creek approximately 100 m upstream of the Yukon River, July 2016.

3.4.8 INDEPENDENCE CREEK, INCLUDING THE KONA TRIBUTARY

Arctic grayling, juvenile Chinook salmon, and slimy sculpin were captured in the mainstem of Independence Creek in 2014 and 2015. Juvenile Chinook salmon were present in low numbers throughout Independence Creek, with the highest numbers closer to the confluence with the Yukon River (Table 18). Slimy sculpin were captured in the downstream sampling station (ID1.9), but not upstream at the ID6.7 sampling station. Arctic grayling were found throughout Independence Creek. In 2014, an Arctic grayling population estimate of 3 Arctic grayling/100 m^2 (±2, 90% CI) was documented at station ID6.7 using multiple-pass electrofishing depletion sampling (PECG 2017).

Two stations were sampled in the Kona Tributary of Independence Creek in 2014 and 2015; one near its confluence with the mainstem of Independence Creek (KT0.1) and one in the upper headwaters of the Kona Tributary (KT5.2). Fish sampling results have documented Arctic grayling at the lower sampling site in the Kona Tributary; however, they were present in low numbers.

Chinook salmon aerial spawning surveys in Independence Creek (July 2013, August 2014, July 2015, August 2015 and August 2016) did not document any spawning activity. Similarly, an aerial spawning survey of Independence Creek in October 2014 did report any chum salmon spawning activity.

Table 18. Baseline fish sampling and capture data in Independence Creek and Kona Tributary 2014 to 2016, ordered by sampling site from downstream to upstream-most site (open water season only).

Sampling Site	Sample Date	Sampling Methods	Total Sampling Effort	Fish Captured
ID1.9	Aug-14	Minnow Trapping	249.2 trap hours	10 Chinook salmon
ID1.9	Aug-14	Electrofishing	1,939 seconds	3 Arctic grayling, 9 slimy sculpin, and 1 Chinook salmon
ID1.9	Oct-14	Minnow Trapping	125 trap hours	6 Chinook salmon
ID1.9	Jun-15	Minnow Trapping	127.9 trap hours	1 Chinook salmon
ID1.9	Jul-15	Minnow Trapping	311.6 trap hours	10 Chinook salmon
ID1.9	Sep-15	Minnow Trapping	382.5 trap hours	1 slimy sculpin and 4 Chinook salmon
ID1.9	May-15	Electrofishing	4,034 seconds	7 slimy sculpin
ID1.9	July 2016	Electrofishing	5,325 seconds	31 slimy sculpin
ID1.9	July 2016	Angling	58 minutes	None
ID6.7	Aug-14	Minnow Trapping	247.5 trap hours	1 Chinook salmon
ID6.7	Aug-14	Electrofishing	1,295 seconds	5 Arctic grayling
ID6.7	Oct-14	Minnow Trapping	103.4 trap hours	None
ID6.7	Jul-15	Minnow Trapping	118.8 trap hours	None
ID6.7	Jul-15	Angling	5.5 hours	8 Arctic grayling
KT0.1	Aug-14	Minnow Trapping	45 trap hours	None
KT0.1	Aug-14	Electrofishing	591 seconds	None
KT0.1	Jun-15	Electrofishing	690 seconds	3 Arctic grayling
KT0.1	Jul-15	Electrofishing	627 seconds	None
KT5.2	Aug-14	Minnow Trapping	47 trap hours	None
KT5.2	Jun-15	Electrofishing	773 seconds	None
KT5.2	Jul-15	Electrofishing	559 seconds	None

3.5 FISH OVERWINTERING

The March 2015 winter fish habitat assessments was completed at six stations in Latte and Coffee creeks and included collection of under-ice video. The March 2016 winter fish habitat and overwintering assessment was completed at 13 stations including Coffee, Latte, Independence, Halfway and YT-24 creeks and included under ice video and fish sampling.

In 2015, ice covered all stations with ice thickness ranging from of 15 to 57 cm. Flowing water was only found at Coffee Creek in 2015 with depths ranging from 37 to 82 cm. In March 2016, all stations on Coffee Creek were covered by 5 to 10 cm of ice (Table 19), with the exception of an ice free glide at station CF2.3 (station 5). Flowing water was present at most samplings stations in 2016, and water depths at sampling stations varied from 22 to 135 cm. Water was deepest at sampling stations in the mainstem of Coffee Creek and was shallower at sampling stations in Latte and Halfway creeks.

Fish sampling in March 2016 was generally conducted in glide or pool habitats, where there was sufficient water depth to set minnow traps. Water temperature was near freezing (range of 0.5 of -0.1 °C) at all sampling stations; in-situ pH ranged from slightly acidic to slightly basic (6.21 to 7.65) and specific conductivity ranged from 242.8 to 402.1 µS/cm.

Dissolved oxygen concentrations differed considerably between sampling stations. In March 2015, dissolved oxygen in Coffee Creek was 10.3 to 13.95 mg/L, at stations CF8.0 and CF5.7, respectively. At sampling stations in Latte Creek, Halfway Creek and the upstream portions of Coffee Creek (CF2.7, CF8.3 and CF10.0) dissolved oxygen concentrations were relatively high, and ranged from 8.84 mg/L to 12.59 mg/L (March 2016; Table 19). In contrast, dissolved oxygen concentrations ranged from 5.85 mg/L to 7.82 mg/L in the downstream most sites in Coffee Creek and Independence creeks (station CF0.5 and ID1.9; March 2016).

In the vicinity of sampling station CF2.7 on Coffee Creek, two small side channels were observed to be free of ice during the March 2016 field investigations. Based upon the lack of ice cover in these channels and the slightly warmer water (up to 0.5°C; Photo 15), these areas are probable groundwater discharge areas. Such areas are often important for overwintering fish and this was confirmed by the capture of juvenile Chinook either within the channels or in the mainstem of Coffee Creek near the outlet of the channels.

Table 19. Summary of winter fish habitat information collected at the Coffee Project, March 2016.

Stream Name	Station Name	Sampling Site Number	Habitat Type	Water Depth (cm)	Ice Thickness (cm)[1]	In-Situ Water Quality			
						Temperature (°C)	Dissolved Oxygen (mg/L)	pH	Specific Conductivity (µS/cm)
Coffee Creek	CF0.5	1	Pool	35	5-10	0.3	5.85	6.81	271.2
Coffee Creek	CF0.5	2	Pool	54	10	0.2	7.35	6.92	269.2
Coffee Creek	CF2.7	1	Glide	25	5	0.1	8.96	6.44	294.7
Coffee Creek	CF2.7	2	Glide	26	5	0	12.29	6.75	291.7
Coffee Creek	CF2.7	3	Not observable due to ice cover	135	5-10	0	11.54	6.88	283.2
Coffee Creek	CF2.7	4	Glide/Pool	45	<5	0.2	9.12	6.21	292.4
Coffee Creek	CF2.7	5	Glide	22	0	0.5	9.16	6.57	285.4
Coffee Creek	CF2.7	6	Pool	126	<5	0.1	8.84	6.79	306.9
Coffee Creek	CF8.3	1	Glide/Pool	80	<5	0	10.84	7.11	401.2
Coffee Creek	CF10.0	1	Pool	41	<5	0	12.59	7.37	374.1
Latte Creek	LC1.6	1	Not observable due to ice cover	26	10	-0.1	8.74	7.24	259.5
Latte Creek	LC 9.9	1	Not observable due to ice cover	-	-	0.0	9.88	6.99	482.1
Latte Creek Trib C	LCC0.1	1	Not observable due to ice cover	-	-	0.0	9.45	8.03	929.0
YT-24	YT0.2	1	Not observable due to ice cover	Frozen to bed, no water found.					
Kona Trib	KT0.1	1	Not observable due to ice cover	Frozen to bed, no water found.					
Halfway Creek	HF6.3	1	Pool	34	5-10	0	11.36	7.65	336.9
Independence Creek	ID1.9	1	Pool	67	5	0	6.55	6.83	242.8
Independence Creek	ID1.9	2	Pool	35	5-10	0.1	7.82	6.77	245.6

[1] Ice thickness varied throughout the areas sampled; however, minnow traps were placed in areas where the ice was thin and easy to clear.

Photo 15. View of probable groundwater fed side channel in Coffee Creek (station CF2.7).

3.5.1 MINNOW TRAPPING AND UNDERWATER VIDEO COLLECTION

Minnow trapping effort and fish capture data from the March 2016 field sampling is shown in Table 20; detailed station specific fish sampling data is included in APPENDIX B. A total of 39 minnow traps were set for a cumulative total of 838.15 hours of minnow trapping effort. A total of 53 fish were captured including 47 juvenile Chinook and 6 slimy sculpin (Table 20; Photo 16). All fish were captured at sampling stations in Coffee Creek with the highest number of fish captured at stations CF0.5 and CF2.7. Slimy sculpin were captured at all four sampling stations in Coffee Creek, although the catch per unit effort (CPUE) was relatively low across all stations (average = 0.22 fish/24 minnow trapping hours by sampling station). Juvenile Chinook were only captured at stations CF0.5 and CF2.7, with CPUE which ranged from a low of 4.80 fish/24 minnow trapping hours to a high of 17.06 fish/24 minnow trapping hours at station CF0.5.

Photo 16. Juvenile Chinook salmon captured in Coffee Creek (station CF2.7) during early March 2016.

Lengths and weights of captured fish are summarized in Table 21; due to the relatively small samples size of captured fish, length and weight data from all stations were grouped together. Only fish that were retained for metals tissue analysis were weighed; this included incidental mortalities of juvenile Chinook and all slimy sculpin. Captured slimy sculpin had fork lengths ranging from 66 to 85 mm, while juvenile Chinook salmon had fork lengths ranging from 60 to 90 mm (Table 21). The mean fork length of both species was 75 mm. Juvenile Chinook weighed between 3.2 and 5.1 grams; the range of slimy sculpin weights was greater (2.3 to 7.1 grams). Mean weights were 4.7 grams for slimy sculpin and 3.9 grams for juvenile Chinook salmon.

Fish observations from underwater video data collected in 2016 are summarized in Table 22. Underwater visibility was very good (5 to 10 m or greater) at all stations where investigations were conducted in 2016; information on the condition of under ice visibility was not recorded in 2015. A total of 150 minutes of underwater video were recorded in 2016 and only a single fish was observed on the collected video data (at station CF0.5, site 1). This species of this fish could not be discerned from the collected video data. A total of 30 minutes of underwater video were recorded in March 2015; no fish were observed in any of the video data collected in 2015.

Table 20. Summary of minnow trapping effort and fish capture data from the Mine study area in March 2016.

Stream Name	Station Name	Sampling Site Number	Number of Minnow Traps Set	Total Set Time (Hours)	Number of Fish Captured		Catch-per-unit-effort (Number of fish per 24 minnow trap hrs)	
					Slimy Sculpin	Juvenile Chinook	Slimy Sculpin	Juvenile Chinook

3.6 PERIPHYTON

Mean chlorophyll-a and ash-free dry mass (AFDM) measured in 2014 and 2015 were very low for all stations[4], which is typical of northern, nutrient poor aquatic habitats (PECG 2017). There was little variation among the stations and there was no relationship between chlorophyll-a and ash-free periphyton mass; differences in chlorophyll-a content may have been due to varying light conditions, nutrient availability, and periphyton taxonomy, which results in different proportions of photosynthetic:non-photosynthetic organisms that comprise periphyton (Barbour et al. 1999). Given that the 2014 and 2015 samples missed laboratory holding times, combined with the low nutrient status of these streams, the results may have underestimated the chlorophyll-a concentrations. Therefore, all streams within the Project area as well as reference sites were re-sampled for chlorophyll-a concentration in August 2016. The 2016 data indicated higher concentrations of chlorophyll-a throughout the sampling locations when compared with 2014 and 2015 data. Chlorophyll-a was lowest in samples collected farthest upstream in each of the watersheds, and increased in downstream locations. This trend existed in Latte Creek, with values of 0.13 mg/cm^2 at the upstream sampling location (LC9.9), and 0.26 mg/cm^2 closer to the confluence (LC2.7), in Coffee Creek (0.57 and 0.88 mg/cm^2) at the upstream and downstream sites, respectively, and in YT-24 (0.61 and 0.76 mg/cm^2) and Halfway creeks (0.30 and 0.69 mg/cm^2) as well (APPENDIX D).

Community composition included blue-green algae (cyanophyta), which comprised approximately 80% of the overall community composition and was the most dominant algal group in the study area; diatoms were the second most dominant group, followed by small percentages of green algae (chlorophyte; PECG 2017). Blue-green algae tended to dominate at higher elevation stations within the Mine study area, whereas higher proportions of diatoms were present further downstream, at lower elevations. The large diatom *Didymosphenia geminata* was confirmed at station ID1.9 in Independence Creek in 2014; this species has become increasingly prolific in British Columbia and Yukon in recent years, and is commonly referred to as 'rock snot' (YISC 2014).

3.7 BENTHIC INVERTEBRATE COMMUNITIES

Benthic invertebrate sampling in 2001 was conducted using a 300 µm mesh surber sampler and did not follow the standardized Canadian Aquatic Biomonitoring Network (CABIN) protocols used in later sampling in 2010, 2014 and 2015. The CABIN protocols provide a standardized method to sample benthic invertebrate communities (NWRI 2008), and allows for robust data analysis by leveraging a large, nation-wide database of invertebrate community data. As such, the data described in this section are from the 2010, 2014 and 2015 studies only. The benthic invertebrate sampling conducted in March and August 2016 focused on collecting samples for metals analysis only, and was not analyzed for benthic invertebrate abundance and diversity (APPENDIX E).

[4] Hold times for chlorophyll-a sample analysis were exceeded for a number of stations during the 2014/2015 baselines studies (PECG 2016).

Sampling in 2010 at the mouth of Coffee Creek showed the highest abundance of benthic invertebrate in all three sampling years (2010, 2014 and 2015) with a total abundance of 9,500 individuals per kick-net. In 2014 and 2015, mean total abundance of benthic invertebrates ranged from 247 to 3,885 individuals per kick-net in the watersheds in the Mine study area. Independence Creek had the highest total abundance followed by YT-24, Coffee Creek, Latte Creek and then Halfway Creek. Total abundance generally increased in an upstream direction within watersheds.

Ephemeroptera-Plecoptera-Trichoptera (EPT) abundances within the study area demonstrated similar patterns to overall abundance. Some stations had high between-year variability, such as at ID1.9 in lower Independence Creek (PECG 2017).

Dipterans were the most dominant benthic invertebrate group in the Mine study area, making up approximately 50% of the overall community composition. The second and third most dominant groups were the mayflies (*Ephemeroptera*) and stoneflies (*Plecoptera*), which contributed approximately 26% and 21% to the overall community composition, respectively. Small percentages of ringed worms (Annelids), and caddisflies (*Trichoptera*) were also present at the majority of stations. In Coffee and Independence creeks, EPT organisms typically dominated stations higher in the watershed; dipteran species dominated further downstream (PECG 2017).

3.8 METAL CONCENTRATIONS IN THE AQUATIC ECOSYSTEM

3.8.1 METAL CONCENTRATIONS IN FISH TISSUE

Fish tissue metal concentrations were analyzed from a total of twenty-four Arctic grayling and seventeen slimy sculpin captured in Coffee, Latte and Independence creeks in 2014 and 2015 (PECG 2017); muscle tissues were collected from Arctic grayling, and full body samples were collected from sculpin. In March 2016, additional tissue samples were collected and analyzed for metal concentrations from seven slimy sculpin and six juvenile Chinook salmon that were captured in Coffee Creek. All fish collected in 2016 were analysed as whole body samples in order to fully investigate uranium concentrations in fish tissues; uranium is stored preferentially in mineralized tissues such as bones. In July additional samples were collected from Coffee, Latte, Independent and Los Angeles creeks, and finally in August 2016 there were 12 juvenile Chinook salmon and one Arctic grayling from Halfway Creek were collected for analysis (Table 6; APPENDIX E). Currently, established tissue concentration guidelines exist for total mercury (CFIA 2011) and methylmercury (CCME 2000a). There are no federal guidelines for tissue concentrations of selenium, however, the EPA has developed guidelines for both tissue and whole body samples (8.5 µg/g dw for whole body and 11.3 µg/g dw for fish tissue, EPA 2015), and British Columbia has developed a muscle tissue and whole body guideline (both set at 4 µg/g dw, BC MOE 2014). Additionally, uranium concentrations in fish tissues were reviewed as uranium can be naturally elevated in some streams in the Mine study area (especially during low flows).

3.8.1.1 Arctic Grayling

Mercury is stored in muscle tissue, generally in the form of methylmercury, and therefore the muscle tissue samples generally had a slightly higher mercury and methylmercury concentrations that the whole body samples; however, the difference was small (Table 23). Baseline total mercury concentrations in all sampled Arctic grayling, including tissue and whole body samples, did not exceed the Canadian Food and Inspection Agency (CFIA) guideline (0.5 µg/g ww; CFIA 2011; Figure 13). In contrast, estimated methylmercury concentrations (95% of total mercury concentrations, Jewett et. al. 2003) in nearly all Arctic grayling sampled in Coffee, Latte, Independence and Los Angeles Creek exceeded the Canadian Council for the Ministers of the Environment (CCME) guideline for the protection of piscivorous wildlife (0.033 µg/g ww; CCME 2000a). Mean concentrations were lowest in Halfway (the only grayling captured in Halfway Creek had a methylmercury concentration below the guideline), Los Angeles, and Independence creeks, while higher methylmercury concentrations were noted in Coffee and Latte creeks (Table 23; Figure 14).

Selenium concentrations in Arctic grayling muscle tissue did not exceed the EPA's interim guideline for fish muscle tissue (11.3 µg/g dw; EPA 2015). The lowest selenium concentrations were found in Arctic grayling muscle tissues collected in Latte Creek, just upstream of the confluence with Coffee Creek. In 2016 whole body selenium concentrations were collected in Coffee Creek at CF10.0, in Latte Creek at LC2.7, in Halfway Creek at HF0.2 (only one grayling) and in Los Angeles Creek at LaC4.8. Mean dry weight concentrations were similar across all sampling sites, ranging from 5.1 µg/g dw at Latte Creek (LC2.7) to a high of 6.5 µg/g dw at Coffee Creek (CF10.0) (Table 23; Figure 15). Nearly all samples from all sites, with the exception of five Arctic grayling from Latte Creek exceeded the BC tissue and whole body guidelines for selenium (which are both set at 4 µg/g dw, BC MOE 2014).

Uranium concentrations in Arctic grayling muscle tissues collected in 2014 and 2015 from all watersheds ranged from less than 0.001 µg/g ww in Latte, Los Angeles, Coffee and Independence creeks to a high of 0.014 µg/g ww in Halfway Creek (Table 23; Figure 16). Whole body uranium concentrations were collected in 2016 from Coffee Creek at CF10.0, in Latte Creek at LC2.7, in Halfway Creek at HF0.2 (only one grayling) and in Los Angeles Creek at LaC4.8. All whole body grayling samples had higher uranium concentrations than muscle tissue samples collected in 2014 and 2015. However, there was no discernable trend was observed in uranium concentrations in Arctic grayling tissues among different sites. The highest mean whole body uranium concentration was at LC2.7, 0.034 µg/g ww, and the lowest at LaC4.8, with a concentration of 0.034 µg/g ww; only one whole body Arctic grayling sample was collected from Halfway Creek, and the concentration was 0.011 µg/g ww. With the exception of Coffee Creek, Arctic grayling generally only populate streams in the LSA during the summer months, when uranium concentrations in the water are lowest; this use of the habitat likely allows the grayling to maintain low tissue concentrations of uranium.

Table 23. Descriptive statistics for Arctic grayling tissue metals concentrations (whole body and muscle tissue samples presented separately).

Creek	Sampling Site	N	Statistic	Mercury (µg/g ww)	MeHg Estimate [1] (µg/g ww)	Selenium (µg/g ww)	Selenium [2] (µg/g dw)	Uranium (µg/g ww)

1. For Arctic grayling, methylmercury was estimated as 94% of total mercury, as per Jewett et al 2003.
2. Selenium is presented as dry weight (dw) in addition to wet weight (ww) to compare with the EPA guidelines, which were calculated as dry weight.

3.8.1.2 Slimy Sculpin

Slimy sculpin samples for metals analysis were collected only from Coffee Creek, the mouth of Latte Creek (LC0.5), Independence Creek, and Los Angeles Creek (only one sample). Mean total mercury concentrations were lowest in upstream Coffee Creek at CF10.0, with a concentration of 0.055 µg/g ww, and highest in fish sampled at the mouth of Latte Creek, where the mean concentration was 0.154 µg/g ww (Table 24). The CFIA guideline for total mercury does not apply to slimy sculpin because they are not a human food source; however, mercury concentrations from all sculpin samples were below the guideline (Figure 13). The estimated concentrations of methylmercury (81% of total mercury, Jewett et al 2003) exceeded the CCME

guideline set for the protection of piscivorous wildlife (0.033 µg/g ww; CCME 2000a) in all creeks where sculpin were sampled including Coffee, Latte (at the mouth), Independence and Los Angeles creeks (Table 24; Figure 14). The lowest concentrations were found in slimy sculpin collected from Independence Creek, while the highest concentrations were found in sculpin collected in the Coffee Creek watershed, including from the mouth of Latte Creek.

Selenium concentrations in slimy sculpin tissue samples varied widely across the LSA, and even within Coffee Creek. Mean selenium concentration in samples collected from Coffee Creek at CF3.9 and CF10.0 and the single sample from Los Angeles Creek exceeded the EPA whole body fish tissue concentration guideline (8.5 µg/g dw; EPA 2015; Table 24). Concentrations were lower (and less variable) in sculpin collected from Coffee Creek at CF2.3 and CF8.0, as well as Latte and Independence creeks (Figure 15).

Uranium concentrations were higher in slimy sculpin tissues, compared with Arctic grayling and juvenile Chinook salmon, due to their high site fidelity and overwintering habits (water quality data indicates that the highest water uranium concentrations are seen in later winter (Lorax 2016). Concentrations of uranium were considerably higher in the Coffee Creek watershed when compared with other stations in the study area. The lowest concentrations were noted in slimy sculpin tissues collected from Isaac and Los Angeles creeks (mean concentrations of 0.015 and 0.011 µg/g ww, respectively) (Table 24; Figure 16).

Table 24. Descriptive statistics for slimy sculpin tissue metals concentrations.

Creek	Sampling Site	N	Statistic	Mercury (µg/g ww)	MeHg Estimate [1] (µg/g ww)	Selenium (µg/g ww)	Selenium [2] (µg/g dw)	Uranium (µg/g ww)
Coffee	CF2.3	5	Minimum	0.077	0.062	1.070	4.374	0.052
			Mean	0.117	0.095	1.418	6.507	0.091
			Maximum	0.168	0.136	1.950	10.263	0.124
	CF3.9	10	Minimum	0.059	0.047	1.620	7.043	0.032
			Mean	0.087	0.071	2.645	15.165	0.069
			Maximum	0.130	0.105	3.460	38.444	0.131
	CF8.0	13	Minimum	0.058	0.047	0.950	3.378	0.021
			Mean	0.125	0.102	1.508	5.881	0.057
			Maximum	0.248	0.201	2.740	10.111	0.146
	CF10.0	11	Minimum	0.038	0.031	2.130	8.680	0.062
			Mean	0.055	0.045	2.675	15.533	0.088
			Maximum	0.097	0.079	3.740	21.429	0.167
Latte	LC0.5	3	Minimum	0.047	0.038	1.150	4.123	0.029
			Mean	0.154	0.125	1.417	5.080	0.101
			Maximum	0.213	0.173	1.880	6.741	0.175

			Mean	0.071	0.058	1.734	7.309	0.029
			Maximum	0.110	0.089	2.760	12.545	0.052
Los Angeles [3]	LaC4.8	1	Minimum	0.084	0.068	2.740	9.514	0.011
			Mean	-	-	-	-	-
			Maximum	0.084	0.068	2.740	9.514	0.011

1. For slimy sculpin, methylmercury was estimated as 81% of total mercury, as per Jewett et al 2003.
2. Selenium is presented as dry weight (dw) in addition to wet weight (ww) to compare with the EPA guidelines, which were calculated as dry weight.
3. Only one sample was collected from Los Angeles Creek

3.8.1.3 Juvenile Chinook Salmon

Juvenile Chinook salmon samples for total metal analysis were collected from Coffee Creek at CF0.5 and CF2.3, and from Halfway Creek at HF0.2. Mean total mercury concentrations in juvenile Chinook salmon were lowest in Halfway Creek at HF0.2, and slightly higher in Coffee Creek at CF0.5 and at CF2.3, with mean concentrations of 0.025, 0.050 and 0.076 µg/g ww, respectively (Table 25). The CFIA guideline for total mercury does not apply to juvenile Chinook salmon because they are not a human food source at the juvenile life stage; however mercury concentrations form all Chinook samples were below the guideline (Figure 13). There are no currently available studies that estimate the percentage of methylmercury relative to total mercury for juvenile Chinook salmon tissue; for the purpose of this report a conservative estimate of 94% of total mercury concentration was used. This percentage is based on the estimated methylmercury concentration for Arctic grayling tissue (Jewett et al 2003), as well as the fact that juvenile Chinook salmon are at a similar or lower trophic level than Arctic grayling and thus could be expected to bio-accumulate methylmercury at comparable rates. Estimated methylmercury concentrations in all juvenile Chinook salmon tissue samples (94% of total mercury) from Coffee Creek exceeded the CCME guideline set for the protection of piscivorous wildlife (0.033 µg/g ww; CCME 2000a). All samples from Halfway Creek had estimate methylmercury concentrations below the CCME guideline (Table 25; Figure 14).

Selenium concentrations in juvenile Chinook salmon muscle tissue in Coffee Creek did not exceed the EPA guideline for muscle tissue (11.3 µg/g dw; EPA 2015) at any sampled stations (Table 25; Figure 15). Only one same from Halfway Creek exceeded the BC selenium tissue guideline (4.0 µg/g dw, BC MOE 2012).

Uranium concentrations in juvenile Chinook salmon tissues ranged from 0.005 µg/g ww in a sample collected from Halfway Creek to 0.0604 µg/g ww, in a sample from Coffee Creek. Concentrations in Coffee Creek were highest at stations further upstream in the watershed (Table 25; Figure 16).

Table 25. Descriptive statistics for Chinook salmon tissue metals concentrations.

Creek	Sampling Site	N	Statistic	Mercury (µg/g ww)	MeHg Estimate [1] (µg/g ww)	Selenium (µg/g ww)	Selenium [2] (µg/g dw)	Uranium (µg/g ww)
Coffee	CF0.5	3	Minimum	0.039	0.037	0.502	2.191	0.012
			Mean	0.050	0.047	0.533	2.391	0.014
			Maximum	0.071	0.067	0.594	2.700	0.017
	CF2.3	3	Minimum	0.058	0.055	0.498	1.302	0.013
			Mean	0.076	0.071	0.534	2.182	0.033
			Maximum	0.100	0.094	0.570	2.767	0.060
Halfway	HF0.2	12	Minimum	0.021	0.020	0.403	2.096	0.005
			Mean	0.025	0.024	0.592	2.997	0.018
			Maximum	0.029	0.028	0.676	4.714	0.037

1. For slimy sculpin, methylmercury was estimated as 81% of total mercury, as per Jewett et al 2003.
2. Selenium is presented as dry weight (dw) in addition to wet weight (ww) to compare with the EPA guidelines, which were calculated as dry weight.

3.8.2 METAL CONCENTRATIONS IN BENTHIC INVERTEBRATES

Benthic invertebrate samples were collected in March and August 2016. March samples were collected at two stations in Coffee Creek and one station in Independence Creek, and August samples were collected from Coffee, Latte, Halfway, YT-24, Independence and Los Angeles creeks. All samples were analyzed for tissue metal concentrations; detailed analysis results are included in APPENDIX E. Benthic invertebrate tissue metal concentration guidelines exist for methylmercury (CCME 2000a). Additionally, uranium concentrations were reviewed as uranium can be naturally elevated in some streams in the LSA. The CFIA total metal tissue guideline does not apply to benthic invertebrates as they are not consumed by humans.

There are no currently available studies that estimate the percentage of methylmercury relative to total mercury for benthic invertebrate tissues; for the purpose of this report a conservative estimate of 54% of total mercury concentration was used. This percentage is based on the fact that different species of invertebrates occupy different trophic levels and accumulate methylmercury at different rates (e.g. range of 22% to 85% of total mercury concentration; Tremblay and Lucotte 1997) as well as the fact that methylmercury concentrations were not collected for all sampled benthic invertebrate taxa described in Tremblay and Lucotte (1997).

Estimated methylmercury concentrations in all benthic invertebrate tissue samples (54% of total mercury) did not exceeded the CCME guideline set for the protection of piscivorous wildlife (0.033 µg/g ww; CCME 2000a) at any sample stations in the Project area; the highest concentration was found in the sample collected from Coffee Creek (CF2.7) in March (0.0226 µg/g ww).

Uranium concentrations in benthic invertebrate tissues were highest in samples collected in March; uranium concentrations in water are at their annual peak during late winter low flows, resulting in increased proportions of groundwater contributions to surface water (Lorax 201.) Uranium concentrations in benthic invertebrate tissues collected from Coffee Creek in March 2016 ranged from 6.97 to 18.1 µg/g ww, and in Independence Creek was 1.26 µg/g ww. The lowest concentrations from August 2016 samples were found in benthic invertebrate tissues collected from YT-24 and Los Angeles creeks, and the highest concentrations were in benthic invertebrate concentrations from Halfway Creek, at HF0.2 (5.76 µg/g ww; Figure 17).

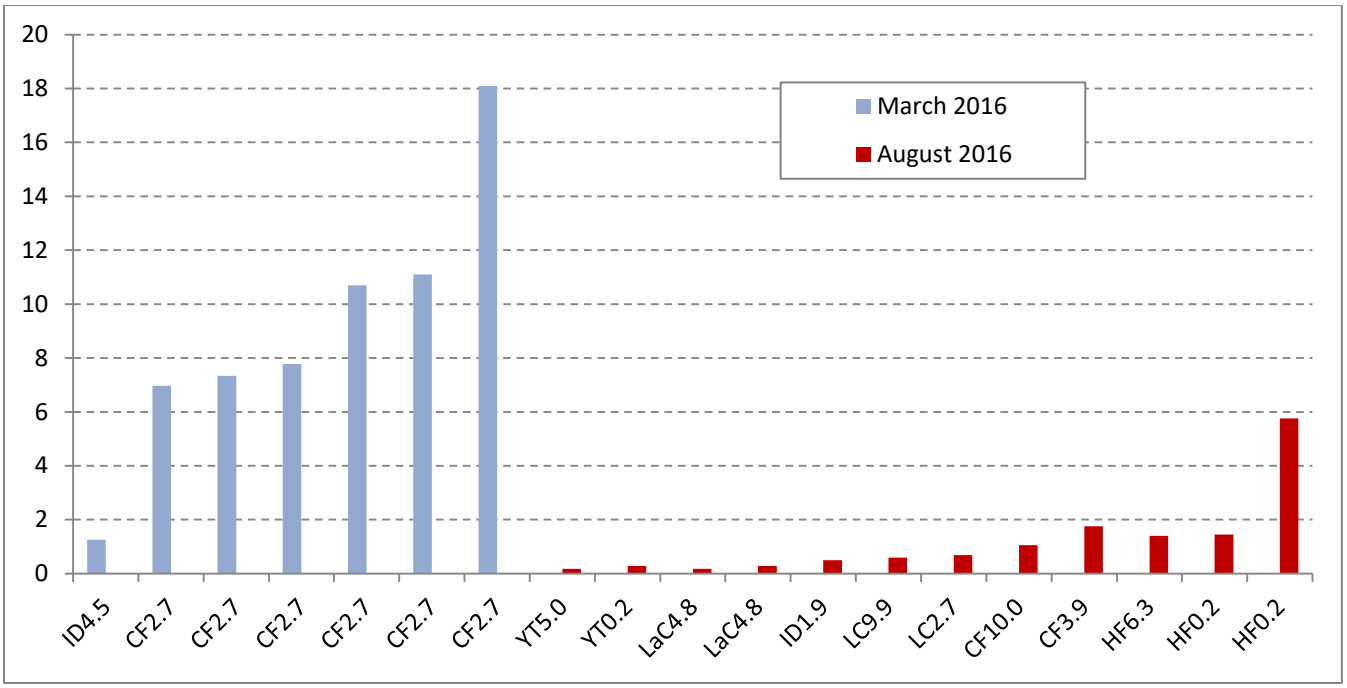

Figure 17. Uranium concentrations in benthic invertebrate tissues collected in March and August 2016.

3.8.3 METAL CONCENTRATIONS IN SEDIMENT

Analyses of baseline metals concentrations in stream sediments collected in the study area in 2014 and 2015 (PECG 2017) indicate that arsenic and chromium are consistently present at concentrations that exceed the CCME interim Freshwater Sediment Quality Guidelines (CCME 2000b). Concentrations of copper, cadmium and mercury were found to exceed the applicable guidelines in only a small number of samples, all located in the Coffee Creek watershed.

Baseline sediment samples collected by PECG in 2014 and 2015 from Coffee Creek and Latte Creek were found to have the highest concentrations of a number of metals. Concentrations from samples collected in 2014 and 2015 exceeded the CCME interim Freshwater Sediment Quality Guidelines for chromium (Coffee Creek CF3.9 and Latte Creek LC2.7), copper (Coffee Creek CF8.0), cadmium (Coffee and Latte creeks, CF8.0 and LC9.9), and mercury (Latte Creek LC2.7).

Analysis of metals concentrations in sediment samples from, Halfway Creek, YT-24 and Independence Creek and the Kona Tributary all indicate that the arsenic concentrations were elevated over the CCME interim Freshwater Sediment Quality Guideline in all samples collected in 2014 and 2015 (CCME 2000b). Additionally, chromium concentrations exceeded the CCME interim Freshwater Sediment Quality Guideline in samples collected from the Kona Tributary, upstream Independence Creek (ID6.7).

3.9 ENVIRONMENTAL DNA SAMPLING

Environmental DNA samples filtered from water collected in March 2016 tested positive for both Arctic grayling and Chinook salmon DNA markers at several sample sites (Table 26). In contrast, all stream sediment eDNA samples tested negative for except for a single replicate at site CF2.3. However, some thawing of stream sediment samples had occurred during transit to the lab and lab staff indicated that the relatively coarse sediment particle sizes present at sample sites may reduce eDNA residence time (as compared to finer sediment; Carim pers. comm. 2016). As such, eDNA results from sediment samples may be considered inconclusive, and are not discussed further in this section. All results discussed in the following paragraphs pertain to eDNA detected in filtered water samples; detailed eDNA collection data and analytical results from both sediment and water samples are included in APPENDIX A. The eDNA persistence time in the aquatic environment is estimated to range from 7 to 25 days (Hobbs et. al. 2015). The station and species specific eDNA persistence may vary for Chinook salmon in the study area; however, none of the DNA collected in March 2016 could have come from adult salmon (which migrate through the Yukon River to spawn in July and August). As such, all positive Chinook salmon eDNA detections from March 2016 are representative of DNA from juvenile Chinook salmon.

Arctic grayling eDNA was detected at three stations in Coffee Creek (CF2.7, CF8.3 and CF10.0; Table 26). Samples collected in the Yukon River also tested positive for Arctic grayling eDNA, with positive detections at all Yukon River sample collection stations (YRD23.0, YRD11.0 and YRD4.1). No Arctic grayling eDNA was detected in Latte Creek Tributary C, or in Latte, Halfway or Independence creeks.

Juvenile Chinook salmon eDNA was detected at all sampled stations in Coffee Creek (CF2.7, CF5.4, CF8.3 and CF10.0; Table 26). No juvenile Chinook salmon eDNA was detected at any other sampled locations in the study area, including the Yukon River.

Table 26. Summary of eDNA detection results in the Mine study area, March 2016.

4 RESULTS – NORTHERN ACCESS ROUTE

A total of 14 species of fish can be found within the streams that are intersected by the NAR including two species of salmon and 12 species of resident freshwater fish species (Table 12). The majority of these species are found only in the Yukon and Stewart rivers. The NAR intersects the upper portion of the Indian River watershed, in a location that is a considerable distance upstream from documented Chinook presence; however, a number of freshwater species are expected to be present (PECG 2017). The other primary watersheds intersected by the NAR (Maisy May, Barker, Ballarat) are smaller in size with the most diverse habitat (e.g. overwintering potential) near the mouths of these watersheds. Placer mining activity is prominent along the NAR (north of the Yukon River) and many stream channels and associated fish habitat has been changed by past activity.

4.1 STREAM CROSSINGS

Fish had been previously documented in the larger streams which the NAR intersects. PECG (2016) captured Arctic grayling at two sites in Maisy May Creek and burbot, slimy sculpin and juvenile Chinook salmon near the mouth of Maisy May (Crossing 91). Fish had been also previously documented in some of the larger streams along the route including the Stewart, Yukon and Indian rivers as well as Ballarat and Coffee creeks.

In 2016, 53 proposed crossings were visited; fish sampling was completed where stream channels were present with an emphasis on streams that did not have previously documented fish presence. Fish were captured in the Indian River (slimy sculpin) and in the upper Barker watershed (Arctic grayling at Crossing 208). Many of the smaller streams had poor habitat quality and/or downstream obstructions (e.g. high gradients[5]) to fish habitat (APPENDIX B and APPENDIX F).

Several of the smaller drainages assessed did not have stream characteristics such as a continuous channel bed where water has scoured a channel or deposited mineral alluvium within the channel. Any drainage that did not meet the criteria of a stream and did not have any fish habitat was referred to a Non-Classified Drainage (NCD).

Of the 56 drainages along the NAR (not including the Yukon and Stewart rivers), 16 were determined to be fish bearing or assumed fish bearing, 19 were determined to be non-fish bearing due to poor habitat and/or the presence of downstream barriers and 21 were determined to be NCD's (Figure 18 to Figure 20). Table 27 outlines all the streams assessed and provides rationale for each designation.

[5] Based on information from BC MOF (1998) stream grades of >20% were used to identify gradient barriers; this would be considered a very conservative for the fish species found in the study area (i.e. species that are known to navigate steep gradients in small streams in BC, e.g. bull trout and rainbow trout are not present).

Table 27. Summary of fish and fish habitat assessment work for road crossing associated with the NAR.

Crossing Number	Stream Name[1]	Avg. Channel Width (m)	Avg. Stream Gradient (%)	Fish Bearing Status[2]	Rationale for Fish Bearing Status
47	Sulphur Creek	n/a	n/a	FB	Not assessed in 2016 due to access restrictions. Considered fish bearing by PECG (2016). Round whitefish and Arctic grayling documented by DFO (2016). Large enough to provide overwintering habitat.
50	Indian River	~15 m	1	FB	Slimy sculpin captured at this site. Arctic grayling also documented in Indian River (PECG 2016).
51	unnamed (Indian River Trib 1)	-	5.0	NCD	Flow through moss, bog. No defined channel banks or alluvial substrate.
52	unnamed (Indian River Trib 2)	0.52	5.0	NFB	Poor habitat near road, spread out and underground flow downstream of road prevents access. No fish captured via electrofishing and minnow trapping.
53	unnamed (Indian River Trib 3)	-	-	NCD	Flow spread out through vegetation, lacks continuous defined channel banks or alluvial substrate.
54	unnamed (Indian River Trib 4)	-	-	NCD	Drainage dry, alluvial substrate only present immediately downstream of culvert.
54.5	unnamed (Eureka Trib)	0.55	23.0	NFB	Drainage is dry upstream of culvert and has an average gradient of 23% downstream, which precludes fish usage.
55	Eureka Creek	~30[a]	2[a]	PFB	Not assessed in 2016 due to active placer mining in area. Sampled by PECG (2016), no fish captured but potential exists given stream size and proximity to the Indian River.
57	unnamed tributary to Maisy May	-	-	NCD	Ditch water collects and flows across the road, no channel or defined banks.
58	unnamed tributary to Maisy May	-	-	NCD	No visible channel, as assessed by PECG (2016).
59	unnamed tributary to Maisy May	-	-	NCD	No visible channel, as assessed by PECG (2016).
60	unnamed tributary of Maisy May	n/a	30	NFB	Channel results from road/ditching drainage, no water at time of survey. Likely only flows during rain/melt events. Steep gradient and poor habitat would preclude fish use. Road planned to be moved away (upslope) from this area.
61	unnamed tributary of Maisy May	-	-	NCD	No stream bed/alluvial bed material downstream of the road. Road planned to be moved away from this area.

