Whitehorse, YT Y1A 0G1

November 24, 2025

REVISION TRACKING LOG

Revision Tracking Log			
Version	**Date**	**Section Updated**	**Description of Update**
0	November 2023	-	First submission of the Reclamation and Closure Plan
1	April 2024	General	Updated with responses to Type A WUL IR4; minor editorial corrections
2	November 2025	Various	Updated with responses to QML IR1 and Type A WUL IR9; updated cost basis (Closure Costs v6)

TABLE OF CONTENTS

LIST OF ACRONYMS AND ABBREVIATIONS XIII

LIST OF SYMBOLS AND UNITS OF MEASURE XVI

1.0 INTRODUCTION 1

1.1 Project Summary 2

1.1.1 Project Schedule 6

1.1.2 Regulatory Context 8

1.2 Mine Closure Philosophy and RCP Guiding Principles 8

1.2.1 Newmont Internal Standards 11

1.2.2 Coffee Gold Mine Guiding Principles and Closure Philosophy 12

2.0 RECLAMATION AND CLOSURE PLANNING 13

2.1 Consultation and Engagement Activities 13

2.2 Sequences and Phases of Reclamation and Closure Planning 14

2.3 Designing and Operating for Closure 14

2.3.1 Reclamation Research 15

2.3.2 Progressive Reclamation 25

2.3.3 Minimizing Project Effects 26

2.3.4 Alternatives Assessment Overview 26

3.0 CLOSURE OBJECTIVES AND DESIGN CRITERIA 33

3.1 Reclamation and Closure Planning Approach 33

3.1.1 Post-mine Vision 33

3.1.2 Closure Principles 34

3.1.3 Project-specific Closure Objectives 36

3.1.4 Component-specific Closure Objectives 38

3.1.5 Water Quality Objectives 41

3.2 End Land Use Planning 43

3.3 Design Criteria 43

3.3.1 Project Component Design Criteria 44

3.3.2 Socio-economic Criteria 44

3.3.3 Quality Management 44

4.0 ENVIRONMENT AND SOCIOECONOMIC DESCRIPTIONS 47

4.1 Physical Environment 47

4.1.1 Weather and Climate 47

4.1.2 Seismic Conditions 59

4.1.3 Air Quality 61

4.1.4 Noise 62

4.1.5 Surficial Geology, Terrain, Soils, and Permafrost 62
4.1.6 Watercourses and Surface Hydrology 71
4.1.7 Surface Water Quality 76
4.1.8 Groundwater 92
4.2 Biophysical Environment 103
4.2.1 Aquatic Environment 103
4.2.2 Vegetation 105
4.2.3 Wildlife 109
4.2.4 Birds 112
4.3 Socio-economic Conditions 114
4.3.1 Demographics 114
4.3.2 Economic Conditions 117
4.3.3 Social Economy 119
4.3.4 Infrastructure and Services 120
4.3.5 Education Services 122
4.3.6 Land and Resource Use 122
4.3.7 Community Health and Well-Being 126
4.3.8 Heritage 128

5.0 PROJECT DESCRIPTION 129
5.1 Coffee Property History 129
5.2 Project Schedule 129
5.3 Project and Ancillary Components 133
5.3.1 Open Pits and Mining Activities 136
5.3.2 Alpha Waste Rock Storage Facility 145
5.3.3 Stockpiles 146
5.3.4 Ore Crushing Facilities 147
5.3.5 Heap Leach Facility 150
5.3.6 Plant Site 158
5.3.7 Camp Site 164
5.3.8 Camp Facilities 164
5.3.9 Bulk Explosive Storage Area 165
5.3.10 Land Treatment Facility 168
5.3.11 Mine Site and Haul Roads 168
5.3.12 Site Water Management Infrastructure 168
5.3.13 Ancillary Infrastructure 173
5.4 Current Conditions (Year -5) 178
5.5 Conditions Two-years Forward (Year -1) 178
5.5.1 Mine-Related Land Disturbance Two-Years Forward 182
5.6 End-of-mine Conditions (End of Year 9) 183

5.6.1 Mine-Related Land Disturbance at End of Mine (Year 9) 185
5.7 Monitoring Activities 186
5.7.1 Monitoring and Inspections of Mine Site and Supporting Infrastructure 186
5.7.2 Monitoring of Physical and Biophysical Environments 187
5.7.3 Monitoring of Socio-economic Conditions 187
5.8 Risk Assessment, Contingency Planning and Adaptive Management 187
5.8.1 Risk Assessment 187
5.8.2 Contingency Planning and Adaptive Management Approach 188

6.0 TEMPORARY CLOSURE 189

6.1 Temporary Closure Scenario Description 189
6.2 Personnel and Consumable Requirements 192
6.2.1 Personnel Requirements 192
6.2.2 Consumable Requirements 193
6.3 Site Security, Monitoring and Maintenance 194
6.3.1 Site Access Restrictions and Maintenance Requirements 194
6.3.2 Open Pit Access Restriction 195
6.3.3 Facility and Infrastructure Security and Hazardous Goods Storage 195
6.3.4 Vehicle and Equipment Use and Storage 196
6.4 Ensuring Geochemical and Physical Stability 196
6.4.1 Heap Leach Facility and ROM Stockpile 196
6.4.2 Alpha WRSF 197
6.4.3 Open Pits 197
6.4.4 Water Management Structures – Diversion Ditches, Alpha and Facility Pond 198
6.4.5 Organic and Frozen Soil Stockpiles 198
6.5 Interim Water and Solution Management 198
6.5.1 Open Pits 199
6.5.2 Heap Leach Facility 199
6.5.3 Facility and Alpha Ponds 200
6.6 Reporting and Monitoring Requirements 201
6.7 Socio-Economic and Community Engagement Aspects of Temporary Closure 205
6.7.1 Management of Socio-economic Aspects of Temporary Closure 205
6.7.2 Managing Community Perceptions through Engagement Focused on Temporary Closure Period 209
6.7.3 Community Commitments, Partnerships and Agreements 211
6.7.4 Community Investments 211
6.7.5 Community Partnerships and Agreements 211
6.7.6 Socio-economic Monitoring and Evaluation During Temporary Closure Period 211

7.0 FINAL RECLAMATION AND CLOSURE MEASURES 212
7.1 Open Pits 217
7.1.1 Pit Lakes and Water Quality Predictions 217
7.1.2 Surface Discharge from Pit Lakes 220
7.1.3 Groundwater Leakage from Pit Lakes 238
7.1.4 Closure Measures 239
7.1.5 Reclamation Activities 239
7.1.6 Remaining Issues and Investigations 239
7.2 Waste Rock Storage Facilities and Stockpiles 241
7.2.1 Alpha WRSF – Closure Measures 242
7.2.2 Stockpile Pads – General Closure Measures 244
7.2.3 Reclamation Activities 244
7.2.4 Remaining Issues and Investigations 244
7.3 Heap Leach Facility and Process Ponds 244
7.3.1 Heap Leach Pad Closure Measures 244
7.3.2 Heap Leach Facility Pond Closure Measures 247
7.3.3 Reclamation Activities 247
7.3.4 Remaining Issues and Investigations 248
7.4 Ore Crushing Facilities 250
7.4.1 Crusher System and Crushed Ore Stockpile Area Closure Measures 251
7.4.2 ROM Stockpile Area Closure Measures 251
7.4.3 Reclamation Activities 251
7.4.4 Remaining Issues and Investigations 251
7.5 Plant Site Closure Measures 252
7.5.1 Bulk Fuel and LNG Storage Areas 253
7.5.2 Reclamation Activities 253
7.5.3 Remaining Issues and Investigations 253
7.6 Camp Site Closure Measures 254
7.6.1 Reclamation Activities 254
7.6.2 Remaining Issues and Investigations 254
7.7 Site Water Management Infrastructure 254
7.7.1 Reclamation Activities 255
7.7.2 Remaining Issues and Investigations 255
7.8 Mine Site Roads and Other Components 256
7.8.1 Haul Roads and Mine Site Roads 256
7.8.2 NAR and On-site Access Road 256
7.8.3 Project Airstrip 262
7.8.4 Laydown Areas 262
7.8.5 Bulk Explosive Storage Area 262
7.9 Environmental Management 262

7.9.1 Air Quality and Dust 262
7.9.2 Spill Management 262
7.9.3 Hazardous Materials Management 263
7.9.4 Erosion and Sediment Control 263
7.9.5 Revegetation 264
7.9.6 Soil Salvage 264
7.10 Material Balance 264
7.10.1 Required Materials 265
7.10.2 Borrow Material and Locations 265
7.11 Maintenance, Monitoring and Reporting Activities 267
7.11.1 Meteorological Monitoring 269
7.11.2 Aquatic Conditions Monitoring 272
7.11.3 Wildlife Monitoring 284
7.11.4 Vegetation Monitoring 286
7.11.5 Fish and Aquatic Life Monitoring 290
7.11.6 Physical Inspections 303
7.11.7 Reporting 305
7.12 Socio-Economic Aspects of Permanent Closure 305
7.12.1 Education and Training Measures 305
7.12.2 Local Employment, Procurement, and Economic Measures 308
7.12.3 Community Infrastructure and Services Measures 313
7.12.4 Traditional Knowledge and Lands and Resource Use Measures 316
7.12.5 Community Health and Well-Being Measures 318
7.12.6 Heritage Resources 320
7.13 Performance Uncertainty and Risk Management 321

8.0 RECLAMATION AND CLOSURE SCHEDULE AND EXECUTION STRATEGY 322

8.1 Schedule Overview 322
8.2 Reclamation Execution Strategy 324
8.3 Equipment Fleet 325
8.4 Site Access and Haul Roads 326
8.5 Site Security 327
8.6 Site Infrastructure 327
8.6.1 Site Camp 327
8.6.2 Site Offices and Labs 327
8.6.3 Emergency Response Team Building 327
8.6.4 Bulk Fuel Storage 327
8.6.5 Waste Management 328
8.6.6 Maintenance Areas and Laydowns 328
8.6.7 Power Generation 328

8.7 Labour Requirements 328

9.0 RECLAMATION AND CLOSURE LIABILITY 330

9.1 Basis of Estimate 330

9.2 SRCE Model 330

9.3 Two Years Forward Liability Estimate 331

9.4 Life of Mine Liability Estimate 332

10.0 REFERENCES 334

LIST OF ACRONYMS AND ABBREVIATIONS

Acronym / Abbreviation	Definition
ABA	Acid Base Accounting
ACG	Access Consulting Group
AMP	Adaptive Management Plan
ARO	Asset Retirement Obligation
As	arsenic
ASTM	American Society for Testing and Materials
ATVs	all-terrain vehicles
BACI	Before-After-Control-Impact
BC-MOE	British Columbia Ministry of Environment
BR	biological reactors
CCME	Canadian Council of Ministers of the Environment
CEC	cation exchange capacity
CFP	Chance Find Procedure
CIRNAC	Crown-Indigenous Relations and Northern Affairs Canada
COSEWIC	Committee on the Status of Endangered Wildlife in Canada
CPUE	catch per unit effort
DCRs	Design Change Requests
DOC	dissolved organic carbon
EBR	Electrochemical Bioreactor
EDI	EDI Environmental Dynamics Inc.
EEM	Environmental Effects Monitoring
EMAMP	Environmental Monitoring and Adaptive Management Plan
EMR	Yukon Department of Energy, Mines and Resources
EQS	Effluent quality standards
ET	Evapotranspiration
ESR	Event Storage Requirement
FA	Financial Assurance
FALMP	Fish and Aquatic Life Monitoring Plan
Fe^{2+}	iron
FFG	Functional feeding group
FMEA	Failure Modes and Effects Analysis
FNNND	First Nation Na-cho Nyäk Dun
FoS	Factors of Safety
FRMP	Forest Resources Management Plan
FSSA	Frozen Soil Storage Area

Acronym / Abbreviation	Definition
GCL	Geosynthetic Clay Liner
GDP	Gross domestic product
Green alder	Alnus viridis subsp. crispa
HC	Halfway Creek
HDPE	high density polyethylene
HRIA	Heritage Resources Impact Assessment
HROA	Heritage Resources Overview Assessment
HLF	Heap Leach Facility
HPG	Habit preference group
HRT	Hydraulic Retention Time
ICMM	International Council on Mining & Metals
ICs	Intermediate Components
KGC	Kaminak Gold Corp.
LCT	Latte Creek Tributary
LLDPE	linear low-density, polyethylene
LNG	liquid natural gas
LOM	Life of Mine
LSA	Local Study Area
LT	Latte Creek
Mn^{2+}	manganese
MAP	Mean annual precipitation
MCI	Multiple Control-Impact Approach
MDMER	Metal and Diamond Mine Effluent Regulations
MSE	Mechanically stabilized earth
NAR	Northern Access Route
NBCC	National Building Code of Canada
NCRs	Non-Conformance Reporting
Newmont	Goldcorp Kaminak Ltd., a wholly owned subsidiary of Newmont Corporation
NH_3	ammonia
NP	neutralization potential
NO_3	nitrate
NO_{2-}	nitrite
non-ML	non-metals leaching
NSERC	Natural Sciences and Engineering Research Council of Canada
ODF	overliner drain fill
PEL	Probable Effects Level
PGA	Peak ground acceleration

Acronym / Abbreviation	Definition
PM2.5	Particulate matter of 2.5 microns or less
POPCs	Parameters of potential concern
PRB	Permeable reactive barrier
PSD	Particle size distribution
PTS	Passive treatment systems
QA/QC	Quality Assurance/Quality Control
QML	Quartz Mine Licence
RCP or Plan	Reclamation and Closure Plan
RFIs	Request for Information
ROM	Run-of-Mine
RSA	Regional Study Area
SARA	*Species at Risk Act*
SEMP	Socio-economic Monitoring Plan
SER	Sustainability and External Relations
SFN	Selkirk First Nation

1.0 INTRODUCTION

The proposed Coffee Gold Mine (the Project) is an open-pit gold mine owned by Goldcorp Kaminak Ltd, a subsidiary of Newmont. The site is located on the south side of the Yukon River in the White Gold District of west-central Yukon, approximately 130 km south of the City of Dawson, 140 km west of Pelly Crossing, 95 km north-east of Beaver Creek, 160 km west-northwest of Carmacks, and 340 km northwest of Whitehorse. In 2017, the Project was submitted for assessment under the YESAA, SC 2003, c.7 for consideration by the YESAB Executive Committee. This Reclamation and Closure Plan (RCP or Plan) has been written to meet the guidance provided in the *Reclamation and Closure Planning for Quartz Mining Projects* (YWB and EMR 2013) and incorporates comments that were received throughout the YESAB screening and assessment process.

The primary objectives of this RCP are to:

- Provide the proposed approach to decommission mine features and reclaim landforms and disturbed areas.
- Outline a monitoring program to be conducted until mitigation and reclamation measures have achieved Project-specific and component-specific closure objectives.
- Provide estimated costs for liabilities associated with three scenarios: current conditions; conditions two-years forward, and conditions at the end of mine life.

This RCP is provided in conjunction with several other plans to meet the requirements for quartz mine applications for a Quartz Mining License and a Water Use Licence under the *Quartz Mining Act* and *Waters Act*, respectively. This RCP has been informed by input and feedback received from Project partners, stakeholders, and First Nations, and developed to provide the level of detail necessary for the licensing stage of the Project. It has been developed in accordance with current industry best practices, corporate standards, and guidance documents. Appendix 1-A provides a Table of Concordance for reclamation and closure plan requirements and closure costing information outlined in Annex 1 of YWB and EMR (2013) – Annotated Outline for Reclamation and Closure Plans.

The general structure of this Plan and a brief description of section content are as follows:

- **Section 1.0 Introduction** – Provides an overview of the proposed Project including the Project schedule, regulatory context, and closure philosophy and guiding principles incorporated into reclamation and closure planning.
- **Section 2.0 Reclamation and Closure Planning** – Describes the key aspects of reclamation and closure planning, including consultation and engagement activities, reclamation research activities, and mine design and operating strategies, and presents the outcomes of the closure alternatives evaluation process.
- **Section 3.0 Closure Objectives and Design Criteria** – Outlines the vision for Project closure and Project-specific closure objectives and summarizes the design criteria for mine components that will remain as part of the landscape post-closure.
- **Section 4.0 Environment and Socioeconomic Descriptions** – Describes the existing physical and biophysical conditions for the Project and surrounding areas, as well as local and regional socio-economic conditions.

- **Section 5.0 Project Description** – Describes the history of the Coffee Property, the proposed Project schedule, and the design/construction and operation of Project components and facilities; characterizes current conditions and anticipated conditions two-years forward and at the end-of-mine; and outlines proposed monitoring and surveillance activities, and the approach to managing potential risks.
- **Section 6.0 Temporary Closure** – For a hypothetical period of temporary closure commencing in Year 1 of mine operation, presents key objectives, socio-economic aspects, and expected site security, monitoring, maintenance, and management activities.
- **Section 7.0 Final Reclamation and Closure Measures** – Presents the measures and monitoring requirements for the decommissioning and closure of mine facilities and infrastructure, as well as socio-economic aspects of closure, to allow for the vision and objectives of the Project closure to be met.
- **Section 8.0 Reclamation and Closure Schedule and Execution Strategy** – Describes the preliminary schedule and strategy for executing the reclamation and closure activities.
- **Section 9.0 Reclamation and Closure Liability** – Presents the cost estimate methodology and liability estimates for current conditions, for conditions two-years forward immediately following construction, and for decommissioning and reclaiming the Project site at the end of the mine life.
- **Section 10.0 References** – Lists all sources of information that have informed the content of this document. Sources of information of greatest relevance are appended.

Newmont retained Ensero Solutions Canada, Inc. and JDS Energy and Mining to lead the development of this RCP.

1.1 Project Summary

The proposed Coffee Gold Mine (the Project) is an open-pit gold mine owned by Goldcorp Kaminak Ltd., a wholly owned subsidiary of Newmont Corporation (Newmont), located on the south side of the Yukon River in the White Gold District of west-central Yukon. The Project site is approximately 130 km south of the City of Dawson, 140 km west of Pelly Crossing, 95 km north-east of Beaver Creek, 160 km west-northwest of Carmacks, and 340 km northwest of Whitehorse. The Project is located wholly within the traditional territory of Tr'ondëk Hwëch'in, partially within the traditional territory of Selkirk First Nation and First Nation of Na-cho Nyäk Dun, and partially within the asserted territory of White River First Nation. The Project contains several gold occurrences within an exploration concession covering an area of more than 600 km^2. The Mine Site will be accessed by road from Dawson via a 16-km stretch of Klondike Highway and 192-km all-season road, referred to as the Northern Access Route (NAR) (Figure 1-1). The NAR includes seasonal barge crossings on both the Stewart and Yukon rivers, with ice bridges and a seasonal winter road in the winter months.

The Project is comprised of four open pits: Supremo, Latte, Double Double, and Kona. Waste rock is proposed to be permanently stored in the Alpha Waste Rock Storage Facility (WRSF) (Figure 1-2). The ore production rate is proposed to be up to approximately 9.0 million tonnes (Mt) per year, producing an estimated total of 67 Mt of heap leach feed over the 10-year Operation Phase. The conceptual-level estimate for waste material to be moved over the life of mine (LOM) is up to approximately 330 Mt based on an average strip ratio of 5.0:1. The ore will be crushed and transported to the Heap Leach Facility (HLF) via overland conveyor or trucks for nine months of the year. During the three coldest months of winter, run-

of-mine (ROM) ore will be stockpiled in the ROM stockpile. Gold will be extracted from gold-bearing leach solution by a six tonnes per day (t/d) adsorption, desorption, recovery carbon plant with mercury retorting to produce a final gold doré product. A total of 2.6 million ounces of gold is planned to be recovered over a 10-year mine life.

The Project phases are defined as follows:

- Construction Phase: Q2 Year –3 to end of Year –1 (30 months)
- Operation Phase: Year –1 to end of Year 9 (10 years)
- Reclamation and Closure Phase: Year 10 to end of Year 21, including a 6-year Post-Mining Closure Stage and a 5-year Active Closure Stage (11 years)
- Post-Closure Phase: Year 21 onwards as determined to be required.

These phases broadly describe the activities occurring within a particular time period; however, some activities will continue from one phase to another as mine site development advances with operational activities (e.g., Open Pits, WRSF). When areas that support mine operations are no longer required, they will be progressively reclaimed. The overall Project schedule is the general expected scenario for mine construction and operation; detailed activities are subject to change depending on detailed mine planning and the timing of receipt of authorizations.

The key Project components as well as the Mine Site layouts for specific periods (i.e., current conditions, two-years forward, and end of mine life) are provided in Section 5. An overview of the Project schedule is described in Section 1.1.1, the regulatory context for the Project is outlined in Section 1.1.2, and information regarding the closure philosophy and guiding principles for reclamation and closure planning is provided in Section 1.2.

1.1.1 Project Schedule

An overview of the Project schedule from discovery of the deposit to the completion of reclamation and closure activities (Post-closure Phase) is shown in Figure 1-3. Additional information on the history of the Project is provided in Section 5.1, and a detailed Project schedule that outlines key activities expected to occur during the Construction and Operation Phases is provided in Section 5.2. Figure 1-3 outlines the expected scenario for mine development, operation, and closure, with the phases broadly describing the activities occurring within that particular time period. The Operation Phase of the Project commences when first gold is produced. The Project phases and anticipated durations are as follows:

- Construction Phase: Q2 Year –3 to end of Year –1 (30 months)
- Operation Phase: Year –1 to end of Year 9 (10 years)
- Closure Phase: Year 10 to end of Year 21, including a 6-year Post-Mining Closure Stage and a 5-year Active Closure Stage (11 years)
- Post-closure Phase: Year 21 onwards as determined to be required.

These phases broadly describe the activities occurring within a particular time period; however, some activities will continue from one phase to another as mine site development advances with operational activities (e.g., Open Pits, WRSF). When areas that support mine operations are no longer required, they will be progressively reclaimed. The overall Project schedule is the general expected scenario for mine construction and operation; detailed activities are subject to change depending on detailed mine planning and the timing of receipt of authorizations.

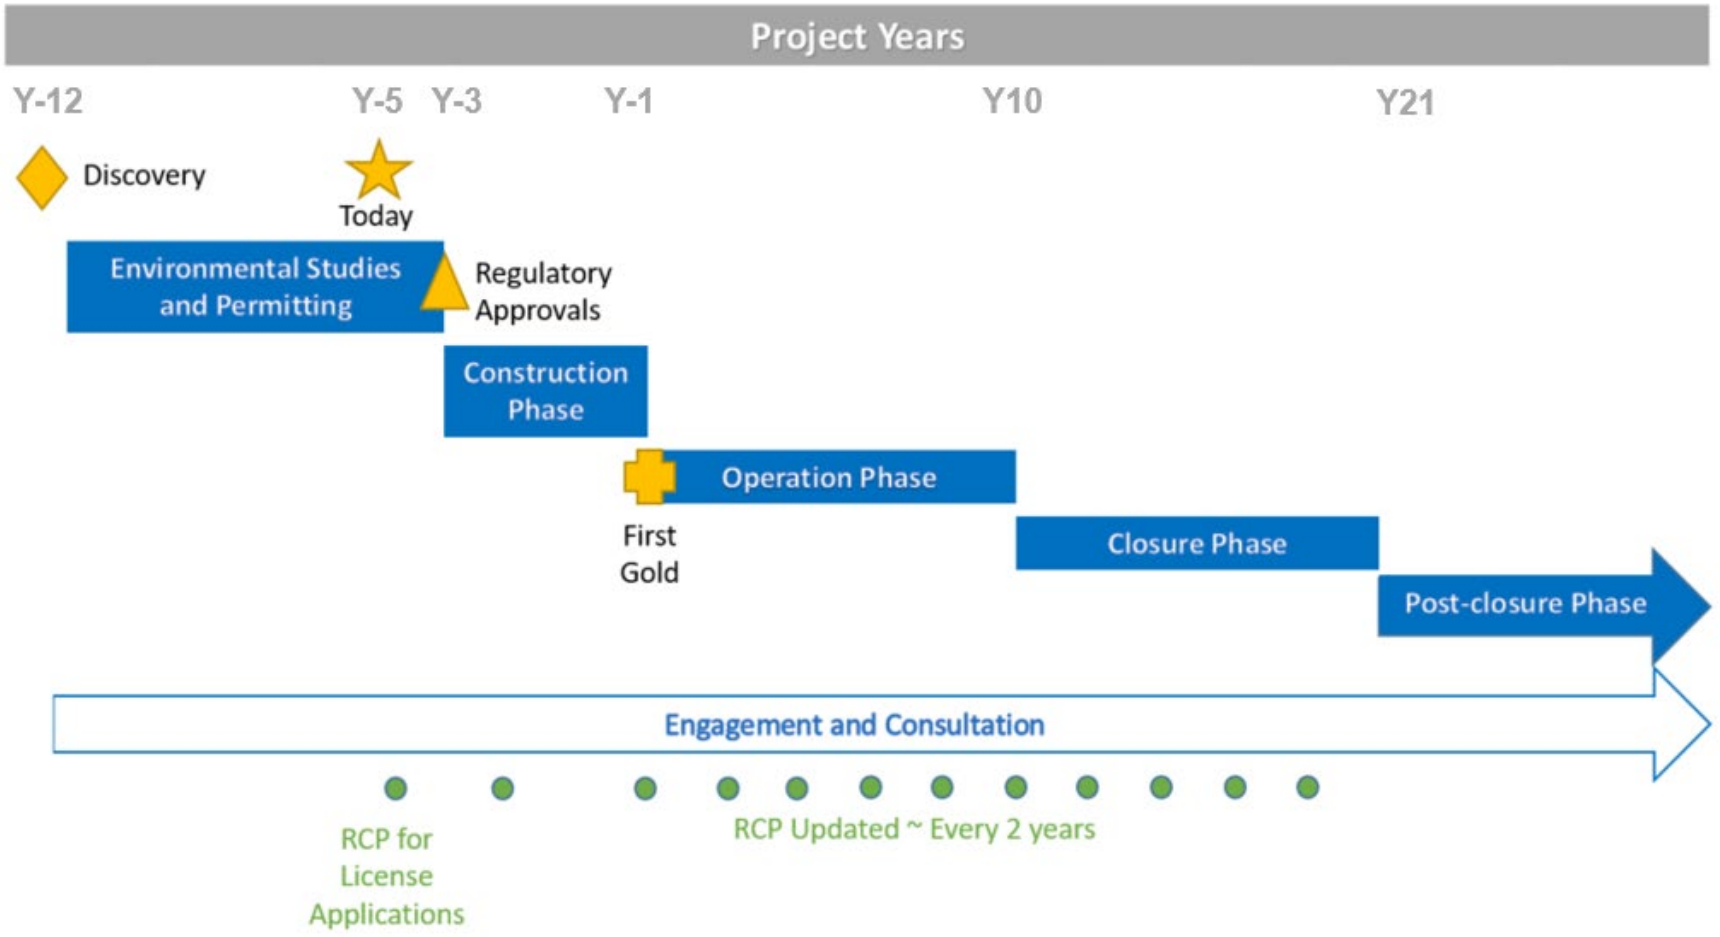

Figure 1-3 Coffee Project Schedule Overview

1.1.2 Regulatory Context

An environmental and socio-economic assessment was completed for the Project pursuant to *Yukon Environmental and Socio-economic Assessment Act* (YESAA) and was subsequently screened by the Yukon Environmental and Socio-economic Assessment Board (YESAB) Executive Committee. A Final Screening Report and Recommendation was issued to the Project's Decision Bodies in February 2022. Following consultation with affected First Nations, the Decision Bodies (Government of Yukon, Natural Resources Canada, and Transport Canada) issued the Decision Document in March 2022 allowing the Project to proceed. As such, Newmont is in the process of developing the requisite licence and permit applications from federal or territorial regulators, municipal governments, and/or First Nations, to advance the Project. Of key importance for the commencement of mine development are the Type A Water Licence and the Quartz Mining Licence.

This Plan has been developed in accordance with the plan requirements and closure costing guidance provided by Yukon Water Board (YWB) and Yukon Department of Energy, Mines and Resources (EMR) (2013) and was also guided or informed by the following documents:

- Yukon Mine Site Reclamation and Closure Policy (EMR 2006)
- Quartz Mining License Application Guide (EMR 2010)
- Preferred Practices for Works Affecting Yukon Waters (YG 2019)
- Guidance Document on Water and Mass Balance Models for the Mining Industry (Golder Associates 2011)
- Dam Guide: Design Expectations and Required Information (YESAB and Yukon Environment 2012)
- Type A and B Quartz Mining Undertakings – Information Package for Applicants (YWB 2012)
- Yukon Mine Site Reclamation and Closure Policy - Financial and Technical Guidelines (EMR 2013)
- Yukon Mine Site Reclamation and Closure Policy - Financial Guidelines (EMR 2014)
- Planning for Integrated Mine Closure: Toolkit (ICMM 2008)
- Umbrella Final Agreement between the Government of Canada, the Council for Yukon Indians, and the Government of Yukon (1993)
- TH Final Agreement (1998)
- SFN Final Agreement (1997).

Appendix 1-A provides a Table of Concordance for Yukon requirements for reclamation and closure plan content and closure costing information, as outlined in YWB and EMR (2013). Newmont commitments that were made during the screening and assessment process, terms and conditions of the Decision Document, and feedback that has been received through consultation related to reclamation and closure planning are provided in Appendix 1-B and have been incorporated into the RCP.

1.2 Mine Closure Philosophy and RCP Guiding Principles

Newmont is the world's leading gold company focused on responsible and sustainable mining through principled environmental, social, and governance practices. As a leader in sustainability in the mining industry, Newmont understands that an effective reclamation and closure plan supports the goal to act as a catalyst for local economic development through transparent and respectful stakeholder, Project partner,

and First Nations engagement, and as responsible stewards of the environment. Newmont integrates closure and reclamation into its business planning, factors it into financial decisions, and considers social benefits in every phase of mining.

Newmont's vision is to make mine closure a smooth transition, with careful management of the environmental and socio-economic challenges as the operation moves through reclamation, monitoring, passive care, and eventual transfer to the government or surrounding communities. Newmont's goal is to perform comprehensive land reclamation to ensure that the local ecosystem is healthy, thriving, and supportive of meaningful uses for nearby communities.

The International Council on Mining and Metals document entitled *Planning for Integrated Mine Closure: Toolkit* (ICMM 2008) highlights the importance of developing a holistic vision for closure through a collaborative and inclusive approach. Figure 1-4 outlines the continuous process for closure planning, which is initially conceptual in nature and progressively becomes more detailed as a mine advances. Reclamation and closure planning, including cost estimating, is a fundamental aspect of meeting Newmont's regulatory and social responsibility and managing the financial health of the company. As such, Newmont is committed to leaving the site in a condition that is safe and stable, that minimizes environmental impacts.

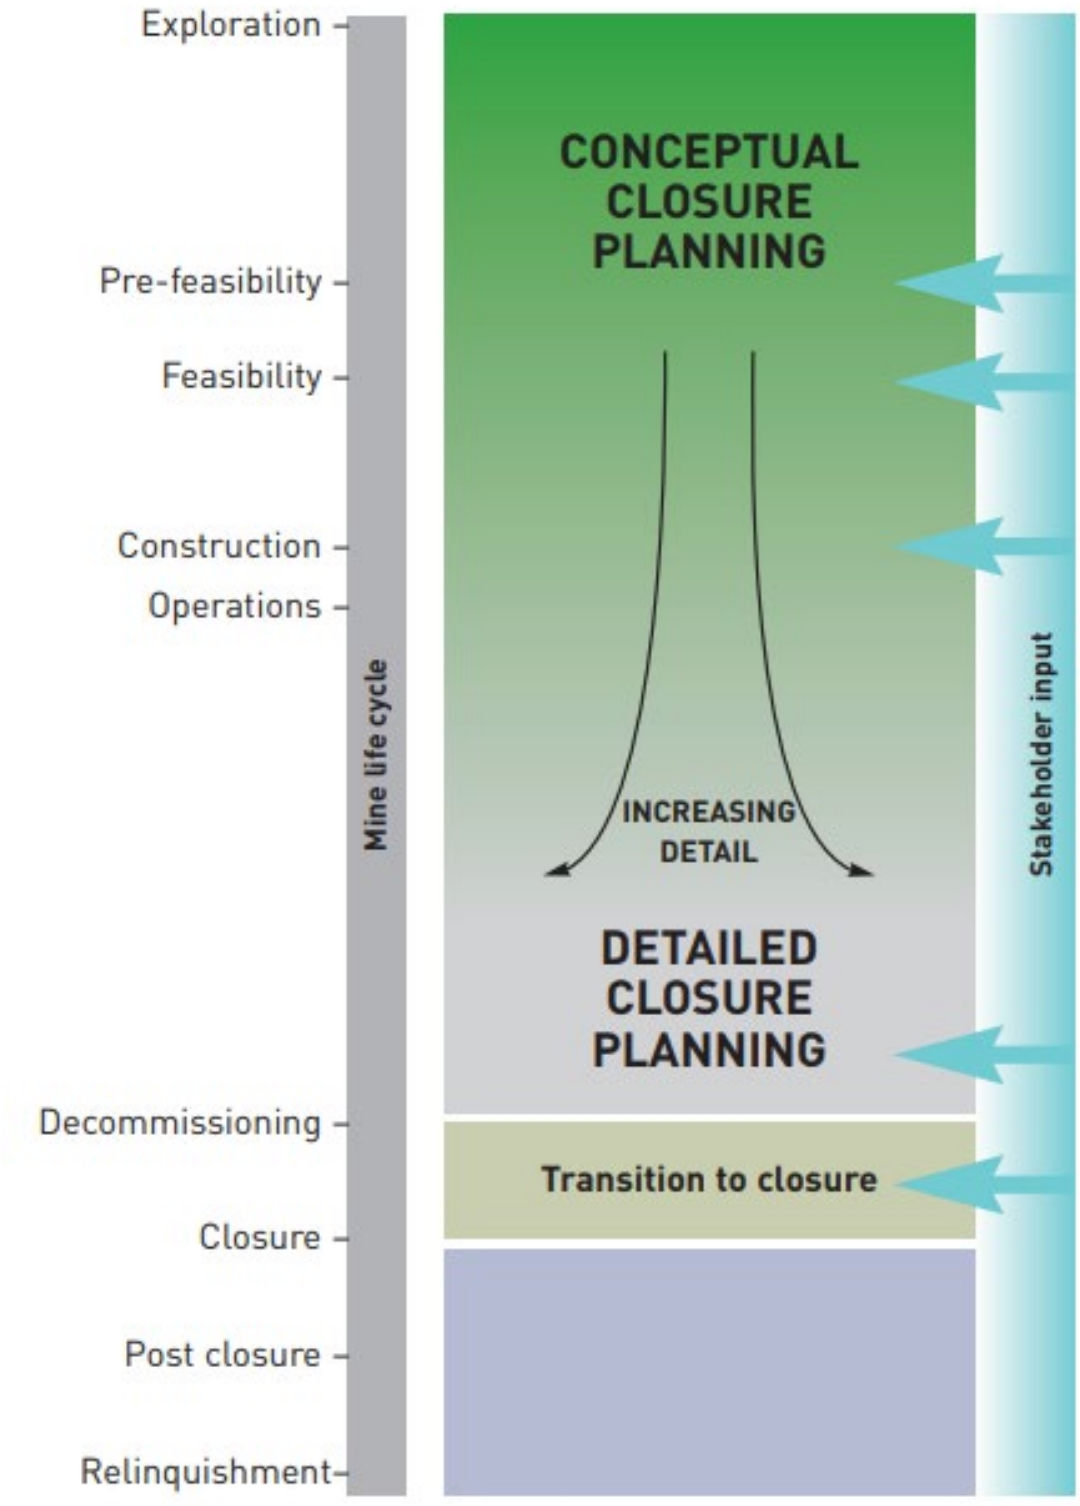

Figure 1-4 Continuous Closure Planning Concept (ICMM 2008)

1.2.1 Newmont Internal Standards

As an important part of Newmont's internal governance process, Newmont has implemented Global Policies and Standards (Global Standards) that are reviewed and preliminarily approved by a Global Policies & Standards Committee. The Global Standards provide the framework and standards for Newmont sustainability management and ensures a consistency of approach for implementing these global policies across the Company.

The Global Standards apply to all directors, officers and employees of Newmont Corporation, its subsidiaries, and any other entities that it controls. A variance request process for existing or future conditions is in place. The process provides an alternative mechanism for those instances where a Newmont site/operation cannot logistically or feasibly conform to a requirement established in a Standard due to special conditions or unique hardships. The Global Standards are intended to be fully integrated into all core business functions, and they emphasize sustainability, responsibility, and accountability at all organizational levels.

The list of Standards is provided in Table 1-1.

Table 1-1 Newmont Global Standards

Global Standards	
Air Emissions Management Standard	Land Acquisition and Involuntary Resettlement Standard
Biodiversity Management Standard	Local Procurement and Employment Standard
Closure and Reclamation Management Standard	People Policy
Code of Conduct	Product Stewardship Standard
Community Investment and Development Standard	Social Baseline and Impact Assessment Standard
Cultural Resource and Management Standard	Stakeholder Relationship Management Standard
Drug and Alcohol Policy (Coffee-Specific)	Tailings Storage Facility and Heap Leach Facility Environmental Standard
Hazardous Materials Management Standard	Tailings Storage Facilities Technical and Operations Standard
Health and Safety Policy	Waste Management Standard
Human Resources Standard	Waste Rock and Ore Stockpile Management Standard
Human Rights Standard	Water Management Standard
Indigenous Peoples Standard	

Reclamation and closure planning follows the Newmont *Closure and Reclamation Management Standard*, which identifies requirements to responsibly close and reclaim mine sites in accordance with Newmont's commitment to protect human health, community needs, and the environment, and to create a positive legacy for future generations. The Newmont *Closure and Reclamation Guidance* document provides specific requirements to implement the Closure and Reclamation Management Standard and outlines the strategies for planning and design, implementation and management, and performance monitoring in alignment with Newmont principles and philosophies. Specifically, the guidance document describes the requirements for:

- Stakeholder engagement

- Developing closure and reclamation strategy and costs
- Collaborative RCP development
- The closure planning process
- Post-mining landform criteria
- Closure and reclamation planning updates
- Record keeping
- Performance monitoring
- Data and information management.

1.2.2 Coffee Gold Mine Guiding Principles and Closure Philosophy

The Yukon Water Board emphasizes the importance of robust reclamation and closure planning, stating that it will endeavour to "…issue licences only when there is a reasonable certainty that an acceptable level of reclamation of the site can be achieved during mining and/or following cessation of mining" (YWB 2012). A principal philosophy followed during Project development of this Plan was to work towards an eventual closure that requires minimal long-term monitoring and maintenance. Newmont intends to implement a technically feasible RCP that is environmentally sound, while respecting local laws, traditional land uses, and public interests. To ensure that this closure philosophy can be achieved, the following guiding principles were emphasized during the development of the Plan:

- Protection of public health and safety.
- Designing for closure, including reclaiming disturbed areas progressively during the Operation Phase, to ensure land use commensurate with surrounding lands.
- Implementing environmental protection measures that minimize adverse environmental and socio-economic impacts (e.g., reducing affected water and controlling contaminants at source).
- Planning for long-term monitoring and maintenance, while minimizing long-term operational activities, to assess effectiveness of closure measures over the long term.

2.0 RECLAMATION AND CLOSURE PLANNING

In order to leave behind local ecosystems that are healthy, thriving, and supportive of meaningful post-mining land use, Newmont is committed to ensuring that reclamation and closure planning begins at the initial stages of a project's planning and development process and continues throughout the mine's lifecycle. Newmont believes that local communities should be involved in closure planning from the outset in order to understand the challenges and to provide an opportunity for communities to become active participants in decision-making.

As per good industry practice and YWB and EMR (2013) guidance, this RCP was developed with input from and in consideration of views of potentially-affected communities and First Nations. The following subsections describe consultation and engagement activities undertaken in support of Project planning, as well as the processes and approaches used to develop this Plan and inform the reclamation and closure planning process.

2.1 Consultation and Engagement Activities

Project engagement with potentially affected parties, including governments (First Nation, Federal, Territorial), local communities, assessment or regulatory authorities, and non-government organizations has been an essential strategy from the onset of Project planning in 2013. Newmont has focused on building relationships into meaningful partnerships, and views consultation not as a single conversation but a series of conversations allowing the creation of capacity and understanding of the Project among potentially affected First Nations and communities.

Consultation and engagement outcomes have led to a greater understanding of expectations and concerns for reclamation and closure of the Project. Input received regarding Project planning, design, implementation, and monitoring for activities or developments that are open to modification has been incorporated in order to minimize potential adverse effects and ensure the Project generates mutual benefits for all partners. Reclamation and closure planning consultation that has been carried out prior to licencing is outlined in Appendix 2-A. Engagement activities related to Project decommissioning, closure, and reclamation for licencing have been completed and will continue throughout the mine life.

Workshop discussions recently held with Newmont and First Nations have provided an opportunity for Newmont to receive various perspectives on important issues to First Nations and affected communities. These workshops have been critical to maintaining clear lines of communication between Newmont and First Nations to identify common goals to advance reclamation and closure planning. Updates based on the outcomes of these discussions have been incorporated into the RCP were applicable, and further updates based on ongoing feedback will be summarized in future iterations of the RCP. First Nation engagement and consultation is ongoing, and any feedback that is received or concerns that are heard during consultation will be incorporated into this plan, where applicable.

Examples of updates that have been incorporated to this RCP based on recent discussions include:

- A commitment to conduct a Failure Modes and Effects Analysis (FMEA) workshop with First Nations to review the base case closure measures with each iteration of the RCP (every 2 years) (Section 2.3.4.4).

- A commitment to revisit the closure alternatives assessment to include additional alternatives that are identified through consultation and engagement, and to revisit the feasibility determinations on alternatives that were considered as the Project advances (Section 2.3.4).
- Clarifying objectives of the Reclamation Research Program to include the intent of protecting the receiving environment (Section 2.3.1).
- Basing “continuous improvement” on enhancing the level of use protection in Halfway Creek (Section 2.3.1).

The outcome of additional discussions related to concerns and feedback received through these workshops will be incorporated into future iterations of the RCP. There is an expectation by all parties consulted that mine development will be carried out in a responsible manner and that measures will be put in place for the protection of the environment as well as human health and safety. In addition, the parties look to see socio-economic benefits from the mine, and that business opportunities accrue to the Yukon. Newmont will continue to consult and work with communities on reclamation and closure plan updates, which will include mitigation measures identified through the Socio-economic Monitoring Plan (SEMP) and activities related to socio-economic aspects of closure (e.g., community contributions, partnerships).

2.2 Sequences and Phases of Reclamation and Closure Planning

This RCP represents the first closure plan for the Coffee Gold Mine submitted for the purposes of mine licensing. Over the life of the mine, successive iterations of this RCP will be reviewed on a regular basis or when there is a significant material change at the site or in the local area and will be submitted at least every two years in accordance with the Yukon Mine Site Reclamation and Closure Policy (YWB and EMR 2013).

Subsequent RCP iterations will continue to advance the level of design for facilities and infrastructure, as well as additional details from lessons learned through reclamation research programs, exploration-related activities, investigative studies, and monitoring programs. Subsequent RCP iterations will provide more detail from reclamation research program and monitoring program results as well as mine operation and will have greater certainty regarding the sequence of closure and reclamation activities to occur progressively during the Operation Phase and during the Closure Phase.

Details on Project sequencing, including the anticipated submission timing of successive iterations of this RCP, are illustrated in Figure 1-4. Each RCP is only considered to be a ‘final plan’ for the period of time for which it is written, as the RCP will continue to evolve as the Project advances through the Operation Phase and into the Closure Phase.

2.3 Designing and Operating for Closure

The Project is designed and will be operated with closure in mind by integrating closure considerations into the mine’s planning and operational processes, minimizing ongoing intervention or operating activities after the completion of mine reclamation and closure activities, as well as planning for long-term monitoring.

Key elements of reclamation and closure planning include:

1) Conducting reclamation research.
2) Scheduling closure and reclamation activities to occur progressively.

3) Designing the Project to minimize effects.
4) Conducting an assessment of closure alternatives for major mine components.

These elements are described below.

2.3.1 Reclamation Research

Reclamation research that is completed or underway at the Project provides substantial direct and indirect benefits to reclamation planning and execution at the site. Knowledge gained through previous reclamation research projects will contribute to the success of achieving the overall Project goals and objectives, and on-site opportunities will be advanced during mine operations to refine various reclamation and closure techniques to achieve the Project-specific closure objectives. The reclamation research program will be advanced based on the end land use planning approach for the site as well as the component-specific closure objectives. The general intent of the programs will be based on the goal of protecting the receiving environment, with continuous improvement focused on enhancing the level of use-protection in Halfway Creek. Planning and advancement of the reclamation research program will be carried out in collaboration with First Nations during construction and operations and will incorporate inputs from continued end land use planning.

Since progressive reclamation is a key activity during the Operation Phase (Section 2.3.2), reclamation prescription testing in actual site conditions as the Project advances, including implementing an appropriate schedule, will allow for refinement prior to the commencement of the Closure Phase. Progressive reclamation opportunities will allow for reclamation prescription refinement to be directed by the ability to achieve the specific performance criteria for each major mine component throughout operations. Ultimately, broad application of successful revegetation treatments can be achieved through on-site trials during progressive site reclamation activities.

In addition to the reclamation evaluations described within this section, Newmont will continue to explore on-site opportunities to study various Project-specific reclamation and closure techniques and work with specialist consultants, First Nations, and other technical groups to address potential constraints to achieving Project-specific closure objectives. Input from Project partners, First Nations and stakeholders regarding the reclamation research program will be incorporated into reclamation planning and design on an ongoing basis; hence, the programs are expected to evolve over time.

Previous reclamation research efforts at the site have been carried out by Newmont and through the Yukon Mining Research Consortium (YMRC), which is facilitated through Yukon University in collaboration with the Natural Sciences and Engineering Research Council of Canada (NSERC). The YMRC is comprised of six major mining companies in northern Canada, including Newmont, with vested interest in developing mining reclamation research projects in northern Canada. A key part of the research process for projects carried out through the YMRC is community engagement, incorporating Traditional knowledge and First Nations world view into the projects. Collaboration on reclamation research activities between industry and First Nations through the YMRC is critical to the development of successful northern mine remediation research programs and will continue through the advancement of research programs at the site.

This section provides a summary of the reclamation research that has been completed to date for the Project, research currently ongoing, and future proposed studies, with results included where possible. The research is presented in three categories: revegetation, treatment technologies, and site characterization.

2.3.1.1 Revegetation Reclamation Research

Revegetation helps to achieve a variety of closure objectives by reducing water infiltration, providing habitat, limiting erosion, and meeting aesthetic expectations (YWB and EMR 2013). Newmont is committed to an adaptable revegetation research program based on the continued end land use planning that will allow the local ecosystem to be left in a healthy state that is supportive of meaningful post-closure land use. The program will be developed with the overall objective of developing successful revegetation protocols throughout mine planning and development for broad application in closure. Outcomes from the program are intended to inform the closure measures and implementation strategies for the site, as well as increase the level of confidence that Project-specific closure objectives will be met.

Component-specific revegetation prescriptions have not yet been evaluated in the early stages of the Project; however, they will be developed as the Project advances, and land use plan evolves, and reclamation material becomes available. Seed sourcing for the revegetation research programs will be carried out through integrated community involvement incorporating Traditional knowledge as well as outcomes of previously completed reclamation research programs. Areas of the Project that are currently identified for revegetation prescriptions as part of final reclamation and closure measures include:

- Disturbed areas around open pits
- The disturbance footprint of the soil stockpiles
- The HLF and event ponds
- Ore crushing and stockpile areas
- Plant site
- Camp site
- Disturbed areas where water management infrastructure has been removed
- Haul roads and mine site roads
- Laydown areas
- Bulk Explosive Storage Area
- Land Treatment Facility.

Other areas, such as the NAR and airstrip, will have surface preparation to promote vegetation establishment without active seeding or planting conducted.

Completed Revegetation Research Programs

Various revegetation research projects have been completed at the Project to support the preliminary development of revegetation prescriptions, including site preparation techniques, and seed collection and mapping. Details of the revegetation research that has been conducted for the Project are provided in Appendix 2-B and are summarized below.

- **2013 Demonstration Site Program – investigation of site preparation techniques and prescriptions:** An assessment of vegetation regeneration success involving combinations of

mechanical reclamation[1], raking pre- and post-seeding, seeding, and bio-engineering in various site prescriptions was initiated in 2013. The assessment was carried out at demonstration sites disturbed by previous exploration activities, including 1m^2 monitoring plots, and cut slopes. In 2015, percent coverage measurements were collected at the site to determine establishment success.

- **2015 Seed Program and Candidate Reclamation Species – seed collection, inventory, and mapping exercise:** A seed collection, inventory and mapping program was implemented in 2015 to determine target plant species for site restoration. In conjunction with this program, Newmont supported the development and implementation of two training programs in partnership with TH and Yukon College, including the Centre for Northern Innovation in Mining and the Yukon Research Centre. These training programs (Introduction to Environmental Monitoring Pilot Project and Northern Terrestrial Restoration) were provided to local First Nations students to promote awareness and understanding of environmental monitoring requirements and to offer students the opportunity to gain experience in experimental design, field sampling techniques, and native seed collection.

  Disturbed and undisturbed vegetation communities were surveyed to identify species naturally recolonizing disturbed areas. A seed source map for target revegetation species was created that integrated both scientific knowledge as well as traditional ecological knowledge from TH elders. The seed map exercise identified over 30 native plant species for potential use in revegetation at the site from 26 different locations.
- **2015 Greenhouse Trials – soil amendments and ecosystem recovery processes using arctic lupine:** At the Yukon Research Centre, greenhouse laboratory experiments using Arctic Lupine[2] were conducted in 2015 to test the relationship between soil amendments and the recovery of ecosystem processes. The greenhouse trials identified the potential for the return of natural ecosystem processes, such as nitrogen fixation, following ecosystem disturbance.
- **2015 Plant-root Interface Study:** This study included the characterization of the rhizosphere (i.e., plant-root interface) of northern native plants that are potential candidates for restoration to increase the understanding of mechanistic linkages between the composition and structure of plant roots, soil bacteria, fungi, archaea, and critical ecosystem functions as restoration proceeds.
- **2015 Plant-soil Transplant Trials:** This study examined the response of plant-soil plugs transplanted onto disturbed drilling fences. The evaluation involved establishing a plot on an existing drill pad and planting plugs from undisturbed subalpine areas within the plots. Growth within the plots was monitored for two years following planting to determine aboveground and belowground growth from the plugs, including identifying the vegetation within the plot, and estimating percent coverage of each vegetation type as well as over the total area.
- **2015 Temporary On-site Nursery:** Environmental Monitors and students from the Northern Terrestrial Restoration program established a temporary nursery at the Coffee exploration camp in 2014 and 2015 as part of a pilot project and participated in native seed potting trials and target species transplants. Newmont will continue to explore options for establishing a nursery.

[1] Mechanical reclamation involved the use of machinery and manual labor to replace the original vegetation layer from where it was removed.
[2] *Lupinus arcticus* - a common native species found at the Project site that promotes ecosystem processes.

Ongoing Revegetation Research Programs

Revegetation reclamation research studies that have been initiated and are currently underway for the Project include:

- **2014 Roadside Stakes and Bundles Plots:** An evaluation of the potential implementation of vegetation plots as an erosion and slumping control measure was initiated in 2014. The evaluation involved planting willow, birch, and balsam poplar cuttings as stakes (vertical cutting placement) or bundles (horizontal cutting placement) in three plots on the upslope side of Java Road. Annual observations are made at the plots to measure and record sprouting success rates.
- **2015 Revegetation and Soil Amendment Trials:** The Yukon Research Centre and Kaminak established revegetation and soil amendment trials in 2015 to test various reclamation techniques in different ecotypes present at the site. These trials were established at the site in conjunction with the Northern Terrestrial Restoration course. The trials are intended to assess various combinations of reclamation techniques including the addition of organic matter applied as a soil amendment, fertilizer, and/or seed. The trials are surveyed on an annual basis. Results from the research trials thus far have demonstrated that organic matter and fertilizer amendments have little to no overall effect on germination rates. However, the addition of fertilizer has affected the percent cover of vegetation found growing at sites, suggesting that aboveground biomass production can be promoted by the use of commercial fertilizers.
- **2021 Revegetation Research Project:** The project conducted by Yukon University through the YMRC aims to define revegetation success within the context of local community expectations, and also evaluates the implementation of living and/or non-living snow fences for a successful revegetation program. Local submissions to public engagements related to mining were reviewed to carry out the first component of the research program. The second component of the research program was initiated in 2021 at a nearby mine site and will be carried out over a period of four years to determine the effect of vertical structures (snow fences) on soil moisture and nutrient profiles. Green alder (*Alnus viridis* subsp. *crispa*), smooth-leaf mountain avens (*Dryas integrifolia*), and soapberry (*Shepherdia canadensis*) snow fences will be evaluated as living snow fences for their effect on revegetation success, and orange fence structures will be used to evaluate the effect of a non-living snow fence on revegetation success. Species selection for revegetation will be based on local expectations of reclamation success. The Year 1 Progress Report for this research program including details of the experimental design is provided in Appendix 2-C.
- **2023 Seed Collection / Seed Bank Program:** Newmont is currently updating the seed collection / seed bank program through Yukon Seed & Restoration that was initiated in 2015. The seed collection / seed bank program is aimed at updating the previous inventory and identifying the native seed sources for the Coffee site in support of the re-establishment of local populations during progressive reclamation. The seed collection / seed bank program will be informed by First Nations traditional knowledge and will be used to support the advancement of the Revegetation Research Project that is ongoing through Yukon University.

Proposed Future Revegetation Research Programs

Advancement of the revegetation research program will occur early in Project development as disturbed areas and reclamation materials become available. Future revegetation research will focus on, but will not be limited to, gathering information in the following areas:

- Bioclimatic zones
- Seasonal windows
- Component-specific target species, seed types and seeding rates
- Propagation methods, life cycles, successional tendencies
- Effects of elevation and/or aspects
- Fertilizer types and application rates
- Evaluation of cover materials (nutrient/moisture profiles).

Specific programs that are proposed for future revegetation reclamation research include the following:

- **Evaluation of natural regeneration on exposed waste rock surfaces** - Further evaluations of successional processes and natural regeneration on exposed waste rock will be established through field trials during mine development to inform the re-establishment rates of vegetation in the Alpha WRSF in closure. Field trials for this program would require areas of exposed waste rock, potentially segregated by waste rock type (i.e., schist, gneiss, and granite), and/or by material type.

  Planning of field trial locations will consider proximity to a natural seed source to supply the propagules necessary for natural regeneration as it is unlikely that waste rock material holds any viable seed bank. Field-based investigations will consist of surveys of existing vegetation on disturbed sites, and revegetation trial plots or vegetative ribbons. Revegetation trial plots and ribbons will typically be multi-year studies. Monitoring of trial plots or ribbons will be performed to quantify vegetation growth, condition, and potential inter-species effects. Annual trial plot data will be compared to identify trends in cover change, growth, species composition, and many other factors.

  A representative location will be selected for the trials during the construction phase, which may include the ROM Stockpile, the waste management area, or the Alpha WRSF. The trials are proposed to be carried out for a minimum of 3 years starting in Year 2.
- **Metals uptake in vegetation** – A program designated for vegetation tissue metal sampling of targeted species (ex. Country foods and diet species of key wildlife species) will be established at select locations, onsite and offsite. Designated sampling locations may include vegetated areas in each type of waste rock (i.e., schist, gneiss, and granite). Vegetation metal sampling is often completed in conjunction with soil sampling locations and assessments of metals concentrations in soil. Vegetation sampling methodology and laboratory analysis will be consistent with vegetation sampling and analysis guidelines provided in the Vegetation Monitoring Plan. Analysis of results would involve a comprehensive desktop review to applicable guidelines and toxicity thresholds to inform a human health risk assessment, in the context of food chain and exposure routes. The human health risk assessment will also be informed by First Nations input regarding potential land use patterns, species types, and site-specific consumption estimates.

  This program will likely occur in similar locations and on a similar implementation schedule to the natural regeneration on exposed waste rock surfaces evaluation. This evaluation may also be carried out as part of the HLF cover revegetation trial described below and will be monitored through implementation of the metal uptake monitoring described in the Vegetation Monitoring Plan.
- **HLF Cover System Revegetation Field Trial Program** – A field-based program for researching revegetation of the HLF cover system will commence once surface area and material is available on the completed Stage 1 of the HLF. The field study will focus on revegetation trials on the cover systems planned for closure of the HLF. Test plots will be established on each cover system,

incorporating a type of experimental design that allows for the statistical comparison of revegetation measures (such as the rate of fertilizer application) and control of external variables (such as spatial differences in substrate). The design layout and data analysis will provide more definitive information on the true effects of revegetation treatments such as fertilizer application or the effects of aspect.

Monitoring of trial plots will be performed to quantify vegetation growth, condition, and potential inter-species effects. Annual trial plot data will be compared to identify trends in cover change, growth, species composition, and many other factors. In addition, container tests of various HLF cover systems may be considered as a cost-effective option for single season evaluations such as testing propagation methods of select species. Results of these investigations will inform the final revegetation measures for individual site components and will be used to determine the criteria for performance inspections and monitoring programs.

The HLF cover revegetation trial plots will be established on the HLF once Stage 1 has been constructed to the maximum extent, and a trial cover has been established, estimated to occur in Year 6. The development of a detailed workplan plan will begin in Year 4.

2.3.1.2 Treatment Technologies Reclamation Research

Completed Treatment Technologies Research

Reclamation research studies that have been completed to evaluate treatment technologies at the site include:

- **Phase I – HLF Water Treatment Plant Treatability Assessment:** A treatability assessment and proof-of-concept for the removal of nitrate, arsenic, and uranium from leach waters was conducted in 2016, and consisted of laboratory assessment tests and evaluation of site water chemistry. Tests included a site water chemistry evaluation, microbial screening tests and treatment effectiveness assessment, Electro-BioReactor (EBR) validation testing, and in-situ denitrification testing. Phase I testing demonstrated removal of nitrate, arsenic, and uranium, and suggests the biological treatment would be effective at removing the contaminants of concern. Details regarding the Phase I treatability assessment are provided in Appendix 2-D.
- **Phase II – Bench-scale Testing:** Continuous flow laboratory column tests were established to develop the overall treatment approach for HLF waters. Testing within this phase removed contaminants of concern to below discharge targets and suggested a multi-stage treatment train as the most effective treatment approach. The recommended multi-stage train consists of physico-chemical pre-treatment, biological EBR treatment, and aerobic post-treatment. The Phase II testing established preliminary design and operational parameters for future on-site pilot-scale test work (Phase III). Details regarding the Phase II bench-scale testing are provided in Appendix 2-D. Appendix 2-D also provides a timeline for completion the HLF water treatment evaluations.
- **Pre-feasibility Level Lab-scale Study - In situ passive treatment of HLF drain down solutions:** A workplan describing the activities to support the feasibility assessment of permeable reactive barrier (PRB) technology at the Project was prepared by Lorax Environmental Services Ltd. and is provided in Appendix 2-E. A laboratory column experiment was conducted in collaboration with Lorax and Newmont to evaluate the use of PRB and biological reactor technologies to treat arsenic, nitrate and uranium in HLF rinse water. Three treatment system configurations were established in

plexiglass vertical columns to assess the treatment of drain down seepage in various mediums. The study was intended to demonstrate proof of principle for the effectiveness of in situ treatment of constituents within the heap, as well as to evaluate a dissolved organic carbon amendment for nitrate treatment.

Study findings indicated that treatment systems operating at a 96-hour hydraulic retention time (HRT) were able to reduce arsenic and uranium concentrations. Additionally, carbon amendments improved nitrate removal within some treatment configurations at an increased HRT. Treatment of some metals, including aluminum, antimony, and selenium, was also reported. An analysis of column residues to determine arsenic and uranium removal mechanisms will be carried out as part of the next steps for this research project. Details of the study and results are provided in Appendix 2-F and Appendix 2-G.

Proposed Future Treatment Technologies Research

Proposed reclamation research projects to evaluate treatment technologies at the site include:

- **Feasibility Level On-site Pilot-scale PRB Treatment (Closure Phase):** A semi-passive treatment system based on the principles of PRB technology is being considered for the Closure Phase of the Project as described in the feasibility assessment work plan (Appendix 2-E). Parameters for the on-site pilot-scale test work will be based on results of the pre-feasibility lab-scale PRB study (Appendix 2-F).

  Should passive treatment be required for closure, field scale PRB treatment trials will be proposed near the HLF once Stage 1 of the HLF has been constructed to the maximum extent, estimated to occur in Year 6. The PRB treatment trials would include an evaluation of potential methods for nitrate reduction prior to treatment within the PRB.

  Development of a detailed workplan for the PRB treatment system will begin in year 4. Construction and commissioning of the small-scale passive treatment system would occur during the first two years of the program, followed by approximately three years of data collection, analysis, and system optimizations. The piloting program would be expected to produce results in approximately Year 10. The specific objectives of each phase of the on-site passive treatment piloting program will be refined prior to implementation should this research program be advanced.

  A workplan that includes specifics for the PRB treatment system, including treatment system objectives and implementation schedule, will be provided in the next iteration of the RCP. An annual report will be prepared to provide an update on work that has been completed to advance the PRB treatment system design, work that is progressing, and work that is still outstanding prior to finalizing PRB implementation.

2.3.1.3 Site Characterization Reclamation Research

Completed Site Characterization Research

Site characterization reclamation research studies that have been completed to evaluate site conditions and optimize closure activities include:

- **2017 Soil Nutrient Testing:** Three topsoil samples from within the footprint of the HLF were tested to measure the soil's ability to retain positively charged nutrients (e.g., Ca^{2+}, Mg^{2+}, K^{+}, NH^{4+}) and

provided an indication of soil moisture retaining characteristics. The results are provided in Section 4.1.5.4.

- **2017 Coffee Mine Site Area Testpitting Program:** 42 drill holes and 72 test pits were completed in 2017 by Tetra Tech to investigate the composition, diggability, and thickness of the overburden in the Mine Site area, which provided a material balance. Additional work was completed by JDS in 2018. Reports for the 2017 and 2018 testpitting work are provided as Appendix 2-H and Appendix 2-I, respectively.
- **2018 Preliminary Ecohydrological Modelling Study:** Preliminary ecohydrological modelling that links conventional reclamation actions and surface water balances was carried out by Integral Ecology Group on potential cover and mine-waste materials. The objective of this work was to provide information on the following:
  - Volumes/depths of materials required for rooting-zone layers of reclamation cover systems, given available material properties and closure objectives.
  - Appropriate vegetation species for reclamation, given landform and cover-system characteristics.
- Expected hydrologic and ecologic performance trajectories for resulting ecosystems, including:
  - expected development of vegetation cover/leaf area over time.
  - expected development of evapotranspiration (ET) on reclamation cover systems over time.
  - expected resultant surface water-balance terms over time (e.g., runoff/interflow/net percolation).

The results of the ecohydrological modeling study are provided in Appendix 2-J.

Proposed Future Site Characterization Research

Proposed site characterization reclamation research studies include:

- **HLF Cover design optimization:** Additional research to optimize the HLF cover design including infiltration, erosion, and stability are proposed at the site. Cover design optimization is also proposed to evaluate various cover materials and aspects. This may involve a desktop review of all available information on HLF cover designs, modelling exercise, as well as field investigations to further characterize the properties of the proposed cover.

  Research on cover design optimization will incorporate outcomes and/or elements of the proposed HLF revegetation research program and will help inform the design of a cover system performance monitoring program. The program will be carried out on the HLF in an area that will be undisturbed, once Stage 1 of the HLF has been constructed to the maximum extent, estimated to occur in Year 6. Detailed workplan development will begin in Year 4. Outcomes of the trials may inform potential modifications to the current cover design described in Section 7.3.1 to improve site environmental performance and/or reduce water treatment needs.
- **Site cover design optimization:** Detailed evaluations of the cover design for site facilities, pads, and decommissioned infrastructure (i.e., roads) will be carried out to optimize and refine the proposed cover strategy for the site. At this time, cover placement at closure is based on the reclamation material prioritization evaluation (Section 7.2.4). The cover design optimization program will be carried out to determine cover performance (infiltration), erosional control performance and cover stability of various available reclamation materials once the materials and

representative areas that will not be disturbed become available. The evaluations will consider various aspects and slope angles and may include additional testpitting to further characterize reclamation material types and available volumes.

A representative location will be selected for the trials during the construction phase, which may include the ROM Stockpile, the waste management area, or the Alpha WRSF. The trials are proposed to be carried out for a minimum of 3 years starting in Year 2.

- **Soil nutrient assessment:** A detailed assessment on the nutrient profiles within various types of soil/reclamation materials at the site may be proposed to support the revegetation research program and to optimize revegetation efforts for each component based on growth medium that is available. This may include characterization of salvaged materials, including overburden and subsoil materials as well as a reference ecosystem with a similarity index to the salvaged material. Soil sampling locations will be selected as sites typical of the soils that the samples are intended to represent. Samples of undisturbed soils would generally be collected on a horizon or homogenous layer basis. Whereas salvaged soils would be collected on the basis of type of material, such as subsurface and overburden material, and on depth intervals within each discrete layer. Depth of sampling will be determined based on the type of material present.

  Nutrient sampling and analysis will be conducted and will likely include at least particle size distribution, percent saturation, electrical conductivity, soluble cations, cation exchange capacity, total nitrogen, total carbon, and macronutrient analysis as well as pH. Results of soil nutrient assessments will be used to establish criteria for evaluating reclamation material. The assessment will commence during site excavation activities and will be carried out at a pre-determined frequency throughout the Operation Phase within the soil stockpiles area.

2.3.1.4 Reclamation Research Implementation Schedule

The implementation schedule for reclamation research considers the overall intent of the reclamation research program to optimize preparedness and procedures for closure of specific mine components. Reclamation knowledge gained early in the construction and operation phases allows for maximum preparedness as well as early refinement of reclamation measures, subjective of continued end land use planning for the site. In addition, reclamation research will generally be carried out using areas and materials that are representative of the actual conditions encountered during closure of applicable mine components. Thus, reclamation research programs are planned to be implemented as early as possible once representative areas and materials become available.

Planning for the implementation of the proposed reclamation research programs will occur prior to and during the construction phase, and workplans will be developed with First Nations and affected communities presenting the approach to each proposed research program. Planning will include selecting representative areas and determining the source of materials that will be used for the reclamation research programs, which will consider the specific needs of each program. Workplans will be advanced during operations to refine the specific locations, materials, timelines, and overall approach to implementing the research programs.

Figure 2-1 provides an overview of the estimated implementation schedule for reclamation research programs as well as the estimated timeline for reclamation research program reporting. The schedule will be refined during operations and provided in future iterations of the RCP and will be primarily associated with mine advancement during each LOM milestone.

Key Activity	Project Phase and Year																							
	Permitting		Construction		Operation									Post-mining Closure						Active Closure					Post-closure
	-4	-3	-2	-1	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21+
Seed Collection / Seed Bank Program																									
Revegetation Research Project (Yukon University)																									
Natural regeneration on exposed waste rock surfaces																									
Metals uptake in vegetation																									
HLF cover system revegetation trials																									
On-site pilot-scale PRB treatment (Closure Phase)																									
HLF cover design optimization																									
Site cover design optimization																									
Soil nutrient assessment																									
*Green highlighted cells indicate years that a report will be produced presenting the outcomes of the research that can be used to inform closure activities.																									

Figure 2-1 Estimated Implementation Schedule for Reclamation Research Activities

2.3.2 Progressive Reclamation

A key element in designing for closure is the incorporation of progressive closure activities including contouring, backfilling, and re-vegetating areas no longer needed for mining during active operations, where practicable. Progressive reclamation will provide opportunities to optimize the reclamation research program in existing site conditions, and will also advance the return of disturbed areas to self-sustaining biological ecosystems, increase confidence and continual improvement in long-term reclamation success, and reduce the overall final cost of reclamation by taking advantage of operational efficiencies. Newmont intends to maximize all opportunities for the operational implementation of progressive reclamation activities. Specific activities that are currently planned to occur progressively during the Operation Phase (Years -1 to 9) include the following:

- Implementation of the reclamation research program.
- Continuous salvage and stockpile of reclamation material including overburden stripped during operations (i.e., expansions of pits, development of new areas). Stockpile management during operations will be imperative to ensure that suitable reclamation material is available at closure. Strategic stockpile placement will also reduce costs associated with long haul distances and reduces requirements to re-handle material.
- Progressive reclamation of disturbed areas within the Mine Site footprint that are no longer required to support mine operations, including rough and loose site preparation and revegetating inactive areas as soon as practical.
- Progressive closure of haul and mine site roads no longer required to support operations.
- Reclamation of exploration areas (re-grade, scarify, and revegetate roads, fill and revegetate trenches) when access is no longer required.
- Proper construction and maintenance of water management structures (channels, ditches, berms, settling basis, etc.) during operations. In the context of these progressive reclamation activities, it is imperative that water management and erosion and sediment control around reclaimed areas is carefully planned to maximize reclamation success, limit the need for future disturbance, and divert clean water away from project areas.
- Regular removal of recyclable / salvageable material and equipment, using available back-hauls during the Operation Phase.
- Minor re-sloping of the Alpha WRSF near the end of the Operation Phase to maintain an overall slope of 3:1, achieve long-term physical stability criteria and appropriate water conveyance for closure.
- Near the end of the Operation Phase, material stored in the frozen soil storage area (FSSA) and deemed unsuitable for reclamation will be co-disposed in the Alpha WRSF. Placement methods, layer continuity, spacing, and thickness will be designed to ensure final stability of the Alpha WRSF landform.
- Partial backfill of Latte and Supremo Pits and closure of disused haul roads.
- Complete backfill of Kona Pit and Double Double Pit, and closure of disused haul roads.
- Progressive regrading of the HLF near the end of operations to maintain the base case closure design.
- Installation of water treatment facility and commencement of water treatment of excess water from the HLF.

Progressive reclamation effectiveness monitoring will be carried out through routine monitoring and visual inspections of progressively reclaimed areas. Results of the effectiveness monitoring will be compared to the performance targets and component-specific closure objectives for the facilities that have been reclaimed. The results will also be compared against the outcomes of reclamation research that has been completed to date. Results of the progressive reclamation effectiveness monitoring program will be used to inform future reclamation research programs and will be used to refine or optimize the closure measures for each facility.

2.3.3 Minimizing Project Effects

The Project has been designed and will be constructed and operated to minimize environmental and socio-economic effects. For example, the use of diversions to minimize the amount of non-contact water from becoming exposed to mine-related contaminants has been incorporated into the water management infrastructure design. Project design has also incorporated various measures for controlling contaminants, such as waste segregation, specific waste storage locations, liners, covers, water collection and treatment, and others. Such measures are described for the various Project components in Section 5.

Conservation of soil is also a very important aspect of minimizing effects, and erosion and sediment control measures will be implemented in all Project phases. Measures to prevent soil loss may include:

- Minimizing the size of the disturbed area (e.g., Project footprint).
- Maximizing the retention of natural vegetation cover and maintaining vegetation buffers (particularly near water).
- Avoiding or minimizing work in unstable areas and steep slopes and limiting disturbance of permafrost.
- Scheduling construction activities and the installation of perimeter sediment controls to mitigate sedimentation in higher risk areas.

Another important aspect of minimizing long-term Project-related effects is to reduce the potential for the establishment of invasive plant species. For this, Newmont has developed several mitigation measures and monitoring activities for implementation during mine operations, which will reduce and mitigate the potential for establishment of invasive plants at the mine in closure. The annual invasive plant surveys will be carried out along the proposed NAR alignment south of the Stewart River, from Maisy May to Ballarat and including the Coffee mine site.

With respect to minimizing long-term adverse social effects, potential risks will be minimized through careful planning and collaboration with Project partners, stakeholders, and First Nations to achieve a holistic understanding of the social context and to create corresponding management plans to monitor and manage risks. Socio-economic monitoring and mitigation measures to minimize potential negative effects to local communities and individuals will be described in the SEMP as well as in future iterations of the RCP.

2.3.4 Alternatives Assessment Overview

Throughout the closure planning process, Newmont has identified and assessed alterative options for closing the major mine components to achieve the Project-specific closure objectives as well as the closure vision for the site. The Closure Alternatives Assessment Report (Appendix 2-K) describes the approach to assessing the various alternative options and identifies the current base case design for closing the major

mine components. The base case closure measures may be re-evaluated as the end land use planning for the Project is advanced in alignment with a final landform that reflects the interests of all stakeholders, First Nations, and the local community. Therefore, although this alternatives assessment was carried out to verify a base case closure design, the process will remain open to including additional alternatives that may be identified through ongoing engagement and Project planning, as well as revisiting the feasibility determinations for each alternative as detailed designs are advanced.

A description of the alternatives assessment process and outcomes are provided here, a summary is provided in Table 2-1, and the detailed report is provided in Appendix 2-K.

The Project mine plan is designed to integrate closure considerations into the planning and operational processes; therefore, the alternatives assessment included both the location of facilities and infrastructure as well as the measures to close them. Specifically, the following aspects were assessed, as relevant to the major mine components:

- Component location for supporting mine development and Coffee Gold Mine closure objectives.
- Means of reclaiming and closing or decommissioning components to meet Coffee Gold Mine closure objectives.
- Timing of closure, involving the reclaiming and closing components either progressively or post-mining.

In the absence of specific Yukon guidance on the assessment of alternatives, this alternatives assessment has been conducted in accordance with the requirements of the *Canadian Environmental Assessment Act, 2012* (*CEAA;* Government of Canada 2012) and the Operational Policy Statement: Addressing "Purpose of" and "Alternative Means" under CEAA 2012 (OPS; Government of Canada 2015). The four steps outlined in OPS to determine the preferred means are as follows:

- **Step 1:** Identify technically and economically feasible alternative means
- **Step 2:** List their potential effects on valued components
- **Step 3:** Select the approach for the analysis of alternative means
- **Step 4:** Assess the environmental effects of alternative means.

These steps were modified in this assessment to evaluate relevant aspects of each component (i.e., both component location and closure measures), optimize and integrate workshop discussions, and to identify 'base case' closure alternatives. The steps that were followed for this assessment are as follows:

- **Step 1:** Identify technically and economically feasible alternative means
- **Step 2:** Identify Potential Effects on Coffee Closure Values
- **Step 3:** Identify Preferred Alternative Means
- **Step 4:** Failure Modes and Effects Analysis.

The following aspects were considered in this assessment:

- Backfilling of open pits
- Location of waste rock storage facilities
- Cover for water rock storage facilities

- Location of heap leach facility
- Cover for heap leach facility
- Decommissioning of water management infrastructure including the Alpha Dam/Pond and west diversion
- Decommissioning of the NAR.

Alternatives to the location and/or closure of other Project components such as mine site roads, haul roads, and buildings have not been evaluated further than what was described in the YESAA Project Proposal, as this type of infrastructure is currently planned to be decommissioned and reclaimed as per Yukon Government requirements or guidelines (EMR 2006, EMR and YWB 2013).

2.3.4.1 Step 1: Identify Feasible Alternative Means

Technical feasibility relates to the appropriateness of an alternative from an engineering or operational perspective and incorporates aspects of known performance, reliability, and implementation for the Project. Economic feasibility of an alternative relates to the overall costs including capital, operating and maintenance, as relevant to the closure aspect. The following approach was taken to identify and describe technically and economically feasible alternative means of closing the Project:

- Select potential alternative means
- Develop criteria to measure the technical and economic feasibility of the alternative means
- Identify the alternative means that are technically and economically feasible based on qualitative evidence and professional judgment
- Document the rationale for the alternative means retained for further consideration in the assessment.

The selection and feasibility assessment of alternative means was informed by a review of available reports, consultation with qualified professionals, and input from various levels of government and First Nations in support of the Yukon Environmental and Socioeconomic Board (YESAB) Executive Committee Project Proposal. Feedback received during various evaluations carried out during Project review under YESAA, including the Preliminary Project FMEA (Appendix 2-L), were integrated into this assessment process. The following technical criteria were used to evaluate the technical feasibility of each alternative:

- Long-term chemical and/or geochemical stability
- Long-term physical stability of infrastructure or facilities
- Physical stability of cover material
- Quantity of natural cover material available
- Ability to meet technical design criteria
- Ability to be progressively reclaimed
- Supports the mine development plan with respect to mining stages
- Location or design provides required capacity/storage
- Does not impound water.

The following economic criteria were used to evaluate the economic feasibility of each alternative:

- Cost to implement is acceptable
- Will not result in resource sterilization
- Maintenance liability is finite.

If an alternative was considered to not meet one or more technical or economic criteria, it was no longer considered a viable option and was eliminated from further consideration. Where technical and economic feasibility screening identified only one feasible closure option, this option was advanced as the base case, and no further evaluation was conducted. Where more than one feasible closure option was identified, the options were advanced for further evaluation under Step 2 of the assessment. Details of the feasibility screening are provided in Appendix 2-K.

2.3.4.2 Step 2: Identify Potential Effects on Coffee Closure Values

Alternative closure measures that were identified as feasible during Step 1 were advanced for further consideration in Step 2 to compare the merits of each alternative in relation to the Project-specific closure values that may be adversely or beneficially affected by them. The assessment was carried out at a level sufficient to distinguish the relative merits of the different options based on the consideration of the advantages and disadvantages of each. The following closure values were selected to represent the intermediate components (ICs) and valued components (VCs) of the Project in this step of the assessment:

- Physical and chemical stability
- Health and safety
- Ecological processes and functions
- Land use
- Socio-economics
- Aesthetics.

The Step 2 evaluations were carried out through workshops held with TH and SFN in August 2018. The closure values were assigned a weight to provide a relative scoring matrix, and the feasible alternatives were ranked to indicate the relative effects on each closure value between alternatives. Based on the descriptors of the advantages and disadvantages of each alternative, the preferred alternative(s) was identified under Step 2 of the assessment, and alternatives requiring further evaluation were identified. The alternatives were then advanced to Step 3 to carry out the additional evaluations and identify the base case closure measures. The alternative rankings carried out under Step 2 are described in Appendix 2-K.

2.3.4.3 Step 3: Identify Preferred Alternative Means

The intent of Step 3 of the assessment was to inform the selection of alternatives that would be identified as the base case closure approach by carrying out the technical and economic evaluations on the alternatives that were identified as requiring additional evaluation. The evaluations that were carried out for select alternatives are described in Appendix 2-K, and include but are not limited to:

- Economic evaluations
- Water management evaluations
- Water quality/balance modelling
- Material balance evaluation

- Cover material performance
- Cover material prioritization
- Cover slope/sediment and erosion stability
- Heap seepage rate
- Infiltration/draindown modelling.

Based on outcomes of the evaluations, as well as results of the Step 2 evaluations, the base case closure measures were identified, and are summarized in Table 2-1. The material balance evaluations will be advanced throughout operations as well as the end land use planning, which may require further evaluation and consideration of alternatives that were not identified as the base case for closure during this Step 3 evaluation.

Additional assessments will be conducted as part of the reclamation research program throughout operations in existing site conditions to optimize the performance of reclamation material. The reclamation research program will include evaluations of cover thickness/type, as well as cover system revegetation capacity and infiltration. Results will be integrated into the closure plan to optimize site reclamation activities.

2.3.4.4 Step 4: Failure Modes and Effects Analysis

The FMEA was completed under Step 4 of the assessment to identify and prioritize key risks of the base case design in order to outline strategies for risk mitigation and maximize risk control resources. A workshop was held in February 2022 to collaboratively rank the failure modes that were identified with respect to the overall objectives for the Project. During the workshop, ten failure modes were evaluated as severe or high-risk. No identified failure modes were evaluated as a fatal flaw that would require modification of the base case design. A residual risk assessment determined that all unacceptable risks could be mitigated, with the exception of three high-risk rankings related to major life of project cost consequences, which were identified as acceptable given the current Project definition.

This FMEA workshop was carried out internally to identify fatal flaws to verify the base case closure design. Future FMEA workshops will be held with every RCP update for alignment with end use planning goals. The future FMEA workshop discussions will include First Nations participation. The FMEA Summary Report is provided in Appendix 2-M.

Table 2-1 Summary of Closure Alternatives Evaluation

Mine Component Considered		Feasible Alternative Means
Open Pit Backfilling	Latte Pit	**Partial backfill- backfill used as haul roads**
		Partial backfill- backfill for other purpose
		Complete backfill – progressively
		Complete backfill – end of mine life
	Double Double	No backfill
		Partial backfill
		Complete backfill
	Kona	No backfill
		Partial backfill
		Complete backfill
	Supremo	**Partial backfill- backfill used to optimize mine development**
		2 WRSFs - West & South
		1 WRSF - Alpha
	Waste storage duration for Kona waste	Temporary Beta WRSF Location
		Permanent Beta WRSF Location
		All Kona waste rock to primary WRSF
Waste Rock Cover	Overall slope steeper than 3:1 but flatter than angle of repose	No cover
		Partial cover on flats
	Overall slope 3:1[1]	**No cover**
		Partial cover on flats
		Complete cover
	Overall slope flatter than 3:1[2]	No cover
		Complete cover

Mine Component Considered		Feasible Alternative Means
HLF Location	**2016 Feasibility Study leach pad**	
	Valley C leach pad	
HLF Cover	2016 Feasibility Study leach pad	*Partial cover*
		(1) 2.5:1 construction and closure slopes; Geosynthetic Clay Liner (GCL) installed on flat surfaces progressively
		(5b) 2.5:1 construction and 3:1 closure slopes by re-grading during closure (wings); GCL installed on flat surfaces progressively and on wings at closure
		(8, 8a) 2.5:1 construction and 3:1 closure slopes by buttressing slopes with waste rock progressively; GCL installed on flat surfaces progressively
		Complete cover
		(5a) 2.5:1 construction and 3:1 closure slopes; all surfaces covered with GCL progressively
		(4) 3:1 construction and closure slopes; all surfaces covered with GCL progressively
		(7) 2.5:1 construction and closure slopes; all surfaces covered with GCL by keying into slopes
		(8b) 2.5:1 construction and 3:1 closure slopes by buttressing slopes with waste rock progressively; GCL installed on all surfaces
	Valley C leach pad	Partial cover
		Complete cover
Decommissioning of Water Management Infrastructure	Alpha Dam/Pond	Remove dam completely
		Create channel without completely removing dam materials
	West Diversion	Partial decommissioning at natural depression drainages
		Complete decommissioning (re-grade to slope)
Decommissioning of NAR	**Decommission Project-associated (new) NAR sections (approximately 37 km)**[3]	
	Leave Project-associated NAR sections (approximately 37 km) in place[3]	
	Close additional road sections beyond those that are Project-specific	

Notes: Bolded cells indicate the base case closure option identified though the alternatives assessment process.

[1] Internal slopes are <3:1, but overall slope is 3:1; [2] Assumes re-grading of slopes and no benches; [3] This alternative was based on the previous NAR new road construction length (37 km). 2023 construction updates for NAR include approximately 29 km of new construction.

3.0 CLOSURE OBJECTIVES AND DESIGN CRITERIA

This RCP has been developed using an objectives-based approach that is consistent with Yukon guidance as well as the International Council on Mining & Metals (ICMM) Integrated Mine Closure Good Practice Guide. The RCP presents a post-mine vision, closure principles, Project- specific objectives, and component-specific objectives that have been developed based on stakeholder and community feedback, professional experience, and standard practices, and follow the Yukon Mine Site and Reclamation Closure Policy Financial and Technical Guidelines (EMR 2013). The financial guidelines apply within the context of security provided with a production licence under the *Quartz Mining Act* and security required pursuant to a water licence under the *Waters Act*. The technical guidelines provide direction on the objectives that have been considered in development of the RCP.

The post-mine vision is the foundation for advancement of end land use planning at the site. End land use planning will be used to refine the Project-specific closure objectives throughout the LOM. The project-specific closure objectives as well as end land use planning will be used to guide the reclamation research in future iterations of the RCP. Reclamation research outcomes will in turn be used to refine closure options and may inform continued end land use planning as the Project advances through construction and operations. The approach to advancing end land use planning at the site is described below.

Design criteria have been developed following applicable regulations and available guidance documents to facilitate Project development. Design criteria has been developed for mine components as well as socioeconomic components and are discussed below. Approaches to quality management, survey and materials testing are also described within this section.

3.1 Reclamation and Closure Planning Approach

The principles and approaches outlined in the Reclamation and Closure Planning for Quartz Mining Projects guidance document (YWB and EMR 2013) were incorporated into the development of the Coffee reclamation and closure objectives. The closure principles are defined by Yukon regulators as the Yukon Fundamental Mine Reclamation and Closure Objectives (YWB and EMR 2013). The post-mine vision and the Project-specific reclamation and closure objectives were defined by Newmont in collaboration with stakeholders and First Nations. The overall Project objective is to allow the mine site to be closed in accordance with the Project-specific and component-specific closure objectives in order to achieve the post-mine vision that has been defined for the Project, and also in accordance with end land use planning that is being advanced for the Project. The Project-specific closure objectives presented herein are reflective of discussions that have transpired during the RCP workshops and will evolve as engagement is ongoing. A table outlining the closure principles, Project-specific closure objectives, and component-specific closure objectives along with the base case closure measures as applicable to each major mine component is provided in Appendix 3-A.

3.1.1 Post-mine Vision

Previous discussions of the Project-specific closure objectives during workshops held with Newmont and First Nations lead to the development of a post-mine vision for the Project, which includes the following key elements:

- The site has returned to pre-mining conditions[3] to the extent practicable, with enhancements for future generations.
- By planning for future generations, First Nation rights, titles, and interests within their Traditional Territory have been protected and respected.

The post-mine vision for the site provides the foundation for development of an end land use planning approach that is within the interest of all stakeholders and First Nations.

3.1.2 Closure Principles

The closure principles for this RCP are based on the Yukon Fundamental Mine Reclamation and Closure Objectives defined by the YWB and EMR (YWB and EMR 2013) and are listed in Table 3-1. Newmont has used these closure principles to guide the development of Project-specific and component-specific closure objectives. Newmont does not foresee any constraints to achieving these fundamental objectives, as the overall objectives for the Project are to permanently close the mine with minimal intervention or ongoing requirements, except for periodic inspections and minimal maintenance.

[3] Pre-mining conditions refers to the state of land, air, water, and resources prior to Project-related activities and disturbances associated with both exploration and mining.

Table 3-1 Closure Principles

Coffee Closure Principles	
Physical Stability	• All mine-related structures and facilities are physically stable and perform in accordance with designs. • All mine-related structures, facilities and processes can withstand severe climatic and seismic events.
Chemical Stability	• Release of contaminants from mine-related waste materials occurs at rates that do not cause unacceptable exposure in the receiving environment.
Health and Safety	• Reclamation eliminates or minimizes existing hazards to the health and safety of the public, workers, and area wildlife by achieving conditions similar to local area features. • Reclamation and closure implementation avoids or minimizes adverse health and safety effects on the public, workers, and area wildlife.
Ecological Conditions and Sustainability	• Reclamation and closure activities protect the aquatic, terrestrial and atmospheric environments from mine-related degradation and restore environments that have been degraded by mine-related activities. • The mine site supports a self-sustaining biological community that achieves land use objectives.
Land Use	• Lands affected by mine-related activities (e.g., building sites, chemical and fuel storage sites, roads, sediment ponds, tailings storage facilities, waste rock storage areas, underground workings, etc.) are restored to conditions that enable and optimize productive long-term use of land. Conditions are typical of surrounding areas or provide for other land uses that meet community expectations. • Site access is consistent with community land use expectations.
Aesthetics	• Restoration outcomes are visually acceptable.
Socio-economic Expectations	• Reclamation and closure implementation avoids or minimizes adverse socio-economic effects on local and Yukon communities, while maximizing socio-economic benefits. • Reclamation and closure activities achieve outcomes that meet community and regulatory expectations.
Long-term Certainty	• Minimize the need for long-term operations, maintenance and monitoring after reclamation activities are complete.
Financial Considerations	• Minimize outstanding liability and risks after reclamation activities are complete.

Source: YWB and EMR (2013) – Yukon Fundamental Mine Reclamation and Closure Objectives

3.1.3 Project-specific Closure Objectives

Project-specific closure objectives based on the closure principles are presented in Table 3-2. The objectives were selected, defined, and refined collaboratively by Newmont and First Nations in a series of closure-related workshops that occurred in May, August, and September 2018. Provisions or objectives contained in the Umbrella Final Agreement (1993) (and also contained in the TH Final Agreement (1998), and SFN Final Agreement (1997)) informed the closure objectives defined for each closure value, as noted at the bottom of Table 3-2.

The intent of the Project-specific objectives will be to ultimately advance activities in accordance with end land use planning for the site, to respect the values and expectations of other land users, and to meet or exceed the intent of the closure principles. The Project-specific closure objectives may evolve as the end land use planning approach is refined.

Further collaboration regarding the closure objectives as mine planning advances will include focused discussion and refinement of the social closure objectives throughout the LOM. This focussed discussion will be aimed at developing the specifics of the high-level social closure objectives described in Table 3-2. In addition, the discussions will inform the development of the social performance criteria that are tied to the objectives. The criteria will be based on information gathered through consultation, as well as through monitoring activities outlined in the SEMP, and community investment, and will be refined through ongoing engagement with First Nations and affected communities.

This collaborative approach is a critical part of defining these objectives and characterizing measures of success that are reflective of the local community and economy. Baseline community data will also be used to guide the refinement of the objectives and performance criteria. As such, the development of the social closure objectives is ongoing and advancement of these objectives as well as outcomes of the discussions will be described in future iterations of the RCP.

Table 3-2 Project-Specific Closure Objectives

Closure Principles	Closure Objectives
Physical and Chemical Stability	• All mine-related infrastructure is physically and chemically stable and performing in accordance with designs, which take into consideration longer term risks such as for severe climatic and seismic events.[A] • Protect and maintain the land, air, and water in a condition that provides for sustainable use.[A, B3, B7, B10, B15, B18, B20] • Ensure water remains substantially unaltered from pre-mining conditions[1] to the extent practicable with respect to quantity, quality and rate of flow, including seasonal rate of flow.[A,B13, B14]
Health and Safety	• Protect the health and safety of people and area wildlife using and accessing the site by emulating pre-mining conditions to the extent practicable.[A]
Ecological Processes and Functions	• Protect or enhance ecological processes and functions in order to maintain ecosystem condition and support diverse, productive, and self-sustaining biological communities, with assemblages and abundances of species that are typical for the geographic area and are consistent with site capabilities that emulate pre-mining conditions.[A, B15]

Closure Principles	Closure Objectives
Land Use	• Protect and maintain environmental quality (a combination physical and chemical stability as well as ecological processes and functions) consistent with the principle of Sustainable Development[2].[A, B3, B7, B15, B18, B20] • Restore lands affected by mining-related activities to allow for future land use similar to surrounding areas to the extent practicable.[A] • Ensure the site and specific assets are available for use post-closure.[A]
Country Food and Traditional Economy	• To protect the long-term optimal productivity, quality, and diversity of the traditional economy, including the health and viability of country foods and other harvestable resources.[A, B4, B14, B15, B18]
Participation and Positive Relationship	• Maintain ongoing positive relationships or partnerships between Newmont and Yukon First Nations through closure and post-closure. [A] • Ensure participation of Yukon First Nations in project planning, and incorporate First Nations knowledge and experience in closure planning and implementation.[A, B2, B5, B9, B10, B17, B19, B21]
Culture and Heritage	• Recognize, protect, and foster the culture, and tangible and intangible heritage of Yukon First Nations for the benefit of future generations. [A, B1, B8, B11, B12, B16]
Community Health and Well-being	• Protect and promote the well-being of affected First Nations, their communities, governments, and internal capacities and structures.[A, B6] • Protect and promote the well-being of other Yukon residents and the interests of the public.[A, B6]
Economics	• Avoid or minimize adverse economic effects on the potentially affected community and First Nations, while supporting economic sustainability during and beyond the LOM.[A, B3, B22, B23]
Aesthetics	• Restore views at the site to pre-mining conditions to the extent practicable to facilitate learning and teaching on the land.[A]
Long-term Certainty	• Increase certainty and decrease risk regarding Post-closure conditions and outcomes (through, as examples, contingency planning, revised closure planning based on improved understanding from operations and reclamation research, and adaptive management[3]).[A] • Minimize the need for long-term operations, maintenance, and monitoring after reclamation activities are complete by reducing outstanding liabilities and risks.[A]

Notes: 1. Pre-mining conditions refers to the state of land, air, water, and resources prior to Project-related activities and disturbances associated with both exploration and mining; 2. Sustainable Development, as defined in the Umbrella Final Agreement, means beneficial socio-economic change that does not undermine the ecological and social systems upon which communities and societies are dependent; 3. In this context, adaptive management includes a systematic and iterative process of monitoring and evaluating changing site conditions to inform adjustments to adaptation options and reduce uncertainty over time.

* Contributing sources of information:

A. Goldcorp Coffee Project Closure Workshops with TH (May and August 2018) and SFN (September 2018) – During the May workshop, TH expressed interest in fully reclaiming the site and access road to pre-mining conditions, with agreement from Goldcorp that this would be carried out to the extent practical.

B. Umbrella Final Agreement (1993), TH Final Agreement (1998), and SFN Final Agreement (1997) – Referred to Objectives and Provisions (common to the three agreements) = B1: 11.1.1.3, B2: 11.1.1.4, B3: 11.1.1.6, B4: 12.1.1.1, B5:12.1.1.2, B6: 12.1.1.3, B7: 12.1.1.4, B8: 12.1.1.5, B9: 12.1.1.6, B10: 12.1.1.8, B11: 13.1.1.1, B12: 13.1.1.2, B13: 14.8.1, B14: 14.9.1, B15: 16.1.1.2, B16: 16.1.1.3, B17: 16.1.1.4, B18: 16.1.1.5, B19: 16.1.1.7, B20: 16.1.1.9, B21: 16.1.1.11, B22: 22.1.1.1, and B23: 22.1.1.2.

3.1.4 Component-specific Closure Objectives

Component specific closure objectives were developed for the project based on the First Nations feedback and the base case closure measures as applicable to each component. The component-specific closure objectives include consideration of the following elements:

- Minimizing infiltration/contact water
- Mitigating pathways for metal update in vegetation and wildlife
- Supporting target ecosystems and habitats
- Measures to ensure arsenic concentrations within the top metre of waste rock storage locations will not exhibit an arsenic concentration greater than 60 mg/kg, on average.

The component-specific closure objectives for each major mine component are intended to guide site specific reclamation and closure research as well as closure planning to ensure that public health and safety and environmental protection goals are met. Similar to the Project-specific closure objectives, the component-specific closure objectives will be refined through the advancement of the end land use planning for the site.

Table 3-3 provides the component-specific closure objectives for each major mine component for the Project. Evaluations will be ongoing and the workplans for each major mine component will be advanced as the level of engineering for the closure measures is advanced.

Table 3-3 Component-Specific Closure Objectives and Closure Measures

Component-specific Closure Objective	Open Pits	Alpha WRSF	HLF	Water Management Infrastructure	NAR	Infrastructure
Minimizing infiltration / contact water	• Evaluations will be ongoing and the workplans for each major mine component will be advanced as the level of engineering for the closure measures is advanced.	• May receive cover based on operations material balance. • West Diversion maintained during the Post-mining Closure Phase. • Minor re-sloping in closure to construct appropriate water conveyance.	• Heap surface compacted, engineered cover installed on flat areas. Store and release cover system on slopes. • Surface drainage system established during cover construction.			
Opportunities to mitigate pathways for metal uptake in vegetation and wildlife	• The reclamation research program will evaluate metals uptake in various growth media, including bare waste rock with a range of arsenic concentrations. Site-specific reclamation efforts will be advanced based on outcomes of research.					
Supporting target ecosystems	• Pits backfilled with waste rock. • Spillway channels constructed to prevent erosion and downstream sedimentation. • Disturbed areas around pit perimeters and spill points revegetated.	• Natural revegetation of WRSF. • Revegetation strategy may be updated based on outcomes of reclamation research program and/or end land use planning.	• Active water treatment will remain in effect until passive water treatment system (if needed) commissioned, or until water quality objectives met. • HLF and HLF ponds revegetated.	• The base of sedimentation ponds will be revegetated. Alpha Pond base reshaped to natural streambed. • Strategic breach locations to protect permafrost. • Conveyance structures regraded to pre-mining drainage patterns. • Disturbed areas revegetated.	• New sections of NAR reclaimed. ○ Culverts, bridges removed, pre-construction surface drainage patterns established. ○ Scarifying and re-contouring surfaces. ○ Disturbed areas revegetated.	• Equipment and infrastructure removed. • Hazardous waste removed from site. Other waste transported offsite or landfilled on-site if on approved landfill item list. • Concrete pads broken up. • Disturbed areas covered and revegetated.

Component-specific Closure Objective	Open Pits	Alpha WRSF	HLF	Water Management Infrastructure	NAR	Infrastructure
Measures to ensure arsenic concentrations within the top metre of waste rock storage locations will not exhibit concentrations greater than 60 mg/kg, on average	• Kona and Double Double Pit backfill will be capped with at least one meter of low arsenic material (at or below 60 mg/kg).	• The Alpha WRSF will be progressively capped with at least one meter of low arsenic material (at or below 60 mg/kg).				

3.1.5 Water Quality Objectives

Use protection site-specific water quality objectives (WQO), have been developed for the site based on the primary receiving environment and will be an extension of the operational WQO into closure. WQO will be utilized to develop the effluent quality standards (EQS) for discharge to the receiving environment, and will guide the continuous improvement measures and/or research to reduce loading of contaminants into the receiving environment, including:

- Advancing the proof-of-concept and detailed design for water treatment technologies and optimizing the systems throughout the Project's Operation Phase.
- Evaluating and updating the water treatment and water management strategies as mine planning advances, and closure concepts are refined.

A summary of the use protection WQO are provided in Table 3-4. The WQO will be intended to meet the long-term protection goals for waterbodies downstream of the mine components. Further details regarding the WQO are provided in the Proposed Site-Specific Water Quality Objectives for Primary Receiving Environments Report (Lorax 2021).

Table 3-4 Summary of Proposed WQO for Halfway Creek, Latte Creek, and YT-24

Parameters		Units	Halfway Creek	Latte Creek	YT-24	Regulatory Source
General Chemistry	SO_4	mg/L	218	309	218	BC-MOE
	Nitrate-N	mg/L	8	8	8	SSWQO
	Nitrite-N	mg/L	0.02	0.02	0.02	BC-MOE
	NH_3-N	mg/L	1.5	1.3	1.8	BC-MOE
	CN_{WAD}	µg/L	5	5	5	BC-MOE
Metals	D-Al[1]	µg/L	445	367	274	SSWQO
	T-Sb	µg/L	9	9	9	BC-MOE (I)
	D-As	µg/L	5	5	5	SSWQO
	D-Cd	µg/L	0.2	0.2	0.10	CCME
	D-Cu	µg/L	4.3	4.7	5.3	SSWQO
	T-Fe	µg/L	1,000	1,000	1,000	BC-MOE
	D-Fe	µg/L	350	350	350	BC-MOE
	T-Pb	µg/L	2	3	1	CCME
	T-Hg	µg/L	0.026	0.026	0.026	CCME
	T-Mo	µg/L	73	73	73	CCME (I)
	T-Ni[2]	µg/L	72	96	25	CCME
	T-Se	µg/L	2	2	2	BC-MOE
	Ag	µg/L	0.25	0.025	0.25	CCME
	U	µg/L	86	31	15	SSWQO/CCME
	D-Zn	µg/L	24	31	26	CCME

Notes: [1] Al-D values for open water period of April to October. For winter period of November to March value is 50 µg/L
[2] Interim Ni WQO proposed for Coffee.
T - Total and D – Dissolved forms
BC MOE – British Columbia Ministry of Environment
CCME – Canadian Council of Ministers of the Environment
SSWQO – Site-specific water quality objectives

3.2 End Land Use Planning

End land use planning is advanced through a process that identifies a collaborative vision for the site via information gathering and consultation and includes refinement/evolution of the objectives as Project planning and reclamation research progresses. The end land use planning approach for the Coffee Mine will follow the guidance provided in the Integrated Mine Closure Good Practice Guide (ICMM 2019), which includes consideration of:

- Traditional land use studies
- Land ownership
- Post-closure land configuration
- Capability of the land to sustain the objectives
- Maximizing land use benefits for all stakeholders, Project partners, and First Nations.

This approach builds an informational database to identify the closure options that would ultimately achieve the post-mine vision for the site. The database will be maintained and updated as discussions with First Nations, local communities, and stakeholders are ongoing. The collective database aims to gain a comprehensive understanding of existing ecosystems and habitats, pre-mining and post-mining land use, socioeconomic context, history, and traditional land use to facilitate the advancement of end land use planning for the Project.

Traditional Land Use studies have been carried out by Newmont in collaboration with First Nations and local communities to achieve a greater understanding of the Project area, and Newmont is committed to advancing this knowledge base through further studies and mapping exercises.

Specific end land use planning expectations for each of the considerations listed above will be defined through a collaborative workshop with First Nations and affected communities, and the approach to end land use planning will be reviewed through regular workshops to identify common values for Project, including consideration of potential land uses at the site (e.g., medicinal plants, wildlife habitat). End land use planning may be modified to reflect evolving community and stakeholder interests that are identified through the workshops throughout the LOM.

Advancement of end land use planning at the site will ultimately result in refined project-specific closure objectives and post-mining ecosystem targets and will guide the reclamation research program. Landscape and/or land use maps will be developed and refined to characterize the post-mining landscape, including landform design and key features. These end land use planning components, including outcomes of workshops described above, will be provided in future iterations of the RCP.

3.3 Design Criteria

Project development and reclamation and closure planning has been guided by many design criteria, ranging from regulatory and guidance-based criteria, constraints imposed by the Project location, and local area characteristics, and criteria (including socio-economic monitoring criteria) established through consultation and engagement activities. A quality management program will be developed to outline the Project quality specifications and design criteria that will align with Newmont's quality objectives. Information related to Project component design criteria, socio-economic effectiveness criteria, and quality management is outlined below.

3.3.1 Project Component Design Criteria

The selected means of reclaiming and/or closing Project components, based on information known at this time, dictate which Project components will remain as part of the landscape post-closure. Mine components that are currently anticipated to remain post-closure in either as-developed or post-closure form include partially backfilled Latte and Supremo Pits, the Alpha WRSF, the ROM stockpile pad, and the covered heap leach pad. The design basis that has been developed thus far for these features is described in the RCP in Sections 5.3.1, 5.3.2, 5.3.3, and 5.3.5, respectively. All other components of the Project, except some ancillary components (e.g., Coffee exploration camp), will be decommissioned and disturbance footprints reclaimed in accordance with best practices and site-specific reclamation criteria and measures, which will be informed by advancement of end land use planning as well as the outcomes of reclamation research activities.

Ultimately, all design, reclamation, and closure criteria will be selected with the intent of demonstrating the effectiveness of the component's design towards achieving Project-specific closure objectives. That is, reclamation and closure-related criteria can be linked to Project-specific and component-specific closure objectives to monitor long-term performance of these components and the achievement of the post-mine vision for the Project.

3.3.2 Socio-economic Criteria

Socio-economic criteria that will define the effectiveness for closure of the Project as a whole are described in Section 7.12 and will be updated based on results of the SEMP as well as discussions with First Nations, local communities, and stakeholders as Project planning advances. Criteria will continue to be monitored during the Closure and Post-closure Phases. Results of the SEMP will be reviewed to determine the effectiveness of closure measures in achieving the socio-economic criteria, and to ensure that the Project-specific closure objectives continue to be met well after decommissioning and reclamation activities are complete.

The SEMP has been developed to align with the interests of affected First Nations and will be updated as discussions regarding socio-economic criteria progress through project planning. Commitments made within the SEMP as well as within benefit agreements with affected First Nations will be used to inform social closure planning in future iterations of the RCP.

3.3.3 Quality Management

Project quality is defined as "*the level to which a finished project meets the expectations of the Owner and as further defined in the project specifications*". Project specifications will define specific quality expectations and be a reflection of Newmont's quality objectives. Specifications will include documents such as:

- Project specific standards or codes
- Drawings
- Functional descriptions
- Contractor work scopes.

The quality management program will define the procedures to which the Project Management Team and contractors will adhere in order to ensure project quality objectives are met. The quality management program objectives are as follows:

- Ensure that the Project will operate safety
- Ensure that the Project meets standards and objectives contained within permits, licenses and other commitments Newmont has made
- Protect the project cost and schedule objectives by minimizing damage, waste, and re-work
- Ensure that specifications are understood by vendors and contractors
- Confirm appropriate vendor and contractor quality surveillance is performed
- Demonstrate the delivered project meets project quality objectives by providing documented evidence.

Quality management on the Project focuses on two key elements: conformance to requirements (producing what was specified) and fitness for use (satisfying real needs). The project is committed to a philosophy of "Behavior Based Quality", where each person is responsible for the quality of their own work. The quality management program will focus on achieving its objectives by implementing a quality regime that will:

- Deliver project outcomes that meet or exceed specified project performance requirements through a systematic approach to the management of loss, and integrating reliability and quality with the reduction of risk to people, the environment, assets and production.
- Implement appropriate site processes, systems and procedures to support construction activities.
- Minimize waste, non-conformances and re-work.
- Mitigate turnover and start-up problems.

The site quality management program will be implemented to support construction execution. The program will be reviewed by the Engineer and Newmont to ensure with certainty that it will support construction activities that conform with the specifications, and that it will support speedy acceptance of the work being performed. Contractor Quality Control Plans will be expected to meet or exceed the requirements of the project quality management program.

Primary activities to support quality management will include survey and materials testing.

3.3.3.1 Survey

Survey will be required to provide layout, and to ensure placement of all reclamation material as well as any manufactured material is in accordance with the final reclamation designs. Survey will also play an important role in stockpile management.