Crossing Number	Stream Name[1]	Avg. Channel Width (m)	Avg. Stream Gradient (%)	Fish Bearing Status[2]	Rationale for Fish Bearing Status
72	unnamed tributary of Maisy May Creek	-	-	NCD	Flow over moss and organics, no alluvial bed material or defined streambanks.
73	unnamed tributary of Maisy May	-	-	NCD	No stream channel evident on either side of road, just seepage from ditch.
74	unnamed (Upper Maisy May Trib)	-	-	NCD	Flow only near road, no defined stream channel upstream or downstream of road, and no alluvial bed materials.
75	unnamed (Maisy May Trib 1)	1.73	6.0	NFB	High gradient downstream of road prevents fish access. Electrofished, no fish captured.
76	unnamed (Maisy May Trib 2)	2.35	5.5	NFB	High gradient downstream of road prevents fish access. Electrofished, no fish captured.
77	unnamed (Maisy May Trib 3)	1.73	4.0	NFB	Some fish potential downstream of road; however, channel on approach to culvert is steep and would not pass fish. NFC during electrofishing.
MMTT-1	Maisy May Tailings Trib 1	-	-	NCD	Spread out flow through vegetation for 40 m upstream of the road. Shallow ponded water upstream. Minnow trapped, no fish captured.
MMTT-2	Maisy May Tailings Trib 2	3.94	1.8	PFB	Shallow flow in wide stream channel, possibly an old channel of Maisy May. Habitat could be used seasonally during high flows.
MMTT-3	Maisy May Tailings Trib 3	-	-	NCD	No flow, no signs of scouring or defined channel. Appears to be only wetted during super high flows in Maisy May, where the stream flows over road into this area. Suggestion to block off flow permanently to prevent fish from entering and possibly getting stranded during flood events.
MMTT-4	Maisy May Tailings Trib 4	-	-	NCD	No stream scouring or channel on Maisy May side of road, small groundwater channel starts 80 m east of crossing and flows south (away from road) into MMTT-5. It also appears that during times of flood in Maisy May, water flows over road at this location. Suggest building up the road to block off flow permanently to prevent flow through old placer mined area.
MMTT-5	Maisy May Tailings Trib 5	1.71	0.5	NFB	Shallow stream, poor fish habitat, flows through vegetation immediately upstream of road. Electrofished, no fish captured.
81	unnamed (Maisy May	3.6[a]	1[a]	FB	Arctic grayling captured by PECG (2016). Minnow traps set in 2016, no fish captured.

Crossing Number	Stream Name[1]	Avg. Channel Width (m)	Avg. Stream Gradient (%)	Fish Bearing Status[2]	Rationale for Fish Bearing Status
	Trib 4)				
83	unnamed (Lower Maisy May Trib 1)	0.67	8.5	NFB	Poor habitat quality, small channel with many obstructions. Electrofished, no fish captured.
84	unnamed (Lower Maisy May Trib 2)	-	-	NCD	No alluvial substrate or defined, continuous channel banks. Seepage flow only.
85	Unnamed Tributary of Maisy May Creek	-	-	NCD	No alluvial substrate or defined, continuous channel banks.
91	Maisy May Creek	4.00	2.5	FB	Burbot, Arctic grayling, Chinook salmon (juveniles) and slimy sculpin captured in Maisy May Creek by PECG (2016) and others.
97	unnamed (North Stewart Trib)	0.49	9.3	NFB	Too steep/shallow, lack of nearby spawning habitat, no fish captured by electrofishing or minnow trapping, multiple obstructions to fish passage.
100	Barker Creek	~10 [a]	2 [a]	FB	Good quality fish habitat, Arctic grayling captured upstream (Crossing 208).
101	unnamed (Lower Barker Trib 1)	3.38	12.0	NCD	Channel bed and banks are not continuous, no fish captured during electrofishing
102	unnamed (Lower Barker Trib 2)	2.12	13.0	NCD	Channel bed/banks not continuous for >100m, poorly defined.
103	unnamed (Lower Barker Trib 3)	2.43	9.5	NFB	Poor habitat and obstructions downstream, no fish captured via electrofishing.
104	unnamed (Lower Barker Trib 4)	3.74	8.0	NFB	Poor habitat and obstructions downstream, no fish captured via electrofishing.
110	unnamed tributary of Barker Creek	0.81[a]	3[a]	NFB	3 m falls 55 m downstream crossing, no overwintering habitat upstream of falls. No fish captured by electrofishing.
111	unnamed (Mid Barker Camp)	4.40	6.0	PFB	No fish captured during electrofishing; however, habitat exists and Arctic grayling have been captured upstream (Agate Creek).
112	unnamed (Mid Barker Tailings 1)	1.30		NFB	Small, poorly defined and shallow stream with downstream obstructions to fish passage.

Crossing Number	Stream Name[1]	Avg. Channel Width (m)	Avg. Stream Gradient (%)	Fish Bearing Status[2]	Rationale for Fish Bearing Status
113	unnamed (Mid Barker Tailings 2)	5.00	2.3	PFB	No fish captured during electrofishing; however, habitat exists.
114	unnamed tributary of Barker Creek	n/a	n/a	NFB	Discontinuous and poorly defined upstream of road, more defined downstream, but goes subsurface occasionally. Gradient barrier downstream of the crossing (24% for over 100 m), no fish captured via electrofishing.
115	unnamed tributary of Barker Creek	n/a	n/a	NFB	Small, poorly defined and shallow stream. Not enough water to sample.
210	unnamed (Upper Barker Trib 1)	2.23	3.0	PFB	Moderate rearing habitat, no fish captured during electrofishing but usage for summer rearing (i.e. Arctic grayling) cannot be ruled out.
209	unnamed (Upper Barker Trib 3)	3.80	4.5	PFB	Moderate rearing habitat, no fish captured during electrofishing but usage for summer rearing (i.e. Arctic grayling) cannot be ruled out.
208	Agate Creek (Upper Barker)	2.35	4.0	FB	Arctic grayling captured.
207	unnamed (Upper Barker Trib 4)	1.23	17.0	NFB	Too steep/shallow, cascades to 0.9 m, no spawning/overwintering nearby. No fish captured during electrofishing.
206	unnamed (Ballarat Headwaters)	-	-	NCD	Water flow through willow and moss, no defined stream channel. No fish captured during electrofishing
205	unnamed (Upper Ballarat)	0.97	11.5	NFB	Barrier located downstream of this site on Ballarat Creek, also habitat poor overall. No fish captured during electrofishing
204	unnamed tributary to Ballarat Creek	-	-	NCD	No drainage found in this location.
203	unnamed (Upper Ballarat Trib)	0.44	10.7	NFB	Low habitat quality, very small channel, poor habitat, very cold water temps. No fish captured during electrofishing.
202	unnamed tributary to Ballarat Creek	-	-	NCD	Small backwatered area at confluence of Ballarat Creek only, otherwise flow through organics with no defined channel.
201	Ballarat Creek (Mid Ballarat)	3.60	2.8	PFB	Moderate overwintering and rearing habitat quality, no hard barriers identified/confirmed downstream. No fish captured via electrofishing.
118	unnamed	11[a]	5[a]	PFB	Substantial stream, no barriers to fish passage.

Crossing Number	Stream Name[1]	Avg. Channel Width (m)	Avg. Stream Gradient (%)	Fish Bearing Status[2]	Rationale for Fish Bearing Status
	(Lower Ballarat Trib 1)				
119	unnamed (Lower Ballarat Trib 2)	n/a	n/a	NFB	No water, steep boulder dominated channel with gradient barrier downstream of road.
200	Ballarat Creek (Ballarat Proper)			FB	Juvenile Chinook salmon documented nearby by WMEC (2001).
WRC-1	unnamed (Winter Road Creek)	0.76	2.8	PFB	Moderate rearing habitat quality, no hard barriers identified and relatively few obstructions downstream.
WRC-2	unnamed tributary to Yukon River	-	-	NCD	Trickle of water through vegetation, no defined stream channel or alluvial bed material.
125	Coffee Creek	21.83	1.5	FB	Fish captured during previous sampling by PECG (2017) and this report (mine sampling). Chinook salmon (juveniles), slimy sculpin and Arctic grayling documented.

[1] Names in brackets are consistent with OnSite Crossing ID (project engineers). 2 Where FB = Fish Bearing, NFB = Non-Fish Bearing, PFB = Potentially Fish Bearing and NCD = Non-Classified Drainage. [a] data from PECG (2016)

4.2 BARGE LANDINGS – YUKON AND STEWART RIVERS

Past work at the barge landings on the Yukon and Stewart rivers indicates that the sites are located in areas that have typical streambank habitat associated with these large rivers. No sampling was completed in 2015; however, it was speculated that these areas would provide migration and rearing habitat for the various species of fish in these rivers. Sampling was conducted in both the Yukon and Stewart rivers in 2016 to provide information on fish species presence within the vicinity of the proposed barge landings.

A total of eight species were captured during 2016 sampling (Table 28) with similar fish species being captured in both the Yukon and Stewart rivers. Northern pike and round whitefish were captured in the Yukon and Stewart rivers only, respectively.

Juvenile Chinook salmon were the most frequently captured species and were captured in three beach seine hauls on the Yukon River where they accounted for nearly 80% of the fish captured (Figure 21). Slimy sculpin and longnose sucker were also captured in all three seine hauls although the number of individuals captured was relatively low. In the Stewart River, juvenile Chinook and longnose sucker were the most common species captured with only the latter captured in all three seine hauls.

Table 28. Summary of fish species captured in the Yukon and Stewart rivers during 2016 as associated with the proposed barge landing locations.

Species	Fish Captured	
	Yukon River	Stewart River
Chinook salmon	✓	✓
Arctic grayling	✓	✓
burbot	✓	✓
northern pike	✓	
longnose sucker	✓	✓
lake chub	✓	✓
slimy sculpin	✓	✓
round whitefish		✓
lake/round whitefish[6]		✓

[6] These species are not discernable at the juvenile life stage without genetic testing.

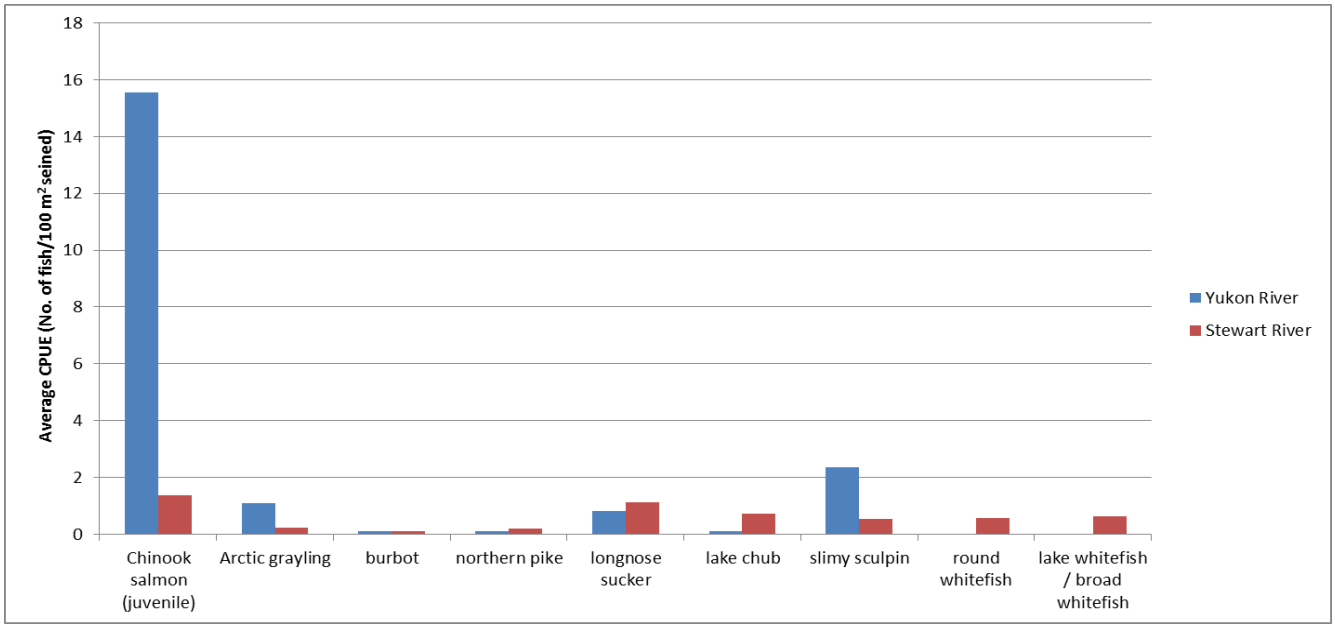

Figure 21. Catch-per-unit-effort (CPUE) of fish captured by beach seining in the vicinity of the proposed barge landings on the Yukon and Stewart rivers.

4.2.1 CHUM SPAWNING SURVEYS

Spawning chum salmon were observed in the Yukon River in September and October 2013 (Figure 22). An unverified salmon species was documented spawning within the study area in October 2014; the timing of the observation indicates that the observed spawning salmon were chum (PECG 2016). During the October 2016 spawning survey, spawning chum were found in six locations within the Yukon River with a total of 263 chum observed (Table 29, Figure 22). The Stewart River was mostly frozen over at the time of the survey; however, three spawning chum were observed in one location near the downstream end of the survey extent (Table 29, Figure 22). All areas were shallow and gravel and cobble bed material. On both rivers, the ice conditions and unseasonably cold temperatures likely reduced the number of spawning sites observed. On the Yukon River a number of the spawning areas located during 2013 were frozen over during the October 2016 survey and thus could not be surveyed.

All documented chum salmon spawning areas in the LSA occur in small, clear water side channels of the Yukon River (Photo 17, Photo 18) and the Stewart River (Photo 19). This suggests that chum salmon spawn preferentially in these clear water locations, rather than the more turbid mainstem or larger secondary side channels of the these large rivers. In addition, the upstream inlet of the spawning channels appears to be disconnected from the flow of the mainstem Yukon River during the fall chum salmon spawning period (i.e. fall months; Photo 10). As such, the naturally turbid river water would be prevented from flowing into this channel during the fall, while chum salmon are spawning/incubating in these areas.

Table 29. Summary of spawning chum salmon observed on the Yukon and Stewart rivers during October 2016.

Stream	Site	Number of Chum Salmon Observed
Yukon River	YR1	50
	YR2	63
	YR3	39
	YR4	42
	YR5	37
	YR6	32
Stewart River	SR1	3

4.3 STEWART RIVER BACK CHANNEL

Previous investigations indicated this channel had limited fish habitat during low flows in the Stewart River (PECG 2016). No fish were captured via minnow trapping (September 2015) in the vicinity of the area that will be encroached upon and dissolved oxygen levels were relatively low (5.19 mg/L; PECG 2016). Given its connection with the Stewart River, it is considered fish bearing and is likely most valuable as refuge habitat when water levels in the Stewart River are high.

During July 2016, fish sampling downstream of the area that will be encroached by the NAR (where the channel is deeper and wider), resulted in the capture of lake chub, northern pike, round whitefish and lake whitefish. During the late October visit, the back channel in the vicinity of the encroachment areas was found to be frozen to bed with no water under the ice (Photo 20, Photo 21). The crew investigated the upstream extent of this channel to determine if it receives flow from the upstream end and found that there was more terrestrial vegetation (i.e. willows) towards the upper end of the channel; however, it appears likely that flow does occasionally enter the channel during high flows in the Stewart River.

In the vicinity of the encroachment areas, this channel appears to be only wetted during high flows in the Stewart River and is most likely used as refuge habitat by species utilize the area downstream (i.e. lake chub, northern pike and perhaps whitefish). The channel bottom is made of fines and organics. No critical habitats will be affected by the encroachment on the edge of this channel.

Photo 20. Downstream view of Stewart River back channel in the vicinity of an encroachment area (right side of photo).

Photo 21. Upstream view of Stewart River back channel in the vicinity of an encroachment area (left side of photo).

5 DISCUSSION

The fish habitat in the study area comprises large river and smaller stream habitat. The Yukon and Stewart rivers provide important overwintering habitat and migration corridors within the region, while tributary streams, depending on their size, provide a variety of rearing habitat and overwintering capabilities. Tributaries that provide overwintering habitat (i.e. Coffee, lower Independence and Maisy May creeks) have more diverse fish assemblages, while smaller tributaries with no overwintering habitat provide some summer rearing habitat for migratory fish (e.g. grayling). Most tributary streams in the area are nutrient-poor and have cool water temperatures, which limit their overall productivity. Many smaller streams in headwater areas have moderate gradients and poor habitats (i.e. limited pool depth) that are not typically used by the species present in the region. Many of the streams along the NAR have been subject to placer mining activities which have resulted in change of stream and riparian morphology. The following sections use all available information to discuss the fish and fish habitat values in each stream with an emphasis on the Mine study area.

5.1 YUKON RIVER

The Yukon River flows within the Mine and NAR study areas and all of the streams near the Mine infrastructure are tributaries of this stream. The river has a relatively diverse assemblage of fish species with numerous species likely to occur within the vicinity of Coffee Creek including both Chinook and chum salmon. Near the study area, adult Chinook use the river as a migration route to spawning areas further upstream. Juvenile Chinook use the main channel of the river during the downstream migration from rearing areas to the ocean. Juveniles may also rear in the main channel during the summer; however, this is not considered ideal rearing habitat for these fish which prefer clear water smaller streams with woody debris and other forms of in-stream cover. The lack of detected Chinook salmon eDNA in river Yukon River water collected in March 2016 provides an indication that Chinook do not overwinter in the Yukon River.

Adult chum have been observed spawning in side channel areas of the Yukon River within the study area in 2013, 2014 and 2016 (Figure 22). These spawners belong to the 'mainstem Yukon River' stock, which spawn in side channels/sloughs of the Yukon River between the White River and the Tatchun Creek area near Carmacks. During 2014, this stock constituted 49% of the Canadian border passage of fall chum salmon (JTC 2015); however, only a small portion of these individuals likely spawn in the portion of the Yukon River within the study area. These chum that spawn within the study area use clear water side channel habitat that appear disconnected from the flow of the mainstem of the Yukon River during fall and winter months. Based on known chum salmon habitat preferences, these channels are likely fed by groundwater throughout the incubation period.

No chum spawning has been documented in close proximity to the barge and winter road landings (Photo 22); the closest location is in a side channel 1.8 km downstream of south barge landing. While the southern winter road landing is located in a side channel, this side channel appears to be frequently fed by river flow

rather than groundwater (Photo 22, all documented spawning locations were in clear water locations on this imagery), no spawning has been observed in this side channel.

Photo 22. Google earth imagery (Sept 19, 2010) of the Stewart River near the locations of barge and winter road landings.

In addition to salmon, the mainstem Yukon River also provides habitat for a wide range of species including Arctic grayling, a valued recreational fish species in the Yukon and species of interest for the Coffee Project due to their presence in the small streams directly downstream of the Project infrastructure. The river likely does not provide spawning habitat for this species; however, it does provides suitable overwintering conditions. The detection of Arctic grayling eDNA in river water samples collected at several locations in the Yukon River provides evidence of Arctic grayling overwintering in the portion of the river within the study area. Arctic grayling often make considerable migrations between spawning, rearing and overwintering locations with smaller streams (such as Coffee, Latte and Independence creeks) used primarily for summer rearing.

Northern pike, burbot and whitefish are also present in the Yukon River. Low numbers of burbot (one fish) and pike (one fish) were captured associated with the barge landing sampling; whitefish were not captured. Northern pike are likely more common in back channel areas where flow velocities and turbidity is low (based on habitat preference and knowledge of them being visual feeders as outlined by McPhail, 2007). Burbot are associated with deep main channels of northern rivers and are found in areas where clear streams enter turbid rivers (McPhail, 2007). Whitefish likely seek out clearer water habitat (moderate size rivers) during the spring/summer when the Yukon River is turbid. All of these species likely use the Yukon River for overwintering purposes when turbidity is low and other overwintering locations are limited.

5.2 STEWART RIVER

The Stewart River provides very similar habitat to the Yukon River; it is also a migration corridor for Chinook and chum salmon that are known to spawn upstream of the NAR. Chum spawning has been documented in clear groundwater fed side channels downstream (~10 km [in 2016] and ~18 km [Rivest Pers. Comm. 2016]) of the barge landings. While spawning survey conditions were not ideal in 2016, there is no similar side channel habitat in the vicinity of the barge crossings (as viewed from the 2016 survey and Project Lidar (Photo 23).

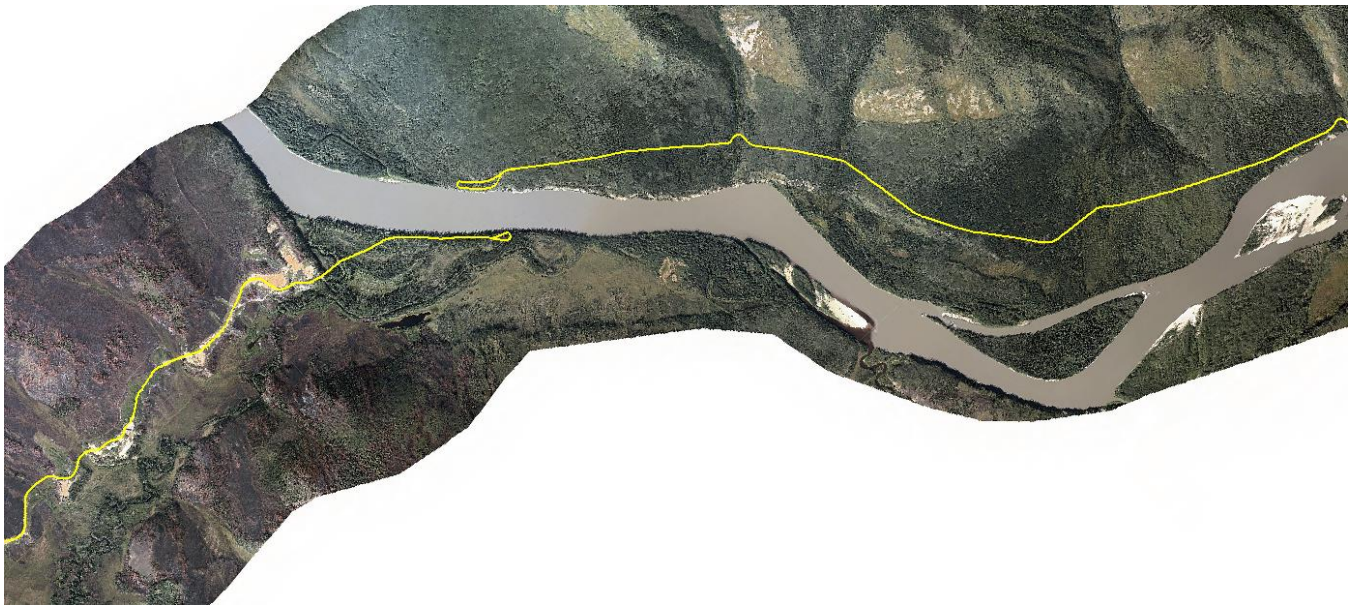

Photo 23. Lidar imagery of the Stewart River near the locations of barge landings (yellow line = NAR).

The Stewart River back channel that will be encroached upon during road construction provides marginal fish habitat that is most likely to be used as refuge habitat during high water events in the Stewart River.

Northern pike, burbot and whitefish are also likely to occur in the Stewart River and utilize similar habitats as the Yukon River (refer to Section 5.1).

5.3 COFFEE CREEK

Aside from the Yukon River, Coffee Creek has the largest catchment in the Mine study area with a total area of approximately 49,000 ha. Three fish species have been documented in the portion of Coffee Creek within the study area, including Chinook salmon (juveniles), Arctic grayling and slimy sculpin.

During the open water season, juvenile Chinook salmon have been captured at sites from the confluence of Coffee Creek and the Yukon River upstream to the Latte Creek confluence, a linear distance of

approximately 8.3 km. These juveniles are presumed to be non-natal and likely originated from spawning areas in the Yukon River watershed upstream of Coffee Creek. This hypothesis is supported by recent spawning surveys and the lack of capture of juvenile Chinook during late June (2015) sampling efforts. The use of small streams for non-natal rearing by juvenile Chinook has been well documented in the Yukon by other researchers including Beacham et al. (1989) and Moodie et al. (2000). This life history strategy allows for juvenile Chinook to access areas which provide productive rearing habitats and may also be associated with predation avoidance (Moodie et al. 2000).

Overwintering habitat was confirmed in the lower 10.0 km of Coffee Creek in early March 2016, as indicated by the capture of slimy sculpin (at stations CF2.7, CF8.3 and CF10.0) and juvenile Chinook (stations CF0.5 and CF2.7) and the detection of juvenile Chinook salmon eDNA water samples collected from all sampling sites. Open water was observed in several side channels in this portion of Coffee Creek, which is often indicative of groundwater discharge in winter. Groundwater discharge influences the presence of juvenile Chinook during the winter months as these areas typically have slightly warmer water temperatures and provide security in terms of sufficient water flows during the winter months. Traditional Knowledge (TH 2012) indicates that Chinook salmon used to spawn up Coffee Creek; however, spawning Chinook were not documented in Coffee Creek during surveys in 2000, 2001, 2014, 2015 or 2016.

Arctic grayling use Coffee Creek for summer rearing and feeding habitat and there is evidence of use for overwintering. PECG (2017) documented Arctic grayling in Coffee Creek from the Yukon River upstream to the Latte Creek confluence in the summer months (a linear distance of approximately 8.3 km). Despite favourable underwater viewing conditions and presence of pool habitat in the lower portions of Coffee Creek no Arctic grayling have been observed or captured during the winter in Coffee Creek. However, positive detection of eDNA of this species in winter at sites in lower (CF2.7) and upper Coffee Creek (CF8.3 and CF10.0) indicate that grayling do overwinter in the stream.

It appears unlikely that Coffee Creek is used by Arctic grayling for spawning. Juvenile grayling (including young-of-the-year) are typically associated with stream margins and would be effectively captured by electrofishing if they were present in the stream. A total of 15 Arctic grayling were captured in Coffee Creek during 2014 and 2015 (PECG 2017) and ranged in size from 134 to 357 mm; YOY were not captured and the majority of individuals captured were over 200 mm in length. The Arctic grayling captured in upper Coffee Creek by PECG (2013) were also consistent with the sampling lower in the watershed; the 12 individuals captured in this area ranged in length from 173 to 238 mm.

Slimy sculpin have been documented in Coffee Creek upstream to the CF10.0 sampling station and likely occur further upstream in the watershed. Given that this species is non-migratory; their presence supports the conclusion that Coffee Creek provides suitable overwintering conditions for fish. In March 2016, slimy sculpin were captured at sampling stations where open water leads were present (CF2.7 and CF10.0) as well as stations where the channel had full ice coverage (CF8.3), indicating that this species overwinters in both habitat types.

Baseline benthic invertebrate tissue metal concentrations in samples collected from Coffee Creek indicates that concentrations of total mercury and methylmercury (calculated) are below the relevant guidelines. In

contrast, calculated baseline Arctic grayling, slimy sculpin and juvenile Chinook salmon tissue methylmercury concentrations exceeded the CCME tissue residue guidelines for the protection of wildlife consumers of aquatic biota (CCME 2000a). Baseline tissue concentrations of selenium in benthic invertebrates, Arctic grayling and juvenile Chinook tissue samples were below the EPA aquatic life ambient water quality criterion for selenium. A small number of sampled slimy sculpin had selenium tissue concentrations above the draft EPA guideline. Selenium concentrations in some Arctic grayling and many slimy sculpin exceeded the BC selenium standard. Uranium concentrations in both invertebrates and slimy sculpin tissue were higher in samples collected from Coffee Creek in March when compared to those collected in August, which is reflective of the baseline uranium concentrations in the creek water, which were highest during low flow conditions experience in late winter (Lorax Environmental 2016).

5.3.1 LATTE CREEK

Latte Creek flows into Coffee Creek approximately 8.3 km upstream from the Yukon River. Latte Creek has a catchment area of approximately 7,000 ha (Lorax Pers. Comm. 2016) and a portion of the headwaters of the drainage are located within the footprint of the Project infrastructure. Two species of fish have been documented in Latte Creek to date including slimy sculpin and Arctic grayling. Slimy sculpin were captured only in the very lower portion of the Latte Creek watershed (LC0.5), in close proximity to Coffee Creek.

Arctic grayling have been captured or observed in Latte Creek from the mouth of the creek upstream to station LC9.9, a linear distance of nearly 10 km. A total of 57 Arctic grayling were captured in the stream during 2014 and 2015 (PECG 2017) and ranged in length from 128 to 355 mm with a mean length of 260 mm. Multiple pass electrofishing was used to estimate the density of Arctic grayling at station LC2.7 and documented a moderate density of individuals (6/100 m^2 during 2014 and 10/100 m^2 in 2015; ± 2, 90% confidence interval in both years; PECG 2017). The lack of YOY captured in the stream indicates that the stream is not used for spawning. PECG (2017) conducted spawning surveys in Latte Creek during mid-June 2015 and did not observe any spawning behaviour nor did they capture any fish that were actively spawning.

Fish overwintering in Latte Creek appears to be unlikely, as determined by observations of the stream during early March 2016. The stream was completely ice covered with no open water leads and had minimal water flow under the ice. Water quality parameters (temperature and dissolved oxygen) were suitable for fish overwintering; however, the limited water depth and lack of deeper pools likely do not provide suitable conditions for overwintering. All eDNA samples collected from water in Latte Creek in March 2016 tested negative for both Arctic grayling and juvenile Chinook salmon DNA. The absence of slimy sculpin in all but the very lower portion of the watershed (adjacent to documented overwintering habitat in Coffee Creek) also supports this conclusion that fish overwintering in Latte Creek is unlikely. Due to the non-migratory nature of this species, their absence is often a good indicator that overwintering habitat is lacking.

Baseline fish tissue concentrations of methylmercury in Latte Creek exceeded the CCME tissue guideline in Arctic grayling and slimy sculpin samples. Uranium concentrations in all fish tissues were among the lowest in the Mine LSA. Baseline benthic invertebrate tissue metal concentrations in samples collected from Latte Creek indicate that concentrations of total mercury and methylmercury (calculated) were below the relevant

guidelines; however, it was noted that concentrations of total and methylmercury were higher at LC9.9 when compared to LC2.7, located closer to the confluence with Coffee Creek.

5.3.1.1 Latte Creek Tributary C

The Latte Creek Tributary C is a small stream (2nd order, 1:50,000) that flows into Latte Creek approximately 10 km upstream from Coffee Creek. The catchment area of this stream is relatively small (344 ha; Lorax Pers. Comm. 2016) and the upper portion of this watershed overlaps with mine infrastructure (e.g. proposed pits).

The stream has a moderate to high gradients, has a poorly defined channel near the mouth and has numerous obstructions to fish passage (described in Section 3.4.5). The only species/life stage that use Latte Creek near the confluence of this stream is sub-adult and adult Arctic grayling. With the exception of the lower 15 m that is influenced by flows in Latte Creek, the poor habitat (small and poorly defined channel, lack of deep pools, high gradient, and numerous obstructions) in this stream is not suitable to this species/life stage.

5.4 HALFWAY CREEK

Halfway Creek is a tributary of the Yukon River and has a catchment area of 2,704 ha (Lorax Pers. Comm. 2016). The total length of the mainstem of this stream is approximately 11 km and a portion of its headwaters are located within the footprint of the proposed WRSF.

The capture of a single Arctic grayling in 2014, 2015 and 2016 and a small number of slimy sculpin in August 2016 at station HF0.0 indicates that the area at/near the confluence with the Yukon River is used by low densities of fish. Previous sampling in July, August, September and October 2013 and in July 2016 ~200 m upstream of the mouth (HF0.2) did not result in the capture any fish; however, one Arctic grayling and 20 juvenile Chinook salmon were captured at this station in August 2016.

Winter fish sampling was conducted during March 2016 at station HF6.3 and no fish were captured. Due to the extensive ice coverage of the stream and minimal water flow/depths under the ice, winter fish sampling could not be completed in the lower portion of the stream; however, the overwintering potential appears to be low. A sufficient amount of water was present in the stream to allow for the collection of eDNA samples from two sites on Halfway Creek (HF6.3 and HF0.2); both sites tested negative for both Arctic grayling and juvenile Chinook salmon.

Based on the fish sampling results from 2013 to 2016 and the fish habitat data collected in the lower, middle and upper reaches of Halfway Creek, fish presence in low numbers is confirmed in the lower 350 m of Halfway Creek. Fish presence is also possible in the lower 900 m that are accessible to fish from the Yukon River. While the barrier 900 m upstream of the mouth is not permanent, there are other obstructions to fish accessing the middle reaches of Halfway Creek (HF6.3), and fish habitat in this area is generally poor due to moderate gradients (~10%) and lack of pools.

In Yukon, headwater streams with moderate gradients (in the range of 10% or higher) are often absent of fish. A study in the Peel River watershed indicated that Arctic Grayling were predicted to be found in only the larger, lower reaches of 3rd order streams, with probabilities in upstream sections declining rapidly to nil (Barker et al. 2011). Barker et al. (2011) indicated that their predictive model reflected observed patterns of grayling presence; with most grayling found in larger, lower-elevation streams with large amounts of surrounding vegetation, often overhanging the stream. They also indicated "Predicted probability of Arctic Grayling presence was near nil in 1st and 2nd order streams and very low in most 3rd order streams, but approached one in most 4th order streams". While this study was in a different area of the Yukon, the results are consistent with the observations of fish distribution in streams adjacent to the Coffee Mine site (e.g. Halfway is a 3rd order, Lower Latte is a 4th order stream and YT-24 is a 2nd order stream). This is also consistent with the habitat modelling completed with the Yukon Placer Secretariat (2010) which indicated low suitability habitat in Halfway Creek above HF6.3.

Baseline fish tissue concentrations of methylmercury in Halfway Creek were below the CCME tissue guideline in Arctic grayling and juvenile Chinook salmon tissue samples; methylmercury concentrations in samples from Halfway Creek were among the lowest in the Mine LSA. Uranium concentrations in all fish tissues ranged from 0.005 to 0.037 µg/g ww, which was average for the Mine LSA. Baseline benthic invertebrate tissue metal concentrations in samples collected from Halfway Creek indicate that concentrations of total mercury and methylmercury (calculated) were below relevant guidelines and uranium concentrations in benthic invertebrate tissues collect both at upstream and downstream sampling locations in Halfway Creek were among the highest of all sites in the Mine LSA sampled in August 2016.

5.5 YT-24

YT-24 Creek is a tributary of the Yukon River and has a catchment area of 1,183 ha (Lorax Pers. Comm. 2016). The total length of the mainstem of YT-24 Creek is approximately 7 km and a portion of its catchment will overlap with the proposed mine footprint. Open water season fish sampling in the stream includes sampling at the confluence of the Yukon River (YT0.0), as well as several stations in the lower reaches of the creek (YT0.2, YT0.6, YT0.9 and YT1.3) and three stations in the upper reaches of the creek (YT4.6, YT5.0 and YT5.9).

Slimy sculpin are the only fish species to have been captured in YT-24; they were found in the lower 50 m of the stream in 2015 and at the confluence with the Yukon River in August 2016 (station YT0.0); however, the Yukon River had back flooded this portion of the stream at the time of sampling in 2015 (PECG 2017) and 2016.

Winter fish sampling and eDNA sampling collection was attempted near the mouth during March 2016; however, no flowing water was located. These findings suggest that overwintering habitat in the stream is absent.

Based on the fish sampling results from 2014 to 2016 and the fish habitat data collected in the lower and upper reaches of YT-24 Creek, fish use occurs at the confluence of YT-24 with the Yukon River and

appears limited in any areas further upstream. Multiple drops in the stream channel of 0.7 m or more impede fish access in the first few hundred meters of the creek and appear to cumulatively present a barrier to fish passage. An additional barrier to fish passage (30% gradient over 7.4 m) further precludes fish presence in the area of YT-24 Creek that is in the vicinity of mine infrastructure.

No fish tissue samples were collected from YT-24, however benthic invertebrate tissue samples that were analyzed to metals concentrations indicate that concentrations of total and methylmercury and uranium were all among the lowest of the benthic invertebrate tissue concentrations analyzed throughout the Mine LSA.

5.6 INDEPENDENCE CREEK

With a catchment area of approximately 22,000 ha (Lorax Pers. Comm. 2016), Independence Creek has the second largest catchment area in the Mine study area. The fish community composition in this stream is very similar to that of Coffee Creek with three species documented including: juvenile Chinook salmon, Arctic grayling and slimy sculpin.

All three fish species have been documented to a linear distance of 6.7 km upstream from the Yukon River confluence with Independence Creek. The CPUE of juvenile Chinook in Independence Creek was generally lower than that of Coffee Creek, particularly during 2014 when capture rates were less than 1 fish per trap day as compared to 5 to 12 fish per trap day in Coffee Creek (PECG 2017). Chinook salmon spawning has not been documented in Independence Creek and, similar to Coffee Creek, it is likely that juvenile Chinook use the stream as non-natal rearing and potentially overwintering habitat.

Arctic grayling in Independence Creek were found in low densities and multiple pass electrofishing at station ID6.7 during 2014 resulted in an estimate of 3 individuals per 100 m^2 with a 90% confidence interval of ±2 fish (PECG 2017). The catch of Arctic grayling in the stream was dominated by sub-adult and adult individuals, although a single YOY was captured at station ID1.9 which indicates that some spawning occurred in the stream. Environmental DNA samples from water collected at a site near the confluence of Independence Creek with the Yukon River (ID1.9) tested negative for both Arctic grayling and juvenile Chinook salmon DNA.

The capture of slimy sculpin in Independence Creek provides an indication that overwintering habitat may be present in the stream. Winter fish sampling during March 2016 did not capture any fish in six minnow traps set at station ID1.9; however, conditions appeared to be suitable for fish overwintering at the time of sampling as indicated by areas of open water and considerable under ice water flow. The winter fish sampling data, combined with the eDNA results, suggest that while overwintering is probable in the creek, it does not appear be as extensive as in Coffee Creek.

Baseline benthic invertebrate tissue metal concentrations in samples collected from Independence Creek indicate that tissue concentrations of total mercury, methylmercury and selenium were all below the relevant guideline levels. In contrast, baseline fish tissue metal concentrations of methylmercury exceeded the CCME

guideline for Arctic grayling and slimy sculpin. Baseline tissue concentrations of selenium exceeded the BC and EPA whole-body guideline in two sampled slimy sculpin. Tissue uranium concentrations in benthic invertebrates and fish were low, compared with benthic invertebrate tissues analyzed from other streams in the Mine site LSA.

5.6.1 KONA TRIBUTARY

The Kona Tributary flows into Independence Creek 7.5 km upstream from the Yukon River and has a catchment area of 1,833 ha (Lorax Pers. Comm. 2016). The upper portion of the watershed is located in proximity to the Project footprint, but is not impacted by it as it is separate by a ridge. Fish sampling occurred at two stations including: KT0.1 in the lower portion of the watershed near Independence Creek and KT5.2 in the upper portion of the watershed. No fish were captured at the upper station and low numbers of adult Arctic grayling were captured and observed at the lower station.

Stream gradient modelling of the upper portion of the watershed near the Project footprint indicates the presence of numerous sections of the stream with moderate to high gradients and therefore fish potential is low in this portion. Winter fish sampling was not attempted in this stream as a suitable location for sampling could not be located and the stream appeared to be frozen to bed.

6 SUMMARY

The fisheries and aquatic resource data collected in the Coffee Gold Project study area provide a comprehensive understanding of the aquatic environment. The following conclusions can be made from the results of this data collection.

- The presence of fish has been confirmed in the larger creeks downstream/near the Mine footprint including Coffee, Latte and Independence creeks. Latte and Coffee Creeks are used by Arctic grayling for summer rearing/feeding purposes. Coffee Creek provides year round rearing habitat for juvenile Chinook salmon and Arctic grayling

- Smaller streams including Halfway Creek, YT-24 Creek and the Kona Tributary have confirmed fish presence only in the very lower reaches (at the mouth only for YT-24). The headwater portions of YT-24 and Halfway Creek and, including the location of the proposed mine facilities, are characterized by moderate stream gradients and poor habitat and are a considerable distance from documented fish habitat (i.e. fish presence).

- Overwintering of fish in the creeks with the Mine study area appears to be unlikely outside of the Yukon River, Coffee and Independence creeks.

- Periphyton sampling indicates that streams have very low primary productivity, which is common of low nutrient, northern watercourses.

- Baseline metals analysis of Arctic grayling, slimy sculpin and juvenile Chinook salmon tissues indicate that the estimated concentrations of methylmercury exceeded CCME tissue guidelines for the protection of aquatic like for all three fish species (Jewett et al. 2003; inferred for juvenile Chinook salmon). Baseline tissue concentrations of selenium were generally below the interim guideline values (EPA 2015), but often exceeded the BC guideline for selenium in sampled fish.

- Baseline uranium concentrations in Coffee Creek invertebrates were higher in the winter compared with the summer which is consistent with the uranium concentrations in the water quality data from the Mine study area.

- Baseline metals analysis of sediment samples throughout the Mine study area indicate that arsenic and chromium are consistently present at concentrations that exceed the CCME interim Freshwater Sediment Quality Guidelines.

- Chum spawning has been documented in groundwater fed side channels of the Yukon and Stewart Rivers. No such areas have been documented in close proximity (i.e. within one kilometre) of the proposed barge or winter road landings.

Attn: Ben Schonewille, Fish & Wildlife Biologist

Dear Ben,

Re: Kaminak Coffee Gold Environmental DNA Assessment of Winter Use by Arctic Grayling and Chinook Salmon

Environmental Dynamics Inc. (EDI), on behalf of Kaminak, is interested in characterizing baseline environmental conditions for Arctic grayling (*Thymallus Arcticus)* and Chinook Salmon (*Oncorhynchus tshawytscha*) at the Kaminak Coffee Gold Project site (the "Project") near Dawson City, Yukon.

The information presented in this report summarizes results of field-based inventory and assessment (completed in March 2016) to characterize winter use of selected lotic systems by these target taxa. Data collected by EDI field staff during these studies is submitted separately.

We are pleased to provide EDI and Kaminak with this final report and hope the information compiled and described is of benefit to both EDI and Kaminak as the Project advances.

Regards,

Jared Hobbs, M.Sc., R.P.Bio.

1.0 INTRODUCTION

As living organisms complete their life processes their genetic material, or DNA, is shed exogenously into the surrounding environment. For aquatic and semi-aquatic species environmental DNA (eDNA) can be collected in water samples, filtered to capture eDNA, and effectively assayed to detect the presence of aquatic and semi-aquatic species without direct observation (Farrington and Lance 2014). This method is referred to as eDNA (analysis) and provides a promising and emerging method for more cost-effective, less invasive and more efficient survey of aquatic species living in natural lotic and lentic systems (Biggs et al. 2014; Herder et al. 2015). The reliable detection of aquatic vertebrate species using eDNA, from a variety of freshwater systems, has been confirmed as an effective survey method for tested species (Waits and Paetkau 2005, Ficetola et al. 2008, Goldberg et al. 2011, Thomsen et al. 2012). Analysis of eDNA is currently being applied to a diverse suite of species in a variety of freshwater habitats including both lotic and lentic systems (Goldberg et al. 2011).

Water and/or sediment samples from habitats potentially inhabited by the species in question, are collected for subsequent analysis of the environmental sample(s) to detect the presence of DNA from the target taxa. Testing for the presence of a species' DNA is completed *ex situ* (in a laboratory) using quantitative polymerase chain reaction (qPCR) methods. qPCR methods enzymatically increase the abundance of a specific sequence of DNA from target taxa in a solution. Next, the DNA sequence for the target taxa is targeted using 'primers' (short fragments of DNA that bind to the target sequence). The PCR process repeatedly subjects the sample to alternating heat (to denature, or separate, the double helix) followed by cooling to copy the original DNA in the sample. This process is repeated many times (e.g. 30-40 cycles) resulting in an exponential increase in copy number of the DNA from the target taxa. Each process, including all cycles, is referred to as a run; samples are typically run between three to eight times, for each sample collected, to arrive at a binary conclusion regarding presence or absence of DNA from the target taxa (Hobbs et al 2015). Samples from each site are then considered collectively to derive a determination of positive or negative at the site level (**see Methods**). The use of a qPCR assay requires development of a set of species-specific primers that target a small section of the genome; primer specificity is key to this process (Farrington and Lance 2014). The primer for Arctic grayling was developed independently, prior to this study, at the National Genomics Center for Wildlife and Fish Conservation in Missoula Montana (by Carim et al 2016); the assay used in this study, for Chinook salmon, was developed by Dr. C. Goldberg, Dr. M.B. Laramie and Dr. D.S Pilliod (Laramie et al. 2015).

The objective of this study was to assess winter season presence of Arctic grayling (*Thymallus Arcticus*) and Chinook salmon (*Oncorhynchus tshawytscha*) (hereafter referred to as Chinook) within lotic reaches associated with the Kaminak Coffee proposed mine site (the Project).The eDNA methods used in this assessment have been confirmed to be effective for both Arctic grayling (Veldhoen et al 2013) and Chinook (Hobbs and Kanary 2016 *in press*) in Yukon. In this study eDNA methods were used to supplement existing information derived from conventional fish survey methods previously applied within Coffee Creek, Latte Creek, Independence Creek, Halfway Creek and the Yukon River. In total, 14 sites were assessed in these five systems, using eDNA methods, to better determine winter use of these reaches by both Arctic grayling and Chinook in February 2016.

2.0 METHODS

2.1 FIELD SAMPLE COLLECTION

2.1.1 Water Sample Collection

Water sample collection followed protocols developed through direct collaboration with Dr. Caren Goldberg and summarized by Hobbs et al (2015). These methods have been successfully applied by Hemmera Envirochem Inc. (Hemmera), in 24 eDNA field studies (at the time of writing of this report), for fourteen species in BC and Yukon. These methods have also been accepted by the BC Ministry of Environment as an approved Resource Inventory Standards Committee (RISC) guidance document (Hobbs et al. 2015). The same methods have been applied and accepted by the Yukon Conservation Center and the Yukon Department of Environment in a previous study (Hobbs and Goldberg 2016). These accepted standards provide detailed guidance regarding appropriate collection and interpretation of qPCR results, for eDNA practitioners engaged in surface water sampling and eDNA qPCR analysis methods. These standards are intended for (and applicable to) use for all freshwater eDNA studies utilizing surface water collection.

Sample collection methods involved the collection of triplicate 1 litre (L) water samples at each sampling location (replication determined on a site-by-site basis as required by study and site-specific limitations). During sample collection, bottles were labelled using a permanent marker with the site and sample ID, (gazetted) location name, Universal Transverse Mercator (UTM) coordinates, collection time and the initials of the field personnel responsible for sample collection. Biologists avoided entering the water during sampling, particularly upstream of the sample collection site, to prevent contamination of the sample water from boots, clothing or other equipment.

For all sites where ice >30 cm thick covered the sample location (e.g., on the Yukon River) an ice auger (Stihl BT 130 with a 10-inch diameter blade) was used to penetrate the ice. For sites where ice cover was relatively less thick an ice spud (chisel) was used as decontamination of the ice spud was more practical. At each site, biologists augured (n=3) or chiseled (n=11) two holes. The downstream hole was used as a rinse hole for sample bottles and other equipment; the upstream hole was used for sample collection. The biologists observed a five-minute wait time before sampling at sites where the ice auger was used to minimize risk of cross-site contamination as the auger could not be thoroughly cleaned between each use.

During sample collection biologists wore clean nitrile gloves and triple rinsed the sample bottles with site water before collection of samples at each site. Each sample bottle was filled with water from the surface immediately beneath the ice layer of the water feature (at smaller features) or in the upwelling water (at all three Yukon River collection locations). Immediately following sample collection, a YSI® brand water quality meter was used to measure water chemistry data at each location. Field biologists recorded

location UTM coordinates, water quality data and site photographs at each sample site location. Water chemistry parameters collected in the field were as follows:

- Temperature (°C)
- pH
- Conductivity (µS/cm)
- Dissolved oxygen (mg/L)

During sample collection biologists placed sample bottles in the cabin of the helicopter to prevent sample freezing as ambient conditions encountered during collection were sub-zero. Genetic material in the water sample was not permitted to freeze prior to off-site filtration and preservation.

2.1.2 Sediment Sample Collection

Sediment sample collection methods involved the collection of triplicate sediment samples at 12 of 14 selected water sample sites (as feasible according to site conditions). The biologists used an ice-spud to move rocks and expose the sediment at the bottom of each sample site. Sediment was then scooped from the bottom of the waterbody using a 4-inch ladle sieve which allowed water to drain out. Approximately 25 – 35 mL of sediment was placed into separately labelled 50 mL falcon tubes for laboratory analysis. All sediment sampling instruments were sterilized and rinsed between sites and water sampling was always completed prior to sediment sampling to avoid introducing disturbed sediment into water samples. In the field sediment was stored in the cargo area of the helicopter to permit freezing before being placed in a cooler, packed with dry ice, for transport (in a frozen state) to the laboratory.

2.2 POST-COLLECTION SAMPLE PROCESSING

2.2.1 Water Sample Processing

Water was collected at each site and processed following standard eDNA surface water sample collection protocols (Hobbs et al 2015). Samples were processed within 12 hours of collection[1] in the same order as collected. Samples were poured into a 250 mL sterile polypropylene filter funnel with a 0.45 µm pore-diameter cellulose nitrate membrane. The sample was filtered through the membrane using a Gast High-Capacity Vacuum Pump (Gauge/Reg; 1.1 cfm/25.5"Hg-60psi/115V) to create a vacuum. Upon completion of filtration, the filter was removed using clean nitrile gloves and sterilized forceps[2]. The membrane was placed in a 2.5”x3.5” coin envelope with two approximately 15 ml of self-indicating silica beads as a desiccant. Envelopes were labelled and placed inside labelled whirl-pak storage bags for shipping.

---

1 Processing is recommended within 24 hours of collection to limit degradation of DNA (Caren Goldberg, *pers. comm.*)

2 Forceps were sterilized by immersing, for 30 seconds, in a 50% bleach/water solution and rinsing in a 100% distilled water solution for >1 minute.

One control sample, using distilled water, was processed using the same filtration procedure. This served as a contamination test of both the filtration and laboratory analysis processes as required by provincial protocol (Hobbs *et al.* 2015). Preserved membranes were shipped to the National Genomics Center for Wildlife and Fish Conservation for subsequent DNA extraction and analysis; distilled water samples were not identified to the lab prior to analysis.

2.2.2 Sediment Sample Processing

Sediment samples were stored in Falcon tubes and shipped in a cooler with ~4 kg of dry ice during transport to the lab. Falcon tubes were shipped to the National Genomics Center for Wildlife and Fish Conservation for subsequent extraction and analysis.

2.3 LABORATORY ANALYSIS

All laboratory testing, including sediment and water samples, were tested at the National Genomics Center for Wildlife and Fish Conservation (a part of the U.S. Forest Service Rocky Mountain Research Station) in Missoula, MT, USA.

2.3.1 Primer Details

Tissue samples from ten Arctic grayling were collected from the study area, as well as ten tissue samples from two conspecific fish species; slimy sculpin (*Cottus cognatus*) and round whitefish (*Prosopium cylindraceum*). The primer used (in this study) for Arctic grayling had not been previously tested on Yukon populations of Arctic grayling. Efficacy of the Arctic grayling primer was confirmed through laboratory testing of the primer, in Montana, using the pure grayling DNA tissue samples collected in Yukon and provided to the lab (by Yukon Government and EDI) for this purpose. The grayling primer was also tested to ensure exclusion of both sculpin and whitefish as these conspecifics have been confirmed to occur sympatrically within the Project study area.

The primer used to test for Chinook is published (Laramie et al 2015) and has been tested and confirmed effective with a 94% detection rate in Yukon (Hobbs and Kanary 2016 *in prep*). For further confirmation Chinook tissue was collected from the study area (Coffee Creek) and sequenced at the National Genomics Center for Wildlife and Fish Conservation laboratory and proved to be an exact match to the eDNA marker (primer) developed by Laramie et al (2015) (C. Kellie *pers. comm*. 2016).

2.3.2 Water Samples

Preserved sample filters were processed in a laboratory dedicated to the analysis of low-quantity DNA sources using a Qiashredder/DNeasy protocol (Goldberg *et al.* 2011). Each filter was extracted and subsequently run in triplicate using a species-specific qPCR assay that included positive and negative controls in each plate, as well as an internal exogenous internal positive control reagents to screen for PCR inhibition. When PCR inhibition was detected, samples were run through a One-Step PCR Inhibitor Removal kit column (Zymo Research) and reanalyzed. When triplicate wells did not test consistently (i.e., one or two tested positive), the sample was reanalyzed to confirm the result.

2.3.3 Sediment Samples

Environmental DNA from sediment samples was extracted using a Mobio PowerSoil® DNA isolation kit to isolate microbial genomic DNA. Cell lysis is achieved by mechanical and chemical methods and total genomic DNA is captured on a silica membrane in a centrifuge. DNA is washed and extracted from the membrane and then used for PCR analysis as described for water samples (**Section 2.3.2**).

3.0 RESULTS

Forty-two surface water samples were collected from 14 sample locations, at 14 spatially distinct aquatic features (sites) between March 1 and March 3, 2016. Concomitant collection of sediment was also completed for 11 of the water collection sites (as feasible); sediment was also collected at a single additional site in the Yukon River at which water was not collected (Site ID: YR998A1). Sampling conditions at all sites were excellent with cold water temperatures and no precipitation or meltwater in the stream for several months preceding or during sample collection

All collected surface water and sediment samples were analyzed, using qPCR methods (as described in Section 2.3) for the presence of eDNA from both Arctic grayling and Chinook. Results are described below.

3.1 WATER SAMPLES

The distilled water control sample yielded a negative result, evidence that appropriate rigour was observed during processing. This result confirms the efficacy of controls used to prevent contamination during all phases of surface water sample-collection, filtration, transport, and qPCR laboratory analysis.

Arctic grayling: The presence of Arctic grayling had previously been confirmed, using traditional methods, at three of the 14 sample sites (21%). The targeted DNA sequence for the species was recovered at six (43%) of the sites sampled including all three of the previously confirmed sites (i.e., a 100% detection rate when compared to known sites). The remaining three sites that tested positive for the presence of eDNA for Arctic grayling suggest winter use, by Arctic grayling, of stream reaches where winter use was previously unknown.

Six of the remaining eight sites that tested negative for winter use by Arctic grayling had been previously surveyed and no evidence of winter use by Arctic grayling had been documented. Negative eDNA results at these six sites serve to further corroborate this conclusion. The final two sites had not been previously surveyed to assess winter use by Arctic grayling; eDNA results from this study suggest these sites are not currently being used by Arctic grayling as winter habitat (**Table 1 and Figure 1**).

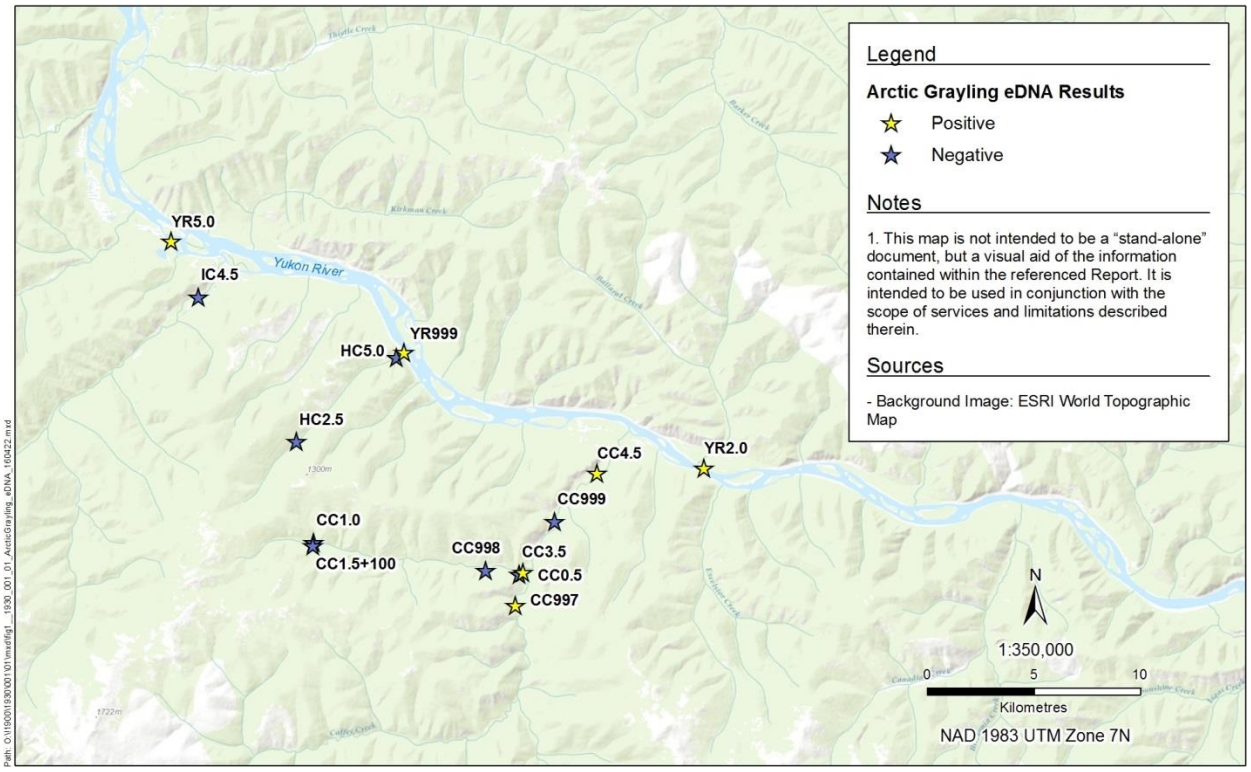

Figure 1 qPCR results for Arctic grayling

Table 1 Results of qPCR Analysis summarized by site and denoting previous confirmation of either Chinook or Arctic grayling.

Site	Grayling winter use previosly confirmed	Grayling detected - filter	Grayling detected - sediment	Chinook winter use previously confirmed	Chinook detected - filter	Chinook detected - sediment

YR5.0	Yes	Yes	No	Yes	No	No
YR998A3	N/A	N/A	No	Yes	N/A	No
YR999	Yes	No	N/A	Yes	No	N/A

Chinook: The presence of juvenile Chinook had been previously confirmed at six of the 14 sample sites, however, the targeted DNA sequence for the species was recovered at only three (50%) of the six known extant (based on data collected in the summer) Chinook sites sampled in February 2016; Chinook DNA was not recovered from any of the three sites in the Yukon River. These three Yukon River sites are known to be used by adult or juvenile Chinook in summer however no data exists for winter use. eDNA results suggest juvenile Chinook are not using these sites (including habitat immediately upstream) during the winter of 2016.

Overwinter use, by juvenile Chinook was unknown at the remaining eight sites; one of these sites tested positive for Chinook salmon DNA during qPCR analysis suggesting this site is also being used as overwintering or year round rearing habitat by Chinook. The remaining seven sites, including Latte Creek, Halfway Creek and Independence Creek each tested negative for Chinook during qPCR analysis (**Table 1** and **Figure 2**).

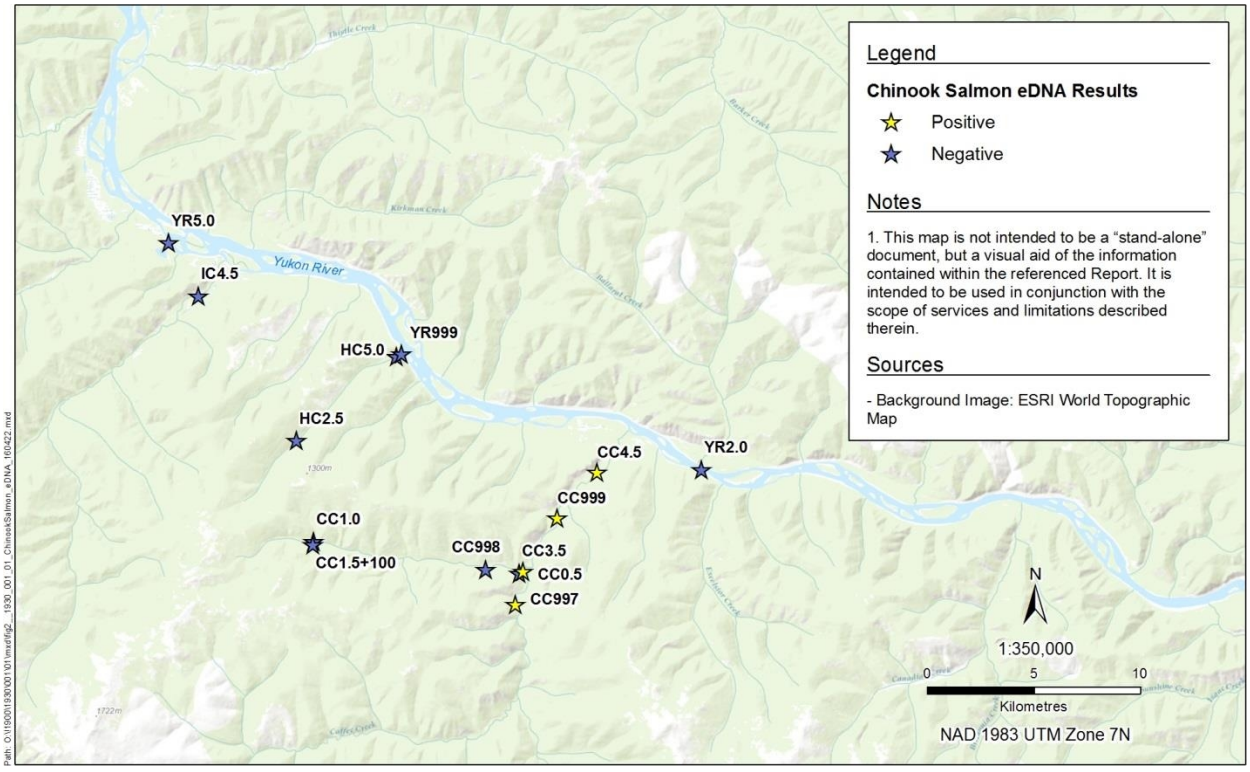

Figure 2 qPCR results for Chinook.

3.2 SEDIMENT SAMPLES

Sediment was collected at 12 sites during surface water sample collection. Only one sediment sample tested positive for the presence of Chinook eDNA during qPCR analysis and no samples tested positive for Arctic grayling eDNA.

4.0 DISCUSSION

Results from the study confirm earlier findings by Veldhoen et al (2014) and by Hobbs and Kanary (2016); eDNA provides a useful, powerful and cost-effective means to establish presence of use of aquatic habitats by both Chinook and Arctic grayling in the Yukon. This study represents the first Canadian, and perhaps global, application of eDNA in near Arctic aquatic ecosystems in winter conditions. There are no published studies to inform degradation rates of eDNA in the stream temperatures (0.5°C) encountered during field collection in this study. There are also no published studies regarding degradation rates in ice-bound lotic systems. As temperature and incidental ambient ultra-violet (UV) exposure are both positively correlated with degradation of eDNA this study provides valuable insight regarding eDNA degradation rates, flushing time and transport distances encountered during these relatively extreme environmental sampling conditions.

Detection of Arctic grayling DNA at 100% of known extant winter areas (n=3) provides further confirmation of methodological efficacy. Detection of Arctic grayling DNA at an additional three sites where previous studies, using conventional techniques, have failed to detect Arctic grayling in winter conditions also demonstrates the applicability and usefulness of eDNA methods. Despite the inherent sensitivity of qPCR methods Arctic grayling eDNA was not detected at eight sites; this suggests that the species was not using these habitats during or in the weeks or months preceding sample collection in February 2016.

Detection of Chinook DNA at three of six sites (50%) where juvenile Chinook have been documented in the spring/summer/fall seasons is corroborative with detection rates from an independent previous eDNA assessment conducted on Chinook in Yukon in 2015 (Hobbs and Kanary 2016). In addition, tests conducted by the lab in Montana confirms the efficacy of the primer used, for Chinook, in this study ("*Chinook tissues that we sequenced from Coffee Creek were an exact match for the eDNA marker developed by Laramie et al."* email from K. Carim, April 7, 2016). eDNA from Chinook was detected at all four sites in Coffee Creek; this indicates that this creek provides winter habitat for juvenile Chinook. Despite the inherent sensitivity of qPCR methods Chinook eDNA was not detected at any of the water samples collected from three sites in the Yukon River in the winter. This observation is more challenging to explain and suggests that juvenile Chinook are absent from proximal reaches in Yukon River during winter. This conclusion merits further investigation.

Finally, sediment sampling was conducted in this study to obviate the need for summer sampling, as eDNA persistence times are known to exceed eDNA persistence times in water. If successful, sediment sampling would have allowed inference of summer use of aquatic systems, by target taxa, at any time of year. By comparison, water sampling only allows inference of use, by target taxa, within a short period (7-21 days) preceding sampling. The negative results from sediment sampling at 11 of 12 sites, including sites that appear to be used during winter by either or both juvenile Chinook or Arctic grayling, demonstrate that further research is required regarding appropriate field sampling, sample storage, sample shipping and eDNA extraction.

The most plausible explanation for the low detection rate associated with sediment samples may be best attributed to sample preservation methods (i.e., samples were subjected to repeated thawing and refreezing during shipment likely causing DNA to denature). A second plausible explanation may be attributed to insufficient sample volume and / or availability of sediment with higher organic content during sampling. During sample collection, at most sites, the streambed was frozen; access to deeper, more organic sediment layers was challenging. As a result, sediment samples collected in this study were largely comprised of course sedimentary material collected from the upper surface layer of the streambed. Flushing would likely have removed DNA from this surface layer (K. Carim pers com: email dated April 7, 2016). Unfortunately, there are few published papers that have attempted and / or described sediment sampling techniques (Turner et al 2015) so this aspect of the project was considered experimental. Concomitant sampling of sediment and water in the winter, if successful, would have theoretically provided information regarding year round habitat use by Chinook and Arctic grayling within the study area. Recognizing the inconclusive comparative utility of results derived from collection of sediment sample and water samples at the same sites future water sampling is recommended, at the 14 sites in this study, during the 2016 summer field season to better understand year-round use of these habitats by both focal fish taxa.

5.0 CLOSURE

This Work was performed in accordance with the contract between Hemmera Envirochem Inc. ("Hemmera") and EDI. ("Client"). This Report has been prepared by Hemmera, based on fieldwork conducted by Hemmera, for sole benefit and use by Kaminak and EDI. In performing this Work, Hemmera has relied in good faith on information provided by others, and has assumed that the information provided by those individuals is both complete and accurate. This Work was performed to current industry standard practice for similar environmental work, within the relevant jurisdiction and same locale. The findings presented herein should be considered within the context of the scope of work and project terms of reference; further, the findings are time sensitive and are considered valid only at the time the Report was produced. The conclusions and recommendations contained in this Report are based upon the applicable guidelines, regulations, and legislation existing at the time the Report was produced; any changes in the regulatory regime may alter the conclusions and/or recommendations.

We have appreciated the opportunity of working with you on this project and trust that this report is satisfactory to your requirements. Please feel free to contact the undersigned regarding any questions or further information that you may require.

CERTIFICATE OF ANALYSIS

MAXXAM JOB #: B673220
Received: 2016/08/25, 14:15

Sample Matrix: Water
Samples Received: 60

Analyses	Quantity	Date Extracted	Date Analyzed	Laboratory Method	Analytical Method
Chlorophyll A (surface)(sin)	30	N/A	2016/08/30	BBY6SOP-00002	SM 22 10200 H m
Chlorophyll A (surface)(sin)	30	N/A	2016/09/01	BBY6SOP-00002	SM 22 10200 H m

Reference Method suffix "m" indicates test methods incorporate validated modifications from specific reference methods to improve performance.
* RPDs calculated using raw data. The rounding of final results may result in the apparent difference.

Sampler Initials: JT

			Spiked Blank		Method Blank	
QC Batch	**Parameter**	**Date**	**% Recovery**	**QC Limits**	**Value**	**UNITS**
8381929	Chlorophyll a	2016/08/30	104	80 - 120	<0.030	ug/cm2
8381932	Chlorophyll a	2016/08/30	111	80 - 120	<0.030	ug/cm2
8384179	Chlorophyll a	2016/09/01	107	80 - 120	<0.030	ug/cm2
8384182	Chlorophyll a	2016/09/01	110	80 - 120	<0.030	ug/cm2

Spiked Blank: A blank matrix sample to which a known amount of the analyte, usually from a second source, has been added. Used to evaluate method accuracy.

Method Blank: A blank matrix containing all reagents used in the analytical procedure. Used to identify laboratory contamination.

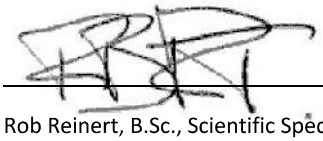
VALIDATION SIGNATURE PAGE

The analytical data and all QC contained in this report were reviewed and validated by the following individual(s).



Rob Reinert, B.Sc., Scientific Specialist

Maxxam has procedures in place to guard against improper use of the electronic signature and have the required "signatories", as per section 5.10.2 of ISO/IEC 17025:2005(E), signing the reports. For Service Group specific validation please refer to the Validation Signature Page.

Version: 2 - Revision

CERTIFICATE OF ANALYSIS – REVISED REPORT

MAXXAM JOB #: B617947
Received: 2016/03/08, 11:45

Sample Matrix: TISSUE
Samples Received: 21

Analyses	Quantity	Date Extracted	Date Analyzed	Laboratory Method	Analytical Method
Elements by CRC ICPMS - Tissue Wet Wt	21	2016/03/22	2016/03/30	BBY7SOP-00002/21	EPA 6020a,200.3 R1 m
Moisture in Tissue	20	N/A	2016/03/30	BBY8SOP-00017	OMOE E3139 3.1 m

Reference Method suffix "m" indicates test methods incorporate validated modifications from specific reference methods to improve performance.
* RPDs calculated using raw data. The rounding of final results may result in the apparent difference.

GENERAL COMMENTS

Revised Report (Version 2R): Client sample IDs for samples OG2665, OG2668, OG2670, and OG2672 have been corrected, and sample reporting order has also been corrected [GRR].

ELEMENTS BY ATOMIC SPECTROSCOPY - WET WT (TISSUE) Comments

Sample OG2657-01 Elements by CRC ICPMS - Tissue Wet Wt: RDL raised due to limited initial sample amount.
Sample OG2658-01 Elements by CRC ICPMS - Tissue Wet Wt: RDL raised due to limited initial sample amount.
Sample OG2659-01 Elements by CRC ICPMS - Tissue Wet Wt: RDL raised due to limited initial sample amount.
Sample OG2660-01 Elements by CRC ICPMS - Tissue Wet Wt: RDL raised due to limited initial sample amount.
Sample OG2661-01 Elements by CRC ICPMS - Tissue Wet Wt: RDL raised due to limited initial sample amount.
Sample OG2662-01 Elements by CRC ICPMS - Tissue Wet Wt: RDL raised due to limited initial sample amount.
Sample OG2663-01 Elements by CRC ICPMS - Tissue Wet Wt: RDL raised due to limited initial sample amount.
Sample OG2664-01 Elements by CRC ICPMS - Tissue Wet Wt: RDL raised due to limited initial sample amount.
Sample OG2668-01 Elements by CRC ICPMS - Tissue Wet Wt: RDL raised due to limited initial sample amount.
Sample OG2666-01 Elements by CRC ICPMS - Tissue Wet Wt: RDL raised due to limited initial sample amount.
Sample OG2667-01 Elements by CRC ICPMS - Tissue Wet Wt: RDL raised due to limited initial sample amount.
Sample OG2665-01 Elements by CRC ICPMS - Tissue Wet Wt: RDL raised due to limited initial sample amount.
Sample OG2669-01 Elements by CRC ICPMS - Tissue Wet Wt: RDL raised due to limited initial sample amount.
Sample OG2671-01 Elements by CRC ICPMS - Tissue Wet Wt: RDL raised due to limited initial sample amount.
Sample OG2672-01 Elements by CRC ICPMS - Tissue Wet Wt: RDL raised due to limited initial sample amount.
Sample OG2682-01 Elements by CRC ICPMS - Tissue Wet Wt: RDL raised due to limited initial sample amount.

Results relate only to the items tested.

8227173	Moisture	2016/03/30			<0.30	%	1.6	20		

Duplicate: Paired analysis of a separate portion of the same sample. Used to evaluate the variance in the measurement.

QC Standard: A sample of known concentration prepared by an external agency under stringent conditions. Used as an independent check of method accuracy.

Spiked Blank: A blank matrix sample to which a known amount of the analyte, usually from a second source, has been added. Used to evaluate method accuracy.

Method Blank: A blank matrix containing all reagents used in the analytical procedure. Used to identify laboratory contamination.

Client Project #: 14Y0306:102
Site Location: COFFEE CREEK
Sampler Initials: BS

VALIDATION SIGNATURE PAGE

The analytical data and all QC contained in this report were reviewed and validated by the following individual(s).

Rob Reinert, Data Validation Coordinator

Maxxam has procedures in place to guard against improper use of the electronic signature and have the required "signatories", as per section 5.10.2 of ISO/IEC 17025:2005(E), signing the reports. For Service Group specific validation please refer to the Validation Signature Page.

QUALITY ASSURANCE REPORT(CONT'D)

EDI ENVIRONMENTAL DYNAMICS INC.
Client Project #: 14Y0306:102
Site Location: COFFEE CREEK

			Matrix Spike		Spiked Blank		Method Blank		RPD		QC Standard	
QC Batch	Parameter	Date	% Recovery	QC Limits	% Recovery	QC Limits	Value	UNITS	Value (%)	QC Limits	% Recovery	QC Limits
8404270	Total Zinc (Zn)	2016/09/24	NC	75 - 125	108	75 - 125	<0.040	mg/kg	18	35	104	75 - 125
8405552	Moisture	2016/09/22					<0.30	%	3.7	20		
8405569	Moisture	2016/09/22					<0.30	%	7.6	20		

Duplicate: Paired analysis of a separate portion of the same sample. Used to evaluate the variance in the measurement.

Matrix Spike: A sample to which a known amount of the analyte of interest has been added. Used to evaluate sample matrix interference.

QC Standard: A sample of known concentration prepared by an external agency under stringent conditions. Used as an independent check of method accuracy.

Spiked Blank: A blank matrix sample to which a known amount of the analyte, usually from a second source, has been added. Used to evaluate method accuracy.

Method Blank: A blank matrix containing all reagents used in the analytical procedure. Used to identify laboratory contamination.

NC (Matrix Spike): The recovery in the matrix spike was not calculated. The relative difference between the concentration in the parent sample and the spiked amount was too small to permit a reliable recovery calculation (matrix spike concentration was less than 2x that of the native sample concentration).

NC (Duplicate RPD): The duplicate RPD was not calculated. The concentration in the sample and/or duplicate was too low to permit a reliable RPD calculation (one or both samples < 5x RDL).

(1) Reference outside acceptance criteria - re-analysis yields similar results.

(2) Recovery or RPD for this parameter is outside control limits. The overall quality control for this analysis meets acceptability criteria.

Remarks:

Maxxam Analytics' laboratories are accredited to ISO/IEC 17025:2005 for specific parameters on scopes of accreditation. Unless otherwise noted, procedures used by Maxxam are based upon recognized Provincial, Federal or US method compendia such as CCME, MDDELCC, EPA, APHA.

All work recorded herein has been done in accordance with procedures and practices ordinarily exercised by professionals in Maxxam's profession using accepted testing methodologies, quality assurance and quality control procedures (except where otherwise agreed by the client and Maxxam in writing). All data is in statistical control and has met quality control and method performance criteria unless otherwise noted. All method blanks are reported: unless indicated otherwise, associated sample data are not blank corrected.

Maxxam Analytics' liability is limited to the actual cost of the requested analyses, unless otherwise agreed in writing. There is no other warranty expressed or implied. Maxxam has been retained to provide analysis of samples provided by the Client using the testing methodology referenced in this report. Interpretation and use of test results are the sole responsibility of the Client and are not within the scope of services provided by Maxxam, unless otherwise agreed in writing.

Solid sample results, except biota, are based on dry weight unless otherwise indicated. Organic analyses are not recovery corrected except for isotope dilution methods. Results relate to samples tested.
This Certificate shall not be reproduced except in full, without the written approval of the laboratory.
Reference Method suffix "m" indicates test methods incorporate validated modifications from specific reference methods to improve performance.
* RPDs calculated using raw data. The rounding of final results may result in the apparent difference.

==========

This report has been generated and distributed using a secure automated process.
Maxxam has procedures in place to guard against improper use of the electronic signature and have the required "signatories", as per section 5.10.2 of ISO/IEC 17025:2005(E), signing the reports. For Service Group specific validation please refer to the Validation Signature Page.

8470433	Moisture	2016/11/16					<0.30	%	2.4	20		

Duplicate: Paired analysis of a separate portion of the same sample. Used to evaluate the variance in the measurement.

Matrix Spike: A sample to which a known amount of the analyte of interest has been added. Used to evaluate sample matrix interference.

QC Standard: A sample of known concentration prepared by an external agency under stringent conditions. Used as an independent check of method accuracy.

Spiked Blank: A blank matrix sample to which a known amount of the analyte, usually from a second source, has been added. Used to evaluate method accuracy.

Method Blank: A blank matrix containing all reagents used in the analytical procedure. Used to identify laboratory contamination.

NC (Matrix Spike): The recovery in the matrix spike was not calculated. The relative difference between the concentration in the parent sample and the spiked amount was too small to permit a reliable recovery calculation (matrix spike concentration was less than 2x that of the native sample concentration).

NC (Duplicate RPD): The duplicate RPD was not calculated. The concentration in the sample and/or duplicate was too low to permit a reliable RPD calculation (one or both samples < 5x RDL).