3.3.3.2 Material Testing

A mobile lab may be required to ensure appropriate turn-around times for Quality Assurance/Quality Control (QA/QC) testing and would be provided by a specialized contractor. The lab could be staffed with two personnel, with one personnel dedicated to construction monitoring, sample collection, and compaction testing with the other dedicated to testing and analysis. A control test will be taken prior to excavation or in stockpile and a record test will be taken after placement.

American Society for Testing and Materials (ASTM) standard sample collection and testing procedures as specified by the design engineer will be followed. Any material that does not meet specification during a control test will not be placed and any material that does not meet specification during a record test will be excavated and replaced. Specifications for particle size distribution (PSD), laboratory compaction, moisture content, specific gravity, organic content, placed moisture content and compaction (by nuclear methods) and others will be set by the design engineer. Testing intervals will also be specified by the design engineer. On-site or off-site geochemical testing and analysis may be required as described in the Waste Rock and Overburden Management Plan (WROMP), Geochemical Monitoring Plan and as specified in the final reclamation designs to ensure that reclamation material is NAG and non-metals leaching (non-ML).

4.0 ENVIRONMENT AND SOCIOECONOMIC DESCRIPTIONS

This section describes the existing environmental and socio-economic conditions for areas with the potential to be directly or indirectly affected by mine-related activities, as well as conditions in reference areas, where relevant. The characterization of existing conditions is representative of pre-disturbance conditions as the Project areas to be developed are currently undisturbed with the exception of localized exploration-related disturbances (refer to Section 5.4 for more information on current site conditions).

4.1 Physical Environment

The Coffee property is located in the northern Dawson Range, forming a moderate plateau that escaped Pleistocene glaciation. As such, the topography of the area is defined by stream erosion resulting in gently rounded hills with tightly incised valleys. Across the property, elevations range from 400 m to 1,500 m above sea level (masl). The property encompasses an area of partially tree-covered hills on the Yukon Plateau, incised by mature drainages that are part of the Yukon River watershed. The Project is situated along a high, undulating ridge that ascends to more than 1,300 masl.

This section describes the physical elements that influence the geographical area of the Mine Site area, including weather and climate, seismic conditions, and the physical environment components with the potential to be affected by mine-related activities, including air quality, noise, surficial geology, terrain, and soils, hydrology, surface water quality, and groundwater.

4.1.1 Weather and Climate

At present, there are two active and continuously recording climate stations (Kona climate station and Km 11 climate station (locations shown in Figure 4-1). In addition, multiple snow courses have been measured at the property, and two standalone tipping bucket rain gauge stations were installed in 2015 at low (430 m) and high (1,300 m) elevations to further refine the orographic gradients at Site. The rain gauge stations were in operation until 2018. Overlapping climate data from these two weather stations, as well as any supplementary precipitation data collected at the rain gauges and snow courses, will be used to update the characterization of the site climatic regime, and refine the water balance models.

The two Project weather stations collect records for:

- Air temperature and relative humidity
- wind speed and direction
- solar radiation
- barometric pressure
- precipitation
- potential evapotranspiration
- snow depth and snow water equivalent.

The instrumental record for the Km 11 climate station now exceeds 9 years in duration and is essentially continuous, while the Kona climate record is approximately three years in duration.

Path: P:\@Drafting\Coffee Gold\Drafting Figures\MxD\Personal_20190627.mxd

There are several regional climate stations operated by the federal agencies of both Canada and the US (Alaska) with sufficient record periods and data quality to inform the characterization of weather conditions at the Mine Site over a longer period of record. To better characterize long-term variability, a synthetic time-series of air temperature and precipitation was derived from statistical relationships between measurements obtained at the Mine Site climate station and the regional climate stations and snow courses. The synthetic record was updated in 2021 to include additional site climate data as well as data from an updated predictor climate station (Dawson A station). Details related to the synthetic climate record are provided in the Site Characterization Plan.

4.1.1.1 Temperature

The Coffee property is located in a subarctic, continental climate with a summer mean temperature of 10°C and a winter mean temperature of -23°C. Summer and winter temperatures extremes can reach 35°C and -55°C respectively.

At the Mine Site, the average annual temperature ranges from -5 to -2°C, with average monthly mean air temperatures ranging from -16.8 to 13.9°C at the Km 11 station, and -15.4 to 11.7°C at the Kona station. Minimum (maximum) recorded temperatures at the Km 11 climate station are -38.2°C (29.7°C), and at the Kona climate station are -36.2°C (23.7°C).

The lowest air temperatures are often experienced in December through February, while July typically experiences the highest temperatures. Evidence of temperature inversion events is present during the winter months in upper elevations of the Project site. Figure 4-2 presents average monthly air temperature from the Mine Site climate stations. Additional information regarding air temperature and temperature inversions are provided in the Site Characterization Plan.

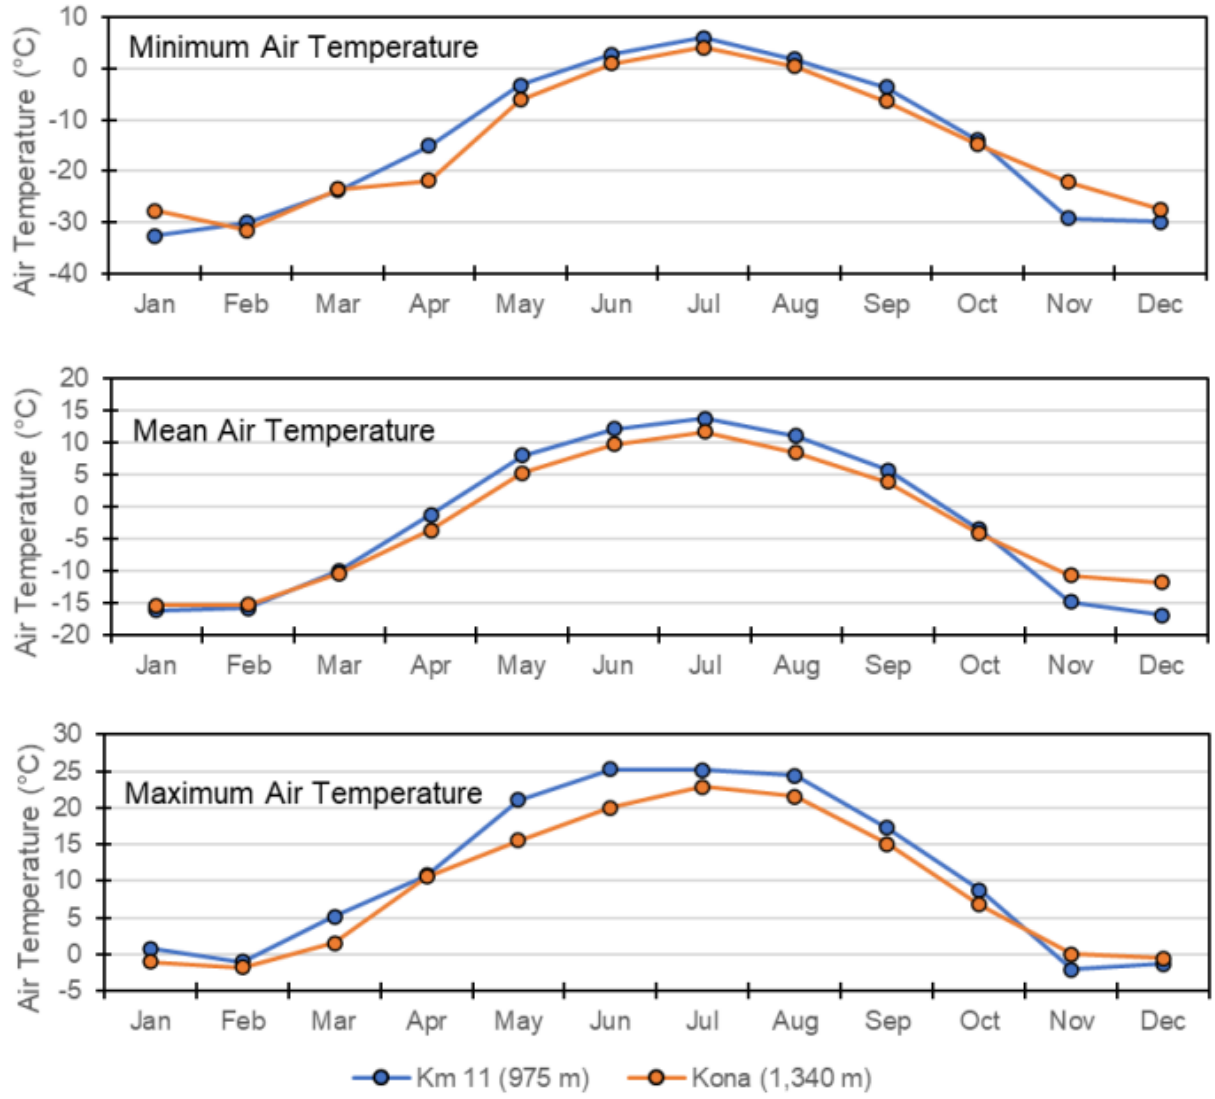

Figure 4-2 **Mean Monthly Minimum (top panel), Mean (middle panel) and Maximum (bottom panel) Air Temperature Records for the Km 11 and Kona Climate Stations**

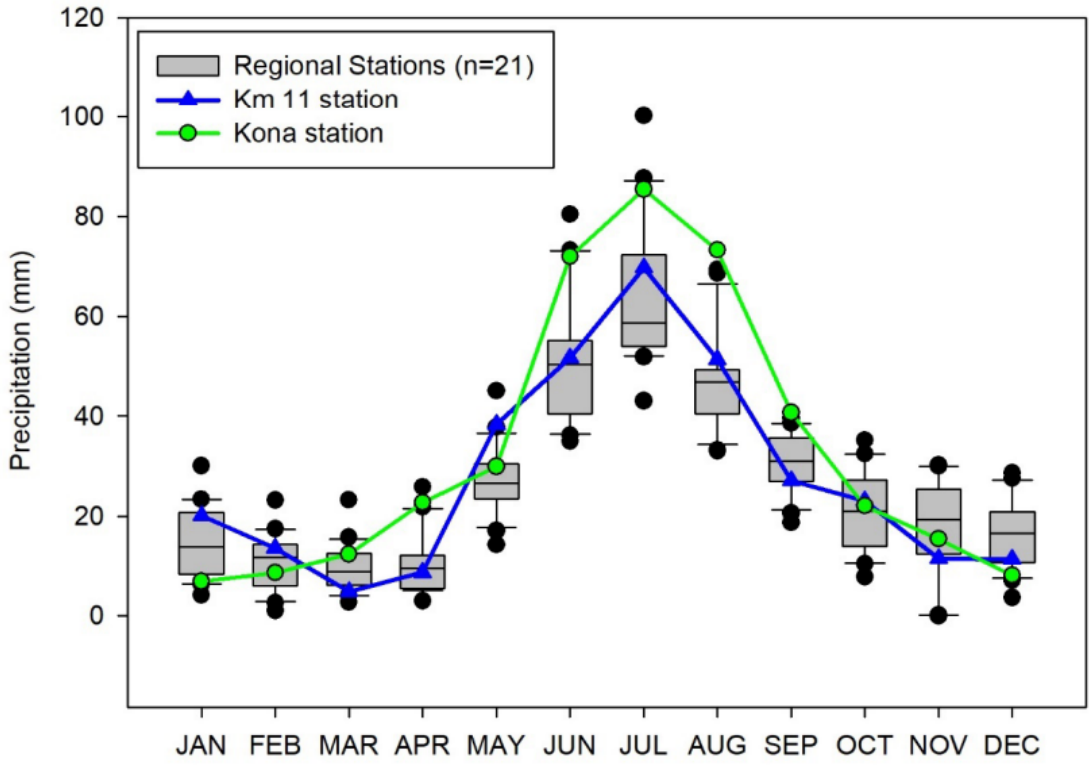
4.1.1.2 Precipitation

Mean annual precipitation (MAP) at the Mine Site measured through gauge and snow course data gathered during the baseline study was 331 mm at 975 m and 398 mm at 1,340 m, with approximately 30% of this amount falling as snow between October and April, and 70% falling as rain from May to September. Based on the synthetic climate record, MAP is estimated to be 504 mm at the Project.

Figure 4-3 shows regional precipitation data from the Km 11 and Kona climate stations, as well as from nearby climate stations. Overall, site and regional precipitation measurements are closely correlated. A summary of measured precipitation for the Mine Site climate stations are provided in Table 4-1 and Table 4-2. Additional information regarding precipitation at the site is provided in the Site Characterization Plan.



Note: The box and whisker plots show the following statistics for the regional stations: median and quartiles (grey box), 5th and 95th percentile values (tails) and outliers (black circles).

Figure 4-3 Comparison of the Measured Monthly Precipitation Signature for the Coffee Gold Km 11 and Kona Climate Stations to nearest Regional Stations (n = 21) with Long-Term Records

Extreme precipitation events typically occur in summer and are attributable to overland convective events. Rainfall monitoring conducted at the main climate station (Km 11) presents variability in terms of timing and magnitude of storms when compared to tipping buckets located at different elevations across the Project site. These observations along with regional analysis of long-term precipitation records indicate variation in precipitation with elevation and in the distribution of storm events across the Project area.

The hydrometeorology baseline report presented summer rainfall events for seven return periods (1:2 year, 1:5 year, 1:10 year, 1:25 year, 1:50 year, 1:100 year and 1:200 year) for varying elevations (600 masl to 1,300 masl). The Project elevations range from 799 to 1236 masl and an average elevation of 1,300 masl was selected for design purposes. The precipitation depths at 1,300 masl for each return period and a 24-hour duration are presented in Table 4-3.

Table 4-3 Estimated Summer Rainfall Depths at 1,300 m Elevation for Various Intervals and Return Periods based on Historical Conditions

Interval	Rainfall (mm) for Various Return Periods						
	1:2	1:5	1:10	1:25	1:50	1:100	1:200
24-hour	38	56	67	80	89	98	106

4.1.1.3 Snowpack and Melt

The average annual snowfall estimate for the Km 11 climate station is 97 mm, and for the Kona climate station is 99 mm. Figure 4-4 shows snowpack accumulation at the Kona climate station from 2018 to 2021. Snowpack typically begins in mid- to late-October each year, and melts over a one- to two-week period between late-March and late-April. The maximum snowpack depth is expected to occur by approximately April 1. Recurrence interval estimates of maximum annual Snow Water Equivalent (SWE) accumulation based on snow survey data indicate that the maximum annual SWE is predicted to range from 79 to 319 mm in a 1:200 interval for dry and wet years, respectively, with a mean of 159 mm SWE. The estimated recurrence intervals for maximum annual SWE are provided on Table 4-4.

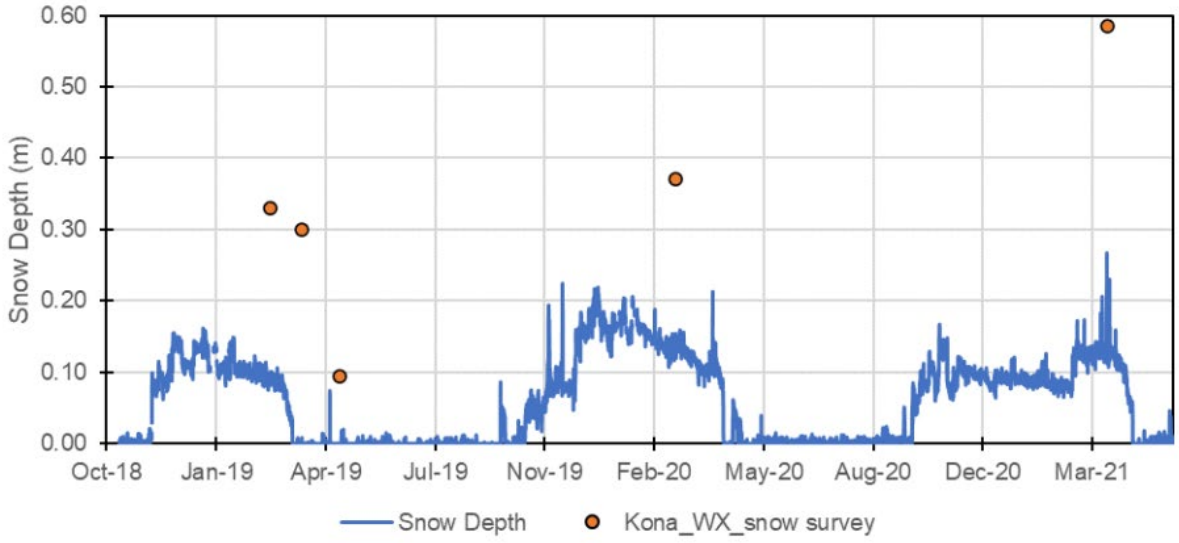

Figure 4-4 Continuous Snow Depth Record Measured at the Kona Climate Station (October 2018 to June 2021)

Table 4-4 Estimated Maximum Snow Pack (Snow Water Equivalent, or SWE) at 1,300 m Elevation for Various Return Periods

	Dry Year						Mean	Wet Year					
Return Period	1:200	1:100	1:50	1:25	1:10	1:5	1:2	1:5	1:10	1:25	1:50	1:100	1:200
SWE (mm)	79	84	91	100	114	128	159	200	225	256	277	298	319

To produce a long-term, daily melt record for Coffee Mine, period of record snow pillow data were assembled from six snow pillow stations in Alaska and the Yukon. Period of record snow pillow data for the six stations indicate peak melt rates of 10-20 mm/day for accumulated snowpack in a typical year. The highest rates calculated from regional data range from 30 to >50 mm/day, which is associated with persisting snowpacks throughout the spring season that are subject to greater solar radiation inputs. This suggests that in a very dry year, the snowpack may melt early in the season, while in a very wet year, the snowpack may melt over a longer period. Additional information regarding snowpack and melt is provided in the Site Characterization Plan.

4.1.1.4 Evaporation

Potential evapotranspiration estimates for both the Km 11 and Kona climate stations indicate average April-October totals of 469 mm and 452 mm, respectively, and are highest throughout the year from May to July. Higher estimates were recorded for the Kona station compared to the Km 11 station from 2019 to 2021 as a result of elevated wind speeds and greater solar radiation associated with higher elevation. Table 4-5 shows the potential evaporation estimates that were derived using the Penman-Monteith and Priestly-Taylor methods. Additional information regarding evapotranspiration at the site, including supplemental calculation methods for comparison, are provided in the Site Characterization Plan.

Notes: P-M: Penman-Monteith, P-T: Priestly-Taylor

4.1.1.5 Climate Change

Potential climate change effects for the Project were assessed to guide long-term Project planning. Modelled historical climate averages and future projections were used to calculate temperature, precipitation, and freeze/thaw date projections specific to the available Representative Concentration Pathway scenarios (RCP4.5, RCP6.0 and RCP8.5) for the Project to the year 2100. Climate change for each Representative Concentration Pathway scenario has been accounted for in the water balance that has been developed for the Project (Lorax 2023b). This was done by extending the synthetic 30-year record through three cycles, and incorporating projected changes in temperature and precipitation that are predicted using published climate models for that time frame. The 2015 Climate Change Projections for the Coffee Creek Region are provided in Appendix 4-A.

Overall, average annual temperatures are anticipated to rise significantly, and net precipitation is projected to increase in the region over the next century, with slightly wetter summers and winters expected. The model indicates that warming is anticipated to be particularly pronounced in the summer in the area of the Coffee property, which will lead to a later freeze-up in fall and an earlier thaw in spring. In tandem, this yields a growing season that is as much as one month longer by the end of the century and implies a notably lengthened duration for above zero temperatures and consequent adverse implications for permafrost integrity (i.e., minor degradation) in the region.

The annual average temperature at the site is approximately -2°C and is forecasted to rise by 3 to 5°C by the end of the century. As with mean temperature, net precipitation in the vicinity of the Coffee Gold Mine is projected to increase by 20% to 35% over the course of this century. Additional information regarding the climate change scenarios for the Project are provided in the Site Characterization Plan.

4.1.1.6 Additional Climate Station Data

Relative humidity generally varies between 50% and 85% on an average monthly basis, with the highest relative humidity values in the winter at the Km 11 station, ranging from 76-83% between November and February. The relative humidity signatures at Km 11 display a notable departure at the Kona station, due in part to the noted temperature inversions at site.

Monthly average wind speeds range from 0.9 to 2.8 m/s at the Km 11 station, with higher wind speeds occurring in the months of April through September compared to October through March. The higher elevation Kona station experiences monthly average wind speeds of 3.7 to 5.1 m/s, with a similar seasonal pattern as noted for the Km 11 record, although maximum wind gust speeds are more often noted in the winter and spring months. The dominant annual wind vector at the Km 11 station and the Kona station is from the south and the southwest, respectively.

Monthly average barometric pressure measured at Km 11 climate station ranged from lows of 1003 mb in December to highs of approximately 1015 mb in July. At the Kona climate station, atmospheric pressures track the monthly pattern observed in the Km 11 record, but are approximately 155 mb lower, reflective of this station's higher elevation.

Solar radiation at the site varies from a monthly average high in June of 0.240 kW/m^2 and 0.256 kW/m^2 to a low of 0.003 kW/m^2 and 0.005 kW/m^2 in December, at the Km 11 and Kona climate stations, respectively.

Since July 2012, the highest recorded hourly solar radiation value is 0.991 kW/m^2 at the Km 11 station, and 1.043 kW/m^2 at the Kona station, reflective of the latter stations' higher elevation.

Additional information regarding relative humidity, wind speeds, barometric pressure and solar radiation at the site are provided in the Site Characterization Plan.

4.1.2 Seismic Conditions

The Project is located in an area of relatively low seismic activity in the St. Elias region, which includes southwestern Yukon Territory, northwestern British Columbia, and southeastern Alaska. The Project is located further northeast, between the Denali and Tintina fault systems, where the rates of seismic activity decrease dramatically (NRC 2016a). Figure 4-5 shows the regional tectonic fault lines and historical seismic activity of Yukon with respect to the Project. In the St. Elias Region, the Pacific tectonic plate is being forced underneath the North American tectonic plate through subduction.

The seismic hazard for the Project area predominantly consists of shallow crustal earthquakes (with magnitudes of up to 7.0 on the Richter Scale) that may occur in the region south of the Project (greater than 100 km) (NRC 2016a). Seismic hazards are influenced by the potential for larger-magnitude earthquakes (with magnitudes from 7.5 to 8.0) occurring further from the Project site (greater than 100 km) on the East Denali fault zone, near the Alaska-Yukon border (NRC 2016a).

A review of the regional tectonics and historical seismicity in the southwest Yukon region was completed to enable the selection of appropriate design earthquake events for key Project components such as the HLF. The closest seismograph stations to the Project are located in Dawson and Beaver Creek (NRC 2016b). The closest historical earthquakes have occurred near Beaver Creek, the most recent being a magnitude 4.2 earthquake in 2012, which is characterized as a light earthquake, slightly felt, but during which zero to minimal damage occurs (Belik 2013, NRC 2016c).

An analysis of seismic hazards in the Project area was performed using the 2015 National Building Code of Canada (NBCC) seismic hazard calculator (NRC 2016d). The peak ground acceleration (PGA[4]) was calculated for the Project area for several return periods (Table 4-6) (USGS 2011, NRC 2016d). Based on the intensity descriptions developed by the USGS, a PGA of 0.025 g is perceived as light, and is not likely to cause structural damage, while a PGA of 0.080 g is perceived as a moderate quake, with very light potential to result in structural damage (USGS 2011).The worst-case peak ground acceleration of 0.17 g (potentially occurring every 10,000 years) would represent a very strong earthquake with the potential to cause moderate structural damage to buildings and structures.

[4] PGA is a measure of how hard the earth shakes and is measured in units of acceleration due to gravity.

4.1.3 Air Quality

Air quality in the Project area is representative of a pristine environment as it is far from any existing industrial or urban areas and has remained unaffected by development. The only existing influence on ambient air quality levels in the Project area is transient forest fire smoke.

Volumetric ambient air quality monitoring of total suspended particulate matter (TSP), PM10 (particulate matter of 10 microns or less), PM2.5 (particulate matter of 2.5 microns or less) was conducted at the Project site in 2015. Table 4-7 provides a summary of 2015 ambient particulate matter concentrations. Very low levels of TSP, PM10, and PM2.5 concentrations were observed in the winter and elevated concentrations were observed in the summer due to the influence of migrating forest fire smoke upwind of the Project site. The conditions during dry summer months are not typical of the region, which are also conducive to high pollen and mold spore counts that can elevate PM2.5 concentrations.

Table 4-7 Ambient Particulate Matter Concentrations Based on Monitoring in 2015 (µg/m^3)

Parameter	AAQS	Season	Minimum Ground-level Concentration	Maximum Ground-Level Concentration	Average Ground-level Concentrations
TSP	120	Winter	1	65	2
		Summer	<1	200	41
$PM_{2.5}$	50	Winter	1	34	2
		Summer	<1	177	40
PM_{10}	25	Winter	1	61	2
		Summer	<1	193	40

Dust fallout rates were measured on site in 2015 using passive dust fall monitoring samplers during the summer and through analysis of particulate matter contained in snow cores during the winter. The average dust fallout rate, measured in milligrams per square decimeters per day (mg/dm^2/day), were 0.17 and 0.5 in the winter and summer, respectively. Organic matter was analyzed to be the primary constituent of the dust deposition, which suggests the Project area under existing conditions is organic in nature (i.e., pollen, mold spores, soot, smoke, etc.).

4.1.4 Noise

Sound surveys were conducted within the Coffee Property in late March 2015 and late June 2015 to record existing conditions during winter and summer, respectively. Existing sound levels (in A-weighted decibels, dBA) recorded at the Mine Site were as follows and are typical for a remote mountainous site:

- During winter, the daytime levels ranged from approximately 25 dBA to 31 dBA
- During winter, the nighttime levels ranged from approximately 22 dBA to 26 dBA
- During summer, the daytime sound levels ranged from approximately 33 dBA to 45 dBA, including time periods with precipitation and periodic thunder
- During summer, the nighttime sound levels ranged from approximately 27 dBA to 57 dBA.

Average daytime noise levels are typically 5 dBA to 10 dBA higher than at night (BC OGC 2009). Noise levels recorded during the summer daytime and nighttime period were elevated due to the prevalence of thunderstorms during the monitoring period. Existing ambient sound levels along the NAR are expected to be relatively consistent with data collected near the Mine Site since population density, land use, and terrain conditions are similar.

4.1.5 Surficial Geology, Terrain, Soils, and Permafrost

The Project area falls within the portion of Yukon that remained unglaciated during the Pliocene to early Pleistocene epochs (3 million to 1.8 million years ago); however, glaciers were present within the Stewart River valley to the north as well as to the west and east of the Mine Site (Duk-Rodkin 1999). This lack of glaciation exposed surficial geology to an extensive period of weathering, resulting in surficial deposits primarily composed of weathered bedrock, colluvium derived from weathered bedrock and loess (very fine-grained silt or clay formed through glaciation and deposited by the wind), and fluvial (river-based) materials.

The Project area is underlain by a package of metamorphosed Paleozoic rocks of the Yukon-Tanana Terrane (which underlies much of central and western Yukon and east central Alaska) that was intruded by a large granitic body in the Late Cretaceous.

The characterization of surficial geology, terrain, soils, and permafrost at the Mine Site was based on the Environmental Baseline Report (Tetra Tech 2016) and was informed by the results obtained through the following investigations and testpitting programs:

- 2015 Geotechnical Field Investigation Report (SRK 2016)
- Fall 2016 Geotechnical Investigation Data Report (Tetra Tech and SRK 2017)
- Summer 2017 Geotechnical Investigation Data Report (Tetra Tech 2017)
- Fall 2018 Test Pitting Program Data Report (Appendix 2-I).

Figure 4-6 shows the locations of geotechnical and hydrogeologic investigations at the site.

At high elevations and along valley slopes, colluvium is likely to be coarse grained, whereas ice-rich resedimented loess and peat form colluvial aprons on lower slopes, and fluvial deposits are found in valley bottoms. These deposits may be subject to gullying, cryoturbation (mixing of materials from various soil horizons due to freezing and thawing), solifluction (gradual mass wasting slope process related to freeze-thaw activity), permafrost processes, periglacial processes (geomorphic processes from seasonal thawing in permafrost areas), landslides, and snow avalanches.

Soils at the Mine Site are predominantly Cryosols (permafrost soils). Unfrozen soils are represented primarily by Brunisols (one of three soil orders for forested soils in Canada). Parent materials within the Mine Site and along the NAR are predominantly colluvium. The dominance of colluvium may be a factor limiting the quality of soils available for reclamation.

Overall, 128 samples of overburden material have been collected for geochemical characterization along with selected samples of topsoil material from the proposed heap leach area for nutrient analysis and particle size descriptions. The locations of overburden sampling are indicated on Figure 4-7. Overall, the results indicate that ex-pit overburden is consistently non-acid generating (NAG) with low metal leaching potential. Overburden material from in-pit boundaries has more variable metal leaching potential, particularly in regard to arsenic. For additional overburden geochemical characterization details, refer to the Geochemical Source Term Report (Lorax 2023a).

4.1.5.1 Terrain Stability and Unique Landforms

The majority of the Mine Site is considered to be relatively geotechnically stable, reflective of the gentle to moderate slopes that predominate on lower valley sides and in uplands. Landslide failure scars and other features are shown on Figure 4-8. Landforms that are relatively unique in the area include tors and collapsed and intact open system pingos. Tors are erosional remnants of a higher plateau level, and are located along ridgetops, primarily in the central and western parts of the Mine Site and along the NAR north of the Stewart River. The tors form towers above otherwise smooth, rounded ridges underlain by granitic bedrock, and are surrounded by either thick colluvium (unconsolidated sediments that gather at the foot of a steep slope) or weathered bedrock.

Pingos are perennial frost mounds that consist of a core of massive ice and are covered by soil and vegetation. Open system pingos result when the water forming the dome of frozen ground is supplied by groundwater moving downslope. The location of a collapsed pingo in the Mine Site study area is shown in Figure 4-8. Collapsed pingos are indicative of the former presence of massive ground ice and ice-rich permafrost that has since thawed, leaving behind a low, circular ridge of material as a result of the sides of the pingo slumping, and a depression, which in this case is filled with water.

4.1.5.2 Permafrost

The Mine Site is largely situated in area of discontinuous permafrost, while the NAR crosses areas of limited permafrost to areas of continuous permafrost. Shallow permafrost typically underlies the northeast-facing slopes vegetated by sparse, stunted black spruce with thick moss cover. Southwest-facing slopes are permafrost-free and covered by almost pure stands of trembling aspen, which require warmer air temperatures and deeper root penetration. Permafrost thicknesses within the Project site are highly variable, ranging from approximately 30 m to 165 m. Permafrost reduces hydraulic conductivity, as groundwater freezes, and pores and cracks in bedrock fill with ice. Since it generally behaves as an aquiclude or aquitard, confining groundwater to the thin seasonal active layer above it, or the bedrock beneath it, the effects of permafrost have been taken into account in the water balance and water management plan that has been developed for the Mine Site.

Ground ice content (percent by volume) of the perennially frozen surficial materials is also highly variable. Some areas of the site are permafrost-free. Ice-poor permafrost is common in upland settings along ridges, and on moderately steep valley sides with convex or straight slopes. Ice-rich permafrost is more common in areas with higher organic accumulation and silt-rich sediments in fluvial valley bottoms. Approximately 34% of the Mine Site is underlain by ice-poor permafrost, 27% is underlain by permafrost with visible excessive ice, and approximately 1% is underlain by ice-rich permafrost. Figure 4-8 shows the test pit locations used to determine the presence and ice content of existing permafrost in and around the Mine Site area. Approximately 21% of the NAR corridor is underlain by ice-rich to very ice-rich permafrost[5].

[5] Project-related sections of the NAR proposed in thaw-sensitive warm permafrost areas, which are sensitive to natural and anthropogenic disturbances, will require special geotechnical considerations to avoid erosion and mass wasting associated with permafrost thaw and thermokarst.

Permafrost-related processes that are active within the Mine Site include cryoturbation, solifluction, active layer detachment, slope creep, frost heave, and thermal erosion. Permafrost temperatures within the Project site have been monitored since 2013 and range from -2°C to -0.6°C. The warmest permafrost temperature (-0.6ºC) was recorded at the bottom of the Halfway Creek valley. The coldest permafrost temperature (-2.0ºC) was recorded at the bottom of YT-24 Creek and on the north-facing slope of the upper Halfway Creek valley. The permafrost classification for the Project site is thus “warm” and therefore, the ground is sensitive to disturbance.

Additional long-term permafrost evaluations were carried out at the Project to determine the timeframe and general thaw duration for permafrost rich soils and the embedded massive ice lenses existing at the mine site. Rate of thawing and thaw duration was evaluated for various climate scenarios. Results from the study indicated perpetually frozen ground in a ‘no climate change’ scenario. Results for various climate change scenarios indicated gradual processes that will see stratified thawing of the sand and gravel material above the ice lenses, followed by thawing of the ice lenses, then thawing of the sand and gravel material below the ice lenses. The Ground Temperature Monitoring Report provided in Appendix 4-B. Additional descriptions of the baseline permafrost conditions at the site are provided in the Site Characterization Plan.

4.1.5.3 Alpha WRSF Area

Geotechnical investigations have been conducted to characterize the subsoil conditions within the Alpha WRSF foundation footprint, which determined that the Alpha WRSF area is underlain by poorly to well graded, grey to dark brown silt, sand, gravel, and cobble mixtures. Surface boulders cover up to 30% of the ground. The extrapolated overburden thickness within the Alpha WRSF footprint ranges from approximately 0.5 m and 2 m on the slopes with depths of up to approximately 10 m in the valley bottoms.

Within the footprint of the Alpha WRSF, the surface is covered with light brown to green, coarse fibrous moss up to 200 mm thick containing rootlets and wood. Dark brown to reddish brown fibrous peat up to 300 mm thick is found beneath the moss or at the surface in some areas. Vegetation in this area generally consists of low shrubs and sparse stunted black spruce.

Northern portions of the Alpha WRSF footprint are on west-facing slopes that contain perennially frozen ground, which is predominantly ice-poor (i.e., with no visible ground ice), and on permafrost-free southeast-facing slopes. Western portions of the Alpha WRSF footprint are on east-facing slopes, which are interpreted to be mostly permafrost-free terrain with the exception of a tributary valley. Additional information regarding the geotechnical conditions in the Alpha WRSF area are provided in the Summer 2017 Geotechnical Investigation Data Report (Tetra Tech 2017) as well as in the Ground Temperature Monitoring Update Technical Memo (Tetra Tech 2023).

4.1.5.4 Heap Leach Facility

The heap leach pad (HLP) and associated ponds will be located on a ridgeline, which slopes from west to east at 7.5% to 20%. The overburden soils in the area typically consist of sandy or gravelly silts, silty or gravelly sands, and silty or sandy gravels. Silty or sandy gravel, rubble (rockfall) or weathered bedrock was observed within the overburden material on the tops of the ridges. Fine contents varied by sampling location, ranging from 12% to 50%. Soil samples from the HLF study area exhibited low to non-plastic characteristics overall. Overburden soils had an average depth of 2 mbgs, with a minimum of < 1 mbgs to a maximum of > 9 mbgs.

Topsoil within the footprint of the HLF primarily organic rich and contains ice. Under the overburden soils exists primarily granitic hard rock materials with a smaller portion of schist below the easternmost portion of the HLF site. Additional geotechnical information in the HLF area is provided in the Heap Leach and Process Facilities Management Plan.

Soil nutrient testing was conducted on three topsoil samples from within the footprint of the HLF and results are summarized in Table 4-8. The nutrient test sample at location TP17-05 O as indicated in Table 4-8 was collected at a depth of approximately 50 cm. The surficial materials at this location were described as moss to a depth of 20 cm and peat to a depth of 40 cm. The nutrient test sample at location TP17-06 O was collected at a depth of approximately 30 cm, and TP17-06 R was collected at a depth of approximately 1 m. The nutrient test sample at location TP17-09 O was collected at a depth of approximately 50 cm, and TP17-09 R was collected at a depth of approximately 1.4 m.

Soils collected from this area are generally sand to sandy loams with low cation exchange capacity (CEC). CEC provides a measurement of a soil's ability to retain positively charged nutrients (e.g., Ca^{2+}, Mg^{2+}, K^{+}, NH^{4+}) and an indication of soil moisture retaining characteristics. Generally, soil with low CEC have a lower water holding capacity than soils with high (e.g., >15 meq/100g) CEC. The low CEC for soils from the HLF area is supported by the low organic carbon content of the samples.

4.1.5.5 Soil Stockpiles and ROM Stockpile Area

Foundation soils within the footprint of the soil stockpiles are anticipated to consist of relatively shallow residual soil and colluvium over competent bedrock. Geotechnical investigations identified a thin (up to 200 mm thick), brown to reddish brown, fine to coarse fibrous moss layer at the surface (Tetra Tech and SRK 2017, Tetra Tech 2017). These thin organic mineral soils are underlain by brown to olive grey sand, silt, cobbles, and rubble up to 2.6 m thick. Trace organics found within the silt and sand layer suggest that this site is colluvial.

Granite bedrock encountered within the area was completely to moderately weathered and medium to coarse grained Permafrost conditions with excess ice were observed in the soil stockpiles area. Excess ice content in frozen overburden material ranged from 2% at a depth of approximately 1.9 m to 45% at a depth of approximately 0.4 m.

Geotechnical investigations within the footprint area of the ROM stockpile indicated permafrost-free conditions. This area was generally overlain with a 100 - 150 mm thick organic layer comprised of roots

and dark moss. An overburden layer approximately 1 m thick was present in the area, consisting of gravel and/or sand. Additional details regarding the geotechnical conditions of the soil and ROM stockpile areas are provided in the test pitting program reports (Tetra Tech and SRK 2017, Tetra Tech 2017).

4.1.6 Watercourses and Surface Hydrology

For Project catchments the dominant drivers of runoff during the open water season are the spring snowmelt during May and June, and intense convective rainfall that occurs frequently from June through September. Surface water is limited to a number of small watercourses that originate on the ridge and flow into the Yukon River. The four catchments near the Mine Site include Latte Creek, Coffee Creek, Halfway Creek, and Yukon Tributary 24 (YT-24), the locations and sizes of which are shown in Figure 4-9. Latte Creek drains the south face of this ridge and has a catchment area of approximately 70 km. Latte Creek flows eastward to its confluence with Coffee Creek, which has a total catchment area of approximately 487 km^2 and generally flows from south to north to the Yukon River. The north face of the ridge is drained by Yukon Tributary 24 (YT-24), located on the eastern side of the Mine Site. YT-24 has a total catchment area of approximately 12 km. Halfway Creek drains the western side and has a total catchment area of approximately 27 km^2. Both YT-24 and Halfway Creek flow northeast to their confluences with the Yukon River.

Figure 4-9	Date: Nov 3, 2023	Drawn by: AS	Reviewed: KP

Path: S:\Geomatics\Projects\103982\03\mxd\MP\RCP\Fig2_1_103982_03_Coffee_KeyCatchment_231103.mxd

Local patterns of streamflow in these catchments are dominated by a snowmelt freshet that typically occurs between late April and early June. These creeks experience peak flows in May due to melting snowpack. Following freshet, stream flow is dominated by precipitation-induced runoff events that occur throughout the summer and autumn months. These high-flow, precipitation-induced events are typically short in duration, persisting over a one- to two-day period. Flows in local creeks and streams typically decrease in October in response to reduced precipitation and freezing temperatures, and several local watercourses experience zero flow conditions throughout the winter (i.e., November through the end of March). Aufeis (*i.e.,* frozen groundwater seepage that accumulates within- and adjacent to local watercourses) is pervasive in creeks and streams at the Project site and melts during the freshet but can occasionally persist into the early summer.

Mean annual runoff estimates at the Mine Site vary from basin to basin. Annual runoff generated in the headwaters of Latte Creek is comparatively high (205 mm), and runoff generated by YT24-0.1 is low (50 mm).Runoff generated in the upper Halfway Creek runoff is on par with upper Latte Creek (145 mm); however, closer to the Yukon River runoff is lower, measured at 94 mm.

Based on measurements at Coffee Creek hydrometric stations, average unit yields across the project site are 10.6 L/s/km^2 for the open water season (May to October) and range from 4 to 16 L/s/km^2, with specifics of the runoff regime for each monitoring station being dependent on drainage characteristics (i.e., basin area, shape, mean elevation, extent of permafrost, *etc.*). Unit yields range from 0.8 – 5.1 L/s/km^2 in October and decrease steadily to annual minima in March before increasing again in April in response to low-elevation snow melt and spring rains. Instantaneous peak flows, expressed as unit yields, are typically between 120 and 200 L/s/km^2, but measurements range widely across the site (from 60 to 270 L/s/km^2).

Generally, wet years are expected to produce up to 10 times more surface runoff than an extreme dry year (1:200-year recurrence intervals). The average runoff for the Mine Site is presented alongside the corresponding annual precipitation estimate for each recurrence interval in Table 4-9.

Table 4-9 Annual Precipitation and Average Annual Runoff Recurrence Interval Estimates

	Recurrence Interval (1:years)	Annual Precipitation (mm)	Average Runoff (mm)	Average Runoff Coefficient
Dry-year	1:200	248	31	0.13
	1:100	267	37	0.14
	1:50	288	43	0.15
	1:25	311	52	0.17
	1:10	349	66	0.19
Median	1:2	459	122	0.27
Wet-year	1:10	573	231	0.40
	1:25	611	297	0.49
	1:50	634	352	0.56
	1:100	652	412	0.63
	1:200	668	478	0.72

The peak flow recurrence interval estimates for drainages within the Mine Site area are presented in Table 4-10. These estimates are based on an analysis of regional streamflow records, while the recorded peak flows are based on the site monitoring records that span the period of 2011-2017.

Table 4-10 Instantaneous Peak Yield Recurrence Interval Estimates for Project Basins Derived from Regional Analysis (L/s/km^2)

Station	Drainage Area (km^2)	1:2 year	1:5 year	1:10 year	1:25 year	1:50 year	1:100 year	1:200 year	Measured Peak Yields

Note: [1]Estimated discharge value, hydrometric station was destroyed during July 15, 2017 flood event. Highest recorded water level prior to record interruption returned a unit yield value of 400 L/s/km^2, albeit with a high degree of uncertainty.
[2]This table is referenced from the 2021 Hydro-meteorology Baseline Report which erroneously labels Station LC-0.2 as LC-0.1. This Station ID is corrected to LC-0.2 here.

While the annual low-flow period typically occurs during the months of November to March in the Project site watersheds, many of the streams are frozen and thus there is effectively no flow. During the summer months, the streams respond rapidly to the periodic convective rainfall events, followed by rapid recessions to baseflows. Early in the summer (June) before the progressive melt of the active layer acts to raise baseflows, the low-flow regime can equal that of the winter months. Accordingly, the low-flow recurrence interval estimates presented in Table 4-11 represent the effective annual low flow estimates for the Project site watersheds.

4.1.7 Surface Water Quality

A multi-year surface water quality monitoring program has been conducted at the Project site since fall 2010 to characterize baseline conditions and to inform the water quality model. The program included all of the drainages potentially affected by the Project, including Latte Creek, Coffee Creek, Yukon Tributary (YT-24), Halfway Creek, and the Yukon River. In addition, Independence Creek was included in the surface water quality monitoring program as a reference site. Descriptions of surface water quality are provided below for representative stations.

In general, water chemistry within the catchment areas is influenced by snowmelt-driven surface runoff and/or groundwater inputs to surface flow, which is based on the seasonal water balance. This seasonality is more pronounced higher in catchments. Surface water quality is characterized by soft to moderately soft water that is low in major ions during freshet periods, and hard to very hard waters, with high levels of major ions during winter low-flow periods. Lower in catchments water chemistry shows a similar seasonality, though annual minimum and maximum amounts are less pronounced. pH remains relatively uniform throughout drainages on an annual basis (7.0 to 8.0). A complete description of the water quality variables and stations per catchment can be found in the Site Characterization Plan and the locations of monitoring stations described below are illustrated in Figure 4-10.

4.1.7.1 Latte Creek

Water chemistry in the Latte Creek can be divided between upper Latte Creek, where the primary inputs are from surface runoff, and mid to lower Latte Creek, which is influenced by both groundwater discharge, as well as surface runoff during the ice-free periods.

Table 4-12 provides a summary of the surface water quality in relevant stations of the Latte Creek catchment. A comprehensive list of surface water quality parameters in Latte Creek is provided in the Site Characterization Plan. Relevant stations include:

- LC-15.5 (Upper Latte Creek)
- LC-11.4 (mid- to lower-reach of Latte Creek)
- LC-0.2 (mid- to lower-reach of Latte Creek).

Limited water samples have been collected at the Upper Latte Creek sampling locations due to lack of measurable flow in winter months, which is likely a function of minimal groundwater discharge in this area.

4.1.7.2 Coffee Creek

Background water chemistry in Coffee Creek can be divided between upper Coffee Creek (e.g., above the confluence with Latte Creek) and lower Coffee Creek. Table 4-13 provides a summary of the surface water quality in relevant stations of the Coffee Creek catchment. A comprehensive list of surface water quality parameters in Coffee Creek is provided in the Site Characterization Plan. Relevant stations include:

- CC-11.6 (Upper Coffee Creek; upstream of Project influences)
- CC-3.2 (Lower Coffee Creek; downstream of confluence with Latte Creek)
- CC-10.9 (immediately downstream of confluence with latte Creek).

Coffee Creek is generally characterized by moderately hard with lower levels of major ions during the open water period of May to September. During low-flow periods, water chemistry is dominated by hard to very hard waters with high levels of dissolved solids.

4.1.7.3 Halfway Creek

Two stations are described for Halfway Creek, HC-6.8, approximately mid-way down the watershed, and HC-1.0, at the mouth of Halfway Creek prior to entering the Yukon River. Water quality parameters for these stations are summarized in Table 4-14. A comprehensive list of surface water quality parameters in Halfway Creek is provided in the Site Characterization Plan.

Parameters and their seasonal variations are consistent with Latte Creek and Coffee Creek catchments, with maximum annual TSS concentrations occurring in summer, coinciding with snowmelt and intense summer rainfall events. Despite seasonal peaks, mean monthly concentrations of total and dissolved trace elements are typically low; however, precipitation events produced elevated concentrations of total As, similar to elevated TSS during these periods.

4.1.7.4 Yukon Tributary 24 (YT-24)

Two stations are described for YT-24, near the mouth at station YT24-0.1 and mid-creek at station YT24-4.9. Monthly water quality parameters for these stations are summarized in Table 4-15. A comprehensive list of surface water quality parameters in YT-24 is provided in the Site Characterization Plan.

Hardness for the Yukon Tributary is characterized as moderately hard to very hard at YT24-4.9 and soft at YT24-0.1. Unlike the Coffee Creek catchment, baseflow in YT-24 is not strongly associated with groundwater recharge. The pH in YT24 is circumneutral (i.e., pH between 6.3 and 7.8).

Measured TSS concentrations in both stations are typically low, although peak flow events are associated with elevated TSS. Consistent with the dominant contribution of snowmelt-driven surface runoff to stream flow, water chemistry commonly shows elevated levels of dissolved organic carbon (DOC), although monthly mean concentrations of most trace elements are low.

4.1.7.5 Independence Creek

Independence Creek is characterized by water quality measured at Station IC-2.7 (Figure 4-10) which reflects water quality conditions in lower Independence Creek and downstream of contributions from three small catchments. The catchments drain the east slope of the drainage divide between upper Latte Creek and Independence Creek (IC-16.1 and IC-14.6) and the eastern slope of the drainage divide of Halfway Creek and Independence Creek (KT-0.3) in Kona Creek. Table 4-16 summarizes the surface water quality at location IC-2.7. A comprehensive list of surface water quality parameters at station IC-2.7 is provided in the Site Characterization Plan.

Parameters and their seasonal variations are consistent with Latte Creek/Coffee Creek, with maximum annual TSS, dissolved organic carbon, dissolved Al, total Fe occurring in summer. Despite seasonal peaks, mean monthly concentrations of total and dissolved trace elements are typically low, with the exception of dissolved Al and total Cu.

4.1.7.6 Yukon River

Table 4-17 summarizes the baseline water quality in the immediate vicinity of the proposed project, at stations YUK-51.3 and YUK-26.1. These stations are located immediately upstream of Coffee Creek and downstream of Independence Creek, respectively (Figure 4-10). A comprehensive list of surface water quality parameters at Yukon River monitoring stations is provided in the Site Characterization Plan.

Yukon River is characterized by consistently hard waters with low to moderate levels of major ions. Measurements for pH are generally circumneutral to slightly basic. The strong seasonal water quality signature is largely absent from the Yukon River, presumably due to its large catchment. The Yukon River shows concentration peaks for certain organic parameters during summer high flows. Despite annual concentration peaks for certain parameters during summer high flows, mean monthly concentrations of total and dissolved trace elements are typically low, falling below CCME and BC long-term guidelines. The pH in Yukon River is relatively consistent between the stations throughout the year (pH of approximately 8.0). TSS concentrations in the Yukon River show maxima coinciding with peak snowmelt months. Mean monthly concentrations of total and dissolved trace elements and most notably for U, are typically low, falling below CCME and BC long-term guidelines.

4.1.8 Groundwater

Existing conditions are provided below for groundwater quantity and groundwater quality. Groundwater quantity refers to the distribution of groundwater and related volumetric fluxes while groundwater quality refers to its chemical composition. Multiple hydrogeological programs have been undertaken at the Coffee mine site to characterize the physical and chemical groundwater system. Data collected in these investigations has been supplanted by geotechnical programs. The well-developed groundwater monitoring network includes eleven conventional monitoring wells, seven Westbay multilevel groundwater monitoring systems, nine combination vibrating wire piezometer (VWP)/thermistor strings, plus twelve stand-alone thermistor strings, twenty-five stand-alone shallow thermistor beads, and four stand-alone VWP strings. The installations span elevations of ~560 masl to ~1,250 masl on multiple slope aspects (Figure 4-11).