(1) Reference outside acceptance criteria - re-analysis yields similar results.

(2) Reference outside acceptance criteria (10% of analytes failure allowed).

(3) Blank Spike outside acceptance criteria (10% of analytes failure allowed).

(4) Recovery or RPD for this parameter is outside control limits. The overall quality control for this analysis meets acceptability criteria.

Fish and Aquatic Resources Baseline

Memorandum

To:	YESAB Reviewers
From:	Pat Tobler
Date:	March 31, 2017
Project No:	17Y0032
Re:	Coffee Gold Project - Fish and Aquatic Resources Baseline Report

The above mentioned baseline report that follows this memo was completed for Kaminak Gold Corporation by Palmer Environmental Consulting Group (PECG) based on their fieldwork around the mine site in 2014 and 2015. Minor edits to this report were completed by PECG in 2017; therefore, the report is dated February 20, 2017.

Dear Ms. Armstrong,

Re: Fish and Aquatic Resources Baseline Report, Coffee Gold Project

Palmer Environmental Consulting Group Inc. is pleased to submit the attached report describing results of the fish and aquatic resources baseline assessment conducted as part of the Coffee Gold Project's baseline collection program carried out in 2014 and 2015.

This report characterizes the pre-development conditions of the fish and aquatic resources in the study area of the proposed Coffee Gold Project and provides a basis for an effects assessment from mine development.

If there are any questions or comments on this report, please contact Rick Palmer at (604) 629-9075.

Thank you for the opportunity to work with you on this project.

Yours truly,

Palmer Environmental Consulting Group Inc.

Executive Summary

This report describes the studies conducted in 2014 and 2015 on the aquatic environments of the Coffee Gold Project, which specifically includes fish and fish habitat, benthic invertebrate and periphyton communities, and sediment quality. The Coffee Gold Project is a proposed open-pit, heap leach gold mine located in the White Gold district of west-central Yukon, approximately 130 km south of Dawson City. The objective of the 2014-2015 aquatic environmental baseline surveys was to characterize the pre-development aquatic environment of the Project area in support of the project proposal to the Yukon Environmental and Socio-economic Assessment Board (YESAB).

The fish and aquatic resources baseline program included sampling at 18 fish community sampling sites, 17 fish habitat sites, and 12 benthic invertebrate, periphyton and sediment sites throughout the project study area. Sampling was conducted in August and October, 2014, and in March, June, July, and September, 2015. Fish habitat was characterized at each fish sampling site including the collection of *in situ* water quality parameters, and an assessment of habitat quality and quantity based on general habitat attributes (e.g., channel width, gradient, substrate composition, cover, stream morphology). A winter fish habitat survey was completed at select sites on Latte and Coffee Creeks in late March, 2015. Various site-specific fish sampling methods were conducted and included backpack electrofishing, minnow trapping, fyke net trapping, and angling. Salmon spawning surveys were conducted in summer 2014, fall 2014, and summer 2015 in Coffee Creek, Independence Creek, and in adjacent sections of the Yukon River. An Arctic grayling spawning survey was conducted in spring 2015 in Latte Creek. Fish samples were obtained from watersheds in the project area for analyzing fish age, diet, and tissue metal concentrations. Sediment sampling was completed for analyzing nutrients, pH, and metal concentrations at sites in the project study area.

Results showed that sediment samples exceeded the arsenic Canadian Council of Ministers of the Environment (CCME) Interim Sediment Quality Guidelines (ISQG) at every station, and also exceeded the arsenic Probable Effects Level (PEL) at AQ05, AQ13, and AQREF1. The ISQG was exceeded for Chromium in the Kona tributary of Independence Creek (AQ13), as well as at the Los Angeles Creek reference site (AQREF2).

Chlorophyll *a* was very low for all sites, which is typical of northern aquatic habitats. Ash-free dry mass (AFDM) values ranged from 0.38 - 1.07 mg/cm^2, with the highest values observed in Halfway Creek (AQ20) and Los Angeles Creek (AQREF2). Dipterans were the most dominant benthic invertebrate group in the project study area (50%), followed by mayflies (26%), and then stoneflies (21%).

Fish habitat quality was greatest in the mainstems of Coffee and Independence Creeks due to their large sizes, ample in-stream cover, and the presence of a wide variety of habitat types available including potential overwintering habitat. The winter fish habitat survey confirmed that there were localized areas for overwintering on Coffee Creek mainstem, however no overwintering habitat was observed in Latte Creek. Good Arctic grayling summer feeding habitat was available in the lower reaches of Latte Creek due to the frequency of substantial pool habitat. Habitat quality decreased in the upper watersheds (Latte

Creek, Kona Tributary, Halfway Creek, Independence Creek) due to steeper, cascade-pool or step-pool segments. In Halfway Creek, there was marginal fish habitat for Arctic grayling (*Thymallus arcticus*) available in the lower watershed (AQ20). YR24 was even smaller and steeper than Halfway Creek, with little to no pool habitat observed for fish rearing at the downstream site (e.g. water depths were generally less than 20cm). A high gradient barrier to fish passage was identified on upper YR24, just upstream of the aquatic site AQ31. The Isaac Creek reference site was smaller and shallower than both Independence and Coffee Creeks, with a mean channel width of 10m, and fewer deep pools (>1m) noted. The Los Angeles Creek reference site was established as an additional reference site in 2015 and was comparable to a range of habitats present in the mine study area.

Arctic grayling, slimy sculpin (*Cottus Cognatus*), and juvenile Chinook salmon (*Oncorhynchus tshawytscha*) were the most dominant fish species captured in the project study area. Juvenile Chinook salmon were present in the mainstems of Coffee Creek and Independence Creek, but were not captured in Latte Creek, Kona Tributary of Independence Creek, Halfway Creek, or YR24. In August 2014, juvenile Chinook salmon (jcs) capture rates were highest in the mainstem of Coffee Creek (5-12 jcs/trap/day), and low to moderate in Independence Creek (0.1-1 jcs/trap/day). Catch per unit effort was slightly lower at all sites in October, however, the presence of juvenile Chinook late in the season suggested that overwintering occurred at most sites in mainstem Coffee and Independence Creeks. At sites in Coffee Creek, capture rates of juvenile Chinook salmon were 8-15 times lower in July 2015 in comparison to August 2014, suggesting that juvenile rearing may exhibit high variability year to year. Capture rates of juvenile Chinook salmon were similar across both years for Independence Creek sites. Slimy sculpin overlapped juvenile Chinook salmon in distribution, but were also present at the downstream end of Latte Creek, and at the mouth of YR24. Arctic grayling were captured at all sites, with the exception of YR24, upper Halfway Creek, upper Latte Creek, and upper Kona Tributary, where no fish were caught. Site AQ04 on lower Latte Creek had the highest number of Arctic grayling captured (n=70). Two years in a row, sampling in lower Halfway Creek produced a single adult Arctic grayling. Low numbers of Arctic grayling were captured in the lower Kona Tributary site, AQ12. In 2014, a reference site was established near the mouth of Isaac Creek, which contained high numbers of juvenile Chinook salmon, slimy sculpin, and low numbers of juveniles from four other fish species. In 2015, low numbers of juvenile Chinook salmon, Arctic grayling, and slimy sculpin were captured at a second reference site located on Los Angeles Creek.

Slimy sculpin and Arctic grayling samples were collected for analyzing baseline metal concentrations in tissues. Mean estimated methylmercury concentrations exceeded the guideline for the protection of fish-eating wildlife in all watersheds. Individual slimy scupin samples in Latte and Coffee Creeks also exceeded the human health guideline for subsistence consumers. No fish samples at any sites exceeded the maximum allowable level of mercury for sale guideline. Mean selenium concentrations in slimy sculpin and Arctic grayling tissues exceeded the selenium guidelines for the protection of freshwater aquatic life in all watersheds. Individual slimy sculpin and Arctic grayling samples throughout the study area exceeded the selenium human health guideline for high consumers of fish. The human health selenium guidelines based on moderate and low fish diets were not exceeded by any individual fish samples.

Similar to results from previous years (Sparling 2001; Laberge and White Mountain 2002), no Chinook salmon were observed spawning in Coffee and Independence Creeks in 2014 or 2015. Results from the

Arctic grayling spawning assessment on Latte Creek suggested that grayling likely spawned elsewhere prior to entering the creek for summer feeding.

1 Introduction

1.1 Overview

This report describes the studies conducted in 2014 and 2015 by Palmer Environmental Consulting Group Inc. (PECG) on the aquatic environments of the Coffee Gold Project (the Project), which specifically includes sediment quality, periphyton, benthic invertebrate, fish habitat and fish community assessments. The purpose of these studies was to characterize the pre-development environment in support of the project proposal to the Yukon Environmental and Socio-economic Assessment Board (YESAB).

The Project is a proposed open-pit, heap leach gold mine located in the White Gold district of west-central Yukon, approximately 130 km south of Dawson City. The Project is wholly owned by the Kaminak Gold Corporation (KGC). The Project encloses several gold occurrences within an exploration concession covering an area of more than 600 square kilometres. The location of the Project is shown in Figure 1, as well as the fish and aquatic resources study area. All watercourses in the Project area eventually discharge into the Yukon River.

1.2 Study Objectives

The overall objectives of the Coffee Gold Fish and Aquatic Resources baseline study were to:

- Characterize fish and fish habitat in streams potentially affected by the Project to identify potential interactions and opportunities for mitigation, and to support an application to YESAB;
- Provide baseline data that will support future environmental effects monitoring programs; and
- To provide a basis for the assessment of any potential reduction of baseline fisheries productivity in order to support the future development of a Fisheries Mitigation and Offsetting Plan.

While some previous data has been collected in this region (see Appendix A: Review of Existing Fisheries and Aquatic Community Information, Coffee Gold Project, Yukon), the aim of the baseline program was to support a successful project submission to YESAB by establishing a thorough, repeatable, and multi-year baseline program. Several aquatic resources in the project area were studied in 2014-2015 including: periphyton, benthic invertebrates, fish and fish habitat, and sediment quality. These aquatic resources were chosen for study as they either directly or indirectly contribute to commercial, recreational or Aboriginal (CRA) fisheries, and/or they provide important indicators of aquatic ecosystem health that can be monitored over time. An overview of the importance of each program is briefly given below:

Sediment analysis is an important environmental monitoring component as sediments provide habitat for algae, plants, microorganisms, and invertebrates, which in turn support higher trophic communities such as fish. Sediment analysis may provide more insight into long-term contaminant levels in comparison to water quality testing, as contaminants are integrated into sediments over time, and are more likely to capture periodic or storm-based contamination events. Long-term accumulated contaminant levels may

be incorporated into the aquatic food web if sediments become re-suspended or are bioavailable. In 2014-2015, sediment samples were obtained and analyzed for nutrients, metals, and grain size.

Periphyton is the assemblage of algae, bacteria, fungi, microinvertebrates, bacteria, and detritus found attached to aquatic substrate such as rocks. The baseline program included the sampling of periphyton biomass, chlorophyll *a* concentrations, and community composition, which provides a mechanism for assessing water quality health and primary productivity in a watershed (BCMOE 2012).

The baseline program focused on determining benthic macroinvertebrate densities, species richness, biodiversity, and overall community composition, which provides insight into the aquatic health and resilience to disturbances. As benthic invertebrates are a common food source for fish, varying benthic invertebrate community health may have cascading trophic effects on fish communities. Benthic macroinvertebrates are also used as an indication of water quality due to varying species tolerance levels and the sentinel nature of the organisms. Biomonitoring of benthic invertebrates is therefore used as part of environmental effects monitoring to determine any potential effects, alongside water quality results and fish community surveys.

Fish contribute ecological, cultural, recreational and commercial value as they support fisheries, and constitute a fundamental role in aquatic ecosystem functioning. The Project study area is dominated by two CRA fish species: Chinook salmon and Arctic grayling. Yukon River Chinook salmon have historically supported valuable commercial, recreational and Aboriginal fisheries, however, the population has experienced significant declines and fishery closures in recent years (JTC 2013; Yukon Salmon Sub-Committee 2014). Arctic grayling is the most popular sport fish in the Yukon (Environment Yukon 2010), and may be targeted for fishing in accessible areas adjacent to the Yukon River. The protection of fish and fish habitat is built into the environmental legislation of the *Fisheries Act*, which aims to ensure that project activities do not impact fisheries productivity. Biomonitoring of fish species provides valuable information about the health of a watershed, as fish are long-lived and have specific habitat requirements that may be sensitive to environmental perturbations. In addition, fish are often positioned at the top of the aquatic food web, allowing them to integrate environmental variability experienced by species at the base of the food chain, and increasing the likelihood of detecting environmental impacts (BCMOE 2012). In the baseline program, sampling was undertaken to determine fish abundance, distribution, life history, and overall health via measurements of fish growth, population size, and metal concentrations of tissues. In addition, fish habitat characteristics were recorded, including physical parameters (e.g., channel size, stream substrate, habitat types) and *in situ* water quality parameters (e.g., temperature, pH, and dissolved oxygen).

Together, the study of sediment quality, periphyton, benthic invertebrates, and fish and fish habitat provides a thorough overview of the baseline conditions for aquatic resources in the project study area.

2 Methods

2.1 Study Area

The study area for the fish and aquatic resources survey of the Coffee Gold Project includes the four watersheds surrounding the project deposit: the mainstem of Coffee Creek to the east, Latte Creek to the south, the Independence Creek watershed to the west, including the Independence Creek Kona Tributary, and the Halfway Creek and YR24 Creek watersheds to the north (Figure 1). These watersheds have the potential to experience near-field project effects due to either overlap with the project footprint, or indirect effects resulting from activities in areas upstream. All of these watersheds eventually flow northward into the Yukon River.

The fish and aquatic resources study area also includes water bodies that may be indirectly affected (mid-to-far field effects), or are suitable for providing reference sites to the proposed Project activities. Mid-field effects include stream locations that may experience occasional effects of low magnitude due to project activities. Far-field effects are stream areas that are located at the most downstream end of the zone of potential influence, and thus would only experience rare and low-level influence from activities upstream. Reference sites are stream areas that are located outside of project effects, and thus are used as indicators of natural baseline variability in the regional area. In 2014, one reference site was established in the Isaac Creek watershed, which is located approximately 30km east from the mouth of Coffee Creek along the Yukon River, upstream of where Excelsior and Britannia Creeks enter the river. In 2015, an additional reference site was established in the Los Angeles Creek watershed, located approximately 10km west from the mouth of Independence Creek along the Yukon River.

2.2 Review of Existing Literature

A review of existing studies completed in the project area was completed in spring 2014, and is attached to this report as Appendix A. The review summarizes fish community data collected from the Coffee, Independence, and Halfway Creek watersheds in 2000-2001 (Sparling 2001; Laberge and White Mountain 2002), 2010 (Laberge and White Mountain 2012), and 2013 (PECG 2013a, b; Access 2014). Benthic invertebrate community data was available for one site in lower Coffee Creek (Laberge and White Mountain 2002, 2012), and no periphyton or sediment quality data had been collected at any sites.

2.3 Field Data Collection

The fish and aquatic resources study program was carried out at 18 fish sampling sites, 17 fish habitat sites, and 12 benthic invertebrate, periphyton and sediment sites throughout the project study area (Table 1, Figure 1). In 2014, field data were collected during August 19 – 30, on fish communities; fish habitat; benthic invertebrate; periphyton; and sediment data. Additional fish community data were collected from October 2 – 7. In 2015, a winter survey of fish habitat took place from March 27-28; spring fish and fish habitat data were collected from June 18 – 23; summer fish community, fish habitat, benthic invertebrate, periphyton, and sediment data were collected from July 24 – August 1; and additional fish and fish habitat

data were collected from September 10-13. A description of the field activities completed during each of the six seasonal assessments is provided in Table 2.

2.4 Field and Laboratory Methods

2.4.1 Sediment

At each site, three replicates per site were collected from three different erosional locations (e.g., undercut banks) using the finest sediment available at each site. Erosional locations were sampled based on Environment Canada recommendations for other mining baseline projects in the Yukon (e.g., Eagle Gold Project). Finer sediments are more useful for determining potential risks to aquatic life, as most chemical contaminants preferentially bind to silts and clays, and finer sediments are more likely to be consumed by benthic invertebrates (BC MOE 2012). Water depths and photos were taken at each sampling location (example photo shown in Figure 2). An additional sample was collected at one of the three replicate locations per site for analyzing particle size distribution. As recommended by the BC MOE (2012), a field split was completed for one replicate at every other site for Quality Assurance and Quality Control (QA/QC).

Figure 2. Example of sediment sampling location, Site AQ11, Coffee Gold Project, 2014

Sediment samples were analyzed for metals, total organic carbon, nutrients, and grain size by CARO Analytical Services. Samples were dried at 60°C, sieved using a 63 micron mesh (as recommended by BC MOE 2012), and digested using a nitric and hydrochloric acid mixture at 95°C for two hours. Inductively coupled plasma mass spectrometry (ICP/MS) was used to analyze samples. Laboratory detection limits for parameters are summarized in Table 3.

Table 3. Sediment Quality Parameters and Reported Detection Limits (RDL) (CARO Analytical) Coffee Gold Project, 2014-2015

Parameter	Units	RDL	Parameter	Units	RDL
Physical					
Carbon, Total Organic	% dry	0.05	Selenium	mg/kg	0.5

Phosphorus	mg/kg	10	< 75 µm	%	0.1
Potassium	mg/kg	10			

2.4.2 Periphyton

Periphyton sampling sites were selected in the project study area with the aim of standardizing depth, velocity, gradient, substrate, and sunlight exposure among sites (OMOE 2012). Sampling was completed in mid-late summer as periphyton communities were expected to have reached their maximum density and diversity during this time period.

At each site, five rocks were chosen randomly and sampled using a 1.7cm diameter syringe sampler. Approximately 50mL of sample was obtained per rock and emptied into a 1L bottle, for a combined 250mL volume per sample. The protocol differed slightly at site AQREF1 in 2014, where four rocks were sampled at a volume of 60mL/sample and a total of 240mL. The process was repeated two more times using un-sampled areas on the same rocks, for a total of 3 samples collected per site. Each of the three bottles was submitted for a separate analysis, which included chlorophyll *a*, biomass and species composition. Sample bottles submitted for chlorophyll *a* and biomass analyses were kept as cool as possible, covered in foil to prohibit entry of light, and delivered to an analytical laboratory within four days[1]. Sample bottles submitted for species composition were preserved using approximately 1mL of Lugol's iodine solution immediately following sampling. Samples were delivered to CARO Analytical Services (Burnaby, BC) for chlorophyll *a* and biomass analyses, and to Plankton R Us (Winnipeg, MB) for species composition enumeration. In 2015, one sample (AQ10), was broken upon arrival to Plankton R Us and thus periphyton community composition results are based only on 2014 analyses for this site.

To obtain chlorophyll *a* concentrations, samples were filtered, ground, extracted using 90% acetone and analyzed on a spectrophotometer. To measure algal ash-free dry mass (AFDM), samples were first dried at 105°C, weighed, and then oxidized at 550°C. AFDM quantifies the organic content of a sample, which is the difference in mass before and after incineration (mg/L).

Prior to species identification and enumeration, 1-2mL sub-samples were sonicated for 10-20s using a Sonifer Cell Disruptor w140, and then allowed to settle in an Ütermohl chamber for 24 hours (Findlay *et al.* 1999). Periphyton cells were then identified to the lowest taxonomic level possible and counted until 100 cells of the most numerous species were found.

2.4.3 Benthic Invertebrates

The Canadian Aquatic Biomonitoring Network (CABIN) protocol was applied at twelve sites in the project study area (Environment Canada 2012). A triangular CABIN protocol kick-net sampler with 400 micron mesh and detachable collection cup was employed. The net opening was faced into the stream current with the flat side of the net resting on the substrate of the stream. The sampler walked backward in the upstream direction, dragging the net along the bottom of the stream while disturbing the substrate with a kicking motion to a depth of ~5-10 cm. Sampling was zig-zagged over the stream bottom from bank to bank in an upstream direction for a timed period of three minutes. All samples were preserved using 85% ethanol and submitted to Cordillera Consulting (Summerland, BC) for species composition analysis.

Benthic invertebrates were identified to the lowest possible taxonomic group, which was to the family level for most aquatic insects, class for oligochaetes and phylum for nematodes. Benthic invertebrate density was reported relative to each kick net sampling event.

[1] Recommended holding times were surpassed for chlorophyll *a* analyses, but not for ash-free dry mass or periphyton taxonomy. Recommended sample temperatures (1-8°C) may have been exceeded during transport to the lab.

2.4.4 Fish Habitat

A total of 17 sites were assessed for fish habitat in the project study area (Table 1). Fish habitat was characterized following a modified version of the methods described in the Resources Inventory Standards Committee (RISC) Fish and Fish Habitat Inventory: Site Card Field Guide (Version 2.0, April 2008) and in the *Fish Habitat Assessment Procedures* guide for the British Columbia government (Johnston and Slaney, 1996), as there are no available watercourse sampling guides established for Yukon Territory. At each site, a minimum of 100m encompassing the fish sampling site was surveyed to assess habitat characteristics.

At each habitat site, stream length and stream width (*i.e*., wetted and bankfull width) was measured with surveyor's measuring tape. Gradient was measured with a Sunnto clinometer. Stream depth was measured with a meter stick, following methods outlined in Johnston and Slaney (1996). Stream stage (water level) was assessed as low, medium or high visually by comparison between stream surface height and bankfull height. Habitat was visually assessed into the following five types:

- ***Pools*** have zero gradient, slow-moving water and a concave bottom;
- ***Runs*** (also called glides) are sections of non-turbulent, fast-flowing water;
- ***Riffles*** are areas of turbulent, fast-flowing water with gravel or cobble substrates and with obvious surface turbulence;
- ***Cascades*** are steep, stepped "riffles" of bedrock or emergent cobble or boulders in channels with gradients greater than about 4%; and
- ***Other*** includes wetland complexes that lack an identifiable primary channel, sloughs, lakes, areas of sub-surface flow or areas where the channel cannot be observed (e.g., under large log jams).

Stream substrate was assessed visually into the following classes:

- fines (or silt);
- small gravel (2-16 mm particle diameter);
- large gravel (16-54 mm);
- small cobble (64-128 mm);
- large cobble (128-256 mm);
- boulder (>256 mm); or
- bedrock.

The percent of the stream surface that provided fish with cover was described using the following classes:

- deep pool (>1m depth);
- large woody debris (LWD);
- boulder;
- cutbank;
- instream vegetation; and
- overhanging vegetation.

The percentage of the overhead forest canopy that was closed was estimated visually.

The percentages of a stream section that belonged to each habitat type had to add to 100%, as did the percentages of the substrate of a stream section that belonged to each size class and the % of the canopy that was closed. However, the percentages of cover provided by the various classes did not have to add up to 100%.

Stream confinement was assessed as:

- unconfined (UC) – the stream bank is not touching the valley wall;
- occasionally confined (OC) – the stream bank is occasionally confined by the valley wall or terraces;
- frequently confined (FC) – the stream bank is frequently confined by the valley wall or terraces;
- confined (CO) – the stream bank is in continuous or repeated contact at the outside of meander bends;
- entrenched (EN) – the stream bank is in continuous contact with the valley walls or terraces due to downcutting; and
- not applicable (NA) – no valley walls exist (e.g., alluvial fans).

In addition, general *in situ* water quality parameters were measured as part of fish habitat assessments including pH, conductivity (µs/cm), temperature (°C), and dissolved oxygen concentration (mg/L and %).

Stream Temperature:

Temperature loggers (TidbiT v2 Temp Logger, Onset Hobo, 2013) were deployed in five creeks during the spring reconnaissance trip (June 1, 2014). The temperature loggers were anchored onto the streambed to reduce dislodging and were set to record stream temperatures every 15 minutes. On October 6-7, 2014, the loggers were downloaded and re-deployed, and the logging interval was changed in 60 minutes (Table 4). One temperature logger (T5) was originally set in a tributary south of the Kona Tributary, and was re-located to site AQ12 on the Kona Tributary in October, 2014. In spring 2015, some of the loggers had been re-located outside of the stream during freshet and were placed back into their original positions. Stream temperatures were again collected during the summer months and downloaded in September, 2015, with the exception of T1 which could not be located for retrieval. For a more thorough record of stream temperatures in the Coffee Gold study area, please refer to the Hydrology Baseline Report.

Table 4. Stream temperature logger locations, Coffee Gold Project, 2014-2015

Watershed	Creek	Logger ID	UTM Co-ordinates (Zone 7V)		Date Installed (2014)	Download Date (2014)	Removal Date (2015)	Description
			Easting	Northing				
Coffee	Coffee	T1	596,813	6,974,174	01-Jun-14	06-Oct-14	-	Lower Coffee Creek, downstream of AQ00
Coffee	Latte	T2	591,817	6,970,662	01-Jun-14	06-Oct-14	12-Sep-15	Lower Latte Creek, near AQ04
YR24	YR24	T3	585,708	6,976,068	01-Jun-14	06-Oct-14	12-Sep-15	Near the creek outlet and AQ30
Halfway	Halfway	T4	584,819	6,977,431	01-Jun-14	06-Oct-14	12-Sep-15	Near hydrology station and AQ20
Independence	Kona	T5	573,598	6,974,768	-	06-Oct-14*	12-Sep-15	Lower Kona tributary, near AQ12

Notes: T1 was not located for retrieval in 2015
**T5 was first installed on October 7, 2014*

2.4.4.1 Winter Fish Habitat Survey

The winter fish habitat survey was conducted on March 27-28, 2015. The objective of the survey was to determine if there was any potential overwintering habitat at sites in Latte and Coffee Creeks (Table 1). Late March was chosen for this survey as it was near the end of the winter season, and thus potentially provided the poorest water quality (e.g., low dissolved oxygen) and flow conditions under ice. An ice auger and chisel were used to conduct under ice assessments, and *in situ* water quality, ice thickness, and water depth measurements were collected where there was sufficient flow.

Prior to the field assessment, habitat mapping from the 2014 open water season was used to identify deep pool habitat sites that were candidates for overwintering habitat. Based on this assessment, the crew surveyed approximately 6 pools starting at the confluence with Coffee Creek to a location approximately 1 kilometer upstream. Further upstream, habitat near sites AQ04 and AQ04.5 were also surveyed. At AQ04, approximately 200 m of the creek was surveyed, upstream and downstream of the site (400 m total), including a location known to be a deep pool in summer. At AQ04.5, the survey covered areas of the creek in the immediate vicinity of the site, as well as the Latte Creek tributary that overlaps with the proposed south waste rock storage facility. On Coffee Creek, the crew surveyed the winter habitat at AQ02 (approximately 300 m downstream from Latte confluence), AQ01, and AQ00. An underwater camera (Aqua-Vu AV Micro II color camera, with an infrared light source) was deployed under the ice for 15 minutes at AQ02 and AQ01 to check for fish presence (no flow was detected at AQ00). The camera was attached to a rod and lowered slowly down to the stream bed, so that the substrate was visible. To maximize the view, the camera was slowly moved up and down (i.e. vertically) over the entire water column and also rotated 360 degrees at multiple depths. The two biologists watched the display for

any fish or movement. Visibility was limited by the extent of the light source and water turbidity, and occasionally by woody debris or sub surface layers of ice.

2.4.5 Fish Community

2.4.5.1 General Fish Community Field Methods:

Various site-specific fish sampling methods were conducted and included backpack electrofishing, minnow trapping, fyke net trapping, and angling. Specific sampling dates and methodologies are further detailed in Appendix F. Electrofishing at all sites was completed using a Smith-Root LR-20 Backpack Electrofisher and a two-person crew under two Scientific Fish Collection Permits (XR 249 2014 and XR 166 2015). Site lengths ranged from 60-275m and were selected to contain multiple mesohabitats (e.g., pool, riffle, run) representative of the reach being sampled. Electrofishing voltage ranged from 150-350V, and was adjusted at each site depending on water conductance, temperature, and expected fish size. Electrofishing effort varied from 430-2276s per electrofishing pass, with an average effort of 937s/pass. Multiple-pass electrofishing was carried out at three sites in 2014 (three-pass at AQ04, AQREF1, and two-pass at AQ10), and at two sites in 2015 (three-pass at AQ04, AQREF2) in order to obtain fish species presence/absence information and standardized density estimates.

Prior to electrofishing, stop nets were positioned at the upstream and downstream ends of the sample section to prohibit fish migration during sampling. Each pass completed had similar effort, and a minimum of 30 minutes was allowed to elapse between passes to allow recovery of un-captured fish. Fish were released into areas outside of the site boundaries after processing and recovery. Stop nets were also deployed at AQ10 in order to prevent escapement of fish from the sampling area. All other study sites did not require stop nets, as they were either too large for creek isolation (e.g., mainstem Coffee Creek), or were small enough with low enough flows that natural barriers to fish passage were present (e.g., lower Halfway Creek, YR24, and Kona Tributary). Headwater sites (Latte Creek: AQ05, AQ06; YR24: AQ31; Halfway Creek: AQ21; Independence Creek Kona Tributary: AQ13) had extremely low temperatures and flows at the time of sampling in late August 2014, and thus were not conducive to electrofishing, which is largely ineffective at low temperatures (<5°C). Similarly, electrofishing was not carried out in October, 2014 at any sites due to very cold water temperatures.

Extensive minnow trapping was conducted over both years and several seasons at the majority of sites (Table 10). In 2014, between eight to ten traps were deployed at all sites during August sampling on the mainstems of Coffee and Independence Creeks, and on Isaac Creek, whereas five traps were set per site in October. Smaller numbers of traps (two to five) were deployed in Latte Creek, Kona Tributary, Halfway Creek, and YR24 in August only. In 2015, five traps were set per site during spring and summer sampling in Coffee Creek, Independence Creek, and at both reference sites. Some additional trapping was carried out at select sites in the fall, with the aim of capturing more fish samples for metals analysis. Minnow traps were made of 0.6cm galvanized steel wire mesh with a conical entrance and were 42cm long with a 23cm diameter. Minnow traps were placed at each site in deep pools or among large woody debris or in slow-moving eddies. Each trap was baited with a perforated bag of Yukon River salmon roe and left to soak for approximately 24 hours.

In 2014, fyke nets were deployed overnight in August at sites AQ00 and AQ02, and in October at AQ03. Site AQ03 was a late addition to the 2014 program and was only sampled in October using a fyke net[2]. In 2015, fyke nets were again used at all three sites in mainstem Coffee Creek. The nets were set in slow-moving pool habitats, and the wings extended to direct fish towards the net entrance. Fyke nets were made of ½'' knotless nylon mesh, a funnel ring size of 2.5'', 24'' diameter aluminum hoops, a main net length of 12', and two wings each of 10' length (Fipec, Quebec, 2014). The nets were equipped with a leaded braid line on the lower net, and plastic floats on the wings.

In 2014, angling using spinning rods was conducted at AQ00 in August, 2014 using a two person crew for 1h. In 2015, angling was completed using both spinning and fly fishing rods at several sites including AQ00, AQ01, AQ02, AQ11, and AQREF2. The number of people fishing and duration varied at each site, with an average of 3.2 rod-hours per site (i.e. cumulative number of hours spent fishing per person per site).

All fish were identified to species and counted in the field. Fork length was measured to the nearest 1 mm with a measuring board (total length was measured for slimy sculpin), and wet weight was measured to the nearest 0.1 g or 1.0 g with a balance, depending on size of fish (Ohaus Scout Pro SP2001). Due to the large number of fish captured at some sites, up to 30 fish/species were measured per sampling event after which fish were counted but not individually measured for length or weight.

In 2014, an Arctic grayling tagging program was initiated to provide insight into annual site fidelity of feeding areas and migration patterns around project watercourses. Arctic grayling greater than 200m in length were tagged using an MK25 implant gun with 12mm Passive Integrated Transponder (PIT) tags (134.2 kHz ISO HDX, Biomark, ID, 2014). Tags were encapsulated in biocompatible glass and provide 100% unique identification. Fish were monitored for a minimum of 20 minutes following tagging to ensure successful re-entry into the stream. Due to time constraints, the tagging program was not continued in 2015, however a portable hand held reader (Biomark 601) was employed to scan captured Arctic grayling for tags. All implanted (n=31) and re-captured (n=4) tags are listed individually in Appendix F4.

In 2014, a small sub-set of slimy sculpin (n=26) from three sites (AQ02, AQ10, AQREF1) were sampled to obtain age (otoliths) and tissue metals analysis data. In 2015, more slimy sculpins were collected from sites that were added late in 2014, or in 2015 (AQ03, AQREF2). The aim was to collect eight samples from each of these sites, however low densities and poor sampling conditions (high and turbid flows) yielded small sample sizes (n=1 at AQREF2 and n=3 at AQ03). In addition, to verify sample quality from 2014[3], some additional samples were acquired from Coffee, Independence, and Isaac Creeks. Three samples were collected from AQ02 and AQREF1, but only one sample could be collected from AQ10 due to high flows. The selection of slimy sculpin for metals analysis provided relevant insight into site-specific metal contamination due to (1) the prevalence of the species in the study area, (2) its demonstrated high site fidelity (Gray *et al.* 2004), and (3) its sensitivity to stream sediment metal loading due to its benthic-dwelling nature.

[2] Due to the addition of AQ03 during the October sampling trip, sites further upstream were originally referred to as AQ03, AQ04 and AQ05 in field notes, August lab submissions, and in Appendix D2 unless otherwise noted. They were subsequently updated as AQ04, AQ05, and AQ06, respectively.

In 2014, three Arctic grayling samples were collected (two from AQ04 and one from AQ11) for analyzing diet, age (scales and otoliths), and metals analysis of tissues. In 2015, an additional 23 Arctic grayling from Latte, Coffee, Independence, and Los Angeles Creeks were lethally sampled for metals and ageing. A sub-set of the 2015 Coffee Creek Arctic grayling samples (n=5) were also sampled for diet analyses. An additional 25 grayling from both mine area and reference watercourses were non-lethally sampled for ageing using scales.

No fish samples were collected from Halfway Creek or YR24 due to very low sample sizes and captured fish being within the Yukon River influence. A total of n=1 Arctic grayling/year caught in lower Halfway Creek precluded any lethal sampling, as the DFO Scientific Collection permit prohibited sampling more than 10% of Arctic grayling captured at any site (XR 249 2014). No fish were captured at YR24 with the exception of five slimy sculpins that were captured in June 2015, all within 30m of the confluence with the Yukon River. Due to this close proximity to the Yukon River, absence of overwintering habitat in YR24, and high likelihood for migrations in and out of the creek outlet, these fish were not considered for providing representative baseline data for metals analyses.

Otoliths and scales were sent to North/South Consultants (Winnipeg, MB) for ageing, stomach contents were preserved using 85% ethanol and sent to Cordillera Consulting for species composition analysis, and dorsal muscle tissue was frozen upon sampling and delivered to CARO Analytical for metals analysis[3]. Slimy sculpin heads were submitted for ageing analyses, and the remaining whole-body was submitted for tissue metals analyses. Arctic grayling metals analyses was performed on a piece of muscle tissue from the dorso-lateral area, as recommended in BC MOE (2012).

Laboratory Methods:

To determine fish ages, a small sub-set (three or four) of intact representative scales were chosen by North/South Consultants from each individual fish sample. Scales were pressed between two glass slides and then viewed using a dissecting microscope under reflected light. Otoliths were set in Cold Cure™ epoxy for 48 hours until hardened, and then cut into thin sections using a Struers Minitom™ low speed-sectioning saw. The sectioned piece was then mounted on a microscope slide and viewed under a dissecting microscope with transmitted light for ageing.

Stomach sample contents (≥212 µm) were identified by Cordillera Consulting to the lowest possible taxonomic group, which was to family for most aquatic insects; Class for oligochaetes; and Phylum for nematodes.

CARO Analytical analyzed metals of fish tissue samples by first weighing and then digesting samples using a mixture of hydrogen peroxide and hydrochloric acid at 95°C for two hours. Samples were then filtered and analyzed using inductively coupled plasma mass spectrometry (ICP/MS). There were 31 total metals analyzed with detection limits reported in Table 5.

[3] In 2014, recommended fish sample temperatures may have been exceeded during transport to the lab.

2.4.5.2 Fish Spawning Surveys

2.4.5.2.1 Salmon Spawning Surveys

Both Chinook and chum salmon are known to migrate through or reside in the Yukon River near the Project area. Spawning salmon enter the Yukon River in Alaska from the Bering Sea and travel hundreds of kilometers upstream before entering Canadian waters. Yukon River Chinook salmon return to the mouth of the Yukon River from mid to late May through to early July, with the peak migration timing into Canadian waters occurring in mid to late July. Chinook salmon spawning typically occurs in Canadian waters from late July to mid-September (Yukon River Panel 2014). The peak migration timing of Yukon River chum salmon into Canadian waters occurs later in the fall in mid-September, with peak spawning occurring from October through to early November (Yukon River Panel 2014).

Salmon spawning surveys were conducted by two fisheries biologists in August 2014, October 2014, and in July-August 2015 (Table 6). A helicopter hovered just above the treeline and travelled at a slow enough speed to allow observations of any spawning activity, such as the presence of adult salmon or areas where salmon had created nests (redds). In Coffee and Independence Creeks, multiple spawning surveys occurred in summer 2015 over the course of a week of fish community sampling. The water clarity was moderate to good during each survey, although water clarity in the Yukon River ranged from turbid in the thalweg to clear in the river margins and side channels. Thus, surveying did not cover the entire Yukon River area from bank to bank.

Table 6. Salmon Spawning Surveys, Coffee Gold Project, 2014-2015

Date	Location	UTM Co-ordinates (Zone 7V, Easting, Northing)

2.4.5.2.2 Arctic Grayling Spawning Survey

In mid-late June 2015, Arctic grayling in Latte Creek were assessed for spawning behavior (territory guarding, spawning congregations, or any courtship displays), external features indicating spawning condition, and internal gonadal development (RIC 1996; Stewart *et al*., 2007a). Arctic grayling in northern ecosystems are known to spawn at or shortly after spring ice break-up which typically occurs from mid-May to mid-June, with some spawning continuing into early July (Stewart *et al*., 2007a). Spawning typically occurs annually after maturity, although some individuals may skip a year after their first spawning season (Stewart *et al.*, 2007a). Stream temperature is a major factor influencing Arctic grayling spawning, with spawning occurring at temperatures above 4°C and with daily means fluctuating between 6-10°C (Stewart *et al*., 2007a). Therefore, timing of the spawning assessment was made based on temperature data available from June-July 2014 which indicated that Latte Creek did not reach adequate temperatures for spawning until early summer.

The Arctic grayling spawning assessment consisted of several components and was carried out from June 18-23, 2015. Upon arrival to site, temperature data from the logger stationed at AQ03 on lower Latte Creek was downloaded and assessed relative to known preferred Arctic grayling spawning temperatures. Temperatures were also monitored using the YSI water quality metre at fish sampling sites AQ03 and AQ04 over the duration of the trip and cross-referenced with the temperature logger data. Sites AQ03 and AQ04 were selected for spawning assessments as they are representative of lower-mid Latte Creek habitat, and are known to support Arctic grayling during the summer months. Fish habitat quality for spawning was assessed over each fishing site concurrent with observations of any fish presence or spawning behavior. Arctic grayling prefer unembedded gravel sized substrate for spawning, at depths <1m, in clear, fast-flowing tributary streams (Stewart *et al*., 2007a). When no spawning behavior was confirmed, each site was electrofished twice over the one week period. Captured fish were assessed for any external signs of maturity state according to the RIC guidelines (1996):

- Immature (IM): Young individuals that have not yet reproduced; fish with underdeveloped gonads. Maturing (MT): Ovaries and testes begin to fill out and take up a large part of the body cavity; eggs distinguishable to the naked eye.
- Mature (M): Fish in full spawning colours; gonads at maximum size; body cavity feels full, especially females; roe or milt is not produced if the body cavity is lightly squeezed.
- Spawning (SP): Fish in full spawning colours; eggs and milt are expelled when body cavity is lightly squeezed (also referred to as gravid).
- Spent (ST): Still have spawning colours; eggs and sperm totally discharged; body cavity feels empty and genital opening is inflamed; gonads empty except for a few remaining eggs or residual sperm.
- Resting (R): Adult sized fish; spawning colours not as apparent; gonads are very small and eggs may not be visible to the naked eye.

At the end of the assessment period, six Arctic grayling were lethally sampled providing a more thorough assessment of sexual maturity state.

2.5 Data Analysis

The standard deviation (SD) was the index of dispersion for all arithmetic means shown in this report, and n was the sample size. All statistical analyses were completed using Statistica version 8 (StatSoft Inc.,Tulsa OK, 2008), with significance levels set to α=0.05.

2.5.1 Sediment

All sediment metrics were calculated as an average over the 2014-2015 period. Sediment data was compared to the Canadian Council of Ministers of the Environment (CCME) Sediment Quality Guidelines for the protection of aquatic life (1999) to identify any parameter exceedances. CCME established two types of guidelines: Interim Sediment Quality Guidelines (ISQG) and Probable Effects Level (PEL). ISQG are concentrations below which adverse biological effects are expected to occur rarely, and PEL are concentrations above which biological effects are expected to occur frequently.

Values below detection limits were replaced with one-half the detection limit. Mean, minimum, maximum and standard deviation were calculated for each parameter by site in Microsoft Excel. While most sites had sample sizes of three for each parameter/year, site AQ11 had only two in 2015 as the third sample was broken during transit to the lab. Thus, results reported for AQ11 are weighed slightly towards 2014 values.

2.5.2 Periphyton

All periphyton metrics were calculated as an average over the 2014-2015 period. Chlorophyll *a* concentrations (µg/L) and periphyton ash-free dry mass (mg/L) were converted to represent mass/area (µg/cm^2 or mg/cm^2) using the known volume sampled per area of substrate at each site. Similarly, periphyton cell density (cells/cm^2) was calculated relative to the sampled substrate area at each site. Periphyton community composition was determined by calculating the relative densities of four main algal groups by site including: Diatoms (*Bacillariophyceae*), green algae (*Chlorophyta*), blue-green algae (*Cyanophyta*), and red algae (*Rhodophyta*).

Taxa richness was calculated as the total number of species present at each site. Where species could not be discerned, the lowest possible taxonomic level identified was substituted. Biodiversity was measured for periphyton samples using the Shannon-Wiener index (H') as follows:

$$H' = -\sum_{i=1}^{R} p_i (\ln p_i) \quad (1)$$

Where R is taxa richness, and p_i is the total number of individuals in the ith species divided by the total number of organisms in the sample.

2.5.3 Benthic Invertebrates

Parameter selection for benthic invertebrates was based on the protocols recommended by the Canadian Aquatic Biomonitoring Network (CABIN), which is supported by the National Water Research Institute (NWRI) of Environment Canada (NWRI 2008).

Benthic invertebrate samples were analysed using the Reference Condition Approach (RCA) as adopted from Environment Canada's Canadian Aquatic Biomonitoring Network (CABIN) protocols. CABIN field sheets were used to collect all the data required for input into the CABIN database. This includes general site and location data, reach data (*i.e*. habitat types, canopy coverage, periphyton coverge, etc.), basic water chemistry, slope, widths, depth, velocity, and substrate data. Once uploaded to the CABIN database, data was compared to the Yukon 2013 reference model using the predictor variables: Channel depth, stream velocity, longitude, precipitation (June), rainfall (Feb, March, June, July), maximum April temperature, and landcover values (Natl-BroadLeafopen, Natl-Bryoids, Natl-MixedWoodOpen, Natl-WetlandHerb). With the exception of stream depth, velocity and longitude values, which were collected in the field, all parameters were generated from GIS layers by PECG.

CABIN analyses include Bray-Curtis, River Invertebrate Prediction and Classification System (RIVPACS) and Benthic Assessment of Sediment (BEAST) Site Assessment Graphs. The Bray-Curtis dissimilarity coefficient is a distance measure that analyses how similar the test sites are to the median of the reference sites; a value of 1 indicates the two sites are entirely different from one another and a value of 0 indicates the two sites are identical in community structure. RIVPACS predicts the probability of a taxonomic group occurring at a test site based on what is expected to occur. Finally, the BEAST analysis is a tool that evaluates whether or not a test site is in reference condition, and if not, then how divergent it is from reference condition. Ordination plots are generated in CABIN and provides an overall indicator of whether a site is in reference condition (unstressed), potentially stressed or stressed.

In addition to the CABIN model outputs described above, traditional community descriptors were also used on benthic invertebrate data. Metrics were calculated as an average over the 2014-2015 period. These include:

- Abundance, calculated as the total number of individuals per kick/net per site,
- Taxonomic richness, calculated as the total number of species present at each site. Where species could not be discerned, the lowest possible taxonomic level identified was substituted,
- EPT taxa richness, defined as the total number of mayflies (Ephemeroptera), stoneflies
- (Plecoptera) and caddisflies (Trichoptera) families per site. These three orders of aquatic insects are typically most sensitive to habitat disturbance,
- Percentage composition, calculated by dividing the density of dominant taxa groups by the total density, and,
- Simpson's diversity (D) and Evenness (E) indices, as defined in Equations (2) and (3) below:

$$D = 1 - \sum_{i=1}^{S} (p_i)^2 \quad (2)$$

$$E = 1/\sum_{i=1}^{S} (p_i)^2 / S \quad (3)$$

Where S is taxa richness, and p_i is the total number of individuals in the ith species divided by the total number of organisms in the sample.

2.5.4 Fish Habitat and Fish Community

Stream Temperature

The period of record for stream temperatures is from June 1, 2014 to mid-September 2015, with the exception of Coffee Creek which has a record from June 1 to October 6, 2014, and the Kona tributary which was first installed on October 7, 2014. Daily and monthly summary statistics (means, maxima, and minima) were calculated during the open water period (June – October) for each creek where a logger was deployed. Where multiple years of data were available, monthly averages were made based on both years. The temperature time series were examined to identify periods where data were suspect (e.g. elevated readings, when logger may have been dry), and any such data were excluded from the calculations. The mean temperatures were calculated as weighted averages based on the number of days of data available. Mean, minimum and maximum daily stream temperature data is included as Appendix E2.

Fish Abundance and Population Density

Relative fish abundance in the study area was determined using a catch per unit effort (CPUE) index, defined as the number of fish caught per 100s of electrofishing effort, or number of fish caught per trap per day. CPUE for minnow trapping was calculated by species and site, per sampling trip season (e.g., June, July, August or October). CPUE for electrofishing was calculated by species and site for the two years combined, as preliminary analyses revealed that data was similar for both years. Fish population estimates were calculated for sites where multiple passes were possible (AQ04, AQ10, AQREF1) using the Zippin two and three-pass exact methods approach as described in Seber & LeCren (1967), Seber & Whale (1970) and Seber (1982). Areas were calculated by multiplying site sampling length (m) with the mean wetted width (m), and then population estimates were divided by area to obtain density estimates (#/100m^2). For sites with multiple passes, CPUE was calculated only using data from the first pass.

Size, Age, Condition

The length-age relationships for Arctic grayling and slimy sculpin were estimated by fitting a von Bertalanffy growth model with non-linear regression. The model was as follows:

$$L_t = L_\infty\left(1 - e^{\left(-K(t-t_0)\right)}\right) \quad (4)$$

where L_t = length (mm) at time t, L_∞ = theoretical maximal length, K = growth coefficient measuring the rate at which the maximal size is attained, and t_0 = theoretical age at zero length. Weighted non-linear regression models with weights set equal to age-class sample sizes were implemented to increase model accuracy. The model for Arctic grayling length-at-age was created using combined data from mainstem Coffee, Latte, and Independence Creek watersheds in order to provide a robust relationship for the overall mine area. For slimy sculpin, only Coffee Creek sculpins (including Latte Creek data) produced a realistic model that was statistically significant. Sculpins from Latte and Coffee Creek were combined due to their close proximity, and low sample size for Latte Creek (n=3). For both species, mean length-at-age was calculated by watershed based on samples collected from five watercourses (mainstem Coffee Creek, Latte Creek, Independence Creek, Isaac Creek, and Los Angeles Creek). Mean age was tested

for statistical differences by watershed using one-way Analysis of Variance (ANOVA) and followed by post-hoc Tukey HSD tests to identify pairwise differences where appropriate. When data did not meet parametric test requirements (e.g., equal sample variances), a nonparametric Kruskal-Wallis H-test was performed.

Weight-length regressions for fish were calculated as:

$$ln\,(W) = a + b \times ln\,(L) \quad (5)$$

where W = weight (g) and L = length (mm), a = the intercept of the regression and b = the slope of the regression. Watershed-specific regressions were completed for each species with sufficient sample sizes (n>30), which included Arctic grayling, slimy sculpin and Chinook salmon. Watersheds were classified according to the following groupings: Coffee Creek mainstem (sites AQ00, AQ01, AQ02), Latte Creek (AQ03, AQ04), Independence Creek (sites AQ10, AQ11), YR24 (site AQ30), Isaac Creek (site AQREF1), and Los Angeles Creek (AQREF2). Only watersheds within a minimum of five fish/species were included in analyses. Combined regressions from fish in the Coffee Creek mainstem, Latte Creek, Independence Creek, YR24, and Halfway Creek are presented in the results to characterize the overall weight-length relationships of fish species in watersheds that may experience project effects. Five outliers were identified and subsequently removed from slimy sculpin weight data in Isaac Creek, and were likely due to the difficulties associated with weighing very small fish in the field.

One sample t-tests were performed on estimated weight-length slope coefficients to determine if slopes significantly differed from the isometric growth value of three. Slope coefficients used in t-tests were estimated using watershed-specific linear regressions. Isometric growth is a requirement for calculating fish condition using the Fulton condition factor (K), as it assumes that fish shape does not change with increasing length. The Fulton condition factor was calculated for slimy sculpin:

$$K = \frac{W}{L^3} \times 100{,}000 \quad (6)$$

Where K = Fulton condition factor, W= weight (g) and L= fork length (mm).

Arctic grayling and juvenile Chinook salmon condition could not be assessed using the Fulton condition factor, due to allometric growth in one or more watershed. Instead, the relative condition factor (K_n) was used to characterize fish condition:

$$K_n = \frac{W}{W'} \quad (7)$$

Where W = fish actual weight (g) and W'= predicted length-specific weight using the length-weight regression for all watersheds (data from reference sites included) outlined in equation 5.

Statistical comparisons of fish condition were made using one-way Analysis of Variance (ANOVA) and followed by post-hoc Tukey HSD tests to identify pairwise differences where appropriate. When data did not meet parametric test requirements (e.g., equal sample variances), a nonparametric Kruskal-Wallis H-test was performed. Only watersheds with n≥5 were included in statistical analyses.

Metals Analysis

Selected total metals were compared among watersheds and included: aluminum, arsenic, barium, cadmium, copper, iron, lead, mercury, manganese, molybdenum, nickel, selenium, strontium, thallium and zinc. Values below detection limits were replaced with one-half the detection limit for analyses.

The mean and standard deviation of each metal were reported by watershed and compared to various guidelines for the protection of aquatic and piscivorous wildlife, as well as to Health Canada standards for mercury levels in fish. Currently, information is lacking for developing safe metal concentration levels for fish, with guidelines available only for selenium and mercury. The selenium concentration guideline of 4mg/kg (dry weight) is a newly developed guideline prescribed by the British Columbia Ministry of Environment (2014) for the protection of freshwater aquatic life, with the aim of preventing selenium bioaccumulation up the food chain. With the 2014 updates, BC also provided Human Consumption Screening values for selenium that is based on Health Canada's recommended equation for ingestion of Se-contaminated fish and the dietary reference value's tolerable upper intake (BC MOE 2014). The screening values vary from 7.3 – 75 µg/g (dry weight) depending on the amount of fish regularly consumed. Selenium concentrations were converted to dry weight using percent moisture:

$$d \quad w \quad ht = \frac{w \quad w \quad ht}{1 \quad -(\%\, m \qquad)} \times 100 \qquad (8)$$

The CCME mercury guideline for the protection of piscivorous wildlife is based on methymercury concentrations (0.033mg/kg), which is the biologically relevant form of mercury due to its potent neurotoxicity to humans and wildlife (CCME, 2000). The proportion of mercury in fish tissue in its methylated form varies by species, and previous studies have demonstrated that in slimy sculpin tissue approximately 83% of total mercury levels are methylated (Raymond and Rossmann, 2009). Arctic grayling tissues have a higher proportion of methylated mercury at approximately 95% (Jewett *et al*. 2003). Thus, for comparing mercury levels with the CCME guideline, 83% and 95% of total mercury values were calculated as estimated methylmercury levels for slimy sculpin and Arctic grayling, respectively. In addition, total mercury was compared with Health Canada mercury guidelines, which range from 0.2mg/kg for subsistence consumers to 0.5mg/kg for the maximum allowable level for sale in Canada. Notably, as slimy sculpin are not consumed by humans the comparison to Health Canada guidelines are not directly relevant, but instead provide an estimation of non-piscivorous fish which may be in turn consumed by piscivorous fish. As mercury is known to both bioaccumulate in aquatic organisms and biomagnify up trophic levels, comparing forage fish mercury values to Health Canada guidelines still provides valuable insight into aquatic ecosystem health.

Diet

An analysis of diet focused on Arctic grayling from Latte and the mainstem of Coffee Creek only. Raw data for the single Independence Creek Arctic grayling is included in Appendix F6. Prey items were sorted by order, and then the mean and standard deviation of prey items per fish was calculated.

2.6 Quality Assurance and Quality Control

All field sampling was completed by two qualified aquatic biologists, with the same methods employed at each site for consistency. All field data was transcribed into excel spreadsheets and plotted to determine data outliers. Original field notes were consulted where necessary to identify transcription errors or potential field equipment errors. Outliers were corrected or excluded where appropriate.

2.6.1 Sediment

Sediment quality samples were collected by an aquatic biologist. Appropriate measures were taken to reduce potential for sample contamination. Field staff wore nitrile gloves when sampling and used pre-cleaned sample bottles supplied by CARO Analytical. Care was taken to ensure the inner portion of the sample container and caps did not touch anything other than the sample itself. Sample containers were kept in the laboratory supplied cooler before and after collection of the sample. All samples were kept cold at all times between sample collection and delivery to the laboratory. Chain of Custody forms accompanied all samples.

Field split samples were collected for one replicate sample at every other site, as recommended by the BC MOE (2012). Relative Percent Difference (RPD) was calculated for field split samples and is provided in Appendix B2. An RPD less than 25% is considered an acceptable difference, and an RPD greater than 25% warrants further examination to ensure that the result was not due to sampling error or analytical error. RPD is only relevant when both values are greater than the Practical Quantitation Limit (PQL), which was defined for this project as three times the detection limit. The PQL is considered the lowest concentration that can be accurately measured, as opposed to just detected. Between zero and four replicate values of the 47 parameters that were measured from each sample had RPDs greater than 25% and met PQL restrictions. This was equivalent to between 0-9% of all parameters (mean 4%), which is considered to be an acceptable level of variability. Most RPDs greater than 25% were for nutrient parameters, with the exception of arsenic, cadmium, and cobalt which had one sample higher than threshold criteria, and manganese and uranium which had 4 and 2 samples over the threshold criteria, respectively. All other metals were below 25% RPD for all sites.

2.6.2 Periphyton, Benthic Invertebrates, and Fish Community

Plankton R Us has over twenty five years of experience with periphyton and plankton taxonomy and enumeration. QA/QC methods included:

- Random sub-sampling to minimize counting bias.
- Analyzing all samples by the same technician to ensure consistency.
- Replicate counts performed on random samples.
- 10-15% of samples were re-analyzed by a secondary technician to ensure accuracy.
- The usage of best management methods supported by scientific literature.

CARO Analytical Services has over twenty years of experience with microbiological analysis, general chemical analysis, and contaminated site testing of water, vegetation, tissue, soil and sediments. They

are a quality management system based on ISO 17025:2005, 'General Requirements for the Competence of Calibration and Testing Laboratories.' As part of their quality assurance and control, CARO routinely employs method blanks, sample duplicates, and laboratory controls samples per every 10 test samples. Results from quality control samples are analyzed to ensure they are within regulation.

Cordillera Consulting has over ten years experience in taxonomic analysis of benthic invertebrates from streams, rivers and lakes of western Canada. The following QA/QC procedures are followed by Cordillera Consulting:

- sorting efficiency – 10% of the whole sample number was resorted with an expectation of >90% efficiency in the sorting process;
- taxonomic efficiency – 10% of the identified sample vials were sent to another taxonomist. The two results were compared with simple statistics and the taxonomists discussed how best to correct their differences and make appropriate changes to the results; and
- taxonomic precision – an externally verified reference collection is maintained by Cordillera Consulting. Any new specimens are sent away to experts of that taxon and the collection is reviewed every five years.

North/South Consultants specializes in the analysis of ageing structures including otoliths and scales. All structures were read by an experienced ageing technician using a confidence index with five denominations ranging from very good to very poor. Independent second readings were made for 10% of randomly selected structures.

3 Results and Discussion

3.1 Sediment Quality

Raw sediment quality data can be found in Appendix B1.

3.1.1 Comparisons to CCME Sediment Quality Guidelines

Sediment quality results compared to CCME guidelines are summarized in Table 7. Out of the seven metals with CCME sediment quality guidelines, exceedances were observed for two: arsenic (As), and chromium (Cr). There were no exceedances recorded for mercury. Arsenic exceedances occurred at every station for the ISQG. Arsenic also exceeded the PEL at AQ05, AQ13, and AQREF1, which are in headwater areas adjacent to the deposit (AQ05, AQ13), or proximate to the Yukon River (AQREF1). The ISQG was exceeded for Chromium in the Kona tributary of Independence Creek (AQ13), as well in the Los Angeles Creek reference location (AQREF2). However, the PEL was not exceeded for chromium at any sites in the study area.

Table 7. Mean Sediment Quality Parameters Exceeding CCME Guidelines, Coffee Gold Project, 2014 - 2015

Watershed	Creek	Site	Interim Freshwater Sediment Quality Guideline (ISQG)	Probable Effects Level (PEL)

	Independence	AQ10	As	-
Isaac	Isaac	AQREF1*	As	As
Los Angeles	Los Angeles	AQREF2*	As, Cr	-

Dashes indicate sample mean did not exceed CCME guidelines

In addition to the mean exceedances outlined in Table 7, plots of mean sediment metal concentrations reveal that individual sediment samples exceeded CCME guidelines for cadmium, chromium, copper, and mercury at some aquatic sites (Figure 3). The majority of sample exceedances occurred in the Coffee Creek watershed, where exceedances of the CCME ISQG occurred at AQ00 (Cr), AQ02 (Cu, Cd), AQ04 (Cr, Hg), AQ04.5 (Cd), and two samples at AQ05 were equal to the mercury ISQG. In the Independence,

Halfway, YR24, and Los Angeles Creek watersheds, there were no individual exceedances for parameters other than the previously noted exceedances for chromium and arsenic. In the Isaac Creek reference site, there was an additional exceedance of the cadmium ISQG for one sample.

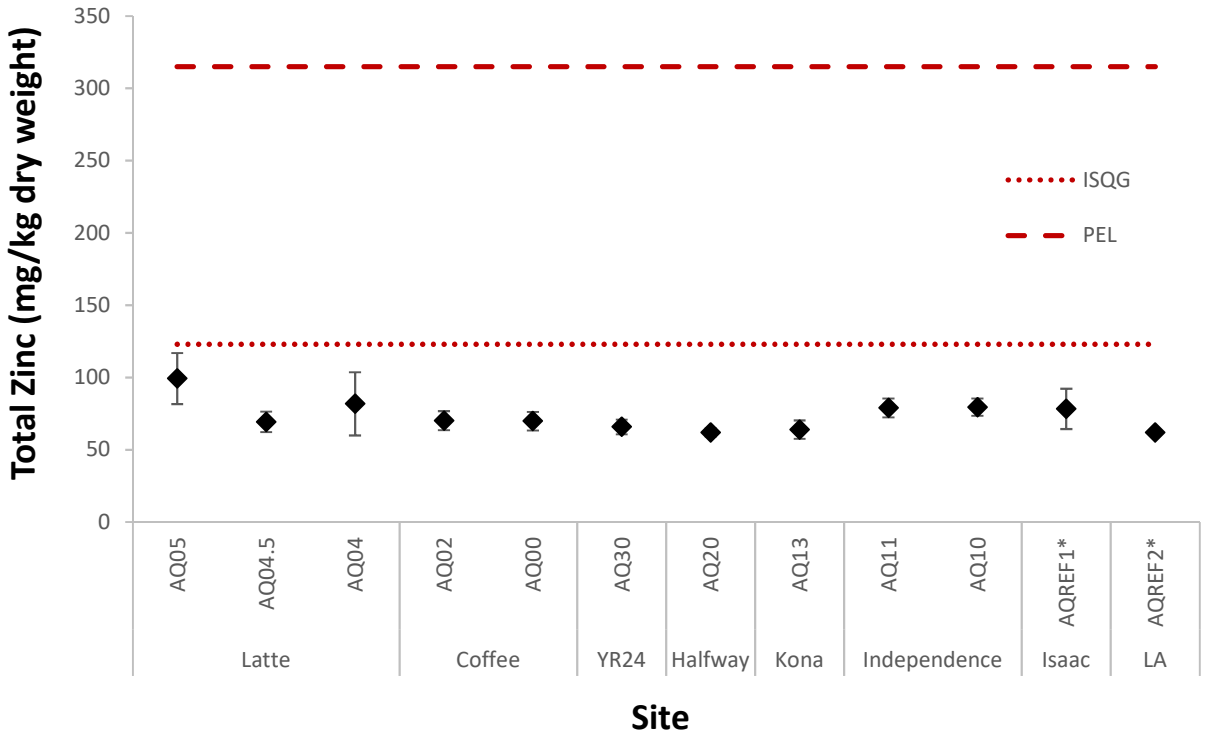

Figure 3. Range of Values (Mean and Standard Deviation) of Selected Total Metals Sediment Quality Parameters, Coffee Gold Project, 2014-2015. Dotted line is CCME Interim Sediment Quality Guideline (ISQG) and dashed line is CCME Probable Effects Level (PEL) guideline. Sites are grouped by watershed including: Latte= Latte Creek, Coffee= sites on mainstem Coffee Creek, YR24= Unnamed tributary between Coffee and Halfway Creeks, HW= Halfway Creek, Kona= Kona Tributary in the Independence Creek watershed, Independence= sites on mainstem Independence Creek, Isaac= Isaac Creek, LA= Los Angeles Creek, and (*) indicates study reference sites.

3.1.2 Sediment Particle Size Distribution

Over 60% of the sediment particle sizes in the study area were less than 300 µm in diameter (Figure 4). In the Coffee Creek watershed, particle size demonstrated a general decreasing trend in a downstream direction. However, a similar pattern for sites in the Independence Creek watershed was not observed. Overall, sites in mainstem Coffee Creek (AQ00, AQ02), Isaac Creek, (AQREF1) and Halfway Creek (AQ20) were comprised of the finest sediment particles in the study area. The Los Angeles Creek reference site (AQREF2) had the lowest amount of fine sediment collected.

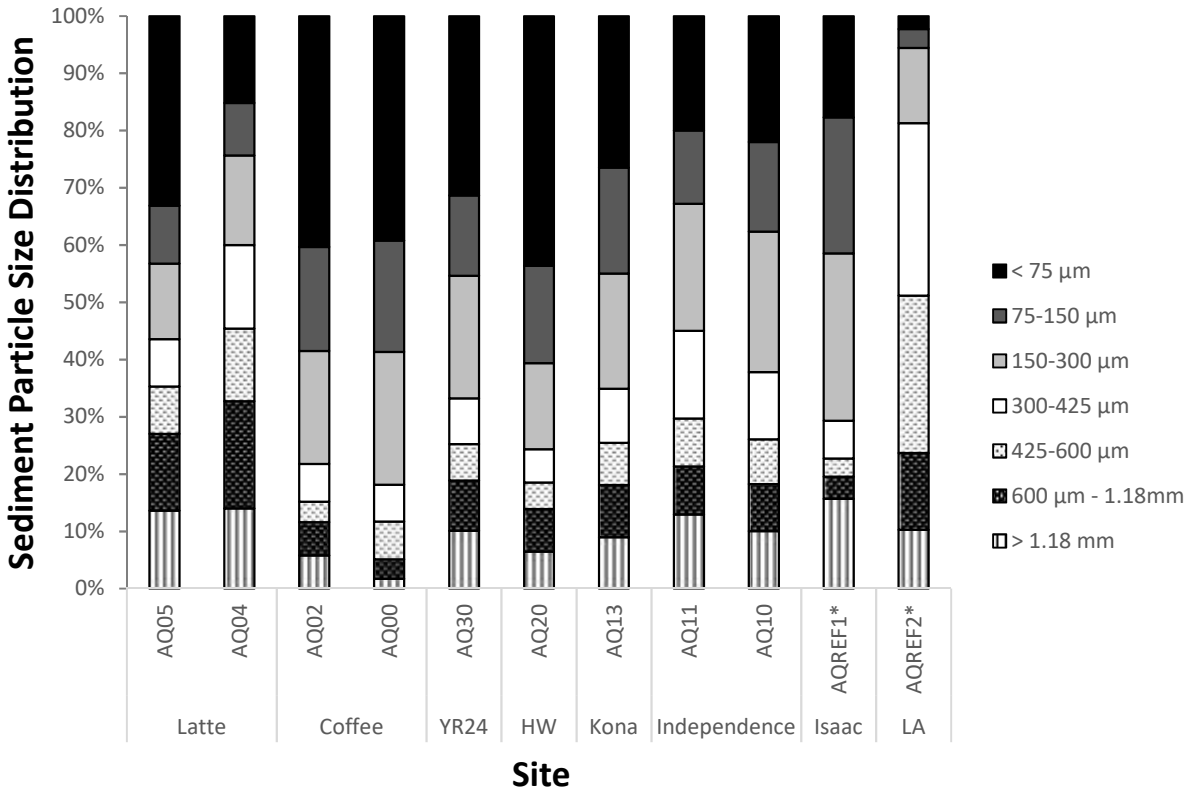

Figure 4. Sediment particle size distribution by site, Coffee Gold Project, 2014-2015. Sites are grouped by watershed including: Latte= Latte Creek, Coffee= sites on mainstem Coffee Creek, YR24= Unnamed tributary between Coffee and Halfway Creeks, HW= Halfway Creek, Kona= Kona Tributary in the Independence Creek watershed, Independence= sites on mainstem Independence Creek, Isaac= Isaac Creek, LA= Los Angeles Creek, and (*) indicates study reference sites.

3.2 Periphyton

3.2.1 Chlorophyll *a* and Periphyton Biomass

Mean chlorophyll *a* was very low for all sites, which is typical of northern aquatic habitats (Stantec 2011) (Figure 5). The lowest chlorophyll *a* value was observed in Independence Creek (mean=0.13 µg/cm^2), followed by Coffee Creek (mean=0.14 µg/cm^2), YR24 and Los Angeles Creeks (0.17 µg/cm^2), Halfway Creek (0.19 µg/cm^2), and then Isaac Creek (0.23 µg/cm^2).

Ash-free dry mass (AFDM) values ranged from 0.38 - 1.07 mg/cm^2, with the highest values observed in Halfway Creek (AQ20) and Los Angeles Creek (AQREF2). The remaining sites were in a similar range and did not display any strong longitudinal trends. The relationship between chlorophyll *a* and ash-free periphyton mass was not significant (Linear regression, R^2=0.17, P=0.18). Differences in chlorophyll *a* content may be due to varying light conditions, nutrient availability, and taxonomy, which result in different proportions of photosynthetic:non-photosynthetic organisms which comprise periphyton (Barbour *et al.*

1999). However, given the remote location of the project, surpassed holding times for chlorophyll *a* analyses may also have affected the accuracy of results.

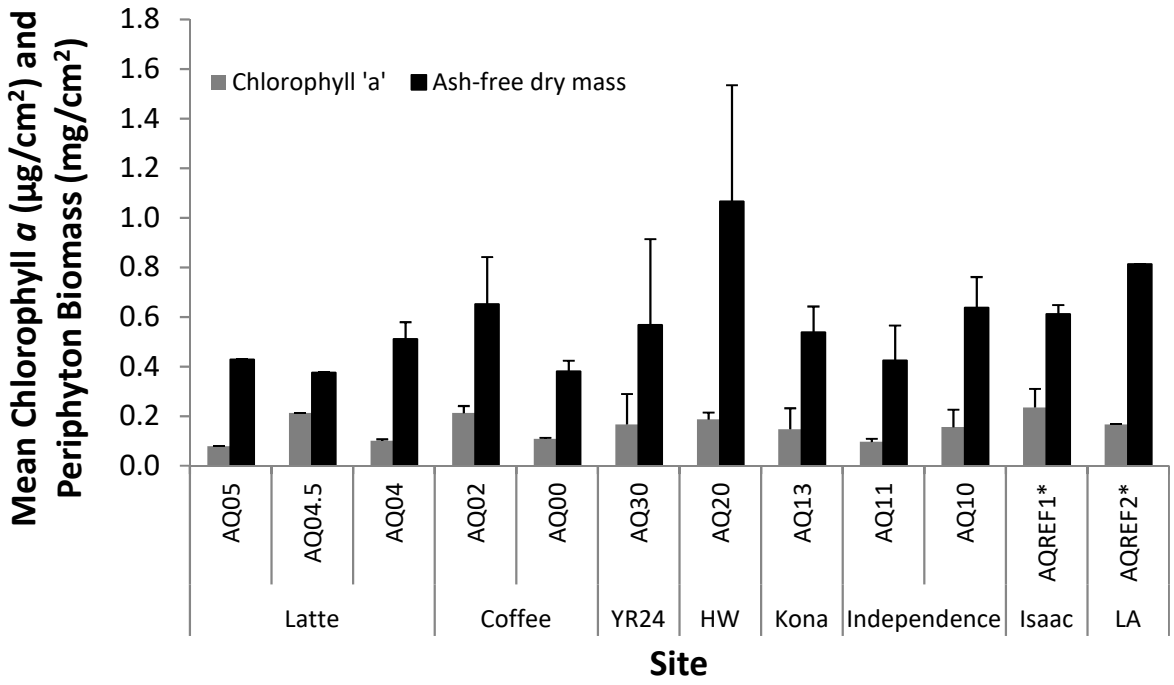

Figure 5. Mean Chlorophyll *a* and periphyton ash-free dry mass by site, Coffee Gold Project, 2014-2015. Sites are grouped by watershed including: Latte= Latte Creek, Coffee= sites on mainstem Coffee Creek, YR24= Unnamed tributary between Coffee and Halfway Creeks, HW= Halfway Creek, Kona= Kona Tributary in the Independence Creek watershed, Independence= sites on mainstem Independence Creek, Isaac= Isaac Creek, and LA= Los Angeles Creek. Bars represent standard deviation and (*) indicates study reference sites.

3.2.2 Periphyton Density

Mean periphyton density was highest in YR24 (497,737 cells/cm^2) and lowest in upper Latte Creek (68,802 cells/cm^2, Figure 6). Within the Coffee Creek watershed, the highest periphyton density was observed in lower Latte Creek (AQ04), with density decreasing longitudinally downstream. Within the Independence Creek watershed, periphyton density was relatively low and similar among all three sites. Periphyton density was intermediate at the Isaac Creek reference site in comparison to AQ30 and AQ20, which are both similarly located adjacent to the Yukon River. The Los Angeles Creek reference site displayed a low periphyton density value that was comparable to densities observed in both Independence and Coffee Creeks.

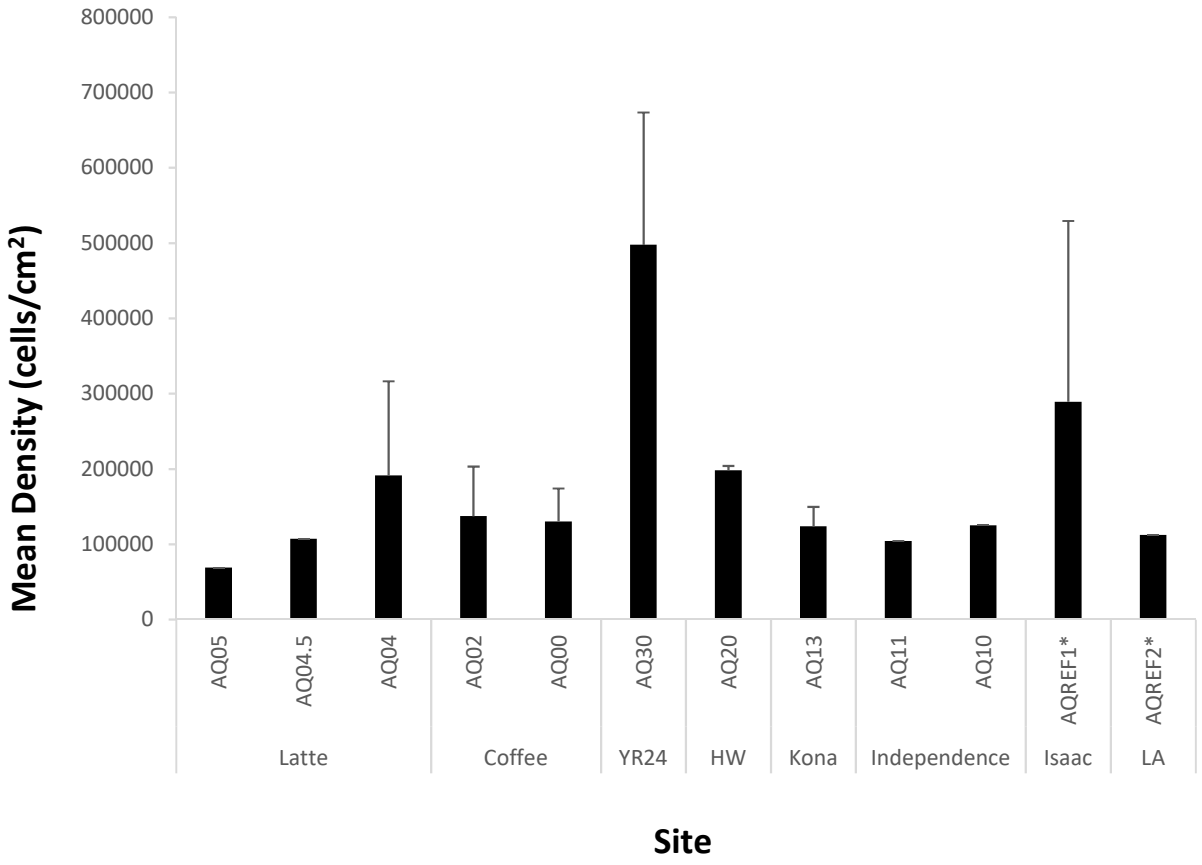

Figure 6. Mean periphyton density by site, Coffee Gold Project, 2014-2015. Sites are grouped by watershed including: Latte= Latte Creek, Coffee= sites on mainstem Coffee Creek, YR24= Unnamed tributary between Coffee and Halfway Creeks, HW= Halfway Creek, Kona= Kona Tributary in the Independence Creek watershed, Independence= sites on mainstem Independence Creek, Isaac= Isaac Creek, and LA= Los Angeles Creek. Bars represent standard deviation and (*) indicates study reference sites.

3.2.3 Periphyton Community Composition

Blue-green algae (Cyanophyta) was the most dominant algal group in the study area (Figure 7), making up approximately 80% of the overall community composition. After blue-green algae, diatoms were the second most dominant group (17%), followed by small percentages of green algae (chlorophyta, 3%). Red algae was not identified at sites within the local study area, but was present (2%) at the Isaac Creek reference site. Within watersheds, blue-green algae tended to dominate at higher elevation sites, whereas higher proportions of diatoms were present further downstream. Sites AQ20 and AQ30 were more similar to higher elevation sites, despite being adjacent to the Yukon River. Of note was the presence of *Didymosphenia geminata* confirmed in Isaac Creek and at AQ10 in Independence Creek in 2014, which is a large diatom that has become increasingly prolific in BC and Yukon in recent years, and is commonly referred to as ‘rock snot’ (YISC, 2014).

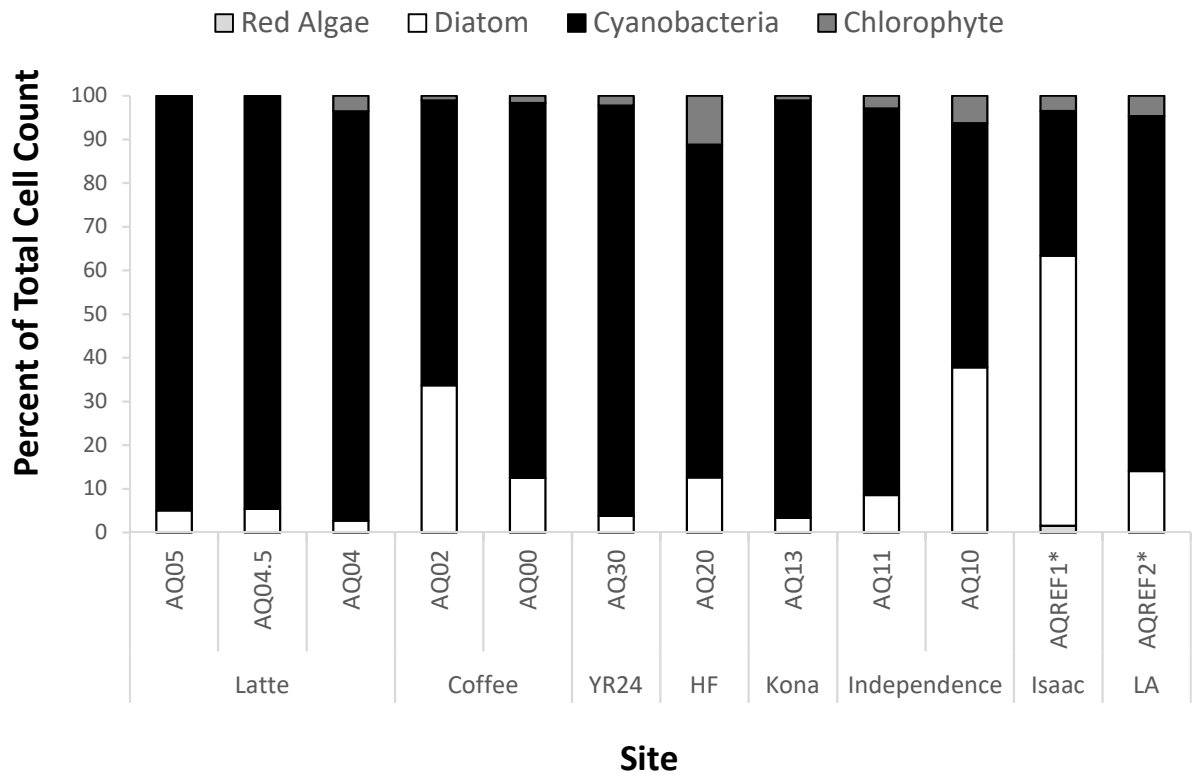

Figure 7. Mean relative cell densities of periphyton communities by site, Coffee Gold Project, 2014-2015. Sites are grouped by watershed including: Latte= Latte Creek, Coffee= sites on mainstem Coffee Creek, YR24= Unnamed tributary between Coffee and Halfway Creeks, HW= Halfway Creek, Kona= Kona Tributary in the Independence Creek watershed, Independence= sites on mainstem Independence Creek, Isaac= Isaac Creek, LA= Los Angeles Creek, and (*) indicates study reference sites.