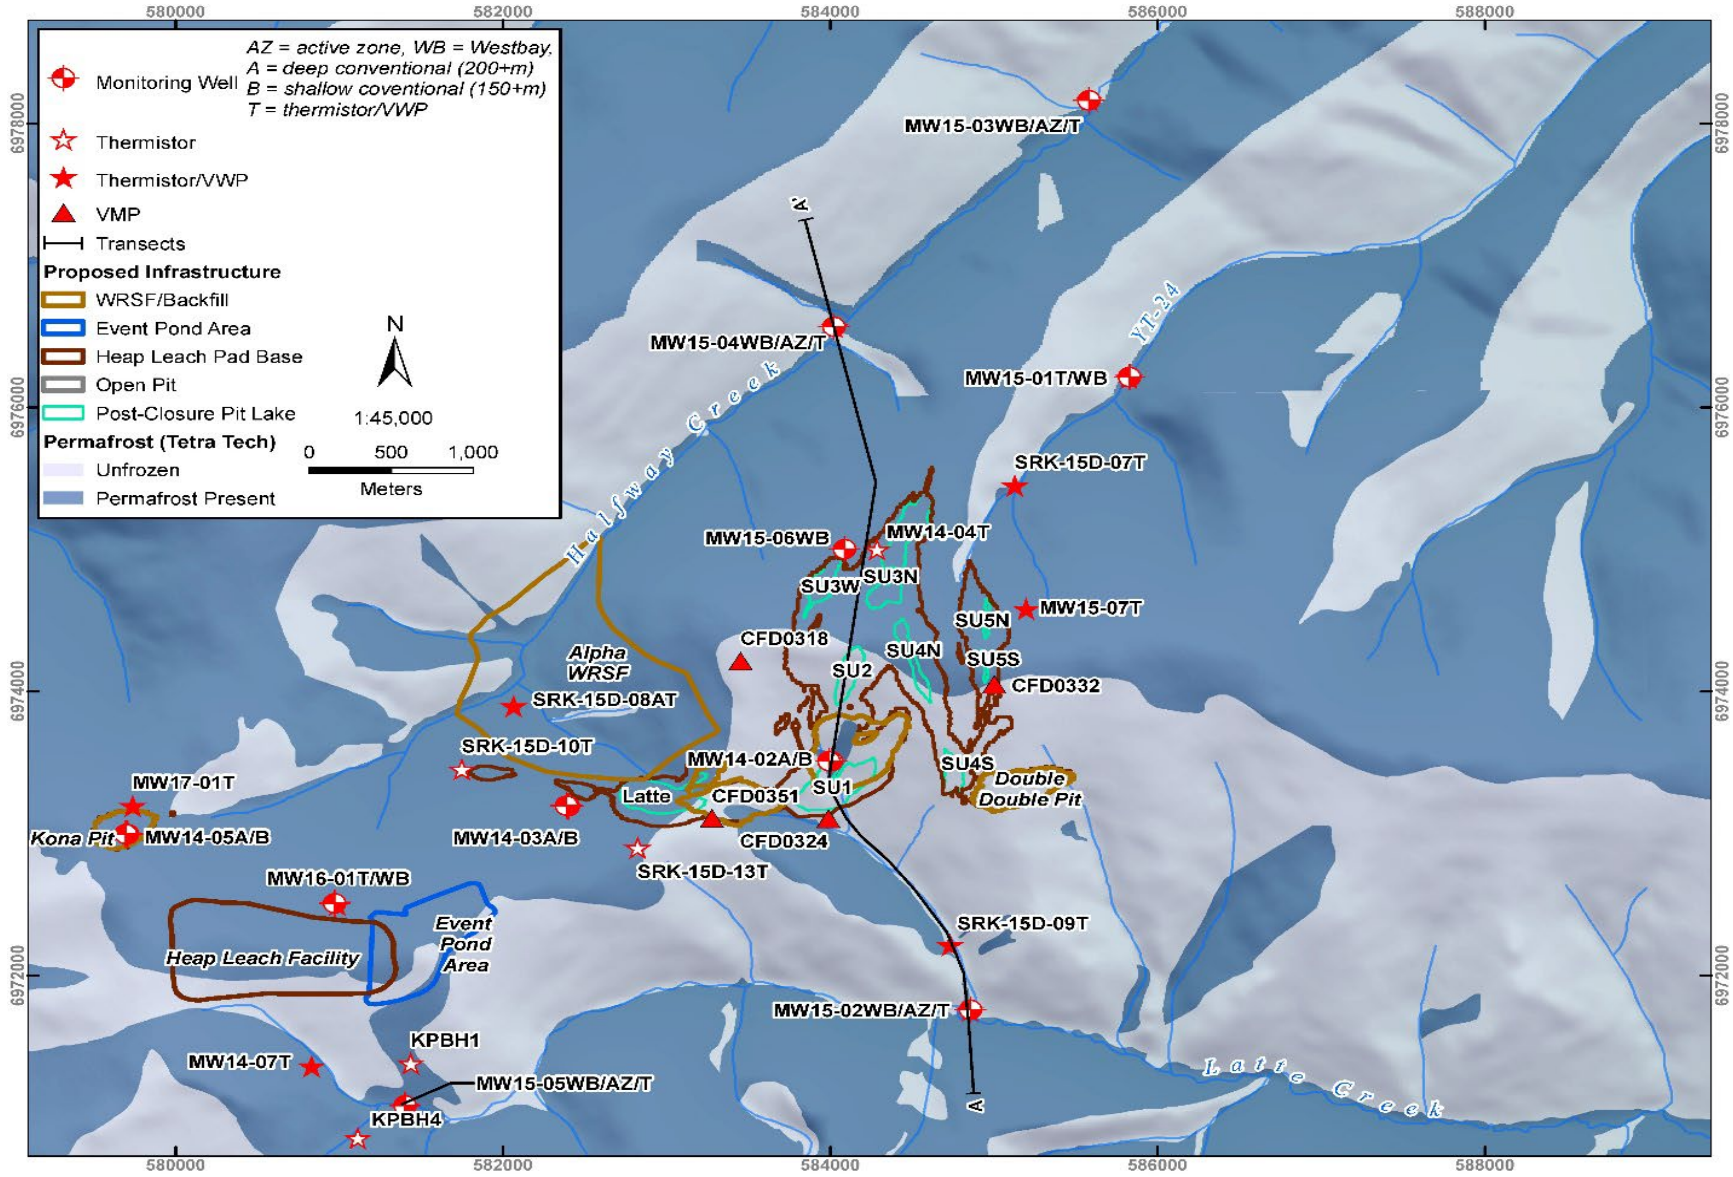

Figure 4-11 Groundwater Instrumentation at the Coffee Project

4.1.8.1 Groundwater Quantity

Overall, the physical hydrogeological data reveal a complex groundwater system influenced by both discontinuous permafrost and a well-developed fracture system. As indicated in Section 4.1.5.2 and illustrated in Figure 4-11, permafrost underlies ~60% of the Mine Site. Overall, permafrost extends to greatest depths in ridge areas and appears to reduce in thickness towards areas of lower elevation; north-facing slopes tend to have thicker and more prevalent permafrost than south-facing slopes. Permafrost is of hydrogeological significance as it is considered to behave like an aquiclude or an aquitard and can confine sub-permafrost groundwater, isolating it from a thin seasonal active layer above it. Hydrogeologic investigations at the Mine Site have focussed on the sub-permafrost groundwater system.

4.1.8.2 Hydraulic Conductivity

Hydraulic testing of bedrock at the Coffee project has been undertaken on multiple lithologies located within pit footprint areas and farther afield. The hydraulic conductivity data are typical of a fractured bedrock system, ranging over several orders of magnitude with values exceeding 1E-06 m/s and others below the resolution of the testing method. Based on the widespread in values for the major rock units and combinations thereof, rock type does not appear to exert a large influence on hydraulic properties. Rather, structural features, which crosscut all lithologies, impart the dominant control on hydraulic conductivity.

Bedrock hydraulic conductivity values are observed to broadly decrease with depth with the exception of deeper tests that specifically targeted geologic structures intersecting the proposed pits and in the currently proposed HLF footprint (Figure 4-12). These structures report a mean K value of 2E-07. Borehole testing near creek channels infer that major creek traces (i.e., Halfway Creek and YT-24) represent permeable fault structures.

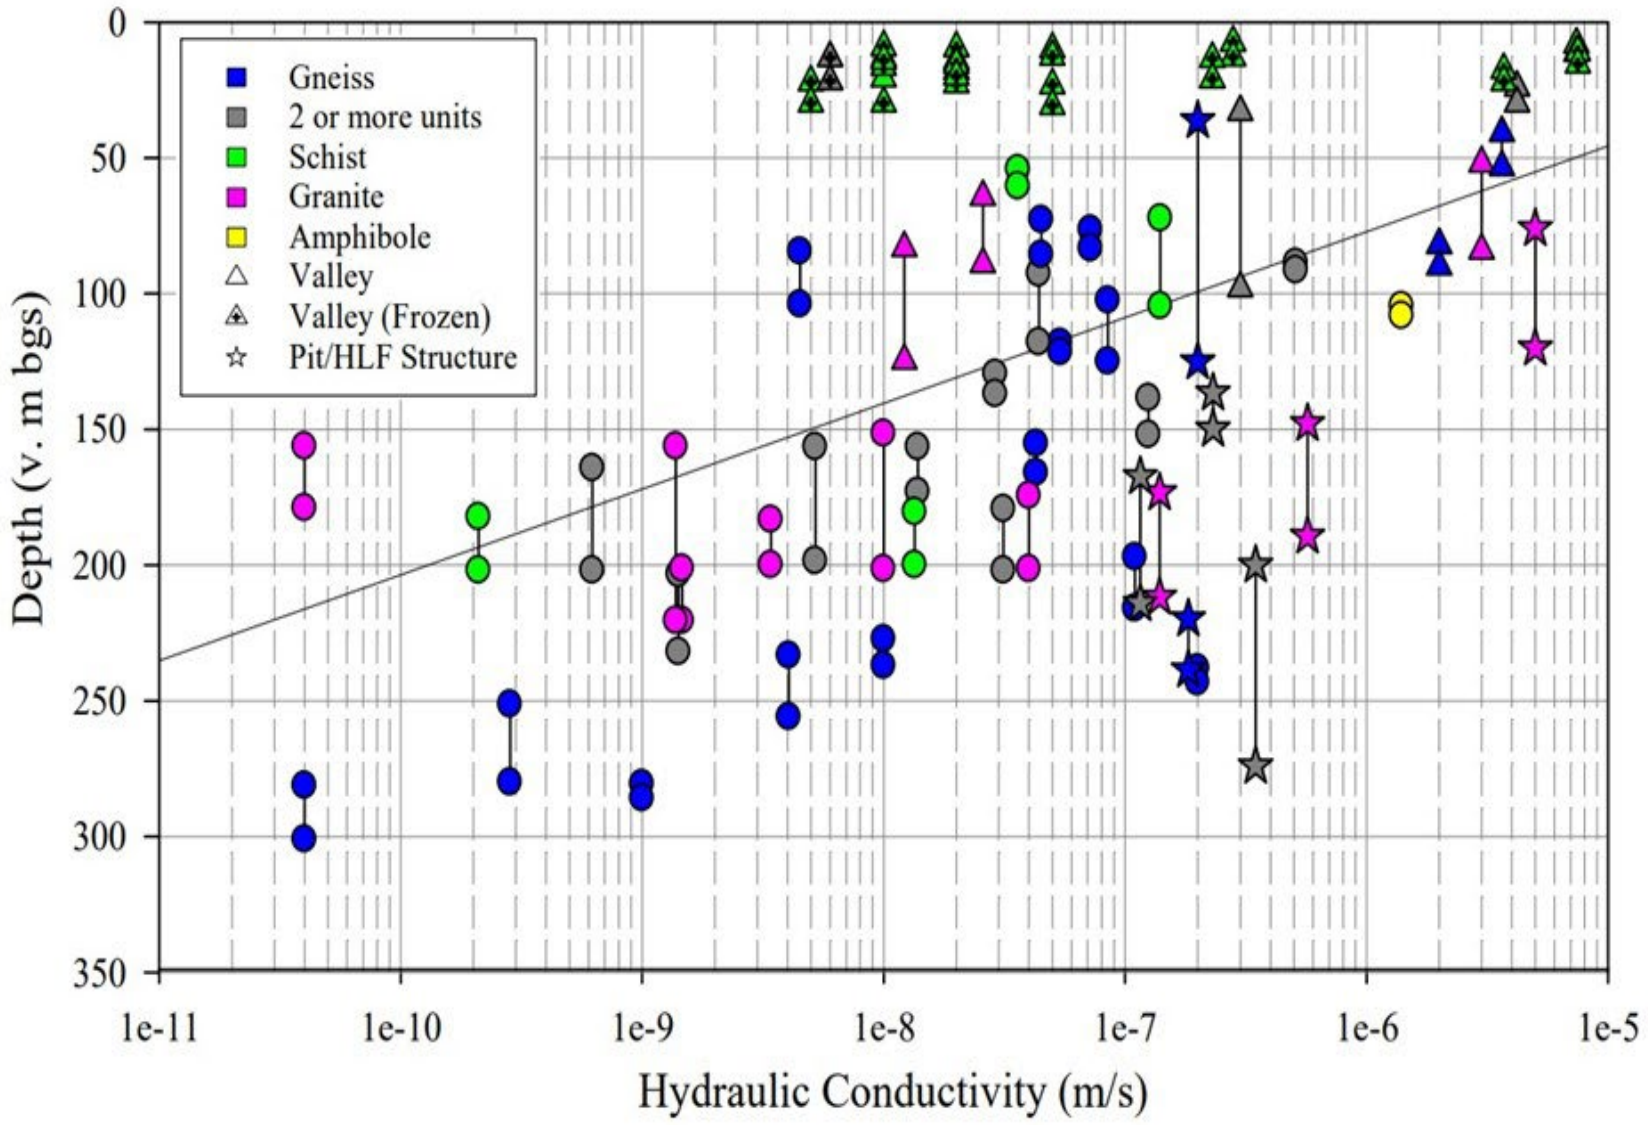

Figure 4-12 Bedrock Hydraulic Conductivity versus Depth

4.1.8.3 Groundwater Levels

In general, groundwater levels are very deep in ridge areas, ranging from 130 m to over 220 m below the ground surface, but artesian conditions are encountered even at moderate to high elevations in the drainages. Water level hydrographs indicate variable response to seasonal recharge patterns, with fluctuations ranging from approximately <1 m to over 30 m. Fluctuations in the range of 0 m to 10 m are typical. The magnitude of seasonal fluctuations is not clearly correlated to well collar elevation, nor to the presence of permafrost. The continuous water level record indicates that the hydrographs at most wells are reasonably insensitive to individual rainfall events; rather, they follow a gradual seasonal increase that peaks anywhere between late summer and winter. The timing of peak groundwater levels is highly variable across the site.

Nested instrumentation revealed both upward and downward vertical hydraulic gradients in both upland and low-lying areas. In some instances, horizontal hydraulic gradients exceed topographic gradients. At monitoring locations where permafrost depth is accurately known, groundwater pressures can exceed the base of permafrost, demonstrating confined conditions. The notable exceptions are the slope draining the SU3W Pit, where the water table is inferred to be at least 50 meters below the base of permafrost, and the slope draining Kona Pit, where water levels are about 20 m below the base of permafrost.

A map of bedrock groundwater head contours is provided in Figure 4-13. Groundwater flows from high elevation (recharge areas) to low elevation, discharging along drainages inferred to represent fault structures. This is evidenced by seepage at surface and upward artesian groundwater pressures registered at piezometers along drainage traces. Where drainages intersect areas underlain by permafrost, the drainage itself may present as a diffuse through-talik that permits discharge of deeper, sub-permafrost groundwater to surface. This phenomenon has been observed in reaches of Halfway Creek. A deeper groundwater flow path ultimately flows toward the Yukon River and deflects northwest toward a regional topographic low point.

Groundwater discharge to creeks (i.e., baseflow) is often overwhelmed by surface runoff and active layer flow during the open water season except following an extended dry period. Minimum baseflow measured in late winter is considered equivalent to groundwater discharge; winter basin yields are estimated to range from 0.0 to 0.7 L/s/km^2. As baseflow component of streamflow increases, concentrations of some parameters including uranium, calcium, magnesium, and strontium are observed to increase in surface water.

4.1.8.4 Groundwater Quality

Groundwater quality is described according to screened lithology. Monitoring wells screened in schist are distributed on the north and south sides of the Mine Site in the vicinity and downstream from the proposed Latte Pit. Monitoring wells screened in gneiss are situated on the north side of the Project in the Halfway Creek and YT-24 drainages. Monitoring wells screened in granite are located adjacent to Latte Creek downstream from the proposed HLF and in the Kona Pit area. One well pair located in the south Supremo/Latte area screens hydrothermal breccia.

Groundwater across the mine site is predominantly circum-neutral (pH 6 to 8), with most samples characterized by pH 6.5 and 8. Groundwater wells show variable influence from weathering of sulfide minerals or dissolution of sulfate minerals, either from the deposits or other disseminated mineralization

across the Project area. This is evidenced by low to substantial sulfate (SO_4) concentrations, which range from 7 mg/L to 1,120 mg/L and variable salinity with specific conductance ranging from 28 microsiemens per centimeter (µS/cm) to 2390 µS/cm. The most saline groundwater is encountered at the most downgradient wells in Halfway Creek and YT-24 (Figure 4-11). These wells lie within a lineament (fault) that crosscuts several drainages and imparts a unique chemical signature on groundwater.

A piper plot of major ion chemistry of groundwater within the Project area is provided in Figure 4-14. The groundwater in gneiss has a wide-ranging major ion chemical signature which ranges from calcium-bicarbonate to mixed magnesium-calcium-sodium-sulphate-type water, reflecting variable influence of sulfide weathering. Groundwater in the granite is calcium-bicarbonate-type but is generally more sodic than other groundwater on site. The groundwater sampled from the hydrothermal breccia and schist tends to be calcium-bicarbonate to magnesium-sulphate.

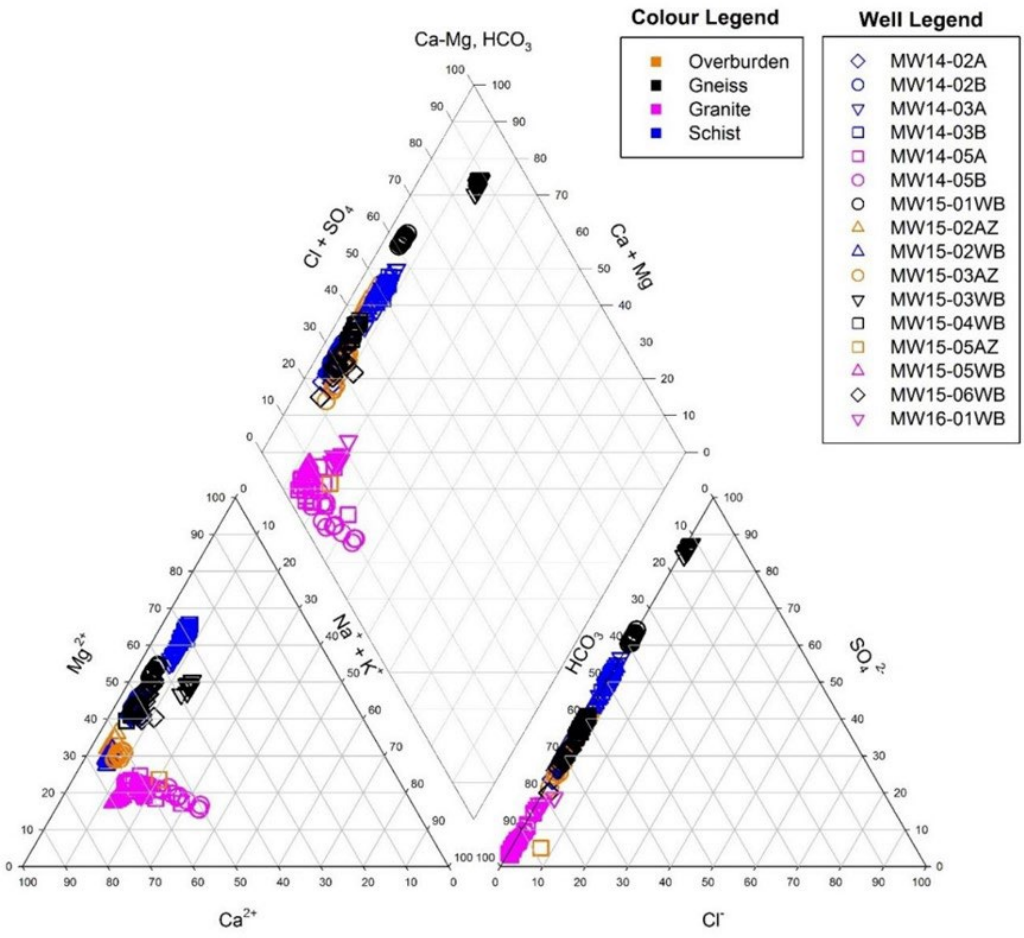

Figure 4-14 Piper Plot of Coffee Groundwater Quality Data (2014 - 2019)

Redox conditions within a groundwater system can be assessed based on the presence and concentration of oxidized and reduced inorganic compounds in groundwater samples. For classification purposes, mildly reducing waters may accompanied contain oxidized compounds such as nitrate (NO_3^-) and nitrite (NO_2^-) in combination with reduced compounds such as ammonia (NH_3) and dissolved manganese (Mn^{2+}). Oxic waters do not contain any reduced compounds. Moderately reducing waters generally lack oxidized parameters while presenting reduced compounds (NH_3, Mn^{2+} and/or dissolved iron (Fe^{2+})). Strongly reducing waters also contain dissolved sulfide (S^{2-}).

Groundwater redox conditions are highly variable across the site. Groundwater sampled from shallow groundwater wells screening overburden is oxic to moderately reducing. Groundwater screened in gneiss varies from oxic to strongly reducing. Groundwater draining gneiss downgradient of the Alpha WRSF is mildly to moderately reducing while groundwater sampled further at the lineament in the Halfway Creek and in the YT-24 drainage is moderately to strongly reducing.

Groundwater redox conditions at monitoring wells screened in granite are mildly to strongly reducing. Monitoring wells in the Kona Pit area present moderately to strongly reducing conditions while groundwater

sampled downstream of the HLF in the upper reaches of Latte Creek is less reducing based on an absence of measurable S^{2-}.

Monitoring wells screened in schist span the entire range of redox conditions from oxic to strongly reducing. The well pair adjacent to the proposed Latte Pit screened mildly to strongly reducing groundwater. Near the Supremo Pit, groundwater-screened hydrothermal breccia is oxic or oxygenated, with very low to negligible concentrations of reduced species.

Average concentrations for selected parameters of concern are summarized in Table 4-18 and Table 4-19. A comprehensive list of dissolved metals concentrations in groundwater is provided in the Site Characterization Plan. Baseline groundwater quality in the Project area is characterized the presence of elevated dissolved arsenic (As) and uranium (U). Dissolved As and U concentrations are generally highest in the bedrock groundwater, ranging from 0.12 to 2650 µg/L and 1.2 to 589 µg/L, respectively.

Dissolved As is measurable in a number of monitoring wells at the site. The highest As concentrations in the Project area were observed in the granitic bedrock beneath the Kona Pit. It is also notable that granite material at the Kona Pit has the highest solid-phase. As concentrations measured in the Project area. It appears that As is naturally attenuated along groundwater pathways.

Dissolved U is generally elevated (> 15 µg/L) across the site, with the highest concentrations measured in wells screening gneiss. Dissolved U concentrations are highest in gneiss in the YT-24 drainage and the Halfway Creek drainage. Notably, the concentrations of dissolved U are lower in the downgradient well in Halfway Creek along the lineament. This drop in U concentrations appears to be related to lineament itself, as dissolved U appear behaves more conservatively than As in the groundwater environment.

4.2 Biophysical Environment

The sections below describe existing conditions in the aquatic and terrestrial environments, including species and habitat distributions, traditional and current uses of resources, and metals levels (if relevant).

4.2.1 Aquatic Environment

The aquatic environment, including current and historical fish presence, distribution, and habitat use, and aquatic resources, is described below based on published and unpublished scientific data. Traditional and local knowledge and survey information collected in the region from 2000 to 2018 at and downstream of the proposed Mine Site area and along the NAR corridor was also used to inform the aquatic environment. Detailed studies have included the following:

- In 2013, Access Consulting Group (ACG) undertook preliminary studies focused on describing fish habitat in the vicinity of the proposed mine site and documenting potential salmon spawning and the distribution of fish species within tributary streams of the Yukon River (ACG 2014).
- In 2014 and 2015, Palmer Environmental Consulting Group collected baseline data to characterize fish and aquatic resources around the proposed mine site and, in 2015, along the NAR (Palmer 2017).
- From 2016 to 2021, EDI Environmental Dynamics Inc. (EDI) collected additional baseline data in local watercourses and along the NAR, including salmon spawning surveys, fish sampling/habitat assessments, periphyton sampling, as well as metals analyses of sediments, benthic invertebrates, and fish tissues.

Aquatic environment surveys and studies that were completed are detailed in the Site Characterization Plan.

A total of 14 fish species inhabit the watercourses adjacent to or downstream of the proposed Mine Site and the NAR, including two species of salmon and 12 resident freshwater fish species. The majority of these species are found only in the Yukon River and Stewart River. There are no aquatic species listed under Yukon or federal *Species at Risk Act (SARA)* listings within the local or regional watercourses.

Slimy sculpin (*Cottus cognatus*), Arctic grayling (*Thymallus arcticus*), and juvenile Chinook salmon (*Oncorhynchus tshawytscha*) are present in Coffee Creek and the Yukon River year-round. Among Yukon River tributary creeks, the highest species diversity and abundance of fish have been documented in Coffee and Independence creeks, which are the two largest creeks in the mine area. These species were also the most common species encountered along the NAR. As the lower portions of Halfway Creek freeze to bed in winter, slimy sculpin is not likely to remain in this portion of the stream.

Arctic grayling are the most widespread species in the local area as they have also been found in Latte, Halfway and YT-24 creeks. They use these smaller creeks for summer rearing only; eDNA data from March 2016 confirmed that Arctic grayling overwinter in Coffee Creek and the Yukon River, but not in any other streams within the local area. It is common for Arctic grayling to use different streams for important life history periods such as spawning, summer rearing, and overwintering.

Fish access to upper reaches of the headwater streams within the proposed mine footprint is limited by gradients, impediments, and low water temperatures (limiting primary production). Along the NAR, fish

presence is typically associated with the larger streams that are crossed, and the likelihood of fish presence decreases with distance from mainstem habitat. Recent surveys have identified Arctic grayling further upstream in Halfway Creek than in previous years, partly owing to changes to a log jam barrier that was previously impeding fish. In addition, a local flooding event in 2017 resulted in changes to the YT-24 Creek stream channel morphology and low water levels, and few fish have since been observed within this channel. An expansion of the study area in recent surveys identified fish presence in Independent Creek tributaries A and B, Dan Man Creek, and Kona Creek. The Stewart River backchannel has been identified as a seasonal fish habitat for fish species including northern pike (*Esox Lucius*), burbot (*Lota lota*), lake whitefish (*Coregonus clupeaformis*), and longnose sucker (*Catostomus catstomus*).

Traditional and current uses of fish resources in the region are generally concentrated in the Yukon River and Coffee Creek. The Yukon River in the vicinity of Coffee Creek has long been an important salmon fishing location for First Nations (TH 2012a), as the area provides rearing, migration, and spawning habitat for Chinook salmon (*Oncorhynchus tshawytscha*) and Chum salmon (*Oncorhynchus keta*); fish camps were set up annually near the mouth of Coffee Creek by several First Nations groups. Traditional Knowledge and current land use speaks to the importance of the Yukon River watershed for these species (Bates and DeRoy 2014, TH 2012a, DRPC 2013). Other fish species of traditional importance that are present in the Yukon River include Arctic grayling, whitefish species, northern pike, burbot, inconnu (*Stenodus leucichthys*), and longnose sucker. During the Project consultation process, First Nations emphasized the importance of the Coffee Creek corridor for salmon runs, wildlife and vegetation, as well as traditional uses, including for travel and fishing.

Traditional Knowledge indicates that Chinook salmon used to spawn in Coffee Creek (TH 2012a). Although spawning Chinook were not documented in Coffee Creek during surveys in 2000, 2001, and 2014 through 2019, spawning chum were observed in groundwater fed side channels of the Yukon River in the local area, and in similar habitats in the Stewart River downstream of the NAR. Coffee, Independence (and occasionally the lower portion of Halfway) creeks are used by juvenile Chinook as non-natal rearing habitat, and Coffee Creek provides Chinook overwintering habitat.

Primary production was found to be very low for all sampling stations, which is typical of northern, nutrient poor aquatic habitats. Chlorophyll-a concentrations increased in samples collected further downstream in each of the watersheds, as stream flows, water temperatures, and nutrient inputs increased. For benthic invertebrates, mean total abundance was variable throughout the local area, with the highest abundance in Independence Creek, followed by YT-24, Coffee, Latte and Halfway creeks.

4.2.1.1 Metal Concentrations

Arctic grayling, slimy sculpin, and juvenile Chinook salmon caught within the local area were analyzed for metal concentrations in tissues. Benthic invertebrate and sediment baseline metal concentrations were also analyzed from these creeks. Methylmercury levels in all slimy sculpin, Arctic grayling, and juvenile Chinook salmon tissues exceeded the Canadian Tissue Residue Guidelines for the Protection of Wildlife Consumers of Aquatic Biota (CCME 2000a). Baseline concentrations of selenium in slimy sculpin exceeded the United States Environmental Protection Agency guideline for whole-body selenium (US EPA 2015) in a small number of samples from fish caught in Coffee and Independence creeks, and Arctic grayling and slimy sculpin sampled from all areas exceeded the BC guideline for selenium (BC MOE 2014).

Methylmercury concentrations in all benthic invertebrate tissue samples were below the CCME Guideline set for the protection of piscivorous wildlife. Uranium concentrations in benthic invertebrate tissues were higher in samples collected in March when compared with August data; this correlated with annual peak uranium concentrations during late winter low flows due to increased proportions of groundwater contributions to surface water.

Analyses of sediment baseline metals concentrations collected throughout the local area indicate that arsenic and chromium are consistently present at concentrations that exceed the CCME Interim Freshwater Sediment Quality Guidelines (CCME 2000b) at many sites, and the Probable Effects Level (PEL) at some sites. Additional details regarding fish and aquatic life studies that have been completed for the site are provided in the Site Characterization Plan.

4.2.2 Vegetation

This section provides a description of vegetation communities based on studies conducted in the area, and First Nation traditional and current use of plant species from several Traditional Knowledge surveys (Bates and DeRoy 2014, TH 2012a, InterGroup Consultants Ltd. 2009). The Project is located within the Klondike Plateau Ecoregion of the Boreal Cordillera Ecozone. Approximately 90% of the local study area occurs within the Boreal Bioclimate zones (Boreal Low and Boreal High), with the remaining area occurring in the Subalpine Bioclimate zone.

Vegetation surveys were conducted in 2014 to 2016, and included ecosystem mapping, rare plant surveys, exotic and invasive species surveys, and vegetation and soil sampling for trace metals analyses. The studies were completed in an area encompassing approximately 800 km², which was delineated based on the height of land and encompassed a minimum buffer of 1 km around the proposed mine site footprint. Along the road alignments, including a 1 km buffer on either side, as shown in Figure 4-15.

Combined, the surveys documented 411 vegetation species including seven tree, 60 shrub, 188 forb, 63 grass, 18 fern/horsetail/clubmoss, 2 aquatic, 36 mosses/liverworts, and 37 lichens. Vegetation at higher elevations consists of subalpine habitats dominated by sparse, deciduous shrubs, while mature spruce forests dominate valleys.

The subalpine landscape is dominated by shrub communities overlaying a well-developed feathermoss and lichen layer. Communities of scrub birch (*Betula glandulosa*), Labrador tea (*Rhododendron groenlandicum*), bog blueberry (*Vaccinium uliginosum*), lowbush cranberry (*Vaccinium vitis-idaea*), and crowberry (*Empetrum nigrum*) are common. The widely distributed dry, shallow hillcrests throughout the area commonly support communities of low-growing shrubs and/or ground shrubs, including scrub birch, mountain avens (*Dryas spp*.), crowberry, Arctic white heather (*Cassiope tetragona*), and lowbush cranberry. A sparse conifer canopy (~15% cover) develops over the shrub layer as the subalpine nears the treeline and the boreal transition.

Below the treeline, the vegetation patterns reflect the discontinuous distribution of permafrost throughout the region. Closed canopy pure or mixed stands of white spruce (*Picea glauca*), black spruce (*Picea mariana*), Alaska birch (*Betula neoalaskana*), and trembling aspen (*Populus tremuloides*) occur on neutral and warm, gentle-to-moderate slopes. Understory species in this area typically include Labrador tea, prickly rose (*Rosa acicularis*), lowbush cranberry, tall bluebells (*Mertensia paniculata*), bastard toadflax (*Geocaulon lividum*), and feathermosses. Dry, moderate-to steep, south-facing slopes support grasslands and aspen forests, overlaying kinnikinnick (*Arctostaphylos uvaursi*), soapberry (*Shepherdia canadensis*), and grasses.

In contrast, stunted black spruce forests occur on cold, north-facing slopes with imperfect-to-poor drainage due to near surface permafrost. Understory species in this area typically include Labrador tea, sedges, cottongrass (*Eriophorum vaginatum*), and cloudberry (*Rubus chamaemorus*). On gentle toe-slopes underlain by permafrost, black spruce communities containing Labrador tea, sedges, red bearberry (*Arctous rubra*), and lichens predominate. Black spruce forests with high lichen cover also occur on better drained, coarser-textured upland, north-facing, lower-to-upper slopes.

Frequent fires in the area has led to young, deciduous-dominated, and mixed wood stands being more common than mature conifer-dominated stands. Wetland and floodplain ecosystems exist in valley bottoms throughout the area but represent a small component of overall area. In additionally, the region has a long history of placer gold mining, and many valley bottoms include historic and/or active placer mines.

No federally listed at risk plant species (i.e., listed either under the Committee on the Status of Endangered Wildlife in Canada (COSEWIC) and/or *SARA*) were observed during rare plant surveys; however, populations of four Yukon Watch List plant species were found:

- Coffee Creek Scorpionweed (*Phacelia mollis*)
- Spotted Lady's Slipper (*Cypripedium guttatum*)
- Small Enchanter's Nightshade (*Circaea alpina ssp. alpina*)
- Dry-spike Sedge (*Carex siccata*).

Baseline surveys for exotic and invasive plants documented populations of 18 invasive plant species, including five rank 1 invasive species (invasive plants range in degree of invasiveness (i.e., concern) from high priority (1) to least concern (7)). The observed rank 1 invasive species are: smooth brome (*Bromus*

inermis), narrow-leaved hawksbeard (*Crepis tectorum*), perennial sow-thistle (*Sonchus arvensis spp. uliginosus*), white sweetclover (*Melilotus albus*), and yellow sweetclover (*Melilotus officinalis*). Invasive plants were most prevalent along roadsides north of the Stewart River, with scattered occurrences along roadsides between the Stewart and Yukon rivers; very few were found within the tenure.

Trace metals sampling was conducted in the vicinity of the proposed mine site to determine the baseline concentrations in soils and four plant species including the following: willow (*Salix* spp.), fruticose lichen (*Cladina* spp.), horsetails (*Equisetum arvense, Equisetum pratense*, and *Equisetum sylvaticum*), and lowbush cranberry.

Trace metal concentrations in soil were below the CCME soil quality guidelines, except for arsenic and chromium, which were naturally elevated in 27% and 4% of the samples collected, respectively. Samples with naturally elevated arsenic levels were generally collected in close proximity to the proposed mine site, while samples with naturally elevated chromium were collected close to the proposed mine site and at control sites ≥15 km relative to the proposed Project footprint. A few soil samples also reported mercury and selenium above the laboratory reportable detection limit. No CCME guidelines currently exist for trace metals in vegetation; therefore, the results were compared to CCME guidelines for soil quality. Additional information regarding trace metals sampling of vegetation is provided in the Site Characterization Plan.

Many of plant species found in the area are currently, or have been previously, used by local First Nations as a source of food, or for medicinal and spiritual use, while others have more practical or decorative uses. Both TH and WRFN members report harvesting berries and other edible plants from the area which would supplement the meat and fish they also harvested from the land (TH 2012a; Bates and DeRoy 2014). According to the Coffee Creek Traditional Knowledge Survey (TH 2012a):

> “Harvesting berries was also an important activity in the Coffee Creek area, where high bush and low bush cranberries could be found. Blueberries were picked in the flats and soap berries were plentiful. William also mentioned gooseberries, which Roland thought to be mossberries.”

Similarly, WRFN members report picking blueberries, highbush cranberries, and blackberries in the Project area (Bates and DeRoy 2014). TK also contains accounts of the continued importance of berries to local First Nations:

> “Among the plants still collected and consumed today [within NND traditional territory] are largely berries such as Low-bush Cranberries, Blueberries, Black Currants, Raspberries, Stone Berries, and High Bush Cranberries” (InterGroup Consultants Ltd. 2009).

Plants have also been harvested for medicinal use such as the pitch from trees and the root or leaves of certain species (Popadynec 2007; InterGroup Consultants Ltd. 2009; TH 2012b; Bates and DeRoy 2014). Use of plants for medicinal and other uses have been documented as follows:

> “Some of the leaves are good, certain leaves are good for medicines…some you make salves. Some are plants. Some are the flowers and all that” (Bates and DeRoy 2014).

> "As the spruce gum is chewed it produces a juice which is swallowed to treat a sore throat. When boiled, spruce gum tea is also used to treat colds. The sticky gum can be used as a salve on cuts or to help remove slivers. Other parts of the spruce tree, such as the cones, the inner bark and the young spruce tips may be used for medicine as well." (Popadynec 2009).

> "Some plants were traditionally collected for medicinal purposes by the Na-cho Nyäk Dun. These plants included yarrow, spruce, pine, balsam, Labrador tea, caribou horn (lichen) and puffballs (fungi)... Most of the medicinal plants used in the area are commonly found throughout the boreal forest." (InterGroup Consultants Ltd. 2009).

In addition to plants harvested for food or medicine, plants were harvested for making tools and equipment, such as baskets, sleds, and snowshoes (Bates and DeRoy 2014, Popadynec 2009). WRFN members report having collected birch bark in the areas around Coffee Creek for use in basket making (Bates and DeRoy 2014). Labrador tea (*Rhododendron groenlandicum*) and bear root (*Hedysarum alpinum*) are other commonly harvested plants (TH 2012a, Bates and DeRoy 2014, Popadynec 2009).

4.2.3 Wildlife

Detailed descriptions of existing conditions for wildlife and wildlife habitat in the area are provided below and are based on wildlife studies undertaken from 2011 to 2018. Additional wildlife investigations were conducted through winter 2019/2020 and summer 2021 that focused on specific target species. Additional details regarding the recent wildlife investigations are provided in the Site Characterization Plan.

Wildlife descriptions below are based on regional and local areas of approximately 13,661 km² and 473 km², respectively, (Figure 4-15) to assess the abundance and distribution of most large and smaller wildlife species in the Project region, respectively. The local area includes the proposed mine site area, the proposed NAR to the junction with the Klondike Highway, and a minimum 1 km buffer around the proposed Project footprint. The regional area encompasses all Game Management Subzones that intersect or are adjacent to the proposed Project footprint. It is bounded on the north by the Klondike Highway, to the east by Grand Valley creek and Dip Creek, and on the south and west by the White and Yukon rivers.

Wildlife species that were traditionally harvested in the region by First Nations include caribou (*Rangifer tarandus*), moose (*Alces americanus*), Canada lynx (*Lynx canadensis*), wolverine (*Gulo gulo*), red fox (*Vulpes vulpes*), American marten (*Martes americana*), American mink (*Neovison vison*), American beaver (*Castor canadensis*), common muskrat (*Ondatra zibethicus*), porcupine (*Erethizon dorsatum*), and snowshoe hare (*Lepus americanus*), among others (Mishler and Simeone 2004, InterGroup Consultants Ltd. 2009, TH 2012a, Bates and DeRoy 2014). The Coffee Creek area in particular was noted as being an important trapping area (TH 2012a, Dobrowolsky 2014).

Focal species and species groups were identified as those of conservation concern, those that are harvested by Indigenous or non-Indigenous hunters, those raised as a concern during Project consultation, those selected as focal species for previous Yukon environmental assessments, and those with the potential to interact with the proposed Project. The focal species include: caribou, moose, thinhorn sheep (*Ovis dallii*), mule deer (*Odocoileus hemionus*), grizzly bear (*Ursus arctos*), black bear (*Ursus americanus*),

grey wolf (*Canus lupus*), wolverine (*Gulo gulo*), a variety of furbearers, collared pika (*Ochotona collaris*), bats, and small mammals; these and other notable species are described further below. The comprehensive list of focus species is provided in the Site Characterization Plan.

Baseline surveys have confirmed the presence of several wildlife species federally listed as at risk by *SARA*, and/or COSEWIC that occur, or have the potential to occur in the Project area, including woodland caribou, grizzly bear, wolverine, cougar (*Puma concolor*), collared pika, and little brown myotis (*Myotis lucifugus*). The comprehensive list of at-risk wildlife species is provided in the Site Characterization Plan.

Three caribou herds, representing two subspecies of caribou, may be found in the regional area. The Fortymile and Nelchina caribou herds are classified as *Rangifer tarandus granti*, which includes the large migratory herds; their status has not yet been assessed by COSEWIC. The Klaza Caribou Herd is classified as *Rangifer tarandus caribou* and is a part of the Northern Mountain population of woodland caribou, which has been assessed by COSEWIC as a species of Special Concern within Canada. Of these, the current annual range of the Fortymile and Klaza caribou herds overlaps the regional area, while the Nelchina Caribou Herd range is on the periphery of the regional area. A small number of Nelchina caribou may enter the regional area during winter, but the number of caribou and time spent is expected to be very low.

The Fortymile Caribou Herd, with an estimated population of approximately 72,000 individuals (2017 minimum count), has been identified as a focal species for the Project due to the recent population recovery and re-establishment of previously abandoned herd range in the north and central Yukon. The herd is known for its long-distance movements between its calving range in east-central Alaska and a large winter range. Historically, the herd used the regional area extensively in all seasons except calving. Following a population crash in the mid-1900s, the herd abandoned large portions of its historic range, including all its range in Yukon. Recent population recovery has resulted in the re-establishment of winter range in Yukon (since 2002) and the regional area (since 2013).

The herd has also increasingly been found in Yukon during the summer months, although use of the regional area since 2013 has, to date, been limited to the winter months. Based on current use patterns, the Fortymile Caribou Herd has the potential to occur within the regional area seasonally between October and April; further population growth and/or further expansion of the herd range may result in the Fortymile caribou also being present in the regional area during the summer months. At present, licensed caribou harvest is closed year-round in all game management sub-zones that overlap the Project footprint, and TH has a voluntary no-harvest program in place for the Fortymile Caribou herd.

The Klaza caribou herd, currently estimated at 1,179 individuals (2012 population estimate), has an annual range that overlaps the southern portions of the regional area, south of the Yukon River. Within this area, small numbers of Klaza caribou are expected to occur during the spring, summer, and/or fall months.

Moose are widely distributed across the region and their overall densities in the regional area are close to the Yukon average, with some northern regions possibly containing higher-than-average densities. Moose densities within 10 km of the NAR are estimated at 247 moose per 1,000 km² based on a 2015 survey, while in the southern sections of the regional area, moose densities are estimated at 170 per 1,000 km² based on a 2012 survey of the region (O'Donoghue et al. 2013). Moose are the primary harvest species within the regional area and are a highly valued species for both First Nations people and licensed hunters. Between 2006 and 2015, 480 moose were harvested by licensed hunters within the regional area (Government of Yukon 2016). With a total mean annual harvest of 48 moose, between 5% and 10% of the

total Yukon annual moose harvest occurs within the regional area. Habitat analyses for the Project focused on the early winter season, when moose congregate in high elevation shrub communities, and late winter habitat, when moose are more restricted in their habitat use. The analyses identified several key concentration areas along the NAR where moose are abundant in the early winter season and indicated that the regional area contains abundant and widespread high quality late winter moose habitat. Additionally, baseline surveys in 2017 identified a mineral lick used by moose located along the NAR between the Yukon and Stewart rivers, which was further monitored in 2020 showing consistent results. Mineral licks are important to ungulate species as they provide essential mineral nutrients which otherwise might be lacking in an ungulate diet (Rea et al. 2004). The 2020 camp wildlife log identified moose, along with black bear, as the most common species reported at the Project site.

Thinhorn Sheep occur in low densities at sporadic, isolated locations within and adjacent to the regional area. Within the local area, a small population of sheep occur along the steep, south-facing bluffs above the Yukon River (referred to as the Ballarat Creek occurrence area). In the past, a maximum of eight sheep have been documented in the Ballarat area (including rams, ewes with young lambs, and assorted nursery sheep); however, more recent Project surveys have documented a maximum of five sheep and no lambs in the Ballarat area 2014-2018. A 2020 aerial survey observed one group of three unclassified sheep on a cliff west of Ballarat Creek, and a solitary unclassified sheep east of Ballarat Creek. Additional information is provided in the Site Characterization Plan.

Thinhorn sheep are known to be a traditional seasonal food source for all four First Nation groups with asserted or established traditional territories that overlap the Project (Bates and DeRoy 2014; InterGroup Consultants Ltd. 2009); however, the areas where sheep hunting traditionally occurs are well outside the RSA. There is no documented Traditional Knowledge of sheep being targeted where they occur along the Yukon River and sheep are not known to be harvested within the regional area at the current time.

Mule deer (*Odocoileus hemionus*) occur in the regional area, but at low numbers along the south-facing slopes of the Yukon, Stewart, and potentially Indian River valleys, and along the Klondike Highway. According to trapping concession holders whose traplines overlap the regional area, mule deer have been present in the Coffee Creek/Yukon River area for at least 30 years and the population appears to be increasing.

Limited information is available information on grizzly bear abundance and distribution within the regional area, but based on observations and harvest records, it can be assumed that grizzly bears use the entire region but occur at relatively low densities (estimated densities for the Klondike Plateau ecoregion and the Yukon Plateau-Central ecoregion are 11 and 15 bears per 1,000 km² respectively). Den surveys conducted in 2016 and 2017 did not locate any grizzly bear dens within 2 km of the NAR and 5 km of the proposed mine site; however, given their large ranges and diverse habitat requirements grizzly bears have the potential to interact with all aspects of the proposed Project footprint. Traditional knowledge in the area notes the White River area is good habitat for grizzly bears, in particular, due to the abundance of highbush cranberry in that area (Calliou 2012a).

Black bears (*Ursus americanus*) are considered abundant and have commonly been observed in the regional and local areas during the May to October non-denning period. During grizzly bear den surveys conducted in 2016 and 2017, several black bears and suspected black bear den sites were located, predominantly on warm-aspect slopes. As a result of their diverse seasonal habitat needs, black bears have the potential to interact with the proposed Project across the entire extent of the Project footprint. The 2020

camp wildlife log, which can be found in the Site Characterization Plan, identified black bear, along with moose, as the most common species reported at the Project site.

Wolverines occur in the regional area and have been observed on a number of occasions during wildlife baseline surveys. A wolverine denning habitat model using remotely sensed snow cover estimates from 2006 to 2015 found that the area likely contains limited high-quality denning habitat. Given the large size of wolverine home ranges there is potential for wolverines to occur at low densities across the entire extent of the Project footprint.

Wolves are assumed to occur throughout the regional area, wherever available prey exists. Although the population in the regional area is unknown, local knowledge and survey observations indicate that wolf populations within the region are healthy and relatively abundant, with 'lots of wolves in the area' (Interview 14, pers. comm. 2016; Interview 15, pers. comm. 2016).

According to Yukon Conservation Services, the regional area overlaps a very active trapping area (K. Meister, pers. comm. 2016). Based on current trapping records, Canada lynx and American marten are key harvest species in the region; however, various other species are also important to local trappers including red fox, coyote (*Canis latrans*), red squirrel (*Tamiascurus hudsonicus*), American mink, river otter, a variety of weasel species and American beaver. Many of the species currently harvested in the regional area have a long history of harvest in the region. The trapping of furbearers for their furs and meat was, and continues to be, an important way of life for local First Nations (InterGroup Consultants Ltd. 2009; Calliou Group 2012a; TH 2012b; Bates and DeRoy 2014).

Collared pika have been assessed by COSEWIC as a species of Special Concern and are known to occur in the region. Baseline surveyed documented the species in many of the talus patches located in the southeastern sections of the regional area; however, no collared pika were observed during targeted surveys in the local area. The little brown myotis, listed as an Endangered species under *SARA,* has been documented in the local area, and is expected to be present in low numbers, in suitable habitats throughout the regional area. A habitat model of potential roosting habitat for little brown myotis indicated that suitable roosting habitat was found in small areas scattered throughout the lower elevations (i.e., below 1,000 masl) of the regional area. Other small mammals that have the potential to occur in the Project area include Arctic ground squirrel (*Spermophilus parryii*), Northern flying squirrel (*Glaucomys sabrinus*), snowshoe hare, and several species of mice, voles, and shrews. While none of these small mammal species are a conservation concern federally or territorially, they remain ecologically important as prey species of larger carnivores and furbearers.

Wood frog (*Lithobates sylvaticus*) is the only species of amphibian expected to occur in the regional area. Adult and juvenile wood frogs were observed incidentally by Project staff on several occasions in lowland habitats within the Yukon and Stewart River valleys, and this species is assumed to occur throughout the regional area in appropriate wetland habitats.

4.2.4 Birds

Bird studies undertaken in the local area from 2013 to 2017 included cliff-nesting raptor surveys, common nighthawk (*Chordeiles minor*) /short-eared owl (*Asio flammeus*) stand-watch surveys, waterfowl surveys, point count surveys for upland birds, sharp-tailed grouse (*Tympanchus phasianellus*) lek surveys, and the collection of incidental observations (EDI 2018a). Bird species distributions and habitat in the local and

regional areas (areas shown in Figure 4-15) are described below. The local area, inclusive of a minimum 1 km buffer around the following infrastructure, encompasses the proposed mine site area, the NAR, as well as previous road alignments to Casino and through the Dawson Goldfields. The RSA included a 10 km buffer around these components.

The Project area lies within the core of Bird Conservation Region (BCR) 4- Northwestern Boreal Forest. The conservation plan for BCR 4 identifies 77 priority bird species within the region, of which 55 are known or expected to occur within the regional area. A total of 119 bird species are expected to occur in the regional area, of which 88 have been documented to date. The diversity of birds within the regional area is representative of the avian community within the central Yukon; however, the lack of lakes and large waterbodies is reflected by the absence of species associated with those habitats.

The regional area provides habitat for nine species at risk or species of conservation concern assessed by COSEWIC and listed under *SARA*, including: horned grebe (*Podiceps auratus*), red-necked phalarope (*Phalaropus lobatus*), peregrine falcon (*Falco peregrinus*), common nighthawk, short-eared owl, olive-sided flycatcher (*Contopus cooperi*), bank swallow (*Riparia riparia*), barn swallow (*Hirundo rustica*), and rusty blackbird (*Euphagus carolinus*). These species have all been documented in the regional area or are expected to occur based on knowledge of regional bird distribution. The Project's potential species list includes 13 species which are on the Yukon Conservation Data Centre (Yukon CDC) Track List and 14 species on the Watch List.

Important raptor habitats within the regional area include cliff faces along the Yukon and Stewart rivers and rock outcroppings (tors) in alpine and subalpine areas, which provide nesting sites for golden eagle (*Auila chrysaetos*), peregrine falcon, and potentially gyrfalcon (*Falco rusticolus*). Baseline surveys documented several active nest areas along the Yukon and Stewart River cliffs used by golden eagle, peregrine falcon, and common raven (*Corvus corax*). Forested habitats also provide habitat for a number of other raptor species including several species of hawks and owls. Most raptor species found in the RSA are migratory and spend only the summer months in the area; however, some species such as northern goshawk (*Accipiter gentilis*), gyrfalcon, and most of the owl species may be year-round residents.

Waterfowl (i.e., ducks, swans, and geese) and other waterbirds (e.g., loons, grebes, gulls) are relatively uncommon in the region due to the limited availability of lakes and large wetlands. Some species of waterfowl can be found in small wetlands within the Yukon River floodplain and along the Stewart River where suitable habitat is present. In the case of the Stewart River, a relatively large wetland complex on the margin of the local area, upstream of Maisy May Creek, had the greatest diversity of waterfowl with species such as trumpeter swan (*Cygnus buccinator*) and Pacific loon (*Gavia pacifica*) encountered. Along the NAR, the Indian River and Dominion Creek valleys contain a combination of natural ponds and ponds created due to placer mining activity that also provide habitat for some species of waterfowl.

Shorebirds in the regional area occupy a variety of habitats including stream margins, wetlands, and alpine areas. The most common shorebird species associated with wetland habitats included Wilson's snipe (*Gallinago delicate*), solitary sandpiper (*Tringa solitaria*), and lesser yellowlegs (*Tringa flavipes*). Spotted sandpiper (*Actitis macularius*) is also relatively common along the margins of larger streams. A single surfbird (*Calidris virgate*) was detected at the extreme southeast margin of the regional area and is notable given that this species is relatively uncommon within the alpine areas of the Dawson Range. Additional shorebird species associated with alpine habitats may also occur within the regional area despite not being detected during field surveys; examples of such species include American golden plover (*Pluvialis*

dominica) and upland sandpiper (*Bartramia longicauda*). Alpine habitats are limited in extent at the southern margin of the regional area.

Upland bird species within the regional area include game birds (grouse, ptarmigan), common nighthawk, belted kingfisher (*Ceryle alcyon*), woodpeckers, and passerines (songbirds); passerine species include flycatchers, shrikes and vireos, jays and crows, larks, swallows, chickadees, kinglets, thrushes, waxwings, warblers, longspurs and sparrows, blackbirds, and finches. Densities of upland bird species are variable throughout the area with the highest density and species diversity occurring in areas disturbed due to forest fires and placer mining activities. Upland coniferous and riparian forest (coniferous, deciduous, and mixed) also had notable densities of birds and contained habitat specialists (e.g., Townsend's warbler (*Setophaga townsendi*)) and species at the northern extent of the breeding range in Yukon (e.g., warbling vireo (*Vireo gilvus*)). Baseline surveys documented 12 bank swallow nesting colonies within the regional area, of which, seven are located in the local area. Sharp-tailed grouse surveys completed along the NAR confirmed the presence of six probable leks in a variety of disturbed habitats including regenerating burns and areas in various stages of placer mining activity; however, all identified lek sites were located more than 3 km from the Project footprint. Traditional knowledge studies available for the area include specific reports of ptarmigan in the Coffee Creek area and some TH members report harvesting grouse there (TH 2012a).

Traditional and current harvest species include various ducks (i.e., species of the genera *Aix*, *Anas*, *Aythya*, *Bucephala*, and *Melanitta*), Canada Geese (*Branta canadensis*), swans, Dusky Grouse (*Dendragapus obscurus*), Ruffed Grouse (*Bonasa umbellus*), Spruce Grouse (*Falcipennis canadensis*), Sharp-tailed Grouse, Willow Ptarmigan (*Lagopus lagopus*), and Rock Ptarmigan (*Lagopus muta*) (Dawson Indian Band 1988, Pearse and Weinstein 1988, Mishler and Simeone 2004, InterGroup Consultants Ltd. 2009, Calliou Group 2012a, Bates and DeRoy 2014).

4.3 Socio-economic Conditions

Baseline socio-economic conditions are described below for the following valued socio-economic components: demographics, economic conditions, social economy, community infrastructure and services, education services, land and resource use, community health and well-being, and heritage resources. The socio-economic monitoring plan (SEMP) that will be implemented during the Project will be used to inform social closure planning, including updating the socio-economic conditions at the site. The updates will include contextual community information that is not typically publicly available. Commitments made in benefit agreements with affected First Nations will also be used to inform social closure planning and socio-economic conditions in future iterations of the RCP.

4.3.1 Demographics

This section describes existing demographic conditions to provide a local and regional context. The Local Study Area (LSA) includes Whitehorse, Dawson, Pelly Crossing, Beaver Creek, and Mayo. Due to Dawson's geographic location in relation to the Project, this community is a key provider of labour, goods, and services associated with the Project. Dawson and Whitehorse are also likely to experience a population influx from Project workers. The Regional Study area includes Yukon Territory and provides broader regional context.

4.3.1.1 Population

The population of Yukon in 2021 was 40,232 people, approximately 0.1% of Canada's population (Statistics Canada 2022). Yukon experienced population growth of over 12% since the previous census in 2016 (Statistics Canada 2022), which represented the largest increase of any province or territory in Canada, and above the average national growth of 5% (Statistics Canada 2022). This growth was mainly due to immigration from other jurisdictions (CBC News 2022). Population density in Yukon is 0.1 persons per square kilometer, well below the national average (4.2 persons per square kilometer) (Statistics Canada 2022).

Whitehorse has the largest population in Yukon, with 34,268 people, representing 78% of Yukon's population (Yukon Bureau of Statistics (YBS) 2022b). Dawson City's population (2,327) is the next largest. The communities of Beaver Creek, Mayo, and Pelly Crossing each have populations of less than 500 individuals (see Table 4-20). The population of Whitehorse has grown by 7,711 (21.5%) between 2011 and 2021, while Dawson City has grown by 393 (20.3%) during the same period. Other smaller communities have experienced reductions in their population since the previous census.

The population of Whitehorse, Dawson City and Pelly Crossing are relatively young compared to the national average, with median ages of 37.7, 39.6 and 36.8 years respectively, compared to 41.1 years at the national level.

Table 4-20 Summary of Local Populations, 2021

Municipality	Population 2021	Percent (%) change since 2016 Census	Men (%)	Women (%)	Median Age
Whitehorse	34,268	+12.4	49	51	37.6
Dawson City	2,323	+14.7	50	50	39.6
Beaver Creek	113	-16.1	54	46	42.8
Mayo	463	-6.0	49	51	48.8
Pelly Crossing	407	-10.5	47	53	36.8

Sources: YBS 2022b, Statistics Canada 2022

First Nation communities report different population figures from the Census. Table 4-21 shows government data compared with data from First Nations government websites or from other documentation. Registered membership does not indicate residence in the local or regional area.

Table 4-21 Summary of First Nation Registered Members

First Nation	Crown-Indigenous Relations and Northern Affairs Canada (CIRNAC) 2021 (as of April 2022)				Number of Registered Members reported by First Nations
	Registered Population	Men (%)	Women (%)	Median age	
Tr'ondëk Hwëch'in	946	50	50	N/A	1,100[6]
Selkirk First Nation	673	49	51	36.3	671
First Nation of Na-cho Nyäk Dun	551	46	54	43.0	602
White River First Nation	164	46	54	36.5	220[7]

Sources: FNNND 2022; Government of Canada 2021b, SFN 2022, TH 2022.

Figure 4-16, the 2021 population pyramid presented by YBS (YBS 2022a), shows population stratified by age and sex. Approximately 51% of Yukon's total population is male and 49% female (YBS 2022b). The age structure of Yukon is changing. In 2021, about a quarter of people living in Yukon were between 30 and 44. These age group have grown substantially over the last 10 years in Yukon, with a growth of approximately 39% between 2011 and 2021 (YBS 2022b).

6 2016 data.
7 Data provided from the 2012 White River – Quartz Exploration Report, provided by WRFN.

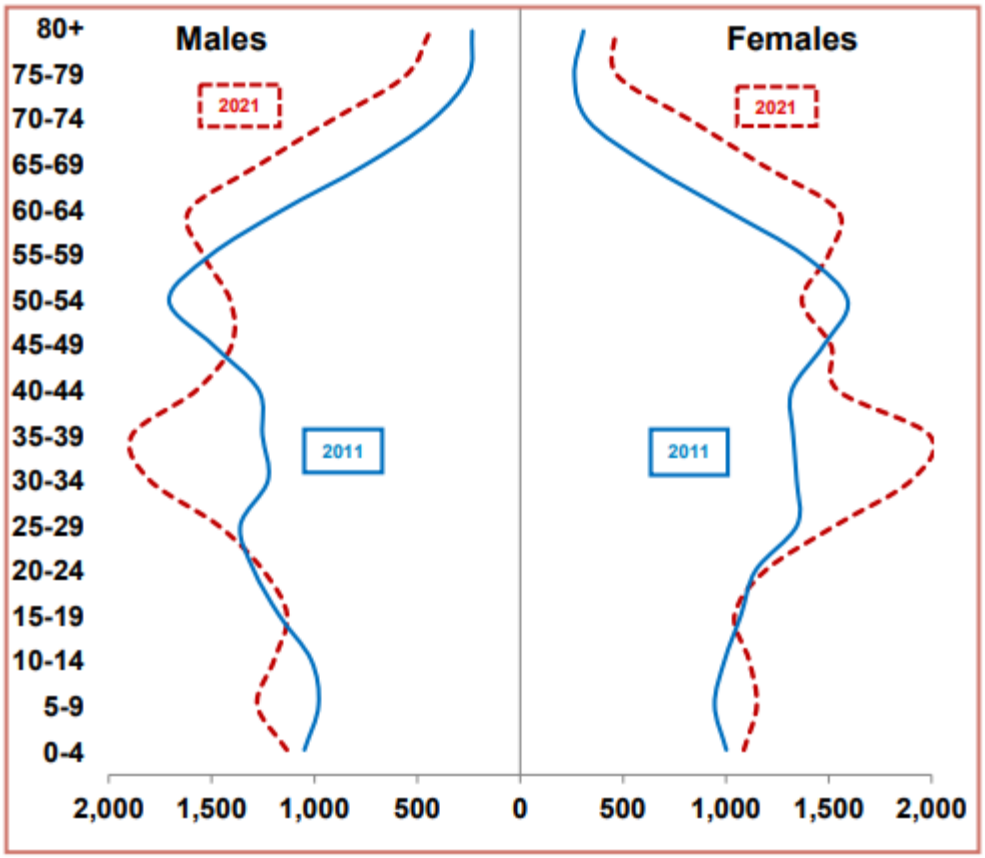

Figure 4-16 YBS 2022 – Population by Age Group and Sex, Yukon, December 31, 2011, and December 31, 2021

The number of senior citizens (60 or over years old) has increased by approximately 3,900 people or 71.7% since 2011, and the number of 30- to 44-year-olds has increased by just over 3,000 people (38.9%). The number of youth has remained steady, with moderate increases in population in some age groups, in particular in the 5 to 9 age group (24.4% increase). The working-age population (aged 15 to 64) represents 70% of the population, compared to 75.2% in 2011.

4.3.2 Economic Conditions

4.3.2.1 Income and Income Distribution

Income levels and distribution vary across the local and regional areas. Table 4-22 displays average income (in dollars) after tax and demonstrates that Whitehorse had the highest median individual income (after tax) in 2016 ($44,183) (Statistics Canada 2016a). All local area communities saw an increased median individual income from 2001 to 2016. (Statistics Canada 2003, 2017).

Table 4-22 Summary of Average Income Among Local Populations

Municipality	Average income ($) 2001	Average after-tax income in 2015 among recipients ($)
Whitehorse	35,040	48,704
Dawson City	28,523	41,316
Beaver Creek	Not Available	Not Available
Mayo	25,027	Not Available
Pelly Crossing	21,330	30,487

Sources: Statistics Canada 2003, 2017.

4.3.2.2 Labour Market

Yukon's April 2022 labour force comprises of 24,500 workers (YBS 2022b), with 23,200 people employed. The Aboriginal[8] labour force comprised 3,700 workers in 2015, or 18% of Yukon's labour force (Statistics Canada 2016a). Yukon's 2022 employment rate was 69.7% in 2022, while the unemployment rate was 5.3% (YBS 2022a). Aboriginal unemployment from the 2016 census was 22.3% (Statistics Canada 2016a).

Sales and service; trades, transport, and equipment operators; and education, law and social, community and government services occupations are the most prevalent occupations for Yukon's labour force. Yukon's 2016 Aboriginal labour force consisted of occupations primarily in trades, transport, and equipment operators; sales and service; and business, finance, and administration (Statistics Canada 2016a, 2016b).

Although mining contributes substantially to Yukon's economy, mining is not a major employer. The goods-producing sector (e.g., forestry, mining, construction) has been negatively affected by the COVID-19 pandemic (Government of Canada 2021a). Less than 16.5% of employment in Yukon come from the goods-producing sector (Government of Canada 2021a). With two new mines soon to be open, Yukon's economic growth is projects to be strong (Government of Canada 2021a).

4.3.2.3 Employment Type and Tenure

Approximately 84% of employed Yukoners worked full-time in 2021, the other 16% worked part-time (YBS 2022c). Labour force participation rate is much lower among Indigenous people in comparison with non-Indigenous people (Government of Canada 2021a). Dawson City's local economy sees seasonal expansion and contraction – both tourism and mining are seasonal - as well as longer-term boom and bust cycles relating to mineral prices.

4.3.2.4 Economic Activity

Yukon's economic sectors include agriculture, energy, film and sound, fishing, forestry, hunting, mining and exploration, tourism, and trapping. The global mineral market dictates Yukon's mineral exploration,

[8] This report uses the term "Indigenous" when referring to individuals identifying themselves as 'First Nations peoples, Métis or Inuit'. Information and data sourced from government agencies and authorities that use other terminology have not been altered and appears in the report as it appears in the original publication. For example, Statistics Canada uses the terms "Aboriginal Peoples," "Aboriginal Population" and "Aboriginal Identity" throughout its tables.

development, and production and plays a key role in Yukon's economy (Government of Yukon 2021a). The mining sector has remained active during the COVID-19 pandemic, supported by strong prices for metals (Government of Yukon 2021a).

Key economic drivers for Whitehorse include government services, tourism, and mining. Dawson City's local economy is currently driven by placer mining and tourism. Community-level data on economic activity in Mayo, Pelly Crossing, and Beaver Creek was not available.

Yukon's cost of living is higher than in southern Canada, and even higher in Yukon communities outside of Whitehorse (Government of Yukon 2021a). High costs of living, in particular fuel and resource costs, were identified as a local challenge in local communities (City of Dawson and TH n.d.).

Between 2011 and 2020, Yukon's gross domestic product (GDP) grew on average 1.9% per year (YBS 2020). Over that time period, GDP ranged from -7.6% to 7.2% (YBS 2020). Forecasted economic growth over the next three years is estimated between 2.4% and 5.5% (Government of Yukon 2021a).

4.3.3 Social Economy

4.3.3.1 Non-wage Economy

Nonprofits provide a diverse array of services and activities to Yukoners. There were 591 non-profit organizations operating in Yukon Territory as of March 2012 (SERNNoCa 2012). Yukon had a 49% volunteer rate in 2010 (Statistics Canada 2015a). Volunteering is prevalent in the Dawson City region (Local Business Focus Group 2016) and is a strategy the Dawson City community uses to address service or funding gaps (KDO 2011a). Bartering[9] is active in the Klondike Region. It contributes to Dawson City's social cohesion by promoting individuals to work together and decreases the cost of living (Interview 11, pers. comm. 2016).

Broad subsistence activities (e.g., hunting, fishing, gathering plants) are conducted by both First Nation and non-First Nation Yukoners (March TH TWG Meeting 2016, Usher and Staples 1988). Subsistence activities contribute significantly to Yukon's economy and are closely related to other socio-economic values including culture, health, and wellness (Usher and Staples 1988).

4.3.3.2 Traditional Economy

The traditional economy is an active and culturally important part of the societies in the First Nations in the Project's local area. The traditional economy involves a complex system of harvesting, processing, production, and technological adaptation. Practices include hunting, trapping, fishing, plant gathering, wood cutting, berry picking, and creating goods from materials gathered from the land (Dobrowolsky 2014, Calliou Group 2012a, KCB 2013).

Tr'ondëk Hwëch'in (TH) are active in the subsistence and traditional economy. This means that families commonly work together to share goods and materials harvested from the land. Instead of paying with

[9] Examples of bartering include exchanges of livestock for services, and vegetables for equipment (Interview 11, Personal Communication 2016).

money, TH citizens give back and reciprocate to those who have shared goods or services by an exchange of other goods and materials. TH's traditional economy contributes to family social cohesion as they promote time spent on the land together. Elders said they see less traditional economy participation now than when they were young. TH citizens do not tend to assign a monetary value to traditional economic activities (TH 2016). Half the survey respondents indicated that they do not sell goods or services from the land, while 25% estimate that they make between $0 and $500, and 12.5% estimate that they make between $2,001 and $5,000. Focus group attendees said they did not give meat or food with the expectation of getting something in return (TH 2016).

White River First Nation's (WRFN's) traditional economy is considered active: over a 13-month study, 90% of members reported hunting, 30% trapped, 95% fished, and 70% conducted gathering activities for a total of 238 harvesting trips (Calliou Group 2012b). No data were available to describe the economic value of the WRFN traditional economy. WRFN does not endorse efforts to monetize its traditional economy.

SFN citizens have reported being actively engaged in traditional use activities throughout the year (KCB 2013). No data were available to describe the current economic value of the overall SFN traditional economy. Previous research found that "…it is estimated that a portion of many of the SFN family's annual income is derived from traditional activities…these products may be sold, used for subsistence purposes, or traded" (KCB 2013).

First Nation of Na-cho Nyäk Dun (FNNND) citizens are active in traditional activities that contribute to well-being and community life including economic, culture, diet, and health. They also facilitate linkages with the land culture, and provide savings compared to store-bought food (DPRA 2010, FNNND 2008).

4.3.4 Infrastructure and Services

This section describes the existing conditions of community infrastructure and services, including the regulatory context.

4.3.4.1 Housing and Accommodation

The City of Whitehorse's 2010 Official Community Plan (City of Whitehorse 2013) calls for more land for residential development and secondary suites to increase housing stock. The draft Official Community Plan (City of Whitehorse 2022) outlines goals and policies related to providing a range of housing types, rental options, and inclusive housing for an aging population. Vulnerable people experience difficulty in finding affordable accommodation in Yukon (Independent Author 2022). With recent migration and population growth in Whitehorse, housing options are expensive and securing accommodations can be competitive.

A Statistics Canada 2011 Household Survey found that housing was the primary change recommended to improve the Dawson City area (Statistics Canada 2013, KDO 2011b). Yukon Housing Corporation says "the increasing (Dawson City) population has resulted in…tightening in rental vacancy rates, accompanied by rising rents and a very large increase in home prices" (YHC 2013). Because rents are relatively high, it can be difficult for lower-income households to find affordable housing (YHC 2013). Dawson City offers accommodation options in the summer, including two campgrounds, an RV park, bed and breakfasts, inns, cabins, hotels, and motels. Many facilities close in the winter months, and accommodation is limited at that time.

4.3.4.2 Physical Infrastructure

Physical infrastructure discussed in this section include landfill services, water and sewage, fire, police, and childcare services in Dawson City. Dawson City is the focal community of this section because of its proximity to the mine site.

The Quigley regional landfill services Dawson City, the Klondike Valley, the Dempster Highway, and the North Klondike (City of Dawson 2016). A community compost is available at Quigley Landfill, as is an E-waste facility, and a free store (City of Dawson 2022a). The landfill is approaching capacity but could be expanded with additional recycling and composting facilities (Interview 4, pers. comm. 2016).

In Dawson, water and wastewater services are supported by Public Works. A public bulk fill station, drinking water come from four groundwater supply wells were brought online in later 2015 (City of Dawson 2022b). A population increase in Dawson City would require expansion of water and sewer infrastructure (Interview 7, pers. comm. 2016).

Dawson City and surrounding area are served by the Dawson City Community Hospital.

Dawson City is served by a volunteer fire department of approximately 25 to 35 members (Interview 4, pers. comm. 2016). Dawson City Fire Department has a municipal coverage area, as well as a mutual aid agreement with a second department, the Klondike Valley Fire Department, which serves the area outside of municipal limits of Dawson City (Interview 4, pers. comm. 2016).

The Dawson City RCMP detachment provides policing services within its jurisdiction, which covers a large area including the Goldfields, the proposed Northern Access Route (NAR), and the Project area.

Dawson City has experienced a shortage in child-care availability that has adversely affected people's ability to work (Windeyer 2015).

4.3.4.3 Transportation

Yukon in general, is served by the Erik Nielsen Whitehorse Airport (YXY), a controlled international airport that supports commercial traffic. Dawson City is served by a Transport Canada-certified regional airport, Dawson City Airport (YDA), which is an uncontrolled airport.

The highway systems of interest for this Project include the Alaska Highway to the North Klondike Highway and the North Klondike Highway to Dawson City. The Alaska Highway extends from Watson Lake through to Whitehorse and continues to Haines Junction and on to Alaska. Traffic for the Project will turn north from the Alaska Highway to the North Klondike Highway at the junction just west of Whitehorse. Upgrades to the highway for the section through Whitehorse are currently underway. The North Klondike highway travels from its junction with the Alaska Highway through the communities of Carmacks, Pelly Crossing, and Stewart Crossing, and turns west north of the Stewart River to the Dempster Highway and Dawson City.

The existing road network extending south from the Klondike Highway that is relevant to the Project include Hunker, Sulphur, Dominion, Black Hills, and Maisey May roads, which are used seasonally by placer miners and not cleared in winter.

A notable component of transportation infrastructure related to this Project is the NAR. The NAR is a 214-kilometre road which provides access to the mine site from the North Klondike Highway (Government of Yukon 2016). The access road will require upgrades of existing roads and the construction of new road.

4.3.5 Education Services

There are 28 schools in Yukon, 15 schools in Whitehorse, and 14 in rural communities. The territory has two post-secondary institutions: Yukon University and Yukon School of Visual Arts. Yukon University has 13 community-based campuses. The main campus is located in Whitehorse, with an average total enrollment of 5,671 students per year since 2008 (Yukon College 2016). Currently, Yukon University's goal is to provide as many community-based programs in communities such as Dawson City, Beaver Creek, Pelly Crossing, and Mayo as possible (Interview 2, pers. comm. 2016). The Yukon School of Visual Arts is located in Dawson City (Yukon School of Visual Arts n.d.). Dawson is relatively well served in terms of facilities and infrastructure, although shortcomings are well-documented (City of Dawson and Tr'ondëk Hwëch'in n.d.).

School enrolment across the territory has increased, as expected with the recent population growth. In 2021, 5,704 students were enrolled in Yukon, compared to 5,102 in 2011; this represents a 12% increase (Government of Yukon 2021b). Whitehorse schools saw steadily increasing enrolment, while enrolment at other community schools was more volatile, fluctuating over time (Government of Yukon 2021b).

4.3.6 Land and Resource Use

4.3.6.1 Non-traditional Land and Resource Use

The majority of land in the local area is Yukon public land, with the exceptions of privately held land in the Klondike Valley. Land use planning takes place at a territorial, regional, and municipal level in accordance with Yukon First Nation Final Agreements (YLUPC 2015).

Water licences within the local region of the Project are for the purposes of placer mining, with the exception of the water licence held by Newmont. The local area falls within the Game Management (GMA) Zone 3 and Zone 5. Currently, caribou and sheep hunting are closed in the GMA 3. Moose are the most popular target animal in the zone. Trapping and small animal hunting is also considered popular within GMA 3. (Interview 13, pers. comm. 2016). The local area overlaps with guide outfitter concession area ID 11 at the barge crossing of the Yukon River and the winter ice road between the Yukon River and Coffee Creek. In Yukon, a valid Yukon hunting licence, angling licence, sportfishing licence, as well as additional permits and stamps for certain species are required (Government of Yukon 2016).

Placer mining activity is focused in the northern portion of the Regional Area near Dawson City, although placer mining has also taken place throughout the local area. There are Prospecting Leases with applications for claims along Coffee and Ballarat creeks within the local area near the Yukon River. Within Yukon, Minto copper-gold-silver mine is the sole operating hard rock mine. Operation at Bellekeno is suspended, Casino and Dublin Gulch proposed mines are under assessment, and the remainder of mining licenses are for exploration (YGS 2015).

The three Forest Resources Management Plan (FRMP) Units which overlap with the Project are the Yukon River South, Stewart River, and Gold Fields. Both the Yukon River South and the Stewart River were

designated as medium and low planning priority. The Goldfields are high planning priority (Dawson FRMP 2013). Recreation in the local area is an economic opportunity for the community (KDO 2011a).

Tourism plays a key role in community economic development. Visitors to Dawson City vary by year but have generally increased recently from 24,060 visitors in 2012 to 37,569 in 2015 (Yukon Department of Tourism and Culture 2015). There are several annual races (dog sleds, canoes, etc.) held within the local area and regional area, which attract local and international participants. Access to and within the regional area is by road, air, water, and non-road access with all-terrain vehicles (ATVs) and snowmobiles, depending on the season.

4.3.6.2 Traditional Land and Resource Use Existing Conditions

Existing conditions for traditional land and resource use are summarized in Table 4-23.

Table 4-23 Traditional Land and Resource Use Activities

	Habitation	Transportation	Subsistence	Cultural and Spiritual Values	Environmental Values
Tr'ondëk Hwëch'in (TH)	TH citizens continue to live on the land at different times of the year in areas which overlap with the local area (Interview 14, pers. comm. 2016; Interview 22, pers. comm. 2016).	Historically, TH are known to have used the rivers and creeks across their Traditional Territory for transport, including the area along the Yukon River close to Coffee Creek, as well as overland routes (Dobrowolsky and Hammer 2001, TH 2012b). Most contemporary traditional land and resource use tends to occur in accessible areas along roads and rivers (TH 2012b).	The land and resources across TH's traditional territory have been providing for their subsistence needs for thousands of years (Ecofor 2012) through seasonal hunting, trapping, and fishing and plant gathering (known to have occurred in the Coffee Creek area) (Dobrowolsky 2014).	The practice of conducting traditional use activities creates important time spent together for families. Coffee Creek and the surrounding area continue to be a place of cultural and spiritual importance to TH citizens (Interview 14, pers. comm. 2016; Interview 22, pers. comm. 2016).	TH citizens are highly aware of the holistic nature of the environment and the complex relationships that characterize it. They value key habitat areas that support wildlife. TH view the animals on their Territory as an economic resource that supports their traditional lifestyle and economy (TH 2012b).
White River First Nation (WRFN)	The mouth of Coffee Creek is an important permanent and temporary habitation area where WRFN ancestors are known to have lived, gathered, and traded (Bates et al. 2014, Easton et al. 2013, TH 2012b, Yukon River Commercial Fishing Association and TH 1997).	As WRFN were historically nomadic people, overland and water transportation linkages played a central role in facilitating the seasonal round, as well as other cultural and spiritual activities.	Subsistence harvesting such as hunting, trapping, and fishing continues to be an important value and contributes to current collective understanding of WRFN's sense of place, as well as food security. (YESAB 2012, Calliou Group 2012b). WRFN members report hunting in a variety of locations throughout the exploration area of the Project.	Use of the land and resources across WRFN's territory facilitates the transmission of language, knowledge, stories, traditional values, and cultural practices (Bates et el. 2014). The Coffee Creek area is culturally and spiritually important because this was a birth and burial place for WRFN ancestors and was the place of marriages and baptism ceremonies (Bates et al. 2014).	WRFN values both the biophysical and inorganic components of the environment and have specific concerns for water quality (YESAB 2012). The Coffee Creek area has environmental value as it is inherently linked to all other aspects of the landscape.

	Habitation	Transportation	Subsistence	Cultural and Spiritual Values	Environmental Values
First Nation of Na-cho Nyäk Dun (FNNND)	Coffee Creek was an important gathering place where ancestors of FNNND would historically stop during their seasonal round (TH 2012b).	Traditionally, FNNND people would travel long distances in accordance with the seasonal round to conduct different subsistence activities (InterGroup Consultants Ltd. 2009).	Traditional foods harvested from the land have always maintained a central role in the diet of FNNND citizens. They continue to comprise a substantial portion of citizen's diet and contribute to FNNND culture (DPRA 2010).	Traditional activities conducted across FNNND traditional territory support socio-cultural ties through the harvesting of traditional foods and the act of sharing and consuming them (DPRA 2010).	Environmental values of FNNND are intrinsically linked to cultural values and practices. For FNNND, maintaining and enhancing the environmental health of their traditional territory is an important value (FNNND 2008).
Selkirk First Nation (SFN)	Historically, SFN ancestors would gather and live at Coffee Creek (Easton et al. 2013, Yukon River Commercial Fishing Association and TH 1997, TH 2012b).	Depending on the season, SFN members would travel by boat or on trails, including by dogsled. There previously was an overland route between Fort Selkirk and Coffee Creek (TH 2012b).	SFN traditional land and resource use has historically and currently remains a central component of SFN culture. SFN uses a diverse range of plants, animals, and resources (Castillo 2012).	Cultural activities continue to contribute to the SFN's social cohesion and community well-being. In the past, Selkirk people used to gather and conduct important cultural and spiritual activities at Coffee Creek (Easton et al. 2013, TH 2012b).	The environment is highly valued by SFN and its citizens, and sustaining a healthy environment is of upmost importance (KCB 2013).

4.3.7 Community Health and Well-Being

A summary of existing regulatory and baseline conditions regarding community health and well-being is provided below.

4.3.7.1 Environmental Quality

The areas at and around the proposed Mine Site were generally undisturbed before mining began. Dust fall in the area reflects natural sources of dust such as tree pollen, as well as deposits during forest fires. Baseline noise is consistent with a quiet environment. Similarly, the areas adjacent to the NAR can be considered in a generally natural state regarding air quality, water quality, soil quality, and the quality of country foods, except perhaps in limited locations around active placer mines. Baseline data shows that natural resources in important harvesting areas such as the mouth of Coffee Creek are good quality, and provide good nutritional, medicinal, and cultural resources.

4.3.7.2 Socio-economic Factors in Health

Socio-economic health factors are described for the region and for the local area where available.

Social Determinants of Health: The health and well-being of individuals and communities are affected by social circumstances and realities such as living conditions, socioeconomic status, and community and family structures.

Health-related Behaviours: Health-related behaviours are individual choices such as not smoking, exercising regularly, and eating nutritiously, which are associated with reducing the incidence of health conditions including diabetes, heart disease, cerebrovascular disease, and certain cancers. Health-related behaviours are often understood by considering social determinants of health.

Housing: Overall, access to housing is an issue, particularly for people who are at risk of homelessness (Independent Author 2022). Housing was frequently mentioned as a concern in Dawson City, in terms of availability, affordability, and adequacy (Interview 2, pers. comm. 2016; Interview 7, pers. comm. 2016; Interview 8, pers. comm. 2016; Interview 20, pers. comm. 2016; Interview 21, pers. comm. 2016; Interview 28, pers. comm. 2016). In 2011, 29% of Yukon First Nations members lived in homes needing major repairs, and 7% lived in crowded homes, with more than one person per room. The corresponding figures for the non-Indigenous population were 12% and 4% respectively (Arriagada 2016).

Family Structure: There is a higher percentage of common-law families with children in Yukon (25.1%), as well as a higher percentage of lone-parent households (20.5%), than in Canada as a whole (16.7% and 16.3%, respectively) (Statistics Canada 2016a).

Children in Care: The Child and Family Services division of Yukon Government Health and Social Services (YGHSS) and the Child Protection Branch respectively provide child placement services and programming intended to reduce family violence, child abuse, and neglect (Government of Yukon 2015a, Government of Yukon 2015b). A recent Children in Care report specified that 64% of Yukon children in care are Indigenous, although only 33% of the child population is Indigenous (Aboriginal Children in Care Working Group 2015).

Children and Youth: With respect to physical and mental health among children and youth, younger urban students are reported better health than their older rural counterparts (Lambe et al. 2019). Mental health

among youth is trending downwards as more youth report feeling sad or hopeless (Lambe et al. 2019). Health of children and youth is dependent on meaningful relationships with family, friends, and the community.

Crime: In 2020, the crime rate in Yukon was the third highest in Canada, behind Nunavut and Northwest Territories, at 22,912 incidents per 100,000 people (YBS 2021).

Family Violence: Yukon recorded a rate of family violence of 707 per 100,000 population in 2019, the third highest rate in Canada behind Nunavut and NWT (Statistics Canada 2021).

Food Security: Yukon households both with and without children have rates of food insecurity somewhat above the national average.

Accidents and Injuries: Yukon has very high rates of unintentional injuries causing death and is typically ranked as the third leading cause of death, behind cancer and heart disease (Statistics Canada 2015b).

Transportation-related Injuries: Motor vehicle collisions in Yukon cause 9.5 deaths per 100,000 people and 441 injuries per 100,000 people, both figures are above the Canadian average (Transport Canada 2020).

Aviation Incidents: Overall, fatality rates for aviation incidents in Yukon are low (TSB 2014a, 2014b).

Infectious Disease: Giardiasis, campylobacteriosis, salmonellosis, and cryptosporidiosis have been observed in Yukon, in addition to *E. coli* and Hepatitis A (YGHSS 2013). Tuberculosis declined in 2012 to 2.9 per 100,000 from a peak of 24.2 cases per 100,000 in 2008 (Government of Yukon 2013). Chlamydia rates are higher in Yukon than in southern Canada (PHAC 2008), but steadily decreased from 2007 to 2012 (Government of Yukon 2013).

Non-infectious Disease: Yukon rates of diabetes appear to be generally lower than the overall Canadian rate and (Statistics Canada 2016b) and obesity rates for Yukon appear to be similar to those for Canada (PHAC 2011).

Mental Health and Wellness: Overall, Yukoners report high rates of community belonging and life satisfaction, although perceived mental health has been decreasing over the past decade. Mental wellness and substance use resources are available and being developed to support, although use and performance of these resources is undetermined (Independent Author 2021). Barriers to accessing mental health supports are prevalent (Government of Yukon 2020).

Workplace Mental Health: Stress and workplace bullying have been found to negatively affect health (Goh et al. 2015, MacIntosh et al. 2014). Shift work and fly-in, fly-out work schedules can be stressful for workers and their families. Mobile workers can experience exhaustion, loneliness, stress, and anxiety.

4.3.7.3 Health Services Structure and Capacity

Access to Medical Care: All Yukon communities have access to a community health centre. 78.8% of Yukoners have access to a regular healthcare provider, compared to 84.9% of Canadians (Government of Yukon 2020). First Nations citizens report racism and stereotyping when accessing health services;

Francophone citizens report the importance of bilingual health and social services (Government of Yukon 2020). Equitable access to medical care that is culturally safe remains a priority.

4.3.8 Heritage

Examination of the ethnography and ethnohistory of the relevant First Nations groups is provided in the Heritage Resources Overview Assessment (HROA) and Heritage Resources Impact Assessment (HRIA) reports.

4.3.8.1 Archaeological and Historical Resources

The Regional Study Area and Local Study Area possess potential for precontact heritage sites that are at least 10,000 years old. Based on previous assessments, 29 heritage sites were identified and recorded within the Local Area. Five are located within the Mine Site. These include three prehistoric lithic sites, one historical artifact site, and one World War II-era plane wreck. Also, 24 previously recorded archaeological and historical sites, including six prehistoric lithic and 18 historical sites, were identified along the NAR. An additional 13 heritage resources had been identified and previously recorded in the Regional Area.

4.3.8.2 Paleontological Resources

The major creek and river valleys as well as areas of permafrost within the Local Area possess potential for the preservation of paleontological resources.

5.0 PROJECT DESCRIPTION

This section provides a brief description of the Coffee Property history (Section 5.1), outlines the Coffee Gold Mine Project schedule (Section 5.2), and describes Project and ancillary components plus associated processes and activities (Section 5.3). In addition, Sections 5.4 to 5.6 describe current conditions (Year -5), conditions two-years forward (Year -1) from start of construction (Year -3), and conditions at the end-of-mine life (end of Year 9), respectively. Sections 5.7 and 5.8 outline proposed monitoring and surveillance activities and the approach to risk management and adaptive management during mine development and operation.

5.1 Coffee Property History

From the turn of the century until 1981, the Coffee Property and surrounding area in the White Gold District in west-central Yukon was explored by sporadic placer expeditions with limited reconnaissance activities for porphyry copper in the 1960s and 1970s. A brief exploration program conducted in 1999 and 2000 resulted in the identification of an open-ended soil gold anomaly. Further grid and ridgetop soil sampling was conducted in 2006 and 2007. In 2009, the Coffee Property was acquired by the original Kaminak Gold Corp. (KGC) from prospector Shawn Ryan.

Upon acquisition of the property, exploration programs were expanded to identify bedrock mineralization through surficial trenching and soil sampling. Through these programs, KGC identified a number of high-tenure soil anomalies for drill follow-up. In subsequent years, KGC continued soil sampling and trenching programs, and undertook drilling programs to test the identified soil anomalies. From 2010 to 2015, KGC completed more than 270,000 metres of drilling across the property, focusing on the Supremo, Latte, Double Double, and Kona deposits. These efforts led to the completion in 2015 of a NI43-101 Feasibility Study (JDS 2016). In July 2016, KGC and the Coffee Property were fully acquired by Goldcorp with the intent of advancing the Project through assessment and licensing and permitting stages, then into construction, operation, closure, and post-closure, as defined below. In 2019, Newmont and Goldcorp combined to become Newmont Goldcorp Corporation, now referred to as Newmont.

5.2 Project Schedule

The Project phases are defined as follows and illustrated along with key activities (based on current information) in Figure 5-1.

- Construction Phase: Q2 Year –3 to the end of Year –1 (30 months), in which mine site components are constructed and pre-production mining occurs
- Operation Phase: Year –1 to Year 9, in which the mine is in operation, with progressive reclamation and closure activities occurring where practicable in areas no longer needed for mining
- Closure Phase: Year 10 to the end of Year 21, during which the rinsing of stacked ore (also referred to as heap leach or heap) on the heap leach pad (HLP) and water treatment activities continue until no longer required, and decommissioning, reclamation, and closure activities are completed. The Closure Phase includes:
    - Post-mining Closure Phase: Year 10 to Year 15, which will focus on HLF re-circulation, cover placement and active water treatment of HLF drain down; and
    - Active Closure Phase: Year 16 to Year 21, which will focus on decommissioning water management infrastructure and site roads.

- Post-closure Phase: Year 21 onward (as determined to be required), in which monitoring and inspections are performed and maintenance activities occur, as needed.

For each phase (after the mine is operational), a summary of general requirements related to reclamation, closure, and/or monitoring activities is provided in Table 5-1. Construction and operation details are provided by Project component in subsequent sections, and final closure measures for each component are provided in Section 7.

Figure 5-1 Schedule of Key Activities by Project Phase and Year

Table 5-1 Closure and Monitoring Activities Planned during the Operation, Closure, and Post-closure Phases

Planned Reclamation and Closure Activities	General Monitoring Activity Requirements
Operation Phase (Closure-related Activities from Year –1 to end of Year 9)	
Closure activities will be undertaken in a progressive manner when pits, the Alpha WRSF and frozen soil stockpile area (FSSA), and stages of the HLP are no longer required to support mine operations. Activities planned during the Operation Phase include the following: • Implementation of the Reclamation Research Program to evaluate site-specific reclamation prescriptions such as revegetation, cover design, and reclamation materials. • Continuous salvage and stockpile of reclamation material including overburden stripped during operations (i.e., expansions of pits, development of new areas). • Progressive reclamation of disturbed areas within the Mine Site footprint that are no longer required to support mine operations. • Progressive regrading of the HLF. • Reclamation of exploration areas (re-grade, scarify, and revegetate roads, fill, and revegetate trenches) when access is no longer required. • Regular removal of recyclable / salvageable material and equipment, using available back-hauls during the Operation Phase. • Partial backfill of Latte and Supremo Pits and closure of disused haul roads. • Complete backfill of Kona and Double Double Pits and closure of disused haul roads. • Installation of water treatment facility at the Plant Site and commencement of water treatment of surplus water. • Near the end of the Operation Phase, material stored in the FSSA and deemed unsuitable for reclamation will be co-disposed in the Alpha WRSF.	Routine monitoring in accordance with conditions of mine operating licenses and permits
Post-mining Closure Phase (Year 10 – Year 15)	
Closure activities that are planned during the Post-mining Closure Phase include the following: • HLF recirculation for rinsing and final gold recovery. • Cover construction and revegetation of rinsed areas of the heap. • Continued water treatment of drain-down rinse water from HLF stages until rinsing of the heap is complete, then until effluent is of suitable quality for discharge or until the passive water treatment system, if required, is commissioned. • Reclamation of disturbed areas within the Mine Site footprint that are no longer required to support closure activities. • Equipment removed from service when no longer required to support closure and reclamation activities. • Closure of Latte Pit and Supremo Pit by allowing them to flood and placing boulder fences at the pit rims. • Reclamation of the soil stockpile area footprints, including FSSA, once stockpiled materials have been used. • Reclamation of the run-of-mine (ROM) stockpile area. • Contaminated sites investigation within the areas of fuel storage and transfer, equipment laydowns, and the bulk explosives storage area • Excavation of any contaminated soil followed by either on-site treatment or temporary storage and removal off-site. • If required, construction and commissioning of passive water treatment system for the HLF. • Continued operation of water conveyance structures and sedimentation ponds until water quality in the ponds meets discharge requirements.	Routine monitoring in accordance with conditions of mine operating licenses and permits, and monitoring of reclaimed areas to observe progress towards achieving Project and component-specific closure objectives.

Planned Reclamation and Closure Activities	General Monitoring Activity Requirements
Active Closure Phase (Year 16 – Year 21)	
• If draindown rinse water from HLF requires passive treatment, continue active water treatment during passive water treatment system commissioning and until HLF water quality has been sufficiently treated to qualify for passive treatment. • Decommissioning of Facility Pond. • Decommissioning of the Alpha Dam/Pond by breaching the dam and constructing a drainage pathway through the footprint of the former dam. • Re-grading the West Diversion Ditch to slope and re-establishing drainage patterns to match pre-mining conditions to the extent practical. • Dismantling and removal of process plant, reagent storage area, laboratory, truck shop and warehouse building, emergency response team building, mine dry and office complex, power plant, and bulk fuel storage and liquid natural gas (LNG) storage facility infrastructure at the Plant site, as well as decommissioning of the bulk explosives storage area and water management infrastructure. • Dismantling and removal of dormitories and kitchen, dining, mudroom, and recreation complex buildings, fresh (potable) water and fire water systems, power plant, sewage treatment plant, and waste management building at the Camp Site. • Decommissioning and closure of the HLF and water management infrastructure, followed by reclamation activities, as relevant. • Decommissioning and reclamation of remaining disturbed areas within the Mine Site footprint, and Project-built (new) sections along the NAR, barge landings, the On-site Access Road, Mine Site roads, and the Project airstrip towards the end of this stage. • Dismantling of the Java Camp.	Routine monitoring in accordance with conditions of mine operating licenses and permits, and monitoring of reclaimed areas to observe progress towards achieving Project and component-specific closure objectives.
Post-closure Phase (Year 21 onwards)	
Closure and reclamation activities are complete.	Ongoing monitoring with schedule frequency and locations being reduced as performance criteria is met and Project-specific closure objectives are achieved.

5.3 Project and Ancillary Components

The following sections describe principal and ancillary components that will support Project construction, operation, and reclamation, and closure activities. Information provided for each Project component includes: its purpose, location, key design features, relevant investigation information, construction sequence, and operational aspects. The descriptions are high-level in nature and provide the level of detail necessary for the licensing stage of the Project. Project detail descriptions are based on environmental management plans, studies, investigations, and assessments (including risk assessments) developed for licencing.

Detailed design and implementation procedures will be finalized following receipt of Project approvals. Designs, methodologies, processes, and procedures will conform to the terms and conditions outlined in the YESAB Decision Document, as well as conditions outlined in regulatory approvals (i.e., Quartz Mining License, Type A Water Use Licence, Yukon *Environment Act* permits, and other permits).

Principal components at the Mine Site include:

- Four open pits – Latte, Double Double, Kona, and Supremo
- One waste rock storage facility (WRSF) – Alpha
- Stockpiles including the FSSA, soil stockpiles, and ROM stockpile
- Crusher system including a 2-stage crushing circuit, crushed ore stockpile, and a conveyor system
- HLF including a lined HLP, event ponds, a rainwater pond, and associated piping and water management infrastructure
- Plant Site including process plant, reagent storage area, laboratory, truck shop and warehouse building, power plant, bulk fuel storage area, and LNG storage facility
- Camp Site including dormitories, kitchen, dining, mudroom, and recreation complex buildings, mine dry and office complex, emergency response team building, potable water and fire water systems infrastructure, sewage treatment plant, and waste management infrastructure
- Bulk explosive storage area
- Land Treatment Facility
- Mine Site roads and haul roads
- Site water management infrastructure including sedimentation ponds and water conveyance structures.

Ancillary components include the Coffee exploration camp and airstrip, and the Java exploration camp, NAR, Project airstrip, and laydown areas.

The Project area encompasses 22,000 hectares (ha), including areas affected and unaffected by the Project. The locations of all components at the Project site are shown on Figure 5-2. Component areas indicated on Figure 5-2 are conservative representations of anticipated component footprints since the layout illustrates the full extent of Project development over the LOM and does not take into consideration areas or components that will be progressively reclaimed. Figure 5-2 provides the layout of the existing components at the site, which includes the ancillary components located to the east of the site.

5.3.1 Open Pits and Mining Activities

Latte, Double Double, Supremo, and Kona Pits will be developed using standard drill and blast methods and mined using conventional shovel and truck methods.

Ore will be transported to the crusher system, where it will be crushed and, then transported to the HLP. Ore will be placed in the ROM stockpile when the crusher is not running and the HLP is not being loaded (Section 5.3.3.3). Waste rock will be transported the Alpha WRSF, or used for construction of Mine Site infrastructure, if suitable. Waste Rock will also be used to selectively backfill mined out pits at Latte and Supremo in order to create causeways and facilitate more-efficient ore haulage routes to the crusher. Additional information regarding open pit mining design and methods are provided in the Mine Operations Plan. Information on the Alpha WRSF is provided in Section 5.3.2 below.

Open pit dimensions and LOM quantities of contained ore and waste rock for each pit are provided in Table 5-2. Over the 10-year Operation Phase, an estimated total of 60 Mt to 67 Mt of heap leach feed will be produced and approximately 300 to 330 Mt of waste material will be generated, based on an average strip ratio of 5:1. A summary of the LOM production schedule by year is provided in Table 5-3.

Table 5-2 Open Pit Dimensions and Life of Mine Quantities of Contained Mineralized Material and Waste Rock

Open Pit	Max. Length (m)	Max. Width (m)	Max. Depth (m)	Mineralized Material (kt)	Waste Rock (kt)
Latte	1,500	360	140	20,962	62,505
Double Double	640	270	140	1,340	9,281
Kona	375	170	90	946	2,933
Supremo	2,150	570	225	36,902	223,959

Note: Conceptual-level production estimate only. Unit definitions: t = tonnes, kt = kilotonne; koz = thousand ounces; t/d – tonnes per day; g/t – grams per tonne.

To maximize economic returns and achieve the target ore production annual rate of approximately 9.0 Mt during the 10-year Operation Phase, the sequence of open pit mining from Project Year –1 to Year 9 is expected to proceed as illustrated in Figure 5-3. Backfilling of waste into pits is estimated to occur as follows:

- Double Double Pit will be mined between Year 1 and Year 3. Waste rock produced from the Double Double Pit will be placed in the Alpha WRSF or used as backfill for the Latte causeway. In operating Years 8 and 9, approximately 8.8 Mt of waste rock from adjacent areas of the Supremo Pit will be backfilled into the mined-out Double Double Pit (i.e., the pit will be progressively closed).
- Latte Pit will be mined in Years -1 to Year 9 and in-pit backfilling will occur in the eastern portion of the pit during portions of Years 3 and 4 to construct a causeway to shorten the ore haulage route to the crusher. Approximately 14 Mt of material will be backfilled into Latte Pit.
- Kona Pit will be mined in Years 8 and 9. Although waste rock from Kona Pit is non-PAG, a small area of ore exposed in the completed pit wall has weak PAG tendencies. To limit exposure of this ore seam to potential oxidation, Kona Pit will be backfilled with 2 Mt of waste rock from Supremo Pit in Year 9 (i.e., progressively closed). Backfilling is currently planned as a progressive closure activity in the winter of Year 9, as frozen waste rock will promote the re-establishment of permafrost to depth.
- Supremo Pit will be mined from Year -1 to the end of Year 9. As shown in Table 5-2, approximately 224 Mt of waste rock will be generated from the development of the northern and southern pits. Most of this material will be stored permanently in the Alpha WRSF, 8.8 Mt will be used to backfill Double Double Pit, and 30.2 Mt will be used to construct a causeway in the southern Supremo Pits during Years 6 through 9.

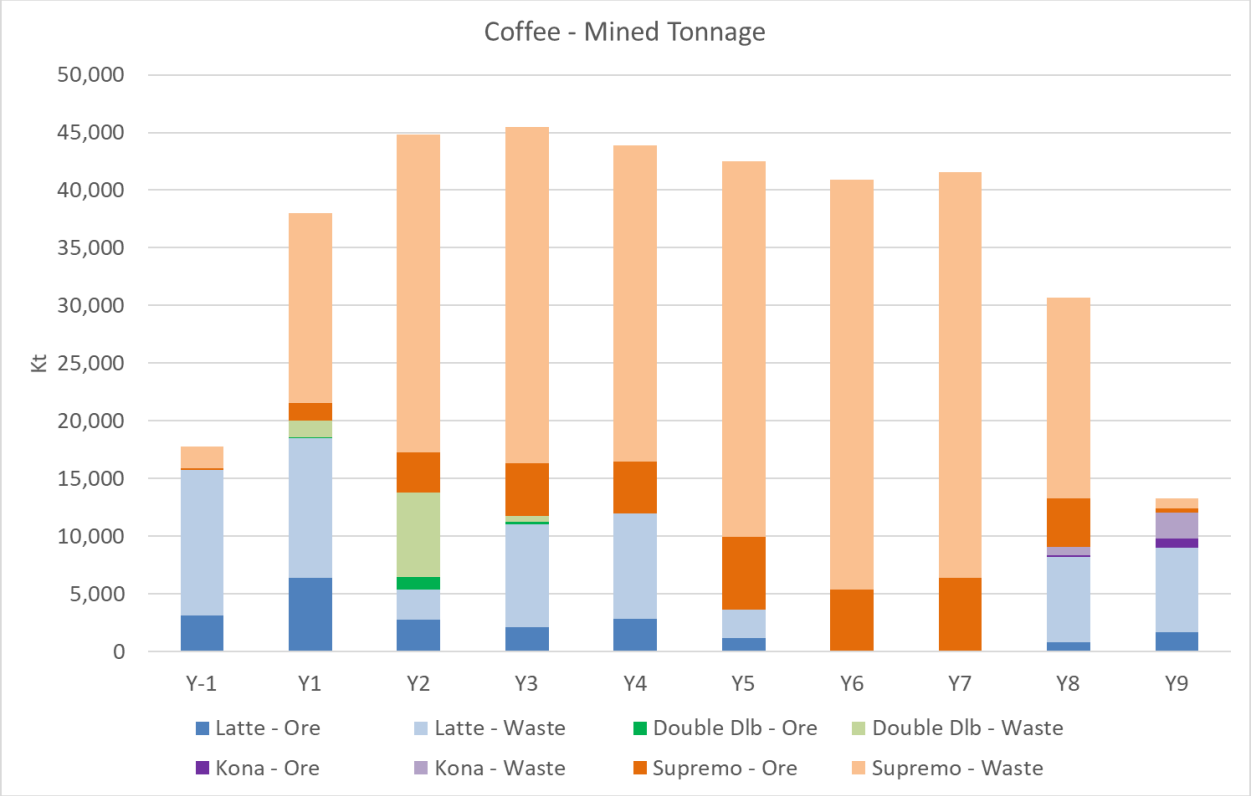

Figure 5-3 Ore and Waste Rock Mining Schedule by Pit Parameters

As the open pits are mined out and closed, some are expected to fill with water and form lakes over time (except for Kona and Double Double Pits which will be completely backfilled during operations), as a result of groundwater, surface runoff, and meteoric water inputs reporting to pits. The location of the in-pit lakes in the Post-closure Phase are shown in Figure 5-4. The rate at which in-pit lakes will develop varies by pit, but all pits are anticipated to fill to their spill elevations within the time frames shown in Figure 5-5. Figure 5-6 and Figure 5-7 show the ultimate drainage patterns from each pit at the end of the Operation and during the Post-closure Phases, respectively. Further details on the open pits and mining activities and water management are provided in the Mine Operations Plan and Water Management Plan, respectively.

5.3.1.1 Pit Stability and Bench Face Angles

While there are no Yukon regulations regarding pit slope designs, Northwest Territories Mine Health and Safety Regulations (15.95) (SNWT 1995) state that each catchment berm shall be designed so that its final width will not be less than 8 m. The design bench width will be 8.5 m in all areas, exceeding the minimum criteria. Overall slope stability analyses were completed in 2015, with a supplemental pit slope evaluation completed in 2019 (Appendix 5-A). The analysis considered both global and bench-scale failures[10] and the recommended bench face angles are as follows:

- Supremo Pit - Benches in the Supremo Pit are not anticipated to be significantly affected by structurally controlled instabilities due to the north-south orientation of the pit. As such, a maximum achievable bench face angle of 75° was estimated for Supremo Pit based on standard operational constraints (further defined in Appendix 5-A).
- Latte and Double Double Pits - The stability of benches on the north pit wall in each pit will likely be controlled by dominant southerly (inward) dipping foliation discontinuities. The analyses indicate a maximum achievable bench face angle of approximately 65° for the north pit walls. Based on operational considerations, south and end pit wall benches are not anticipated to be governed by geologic structure controls and are estimated to have a maximum achievable bench face of 75°.
- Kona Pit - Benches on the west Kona Pit wall have a slightly higher probability of structurally controlled instabilities fostered by a moderately east (inward) dipping joint set. The analyses indicate a maximum bench face angle of approximately 70° is achievable on the west wall. Based on operational constraint, the other pit walls are estimated to have a maximum achievable bench face of 75°.

The Alpha WRSF, soil and ROM stockpiles, and in-pit backfill are currently designed to fall within the Moderate Consequence and High Confidence categories based on the “Guidelines for Mine Waste Dump and Stockpile Design” (Hawley & Cunning, 2017). Corresponding minimum recommended Factors of Safety (FoS) are 1.2 to 1.3 for static and 1.0 to 1.05 for pseudo static loading conditions according to the guidelines. Additional information regarding the FoS design acceptability criteria is provided in the MOP.

[10] A global failure is considered to occur relatively deep through the rock mass and is of sufficient scale to impact high inter-ramp and/or overall slopes. Bench scale failures typically involve only one or two bench levels in the pit and can be described as block or wedge-type failures involving the translation of a block of rock delineated by one or more structural features, such as minor discontinuities or faults.

5.3.2 Alpha Waste Rock Storage Facility

Over the LOM, a total of 300 Mt to 330 Mt of waste rock will be produced and transported to either the permanent Alpha WRSF in the headwaters of the Halfway Creek watershed, backfilled to the open pits or used for site construction purposes (Table 5-4). Although the majority of waste rock from the open pits is planned to be deposited in the WRSF, some suitable waste rock will be used in the construction of mine site infrastructure (e.g., site roads, sedimentation embankments, water management structures, laydown areas, heap leach pad and associated ponds).

Table 5-4 Estimated Annual Waste Allocations by Destination

Destination (Mt)	Y- 1	Y1	Y2	Y3	Y4	Y5	Y6	Y7	Y8	Y9	Total
Alpha WRSF	14.4	30.1	37.5	26.0	30.3	26.8	26.5	26.2	17.8	3.2	**238.8**
Alpha WRSF - waste from Kona	-	-	-	-	-	-	-	-	0.7	2.1	**2.8**
In-pit Backfill (LA, SU, and DD)	-	-	-	12.5	6.3	8.3	9.0	9.0	7.0	3.0	**55.0**
In-pit Backfill (Kona)	-	-	-	-	-	-	-	-	-	2.0	**2.0**
TOTAL	**14.4**	**30.1**	**37.5**	**38.5**	**36.6**	**35.1**	**35.5**	**35.2**	**25.5**	**8.3**	**298.7**

The Alpha WRSF will be located on the southeastern slope of the Halfway Creek drainage basin (Figure 1-2). Both the west facing slope below the east side of the ultimate Alpha WRSF, and the southeast-facing slopes below the northwest side of the ultimate Alpha WRSF are interpreted to be ice-poor. The area ranges from permafrost-free terrain on predominantly south-facing slopes to perennially ice-poor frozen ground on slopes with less southern exposure (Section 4.1.5). A tributary valley on northeast-facing slopes were interpreted to be underlain by moderately to ice-rich permafrost with visible excess ice.