3.2.4 Periphyton Taxonomic Richness and Biodiversity

Mean taxonomic richness in the Coffee Gold study area was overall low, ranging from 10-14 taxonomic groups (Figure 8). Richness was highest at sites in upper Latte Creek (AQ04.5), lower Coffee Creek (AQ00), lower Independence Creek (AQ10), and the two reference sites, with each site having 13-14 taxa present. Richness was lowest in YR24 and in the Kona tributary of Independence Creek. There was little indication of any trends in taxonomic richness in the study area, as mean richness values were fairly similar at all sites and substantial variability between years was observed.

Patterns of biodiversity were similar to what was noted for species richness, with a significant correlation between the two indices (Linear regression, R^2=0.45, P=0.02). Mean biodiversity ranged from 0.99 at AQ05 to 1.74 at AQ10. By watershed, Coffee Creek displayed the lowest overall mean biodiversity (1.31), followed by Independence Creek and YR24 (1.41), Los Angeles Creek (1.59), Halfway Creek (1.67), and then Isaac Creek (1.70).

Sites are grouped by watershed including: Latte= Latte Creek, Coffee= sites on mainstem Coffee Creek, YR24= Unnamed tributary between Coffee and Halfway Creeks, HW= Halfway Creek, Kona= Kona Tributary in the Independence Creek watershed, Independence= sites on mainstem Independence Creek, Isaac= Isaac Creek, and LA= Los Angeles Creek. Bars represent standard deviation and (*) indicates study reference sites.

3.3 Benthic Invertebrates

3.3.1 Benthic Invertebrate Abundance

Mean total abundance of benthic invertebrates ranged from 247 individuals per kick-net to 3885 individuals per kick-net in the project study area (Figure 9). Overall, Los Angeles Creek displayed the highest total abundance (3210), followed by Independence Creek (2092), YR24 (1291), Coffee Creek (762), Halfway Creek (466), and then Isaac Creek (306). Within watersheds with multiple sites, total abundance generally increased in an upstream direction. Site AQ10 in mainstem Independence Creek had a notably high mean abundance of benthic invertebrates (3885/kick-net).

Ephemeroptera Plecoptera Trichoptera (EPT) abundances within the study area demonstrated similar patterns to overall abundance, with a significant relationship observed between the two indices (Linear regression, R^2=0.62, P<0.01). EPT abundance was highest at AQREF2 (1880 EPT organisms/kick-net), lowest at the Isaac Creek reference site (90 EPT organisms/kick-net), and showed no strong longitudinal

patterns within watersheds. Some sites had high between-year variability, such as at AQ10 in lower Independence Creek (standard deviation=838).

.

Sites are grouped by watershed including: Latte= Latte Creek, Coffee= sites on mainstem Coffee Creek, YR24= Unnamed tributary between Coffee and Halfway Creeks, HW= Halfway Creek, Kona= Kona Tributary in the Independence Creek watershed, Independence= sites on mainstem Independence Creek, Isaac= Isaac Creek, and LA= Los Angeles Creek. Bars represent standard deviation and (*) indicates study reference sites.

3.3.2 Benthic Invertebrate Community Composition

Dipterans were the most dominant benthic invertebrate group in the project study area, making up approximately 50% of the overall community composition (Figure 10). The second and third most dominant groups were the mayflies (*Ephemeroptera*) and stoneflies (*Plecoptera*), which contributed approximately 26% and 21% to the overall community composition, respectively. Small percentages of ringed worms (Annelids), and caddisflies (*Trichoptera*) were also present at the majority of sites. The Isaac Creek reference site had the highest percentage of Dipterans and the lowest relative contribution from the “pollution sensitive” EPT organisms. Within the multi-site watersheds (Coffee and Independence Creeks), EPT organisms typically dominated sites higher in the watershed, whereas Dipteran species dominated at larger creek sites further downstream.

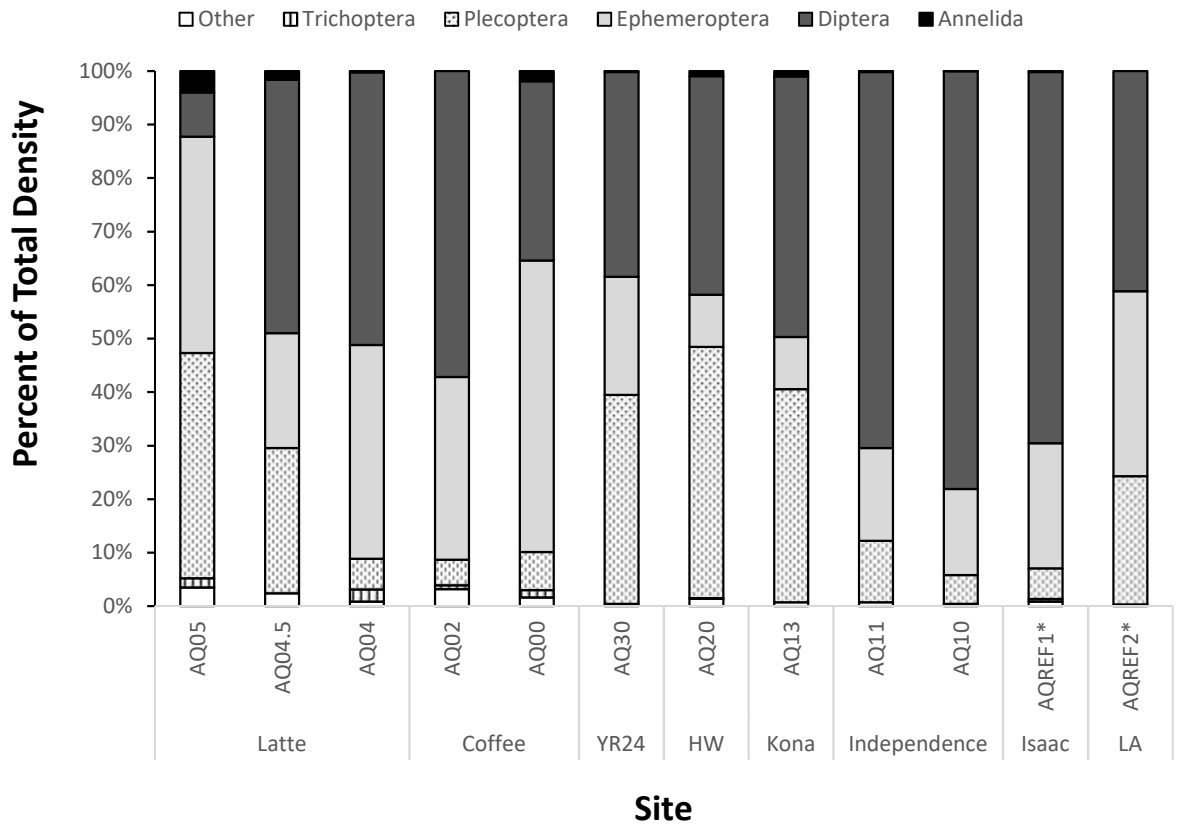

Figure 10. Relative densities of benthic invertebrate communities by site, Coffee Gold Project, 2014-2015. Sites are grouped by watershed including: Latte= Latte Creek, Coffee= sites on mainstem Coffee Creek, YR24= Unnamed tributary between Coffee and Halfway Creeks, HW= Halfway Creek, Kona= Kona Tributary in the Independence Creek watershed, Independence= sites on mainstem Independence Creek, Isaac= Isaac Creek, LA= Los Angeles Creek, and (*) indicates study reference sites.

3.3.3 Benthic Invertebrate Taxonomic Richness, Biodiversity, and Evenness:

Benthic invertebrate taxonomic richness was highest at AQ02 in the Coffee Creek watershed (34 taxa), and lowest at the Independence Creek Kona tributary (18 taxa, Figure 11). There were no apparent within-watershed patterns for taxonomic richness, although the mainstem sites on Independence Creek displayed higher richness values in comparison to AQ13 in the headwaters. Both reference sites displayed intermediate richness values (21-26).

Simpson's diversity values displayed similar patterns to those observed for taxonomic richness (Figure 12). Sites AQ04.5 and AQ11 demonstrated the highest and lowest values, respectively. At the watershed-level, Los Angeles Creek supported the highest diversity values (0.87), sites in YR24, Halfway Creek, and Coffee Creek supported intermediate values (0.78-0.86), and sites in Independence Creek contained the lowest diversity value (mean=0.75).

Simpson's evenness ranged from 0.15- 0.46, with the lowest and highest sites also being the two that were positioned closest together in upper Latte Creek (Figure 12). Generally, evenness decreased in a downstream direction within the Coffee and Independence watersheds.

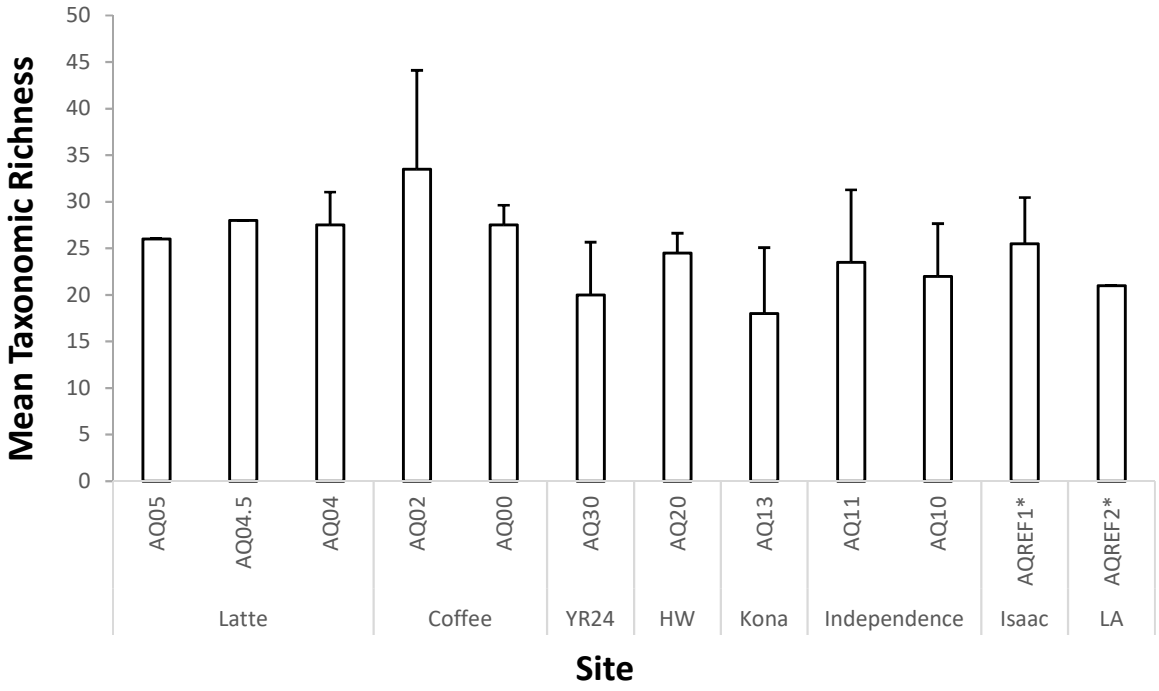

Figure 11. Mean Taxonomic Richness of benthic invertebrate communities by site, Coffee Gold Project, 2014-2015. Sites are grouped by watershed including: Latte= Latte Creek, Coffee= sites on mainstem Coffee Creek, YR24= Unnamed tributary between Coffee and Halfway Creeks, HW= Halfway Creek, Kona= Kona Tributary in the Independence Creek watershed, Independence= sites on mainstem Independence Creek, Isaac= Isaac Creek, LA= Los Angeles Creek, and (*) indicates study reference sites.

3.3.4 CABIN

CABIN analyses are summarized in site assessment reports (Appendix D2). The BEAST prediction results show that based on the benthic invertebrate communities, the majority of Coffee Gold study area sites belong to Group 1 (probabilities: 50 – 95%) with the exception of site AQ05 which belongs to Group 2 (probability: 48%). The Bray-Curtis analysis indicated that of the 12 sites assessed in CABIN, site AQ05 in upper Latte Creek and AQ13 in upper Kona were most similar in community structure to reference condition (0.81-0.84). However, all sites in the Coffee study area and reference areas were highly dissimilar from reference conditions (range 0.81-1). The RIVPACS tools assesses sites using the ratio of observed to expected (O:E) score, where sites with O:E ratios close to 1 are in good condition. All sites were close to the value of 1, with values ranging from 1.04-1.09 (Table 8).

Table 8. RIVPACS Observed/Expected Taxa Ratios

Site	Year	Description	Result

The BEAST site assessment graphs display each test site in relation to the reference sites of the Yukon 2013 reference model. The degree of deviation from reference condition can indicate the severity of impairment. The different levels of deviation range in order from (1) reference condition, (2) mildly divergent, (3) divergent, and (4) highly divergent. Of the twelve sites tested, most sites were in the mildly divergent category, which indicates potential anthropogenic stress. Some of the stress ratings differed for each site by year, with 2015 results typically having a more stressed rating. One exception was site AQ13, which was considered unstressed (reference condition) in 2015 and divergent from reference

conditions in 2014. Highly divergent years were observed in 2015 at sites AQ10, AQ11, AQ30, and AQREF2.

3.4 Fish Habitat

A total of 17 sites were assessed for fish habitat quality around the study area (Figure 1, Table 9). Site-specific habitat information, site photos and *in situ* water quality data is included as Appendix E1. Fish habitat quality was highest in the mainstems of Coffee and Independence Creeks due to the presence of a wide variety of habitat types available (e.g., deep pools, side channels, slow moving riffles), and ample in-stream habitat cover (e.g., woody debris, undercut banks), that could potentially support a range of fish species throughout their various life history activities. Coffee Creek was the largest watercourse with the primary mainstem channel ranging from 15-22m wide, and numerous deep pools observed (>1.5m). Independence Creek was the second largest watercourse, with mean channel widths of 12m and 23m at Sites AQ10 and AQ11, respectively.

Tributaries of Coffee and Independence Creeks were relatively smaller than the creek mainstems (mean widths from 4-6m and 2-3m, respectively), and contained better quality habitat in the lowermost reaches (e.g., pool habitat, gravel substrates, lower stream gradients). Good Arctic grayling habitat was available in the lower reaches of Latte Creek due to the frequency of substantial pool habitat. Site AQ12 in the lower Kona tributary had much lower habitat quality than the mainstem of Independence Creek as water depths were low, and there were few pools noted for supporting fish feeding or rearing. Sites in the upper watersheds of both Latte Creek and Kona Tributary were of poorer habitat quality, as they contained higher gradient (means=7-11%), cascade-pool or step-pool segments dominated by larger cobble or boulder substrates, and little to no gravels. During the habitat mapping of Latte Creek, several hindrances to upstream fish passage were noted in the upper watershed due to steep natural drops. No permanent barriers to fish migration were noted.

Additional fish habitat surveying was completed in 2015 for a Latte Creek tributary (Tributary “C”) that overlaps with the south proposed waste rock storage facility. The watercourse was a small (mean channel width=0.82m), shallow (mean channel depth=0.26m), medium gradient (5-10%) channel dominated by gravel and fine substrates. Natural obstructions to fish passage were observed, such as sudden steep drops, but no permanent barriers to fish migration were noted. Supplementary hydrometric and water quality data for this tributary indicates that the streamflow is often groundwater dominated and may occasionally lose its surficial connection to mainstem Latte Creek (*pers. comm*., Lorax Environmental 2015). Thus, the noted habitat constraints suggest low suitability for Arctic grayling, especially at distances further from mainstem Latte Creek.

Halfway Creek and YR24 were relatively smaller watercourses, with mean widths of 4m at sites proximate to the Yukon River (AQ20, AQ30), decreasing to 2-2.5m widths in the headwaters (AQ21, AQ31). In Halfway Creek, there was marginal fish habitat for Arctic grayling available in the lower watershed (AQ20). YR24 was even smaller and steeper (8%) than Halfway Creek, with little to no pool habitat observed for fish rearing at the downstream site (e.g. water depths were generally less than 20cm). Habitat quality decreased in the upper watersheds due to steeper (means=10-11%), boulder-dominated cascade-pool segments. In September 2015, a high gradient (30%) barrier to fish passage was

documented immediately upstream of site AQ31, and downstream of the proposed waste rock storage facility (Figure 13).

Figure 13. High gradient (>30%) barrier to fish passage, upper YR24, September 2015

The Isaac Creek reference site was smaller and shallower than both Independence and Coffee Creeks, with a mean channel width of 10m, and fewer deep pools (>1m) noted. The site was low gradient, with moderate fish cover including small woody debris, undercut banks, overhanging vegetation and deep pools. The site was differentiated by its close proximity to the Yukon River and the potential for backwatering at the creek mouth. It had the highest percentage of fine substrate in the project study area, and also the most turbid water observed. Due to the shallow depths and sandy substrates, the site provided moderate habitat potential for juvenile Arctic grayling rearing, and low habitat potential for supporting adult Arctic grayling summer feeding.

The Los Angeles Creek reference site was established as an additional reference site in 2015 in order to document habitat more comparable with the range of habitats present at potential mine study sites. In addition, the site is well away from the influence of the Yukon River located 6km downstream. The site was low gradient and had moderate fish cover including large woody debris, undercut banks, and some deep pools providing excellent rearing/feeding habitat and potentially also overwintering. The site provided good potential for Arctic grayling spawning habitat with pockets of fine gravel present.

Table 9. Fish Habitat Characteristics, Coffee Gold Project, 2014 - 2015

Stream temperatures:

Mean stream temperatures in the Coffee Gold study area did not rise above 5°C in any of the creeks, with the exception of mainstem Coffee Creek. The highest temperatures observed in mainstem Coffee Creek were during August, where mean and maximum daily temperatures approached 8°C and 11°C, respectively. However, based on other seasonal site trends it is likely that Coffee Creek temperatures peaked during July, when the logger was dislodged and not consistently recording water temperatures. Unreliable temperature data was removed during data screening and is not presented here (see methods section 2.5.4).

Latte Creek and Halfway Creek had similar temperature trends, with peak mean stream temperatures just below 5°C noted in July. YR24 was colder than Halfway and Latte Creeks during the period of record. The temperature record for the Kona Tributary had extended periods when the logger was likely out of water, and as a result the monthly average temperature is based on only six days of data near the end of June (June 22nd to 27th), and on fifteen days each for July and September. Reliable data were not available for August. The available record for the Kona tributary suggests that this site is generally colder than the other creeks.

Where the temperature record included the winter months, the onset of freezing temperatures generally occurred in mid to late October. In the Kona tributary freezing started in early October.

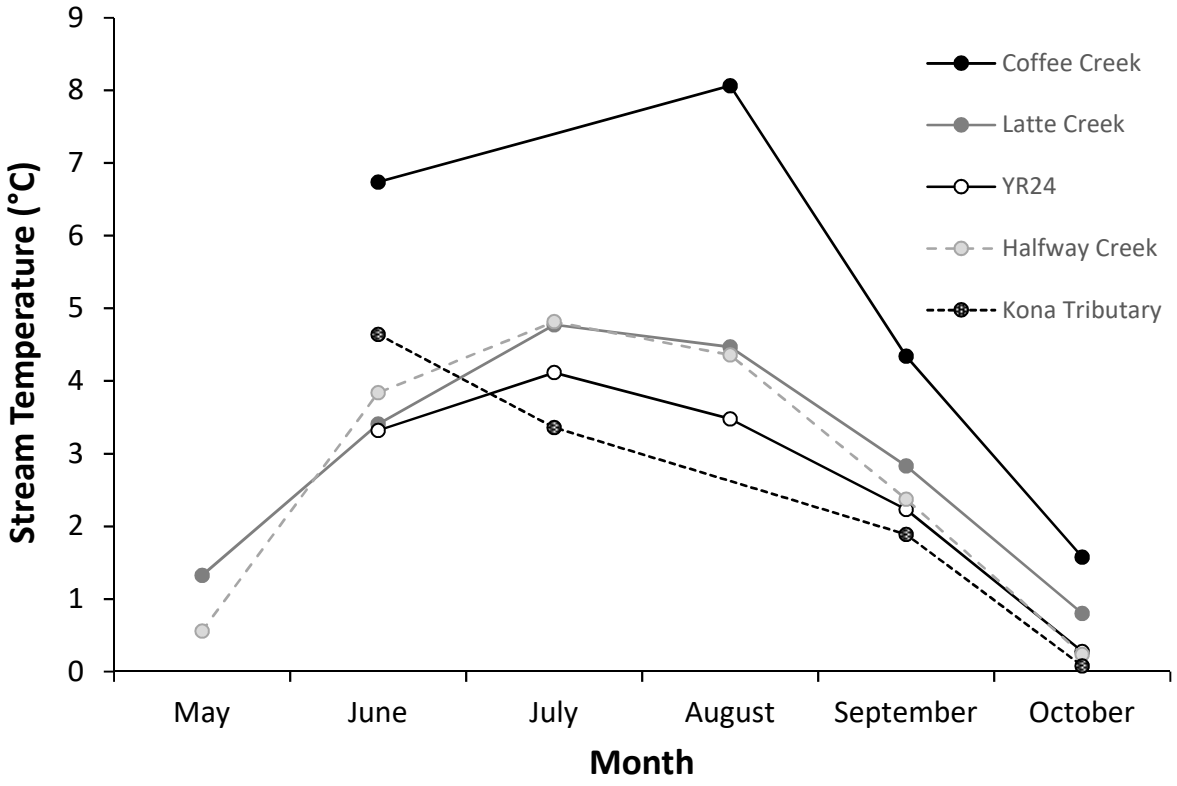

Figure 14. Mean monthly stream temperatures, Coffee Gold Project, 2014-2015

3.4.1 Winter Fish Habitat Survey

Results from the winter fish habitat survey on Latte Creek indicated a very low likelihood of fish utilization in winter, owing to lack of wetted habitat, and/or heavy ice cover. Lower Latte Creek was dry beneath the ice or frozen to the bottom in all surveyed areas with the exception of some localized over-ice flow. Upstream on Latte Creek, the creek was generally frozen to bottom, and any flow detected was over or through layers of ice. At AQ04, the creek was dry under ice at the location of a deep summer pool. Latte Creek Tributary C had some flow, but was heavily glaciated, and the water was running through or over layers of ice, as well as over land, with no defined channel or exposed substrate. The estimated flow in the tributary where it entered Latte Creek was 2 L/s. Dissolved oxygen measured *in situ* at the tributary input was 9.69 mg/L. Overall, suitable overwintering habitat (e.g. deep pools which were not frozen to bottom) was not detected on Latte Creek.

On Coffee Creek, under ice flow was detected at AQ02 and AQ01, however no fish were observed with the underwater camera. Water depths of 0.66 m and 0.37 m were measured at AQ02, beneath 0.44 m and 0.57 m of ice, respectively. At the deepest location (0.66 m depth) dissolved oxygen was 10.3 mg/L, temperature was 0.03°C, and pH was 6.70. At AQ01, water depth was 0.82 m at one drill hole, and ice thickness was 0.15 m. Water quality was measured *in situ* at this location; dissolved oxygen was 13.95 mg/L, temperature was 0.26°C, and pH was 7.27. The underwater camera showed layers of ice throughout the water column, and anchor ice on the stream bed. The creek was frozen to bottom or dry under ice at several other known summer pool locations within AQ01 and AQ02. At AQ00, two deep (>1 m) summer pools within the site were dry. No flow was observed at AQ00. Overall, Coffee Creek appeared to provide some potential overwintering habitat, but the nature and locations may vary year to year depending on temperatures and local climatic conditions.

3.5 Fish Community

Arctic grayling, slimy sculpin, and juvenile Chinook salmon were the most abundant fish species captured in the project study area (Table 10, Table 11, Table 12). Round whitefish (*Prosopium cylindraceum*) are also known to be present in the Coffee Creek watershed but were not captured in 2014 or 2015 (PECG 2013). No Chinook salmon were observed spawning in Coffee and Independence Creeks in 2014-2015 or in previous years (Sparling 2001; Laberge and White Mountain 2002). However, salmon were observed spawning in the Yukon River proximate to the project area during the October survey in 2014. Due to the timing of the survey, it is assumed that the observed spawners were chum salmon. Currently, there are no known fish species at risk in the regional area of the Project.

Effort and catch per unit effort is based on Pass 1 only

3.5.1 Fish species Composition, Relative Abundance and Distribution

3.5.1.1 Coffee Creek

Minnow trapping was the most effective method for capturing juvenile Chinook salmon (jcs), with the highest mean catch/trap/day at site AQ00 in August 2014 (12.0 jcs/trap/day), at site AQ01 in October 2014 (6.7 jcs/trap/day), and at site AQ00 in July 2015 (1.4 jcs/trap/day) (Table 10 and Table 11). Capture rates of juvenile Chinook salmon were 8-15 times higher in August 2014 in comparison to July 2015, suggesting that juvenile rearing in Coffee Creek may exhibit variability year to year. Low numbers of juvenile Chinook salmon observed at the three Coffee Creek sites in fall 2014 indicated that overwintering likely occurred in the creek. However, it is noted that fish may not feed as actively during lower fall temperatures, and thus the lowered capture rate may not be indicative of any decline in abundance. Spring sampling in 2015 yielded almost no juvenile Chinook, suggesting that the fish had already left for their seasonal migration, or had not survived the winter.

Electrofishing was the most effective method for capturing slimy sculpin, with 1.8 and 1.7 sculpins/100s of electrofishing captured at sites AQ02 and AQ00, respectively (Table 12). Angling was the most effective method for capturing Arctic grayling in the study's larger systems such as mainstem Coffee Creek that are difficult to adequately isolate to prevent escapement during electrofishing. The highest catch per unit effort of angling (rod-hour) was at AQ02 (5.3 Arctic grayling per rod-hour), followed by AQ00 (2.3 Arctic grayling per rod-hour), and then AQ01 (2.0 Arctic grayling per rod-hour). Fyke trapping also produced small numbers of Arctic grayling, but was much less effective overall.

In Latte Creek, only Arctic grayling and slimy sculpin were present. Slimy sculpin were only captured at the most downstream site (AQ03), and near the mouth of Latte Creek. Further upstream, Arctic grayling were captured in relatively high densities at site AQ04, with an approximate population estimate of 6 Arctic grayling/100 m^2 in 2014, and 10 Arctic grayling/100 m^2 in 2015 (±2 grayling, 90% confidence intervals for both years). No slimy sculpin were captured at AQ04, suggesting that the species distribution may not extend far upstream. At the furthest upstream sites, AQ04.5, AQ05 and AQ06, no fish were caught using two sampling methods and over two seasons of sampling, however one adult Arctic grayling was observed at the furthest downstream site in summer 2015, at AQ04.5.

3.5.1.2 Independence Creek

Arctic grayling, juvenile Chinook salmon, and slimy sculpin were captured in mainstem Independence Creek. In 2014, juvenile Chinook were present in relatively low numbers at both sites (0.96 jcs/trap/day at AQ10 and 0.10 jcs/trap/day at AQ11) in August, and only at the most downstream site (1.15 jcs/trap/day at AQ10) in October. Capture rates were similar in summer 2015, with 0.83-1.15 jcs/trap/day at AQ10 and no juvenile Chinook captured at AQ11. In addition, a single juvenile Chinook was captured at AQ10 in spring 2015, and four juvenile Chinook remained during September 2015 sampling at this site. Slimy sculpin were captured at AQ10 at a rate of 1.18 sculpins/100s of electrofishing, but were not captured at AQ11 further upstream. Arctic grayling were present at both sites, with a higher CPUE observed at AQ11 (0.39 grayling/100s of electrofishing at AQ11, 0.21 grayling/100s of electrofishing at AQ10). In 2014, data was available for producing a population estimate at AQ11 using the two-pass sampling method (Seber

and Le Cren 1967), which estimated that there were approximately 3 Arctic grayling/100m^2 (±2, 90% CI). Flows were too high in 2015 to effectively isolate AQ11 for multiple pass electrofishing, and instead angling was used, with 1.45 Arctic grayling captured per rod-hour.

Two sites were sampled in the Kona tributary, one far downstream near its confluence with mainstem Independence Creek (AQ12), and one in the upper headwaters (AQ13). In 2014, no fish were captured at either site during August sampling, however, several Arctic grayling were observed at AQ12 while deploying minnow traps in the stream. In June 2015, three Arctic grayling were captured while electrofishing at a rate of 0.43 fish per 100s of effort. No fish were captured during summer sampling in July 2015 (627s of effort).

3.5.1.3 YR24

YR24, located between Coffee and Halfway Creeks, was sampled in late August 2014 using minnow traps and electrofishing. No fish were captured and the site was not re-visited in October of that year. In 2015, sites AQ30 and AQ31 were electrofished in both June and July. In June, five slimy sculpin were captured within 50m of the Yukon River, which was back-flooded into the creek at the time of sampling. No fish were caught at AQ30 during the subsequent July trip. Higher in the watershed, no fish were captured at AQ31 during either sampling period (effort ranged from 748-755s per sampling event).

3.5.1.4 Halfway Creek

Halfway Creek was sampled in late August 2014 using minnow traps and electrofishing. A single adult Arctic grayling was captured in a pool habitat at AQ20, producing a CPUE of 0.15 grayling/100s of electrofishing. The site was not re-visited in October. In 2015, sites AQ20 and AQ21 were electrofished in both June and July. Again, a single adult Arctic grayling was captured in a pool at AQ20. No fish were captured at AQ21 during either sampling period (effort ranged from 845-896s per sampling event).

3.5.1.5 Isaac Creek

Isaac Creek was comprised of the most diverse fish community in the study area, with a total of six fish species present: Arctic grayling, slimy sculpin, juvenile Chinook salmon, juvenile burbot (*Lota lota*), longnose sucker (*Catostomus catostomus*), and Arctic lamprey (*Lethenteron camtschaticum*). The most dominant species were slimy sculpin and juvenile Chinook salmon, which made up 39% and 56% of the catch, respectively. Juvenile Chinook salmon were caught at approximately 4.0 jcs/trap/day in August 2014, 3.6 jcs/trap/day in October 2014, and then rose markedly to 16.7 jcs/trap/day in July 2015. Electrofishing in 2014 yielded 4.6 fish/100s of electrofishing, with the majority of the catch being slimy sculpin. A three-pass population estimate of the site estimated that there were 11 juvenile Chinook salmon/100m^2 ±3 fish (90% CI). A population estimate for all fish species combined was not possible due to a violation of the assumption that probability of capture is the same for all passes.

3.5.1.6 Los Angeles Creek

Arctic grayling, slimy sculpin, and juvenile Chinook salmon were captured at AQREF2 in Los Angeles Creek in low abundances. All fish were caught during summer and fall sampling events; no fish were captured with minnow traps in June. Using minnow traps, the rate of catch was 0.53 jcs/trap/day in July and 0.13 jcs/trap/day in September 2015. Electrofishing efforts yielded a single slimy sculpin (in the

second electrofishing pass), and one adult Arctic grayling, however more grayling were observed in deep pools not accessible to backpack electrofishing. Angling efforts at this site yielded one additional adult Arctic grayling, but conditions were not suitable as heavy rains reduced visibility.

3.5.2 Size, Age and Condition

3.5.2.1 Arctic grayling

Arctic grayling length-at-age was characterized for the local study area using a von Bertalanffy growth curve (R^2=0.98, P<0.01 for all parameters; Figure 15). Ages from the Coffee (mainstem), Latte, Independence and Los Angeles Creek watersheds ranged from 2-9 years, with mean ages of 4-6. On average, Arctic grayling from Independence Creek exhibited the lowest length-at-age, whereas mainstem Coffee Creek Arctic grayling had the highest length-at-age (Table 13). However, among-watershed differences of mean age were not significant (ANOVA, $F_{3,47}$=2.63, P=0.06).

	Total	**2**	**261**	**13**

Notes: n=sample size, SD=Standard deviation
**Reference site*

Arctic grayling lengths ranged from 48-357mm, with the majority of individuals between either 50-75mm or 175-350mm (Figure 16). In the Coffee Creek watershed, no young-of-the-year were captured as all Arctic grayling were greater than 113mm (Figure 15; PECG 2013a). The largest Arctic grayling captured in the study area were from Latte Creek, where two grayling exceeded 350mm in length. A single young-of-the-year was caught in the Independence Creek watershed at AQ10. In contrast, the majority of Arctic grayling caught at the Isaac Creek reference site were young-of-the-year (48-72mm), with only one fish large enough to likely represent an older age class (121mm; Figure 15; PECG 2013a).

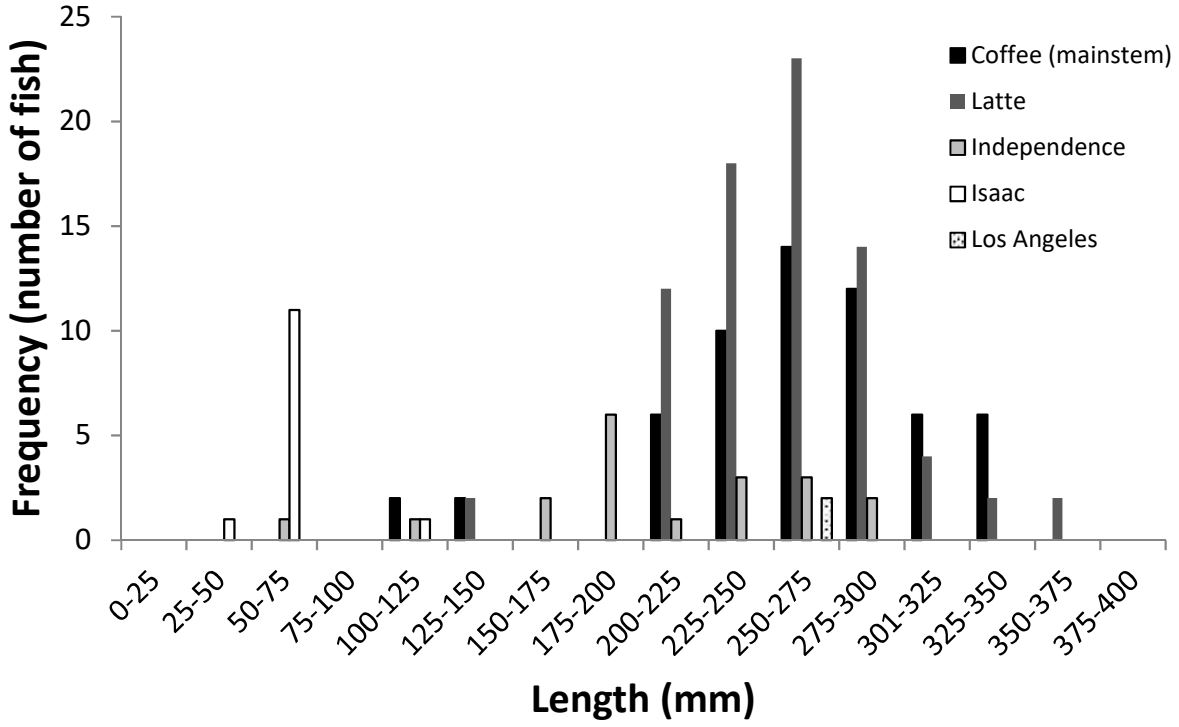

Figure 16. Arctic grayling lengths in the Coffee Gold study area, 2014-2015

Arctic grayling weight-length regressions for each watershed were significant (Figure 17, Linear regressions $R^2 \geq 0.96$, df≥1,11, P<0.01). Fish growth can either be allometric, meaning that the length:weight ratio changes over time, or isometric, meaning that the length:weight ratio remains consistent throughout growth. In the combined model for mine area sites (Latte, Coffee, Halfway, and Independence Creeks), fish growth was allometric (slope>3) with fish becoming heavier as length increased. In contrast, fish growth for Isaac Creek grayling was isometric (slope=3). Relative condition factors based on the combined length-weight regression were similar among watersheds, with the exception of mainstem Coffee Creek which was significantly lower than Latte and Independence Creeks (Figure 18, Kruskal Wallis, H_3=15.12, P=0.02; Post-hoc multiple comparison test, P<0.05).

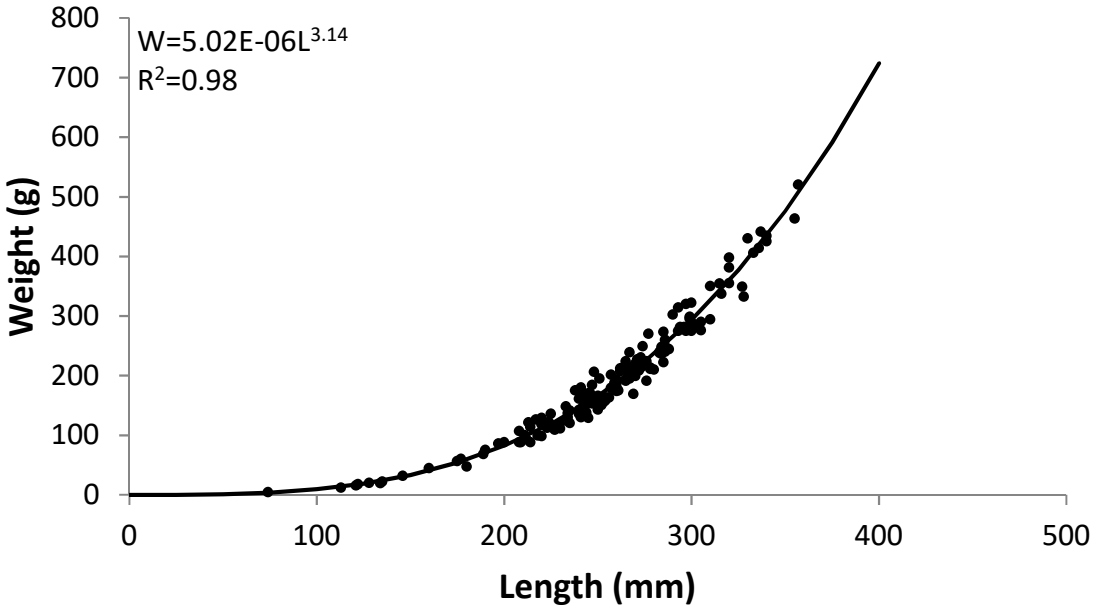

Figure 17. Arctic grayling weight-length relationship for Latte, Coffee, Independence, and Halfway Creeks, Coffee Gold Project, 2014-2015

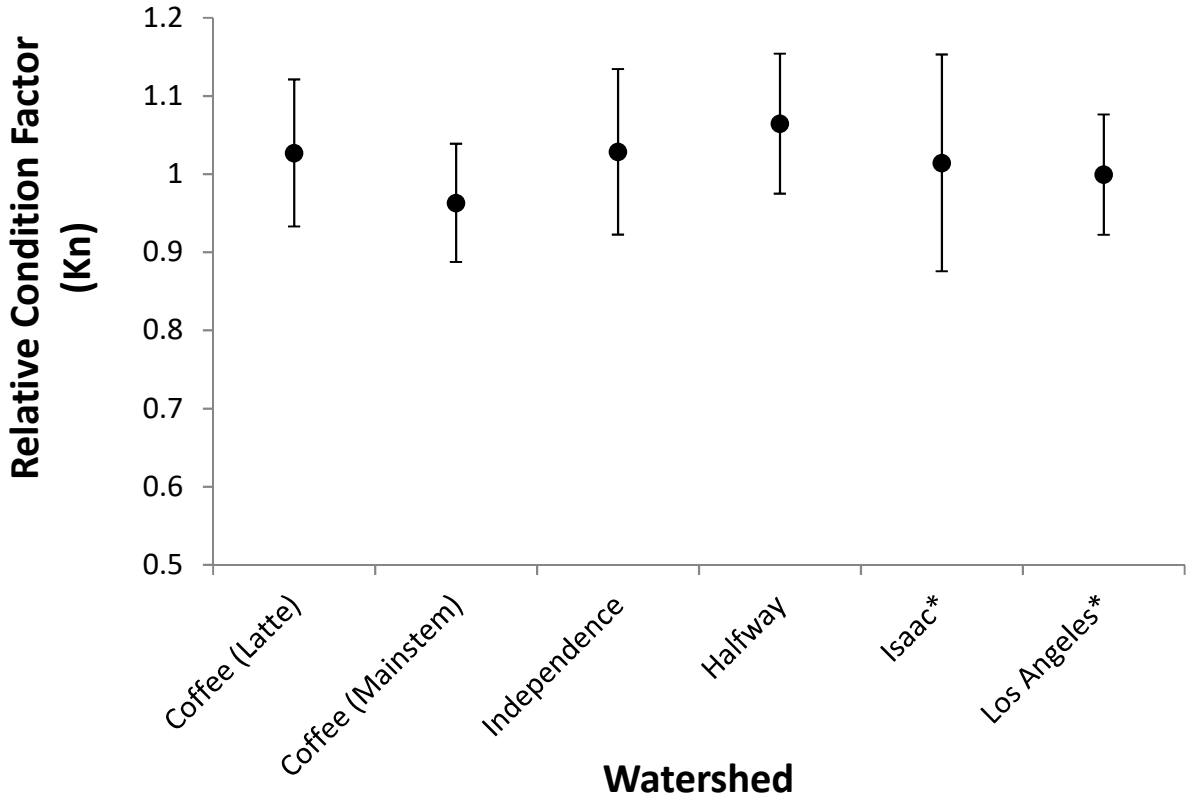

Figure 18. Arctic grayling relative condition factor (Kn) by watershed, Coffee Gold Project, 2014-2015. Bars represent standard deviation and (*) indicates a fisheries reference site

3.5.2.2 Slimy sculpin

Coffee Creek slimy sculpin length-at-age was characterized using a von Bertalanffy growth curve (R^2=0.95, P≤0.01 for all parameters; Length=115(1-$e^{-0.2965Age+2.6487}$)); (Table 14, Figure 19). Similar growth curves for the combined model or other separate watersheds are not presented here; parameter confidence intervals were too high and models were not statistically significant. Ages from the Coffee (mainstem), Independence, Isaac and Los Angeles Creek watersheds ranged from 1-7 years, with mean ages of 2-5. On average, Arctic grayling from Isaac Creek exhibited the lowest length-at-age, whereas mainstem Coffee Creek Arctic grayling had the highest length-at-age. However, among-watershed differences of mean age were not significant (Kruskal Wallis, H_2=4.28, P=0.12).

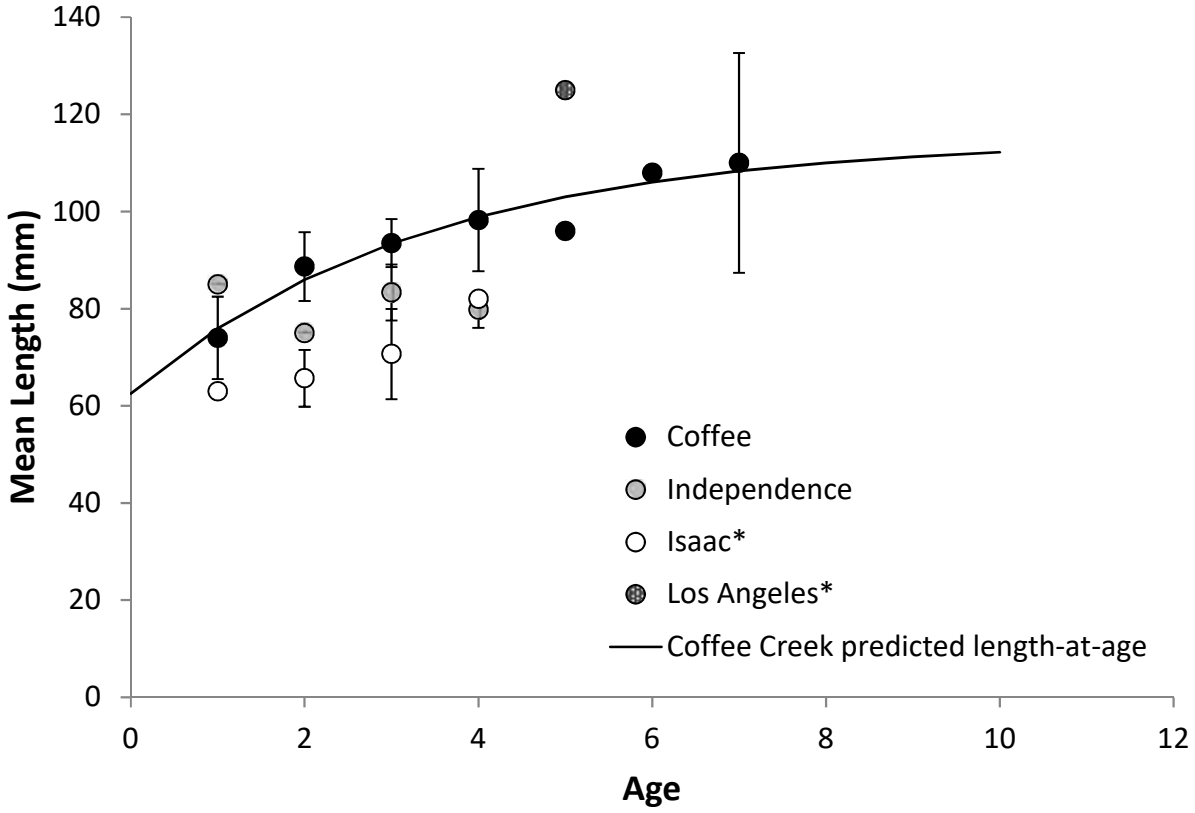

Figure 19. Length-at-age for slimy sculpin in the local study area, Coffee Gold Project, 2014-2015. Length-at-age von Bertalanffy relationship presented for Coffee Creek slimy sculpins. Bars represent standard deviation and (*) indicates a fisheries reference site

Notes: n=sample size, SD=Standard deviation
**Reference site*

Slimy sculpin lengths ranged from 19-126mm in the study area (Figure 20). The smallest slimy sculpins observed (<30mm) were noted in Isaac Creek. Length distributions were similar for all watersheds, being unimodal and converging around expected adult size. However, mean length was substantially higher for Latte Creek sculpins (99 mm, n=13), relative to the other watersheds which ranged from 67 – 77 mm.

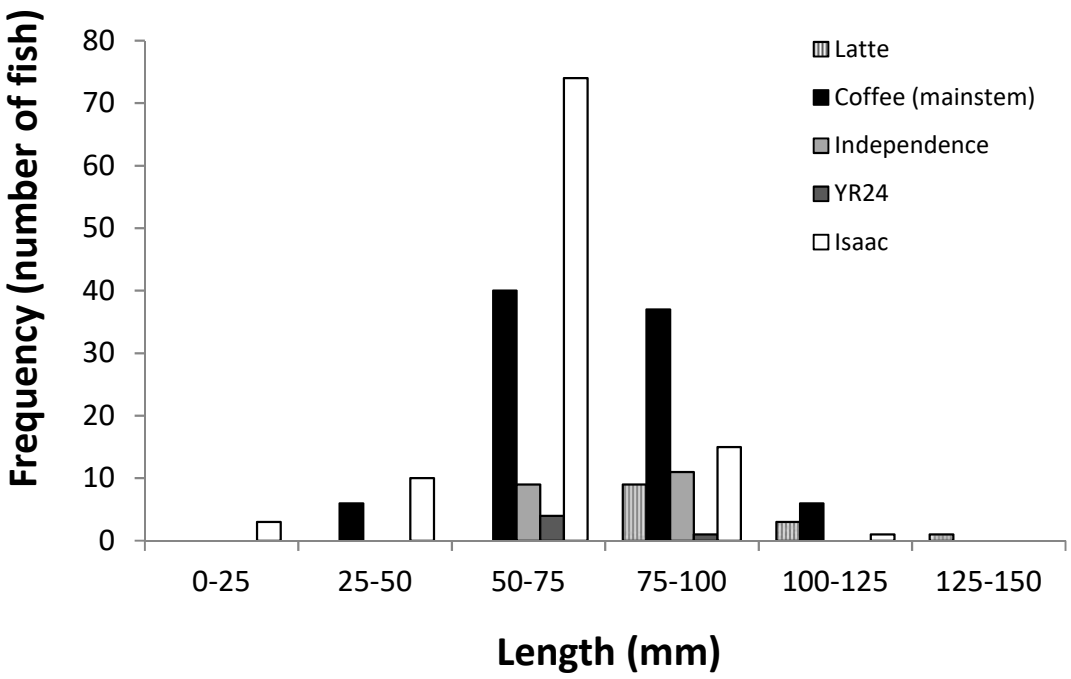

Figure 20. Slimy sculpin lengths in the Coffee Gold study area, 2014-2015

Slimy sculpin weight-length regressions for each watershed were significant (Figure 21, Linear regressions $R^2 \geq 0.53$, df≥1,3, P≤0.01). Fish growth was isometric for all watersheds, meaning that fish did not change shape as they increased in length (slope=3). Slimy sculpin condition was highest in Independence Creek (1.30), and lowest in YR24 (0.96), with Independence Creek having significantly higher condition than all four watersheds (Figure 22, ANOVA, $F_{4,219}=7.8$, P<0.01; Tukey post-hoc HSD Test, P≤0.01). In addition, slimy sculpins from Coffee Creek mainstem had significantly lower condition than sculpins from Isaac Creek (P=0.048).

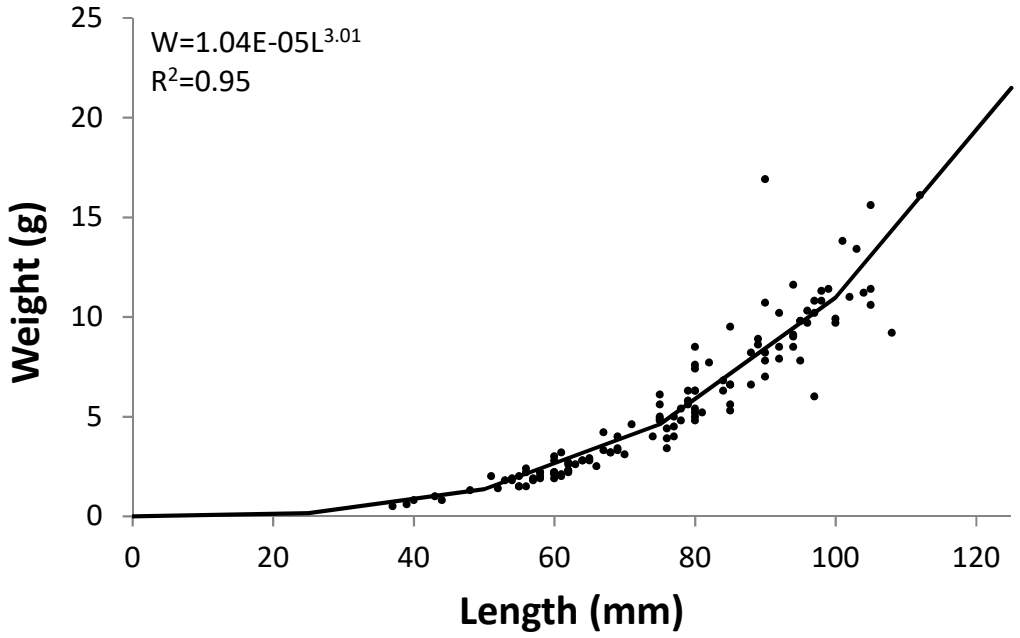

Figure 21. Slimy sculpin weight-length relationship for Latte, Coffee, YR24 and Independence Creeks, Coffee Gold Project, 2014-2015

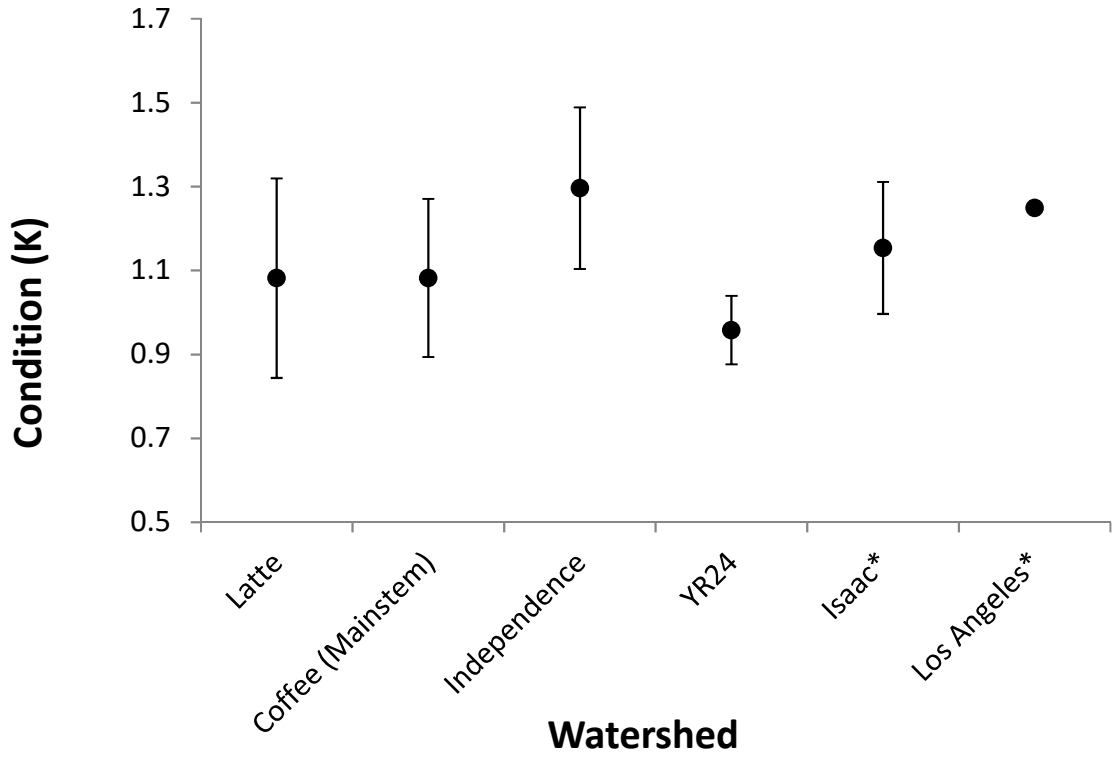

Figure 22. Slimy sculpin Fulton's condition factor (K) by watershed, Coffee Gold Project, 2014-2015. Bars represent standard deviation and (*) indicates a fisheries reference site

3.5.2.3 Chinook salmon

Juvenile Chinook salmon lengths ranged from 48-110mm in the project study area (Figure 23). Juvenile Chinook in Los Angeles Creek had the highest mean length (79mm), followed by Coffee and Independence Creeks (77m), and then Isaac Creek (68mm).

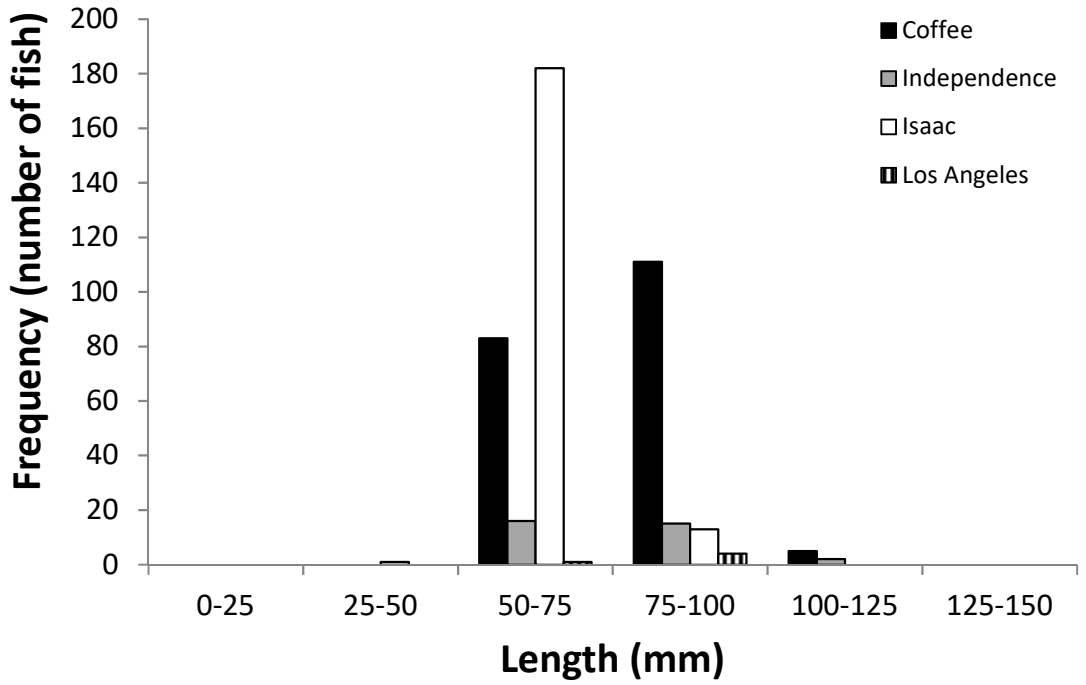

Figure 23. Juvenile Chinook salmon lengths in the Coffee Gold study area, June-October, 2014-2015

Juvenile Chinook salmon weight-length regressions for each watershed were significant (Figure 24, Linear regressions $R^2 \geq 0.81$, df≥1,3, P≤0.01). Fish growth was allometric for individuals in Coffee Creek (slope<3), with fish becoming proportionately lighter as length increased, and isometric for all other watersheds (slope = 3). Relative condition factors based on the combined length-weight regression were similar among all watersheds, with the exception of Coffee Creek which had significantly higher relative condition than Independence Creek (Figure 25, Kruskal Wallis, $H_3=10.44$, P=0.02; Post-hoc multiple comparison test, P=0.02).

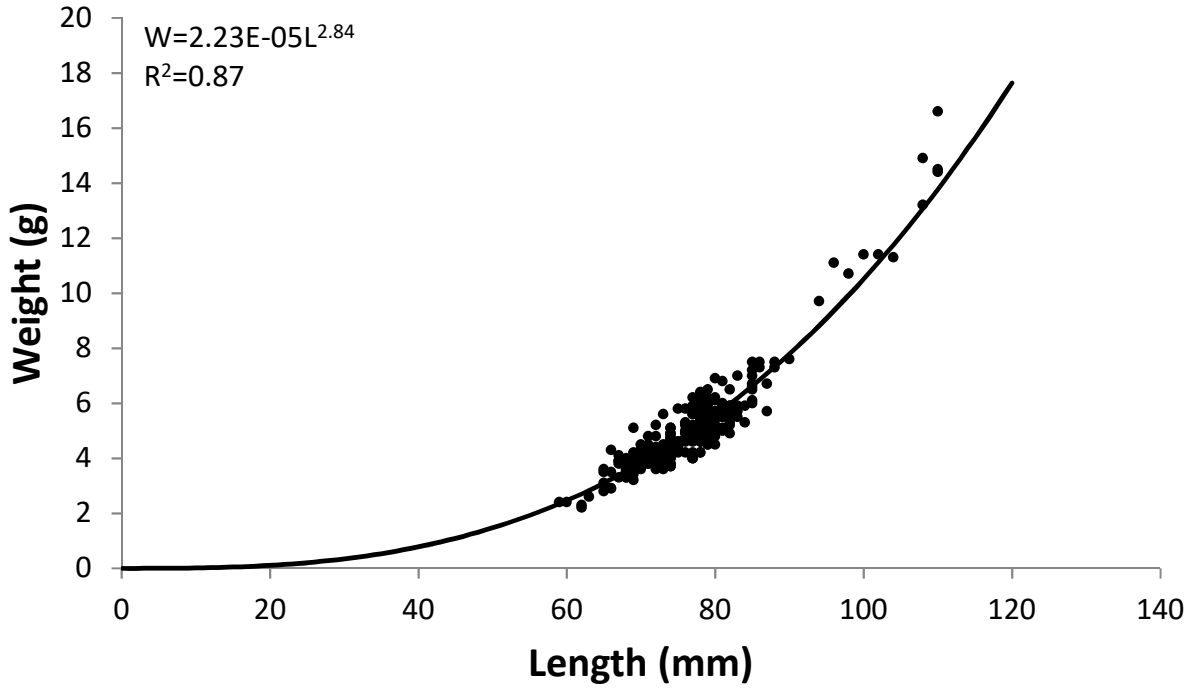

Figure 24. Juvenile Chinook salmon weight-length relationship for Coffee and Independence Creeks, Coffee Gold Project, 2014-2015

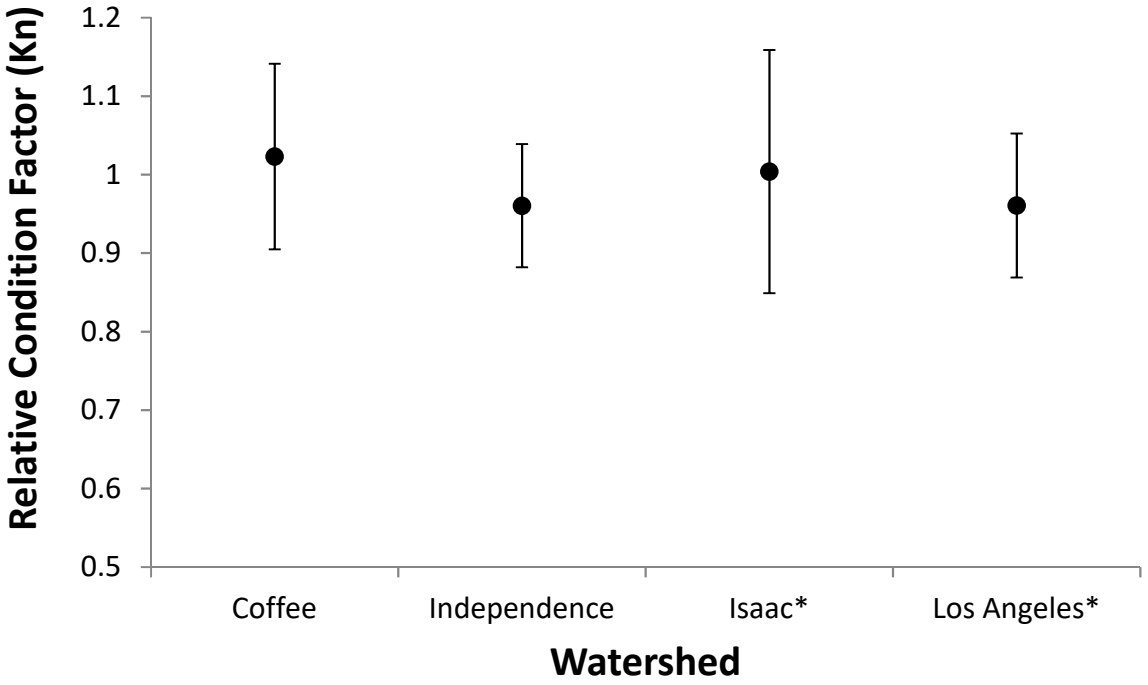

Figure 25. Juvenile Chinook salmon relative condition factor (Kn) by watershed, Coffee Gold Project, 2014-2015. Bars represent standard deviation and (*) indicates a fisheries reference site

3.5.3 Tissue Metal Concentrations

Selected metal concentrations in Arctic grayling and slimy sculpin tissues were compared among watersheds including Coffee Creek (mainstem), Latte Creek, Independence Creek, and the Isaac and Los Angeles Creek reference sites (raw data can be found in Appendix F5). Certain metals are required for fish physiological processes but may become toxic above certain thresholds (e.g., copper, selenium, zinc). In contrast, there are several non-essential metals that have no determined biological role and may be toxic even at low concentrations (*e.g.,* cadmium, lead, nickel). The only guidelines currently available to determine safe metal concentrations in slimy sculpin are for selenium and mercury. As there are no other guidelines developed, noted differences among watersheds may not provide insight into adverse metal effects. However, as guidelines may be developed in the future, it is important to characterize baseline metal concentrations within the project study area prior to development.

It should be noted that results from the metals analysis of fish tissues in 2014 may have been affected by potential thawing of samples during transit. However, results for slimy sculpins were within the range of values observed in nearby watersheds for the Casino Project and can therefore be considered as reliable baseline (PECG 2013a). Sub-sampling of sculpin tissues from some of the same watersheds in 2015 identified some potential differences between years, although guideline exceedances were overall similar for selenium and mercury. Based on these apparent differences between years, further sampling of these watersheds would be beneficial for characterizing more accurate baseline metal concentrations in the mine area.

3.5.3.1 Arctic grayling

Mean estimated methylmercury concentrations exceeded the guideline for the protection of piscivorous wildlife in all watersheds for Arctic grayling (CCME, 2000). In contrast, Health Canada total mercury guidelines were not exceeded by Arctic grayling tissues in any watershed (Health and Welfare Canada 1979; Canadian Food Inspection Agency, 2011). The guideline for the protection of piscivorous wildlife is conservatively based on one avian species (the storm petrel) that consumes almost its entire body weight each day, and thus is highly sensitive to methylmercury bioaccumulation (CCME, 2000).

Mean selenium concentrations in Arctic grayling tissues in all four watersheds exceeded the selenium guidelines for the protection of freshwater aquatic life, which were recently updated in spring 2014 (Table 15; BC MOE 2014). The mean selenium concentrations did not surpass the human health guidelines for selenium with the exception of Independence Creek samples, which exceeded the lowest guideline of 7.3 mg/kg, provided for high consumers of fish. In addition, approximately 33-38% of individual samples in all watersheds exceeded the lowest guideline provided for high consumers of fish, with the exception of Arctic grayling in Latte Creek which were all below the guideline. The human health selenium guidelines based on moderate and low fish diets were not exceeded by any individual Arctic grayling samples. Selenium toxicity can produce varying effects on fish and aquatic organisms including liver and ovary abnormalities (Sorensen 1998), impaired growth (Dobbs *et al.,* 1996), reduced reproduction (Lemly 2004), and teratogenesis during early development (Lemly and Smith 1987).

Overall, Independence Creek Arctic grayling tissues demonstrated the highest mean metal concentrations with greater barium, cadmium, selenium, strontium, and zinc concentrations in comparison to grayling from mainstem Coffee, Latte and Los Angeles Creeks (Table 15). The second overall highest tissue metal concentrations were observed in Los Angeles, where grayling demonstrated the highest mean concentrations of arsenic, manganese and thallium in comparison to grayling from other watersheds. Latte Creek grayling exhibited the lowest metal concentrations overall, except for mercury, selenium, and thallium where they had the highest (mercury) and second highest (barium, cadmium, copper) values relative to other watersheds. Uranium concentrations were low among all watersheds, with all values within 3x the laboratory detection limits (0.001-0.003 mg/kg wet weight).

Table 15. Selected total metal concentrations in Arctic grayling muscle tissue, Coffee Gold Project, 2014-2015

3.5.3.2 Slimy Sculpin

2014 Data:

Mean estimated methylmercury concentrations exceeded the guideline for the protection of piscivorous wildlife in all watersheds for slimy sculpin. In contrast, Health Canada total mercury guidelines were not exceeded by mean mercury concentrations of sculpin tissues in any watershed. However, as people do not consume slimy sculpin, the comparison to Health Canada guidelines are not directly relevant.

Mean selenium concentrations in slimy sculpin tissues in all three watersheds exceeded the selenium guidelines for the protection of freshwater aquatic life (BC MOE, 2014). The mean selenium concentrations did not surpass the human health guidelines for selenium, although there were one to two sculpins in each watershed that individually exceeded the lowest guideline provided for high consumers of fish. The human health selenium guidelines based on moderate and low fish diets were not exceeded by any individual sculpin samples. Again, it should be noted that people do not consume slimy sculpin and thus the comparison to human health guidelines are not directly relevant.

Overall, Independence Creek slimy sculpin tissues demonstrated the highest mean metal concentrations with greater aluminum, arsenic, copper, iron, lead, molybdenum, nickel and thallium concentrations in comparison to sculpins from Coffee and Isaac Creeks (Table 16). The second overall highest tissue metal concentrations were observed in Isaac Creek, where sculpins demonstrated the highest mean concentrations of barium, cadmium, manganese, selenium, strontium, and zinc in comparison to sculpins from Independence and Coffee Creeks. Coffee Creek sculpins often exhibited the lowest metal concentrations overall, except for mercury, selenium, and thallium where they had the highest (mercury) and second highest (selenium, thallium) values relative to other watersheds.

[a]Health Canada mercury guidelines range from 0.2-0.5 for subsistence consumers (Health and Welfare Canada 1979) and maximum allowable level for sale (Canadian Food Inspection Agency 2011), respectively

[b]Methylmercury is estimated based on 83% of total mercury for slimy sculpin (Raymond and Rossmann 2009)

[c]Canadian Council of Ministers of the Environment tissue residue guideline (CCME 2000) to protect piscivorous wildlife from methylmercury toxicity

[d]Selenium is reported in mg/kg dry weight

[e]British Columbia Ministry of Environment aquatic life (whole-body) selenium guideline (BC MOE 2014) for the protection of freshwater aquatic life

[f]British Columbia Ministry of Environment human consumption selenium screening values for low (0.03 kg/day), medium (0.11 kg/day), and high (0.22 kg/day) fish intake (BC MOE 2014)

2015 Data:
Poor sampling conditions (high flows, turbid waters) and low densities of fish lowered sample sizes in Latte and Los Angeles Creeks, where only 1-3 of 8 desired samples were collected in 2015. An additional three samples were obtained at AQ02 and AQREF1 in order to provide verification for sample quality in 2014. Results from these sites are summarized in Table 17.

Overall, guideline exceedances were generally similar to 2014 for both mercury and selenium. All watersheds had mean estimated methylmercury values that exceeded the guideline for the protection of piscivorous wildlife, which was also observed in 2014 (Table 17). One indication of potential between-year differences was for total mercury, as 2/3 slimy sculpin Coffee Creek samples exceeded the human health guideline for subsistence consumers, whereas in 2014 only 1/9 samples exceeded this level. The guideline was also exceeded at Latte Creek, where 2/3 sculpins had values greater than 0.2 mg/kg wet weight. No samples at any sites exceeded the maximum allowable level of mercury for sale guideline (Canadian Food Inspection Agency, 2011).

As was observed in 2014, mean selenium concentrations in slimy sculpin tissues in 2015 exceeded the selenium guidelines for the protection of freshwater aquatic life in all watersheds (BC MOE 2014). Individual samples in Independence, Isaac, and Los Angeles Creek exceeded the selenium human health guideline for high consumers of fish. However the rate of exceedances was comparable to results in 2014 (0-2 sample exceedances per site). The human health selenium guidelines based on moderate and low fish diets were not exceeded by any individual slimy sculpin samples.

Uranium:
Uranium concentrations for all watersheds over both years ranged from 0.006 – 0.175 mg/kg wet weight per slimy sculpin sample. The highest uranium concentrations were observed in Latte Creek (mean=0.10 mg/kg wet weight) and mainstem Coffee Creek (2014 mean=0.05 mg/kg wet weight, 2015 mean=0.08 mg/kg wet weight). The remaining watersheds had mean uranium concentrations ranging from 0.011 – 0.024 mg/kg wet weight. While there are no available guidelines for assessing healthy uranium levels, uranium results for Coffee Gold slimy sculpins were within the range of values observed in nearby watersheds for the Casino Project (PECG 2013a).

3.5.4 Arctic Grayling Diet

Coffee Creek Arctic grayling primarily fed on dipteran species (50%), followed by mayflies (*Ephemeroptera*=27%), caddisflies (*Trichoptera*=16%), and stoneflies (*Plecoptera*=3%) (Figure 26; Appendix F6). The remaining stomach contents consisted of low abundances of annelids, and species from the orders *Coeloptera, Hemiptera*, and *Chelicerata*. The number of prey items per fish was relatively high, with an average of 218 items per fish. During sampling, it was often noted that stomach fullness was high for Latte and Coffee Creek Arctic grayling. While this only provides a snapshop of diet, it is worth noting that none of the Arctic grayling sampled were piscivorous. Low frequencies of Arctic grayling piscivory have been documented elsewhere in Yukon and NWT streams (e.g., Bishop 1967; de Bruyn and McCart 1974; Mathers 1981; Jessop *et al.* 1993).

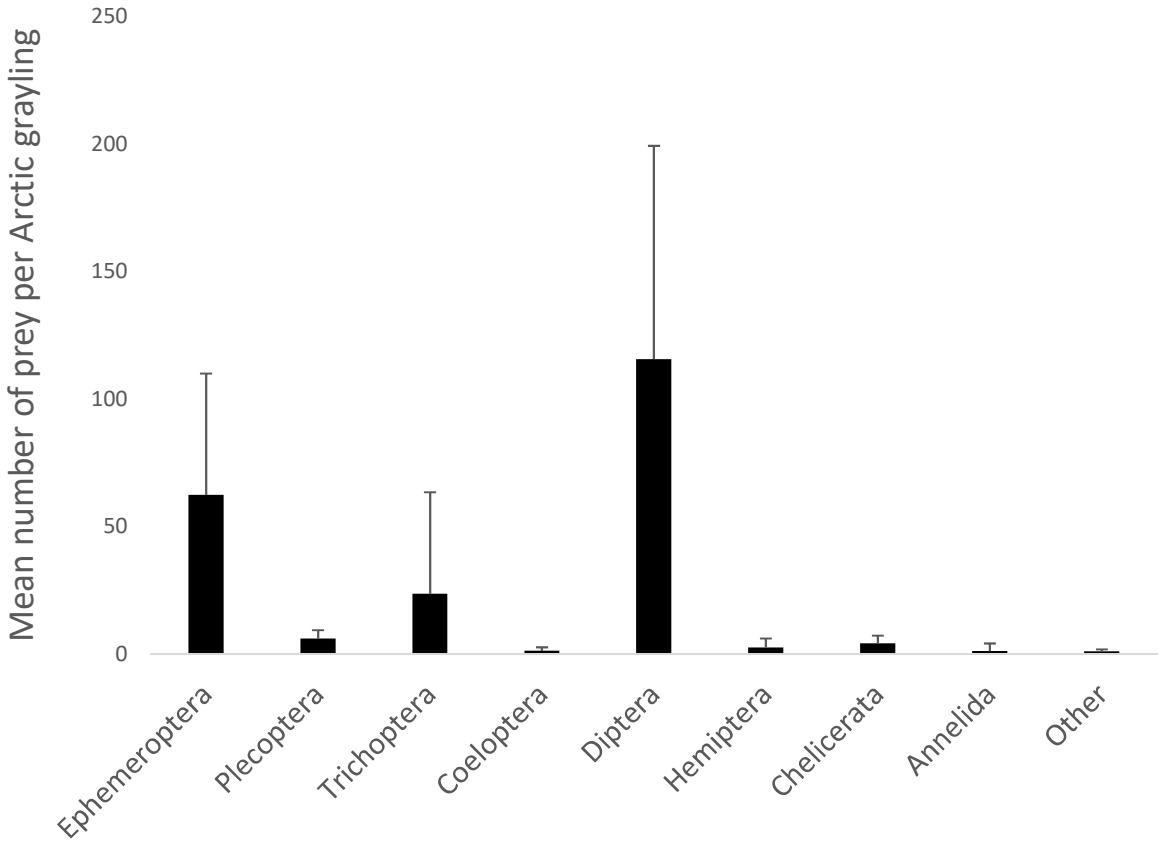

Figure 26. Mean number of prey per Arctic grayling, Coffee Gold Project, 2014-2015. Results are an average based on two grayling from Latte (AQ04) and five grayling from mainstem Coffee Creek (AQ02). Bars represent standard deviation

3.5.5 Arctic Grayling Tagging Program Results

Out of 31 Arctic grayling tagged in late August, 2014, four individuals were re-captured in late July, 2015. All four Arctic grayling were tagged and re-captured at the same site in mid Latte Creek, AQ04. Based on

external observations, all four grayling were likely male and varied from 244 – 357mm in length. Two grayling were determined to be in their eighth year based on scale ageing analysis. Growth between tagging and re-capture (change in length) was negligible and in all cases fish weight had decreased, with reductions of approximately 15-60g observed. Although there is room for measurement error with live fish, these findings suggest that the beginning of the 2015 growth season may have been poor, and/or that the bulk of growth was yet to occur.

3.5.6 Spawning Surveys

3.5.6.1 Salmon Spawning Surveys

In 2014, salmon spawning surveys were completed on Coffee and Independence Creeks in late August and early October, and also on the Yukon River proximate to the study area in October (Table 6). In 2015, salmon spawning surveys were completed on Coffee, Independence, and the Yukon River throughout a week of sampling in late July. No evidence of spawning was observed in either Coffee or Independence Creeks during any sampling period. However, in fall 2014 several salmon were spotted in a Yukon River side channel adjacent to the Coffee Creek camp (UTM: 7V 0596480 6977159), and are assumed to have been chum salmon due to the timing of the survey.

3.5.6.2 Arctic Grayling Spawning Survey

A total of 16 Arctic grayling were captured and visually assessed for spawning condition at two sites in Latte Creek from June 18 – 23, 2015. Approximately 200m of stream length was surveyed at AQ03, just upstream of the Latte Creek confluence with Coffee Creek, and an additional 120m of stream length was surveyed at AQ04 which is a high density summer feeding site. Fish habitat at AQ03 had low potential for supporting Arctic grayling spawning, with a small percentage (<5%) of unembedded gravel substrate noted (Stewart *et al*., 2007a). Habitat at AQ04 in the mid-section of Latte Creek had moderate to good potential for supporting Arctic grayling spawning based on suitable channel size, flow, and a high percentage of unembedded gravel substrate. Prior to electrofishing, the stream lengths were walked and fish were observed to determine any potential spawning behavior such as territory guarding, spawning congregations, or any courtship displays (*e.g.,* pairing up). No spawning behavior was noted, and electrofishing commenced. Lengths of captured Arctic grayling suggested a mature size (220-316mm). An external check of secondary sexual characteristics was made for each fish, and all fish appeared to be in the resting stage *i.e.,* spawning colours were not as apparent, the genital opening was not inflamed, the body cavity did not feel empty (as you would expect for a fish that had recently spawned), and no roe or milt was expelled when applying pressure to the body cavity (RIC 1996).

Dissection of six Arctic grayling samples (n=2 from AQ03, n=4 from AQ04; two females and four males total) provided a more in-depth assessment of gonad development and confirmed results based on external observations. The gonads only partly filled the body cavity, and showed no sign of recent expulsion. Female fish eggs were approximately 1mm diameter, which is less than 1/2 the size of grayling that are ready to spawn (2.5-2.7mm, Figure 27, Stewart *et al*., 2007a). The rate of gonad development suggests that Arctic grayling in Latte Creek had already spawned and begun re-development for 2016. As 2015 was an early spring, Arctic grayling spawning which typically coincides with the ice break-up may

have occurred as early as the beginning of May in nearby systems. Furthermore, gonadal development of Yukon Arctic grayling is typically accelerated due to the shortened northern growing season, and thus the state of maturity observed further supports the theory of early spawning and subsequent gonadal generation (*pers. comm*., von Finster, 2015). All six of the Arctic grayling stomachs were completely full, suggesting heavy active feeding in the stream. In contrast, spawning Arctic grayling are known to only passively feed before and during spawning activities (Stewart *et al*., 2007b).