The organic layer within the Alpha WRSF footprint will be left in-place to preserve permafrost, except where foundation soil conditions may require removal to bedrock prior to facility development (will be determined by the results of further geotechnical investigations and design studies). The Alpha WRSF will have an estimated capacity of 250 Mt and a total footprint of approximately 210 hectares. Construction of the Alpha WRSF will begin during pre-stripping and will continue until the end of the Operation Phase (Year 9).

The Alpha WRSF will be constructed with primarily 40 m high benches or lifts with a 60 m wide safety berm left on each lift, with progressive regrading during the Operation Phase to achieve final overall slope angles of 3.0H:1V. The slopes of the WRSF are not planned to be re-shaped at the end of mine life. The lowest topographic point of the dump will be 815 masl, and the highest point will be an elevation of approximately 1,150 masl, although the final configuration will be subject to minor revisions during detailed design. The maximum height of waste will be 350 m.

Due to the coarse particle size of stored waste rock material, the Alpha WRSF is anticipated to be free-draining, meaning that water will pass through the waste rock without buildup of significant pore water pressures. For the purposes of effectively managing water, a rock drain will be developed beneath the Alpha WRSF to convey runoff from the upper portion of the Halfway Creek catchment, meteoric water infiltrating through the WRSF, and groundwater discharge to the Halfway Creek channel covered by the WRSF. Where appropriate, surface water will be managed by a series of diversion channels located around

the Alpha WRSF. Section 5.3.11 provides additional information on the rock drain and diversion channels associated with the Alpha WRSF. Further details regarding the Alpha WRSF, including layout and cross-sections, are provided in the WROMP.

5.3.2.1 Alpha WRSF Geotechnical Design Criteria

Newmont will ensure that each WRSF and stockpile is constructed to the appropriate geotechnical design criteria. The geotechnical design criteria for the Alpha WRSF were selected based on guidelines from the British Columbia Mine Waste Rock Pile Research Committee (1991) and experience of the technical experts responsible for the design. The WRSF will be designed to meet or exceed the acceptable design criteria for short-term conditions during operations and long-term closure.

The Alpha WRSF, soil and ROM stockpiles, and in-pit backfill are currently designed to fall within the Moderate Consequence and High Confidence categories based on the “Guidelines for Mine Waste Dump and Stockpile Design” (Hawley & Cunning, 2017). Corresponding minimum recommended FoS are 1.2 to 1.3 for static and 1.0 to 1.05 for pseudo static loading conditions according to the guidelines. Additional information regarding the Alpha WRSF FoS design acceptability criteria is provided in the WROMP.

5.3.3 Stockpiles

5.3.3.1 Frozen Soil Storage Area (FSSA)

Upon excavation, frozen soils will be segregated by type (defined primarily by ice content) to permit recovery of materials for use in reclamation activities. Ice-rich soils, those soils containing more than 15% visible ice, will be stored in the FSSA located on the east side of the Alpha WRSF. As necessary, a small berm will be constructed around the perimeter of the FSSA to provide initial containment and filtering. Eventually all soils placed in the FSSA will be contained by waste rock placed around it as mining progresses. Based on the current material balance (see Appendix 2-I), it is expected that frozen soil will be co-disposed with waste rock in the Alpha WSRF in thin horizontal lifts. Further details regarding the FSSA, including sizing of the FSSA stockpiles and frozen material management, are provided in the WROMP.

5.3.3.2 Soil and Overburden Stockpiles

The Project site will have five temporary stockpiles which will be used for stockpiling material until it is needed for site reclamation and revegetation activities. The stockpiles will be located immediately north of the heap leach pad, and topographically above the Alpha WRSF, with slope angles of approximately 10° to 12°. During mine site construction and over the course of mine operations, overburden material, including organic overburden and mineral overburden, is expected to be removed from the footprints of the four open pits, the HLP, site infrastructure pads and portions of the WRSF footprints, and placed in the soil stockpiles, if suitable as reclamation material.

Material deemed suitable for reclamation purposes is currently assumed to include the upper organics layer and upper silt layers plus 200 mm of the lower gravel layer. These materials, with *in-situ* thicknesses ranging from approximately 1.3 m to 2.7 m across the Mine Site, are not anticipated to be ice-rich. A soil salvage program will be implemented during construction and operations to segregate the organic overburden and mineral overburden to the extent practical to provide suitable material for reclamation. Soil salvage program details are provided in Section 7.9.6. For details on the mine site material balance including sources of

material and estimated thicknesses and volumes, refer to Section 7.10. The total volume of material to be stored is estimated to range from 2.6 Mm^3 to 2.8 Mm^3.

The soil stockpiles have been designed with a cumulative footprint of 35.9 ha and a maximum capacity of 5.1 Mm^3 with side slopes at the angle of repose (approximately 1.7H:1V). A slope stability assessment of this design is provided in Appendix 5-B. The stockpile area is sufficient to hold the current estimated 2.6 Mm^3 to 2.8 Mm^3 of suitable reclamation material to be stripped from the site, assuming a 15% bulking factor, as well as up to approximately 600,000 m^3 of ice-poor frozen soils (i.e., soils that contain less than 15% visible ice), if required. Stored material will be used progressively starting in Year 2 for mine reclamation purposes. Further details regarding the soil and overburden stockpiles are provided in the WROMP.

5.3.3.3 Run-of-Mine Stockpile

The ROM stockpile will be located directly east of the primary crusher and will operate over the entire mine life starting in pre-production. The ROM stockpile foundation will be on mostly permafrost-free southeast- to east-facing slopes near the ridgetop that dip 12° to 19° towards Latte Creek.

Newmont will ensure that the ROM stockpile is constructed to the appropriate geotechnical design criteria. The Alpha WRSF, soil and ROM stockpiles, and in-pit backfill are currently designed to fall within the Moderate Consequence and High Confidence categories based on the “Guidelines for Mine Waste Dump and Stockpile Design” (Hawley & Cunning, 2017). Additional information regarding the ROM Stockpile FoS design acceptability criteria is provided in the WROMP.

The ROM stockpile will be constructed on top of a graded pad that will require approximately 3.9 Mm^3 of waste rock material to construct. The graded pad will have a maximum height above the original ground of approximately 50 m at the southeast corner and the ROM material will be stacked on top of the pad to a maximum height of approximately 30 m. A 20-m-wide safety berm or offset will be left between the crest of the ROM waste rock foundation pad and the toe of the ROM stockpile along the south side where the pad height will reach its maximum of 50 m. This will result in a maximum overall slope angle of approximately 2.0H:1V. A slope stability assessment of this design is provided in Appendix 5-B.

The stockpile is designed with a maximum capacity of 3 Mt within a footprint of approximately 13 ha. The amount of ROM material stored at the facility will fluctuate, with peak volumes expected to occur during the winter months of January to March when the crusher is not running. The ROM stockpile will also be used to temporarily store ore produced during the pre-production period in Year -1 until the HLP is ready to receive crushed ore, as well as to smooth ore feed and grade to the crusher (e.g., ore will be stored on the ROM stockpile when the mining rate or when ore feed exceeds the throughput rate of the crusher).

All ore stored on the pad will be processed during the Operation Phase. Seepage from the ROM stockpile will drain towards Halfway Creek and Alpha Pond. Further details regarding the ROM stockpile, including layout and cross-sections, are provided in the WROMP.

5.3.4 Ore Crushing Facilities

Ore crushing facilities, located south of Latte Pit, and associated equipment will include a haul truck apron, mechanically stabilized earth (MSE) wall, dump hopper, primary and secondary crushing plants, secondary

screening plant, and lime silo, a 10,000-tonne capacity crushed ore stockpile, as well as an interlinking system of conveyors. The crushed ore stockpile will provide approximately 10 hours of material storage for loading into haul trucks and transportation to the HLP. These facilities are located in an area with bedrock relatively close to the surface, and will be placed on mat foundations and slabs, with equipment and column loads supported on pads and pedestals.

ROM ore will be trucked from the open pits to the crushing plant, where it will be reduced to produce the target crush size of 80% of the product passing (P_{80}) of 50 mm. The process flow diagram for primary and secondary crushing is shown in Figure 5-8. The crushing plant and haul trucks will operate for a minimum of 275 days per year (contingent upon operational conditions and pad thermal balance). During the coldest part of the year (January through March) crushing and heap leach pad loading activities will be suspended. Heap leach loading will depend on the seasonal conditions each year and the amount of heat available in the HLP for processing. If conditions allow, crushing may be performed year-round. When the crushing plant is not operational, ROM ore will be stored in the ROM stockpile (Section 5.3.3.3).

Crushed rock will then be conveyed to the crushed ore stockpile via truck or overland conveyor. To aid in dust suppression at the ore crushing facility, dust mitigation between the feed and discharge ends of the screens, crushers, and feeders have been incorporated into the design. All conveyors will be covered between crushing and screening stations. Further details regarding the ore crushing and process facilities are provided in the Heap Leach and Process Facilities Plan.

DWG NO. NMCCOF03C-G-GAD-0005 REV. B

5.3.5 Heap Leach Facility

The HLF will be located at the top of a ridge in the headwaters of the Latte Creek and halfway Creek watersheds. The HLF will consist of a conventional HLP, three Event Ponds, a Rainwater Pond, solution distribution piping (for delivery of barren solution to the heap), and collection piping (to convey gold-bearing solution to the event ponds and process plant). The general arrangement of the HLF is shown in Figure 5-9 and key operating criteria for the HLF are summarized in Table 5-5.

The design basis and processes specific to the HLP, water collection and storage infrastructure, and heap leaching and rinsing processes are described below. The Heap Leach Pad Engineering Report for the HLF and supporting appendices (containing design criteria, engineering drawings, technical specifications, hydrology and hydraulics, stability analyses, water balance and storm event runoff evaluations, and calculations) are provided in the Heap Leach and Process Facilities Plan. The design of the HLF will evolve as the Project advances and additional studies are completed to inform detailed design.

The designs for the HLP incorporate a single-side textured 2.0 mm linear low-density, polyethylene (LLDPE) liner. A geosynthetic clay liner (GCL) will be used in lieu of a 300mm thick layer of compacted low permeability material. GCL will be placed underneath the geomembrane and will provide equal or greater protection than 300 mm material having a saturated hydraulic conductivity of no greater than 5x10E-9 cm/sec. Additional details regarding the design criteria for the heap leach pad are provided in the Heap Leach and Process Facilities Plan.

Table 5-5 Heap Leach Facility Key Operating Parameters

Ore Preparation	Crush to P80 = 50 mm No Agglomeration
Ore preparation	Crush to P80 = 50 mm
	No agglomeration
Ore stacking	Truck dumping Conveyor stacking Average annual stacked tonnage: 6.7 Mt/yr 275 days/year (April 1 – Dec. 31, subject to ambient conditions during operations) 67 Mt design heap capacity 69 Mt maximum heap capacity
Heap geometry	~115 m maximum heap height 10 m nominal lift thickness Angle of repose of each lift 10 m to 14 m wide benches between lifts 2.5H:1V or flatter overall toe-to-crest heap slope
Solution irrigation	10 L/m^2/hr 1,100 m^3/hr nominal 365 days per year
Heap rinsing	Solution recirculated for rinsing in 10 areas of the HLP, then controlled draindown.
Barren solution heating	Increase gold-bearing solution temperature to minimum 8° C at process plant (to provide at least 6° C at drip emitters)
Pond Capacities	Total available storage volume at freeboard (at crest): EP-1N: 112,791 m^3 (122,184 m^3) EP-1S: 90,312 m^3 (98,697 m^3) EP-2: 339,819 m^3 (376,942 m^3) Rainwater: 53,016 m^3 (59,326 m^3)
Raincoats	Identified as an opportunity in operations to allow for more flexibility in water quality management but are not required from a flow quantity perspective

Note: a. The capacities of the event ponds include seasonal water accumulation, full heap drainage, the 24-hour PMP storm event, and seasonal solution accumulation.

5.3.5.1 Heap Leach Pad

The heap leach pad will be a conventional, relatively level pad with an ultimate footprint of 1 Mm^2, constructed directly on bedrock or structural fill after the removal of overburden and ice-rich material by grading the local terrain and using competent waste rock for fill that supports a multi-lift, free-draining 67 Mt heap. Major grading of the first stage of the pad area is proposed for Year –2 with the final grade completed in Year –1. The HLP will be developed progressively in five stages over the LOM.

The system consists of two layers of synthetic liners with leak detection below and a hydraulic head control or drainage layer on top of the liners. The leach pad liner system will be a 2.0 mm LLDPE geomembrane over a reinforced GCL liner. The bottom side of the LLDPE liner will be aggressively textured to provide a close bond with the GCL.

Horizontal piezometers will be located in each of the stages to allow measurement of the phreatic surface. A layer of overliner drain fill (ODF), consisting of the engineered specified manufacture rock meeting hydraulic conductivity rates will be place at a depth directly over collection piping and liner for protection. In addition to the best practice QA/QC that is performed during installation of liner, a leak detection survey will be performed after the ODF is placed.

Ore will be transported to the HLP by 144-tonne trucks or radial stacking conveyors and stacked in 10 m lifts at the ore's angle of repose. Benches will be constructed between lifts to produce a 2.5H:1V or flatter overall toe-to-crest slope. Construction and operational stages for the HLP are summarized in Table 5-6. As the pad stages expand to the west, temporary interceptor ditches will be constructed to divert upgradient runoff from tributary areas that are composed of native soils. Information on the leaching and rinsing processes is provided in Section 5.3.5.

Table 5-6 HLP Stacking Metrics by Stage

Heap Leach Pad Stage	Construction Year	Cumulative Pad Stage Area (m^2)*	Pad Cumulative Capacity (Mt)	Heap Crest Elevation (masl)
Stage 1	Year –1	247,000	4	1,324
Stage 2	Year 1	429,000	15	1,350
Stage 3	Year 2	699,000	32	1,388
Stage 4	Year 4	921,000	50	1,392
Stage 5	Year 7	1,053,000	69	1,392

*Leach pad area within the HLF containment system. Does not include lined pond area.

5.3.5.2 HLF Surface Water Management

Conventional external ponds for events and clean water storage from precipitation runoff will be constructed as storage volume requirements increase, as determined by the leach pad area. Small embankment dams will be used to create four ponds: the south Event Pond 1 (EP-1S), north Event Pond 1 (EP-1N), Event Pond 2 (EP-2), and the Rainwater Pond (Figure 5-9).

The HLF Water Balance Model resulted in two distinct inflows for EP-2; therefore EP-2 is segregated into two ponds, one for containment of process solution pond and one for direct precipitation and EP-1N and EP-1S overflow only. The event ponds containing solution will be lined with two high density polyethylene (HDPE) geomembrane liners, separated by a drainage layer and underlain by a GCL. The portion of EP-2 for containment of direct precipitation as well as the rainwater pond will be single lined.

Water will be routed from the heap leach pad to the event ponds via the north and south event and rainwater channels. The Event Ponds are designed to contain a combination of upset conditions including:

- Heap draining during an extended power or pumping outage
- Extreme precipitation and freshet events
- Cumulative water storage during wet years or temporary shut-downs.

The Rainwater Pond is designed to receive water from the interior channel of both the north and south perimeter channels once a channel divider is installed. The primary purpose of this interior channel is to receive solution from precipitation if raincoats were installed.

The event ponds and the rainwater pond will be constructed in Year –1 to provide containment for the drainage the HLP. The approximate capacities of the ponds are:

- EP-1N: 112,791 m^3
- EP-1S: 90,312 m^3
- EP-2: 339,819 m^3
- The Rainwater Pond: 53,016 m^3.

Normal operating volumes in Event Ponds EP-1N and EP-1S will increase over time as the lined footprint of the HLP increases and the system receives more and more meteoric water. Event Pond levels are expected to peak during Stage 3 as the lined footprint grows to nearly three times what it was in Stage 1.

All ponds are sized to contain the following cumulative volume: the runoff from a PMP, full heap drainage during a power outage or pump failure, and seasonal water accumulation. Stormwater conveyance outside the HL footprint otherwise known as interceptor ditches were designed to convey the 100 year 24-hr event. A leak detection sump will be installed in the lowest corner of each pond.

Further details regarding HLF surface water management are provided in the Heap Leach and Process Facilities Plan and the Water Management Plan.

5.3.5.3 Heap Leaching Process

The north and south halves of the leach pad will be separated hydraulically, with the south half sloping and draining to the southeast and the north half sloping and draining to the northeast. The design also includes hydraulic separation of the leach solutions by cell (approximately every 100 m of pad in the east-west or long axis direction) and by stage (Stages 1 through 5). Each cell will be separated by a drainage ditch or berm, preventing solution from one cell from entering the adjacent cell. The stages will be separated in a similar way but with a larger berm to provide more definitive separation. Because there is always some lateral spreading of solution within the heap during irrigation, there will be some solution cross over from a cell under irrigation to an adjacent cell, but this is expected to be limited to a horizontal distance of under half the width of a cell.

Heap leach ore processing will entail the use of dilute cyanide solutions under pH conditions ranging between pH 9 and 10.5. Except for the addition of make-up water, the leaching process circuit is a closed circuit. Barren solution will be irrigated onto the heap using drip irrigation, with each lift irrigated for nominally 45 days before the subsequent lift is stacked and leached. Gold-bearing solution will be collected into the collection piping network at the base of the HLP above the liner system and will flow to the ADR (adsorption, desorption, and recovery) process plant by gravity for gold recovery. During upset conditions solutions are directed through an automatic overflow system or through manual control by the heap leach operators to the event ponds. Any process solution accumulated in EP-2 will be pumped to the process plant and recirculated to the heap or treated in the water treatment plant and discharged to the Alpha Pond via the Alpha rock drain. A secondary option during upset conditions in the ADR plant is to move solution to the event ponds EP-1N and EP-1S by activating control valves.

Outside makeup will not frequently be required. The highest demand for make-up water will occur during winter months when solution storage ponds have been mostly emptied. Each pad stage will be separated from the adjacent stage by a temporary ditch or berm to divert upgradient runoff from tributary areas that are composed of native soils.

While the dissolution of gold is the primary chemical process occurring during cyanide leaching, other metals are liberated during the leaching process, both as a result of complexation reactions with cyanide (e.g., Cu-CN, Cd-CN, Zn-CN) and increased solubility under elevated pH conditions (e.g., As and U). In addition, natural degradation of CN in situ within the heap leach results in elevated concentrations of nitrogen species in heap leach solutions. Development of estimates of HLF solutions is described in detail in the Coffee Project Geochemical Source Term Report (Appendix 7-A).

Solution removal and active treatment is required by Year 2 and continues throughout operations into early closure. Once the heap leach facility has completed closure activities including cover placement and seepage volumes have decreased, seepage waters will be directed to semi-passive treatment using reclaimed event ponds. Estimates of heap leach solution chemistry have been developed from site-specific metallurgical testwork performed on Coffee ores and from analogue gold heap leach operations, including early phase barren solution chemistry from the Eagle Gold Project, YT. Early and late phase HLF solution predictions are summarized in Table 5-7.

Table 5-7 Early and Late Phase HLF Solution Chemistry Estimates

Parameter	Units	Early Phase HLF Solution	Later Phase HLF Solution
pH	s.u.	9 to 10	8.4
$N\text{-}NH_3$	mg/L	72	0.06
$N\text{-}NO_3$	mg/L	50	307
$N\text{-}NO_2$	mg/L	1	1.9
Cl	mg/L	300	123
Sulphate	mg/L	1100	2516
Total Alk	$mg/CaCO_3/L$	600	87
WAD-CN	mg/L	130	0.2

Se-D	mg/L	0.007	0.005
U-D	mg/L	0.1	0.685
Zn-D	mg/L	0.7	0.052

From Year 10 through Year 15 no additional ore stacking will occur, but irrigation of the heap will continue for gold production and rinsing. Upon completion of active leaching operations, solution management will be required until such time as the closure cover is established, and clean runoff is diverted off the facility. Once the solution draindown rate falls to a level that can be safely and passively contained in the post-closure event pond(s), active solution management can cease (i.e., no pumping).

The results of heap draindown water balance modelling is provided in the Heap Leach and Process Facilities Plan. The model tracked the dewatering of the heap during the Operation and Closure Phases. Predictions incorporated solution application and irrigation rates, dewatering rates, and the site synthetic

climate record (including precipitation, temperature, evaporation) to track heap system storage and volumetric water contents on a monthly basis.

Progressive closure of the HLP is currently anticipated to begin in Year 10, with rinsing starting in 10 recirculation areas as described in the Heap Leach and Process Facilities Plan. A description of HLF closure including rinsing activities is provided in Section 7.3.1.

Suitable final effluent water quality conditions will be achieved prior to final release to the environment through a combination of measures that are further described below, including:

- Chemical stabilization of the heap through recirculation (rinsing) with barren solution until the chemistry of the heap effluent reaches approximate equilibrium with the rinse solution
- Construction of low infiltration covers to limit infiltration and reduced heap seepage volumes
- Provision to implement (if necessary) passive treatment using permeable reactive barriers (PRBs) technology for “polishing” of heap solutions within event ponds.

5.3.5.4 Water Treatment

Operation of the heap leach facility is projected to generate a positive water balance with the need to manage and remove (e.g., discharge) excess solution to maintain adequate storage in the event ponds system (i.e., Event Storage Requirement (ESR)) throughout operations and early closure of the heap leach facility. The most important solution removal strategies include pumping of water to active treatment during both operations and early closure and the release of net infiltration water at closure through semi-passive treatment.

Beginning in about Year 2, the HLF is expected to produce surplus water with elevated concentrations of parameters indicated above. A water treatment plant will be constructed by Year 1 and commissioned in Year 2 or earlier to ensure that there is on-site water treatment capability in advance of surplus water conditions.

The heap leach WBM (Forte 2022) indicates solution removal needs to commence in Year 2 to maintain ESR. The solution removal rates, and schedule utilized in the WBM to maintain ESR for operations and into early closure are:

- **25 L/s** (90 m^3/h) beginning in Year 2 through to Year 7. This is the maximum solution removal rate required during normal operations over this period to maintain the ESR
- **35 L/s** (126 m^3/h) from Year 7 to Year 16 is the max Solution Removal rate required to maintain the Event Storage Requirement Year 7 to Year 16
- **14 L/s** (50 m^3/h) beginning in Year 16 after cover placement is complete.

The duration of active water treatment through the WTP is unknown at this time. However, for the purposes of water quality modeling, active water treatment expected to operate up to Year 20 when Alpha Pond is decommissioned and five years following completion of HLF cover placement.

The proposed water treatment system and the results of bench-scale testing is described in the Heap Leach and Process Facilities Plan as well as in the Coffee Mine Conceptual Water Treatment Design for Permitting Report (Appendix 5-C). In summary, the proposed system is a multi-stage process including:

1. Flow Equilibration
2. Cyanide Destruction
3. Breakpoint Chlorination
4. Physico-Chemical Treatment
5. Membrane (UF/RO) Filtration
6. Solids Handling
7. Denitrification

5.3.6 Plant Site

Infrastructure at the Plant Site includes the process plant, reagent storage area, laboratory, truck shop and warehouse building, power plant, bulk fuel storage area, and an LNG storage facility (Figure 5-10). A summary of the Plant Site components is provided below, and additional information is provided in the General Mine Development Plan.

5.3.6.1 Process Plant and Reagent Storage Area

The process plant will be located in a pre-engineered building adjacent to the HLF to minimize pumping and piping requirements for gold-bearing and barren solutions. To minimize the potential for differential settlement, the building will be founded on competent bedrock and/or engineered fill.

The external building dimensions will be approximately 33 m wide by 65 m long by 24 m tall (subject to final design refinement). The process plant building will house the barren solution, gold-bearing solution, raw water, and rinse water tanks, the ADR carbon process plant, electrowinning, a control room, and an office (Figure 5-11). Tank and column loads will be supported on pads and pedestals. The building will be equipped with a 10-t overhead crane for equipment maintenance, as well as dust control and fume extraction systems. Process reagents such as sodium hydroxide, hydrochloric acid, and anti-scalant solutions, as examples, will be stored within the building.

The process plant will have concrete walls for secondary containment around all tanks containing cyanide and other reagents (i.e., containment for minimum of 110% of the largest tank volume). Containment will also be provided around the acid wash, strip, and reagent mixing areas.

The process plant will be heated by a combination of waste heat from the power plant, along with heat captured from the barren solution boiler, located adjacent to the process plant building. The boiler is designed to heat the solution by a minimum 8°C to provide a minimum discharge temperature at the HLP drip emitters of at least 6°C; final thermal capacity will be determined during detailed design and early-stage operations. Redundancy for process plant heating will come from a truck shop bypass line that allows the truck shop to be isolated from the power plant waste-heat recovery loop. By isolating the truck shop, it will be possible to direct the heat to the process plant if the barren solution boiler is not operational.

As indicated above, gold extraction will utilize sodium cyanide heap leaching technology. Gold-bearing solution will be transported by pipe to the process facility where it will be processed via conventional gold recovery methods at an on-site ADR carbon plant. The end product of the ADR plant is poured doré bars, which will be shipped off-site by aircraft for further refinement.

5.3.6.2 Laboratory

A small laboratory will allow for the testing of samples from exploration, mining, processing activities, as well as minor environmental testing (e.g., TSS monitoring from water samples). Environmental samples for major environmental testing will be sent off-site to an accredited laboratory for third-party analysis and reporting. The on-site laboratory will be equipped to perform sample preparation and assays by atomic absorption, fire assay, and cyanide soluble analyses. A metallurgical test work area will also be included for process optimization.

5.3.6.3 Truck Shop and Warehouse Building

A truck shop and warehouse will consist of six maintenance bays, one wash bay, and a warehouse. The truck shop complex will be approximately 1,670 m^2, with dimensions of approximately 43-m-long by 40-m-wide by 12-m-tall structural steel, pre-engineered building (subject to final design refinement). The facilities will be designed for repair and maintenance of mining equipment and light vehicles, as well as storage for spare parts, consumables, and other materials and equipment.

5.3.6.4 Power Plant

A single captive power plant will be installed to meet the electrical power demand necessary to support the Project. The power plant will be capable of generating 9 megawatts (MW) of electrical power will be installed with N+2 (4+2) redundancy to allow for reliable operations. Each generator will be 2.25 MW or larger and will be capable of burning both diesel and LNG fuels. Subject to final design and procurement, each generator will be prime-rated for 2.250 MW running at 1,800 revolutions per minute (rpm) and generating power of 4,160 volts (V). The peak gross power will be 9 MW (four operating generator sets (gensets) @ 100%; 4 x 2.25 MW). Power will be distributed throughout the Plant Site and to the crusher area at 4,160 V. There will be five distribution feeders, including two spare positions.

The power plant will be modular with all gensets interconnected. Each genset will be packaged in a walk-in, sound-attenuated enclosure that is constructed, assembled, and tested prior to shipment to site. The power plant will also include an electrical building.

Given the modular and expandable nature of the power plant three gensets will be mobilized in Year –2 to provide Construction-phase power. Two additional gensets will be added in Year –1 in advance of plant start-up, the rest of the gensets will be added in Year 1 to achieve the N+2 (4+2) configuration. However, should procurement opportunities arise, all gensets may be installed simultaneously. During normal power plant operation, genset waste-heat recovery units will be used to heat buildings. Additional temporary heating units will be installed at the camp and power plant, if required, to meet peak winter demands.

5.3.6.5 Bulk Fuel Storage

Four 4 million litre (L) diesel fuel tanks will be field-constructed within the bulk fuel storage area in Year -2. The general arrangement of the bulk fuel storage area and section details are provided in Figure 5-12. Additional infrastructure for tank filling and fuel dispensing infrastructure will be installed once tank construction is completed.

5.3.6.6 LNG Storage Facility

An LNG storage facility is proposed within the Plant Site. Two Type C LNG ISO-certified tanks rated for 116 psi will be used for storage. The facility will include an earthen impoundment to provide secondary containment for 110% of the maximum storage volume and to contain any spills that occur during offloading from the tanker truck to a storage tank.

5.3.7 Camp Site

The Camp Site consists of the camp facilities and dormitories as well as the mine dry and office complex, emergency response team building, communications systems, waste management infrastructure, sewage treatment plant and fire and potable water infrastructure. The location of the Camp Site is shown on Figure 5-10. A summary of the Camp Site components is provided below, and additional information is provided in the General Mine Development Plan.

5.3.8 Camp Facilities

The operation camp accommodations will consist of single-occupancy rooms with en-suite washrooms. The facilities are planned to include several dormitory wings and centralized kitchen, dining, and recreation buildings that will include a complete kitchen, dry food storage, walk-in freezer, dining room, first-aid room, mudroom, housekeeping facilities, reception desk, lobby, and recreation area.

The facilities will be skid-mounted, hard walled, prefabricated facilities constructed for year-round usage. Primary heating for the camp will be forced air propane, and secondary heat will be electric baseboard heaters.

5.3.8.1 Mine Dry and Office Complex

A single large mine dry and office complex will be assembled from modular units manufactured off-site and placed on wood cribbing. The mine dry facility, with capacity for 85 workers during shift change, will be used during the Construction and Operation phase. The office complex will contain a large open office area, private offices, main boardroom and meeting rooms, and a mine operations line-up area.

5.3.8.2 Emergency Response Team Building

An emergency response building will be located adjacent to the mine dry and office complex. The building will house an ambulance and a fire truck. An emergency medical responder will be on site 24 hours a day to provide emergency care. For additional information regarding emergency response infrastructure, refer to the General Mine Development Plan. For information regarding emergency response equipment, refer to the Emergency Response Plan.

5.3.8.3 Potable Water and Fire Water Infrastructure

Fresh water supplied from a well field that is located near the Yukon River will be transported by a freshwater pipeline or a water truck to the combined fresh/fire water tank at the Camp Site. The fresh/fire water tank is designed at 230 m^3 with 130 m^3 dedicated to firewater and 100 m^3 for process water. The tank has been designed with the bottom of the tank dedicated to fire protection services.

Water for use as potable water will be pumped from the tank to the potable water treatment plant. Potable water treatment will consist of filtration, ultraviolet and chlorine disinfection. Treated water from the potable water treatment plant will be stored in an insulated and heated potable water storage tank capable of accommodating potable water demand variances for distribution to camp, office, plant, and mine dry facilities as needed.

5.3.8.4 Sewage Treatment Plant

The sewage treatment plant will be pre-assembled offsite prior to transportation to and installation at the Camp Site. Sewage will be treated by a membrane bioreactor plant that includes influent screening, an equalization and bioreactor tank (to handle the daily peaks in flow), a membrane system, a treated effluent storage tank, and ultra-violet disinfection. The treated effluent will be sent to a dispersion field that will drain towards the Latte Creek catchment.

Sewage treatment plant sludge will be disposed of in a manner that will not be an attractant to wildlife or pose any human health risk. This may be achieved either through the waste incinerator or by composting to create additional quality soil for reclamation.

5.3.8.5 Waste Management Infrastructure

In addition to waste material or water generated from mining and ore processing activities, several types of waste will be generated during the Project. The waste will be transported to the waste management facility for segregation and management. The waste management facility will include a waste management building, landfill, composting unit/facility, incinerator, and a storage facility. Containment at the waste management pad will include berms, an impermeable liner, and a sump. A fence will surround the perimeter of the waste management area to provide security and restrict wildlife access. The waste management building will have approximate dimensions of 36 m by 18 m and will be located adjacent to the incinerator building.

The landfill will be used for the disposal of inert, solid, non-salvageable, non-hazardous, non-leaching, inorganic, and non-putrescible waste materials. All material disposed of in the on-site landfill will be on the Approved Material List.

Organic kitchen wastes will be separated and burned daily in the incinerator to limit wildlife attraction associated with the disposal of food waste. The dual-chamber diesel-fired incinerator will be capable of burning site waste generated based on maximum daily occupancy. Organic kitchen waste may also be composted to create additional quality soil for reclamation purposes and reduce diesel consumption by incinerator.

5.3.9 Bulk Explosive Storage Area

The bulk explosives storage area will be located north of the Kona Pit, as shown on Figure 1-2. As shown in the explosives storage area layout provided on Figure 5-13, the area will consist of three main components: bulk AN storage, emulsion plant and mixing, and storage magazines.

The powder magazine will be two 40-foot container magazines, each capable of holding up to 32 tonnes of packaged explosives products. The cap magazine will be a 20-foot container magazine capable of holding up to 600 cases of detonators and caps. Each magazine will be surrounded on three sides with earthen

berms to prevent propagation and movement. The emulsion plant and mixing area will include a 60 tonne AN silo and a 100-tonne emulsion silo.

The emulsion plant will be constructed on the emulsion pad with a dedicated wash bay, shop, electrical and mechanical buildings, and office for plant operations. All these items will be provided in modular containers for quick assembly and minimal need for civil foundations. Power to this facility will be via a 500-kW generator, filled by the site fuel truck as needed. A 60 tonne AN silo will hold the daily AN requirement of prill (pellets) that will be stored for use during NAR outages. Liquid AN solution will also be stored on this pad for daily consumption during NAR operational periods.

The AN storage area is sized to allow for a minimum 15 weeks of storage or up to 3,100 tonnes of AN prill (pellets) and will be lined with a HDPE liner to provide spill containment. Sufficient quantities of AN prill will be stockpiled in tote bags at the AN facility prior to the close of the NAR during freeze-up and break-up to allow for ongoing blasting operations during these periods. Additional details regarding the bulk explosives storage area are provided in the Explosives Management Plan.

5.3.10 Land Treatment Facility

The land treatment facility will be a multi-use facility where different media (i.e., soil, water, snow, and ice) contaminated with hydrocarbons and antifreeze will be treated. The land treatment facility will be located to the east of the Supremo Pit footprint and will have the capacity to treat up to 2,400 m^3 of contaminated media at any one time in treatment cells. The facility will be equipped with a sump for pumping snow melt and/or excess water from the cells, which will then be primarily used for operation of the land treatment facility. A continuous sheet of HDPE impermeable liner sandwiched between layers of geotextile will be installed under the land treatment facility and in its berms. Welds used in installing the liner will be tested to ensure the impermeability of the liner, and records of the welds will be retained on-site.

5.3.11 Mine Site and Haul Roads

The Mine Site road network will include a total of approximately 37 km of mine site haul roads, including the roads used by site personnel to access Mine Site areas and the Project airstrip. While staying within the overall Project footprint, the exact layout and location of haul roads will be modified during mine construction and operations to facilitate safe travel of light and heavy vehicle traffic around the Mine Site, as required.

Mine Site roads will be used for smaller vehicles (e.g., light trucks) to access the Project airstrip, bulk explosive storage area, and other site infrastructure. The mine site roads, which are designed for light and medium trucks, will be constructed with embankment (rock) fill material with a minimum travelling surface width of 8 m and a maximum grade of 10%. Roadbed material thicknesses will depend on existing ground conditions. The rock material will be sourced from infrastructure earthwork activities or from open pit waste rock.

External pit haul roads will be used by mining equipment and heavy-duty vehicles to access the open pits, ore crusher, ROM stockpile, Alpha WRSF, and HLF. To the extent possible, these roads will be constructed using all-fill techniques to achieve design alignment and grade, with suitable non-PAG material sourced from the open pits. The haul roads will be 30 m wide, and the depth of roadbed material will vary depending on the existing ground conditions.

5.3.12 Site Water Management Infrastructure

The Mine Site is located near the headwaters of three watersheds: Halfway Creek, YT-24 Creek, and Latte Creek (Figure 4-9). Surface drainages within the Mine Site are limited to small seeps and springs, which may be encountered during mine development. Water management infrastructure that will be in place during the Operation Phase is shown in Figure 5-14 and at the end of the Closure Phase in Figure 5-15.

Mine site water management is described as follows:

- *Alpha WRSF and Alpha Pond:* The Alpha WRSF will be situated in the upper Halfway Creek catchment and will include a rock drain to safely convey flow beneath the facility into Alpha Pond. Precipitation and snowmelt that infiltrate the Alpha WRSF will report to the rock drain and be collected in Alpha Pond. Contact water collected in Alpha Pond will be discharged to Halfway Creek starting in Year -1. A diversion channel will be developed on the west slope of the Halfway Creek catchment to divert clean runoff away from the Alpha WRSF and into Halfway Creek, downstream

of Alpha Pond. Ultimately, Alpha Pond will be decommissioned during the Active Closure Phase and water conveyed through the rock drain will discharge directly into Halfway Creek.

- *Heap Leach Facility:* From a water management perspective, the HLF will be operated predominantly as a closed system for most of the Operation Phase, as outlined in Section 5.3.5. The highest demand for process make-up water will occur during winter months when solution storage ponds have been emptied. Makeup water will be used, as needed, in priority sequence from the Event Ponds, Rainwater Pond, Facility Pond, open pit sumps or pit lakes, and groundwater wells near the Yukon River. Treatment of surplus rinse water will be required in Year 2 to remove residual cyanide. Treated water of acceptable quality will be discharged towards Alpha Pond via the Alpha Rock Drain, and ultimately discharged into Halfway Creek drainage during the Operation Phase and early Closure Phase (Figure 5-6). The water treatment plant will continue to operate until water volumes (e.g., seepage flow) and quality is suitable for either direct discharge to upper Halfway Creek or receives additional treatment through semi-passive treatment cells within the events ponds and/or through the backfilled Latte Pit (Figure 5-7).
- *Plant Site:* The rock pad foundation for the Plant Site area will be graded to convey contact water to a local sedimentation pond, the Facility Pond, which will be excavated below natural ground beneath the pad. A drainage ditch will be constructed along the perimeter of the ROM ore stockpile to facilitate drainage of runoff and stockpile seepage towards Facility Pond. Water collected in the Facility Pond may be used as makeup water for the HLF, used for dust suppression or discharged via pumped pipeline towards Alpha Pond, pending water quality. The pond will be equipped with an emergency spillway, which will operate under large flood events only, discharging towards Alpha WRSF.
- *Latte Pit:* Latte Pit will be one of the first pits to be developed. The meteoric water that collects in the Latte Pit during mining will be used for dust suppression, pumped to the Facility Pond, used as makeup water to the HLF (by way of the facility pond or pumped to the HLF event ponds), or will be conveyed with excess water from the Facility Pond towards Alpha Pond for sedimentation control and discharge to Halfway Creek. If used for dust suppression, the water sourced from this pit will be used only on mine haul roads, and volume of water applied to road beds will be targeted such that surface runoff is minimal to zero, with no surface discharges to receiving watercourses. Following the completion of active mining in isolated areas of the Latte Pit, inactive mining areas will be used for storage of water collected in other active mining areas. The temporary pit lake will provide sediment control in advance of pumping water for makeup at the HLF or for use in dust suppression. If active monitoring shows that pit lake water quality meets the discharge criteria for the receiving environment (i.e., Alpha Pond effluent quality standards (EQS) or Latte Creek EQS), water may also be discharged directly to the environment via controlled spill point channels.
- As the mine operation phase progresses, water temporarily stored in Latte Pit will be dewatered to the extent required and pumped to the Facility Pond, and ultimately discharged to Halfway Creek via Alpha Pond in the years prior to backfilling. Once backfilling is complete, the main pit will spill towards Latte Creek, while each of the 3 minor pits will spill towards Alpha Pond. Active water quality monitoring during the final pit lake development will determine whether additional water management measures, such as water treatment, will be required to ensure any water that spills towards Latte Creek meets the Latte Creek EQS.
- *Supremo Pit:* During mining, meteoric water that accumulates in active mining areas will be prioritised for use as dust suppression. Additional inflows will be pumped to one of three primary areas. During years where active mining in Latte Pit is complete, water will be pumped for storage

to the Latte Pit, and eventually discharged to Alpha Pond. While active mining or backfilling is ongoing in Latte Pit, water may be pumped to Alpha Pond directly. Following the completion of active mining in these areas, the pits will be flooded. Water from pit lakes may continue to be pumped towards Facility Pond and Alpha Pond to discharge into Halfway Creek throughout the operations period. Spill points from the final flooded pits will discharge to the natural environment via Latte Creek and YT-24, as well as towards Alpha Pond. Active water quality monitoring during the final pit lake development will determine whether additional water management measures, such as water treatment, will be required to ensure any water that spills towards Halfway Creek, Latte Creek or YT-24 meets the site-specific effluent quality standards (Alpha Pond EQS, Latte Creek EQS and YT-24 EQS, respectively).

- *Kona Pit:* During mining, water collected in the pit will be pumped towards Alpha Pond via the Alpha WRSF rock drain. Water may also be pumped towards Event Ponds for water treatment if it does not meet the Alpha Pond effluent quality standards (EQS). Upon completion of mining in Kona, Supremo waste rock (gneiss) will be used to backfill the Kona Pit as the mine schedule permits to cover granite ore exposures which are mildly acidic and attenuate metal leaching and arsenic release from the granite pit walls. The remaining basin will then be allowed to flood, and the final spill point will be towards the Alpha WRSF rock drain. Active water quality monitoring during the final pit lake development will determine whether additional water management measures, such as water treatment, will be required to ensure any water that spills towards Halfway Creek meets the Alpha Pond EQS.
- *Double Double Pit:* A diversion channel will be built to the north side of the Double Double Pit to divert clean runoff (non-contact water) away from the Double Double Pit into Latte Creek. During active mining, meteoric water will be used for dust suppression, pumped towards the Facility Pond or Event Ponds for makeup water or conveyed towards Alpha Pond if water quality meets the Alpha Pond EQS. Following active mining, Double Double Pit may become a temporary pit lake, storing excess pit water collected in surrounding active mining areas. Pending the water quality at this time, water from the flooded Double Double pit lake may be discharged towards Latte Creek if it meets the Latte Creek EQS, or conveyed towards Alpha Pond if it meets the Alpha Pond EQS.

Additional details regarding the site water management infrastructure are provided in the Water Management Plan. Additional details regarding the Alpha WRSF rock drain, including stability analysis, are provided in the WROMP.

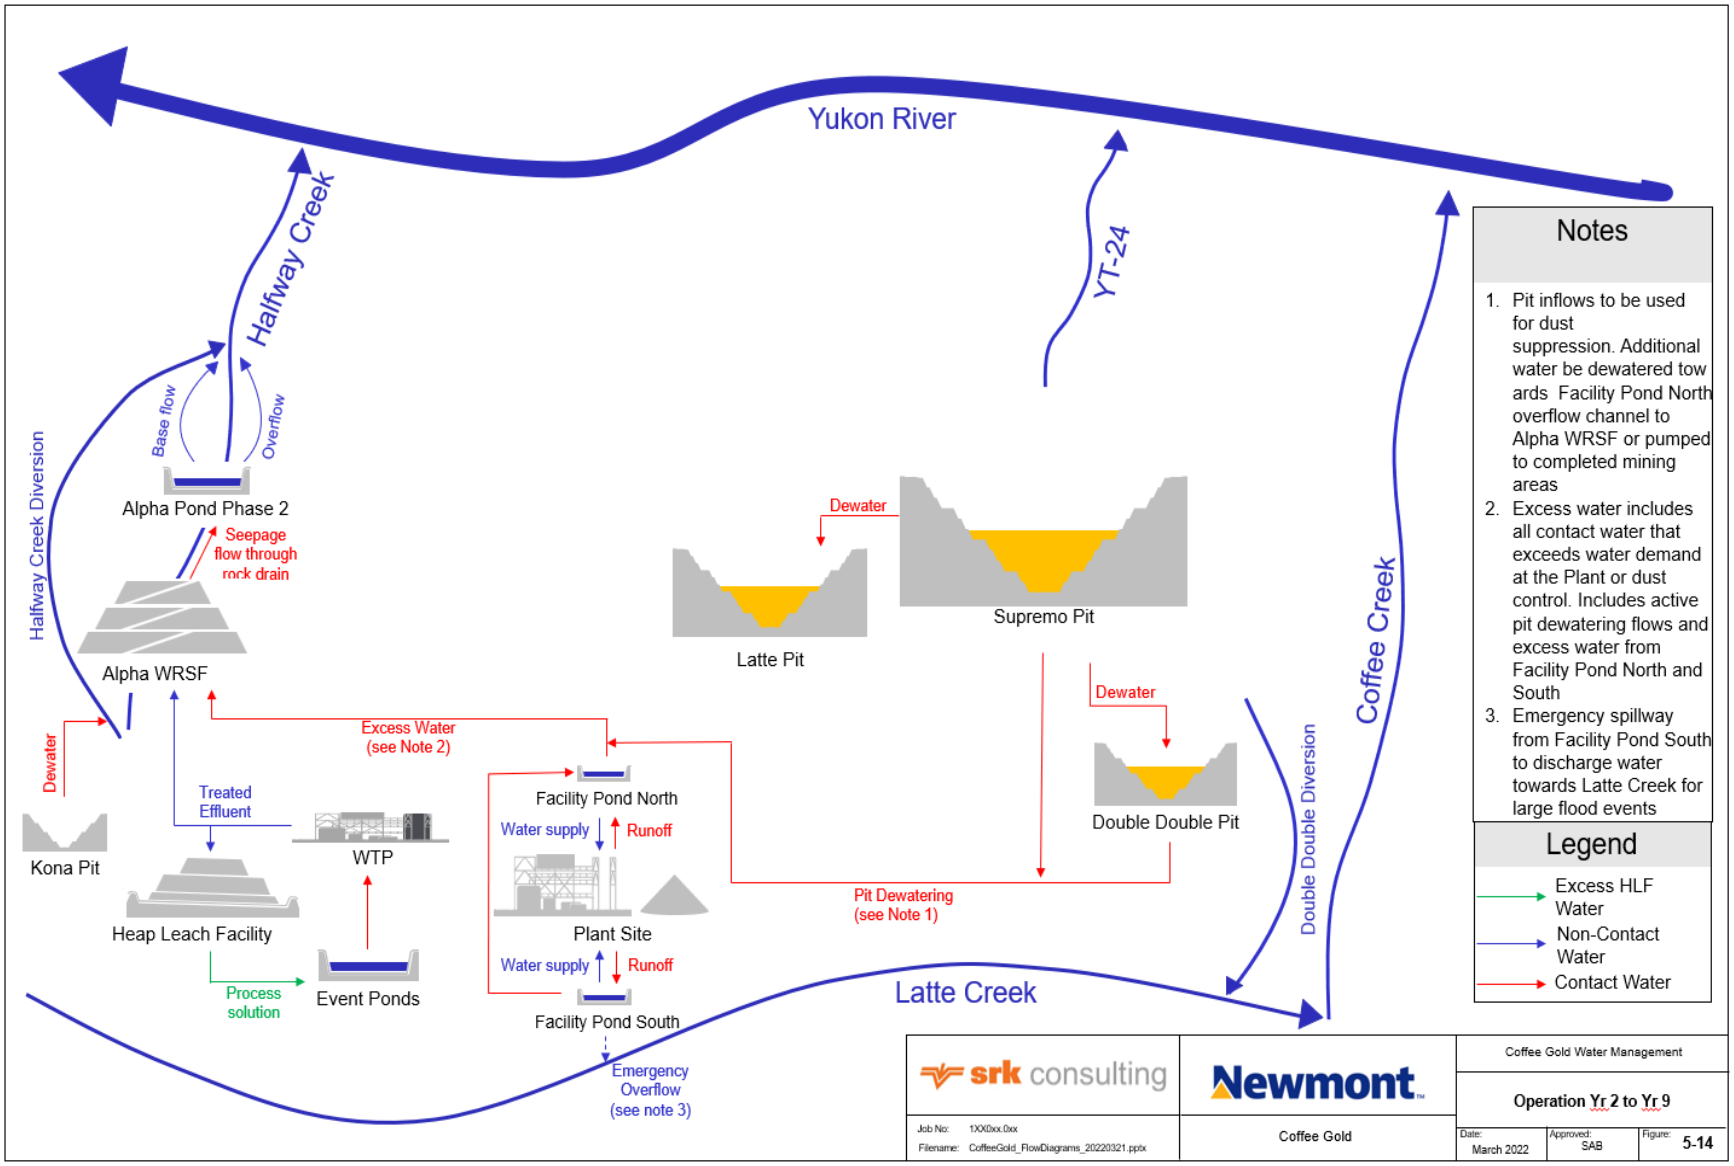

Figure 5-14 Water Management Infrastructure - Operation Phase Activities

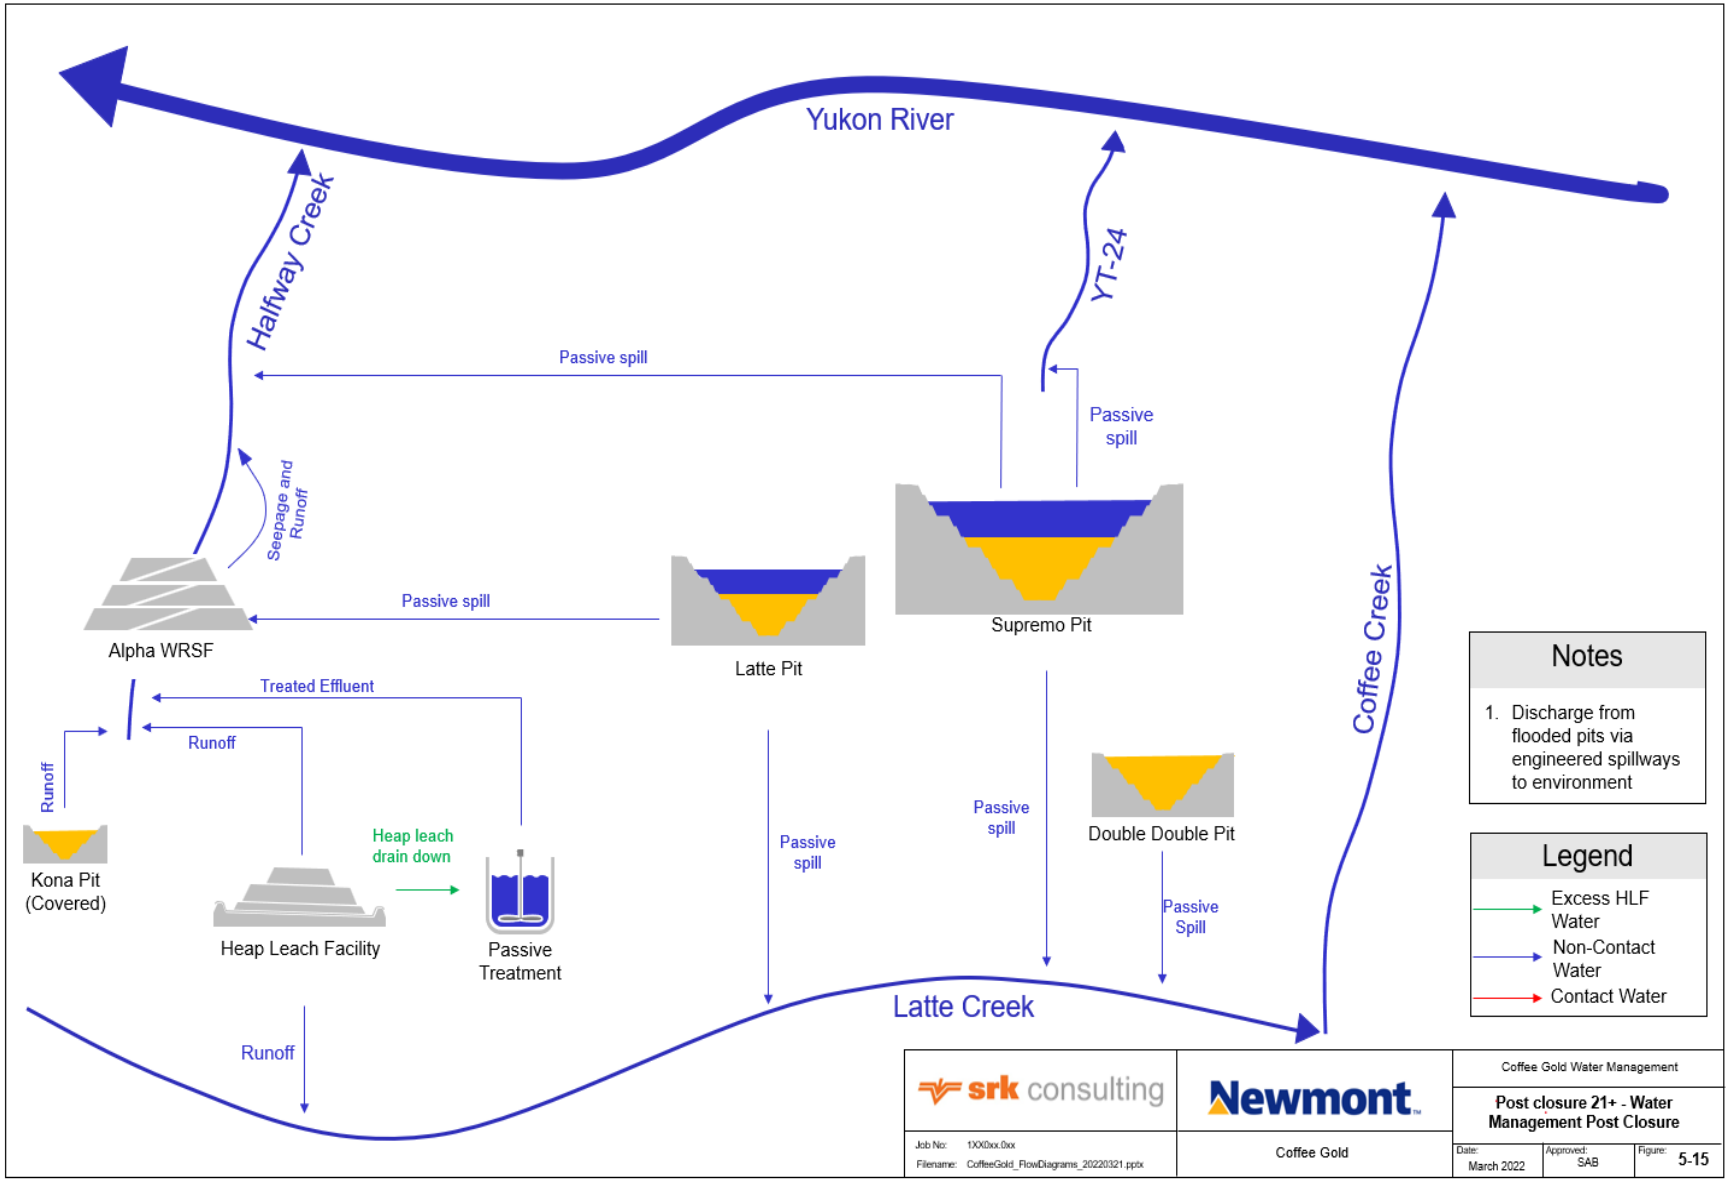

Figure 5-15 Water Management Infrastructure – End of Closure Phase (Year 21)

5.3.13 Ancillary Infrastructure

Ancillary components include the NAR, the airstrip, and laydown areas.

5.3.13.1 Coffee and Java Exploration Camps and Roads

The existing Coffee exploration camp near the Yukon River is currently used to accommodate up to 80 personnel working on the Coffee Project. The general arrangement of the Coffee exploration camp is shown in Figure 5-16. This camp will be used until facilities are operational at the 200-person capacity Java exploration camp.

Existing roads will be used to the extent possible to minimize disturbance, including the 29 km On-site Access Road from the barge landing on the south bank of the Yukon River to the property exploration areas in the Mine Site area.

Once the Project Camp is operational, the Coffee exploration camp is envisaged to be maintained to accommodate exploration personnel, contractors, and visitors, or for cultural events and activities. When the Project Camp is decommissioned during the Closure Phase, the Java camp may be used to accommodate personnel involved with the final reclamation and closure activities and monitoring activities.

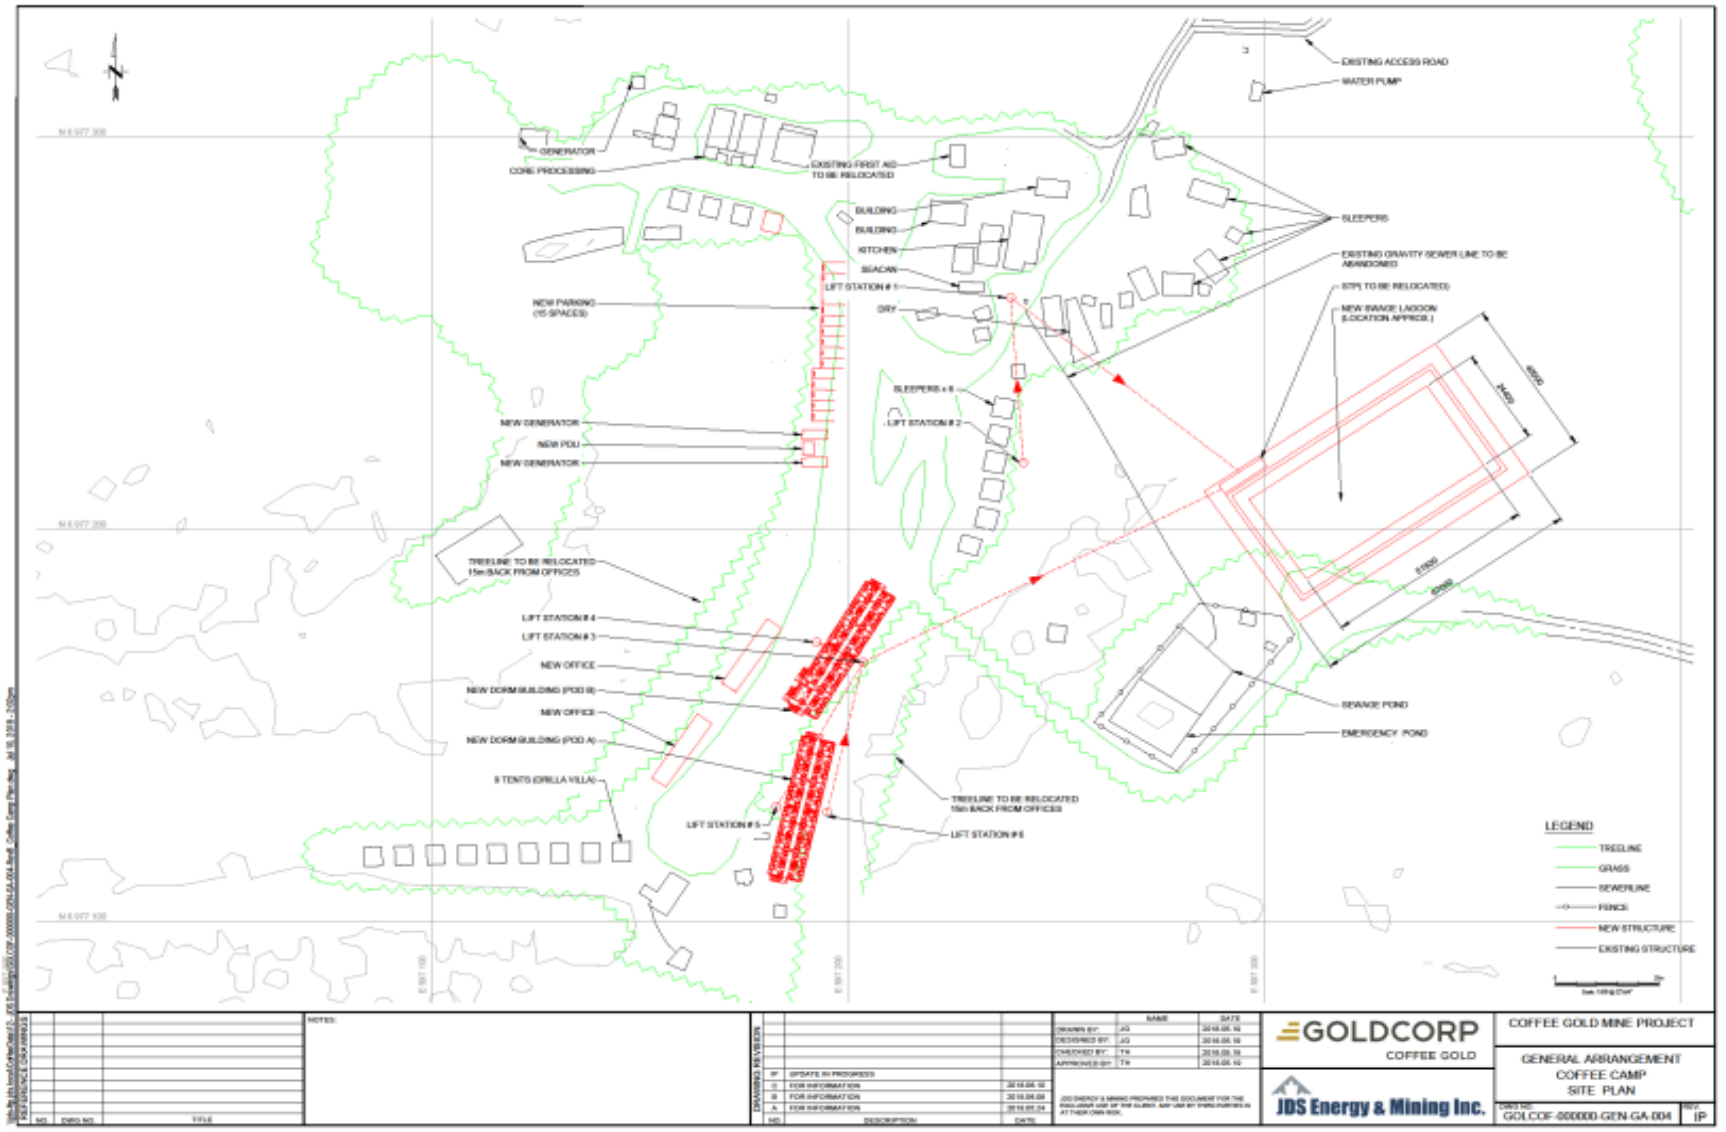

Figure 5-16 General Arrangement of Coffee Exploration Camp

5.3.13.2 NAR

The NAR consists of a 16-km stretch of Klondike Highway and 192-km all-season road. The NAR will be comprised of 61 km of existing Yukon government-maintained road, 5 km of winter road, and 126 km of road modifications, including approximately 31 km of new single-lane, forestry-type access road that will be constructed to support Project construction, operation, and reclamation and closure activities.

The upgraded and newly constructed sections of the NAR road will primarily consist of a single-lane road with pullouts that will support two-way traffic. The finished road will have a width of approximately 5 m, and maximum gradients of between 8% and 10% Design speeds will be between 30 km per hour and 50 km per hour, depending on the terrain.

The NAR will be operated on a year-round basis except for periods when the Stewart River and Yukon River are either freezing up in the fall through early winter or breaking up in the spring. During the open-water period, barges will be utilized to ferry transport trucks delivering fuel and freight across the Stewart and Yukon Rivers. During the winter months when the rivers are frozen, ice roads will be established to enable transport trucks to drive across the rivers.

Four barge landings will be required – two on either side of the Stewart and Yukon rivers. Each barge landing will consist of a concrete ramp for docking of an upstream-facing barge and the ramp will be installed on a grade that will help minimize stream bottom interference. Barge landings will include an area to allow for a B-Train tractor-trailer to easily embark and disembark from the barge then proceed along the NAR. Landings will also allow for storage of the barge, maintenance supplies, and emergency response materials. On the southern bank at each barge crossing, barge fuel will be stored in a single 20,000-L double-walled tank that will be placed inside HDPE-lined berms a minimum of 30 m from the waterline. The fuel tank will be filled by fuel trucks as required.

In conjunction with the ice road on the Yukon River, a 4.1-km-long winter road will be constructed seasonally from the east side of the bridge crossing Coffee Creek to the barge landing on the south side of the Yukon River. Since no river access will be possible during fall freeze-up and spring thaw, the mine plan provides for on-site storage of a sufficient supply of fuel and consumable materials during these periods.

5.3.13.3 Airstrip

Air transportation will be the primary means of transportation for Mine Site personnel and incidental freight. Fixed wing aircraft will be chartered from Whitehorse or the City of Dawson for delivery of bulk freight on an as-needed basis (e.g., for catering supplies during periods when the NAR is closed). Site personnel will be mobilized to site from Whitehorse and Dawson.

The all-weather airstrip will be located approximately 7 km east of the camp site and will be 1,600-m long by 45-m wide, with a 12.5 m safety area on each side and a 60 m safety area at each end. The taxiway to the apron area will be 15 m wide with 6-m graded areas on each side. The concrete apron will be approximately 75 m by 33 m and will be large enough for two aircraft to maneuver and park. The airstrip is designed to handle turboprop passenger aircraft similar in size to an ATR-300 or Dash-8. The airstrip is also sufficiently sized to handle cargo aircraft up to a de Havilland DHC-5A Buffalo.

The airstrip will be equipped with a GPS Instrument Approach system allowing for instrument flight rules approaches and departures under suitable weather conditions. Lighting will include runway edge lighting, taxiway edge lighting, precision approach path indicators, and an omni-directional approach lighting system.

A pre-fabricated modular operations centre containing radio equipment for ground-to-air communications will be located on the airstrip apron. A dedicated diesel generator located at the flight operations centre will provide power for airstrip operations; alternative power generation options for airstrip operations will be evaluated during detailed design, and may include renewable power, if feasible. The airstrip layout is shown on Figure 5-17. Additional details regarding the Project airstrip are provided in the General Mine Development Plan.

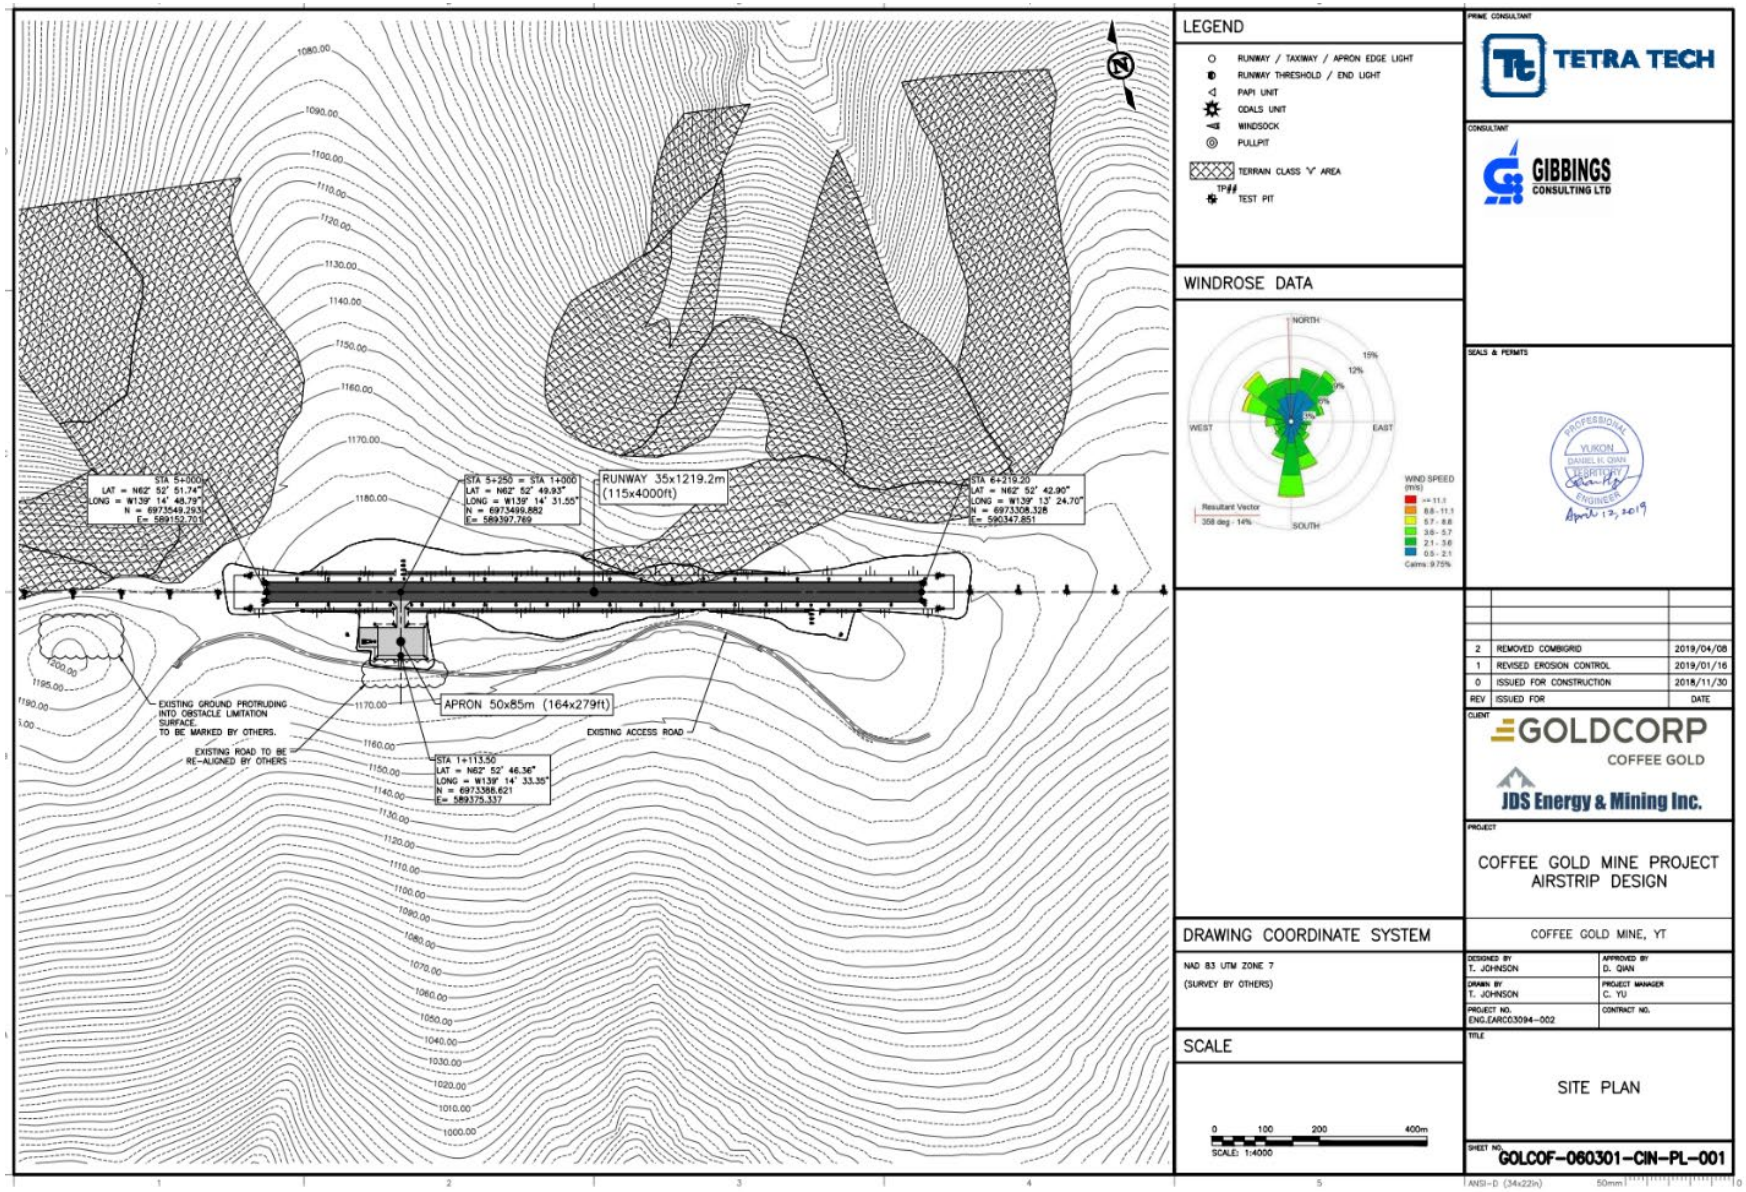

Figure 5-17 Project Airstrip General Arrangement

5.3.13.4 Laydown Areas

Laydown areas for major process plant consumables will be located next to the truck shop building and at the crusher area. Materials that do not require protection from the elements may be stored in the laydown yard.

Additional laydown areas will be created as needed. Should additional storage area for construction materials be required, the area east of the Plant Site may be utilized.

5.4 Current Conditions (Year -5)

Current infrastructure supporting the Coffee Project includes the Coffee exploration camp and airstrip, the On-site Access Road, and exploration laydown areas (Figure 5-2). The Java exploration camp is currently being constructed and only camp pads are in place. The Coffee exploration infrastructure and Java exploration camps will be used to accommodate construction and support personnel until the Camp Site facilities are completed early in the Construction Phase.

Since the existing infrastructure that is used to support exploration activities is permitted under Quartz Mining Land Use Permit #LQ00312 and Type B Water Use Licence MN12-014, the requirements for reclamation of any disturbances and decommissioning of any buildings and infrastructure are addressed under these regulatory instruments. Hence, the liabilities for closure and reclamation of exploration-related infrastructure and disturbed areas are not incorporated as part of the Project closure costing for current conditions at this time. The Java exploration camp and the On-site Access Road will transition to Project-associated liabilities during the Construction Phase and will be included as current liabilities in subsequent iterations of this RCP.

5.5 Conditions Two-years Forward (Year -1)

This section describes principal Project components that will be in place to support Project activities occurring by Project Year -1 (two years forward from start of construction (Year -3)), as well as the expected aerial extent of Project-related surface disturbance. The layout of the Mine Site in Year -1 is shown in Figure 5-18 and includes the following infrastructure and facilities:

- Crusher area earthworks
- Heap leach facility earthworks
- Plant Site earthworks including process plant, truck shop and bulk fuel storage pads
- Camp Site including dormitories, and kitchen, dining, and recreation complex buildings, fresh (potable) water and fire water systems, sewage treatment plant, and waste management facility
- Partial soil stockpile and frozen soil storage area
- Bulk explosive storage area
- Mine site and haul roads
- Power plant
- Site water management Infrastructure including Facility and Alpha Ponds and conveyance structures
- Ancillary components within the Mine Site include laydown areas.

Supporting ancillary infrastructure includes the Coffee exploration camp, access infrastructure including the NAR, the Project airstrip, and the On-site Access Road. Key activities conducted by Year -1 are summarized by Project component in Table 5-8.

Table 5-8 Summary of Key Activities and Infrastructure in Place in Year -1

Project Component	Key Activities
Overall Mine Site	Confirmatory geotechnical drilling in select areas at the Mine Site, as necessary
	Mobilization of mobile equipment and construction materials
	Clearing, grubbing, and grading of areas to be developed within the mine site
	Construction material to provided foundation and fill material for roads construction and other infrastructure development
Stockpiles	Development and use of soil stockpiles for vegetation and overburden
	Development and use of frozen soil storage area
Heap Leach Facility	Construction of Stage 1 of the heap leach pad
Plant Site	Process plant pad earthworks and facilities construction
	Truck shop pad earthworks and facility construction
	Bulk fuel storage pad earthworks and facility construction
	Crusher pad earthworks and facility construction
	Crusher pad Power Plant and facility construction
Camp Site	Construction and operation of dormitories, kitchen, dining, and recreation complex buildings; mine dry and office complex; emergency response and training building; fresh (potable) water and fire water use systems; and sewage treatment plant
	Construction and operation of waste management facilities including incinerator
Waste Management Facilities	Construction and use of waste management facilities
	Construction and use of Landfill
	Construction and use of Land Treatment Facility
Bulk Explosive Storage Area	Construction of storage facilities for explosives components and on-site use of explosives
Mine Site and Haul Roads	Construction and maintenance of mine site service roads and haul roads
Site Water Management Infrastructure	Development and use of sedimentation ponds and conveyance structures, including discharge of compliant water
Ancillary Components	Upgrading of existing road sections for NAR, including installation of culverts and bridges
	Construction of new road sections for NAR, including installation of culverts and bridges
	Development, operation, and maintenance of temporary work camps along road route
	Vehicle traffic, including mobilization and re-supply of freight and consumables
	Development, operation, and maintenance of barge landing sites on Yukon River and Stewart River
	Operation of barges on Stewart River and Yukon River, including barge mobilization of equipment for NAR construction
	Annual construction, operation, maintenance, and removal of Stewart River and Yukon River ice roads
	Annual construction and operation of winter road on the south side of the Yukon River
	Construction, operation, and maintenance of permanent bridge over Coffee Creek
	Construction and maintenance of the Project airstrip
	Construction Project airstrip and use of Project airstrip by aircraft
	Use of laydown areas
	Use of Coffee Exploration Camp and airstrip (and associated air traffic)

5.5.1 Mine-Related Land Disturbance Two-Years Forward

The Project area encompasses 22,000 ha and includes areas unaffected and potentially affected by the Project. The total mine-related land disturbance area (excluding exploration related land disturbances) at the end of Year -1 is estimated at approximately 705.7 ha, as outlined in Table 5-9. The spatial extent of disturbance within the Project area has been estimated based on the footprint areas for Mine Site infrastructure and facilities (shown in Figure 5-18) and transportation infrastructure (shown in Figure 1-2 for the On-site Access Route and Project airstrip and southern portion of the NAR, and Figure 1-1 for the NAR). The footprint areas estimate provided in Table 5-9 include the following buffers to allow for modifications that may arise during detailed design:

- 10 m from the perimeter of mine site infrastructure and facilities (other than transportation corridors)
- 10 m either side of the centerline for the On-site Access Route
- 10 m either side of the centerline for the Yukon River and Stewart River ice roads
- 50 m from the perimeter of the Project airstrip running surface
- 50 m either side of the centreline for the newly constructed portion of the NAR (i.e., those sections that are newly constructed to support Project activities and will be reclaimed)
- 50 m from the perimeter of spoil and borrow sites along the NAR.

Associated liabilities to decommission and close facilities and infrastructure and reclaim disturbed areas for conditions two-years forward are provided in Section 9. In cases where facilities and infrastructure are fully constructed or operational, the closure measures described in Section 7 will apply. For components where earthworks are underway, liabilities reflect reclamation activities including re-sloping and revegetation requirements, as applicable, across the entire component footprint area.

Table 5-9 Mine-Related Land Disturbance Two-Years Forward (Year -1)

Mine Feature	Disturbance Footprint Area End of Year -1 (ha)
Open Pits[a]	**27.9**
Double Double	0
Latte	20.8
Kona	0.0
Supremo	7.1
Waste Rock Storage Facilities and Stockpiles[a]	**80**

Camp Site	4.0
Bulk Explosive Storage Area	8.7

Mine Feature	Disturbance Footprint Area End of Year -1 (ha)
Alpha Pond	7.5
Facility Pond	2.3
Water Management Infrastructure	8.2
Roads and Airstrip	**424.7**
On-site Access Road to Project Airstrip[a]	9.0
Mine Site Haul Roads[a]	20.5
Project Airstrip[b]	15.9
NAR – Project Portion[c]	290
Potential Spoil and Borrow Sites along NAR[b]	n/a
Yukon River and Stewart River Ice Roads[a]	n/a
Yukon River Winter Road	4.3
TOTAL AREA OF DISTURBANCE	**705.7**

Notes:

a. Area includes 10 m buffer from centreline of roads or from perimeter of mine features.

b. Area includes 50 m buffer the perimeter of the Project airstrip running surface and the perimeter of spoil and borrow sites along the NAR.

c. Area represents the approximately 29 km portion of access route that is newly constructed to support mine development and operations and includes 50 m buffer either side of the centerline.

5.6 End-of-mine Conditions (End of Year 9)

For the purpose of estimating liabilities at the end of the LOM (Year 9), this section outlines principal Project components that will be in place at the end of the Operation Phase and the extent of mine-related disturbances. In addition to access infrastructure including the NAR, Project airstrip, and the On-site Access Road, the following mine facilities and infrastructure will exist at the Mine Site at the end of Year 9 (as shown on Figure 5-19):

- Supremo and Latte open pits
- Alpha WRSF
- Soil stockpiles and FSSA
- ROM stockpile pad
- Crusher system including crushing circuits, crushed ore stockpile pad, or crushed ore conveyor system connecting the crusher system area to the HLF
- Heap leach facility with 67 Mt of ore
- Plant Site including process plant, reagent storage area, laboratory, truck shop and warehouse building, power plant, bulk fuel storage area, and LNG storage facility
- Camp Site including dormitories, and kitchen, dining, mudroom, and recreation complex buildings, mine dry and office complex, Emergency Response Team building, potable water and fire water systems infrastructure, sewage treatment plant, and waste management infrastructure
- Bulk explosive storage area
- Mine site and haul roads
- Site water management infrastructure including the Alpha and Facility Pond, diversion, and conveyance structures (i.e., ditches and culverts)
- Laydown areas.

5.6.1 Mine-Related Land Disturbance at End of Mine (Year 9)

Mine Site and ancillary infrastructure to be closed, decommissioned and/or areas to be reclaimed at the end of Year 9 are summarized in Table 5-10. The total outstanding area of disturbance at the end of Year 9 is approximately 979.9 ha. As with the disturbance area estimates provided in Section 5.5 for the two-years forward condition, the estimates provided in Table 5-10 include buffers to allow for modifications that may arise during detailed design (see table notes for specific distances).

The final measures to decommission, close, and/or reclaim these components are described in Section 7 and associated liabilities to complete all closure measures are provided in Section 9.

Table 5-10 Mine-Related Disturbance Areas at End of Mine Life (Year 9)

Mine Feature	Disturbance Footprint Area End of Year 9 (ha)	Area Progressively Reclaimed
Open Pits[a]	177.0	
Double Double	11.3	Yes – pit completely backfilled
Latte	32.9	Yes – pit partially backfilled
Kona	6.2	Yes – pit completely backfilled
Supremo	126.6	Yes – pit partially backfilled
Waste Rock Storage Facilities and Stockpiles[a]	205.1	
Alpha WRSF	161.8	No
Soil Stockpiles	16.0	No
ROM Ore Stockpile Pad	23.4	No
Crusher Area including Crushed Ore Stockpile Pad	3.9	No
Heap Leach Facility[a]	129.8	
Heap Leach Pad and Infrastructure	121.8	Yes – during Closure Phase
Event and Rainwater Ponds	8.0	No
Supporting Mine Infrastructure/Facilities[a]	43.3	
Plant Site	12.6	No
Camp Site	4.0	No
Bulk Explosive Storage Area	8.7	No
Alpha Pond	7.5	No
Facility Pond	2.3	No
Water Management Infrastructure	8.2	No
Roads and Airstrip	424.7	
On-site Access Road to Project Airstrip[a]	9.0	No
Mine Site Haul Roads[a]	20.5	No
Project Airstrip[b]	15.9	No
NAR – Project Portion[c]	290	No
Potential Spoil and Borrow Sites along NAR[b]	n/a	Yes – reclamation completed post-construction
Yukon River and Stewart River Ice Roads[a]	n/a	Temporary during winter months
Yukon River Winter Road	4.3	No
TOTAL AREA OF DISTURBANCE	979.9	

Notes: n/a – areas progressively closed and/or reclaimed during the Operation Phase, or not requiring further works.
a. Area includes 10 m buffer from centreline of roads or from perimeter of mine features.
b. Area includes 50 m buffer the perimeter of the Project airstrip running surface.
c. Area represents the approximately 29 km portion of NAR constructed to support Project development and operations and includes 50 m buffer either side of the centerline.

5.7 Monitoring Activities

This section outlines the surveillance and monitoring requirements for the Mine Site, the physical and biophysical environments, and socio-economic conditions during the Construction and Operation Phases. Monitoring will be conducted following the procedures outlined in the Environmental Monitoring and Adaptive Management Plan (EMAMP) and associated monitoring plans as well as the SEMP. Where relevant, management and protection plans are referred to, as these documents provide detailed information. Operations monitoring programs will continue into the Closure Phase until the programs are either no longer required or have been adapted for closure. Monitoring and reporting requirements for the Closure and Post-closure Phases are documented in Section 7.11.

5.7.1 Monitoring and Inspections of Mine Site and Supporting Infrastructure

During mine development and operation, regular inspections will be conducted to confirm compliance with applicable permits and licenses. Infrastructure such as the Alpha WRSF, HLF and process facilities, open pits, water management infrastructure, fuel and storage tanks, and all roads (including the NAR) will be inspected to confirm physical stability and integrity in accordance with design criteria. On-site personnel will coordinate follow-up investigations by appropriate professionals, as necessary.

Plans that are relevant to facility and infrastructure performance during mine construction and operation and relevant to operational processes or procedures that will be monitored include the following (and should be referred to for additional information):

- Access Route Construction Management Plan
- Access Route Operation Management Plan
- Air Quality and Greenhouse Gas Management Plan
- Cyanide Management Plan
- Environmental Monitoring and Adaptive Management Plan (EMAMP)
- Erosion and Sediment Control Plan
- Explosives Management Plan
- General Mine Development Plan
- Waste and Hazardous Materials Management Plan
- Heap Leach and Process Facilities Management Plan
- Mine Operations Plan
- Noise Management Plan
- Spill Contingency Plan
- Vegetation Protection Plan
- Waste Rock and Overburden Management Plan
- Wildlife Protection Plan
- Water Management Plan.

5.7.2 Monitoring of Physical and Biophysical Environments

Physical and biological components will be monitored at designated locations in accordance with license conditions, generally as per the monitoring program outlined for the Construction and Operation phases in the EMAMP. Refer to the EMAMP for monitoring details for these specific environmental aspects: meteorological conditions, physical conditions, geochemical conditions, vegetation, surface water quality, hydrology, groundwater, fish and aquatic life, wildlife, air quality and greenhouse gases, and noise.

5.7.3 Monitoring of Socio-economic Conditions

Socio-economic conditions will be monitored during the Construction and Operation phases in accordance with the SEMP. Results from monitoring will be used to evaluate effectiveness of mitigation and enhancement measures and to implement adaptive management, as necessary. Future RCP iterations will by updated with results from the SEMP as well as through consultation with First Nations to reflect the socio-economic conditions of the community through the Closure and Post-closure Phases.

5.8 Risk Assessment, Contingency Planning and Adaptive Management

Newmont understands that the construction, operation, closure, and reclamation of any mine involves performance uncertainty, and that risk management planning is a requirement. Mechanisms to understand and manage risk during all Project phases will include undertaking risk assessments on a regular basis and having a robust adaptive management plan. The approach to assessing Project risks and adaptive management is outlined below.

5.8.1 Risk Assessment

Project-related risks have been assessed during Project planning using the FMEA approach, as discussed in Section 2.3.4. A Preliminary Project FMEA was conducted in March 2018 based on a conceptual level of design to identify potential failure modes for Project components, and their potential causes and consequences. Key Project components assessed in the Preliminary Project FMEA included open pits, WRSFs and material stockpiles, HLF, and water management infrastructure. The 2018 Preliminary FMEA Report is provided in Appendix 2-L.

Based on the preliminary analysis, a total of 158 failure modes were identified, with all but one failure mode assessed to be low or moderate risk. A slope failure around Alpha Pond was identified as a moderately high risk, almost certain to occur, and having the potential to result in minor consequences.

As part of the alternatives assessment, a FMEA workshop was held in February 2022 to identify and prioritize key risks of the base case design and outline strategies / future studies to mitigate Newmont's residual risks within the near- short- and long-term. The base case design represents the closure measures that were identified through the alternatives assessment process as described in Section 2.3.4. The 2022 FMEA process aimed to evaluate risks at the site based on the Project as a whole and focused on specific site components to facilitate this comprehensive analysis.

During the workshop, ten failure modes were evaluated as severe or high-risk. No identified failure modes were evaluated as a fatal flaw that would require modification of the base case design. A residual risk assessment determined that all unacceptable risks could be mitigated, with the exception of three high-risk rankings related to major life of project cost consequences, which were identified as acceptable given the

current Project definition. The FMEA ultimately verified confidence with the Base Case design that was identified through the alternatives assessment process. The 2022 FMEA Summary Report is provided Appendix 2-M.

5.8.2 Contingency Planning and Adaptive Management Approach

Mine sites are management-intense operations, as indicated by the list of management plans provided in Section 5.7.1 for the Coffee Gold Mine. These management plans, which outline management and response actions for expected conditions and anticipated events at the site during construction and/or operation activities, are required for both operational control and regulatory approval. As the Project advances through the detail design stage and mine operations commence, these plans will become more prescriptive, and the uncertainty in the range of conditions expected will be reduced.

A detailed Surface Water Quality and Aquatic Life Adaptive Management Plan (AMP) (provided as part of the EMAMP) was developed to support project licencing, and detailed AMPs will be developed for additional components as the mine planning advances. The Surface Water Quality and Aquatic Life AMP outlines the approach to make efficient and effective decisions to guide responses to unforeseen events or unexpected conditions during the Construction and Operation phases. The water quality early warning triggers for adaptive management that are identified for the site in the EMAMP will be extended for reclamation and closure and will be applied for all watercourses. Conditions at the Project will be managed adaptively when mitigation measures may not function as intended or when broad-scale environmental change occurs. The adaptive management framework that will apply during the post-closure phase will be similar to that applied during the Operation Phase. A specific closure/post-closure AMP will be developed during the Operation Phase and will be based on actual site conditions and data. The detailed Closure AMP will be described in future iterations of this plan once site performance is better understood during construction and operations. For additional details, refer to the EMAMP.

6.0 TEMPORARY CLOSURE

Temporary closure is managed as part of the Yukon Government's commitment to ensure that mining developments are managed in a sound and sustainable manner and with greater benefits for all Yukon residents (Government of Yukon 2014). As per YWB and EMR (2013): Temporary closure is a closure in which mining related activities cease with the intent of resuming activities in the near future. Temporary closure may be planned or unplanned and could arise from a variety of circumstances including financial challenges, design failures, extreme climatic conditions, etc. A temporary closure event "is considered to last more than six months and no longer than five years, unless otherwise specified in an approved reclamation and closure plan." (EMR 2013).

In accordance with YWB and EMR (2013) guidance and the Yukon Mine Site Reclamation and Closure Policy (EMR 2006), the following sections describe the measures and activities related to ensuring public health and safety, protecting the environment, and managing risks associated with potential temporary closure of the site, as well as monitoring and reporting program requirements.

In the event of a Temporary Closure, a full review of the Reclamation and Closure Plans, liability estimate, and security may be undertaken. If, while in temporary closure, the decision is made to enter permanent closure, Newmont will provide regulators with an updated Reclamation and Closure Plan.

To minimize outstanding liabilities and risks while the site is in a state of temporary closure, the primary objectives include:

- Confirming that all mine-related landforms, infrastructure, and facilities are physically and chemically stable and performing in accordance with designs
- Confirming that all mine-related landforms, infrastructure, and processes can withstand severe climatic and seismic events
- Eliminating or minimizing health and safety hazards to site personnel, the public, and area wildlife by preventing access to areas that pose a risk
- Confirming that mine-related disturbances (e.g., building sites, hazardous materials storage sites, roads, etc.) are not going to adversely affect aquatic and terrestrial environments to prevent future long-term uses or a self-sustaining ecosystem.

A hypothetical scenario that is relevant to an early stage of the Coffee Gold Mine and this iteration of the RCP is outlined below, followed by details pertaining to associated on-site activities and socio-economic aspects of a temporary closure.

6.1 Temporary Closure Scenario Description

A temporary suspension of operating activities at the Coffee Project could result with a change in market conditions or mine-related factors and could be either a planned or unplanned event. This section describes the activities to be caried out during a temporary care and maintenance period. For the purposes of this RCP, temporary closure is assumed to occur at the end of Year 1 in the Operation Phase. This hypothetical temporary closure scenario has been selected as this RCP is anticipated to be updated every two years, and it is unlikely that a temporary closure would occur due to market conditions or another unplanned event during the Construction Phase. Subsequent RCPs will describe a temporary closure period mid-way through or towards the end of the Operation Phase. This hypothetical temporary closure scenario occurs

when the heap leach is at its largest footprint before the active water treatment plant is commissioned. Hence, this scenario was selected as it is considered conservative based on water accumulation within the event ponds prior to treatment and release through the active water treatment plant, and also based on the earliest period for a temporary closure to occur that is applicable to this iteration of the RCP.

The suspension of full operations is assumed to occur continuously for a two-year period (note that some operation activities must continue, as described below). The allowable duration of temporary closure would ultimately be defined by conditions specified in Water Licence and Quartz Mining Licence. Temporary closure activities would continue until mining resumes or until the decision is made to permanently close the mine (i.e., prevailing conditions for the resumption of operations are not favorable)[11].

The 'highest risk' scenario for temporary closure will vary depending on the phase of the mine. The 'highest risk' time for a temporary closure to occur early in the mine life is when the heap leach is at its largest footprint prior to the active water treatment plant being commissioned (i.e., end of Year 1). A contingency water treatment plan for the period prior to installation of the active water treatment plant in Year 2 is described within the Contingency Water Treatment Plan (WesTech 2023), appended to the Heap Leach and Process Facilities Plan.

Mine infrastructure and facilities within the Mine Site area at the end of Year 1 are shown in Figure 6-1, and include the following:

- Partially developed Latte, Supremo, and Double Double open pits
- Partially developed Stage 2 of HLF pad, Event Ponds EP-1N and EP-1S, EP2, and a rainwater pond
- Partially developed Alpha WRSF, including the frozen soil stockpile area
- Partially developed soil stockpile
- ROM stockpile area
- Crusher system and crushed ore stockpile area
- Camp and Plant sites, and waste management areas
- Mine site and haul roads
- Emulsion Plant
- Water management infrastructure including the Facility Pond and Alpha Pond, diversion berms, and rock drains
- Airstrip
- NAR and Mine Site Access Route.

11 If temporary closure is going to exceed the allowable duration, permanent closure activities must commence unless an extension to the temporary closure period is approved by regulators.

6.2 Personnel and Consumable Requirements

During a temporary closure period, Newmont will be a responsible steward of the site and demonstrate its commitment to re-opening the site by continuing to retain full-time care and maintenance and HLF operations staff. It is anticipated that on-site personnel will include a site manager, environmental technicians, HLF operation staff, and supporting personnel (for site maintenance and camp operation) who will work on shift rotations to provide adequate coverage. On-site staff will be responsible for a variety of measures including, but not limited to, the following:

- Inspecting the site on a daily basis to observe and document the condition of any changes to site security, safety measures, and mine infrastructure
- Monitoring and reporting as per regulatory requirements
- Documenting potential environmental or health and safety issues and response to any security/safety breaches as required
- Implementing and supporting safety and security controls, controlling access to site, first aid, emergency and spill response, and communications
- Coordinating specialist contractors such as mechanics, electricians, biologists, and engineers to assist with requirements on an as needed basis
- Inspecting mobile and stationary equipment to ensure no leaks or tampering has occurred, and installing drip trays underneath all parked mobile equipment
- Providing for snow removal and dust control for roads and the airstrip, as necessary (and other applicable measures)
- Supporting water management activities such as pumping for recirculation and processing activities such as operation of the ADR Plant at the HLF
- Inspecting water management infrastructure to ensure water is flowing as per site designs (ensure channels and culverts are free and clear, ensure no bypass or leakage of ditches and channels, ensure erosion is limited and controlled, etc.)
- Ensuring active water management equipment including pumps are operational and pipelines are clear of blockages and not leaking
- Ensure backup power is available in the quantities required to operate critical systems.

6.2.1 Personnel Requirements

Personnel requirements during temporary closure will be greatly reduced compared to requirements during mine operations. Hiring and staffing best practices will be implemented to ensure sick leave and vacation are covered and the appropriate amount of key personnel remain on site for temporary closure operations. The expected personnel required during this hypothetical temporary closure period and shift rotation details are listed in Table 6-1 by position. Newmont will ensure that the appropriate skilled and experienced personnel are hired, trained, and retained to manage the critical activities on site during temporary closure, specifically operation of the HLF. Operation of the HLF would primarily be the responsibility of the following personnel: Operations Foreman, ADR Operators, Millwrights, Tradespeople, Labourers/Apprentices. Monitoring of the HLF systems from an environmental perspective, including water balance will be the responsibility of the Environmental Personnel.

Table 6-1 Personnel Required for Temporary Closure Period

Position	Total Compliment	Shift Rotation (Weeks in x Weeks out)

Total Temporary Closure Staff	52	
Maximum Expected Staff On-site	29	

6.2.2 Consumable Requirements

Consumables required during a temporary closure period will be significantly reduced from operations of the entire mine, as mining- and processing-related activities will no longer occur or will be reduced. The primary consumables will be diesel fuel and LNG, which is required for power generation to run the HLF pumps, camp, and associated facilities, and for surface equipment operations. Table 6-2 provides the estimated annual power requirements (in kilowatt hours per year (kWh/yr) and fuel requirements (in litres per year (L/yr)) for temporary closure.

Table 6-2 Estimated Annual Power and Fuel Requirements

Area	Power Requirements(kWh/yr)	Fuel Requirements (L/yr)
HLF & Process Plant Facilities	5,000,000	1,270,000
Camp and Infrastructure Facilities	3,000,000	760,000
Surface / Support Equipment	N/A	730,000
Totals	8,000,000	2,760,000

6.3 Site Security, Monitoring and Maintenance

The key measures to be undertaken during a temporary closure period at the Mine Site are associated with ensuring that the site is secure and safe to minimize health and safety risks and ensuring compliance with all regulatory and licensing requirements to manage risks associated with temporary closure of the site.

Prior to the onset of care and maintenance activities during a temporary closure, operations personnel would complete all necessary outstanding repairs; winterize water collection and diversion systems, mobile equipment, buildings, and other site infrastructure. Waste materials stored in waste transfer areas would be transported to appropriate disposal, recycling, or salvage facilities, and hazardous waste materials not required for water treatment or care and maintenance activities would be removed from site. Care and maintenance activities will be planned to adhere to all safety and environmental standards.

At the onset of temporary closure, a care and maintenance program will be implemented to a level such that all mining infrastructure and processes are in operable condition for a period of up to two years (as per the hypothetical scenario) so that full operations can resume in a timely manner should the decision be made to recommence production.

Measures and activities that are likely to be undertaken during a two-year temporary closure are described below, along with specific activities relevant to infrastructure and facilities that will be in place at the end of Year 1.

6.3.1 Site Access Restrictions and Maintenance Requirements

The NAR will remain operational to allow for camp and plant supplies and fuel to be delivered. Access to the site will be restricted and enforced on a 24-hour per day, year-round basis. Site security is expected to be comparable to the operational period with access to the site controlled by the barge crew in the summer and ice bridge attendants at the crossing points on the Yukon River and Stewart River in winter. In the event that an attendant or barge is not required, a gate will be installed along the access road south of the Yukon River to prevent passage. During the spring thaw and fall freeze-up or other river access limiting circumstances, the site will only be accessible from the maintained airstrip. Personnel accessing the site will be required to be on an approved site manifest to ensure that site management has oversight over the personnel accessing the mine site. All visitors will be required to check in with the camp administrator upon arrival.

The NAR will require periodic visual inspections to monitor for physical stability and operational safety concerns, and to minimize potential risks to the surrounding environment in the event of a washout. Additional details pertaining to NAR inspection and maintenance requirements are provided in the Access

Route Operational Management Plan. Site roads and the airstrip will also be regularly inspected and maintained. Care and maintenance personnel will conduct routine maintenance tasks (e.g., snow removal), as required. Private contractors may be retained to complete maintenance of surface drainage infrastructure or grading as conditions warrant.

In addition to restricting mine site access, further security measures may be implemented for open pits, mine and processing facilities, vehicles and equipment, and hazardous materials that are not required during temporary closure. These additional security measures are discussed below.

6.3.2 Open Pit Access Restriction

The development of open pits will cease during temporary closure. The primary goal during temporary closure at open pit locations relates to the protection of human health and safety. Site access control is a key measure to minimize this risk. While access to the open pits will be restricted, they will remain accessible to authorized personnel to complete routine tasks related to water management and geotechnical inspections.

Any road that runs directly adjacent to an open pit will have a berm maintained to ensure that unauthorized access to the pit is restricted. The berm will also act as a visual queue for wildlife to avoid walking into the pit. Large boulders or a gate will be placed at the pit access point(s) to allow for light vehicle and pedestrian access while restricting access for mobile equipment during temporary closure.

A qualified geotechnical professional will establish an open pit inspection schedule that will allow for access by authorized personnel on a regular basis. If the inspection schedule is not followed for any reason, access to the open pit will be completely restricted until such time as an inspection can be completed by a qualified person.

6.3.3 Facility and Infrastructure Security and Hazardous Goods Storage

A portion of the main camp complex will be utilized throughout temporary closure. To support personnel during temporary closure, site services such as the potable water treatment, sewage treatment, power generation, and communication infrastructure will remain operational. All site buildings not in use will be kept locked and secured and structural inspections and maintenance will be provided by care and maintenance staff and qualified personnel, as necessary.

All waste will be handled, stored, managed, and disposed of as per the Waste and Hazardous Materials Management Plan. Domestic waste from camp operations will be the primary source of waste during temporary closure.

The Plant Site will remain operational during temporary closure to support the activities outlined below for the HLF and gold recovery. Routine operating protocols outlined in the Heap Leach and Process Facilities Plan will apply and tanks and storage areas containing hazardous materials such as chemicals and reagents will be secured, with containment provisions complying with applicable regulations. Depending on the nature of temporary closure, other hazardous materials will either be removed from the Mine Site (e.g., bulk explosives) and/or stored in a safe and secure manner with primary and secondary containment, as required. Tanks may be drained and stabilized over the temporary closure period based on recommendations from mechanical and chemical suppliers, contractors, and engineers.

6.3.4 Vehicle and Equipment Use and Storage

Care and maintenance activities during temporary closure for supporting infrastructure and equipment are focused on maintaining all necessary services and equipment to support required activities and to minimize health and safety risks. Hence, vehicles and mobile equipment required for site maintenance will be kept on-site in good operable condition, and mobile equipment not required for site maintenance will be stored in appropriate areas. Mining equipment will be stored on site in no load condition.

All hazardous fluids will be drained from non-essential mobile equipment based on recommendations from mechanical and chemical suppliers and handled and disposed of as per standard procedures. Equipment not required during temporary closure will be stored and secured in laydown or stockpile areas or inside buildings such as the truck shop. Drip trays will be placed under all parked mobile and mining equipment.

6.4 Ensuring Geochemical and Physical Stability

These sections describe measures to be undertaken during temporary closure to ensure geochemical and physical stability of the heap leach pad, ore stockpile, Alpha WRSF, open pits, water management structures, and soil stockpiles.

6.4.1 Heap Leach Facility and ROM Stockpile

Assuming temporary closure occurs at the end of Year 1, approximately 10.54 million tonnes (Mt) of ore will be present on the heap leach pad with an additional ~0.72 Mt on the ROM stockpile. Sources of ore during this period come primarily from Latte (9.53 Mt), Supremo (1.69 Mt) and much lesser quantities from Double Double (0.04 Mt). Ore from Latte, Double Double and Supremo is characterized as non-PAG. Ore material from Latte is dominantly schist and ore from Double Double and Supremo are dominantly gneiss. Both gneiss and schist ore have low sulphide (S) content and sufficient neutralization potential (NP) to maintain a neutral drainage pH (rinse pH of 6.7 – 8.7). Hence, the schist and gneiss ore are classified as non-PAG or non-reactive and therefore present little to no acid generation in the HLF.

While ore material is non-PAG, the geochemical characteristics and cyanide leaching conditions (e.g., elevated CN and pH) result in significant metal leaching potential if left completely exposed. While not subjected to cyanide leaching, run-of-mine ore on the ROM stockpile also has significant metal leaching potential. To ensure that seepage drainage from the ROM stockpile does not result in poor drainage water quality entering the Facility Pond, stockpiled ore remaining on the ROM stockpile pad will be transferred and stacked onto the heap leach pad during temporary closure. If temporary closure commences when the stockpile is frozen, ROM ore will remain in the stockpile until thawed and then placed on the HLF. It is important that non-frozen ore material is stacked on the heap to maintain thermal integrity of the HLP.

Should the temporary closure scenario require material to be stored on the ROM pad for more than one year, an evaluation will be carried out to determine the long-term attenuation capacity of the ROM stockpile pad for key constituents of concerns (arsenic and uranium). This will inform the suitability of short-term storage on the ROM stockpile or additional mitigation measures that may need to be implemented should this be required.

The primary physical stability concern for the HLF is to ensure that it does not freeze and maintains thermal integrity throughout the temporary closure period. Two primary strategies will be used to minimize the potential for freezing, including:

- Continuous circulation of heap leach solutions to provide a heat source to prevent freezing of the ore pile during sub-zero conditions. Recirculation of solutions also maintains the HLF as a "zero discharge" facility during temporary closure and will eliminate the need for water treatment[12]
- Deployment of raincoats (geomembrane covers) to fully cover the heap to prevent meteoric water infiltration into the heap and excess water accumulation, and provide some insulation to the ore, with the exception of areas under operation, reclamation or for other needs. Raincoat inventory requirements on site will consider the amount necessary for a possible temporary closure scenario in Year 1.

6.4.2 Alpha WRSF

At the end of Year 1, waste rock will have been generated from Latte, Double Double, and Supremo Pits. As indicated above, the majority of mining occurs in Latte and Supremo Pits. Approximately 24.72 Mt of waste rock from Latte Pit and approximately 18.32 Mt of waste rock from Supremo Pit will be placed in the Alpha WRSF. Approximately 1.46 Mt of waste material will be produced from Double Double Pit, which also will report to the Alpha WRSF.

Waste rock from these three open pits is non-PAG but exhibits metal leaching potential. Water balance and water quality modeling has indicated that seepage from the Alpha WRSF can report to Alpha Pond and be discharged directly to Halfway Creek (Lorax 2023b). As such, additional geochemical stabilization measures are not required or anticipated for these facilities during temporary closure. Routine water quality monitoring of Alpha Pond and receiving environment will occur during temporary closure to ensure the predictions of the water quality model remain valid.

A geotechnical engineer will be retained to conduct annual physical stability monitoring of the Alpha WRSF. Any repairs or maintenance of the facility, or improvements to runoff, erosion and sediment control will be undertaken on recommendation from the inspections.

6.4.3 Open Pits

Exposed open pit walls in the Latte, Double Double, and Supremo Pits are predicted to be non-PAG; however, metal leaching from contact with meteoric water will accumulate in pit voids. Water quality modeling has indicated that water accumulating in pit voids can be directly discharged (dewatered on a regular basis, from the Supremo (SU1) at a minimum) to the receiving environment without adversely affecting aquatic life. Therefore, additional geochemical stabilization measures are not required for Latte, Double Double, and Supremo Pits.