Figure 27. Arctic grayling egg size, AQ04 in mid Latte Creek, Coffee Gold Project, June 23, 2015.

Stream temperatures from Latte Creek were recorded using an in-stream temperature logger located at AQ03 that ran from June 1, 2014 – September 2015 (Figure 28). Temperatures at this site were colder than preferred Arctic grayling spawning temperatures (above 4°C, with daily means between 6-10°C) throughout the expected spawning period of mid-May to mid-June (Stewart *et al*., 2007a). Further, mean daily temperatures were only reaching 5°C in early July, well past ice break-up and indicative of a permafrost-dominated system. While completing the Arctic grayling spawning assessment, spot temperatures measurements were obtained at several sites along Latte Creek and compared to the in-stream temperature logger record. Stream temperatures at AQ04 were warmer than those recorded at AQ03, with a maximum discrepancy of 1.8°C. Taking this potential difference into account, Latte Creek stream temperatures in the mid-watershed (AQ04) may have reached the bottom of the preferred spawning temperature range by early July.

Results from the Arctic grayling spawning assessment on Latte Creek suggested that spawning likely occurred elsewhere, either in Coffee Creek or even in other watersheds nearby. Stream temperatures were marginal at best for supporting spawning activities, and Arctic grayling behavior and gonadal development all indicated that the fish were in a “resting” maturity state. Furthermore, active feeding suggests that the Arctic grayling were beyond their spawning period and had entered their summer feeding stage.

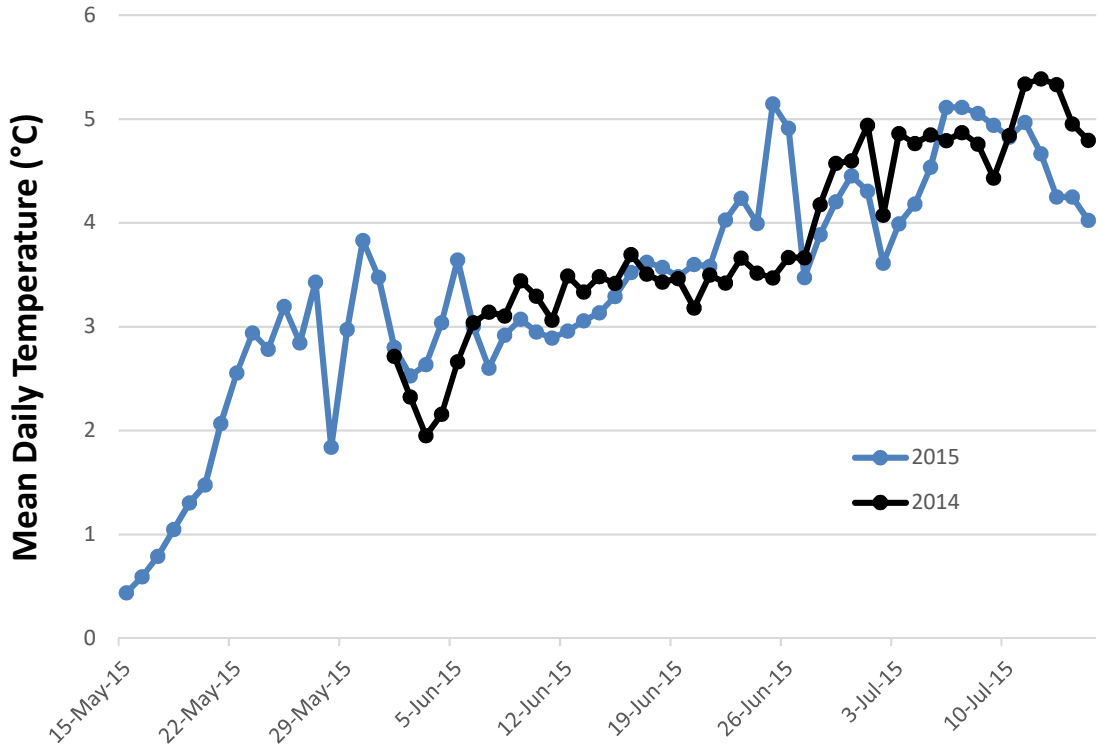

Figure 28. Mean Spring – Early Summer Daily Temperatures at AQ03 in lower Latte Creek, Coffee Gold Project, 2014-2015.

4 Summary

The fish and aquatic resources study program was conducted at 18 fish sampling sites, 17 fish habitat sites, and 12 benthic invertebrate, periphyton, and sediment sites throughout the project study area in August and October, 2014, and in March, June, July, and September, 2015. Watersheds within the local study area are Coffee Creek, Independence Creek, YR24 (between Coffee and Halfway Creeks), and Halfway Creek, with two reference sites located in Isaac and Los Angeles Creeks. Quality of fish habitat was assessed through investigations of aquatic communities (e.g., periphyton, benthic invertebrates), physical fish habitat parameters (e.g., stream size, gradient, habitat type), and physicochemical fish habitat parameters (e.g., sediment quality). The Coffee Gold study area provided non-natal rearing habitat for juvenile Chinook salmon, which is a highly valued CRA fish species in the Yukon. Adult and sub-adult Arctic grayling had the most widespread distribution in the Coffee Gold study area, with Latte Creek supporting high density summer feeding habitat. Currently, there are no known fish species at risk in the regional area of the Project.

4.1 Sediment Quality

Of the seven metals with CCME sediment quality guidelines, exceedances were observed for two: arsenic (As), and chromium (Cr). There were no exceedances recorded for mercury. Arsenic exceedances occurred at every station for the ISQG. Arsenic also exceeded the PEL at AQ05, AQ13, and AQREF1, which are in headwater areas adjacent to the deposit (AQ05, AQ13), or proximate to the Yukon River (AQREF1). The ISQG was exceeded for Chromium in the Kona tributary of Independence Creek (AQ13), as well as at the Los Angeles Creek reference site (AQREF2). Over 60% of the sediment particle sizes in the study area were less than 300 µm in diameter.

4.2 Periphyton and Benthic Invertebrates

Chlorophyll *a* was very low for all sites, which is typical of northern aquatic habitats. Ash-free dry mass (AFDM) values ranged from 0.38 - 1.07 mg/cm^2, with the highest values observed in Halfway Creek (AQ20) and Los Angeles Creek (AQREF2). Mean periphyton density was highest in YR24 (497,737 cells/cm^2) and lowest in upper Latte Creek (68,802 cells/cm^2). Blue-green algae (*Cyanophyta*) was the most dominant algal group in the study area, making up approximately 80% of the overall community composition. Mean taxonomic richness in the Coffee Gold study area was overall low, ranging from 10-14 taxonomic groups. Mean biodiversity ranged from 0.99 at AQ05 to 1.74 at AQ10.

Overall, Los Angeles Creek displayed the highest total abundance of benthic invertebrates (3210), followed by Independence Creek (2092), YR24 (1291), Coffee Creek (762), Halfway Creek (466), and then Isaac Creek (306). EPT abundances within the study area demonstrated similar patterns to overall abundance, with a significant relationship observed between the two indices. Dipterans were the most dominant benthic invertebrate group in the project study area, making up approximately 50% of the overall community composition. Benthic invertebrate taxonomic richness was highest at AQ02 in the Coffee Creek watershed (34 taxa), and lowest at the Independence Creek Kona tributary (18 taxa). Simpson's diversity values displayed similar patterns to those observed for taxonomic richness.

4.3 Fish and Fish Habitat:

Fish habitat quality was greatest in the mainstems of Coffee and Independence Creeks due to their large sizes, ample in-stream cover, and the presence of a wide variety of habitat types available including potential overwintering habitat. Good Arctic grayling summer feeding habitat was available in the lower reaches of Latte Creek. In Halfway Creek, there was marginal fish habitat for Arctic grayling available in the lower watershed (AQ20). YR24 was even smaller and steeper than Halfway Creek, with little to no pool habitat observed for fish rearing (*e.g*. water depths were generally less than 20cm). A high gradient barrier to fish passage was identified on upper YR24, just upstream of the aquatic site AQ31. Site AQ12 in the lower Kona tributary had much lower habitat quality than the mainstem of Independence Creek as water depths were low, and there were few pools noted for supporting fish feeding or rearing. Sites in the upper watersheds of Latte Creek (AQ04.5, AQ05, AQ06), Independence Kona tributary (AQ13), Halfway Creek (AQ21) and YR24 (AQ31) contained lower quality habitat for fish due to higher gradients, lack of deep pools, and many natural obstructions to fish passage. No fish were caught at these headwater sites using two sampling methods over two seasons (spring and summer), however one grayling was observed

at AQ04.5 in summer 2015. Latte Creek Tributary C, which intersects with the proposed south waste rock storage facility, was a small, shallow, medium gradient channel with low suitability for supporting Arctic grayling.

Slimy sculpin, juvenile Chinook salmon, and Arctic grayling were commonly found in fish-bearing project area streams. Currently, there are no known fish species at risk in the regional area of the Project. Juvenile Chinook salmon were present in the mainstems of Coffee Creek and Independence Creek, but were not captured in Latte Creek, Kona Tributary of Independence Creek, Halfway Creek, or YR24. Slimy sculpin overlapped juvenile Chinook salmon in distribution, but were also present at the downstream end of Latte Creek (AQ03), and at the mouth of YR24 (AQ30). Arctic grayling were captured at all sites, with the exception of YR24 (AQ30, AQ31), upper Halfway Creek (AQ21), upper Latte Creek (AQ05, AQ06), and upper Kona Tributary (AQ13). Site AQ04 on Latte Creek had the highest number of Arctic grayling captured, with a total catch of 70 sub-adult and adult grayling (>128mm). Two years in a row, sampling in lower Halfway Creek (AQ20) produced a single adult Arctic grayling. Low numbers of Arctic grayling were captured in the lower Kona Tributary site, AQ12. In 2014, a reference site was established near the mouth of Isaac Creek, which contained high numbers of juvenile Chinook salmon, slimy sculpin, and low numbers of juveniles from four other fish species. In 2015, low numbers of juvenile Chinook salmon, Arctic grayling, and slimy sculpin were captured at a second reference site located on Los Angeles Creek, approximately 6km upstream from the Yukon River.

Juvenile Chinook salmon were captured in high numbers along the mainstem of Coffee Creek upstream to its confluence with Latte Creek, however capture rates were much higher in summer 2014 (8-15x) than in summer 2015. For example, during the August 2014 sampling a total of 122 juvenile Chinook were caught using ten minnow traps set overnight at AQ00; 72 were caught at AQ01, and 62 were caught at AQ02. In the mainstem of Independence Creek lower numbers of juvenile Chinook salmon were captured in both 2014 and 2015. Catch per unit effort was slightly lower at all sites in October 2014, however, the presence of juvenile Chinook late in the season suggested that overwintering occurred at most sites in mainstem Coffee and Independence Creeks.

Slimy sculpin (n=37) samples were collected from AQ02, AQ03, AQ10, AQREF1, and AQREF2 for analyzing baseline metal concentrations in tissues. Mean estimated methylmercury concentrations exceeded the guideline for the protection of fish-eating (piscivorous) wildlife in all watersheds. Individual slimy scupin samples in Latte and Coffee Creeks also exceeded the human health guideline for subsistence consumers (0.2 mg/kg wet weight). No samples at any sites exceeded the maximum allowable level of mercury for sale guideline. Mean selenium concentrations in slimy sculpin tissues exceeded the selenium guidelines for the protection of freshwater aquatic life in all watersheds. Individual samples in Coffee, Independence, Isaac, and Los Angeles Creek exceeded the selenium human health guideline for high consumers of fish (1-2 samples per watershed/year). The human health selenium guidelines based on moderate and low fish diets were not exceeded by any individual slimy sculpin samples.

Arctic grayling (n=26) samples were collected from AQ00, AQ02, AQ03, AQ04, AQ11, and AQREF 2 for analyzing baseline metal concentrations in tissues. Mean estimated methylmercury concentrations exceeded the guideline for the protection of fish-eating (piscivorous) wildlife in all watersheds, but did not surpass Health Canada standards for mercury levels in fish. The mean selenium concentrations did not

surpass the human health guidelines for selenium with the exception of Independence Creek samples, which exceeded the lowest guideline, provided for high consumers of fish. In addition, approximately 33-38% of individual samples in all watersheds exceeded the lowest guideline provided for high consumers of fish, with the exception of Arctic grayling in Latte Creek, which were all below the guideline. The human health selenium guidelines based on moderate and low fish diets were not exceeded by any individual Arctic grayling samples.

Similar to results from previous years (Sparling 2001; Laberge and White Mountain 2002), no Chinook salmon were observed spawning in Coffee and Independence Creeks in 2014 or 2015. Results from the Arctic grayling spawning assessment on Latte Creek suggested that grayling likely spawned elsewhere prior to entering the creek for summer feeding. Stream temperatures were marginal at best for supporting spawning activities, and Arctic grayling behavior and gonadal development all indicated that the fish were in a "resting" maturity state.

Review of Existing Fisheries and Aquatic Community Information, Coffee Gold Project, Yukon

PALMER ENVIRONMENTAL CONSULTING GROUP INC.

470 Granville Street, Suite 630, Vancouver, BC V6C 1V5 t 604-629-9075

June 5, 2014

Rory Kutluoglu
Kaminak Gold Corporation
1020 - 800 West Pender Street
Vancouver, British Columbia
V6C 2V6, Canada

Dear Mr. Kutluoglu,

Re: Review of Existing Fisheries and Aquatic Community Information, Coffee Gold Project, Yukon

Palmer Environmental Consulting Group (PECG) was retained by Kaminak Gold Corporation to identify and compile any existing fish and aquatic community (e.g., benthic invertebrate, periphyton) data within the Coffee Gold Project area. The purpose of the review was to determine if any existing data or noted data deficiencies could be incorporated into the baseline dataset and/or be used to guide the development of the baseline study design. A desktop review of pre-existing information was completed and consisted of environmental consultant aquatic study reports, government databases and reports, academic literature, salmon management advisory bodies (e.g., Yukon River Panel reports), and baseline data collected by PECG on upper Coffee Creek. Documents and databases which were found to include relevant information are listed below:

- Access Consulting Group. 2014. Memorandum: Kaminak Coffee 2013 Fisheries Summary Report. Prepared for Kaminak Gold Corporation, May 30, 2014.
- Fisheries and Oceans Canada. 2001. Yukon Fisheries Information Summary System (FISS) and Fish Sampling. Accessed April 2014 at http://cmnmaps.ca/fiss_yukon/.
- Laberge Environmental Services and White Mountain Environmental Consulting. 2002. Investigations into Fish Habitats of Selected Tributaries to the Yukon River between McGregor Creek and Coffee Creek 2000/2001. Prepared for Selkirk First Nation, August 2002.
- Laberge Environmental Services and White Mountain Environmental Consulting. 2012. Investigations into the Implications of Regional Background Low-level Concentrations of Dissolved Copper to the Freshwater Fishes of the Yukon River, 2010. Prepared for Selkirk First Nations.
- PECG. 2013a. Casino Project Fish and Aquatic Resources Baseline Report, Prepared for Casino Mining Corporation, YT, November 12, 2013.
- PECG. 2013b. Casino Project: 2013 Aquatic Studies Technical Memo, Prepared for Casino Mining Corporation, YT, October 15, 2013. (Appendix F of PECG 2013a).

- Sparling, P., White Mountain Environmental Consulting, 2001. Fish Habitat and Utilization Assessment for 58 Tributaries to the Yukon River between McGregor and Coffee Creeks, July 2000. Prepared for Selkirk First Nation, February 2001.
- Yukon Placer Secretariat, 2010. Yukon Placer Fish Habitat Suitability Map – Yukon River South Watershed (Map 1 of 7) (Category A). Revised September 2010. Accessed April 2014 at http://www.yukonplacersecretariat.ca.

Furthermore, one additional report was referenced on the FISS database, but could not be accessed at this time:

- Duncan, J. 1997. Summary of Streams in the Tr'on dek Hwech'in Traditional Territory: A search for Candidate Streams to Support a Program based on a Klondike Area Central Incubation/Outplanting Facility. Prepared by Duncan Contracting.

Fish and Aquatic Resources Baseline Review Results:

1. Fish and Fish Habitat in Lower-Mid Coffee Creek

Fisheries sampling and aquatic habitat assessments were carried out in lower-mid Coffee Creek (Figures 1 and 2) during 2000 (Sparling 2001), 2001 (Laberge and White Mountain 2002), 2010 (Laberge and White Mountain 2012) and 2013 (Access 2014). A summary of the fish habitat assessment results, sampling effort, and fish catch are provided in Tables 1 and 2.

Just upstream of its confluence with the Yukon River, Coffee Creek had an average channel width of 25m (Figure 3, Table 1), and was noted to provide excellent fish habitat for a variety of fish species and life history stages (Sparling 2001). Habitat required for supporting overwintering and spawning activities were observed, such as deep pools and abundant gravel substrates. Fish sampling over multiple years demonstrated that lower Coffee Creek supported high abundances of juvenile Chinook salmon, as well as slimy sculpin, and Arctic grayling fry and juveniles (Table 2). Individual fish measurements were collected and reported for juvenile Chinook salmon and slimy sculpin in 2010 (Table 3).

During 2013, Coffee Creek was sampled with minnow traps at sites that ranged from 2-8 km upstream from the Yukon River (Figure 2, Table 2). High numbers of juvenile Chinook salmon were captured in late October at CC-0.5, with a CPUE of 13.7 fish/trap-day. Sampling in the adjacent western tributary (Site CC-3.5) yielded two juvenile Chinook salmon in August, with no fish caught in late July, September, or October. No fish were caught further downstream at site CC-4.5 in late July, August, or September, with only one juvenile Chinook salmon and one slimy sculpin captured in late October. The timing and size (mean length = 71 mm) of the captures from this study indicated that mid Coffee Creek was heavily used by 0+ juvenile Chinook salmon for overwintering.

Chinook salmon spawning surveys were conducted on Coffee Creek during field studies in 2000 and 2001 (Sparling 2001; Laberge and White Mountain 2002). The timing of both spawning surveys were decided in consultation with Fisheries and Oceans Canada (DFO). There was no evidence for Chinook salmon spawning in Coffee Creek during an aerial spawning survey completed on August 17, 2000 (Sparling 2001). Results from the 2001 study were not detailed in the report. Despite the lack of documented spawning observations, Selkirk First Nations elders reported that the river was a significant spawning location in the past (Laberge and White Mountain 2002).

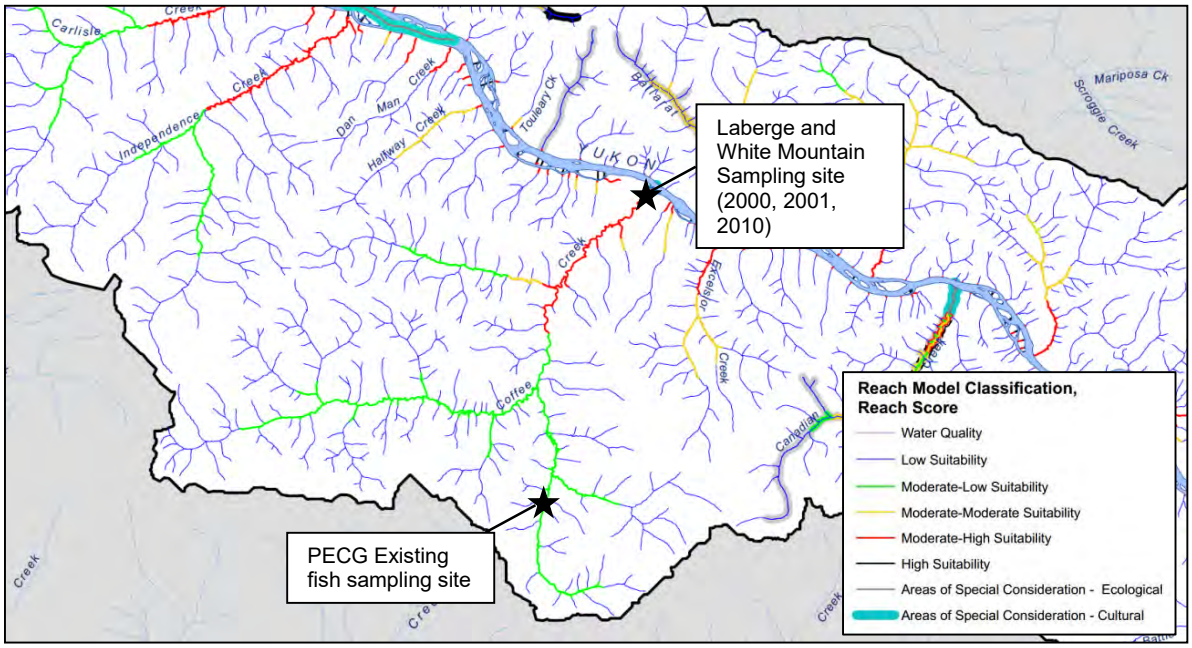

Figure 1. Excerpt of Coffee Project Study Area from Yukon Placer Fish Habitat Suitability Map – Yukon River South Watershed (Map 1 of 7). Black stars indicate fisheries sampling sites on Coffee Creek established by Laberge and White Mountain (2000, 2001, 2010) and PECG (2012-2013).

Notes: MT=Minnow trap, GN=gill net, EF=electrofishing, jcs=juvenile Chinook salmon, CCG=slimy sculpin, GR=Arctic grayling, NFC=no fish caught

Table 3. Lower Coffee Creek individual length and weight measurements for juvenile Chinook salmon and slimy sculpin, August 2010 (Laberge and White Mountain 2012)

Species	Sample size	Mean Length (mm)	Length range (mm)	Mean Weight (g)	Weight range (g)
Chinook salmon	26	77.7	72-93	2.9	1.9-8
Slimy sculpin	18	62.2	40-82	1.97	0.4-3.4

2. Fish and Fish Habitat in Upper Coffee Creek

Baseline fisheries data on upper Coffee Creek is available from PECG (2013a), as a reference site was established there as part of the adjacent Casino Mine Project in 2012 (Figures 1 and 4). Two years of sampling at this site yielded a total of 12 Arctic grayling and one round whitefish at a rate of 0.8 fish per 100s of electrofishing effort. Arctic grayling lengths varied from 150-250mm, which suggested that the upper reach of Coffee Creek predominantly supported sub-adult and adult rearing. The single round whitefish captured was 265mm in length. A habitat assessment of the site was carried out in 2013, with detailed results reported in Appendix A4 of the 2013 Aquatic Studies Technical Memo (PECG 2013b). Briefly, the site was low gradient (2%) with a mean channel width of 3m, and followed a run-riffle sequence (Figure 4). Abundant overhanging vegetation and undercut banks provided good quality seasonal rearing habitat, however, a lack of deep pool habitat likely precluded fish overwintering. The bed substrate was dominated by large cobble and fines, suggesting a low potential for salmonid spawning activities.

Figure 4. Upstream view at PECG Reference Site on Upper Coffee Creek, July 2013

3. Yukon Placer Fish Habitat Suitability Maps

Based on the Yukon Placer Fish Habitat Suitability mapping, lower reaches of Coffee Creek were classified as **moderate-high** suitability and thus contain highly suitable habitat for juvenile Chinook salmon rearing, as well as high quality habitat for a broad range of adult and juvenile resident fish species (Figure 1). There was no Coffee Creek habitat designated as high suitability, which are defined as watercourses that provide spawning habitat for salmon or critical migratory corridors required to access salmon spawning areas. There is, however, a Cultural Area of Special Consideration located at the most downstream end of Coffee Creek. Cultural Areas of Special Consideration are watercourses that are identified by First Nations as containing culturally important fisheries or aquatic resources, and may also include anadromous (e.g., Chinook salmon) or non-anadromous fish production. Further upstream were areas of moderate-moderate suitability (yellow), moderate-low suitability (green), and low suitability (blue) (Figure 1). The Yukon Placer Secretariat defines these habitat types as:

- **Moderate-moderate** suitability habitats are defined as watercourses that are suitable for rearing juvenile Chinook salmon, although the habitat parameters and conditions are not as restricted as moderate-high suitability habitats within the watershed. These watercourses are also highly suitable for a broad range of adult and juvenile resident fish species.

- **Moderate-low** suitability habitats are defined as watercourses suitable for rearing juvenile Chinook salmon, although utilization may be limited at times due to environmental factors or conditions. These watercourses are typically highly suitable for non-anadromous resident fish species such as Arctic grayling.

- **Low** Habitat Suitability Watercourses (formally Freshwater Fisheries Production Zone) are areas within watercourses that are utilized by a variety of fish species and are typically relatively abundant within a watershed. As a function of gradient and distance from Chinook salmon production areas these streams are likely not utilized by rearing juvenile Chinook salmon, but may be highly suitable for and used by non-anadromous resident fish species.

4. Yukon Fisheries Information Summary System (FISS) Database

The Yukon FISS database was reviewed for determining previous fish studies or information relating to Coffee Creek. Notably, the database was last updated in 2001, and does not include any potential information gathered over the past 13 years. In addition to the work conducted by Laberge Environmental Services and White Mountain Environmental, the FISS database references the Yukon Placer Secretariat (Reference #800001), summarized above, and Duncan 1997 (Reference #DFO0016), which is not accessible for review at this time. Personal communications with Siegi Kriegl, a Fisheries Officer Fishery out of DFO Whitehorse were recorded in 1996 (Reference #11055), and indicated unconfirmed reports of chum salmon spawning in lower Coffee Creek, as well as an operational commercial fishery in the Yukon River off the mouth of Coffee Creek. Within the list of personal communications with Mr. Kriegl, there is also reference to Chinook salmon, and round whitefish, with no further details available (Reference

#11055). Also in 1996, personal communications with Nick De Graff from the Department of Renewable Resources, Yukon Territorial Government (Reference #11063), indicated that there was a First Nations fishery on Coffee Creek.

5. Benthic Invertebrates and Periphyton

Benthic invertebrate sampling on Coffee Creek was carried out in July 2001, and on August 3, 2010 (Laberge and White Mountain 2002, 2012). In 2001, sampling was conducted using a 300µm mesh surber sampler with an area of 0.0929 m^2. The benthic invertebrate community in Coffee Creek exhibited the lowest density (204 individuals/m^2) and diversity (14 taxon) of the eleven Yukon River tributaries sampled (Laberge and White Mountain 2002). In addition, the Coffee Creek benthic invertebrate community had the highest (61%) and lowest (19%) relative percentage of Ephemeroptera (mayflies) and Diptera (true flies), respectively.

The benthic invertebrate survey on Coffee Creek in 2010 employed a 363µm mesh kick-net and followed Canadian Aquatic Biomonitoring Network (CABIN) sampling protocols (Appendix D, Laberge and White Mountain 2012). In opposition to results from 2001, Lower Coffee Creek had the highest benthic invertebrate density of the 17 Yukon River tributaries sampled, with 9500 individuals/sample. The noted difference in benthic invertebrate density between 2001 and 2010 may be attributed to a change in community structure between the two time periods, or a difference in sampling methods (Page & Sylvestre 2006[1]). Taxa richness was moderate (18 taxa) and Simpson's diversity was high (0.85) relative to the other streams. Further, the number of sensitive EPT taxa present (15 taxa) was higher than 15 of the other tributaries sampled. Using the Yukon Reference Model which incorporates a database of 439 reference sites throughout the Yukon River drainage, Coffee Creek was determined to be a potentially stressed system and not in reference condition.

No existing information on primary producers (e.g., periphyton) in Coffee Creek was identified during this review.

6. Other watercourses:

Other watercourses within the potential project area include Halfway Creek, Dan Man Creek, and Independence Creek, which are located west of Coffee Creek and north (downslope) of the potential project activities (Figures 1 and 2). Minnow traps were deployed on Halfway and Independence Creeks during summer 2013 (Access 2014). Low numbers of juvenile Chinook salmon and slimy sculpin were captured at sites in Independence Creek, whereas a single Arctic grayling (length=125mm) was captured in Halfway Creek (Table 4). As only minnow traps were used, other fish sampling methods (e.g.,

[1] Page, N., and Sylvestre, S. 2006. Comparison of Two Benthic Invertebrate Sampling and Analysis Methods for Streams in Greater Vancouver. Available online at: http://www.raincoastappliedecology.ca/. (Accessed May 2014).

electrofishing, seining) are recommended for further characterizing the fish communities in these creeks. The presence of juvenile Chinook salmon in Independence Creek in late October suggested that some overwintering may occur in this system.

The Yukon Placer Fish Habitat classifications for the three creeks currently range from moderate-high to low suitability (Figure 1). In agreement with the minnow trapping results, Independence Creek contains the most moderate-high habitat which extends for several kilometers upstream of the Yukon River. Halfway Creek contains a short reach of moderate-high suitability habitat, followed by moderate-moderate suitability, and then low suitability. Based on the suitability mapping, Dan Man Creek appears to have the lowest quality habitat of the three watercourses.

Minimal information was available for these watercourses on the FISS database. Search results indicated that there was suspected Chinook salmon rearing in all three creeks, as well as suspected northern pike rearing in Independence Creek. No further information was identified or reviewed for these creeks.

Table 4: Summary of minnow trapping effort and catch on Independence and Halfway Creeks (Access 2014)

Site Assessment Report

A. Site Description

CABIN Study Name	YK-Coffee Gold Baseline-PECG
CABIN Site Code	AQ00
Sampling Date	Aug 29 2014
Know Your Watershed (KYW) Basin	Upper Yukon
Province / Territory	Yukon Territories
Terrestrial Ecological Classification	Boreal Cordillera Ecozone Klondike Plateau Ecoregion
Coordinates (decimal degrees)	62.88524 N, 139.09500 W
Altitude	1427
Feature Name	Coffee Creek
Stream Order	

B. CABIN Assessment Results

REFERENCE MODEL SUMMARY	
Model Name	Yukon 2013
Analysis Date	December 11, 2015
Taxanomic Level	Family

Laboratory Certified Data Reports

- **G1. CARO Analytical**

CERTIFICATE OF ANALYSIS

REPORTED TO	Palmer Environmental Consulting Group Inc. 470 Granville Street - Suite 630 Vancouver, BC V6C 1V5	**TEL** **FAX**	(604) 629-9075 -
ATTENTION	May Quach	**WORK ORDER**	4090358
PO NUMBER		**RECEIVED / TEMP**	Sep-04-14 13:25 / 14°C
PROJECT	Coffee Gold	**REPORTED**	Sep-17-14
PROJECT INFO		**COC NUMBER**	B 24489

General Comments:

CARO Analytical Services employs methods which are conducted according to procedures accepted by appropriate regulatory agencies, and/or are conducted in accordance with recognized professional standards using accepted testing methodologies and quality control efforts, except where otherwise agreed to by the client.

The results in this report apply to the samples analyzed in accordance with the Chain of Custody or Sample Requisition document. This analytical report must be reproduced in its entirety. CARO is not responsible for any loss or damage resulting directly or indirectly from error or omission in the conduct of testing. Liability is limited to the cost of analysis. Samples will be disposed of 30 days after the test report has been issued unless otherwise agreed to in writing.

ANALYSIS INFORMATION

REPORTED TO	Palmer Environmental Consulting Group Inc.	**WORK ORDER**	4090358
PROJECT	Coffee Gold	**REPORTED**	Sep-17-14

Analysis Description	Method Reference	Technique	Location
Available Cations (Ca/Mg/K/Na)	MSSMA 4.51	1N Ammonium Acetate Extraction, Atomic Spectroscopy	Sublet
Available NH4-N and NO3-N in Soil	Carter 4	Nitrate and Exchangeable Ammonium Nitrogen	Sublet
Carbon, Total Organic in Solids	Carter 21.2	Catalytic Combustion and Infrared Detection	Kelowna
Moisture	ASTM D2974-87 *	Gravimetry (Dried at 105C)	N/A
Particle Size - Dry Sieve Fractions	N/A	N/A - RMD Inorganics	Richmond
pH in Soil (1:2 Soil/Water)	Carter 16.2 / APHA 4500-H+ B	1:2 Soil/Water Slurry / Electrometry	Richmond
Phosphorus, Available (Bray)	UBCPLMM 6.1	Bray Extraction, Colorimetric	Sublet
Strong Acid Leachable Metals	BCMOE SALM V.2 / EPA 6020A	HNO3+HCl Hot Block Digestion / Inductively Coupled Plasma-Mass Spectroscopy (ICP-MS)	Richmond

Note: An asterisk in the Method Reference indicates that the CARO method has been modified from the reference method

Method Reference Descriptions:

APHA	Standard Methods for the Examination of Water and Wastewater, 22nd Edition, American Public Health Association/American Water Works Association/Water Environment Federation
ASTM	ASTM International Test Methods
Carter	Soil Sampling and Methods of Analysis, 2nd Edition (2007), Carter/Gregorich
EPA	United States Environmental Protection Agency Test Methods
MSSMA	Manual on Soil Sampling and Methods of Analysis, J.A. McKeague
UBCPLMM	Methods Manual, Pedology Laboratory, 1977/1981, L.M. Lavkulich, UBC Department of Soil Science

Glossary of Terms:

MRL	Method Reporting Limit
<	Less than the Reported Detection Limit (RDL) - the RDL may be higher than the MRL due to various factors such as dilutions, limited sample volume, high moisture, or interferences
%	Percent
% dry	Percent (dry weight)
% wet	Percent (wet weight)
mg/kg dry	Milligrams per kilogram (dry weight)
pH units	pH < 7 = acidic, ph > 7 = basic

REPORTED TO	Palmer Environmental Consulting Group Inc.	**WORK ORDER**	4090358
PROJECT	Coffee Gold	**REPORTED**	Sep-17-14

The following section displays the quality control (QC) data that is associated with your sample data. Groups of samples are prepared in fibatchesfl and analyzed in conjunction with QC samples that ensure your data is of the highest quality. Common QC types includ

- **Method Blank (Blk)**: Laboratory reagent water is carried through sample preparation and analysis steps. Method Blanks indicate that results are free from contamination, i.e. not biased high from sources such as the sample container or the laboratory environment
- **Duplicate (Dup)**: Preparation and analysis of a replicate aliquot of a sample. Duplicates provide a measure of the analytical method's precision, i.e. how reproducible a result is. Duplicates are only reported if they are associated with your sample data.
- **Blank Spike (BS)**: A known amount of standard is carried through sample preparation and analysis steps. Blank Spikes, also known as laboratory control samples (LCS), are prepared from a different source of standard than used for the calibration. They ensure that the calibration is acceptable (i.e. not biased high or low) and also provide a measure of the analytical method's accuracy (i.e. closeness of the result to a target value).
- **Standard Reference Material (SRM)**: A material of similar matrix to the samples, externally certified for the parameter(s) listed. Standard Reference Materials ensure that the preparation steps in the method are adequate to achieve acceptable recoveries of the parameter(s) tested.

Each QC type is analyzed at a 5-10% frequency, i.e. one blank/duplicate/spike for every 10 samples. For all types of QC, the specified recovery (% Rec) and relative percent difference (RPD) limits are derived from long-term method performance averages and/or prescribed by the reference method.

General Comments:

CARO Analytical Services employs methods which are conducted according to procedures accepted by appropriate regulatory agencies, and/or are conducted in accordance with recognized professional standards using accepted testing methodologies and quality control efforts, except where otherwise agreed to by the client.

The results in this report apply to the samples analyzed in accordance with the Chain of Custody or Sample Requisition document. This analytical report must be reproduced in its entirety. CARO is not responsible for any loss or damage resulting directly or indirectly from error or omission in the conduct of testing. Liability is limited to the cost of analysis. Samples will be disposed of 30 days after the test report has been issued unless otherwise agreed to in writing.

REPORTED Sep-17-14

Analysis Description	Method Reference	Technique	Location
Available Cations (Ca/Mg/K/Na)	MSSMA 4.51	1N Ammonium Acetate Extraction, Atomic Spectroscopy	Sublet
Available NH4-N and NO3-N in Soil	Carter 4	Nitrate and Exchangeable Ammonium Nitrogen	Sublet
Carbon, Total Organic in Solids	Carter 21.2	Catalytic Combustion and Infrared Detection	Kelowna
Particle Size - Dry Sieve Fractions	N/A	N/A - RMD Inorganics	Richmond
pH in Soil (1:2 Soil/Water)	Carter 16.2 / APHA 4500-H+ B	1:2 Soil/Water Slurry / Electrometry	Richmond
Phosphorus, Available (Bray)	UBCPLMM 6.1	Bray Extraction, Colorimetric	Sublet
Strong Acid Leachable Metals	BCMOE SALM V.2 / EPA 6020A	HNO3+HCl Hot Block Digestion / Inductively Coupled Plasma-Mass Spectroscopy (ICP-MS)	Richmond

Method Reference Descriptions:

APHA	Standard Methods for the Examination of Water and Wastewater, 22nd Edition, American Public Health Association/American Water Works Association/Water Environment Federation
Carter	Soil Sampling and Methods of Analysis, 2nd Edition (2007), Carter/Gregorich
EPA	United States Environmental Protection Agency Test Methods
MSSMA	Manual on Soil Sampling and Methods of Analysis, J.A. McKeague
UBCPLMM	Methods Manual, Pedology Laboratory, 1977/1981, L.M. Lavkulich, UBC Department of Soil Science

Glossary of Terms:

MRL	Method Reporting Limit
<	Less than the Reported Detection Limit (RDL) - the RDL may be higher than the MRL due to various factors such as dilutions, limited sample volume, high moisture, or interferences
%	Percent
% dry	Percent (dry weight)
mg/kg dry	Milligrams per kilogram (dry weight)
pH units	pH < 7 = acidic, ph > 7 = basic

REPORTED TO	Palmer Environmental Consulting Group Inc.	**WORK ORDER**	4090397
PROJECT	Coffee Gold	**REPORTED**	Sep-17-14

Analyte	Result / *Recovery*	MRL / *Limits*	Units	Prepared	Analyzed	Notes
Sample ID: AQ04-1 (4090397-01) [Soil] Sampled: Aug-30-14 08:40						
General Parameters						
Carbon, Total Organic	**6.12**	0.05	% dry	N/A	Sep-11-14	
pH	**5.7**	0.1	pH units	Sep-10-14	Sep-10-14	
Fertility / Nutrient Parameters						
Nitrogen, Ammonia as N, Available	**5.0**	1.0	mg/kg dry	N/A	Sep-12-14	
Nitrogen, Nitrate as N, Available	**9.7**	1.0	mg/kg dry	N/A	Sep-12-14	
Phosphorus, Available	**5**	2	mg/kg dry	N/A	Sep-12-14	
Exchangeable Ions						
Calcium, Available	**2500**	5	mg/kg dry	N/A	Sep-12-14	
Magnesium, Available	**267**	5	mg/kg dry	N/A	Sep-12-14	
Potassium, Available	**192**	5	mg/kg dry	N/A	Sep-12-14	
Sodium, Available	**37**	5	mg/kg dry	N/A	Sep-12-14	
Strong Acid Leachable Metals						
Aluminum	**20600**	20	mg/kg dry	Sep-09-14	Sep-10-14	
Antimony	**0.8**	0.1	mg/kg dry	Sep-09-14	Sep-10-14