A geotechnical engineer will be retained to conduct annual physical stability monitoring of the open pits. Any repairs or maintenance of the facility, or improvements to runoff, erosion and sediment control will be undertaken on recommendation from the inspections.

12 The current HLF water balance model indicates there is enough event storage without needing water treatment during care and maintenance. The event storage requirement includes storage for the PMP applied to the lined area of the HLF, plus volume for a 72-hour draindown.

6.4.4 Water Management Structures – Diversion Ditches, Alpha and Facility Pond

The objective during temporary closure for water management facilities is to ensure short-term physical stability to maintain the integrity of the site-wide water management. Maintenance of open pits and the West Diversion Ditch, if built, will be required to maintain the integrity of these structures. Routine inspections of culverts and ditches will be performed to ensure structure integrity (i.e., no sloughing or blockages), especially after significant precipitation events. Excess sediment that accumulates in the ditches will be excavated to maintain open channels. Prior to freshet, visual inspections of snow and ice accumulation will be performed, and excavation of these materials may be necessary for the ditches and culverts to perform during snowmelt runoff.

The Alpha and Facility Pond will be inspected and maintained to ensure that sediment and/or excess water does not accumulate in the ponds to minimize the potential for overtopping of the facilities and to ensure they are physically stable. Care and maintenance personnel will take readings from staff gauges on a daily basis. Accordingly, all electrical and pumping components will remain operable during the temporary closure period. Sediment excavation will occur on an as needed basis if accumulation is hindering the performance of the facilities.

A geotechnical engineer will be retained to inspect the Alpha and Facility Pond on a routine basis. Any repairs or maintenance of the facility, or improvements to erosion protection of the dam facility will be undertaken on recommendation from the inspections.

6.4.5 Organic and Frozen Soil Stockpiles

Organic material and overburden from pre-stripping within the footprints of Project components will be stored in soil stockpiles. There are no concerns with these stockpiles during temporary closure, and the material is available for use as needed for reclamation activities. Temporary soil stockpiles will have small ditches constructed at their toes, along with installation of silt fences and/or stilling basins to mitigate any erosion potential during temporary closure.

Frozen soils excavated during pre-stripping will be stored in the FSSA. There are no concerns with this stockpile during temporary closure, as a small berm will be in place to contain the FSSA on a routine basis to ensure physical stability. Any repairs or maintenance measures will be undertaken on recommendation from the inspections.

6.5 Interim Water and Solution Management

This section outlines the water management and monitoring-related activities to be undertaken during the two-year hypothetical temporary closure period for key infrastructure including open pits, the HLF, and Facility and Alpha Ponds. Where relevant, management plans are referred to for details pertaining to the management of clean water, contaminated water, or process solutions. In addition, for detailed information pertaining to water management equipment and infrastructure, facility designs and drawings, processes, and flow diagrams, etc., refer to Section 5. Specific details regarding control or shutoff switches for all tanks, pumps, pipelines, and ponds will be provided in as-built drawings after construction and will be referenced in future RCP iterations.

6.5.1 Open Pits

At the end of Year 1, Latte, Supremo (SU1), and Double Double Pits will have voids that will collect meteoric water; neither pit is expected to experience groundwater inflows. Pit dewatering capabilities (e.g., sumps and piping) will remain in place to allow for periodic discharge of pit water collected in Latte, Supremo (SU1), or Double Double Pits to minimize the amount of water collecting in these facilities and allow for an easier transition to mining upon termination of temporary closure, provided discharge water quality criteria are satisfied. All pit dewatering operations will be conducted in accordance with the Water Management Plan.

It is relevant to note that pit dewatering is not a necessary activity for physical or chemical stability of the pits and pit dewatering is not required to prevent uncontrolled pit spillover, except for Supremo as described below. At end of Year 1, Latte, Supremo (SU1), and Double Double have approximately 1,649,000 m^3, 17,000 m^3, and 136,000 m^3 of available pit lake volume, respectively. Meteoric inputs to Latte, Supremo (SU1), and Double Double on an annual basis are on the order of 64,000 m^3 (Latte), 121,500 m^3 (Supremo) and 21,500 m^3 (Double Double), which are well below the available storage volume for the Latte and Double Double Pits. At the end of Year 1, Supremo Pit has a relatively large surface area to storage volume ratio, leading to annual inflow rates that are higher than the available pit void storage. It is anticipated that the Supremo Pit will need to be regularly discharged to the environment or stored on-site for treatment during a temporary closure scenario occurring around Year 1.

6.5.2 Heap Leach Facility

There are two primary objectives for managing the HLF during temporary closure include:

- Ensuring the heap leach does not freeze
- Maintaining the HLF in a “zero discharge” condition.

In accordance with the Heap Leach and Process Facilities Plan, a small operations crew will continue to irrigate the heap with barren solution, collect and store gold-bearing solution, operate gold recovery facilities, and maintain the facility as a zero-discharge facility. Maintenance of HLF infrastructure (e.g., process equipment) will be completed as required during temporary closure.

To avoid freezing of the heap leach and to facilitate year-round HLF operation during temporary closure, operating requirements will be similar to those currently proposed during January through March of each year for routine operations. The following activities will be conducted as required:

- Within three months of a temporary closure event, Newmont will provide regulators with a short term (covering at least 2 years) HLF water balance for solution recirculation, contingency volume, and time available and volume and quality of water required for HLF recirculation. This water balance will consider the maximum possible accumulation to increase conservatism associated with water management predictions.
- Other items that will be considered in the HLF water balance and subsequent risk assessment and strategic planning include but are not limited to: event pond storage volume and duration; rinsing and draindown of HLF as opposed to recirculation.
- Within three months of a temporary closure event, Newmont will provide regulators with an implementation plan for the Water Treatment Plant (if not operational), including execution of the start of a pilot plant program if the Water Treatment Plant is not available.

- If Newmont chooses to cease recirculation, the Water Treatment Plant must be constructed and commissioned.
- Barren solution will be heated November through March of each year.
- Gold-bearing, barren, and wash water will be stored in tanks at the plant (rather than ponds, which will only being used in upset conditions).
- The recirculation of process solutions and recovery of gold will continue until operations resume or a decision is made to cease recirculation. The latter may occur once the water treatment plant has been commissioned if all economically recoverable gold has been processed or if the mine progresses towards permanent closure.
- Monitoring of leak detection systems will continue. An annual water balance will be performed to ensure solutions are not accumulating in the HLF. As a contingency, if solutions are demonstrated to be accumulating in the heap, excess water could be released to EP1 and stored until operations resume, or released following water treatment if the ESR is predicted to be infringed upon.
- Raincoats will be deployed to cover the entire stacked ore portion on the HLP to:
    - Maintain ore and solution temperatures within the heap
    - Eliminate dust generation in windy conditions
    - Eliminate or minimize precipitation infiltration into the heap to avoid surplus of water and the associated need to treat for discharge
    - Maximize runoff for storage for later use as make-up water or discharge as non-contact water depending on operational water needs.

A temporary closure scenario was evaluated through the HLF Water Balance Model to assess heap solution buildup within the event ponds and potential water treatment needs should temporary closure occur prior to when the water treatment plant would be commissioned in Year 2. The outcome of the water balance model predicts that, for the period of temporary closure prior to when the water treatment plant is available, the ponds would contain approximately 160,000m^3 of solution, which is within the pond storage volume available for operations. In this scenario, the pond volume infringes upon the event storage requirement (ESR) in Year 10, and overflows in Year 18, if it is maintained as a ”zero discharge” facility. Additional details are provided in the Contingency Water Treatment Plan (WesTech 2023), appended to the Heap Leach and Process Facilities Plan.

6.5.3 Facility and Alpha Ponds

Water management infrastructure will be operated, maintained, and monitored in accordance with license requirements and the Water Management Plan. During temporary closure, monitoring of discharge water quality and downstream water quality will be conducted in accordance with Operation Phase requirements outlined in the Water Management Plan and the EMAMP.

In the Facility Pond, pumping systems will remain in place to allow for control of water volumes in the ponds. Water collected in the Facility Pond during temporary closure will primarily come from runoff of the plant site area. As outlined above, stockpiled ROM ore will be removed and stacked onto the heap leach pad at the onset of temporary closure. Water that meets discharge water quality standards will be periodically released to either the Latte catchment or pumped to Halfway Creek and Alpha Pond.

In Alpha Pond, pumping systems will be maintained to avoid the potential for overtopping of this facility during temporary closure. Discharge rates (linked to flow conditions in Halfway Creek) will be detailed in the Water Management Plan. Water management infrastructure details including process flow diagrams and shut off switches will be provided in future RCP iterations.

6.6 Reporting and Monitoring Requirements

This section summarizes reporting, monitoring, and maintenance requirements during the hypothetical temporary closure period. It is anticipated that at the onset of a temporary closure period, Newmont will submit a notice of closure within a specified period to the appropriate regulators, Project partners, and stakeholders (as dictated by licenses). The notice of closure will describe the following:

- Reasons for and anticipated duration of the suspension of operations
- Actions that will be taken to maintain compliance with mine licenses and permits
- Any events which would reasonably be anticipated to result in the resumption of mining or the permanent closure of the mine.

In addition, Newmont will submit to the appropriate authorities an updated Reclamation and Closure Plan early in the temporary closure period. This updated plan will document any anticipated increases in liability associated with temporary closure, or costs incurred for implementing temporary closure, and will provide an environmental monitoring, management and reporting plan that is consistent with site authorizations. The plan will be implemented to ensure that the site remains secure and stable, and to demonstrate that the site continues to meet performance expectations.

During temporary closure, regular inspections will be conducted to confirm compliance with applicable permits and licenses. Once permit requirements for inspections are known, a detailed inspection frequency schedule will be provided to stakeholders and First Nations. Infrastructure such as the Alpha WRSF, HLF and process facilities, open pits, water management infrastructure, fuel and storage tanks, and all roads (including the NAR) will be inspected to confirm physical stability and integrity. Care and maintenance personnel will coordinate follow-up investigations by appropriate professionals, as necessary. The key management plans that are relevant to facility and infrastructure performance during temporary closure are listed below. In addition, management plans that are relevant to monitoring and maintenance requirements in order to ensure that the site is secure and safe, to minimize health and safety risks, and to remain in compliance with all regulatory and licensing requirements, are listed below.

- Access Route Operation Management Plan
- Air Quality and Greenhouse Gas Management Plan
- Cyanide Management Plan
- Environmental Monitoring and Adaptive Management Plan
- Erosion and Sediment Control Plan
- Explosives Management Plan
- General Mine Development Plan
- Hazardous Materials and Waste Management Plan
- Heap Leach and Process Facilities Plan
- Mine Operations Plan

- Noise Management Plan
- Spill Contingency Plan
- Vegetation Protection Plan
- Waste Rock and Overburden Management Plan
- Wildlife Protection Plan
- Water Management Plan.

Annual geotechnical inspections of the HLF, WRSF, open pit walls, all contact and non-contact water management infrastructure, and any other surface infrastructure elements possibly affecting permafrost will be carried out by a qualified geotechnical engineer licensed to practice in the Yukon. Any repairs or maintenance of the infrastructure or facilities, or improvements to runoff, erosion and sediment control measures will be undertaken and documented on recommendation from the inspections.

Climate, surface water quality, hydrology, groundwater, and biological components will be monitored at designated stations in accordance with the license conditions, generally as per the monitoring program outlined for the Operation Phase in the EMAMP. Care and maintenance personnel will coordinate and support professionals in conducting some elements of the monitoring program, such as non-routine water quality and biological monitoring, as necessary.

Table 6-3 summarizes monitoring and surveillance activity details by mine component. Observed physical changes on the site may warrant a follow-up investigation by appropriate care and maintenance personnel, or specialized contractors or consultants.

Table 6-3 Temporary Closure Monitoring and Surveillance Activity Details by Mine Component

Mine Component	Type of Inspection	Frequency	Responsible Person	Deliverable
Open Pits	Geotechnical	Quarterly	Geotechnical Engineer (Yukon P.Eng)	Inspection Report
	Water Level and General Visual Inspection	Weekly	Care and Maintenance Personnel	Weekly Log, included in Monthly and Annual Reports
	Automated water level reading	Daily	Care and Maintenance Personnel	Electronically stored and reported in Quarterly and Annual reports

	Tank Dips	Monthly	Care and Maintenance	Tank Inventory Logs

Mine Component	Type of Inspection	Frequency	Responsible Person	Deliverable
Equipment Laydowns including Mobile Equipment	General Visual Inspection	Weekly	Environmental Monitors	Inspection Reports
Land Treatment Facility	Soil Samples	As per permitting requirements	Environmental Monitors	Sample Log and Annual Reports
Waste Management Area and Hazardous Materials Storage Area	General Visual Inspection	Weekly	Care and Maintenance Personnel	Inspection Reports
Site Roads (including the NAR)	General Visual Inspection	Weekly	Care and Maintenance Personnel	Inspection Reports
Pumps / Pipelines	Confirmation of Operation	Daily for operating pumps	Care and Maintenance Personnel	N/A
	Check for Flow and Absence Leaks	Weekly for operating pipelines	Care and Maintenance Personnel	N/A
Buildings and Structures	Structural Inspection	Annual or as required prior to access	Structural Engineer (Yukon P.Eng)	Inspection Report
	Industrial Hygiene	Prior to any resumed occupancy	Contractor	Inspection Report

6.7 Socio-Economic and Community Engagement Aspects of Temporary Closure

Temporary closure has the potential to reduce the Project's direct workforce, as well as business activity from suppliers, who in turn reduce economic activity in the Project's area of influence. The hypothetical two-year temporary closure scenario described above has been used to identify socioeconomic aspects of, and management actions for, temporary closure.

6.7.1 Management of Socio-economic Aspects of Temporary Closure

Temporary closure and permanent closure have similarities, but the management of socio-economic aspects during a temporary closure period differ in some important ways:

- In general, a mine operator does not have the same amount of time to prepare itself for temporary closure as it does for permanent closure. Therefore, there is less lead time to notify key communities and partners such as workers, suppliers, First Nations partners and governments that share revenue, etc., hence, timeframes to manage the socio-economic aspects of temporary closure, including related consultation and engagement, are more compressed at the beginning of a temporary closure period. For this type of hypothetical scenario, market conditions will ultimately determine the timing and length of temporary closure.
- Temporary closure periods are often of an uncertain length, leaving communities, government organizations, and businesses unsure as to how much time and energy to place into shorter-term coping strategies. Therefore, a period of temporary closure involves repeated and/or ongoing engagement to share information with key stakeholders and communities as this information becomes available.

Table 6-4 describes various potential aspects of temporary closure related to socio-economic components and ways in which they could be managed, as well as the various responsibilities for management activities, acknowledging the roles of various groups and parties in the socio-economic context.

Table 6-4 Management of Socio-economic Aspects of Temporary Closure

Valued Socio-economic Component	Potential Direct and/or Indirect Socio-economic Effect from Temporary Closure	Proposed Activities to Manage Potential Socio-economic Effects of Temporary Closure	Proposed Timeframe for Management Activities
Demographics	Changes in populations in the local area as direct and indirect workforce is unsure of employment status and relocates for longer-term employment	Newmont: Share information as soon as possible with First Nations and municipal planners on timing and nature of the temporary closure period. Inform Health and Social Services of the temporary closure as soon as possible and inform them of services that Newmont has in place for affected employees as well as implications outside of Newmont's ability to support. First Nation governments and municipal planners: Ask questions and participate in conversations on workforce	Engagement to begin as soon as a temporary closure is certain to occur. Quarterly meetings to take place during the temporary closure period.
Economic Conditions	Temporary decrease in direct and indirect employment Temporary decrease in Project-related purchases of goods and services Temporary changes to mine-related revenue (royalties and taxes)	**Newmont:** Share information promptly and transparently with potentially affected parties and First Nations, as well as with Health and Social Services, about extent and nature of reductions to workforce and purchases of goods and services. Engage proactively with any parties potentially affected by changes to royalties and taxes. Create a Workforce Transition Strategy to provide information to employees and contractors. Define approach to incentivizing retention of existing staff during the period between announcement and start of temporary closure period. Incorporate temporary-closure-related financial literacy support for workers through the Employee Assistance Program. **Workers and suppliers:** Participate in conversations with Newmont about timing and anticipated length of temporary closure period. Other mining companies: Participate in conversations with Newmont about how to align workforce needs related to temporary closure. **First Nations, territorial, and municipal governments, and local communities:** Participate in conversations about potential effects of temporary closure. Ask questions and raise concerns, as needed.	Engagement to begin as soon as a temporary closure is certain to occur with the following: • Workers • First Nations and other communities • Goods and service suppliers • Territorial and municipal governments • Other mining companies Quarterly meetings to take place during the temporary closure period.

Valued Socio-economic Component	Potential Direct and/or Indirect Socio-economic Effect from Temporary Closure	Proposed Activities to Manage Potential Socio-economic Effects of Temporary Closure	Proposed Timeframe for Management Activities
Social Economy	Temporary increase in non-wage (bartering goods and services, land-based subsistence) and traditional economic activities as a result of a reduction in workforce	**Newmont:** Reinforce the message that site access during Temporary Closure remains the same as during Operations. Develop and share plain language communication materials about the temporary closure period (when, why, how) that includes key contact information and information about access restrictions. **First Nations and local communities:** Participate in conversations about potential effects of temporary closure. Ask questions and raise concerns, as needed.	Distribute plain language temporary closure information to interested parties within one month of notifying of imminent period of temporary closure. Engage communities and First Nations on temporary closure.
Infrastructure and Services	Temporary increase in demand for community-based career services Temporary increase in demand for community services related to health and wellbeing (e.g., prevention of depression, substance abuse)	**Newmont:** Identify community-based partners who may be receiving regular community support either in financial or in-kind donation and ensure that they are informed of any potential changes to the level of support. Develop and share plain language communication materials about the temporary closure period (when, why, how) that includes contact information for support services and key Newmont contacts. **Community-based service providers (careers and community health and well-being):** Participate in conversations about potential effects of temporary closure. Ask questions and raise concerns, as needed.	Distribute temporary closure information to interested parties within one month of notifying of imminent period of temporary closure. Quarterly meetings to take place during the temporary closure period.
Education Services	Temporary increase in demand for industry-related training as workers retrain for potential career changes	**Newmont:** Share information about the extent and nature of reductions to the workforce with education service providers and request feedback regarding available training programs. Develop and share plain language communication materials about the temporary closure period (when, why, how) that includes contact information for education services providers and key Newmont contacts. **Yukon University and other training providers, TH Human Resources & Education Department, SFN Citizen Development Department, WRFN Employment and Training Department, FNNND Education and Training Department, Yukon Department of Advanced Education:** Participate in conversations about potential effects of temporary closure. Ask questions and raise concerns, as needed. Provide feedback to Newmont regarding available training programs.	Distribute temporary closure information to interested parties within one month of notifying of imminent period of temporary closure. Quarterly meetings to take place during the temporary closure period.

Valued Socio-economic Component	Potential Direct and/or Indirect Socio-economic Effect from Temporary Closure	Proposed Activities to Manage Potential Socio-economic Effects of Temporary Closure	Proposed Timeframe for Management Activities
Land and Resource Use	Temporary increase in time for and interest in land and resource use activities due to increased time available	**Newmont:** Share information with land and resource users. Increase signage and/or other forms of notification about access restrictions. Monitor potential trespass events and adapt access controls as needed. Develop and share plain language communication materials about the temporary closure period (when, why, how) that includes key contact information and information about access restrictions. **Trapline holders and other resource users:** Participate in engagement events and share concerns as needed.	Distribute temporary closure information to interested parties within one month of notifying of imminent period of temporary closure. Quarterly meetings to take place during the temporary closure period. Review trespass and potential trespass events monthly.
Community Health and Well-being	Temporary increase in mental and physical health concerns (depression, substance abuse, etc.) related to uncertainty in professional future	**Newmont:** Share information with service providers about the extent and nature of reductions to the workforce and request feedback regarding available health services or programs. Develop and share plain language communication materials about the temporary closure period (when, why, how) that includes contact information for support services. **First Nations, municipal, and territorial governments:** Participate in conversations about potential effects of temporary closure. Ask questions and raise concerns, as needed. Provide feedback to Newmont regarding any updates or changes to available health services or programs.	Distribute information to employees and interested parties within one month of notifying of imminent period of temporary closure. Quarterly meetings to take place during the temporary closure period.
Heritage	No effects to tangible heritage foreseen as a result of temporary closure	No specific actions foreseen	Not applicable

6.7.2 Managing Community Perceptions through Engagement Focused on Temporary Closure Period

Temporary closure may create community misconceptions regarding the nature of closure, the activities permitted on site during temporary closure and the on-going care and maintenance activities conducted during temporary closure. Newmont can pre-empt any misperceptions through targeted engagement and transparent communication. Table 6-5 outlines the various topics and groups Newmont anticipates that it will engage with at the onset of a temporary closure period.

Table 6-5 Engagement to Disseminate Temporary Closure Information

Topic Related to Temporary Closure	Reason to Engage	Groups to Engage	Proposed Engagement Method and Timing
Site access	Potential perception that temporary closure means that pre-development land access can occur. Site access presents human health and safety risks.	Trapline holders First Nations Governments	Develop plain language communication materials about the temporary closure period (when, why, how) that includes contact information and information about access restrictions. Distribute information within one month of notifying of imminent period of temporary closure.
Environmental conditions at site	Potential misperceptions about environmental or health/safety conditions at site could negatively affect Newmont's public image and trust as an operator.	Public at large	Provide ongoing updates through website and annual plain language communication materials that includes environmental monitoring results. Periodic employee highlights on website to communicate ongoing monitoring and compliance reporting activities.
Ability to respond to an accident or malfunction	Potential perception that Newmont would not have the workforce or funding available to respond to or remediate the site should an accident or malfunction occur.	Public at large	Provide ongoing updates through website and annual plain language communication materials that include environmental monitoring results. Periodic employee highlights on website to communicate ongoing site maintenance and oversight.
Communities feel abandoned	Potential perception that Newmont is abandoning the communities in the local area.	Communities and Public at large	Develop and disseminate annual plain language communication materials about the temporary closure period to explain site status, ongoing monitoring and maintenance activities, a summary of environmental monitoring results, and key contact information.
Concern about status of legacy projects	Potential perception that Newmont-funded legacy projects will not be completed.	Communities	Communication with recipients regarding legacy project funding and project status.

6.7.3 Community Commitments, Partnerships and Agreements

Newmont has developed several internal standards to guide the development of beneficial and strategic partnerships as part of mine planning and execution. In alignment with these standards, Newmont is committed to considering the potential for closure events to affect community investments, partnerships, and agreements. These standards include:

- Community Investment and Development Standard
- Indigenous Peoples Standard
- Local Procurement & Employment Standard
- Social Baseline & Impact Assessment Standard
- Stakeholder Relationship Management Standard.

In addition, Newmont is committed to transparent communication with stakeholders as well as respect for all cultures in alignment with the Newmont Internal Sustainability and Stakeholder Engagement Policy. Newmont will respect all bi-lateral agreements with First Nations, and bi-lateral dialogues will be established to ensure commitments to First Nations are upheld. The following sections describe Newmont's approach to implementing these standards in the event of a two-year temporary closure period.

6.7.4 Community Investments

Newmont is committed to reducing potential negative effects to local communities and organizations as a result of temporary closure of the Coffee Gold Mine and the voluntary community investments Newmont may make. Newmont will manage potentially adverse outcomes in two ways:

- **Preventive management:** Newmont will enter into community investment commitments considering whether the partner organization has other sources of funding and will define an exit strategy for its financial participation. Newmont will enter into community investment partnerships that have a low probability of increasing a partner organization's financial vulnerability in the event of temporary closure.
- **Ongoing engagement:** community investment partners with ongoing or preceding commitments will be engaged before and during the temporary closure period to discuss and determine if or how the partner has the potential to be affected.

6.7.5 Community Partnerships and Agreements

Newmont structures its agreements to include considerations that account for a temporary closure event. The contents of these agreements are confidential.

6.7.6 Socio-economic Monitoring and Evaluation During Temporary Closure Period

Socio-economic monitoring during a temporary closure period will focus on a limited number of topics:

- Number of trespass events and potential safety-related issues
- Number and types of complaints received through an established feedback mechanism regarding the management of temporary closure.

7.0 FINAL RECLAMATION AND CLOSURE MEASURES

This section of the RCP describes the specific final reclamation and closure measures that will be implemented for mine components during the Closure Phase, additional requirements for waste management, maintenance, monitoring, and reporting anticipated for the Closure and Post-closure Phases, socio-economic aspects related to the Closure and Post-closure Phases, and how performance uncertainty and risks will be managed during the Closure Phase.

The closure activities that are anticipated to occur within each Project phase are described below. The Project will advance to the Post-mining Closure Phase once mining activities cease, and recirculation of the HLF for rinsing and final gold recovery is initiated. The site will progress from the Post-mining Closure Phase to the Active Closure Phase once the on-site water quality is determined to have achieved applicable standards allowing for operational water management infrastructure decommissioning activities to commence. The Post-closure Phase will be initiated once water management and required site access infrastructure has been decommissioned, and post-closure monitoring and maintenance activities commence.

During the Closure Phase, numerous personnel will be on site year-round as required, as the key activities for each Project phase will include:

- Operation Phase (Year-1 to Year 9):
  - Implementation of the reclamation research program.
  - Continuous salvage and stockpile of reclamation material.
  - Progressive reclamation of areas no longer required for operations.
  - Progressive regrading of the HLF.
  - Progressive regarding of the WRSF.
  - Progressive closure of haul and mine site roads no longer required to support operations.
  - Reclamation of exploration areas.
  - Regular removal of recyclable / salvageable material and equipment.
  - Progressive complete backfill of Kona and Double Double Pits.
  - Partial backfill of Latte and Supremo Pits.
  - Installation of water treatment facility at the Plant Site and commencement of water treatment of surplus water.
- Post-mining Closure Phase (Year 10 to Year 15):
  - HLF recirculation for rinsing and final gold recovery.
  - Cover construction and revegetation of rinsed areas of the heap.
  - Continued water treatment of draindown rinse water from HLF stages.
  - Reclamation of disturbed areas within the Mine Site footprint that are no longer required to support closure activities, including the crusher system and ROM stockpile area, using overburden salvaged and stockpiled during mine site development and operations.
  - Equipment removed from service, cleaned, and demobilized from site, or landfilled if material is included on the approved landfill item list when no longer required to support closure and reclamation activities.

- Closure of Latte Pit and Supremo Pit by allowing them to flood and placing boulder fences at the pit rims.
- Reclamation of the soil stockpile area footprint(s) once stockpiled materials have been used.
- Reclamation of the frozen soil storage area footprint once stockpiled materials have been used.
- Reclamation of the ROM stockpile area.
- Contaminated sites investigation within the areas of fuel storage and transfer, equipment laydowns, and the bulk explosives storage area to determine the presence and/or extent of soil contamination.
- Excavation of any contaminated soil followed by either on-site treatment or temporary storage and removal off-site.
- If required, construction and commissioning of passive water treatment system for the HLF.
- Continue routine monthly, annual, and event-driven monitoring at conveyance structures and sedimentation ponds and their dams for stability, signs of seepage, blockage due to ice or foreign debris and significant erosion, or damage to any geosynthetic components.
- Continued operation of water conveyance structures and sedimentation ponds until water quality in the ponds have stabilized.
- Continue monitoring of surface water quality and infrastructure in accordance with conditions of the WUL and QML.

- Active Closure Phase (Year 16 to Year 21);
  - If draindown rinse water from HLF requires passive treatment, continue active water treatment during passive water treatment system commissioning and until HLF water quality has been sufficiently treated to qualify for passive treatment.
    - Once water quality in the sedimentation ponds has stabilized: Decommissioning of water conveyance structures
    - Decommissioning of the Facility Pond
    - Decommissioning of the Alpha Dam/Pond by breaching the dam and constructing a drainage pathway through the footprint of the former dam.
  - Re-grading the West Diversion Ditch to slope and re-establishing drainage patterns to match pre-mining conditions to the extent practical.
  - Dismantling process plant, reagent storage area, laboratory, truck shop and warehouse building, and bulk fuel storage and LNG storage facility infrastructure at the Plant site, as well as decommissioning of the bulk explosives storage area and water management infrastructure that is no longer needed.
  - Dismantling and removal of dormitories and kitchen, dining, mudroom, and recreation complex buildings, emergency response team building, mine dry and office complex, fresh (potable) water and fire water systems, sewage treatment plant, and waste management building at the Camp Site. This work will be done progressively to support reclamation activities, with a section of the Project camp remaining in place until final demolition and demobilization.
  - Dismantling final reclamation infrastructure including active water treatment plant and power plant once no longer required.
  - Decommissioning and reclamation of new road sections along the NAR, barge landings, the On-site Access Road, Mine Site roads, and the Project airstrip.

  - Dismantling of the Java Camp.
  - Continue monitoring of surface water quality and infrastructure in accordance with conditions of the WUL and QML.
- Post-closure Phase (Year 21 onward);
  - Passive water treatment, if required.
  - Post-closure monitoring and site maintenance.

The general arrangement of Project components within the Mine Site area at the commencement (Year 10) and end (Year 21) of the Closure Phase are shown in Figure 7-1 and Figure 7-2, respectively. Details pertaining to all Project and ancillary components, as well as the extent of disturbance occurring at the start of Year 10, are provided in Section 5.

7.1 Open Pits

For open pits, the YWB and EMR (2013) performance targets for closure are to meet water management objectives, protect humans and wildlife from topographic hazards, and prevent subsidence. In general, the information that is required shall demonstrate expected performance and/or management measures pertaining to pit stability, backfilling, surface water management and sediment control, and minimizing safety risks while meeting the requirements of the Yukon *Workplace Health and Safety Regulations*. In addition, pit water quality predictions and long-term predictions of loading to receiving waters (including interactions between pits and local groundwater) is required, as well as descriptions of pits being used to support site water management/treatment activities.

Since Kona and Double Double Pits are completely backfilled during the Operation Phase, this section presents information primarily for the Latte and Supremo Pits, which at the start of the Closure Phase in Year 10, will have been partially backfilled to support mine operations. Additional backfilling during closure of these pits is not currently proposed; however, further evaluations as the mine plan advances may require modifications to the proposed base case closure design. Pit design details and the results of stability analyses are provided in Section 5.3.1. Pit instability risks during the Closure and Post-closure Phases will be minimized by adhering to pit closure designs.

7.1.1 Pit Lakes and Water Quality Predictions

A total of nine pit lakes are predicted to develop once mining activities ceases, as shown on Figure 7-2. The generalized flow paths of pit spill directions and general groundwater catchments during the Post-closure Phase are shown on Figure 7-3. Figure 7-4 illustrates the anticipated timelines for pit development and management activities (i.e., dewatering during mining), and the duration of pit filling to the spill or decant elevation.

Table 7-1 presents the water volume capacity in each pit (assuming no additional backfill is placed in the pits post-mining), the spill elevation, and the approximate year (or range of years) that spilling is projected to occur. The elevation is in metres above sea level (masl). Pits Latte East, SU1, SU2W, SU3W, SU4W and SU5 are predicted to reach the spill elevation near the end of the Operation Phase due to their small size and timing of development. Although a lake will not form in the Double Double Pit or the Kona Pit as they will be backfilled, meteoric water will collect in the pore spaces. Surface runoff from the Double Double Pit backfill will report to Latte Creek, and runoff from the Kona Pit backfill will report to Halfway Creek via the Alpha WRSF rock drain.

Pit water quality predictions from the Water Quality Model (WQM) are presented for Base Case conditions and for Upper Case conditions in the Water Quality Model Report (Lorax 2023b). Predictions of downstream water quality at receiving environment are also provided in the Water Quality Model Report (Lorax 2023b). Predictions are provided for sulphate, nutrients (ammonia, nitrite, nitrate, total phosphorus), weak acid dissociable (WAD) cyanide, dissolved aluminum, and total metals.

Based on the pit lake and receiving environment water quality predictions, water treatment is not predicted to be required for any pit.

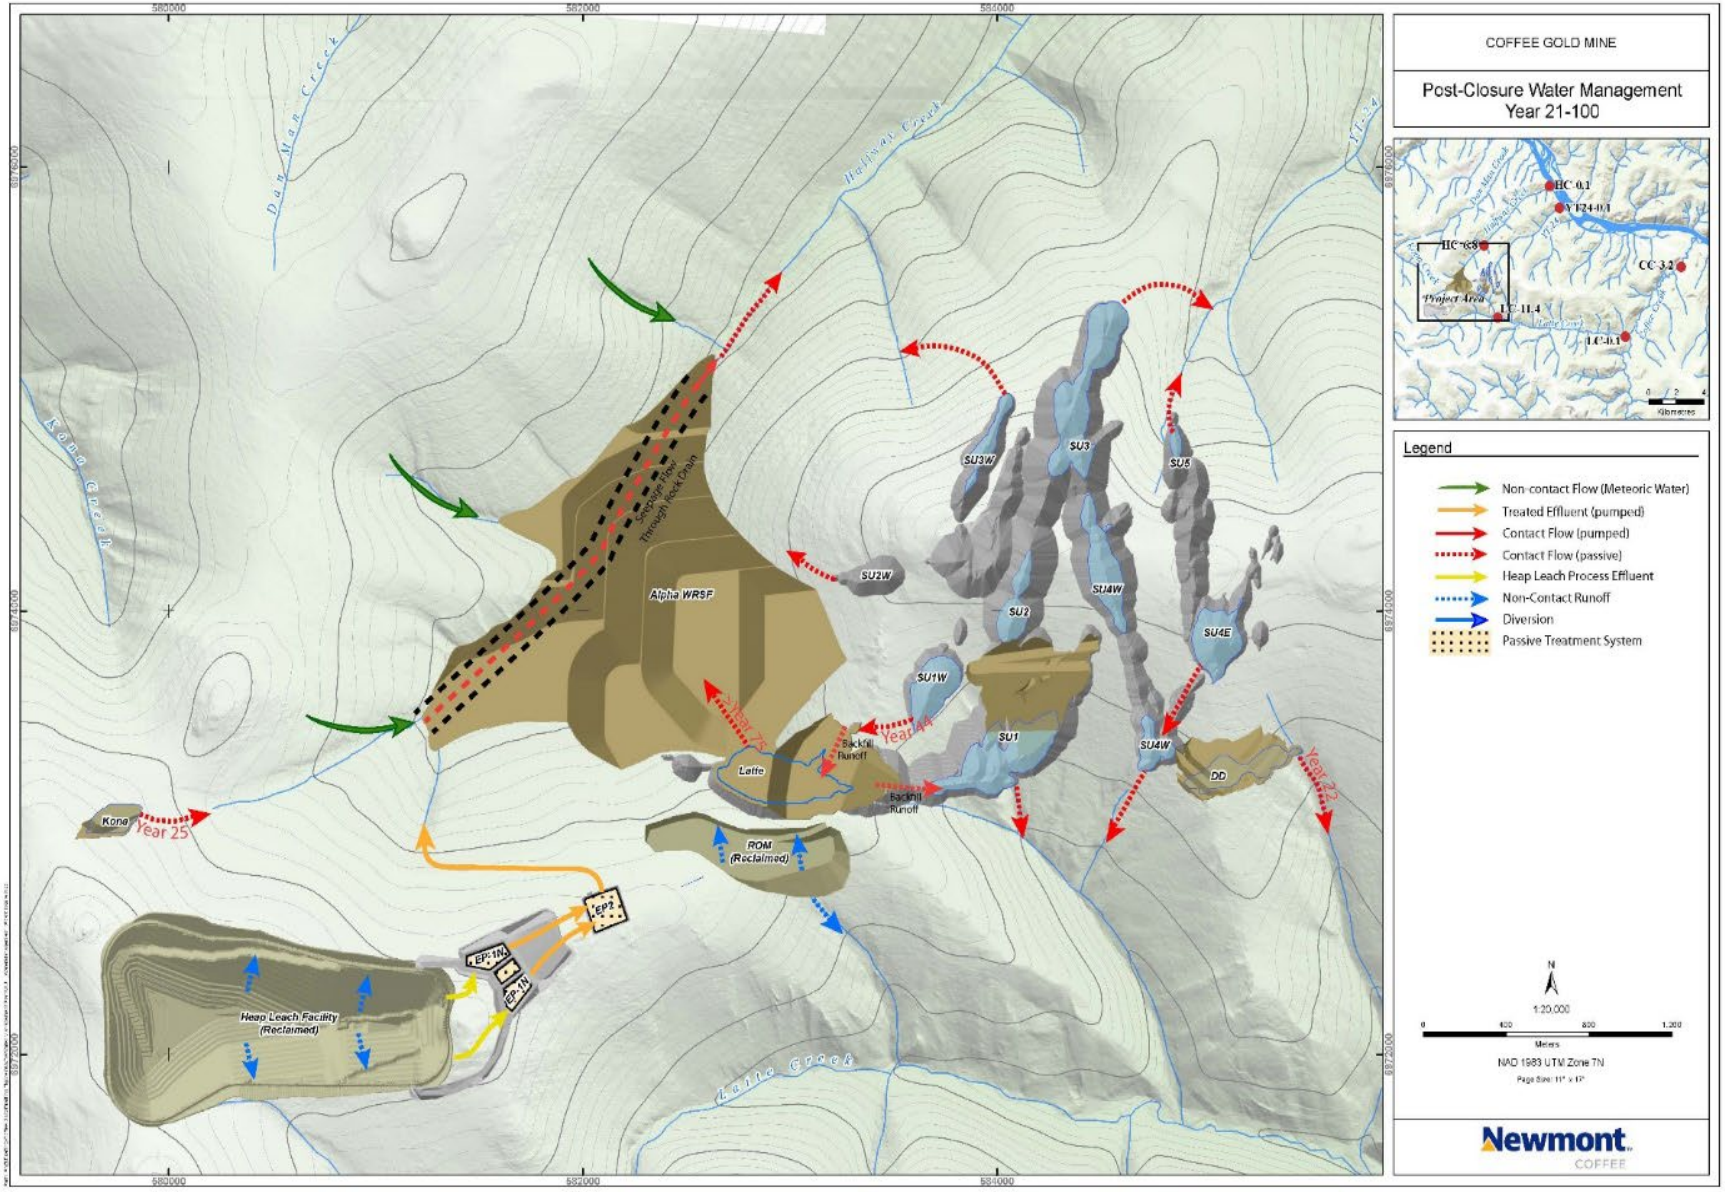

Figure 7-3 Pit Lake Schematic for Post-closure Phase

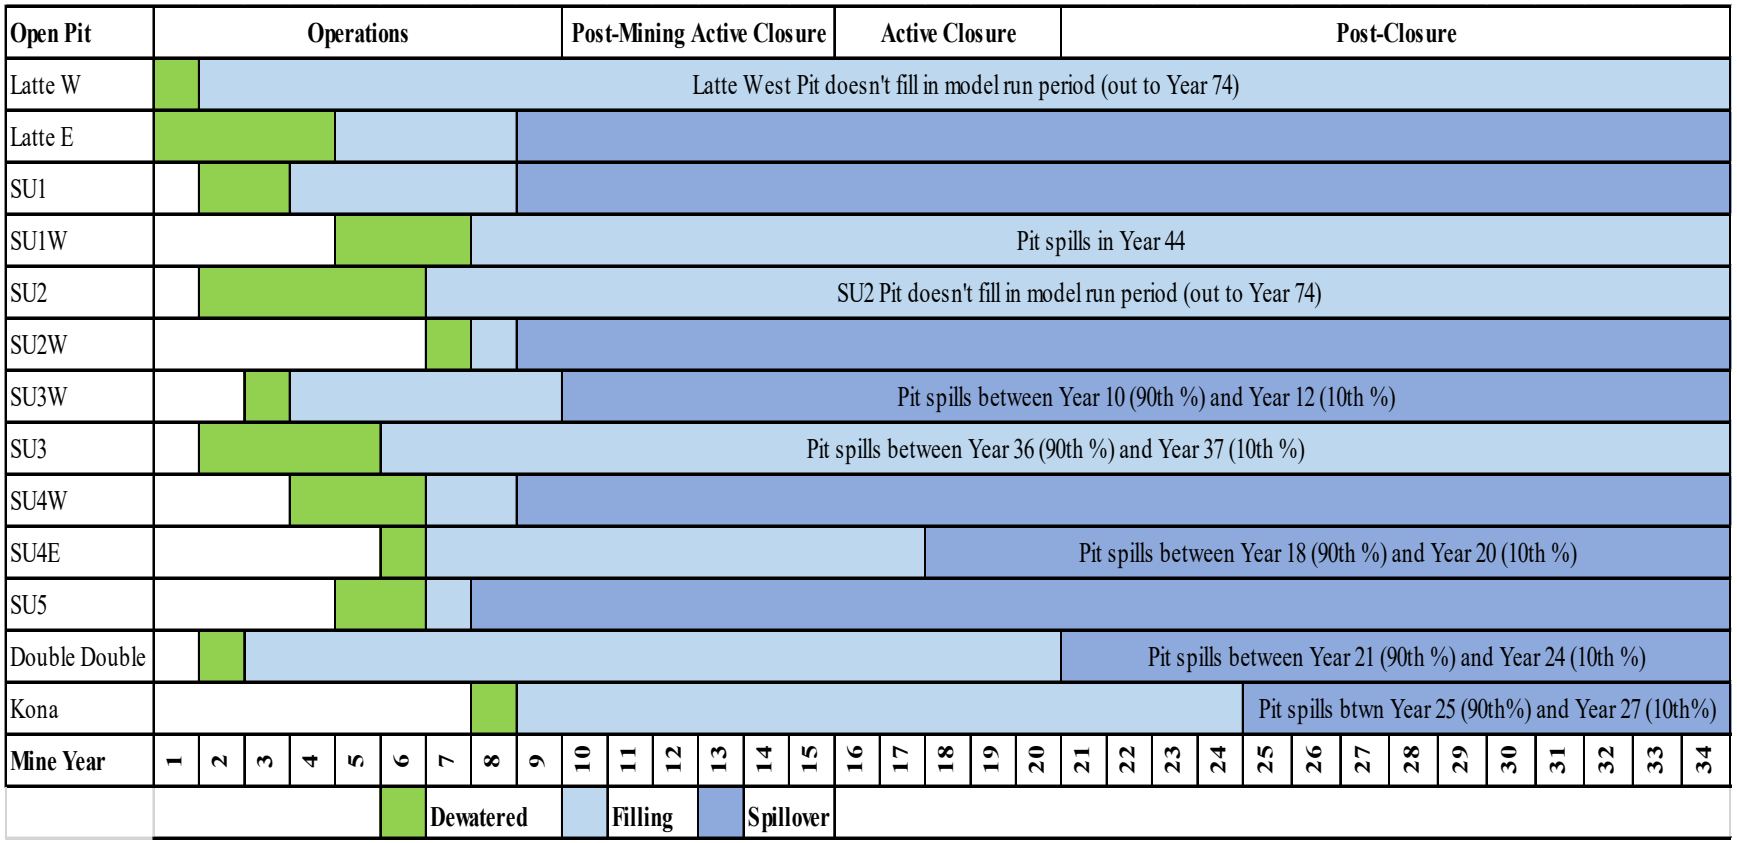

Percentile ranges for predicted spill dates are provided where this is not predicted to occur in the same year by all model iterations

Figure 7-4 Open Pit Dewatering Schedule and Predicted Years to Spillover Elevation

Table 7-1 Water Volume Capacity, Spill Elevation, and Predicted Spill Date for Pits Post-Mining

Pit Name	Pit Water Capacity (m^3) to Spill Elevation[1]	Spill Elevation (masl)	Predicted Spill Date[2]
Latte East[3]	1,416,400	954	Year 9
Latte West	1,160,000	1,030	>Year 2100
SU1[3]	1,416,400	954	Year 9
SU1W	2,200,000	1,090	Year 44
SU2	1,360,751	1,130	>Year 2100
SU2W (no lake)[4]	NA	NA	Year 9
SU3	502,898	1,090	Year 36 to 37
SU3W	168,729	1,190	Year 10 to 12
SU4W	255,800	1,044	Year 9
SU4E	306,780	1,147	Year 18 to 20
SU5	88,416	1,204	Year 8
Double Double (no lake)	399,390	1,044	Year 21 to 24
Kona (no lake)	249,417	1,230	Year 25 to 27

[1] Total pit shell volume including backfill pore space
[2] Range of predicted spill dates based on the 10th and 90th percentile model outputs
[3] Latte East and SU1 form a combined pit lake
[4] SU2W has no pit void below the spill elevation, therefore a pit lake does not form in this pit

7.1.2 Surface Discharge from Pit Lakes

Discharge rates from the pit lakes, as well as from the backfilled Kona and Double Double Pits are outlined in this section. Discharge rates for both surface and groundwater flows are provided in litres/second, and the range of predicted surface flows are summarized for the average, 10th and 90th percentiles from the multi-iteration model outputs. Note that because the Base Case model assumes that the baseline site climate regime is altered by climate change (i.e., the RCP6.0 scenario), the monthly flow distributions presented here are shifted earlier in the year by the projected warmer spring temperatures later in this century.

7.1.2.1 Latte East and West

The Latte West Pit is not predicted to fill to the spill elevation over the course of the model run (*i.e.*, out to calendar year 2100; Figure 7-5). The Latte East Pit is predicted to fill to the spill elevation by Year 5 (2031; Table 7-1; Figure 7-5), with average monthly predicted surface flows ranging from 0.25 L/s in November to 13.25 L/s in April (Table 7-2 and Figure 7-6).

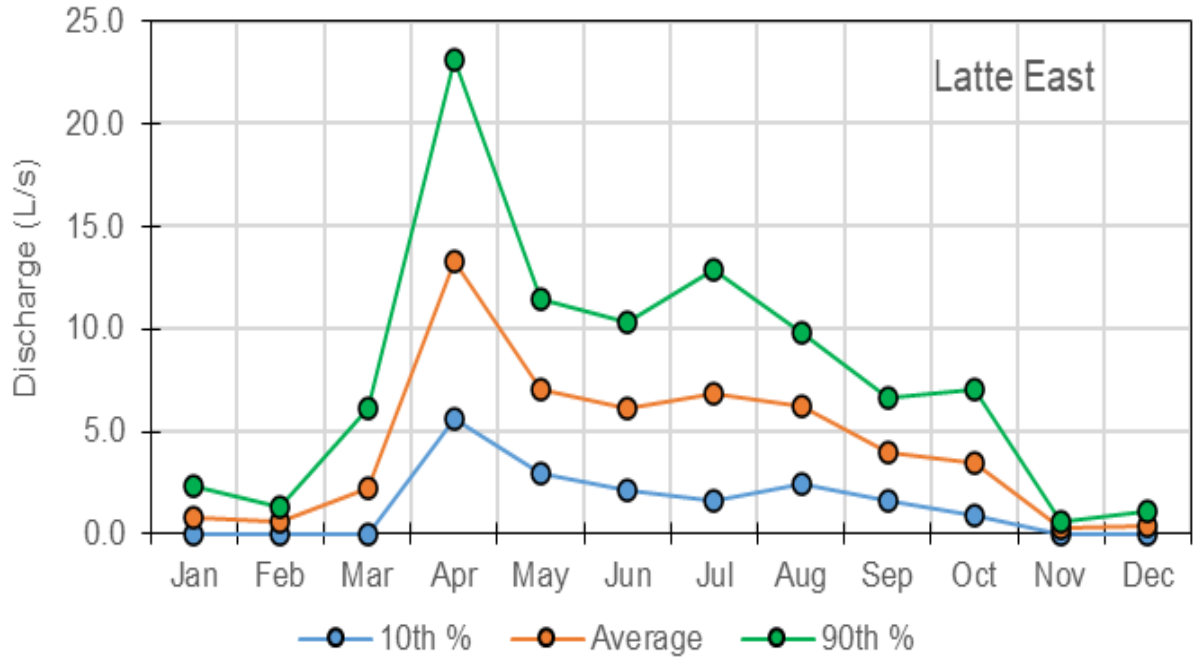

Figure 7-6 Latte East Pit Lake Surface Discharge Rates

7.1.2.2 Supremo

For the eight Supremo pit lakes, information is provided below on expected dates of pit lake spilling, discharge rates to surface waters, and flow routing to receiving streams.

SU1 and SU1W Pit Lakes

The SU1 pit lake, situated in the topographic low of the Supremo Pit complex, will receive runoff from non-contact and contact areas (including SU1W, SU2, in pit WRSF infiltration, and seepage from the Latte East Pit Lake). This pit lake will spill directly to Latte Creek.

The SU1 pit lake is predicted to reach the spill elevation in Year 8 (2034), while the SU1W pit lake is expected to reach the spill elevation in Year 44 (2070; Figure 7-7). Average monthly surface discharges from these pit lakes are predicted to range from 0.45 to 33.4 L/s, and 0.17 to 6.7 L/s, for the SU1 and SU1W Pits, respectively (Table 7-3 and Figure 7-8).

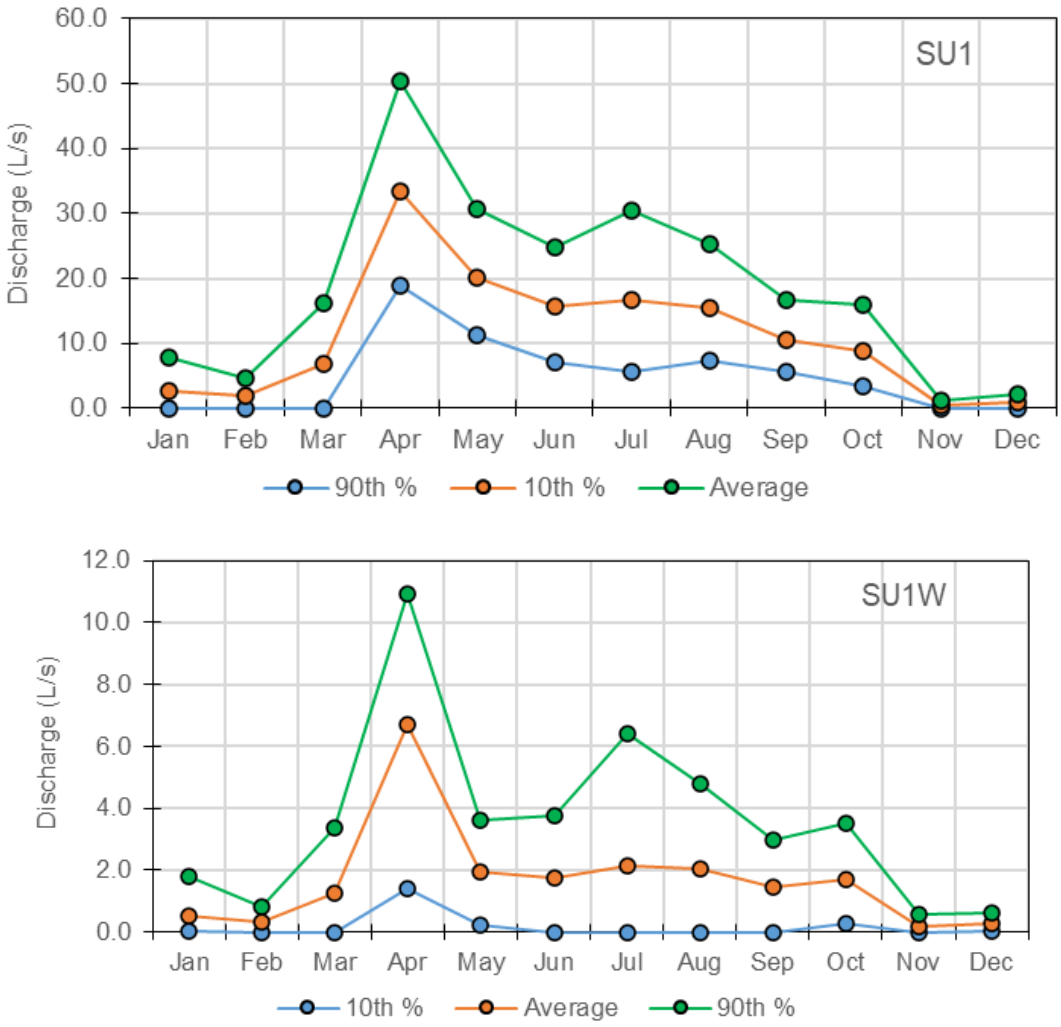

Figure 7-8 SU1 (top) and SU1W (bottom) Pit Lake Surface Discharge Rates

SU2 Pit Lake

The SU2 pit lake sits in the topographic high of the Latte catchment and Base Case WBM predictions indicate that it is not expected discharge via surface until after Year 74 (2100; Figure 7-9). Once full, the SU2 pit lake will discharge via surface through the Supremo backfill causeway to SU1. Note that the SU2W Pit does not form a lake, as its cross-sectional profile does not support a void volume below the spill elevation. Runoff from this pit shell will report to the Alpha WRSF rock drain, and monthly average discharge rates are predicted to range from 0.01 L/s in November to 0.74 L/s in April (Table 7-4 and Figure 7-10).

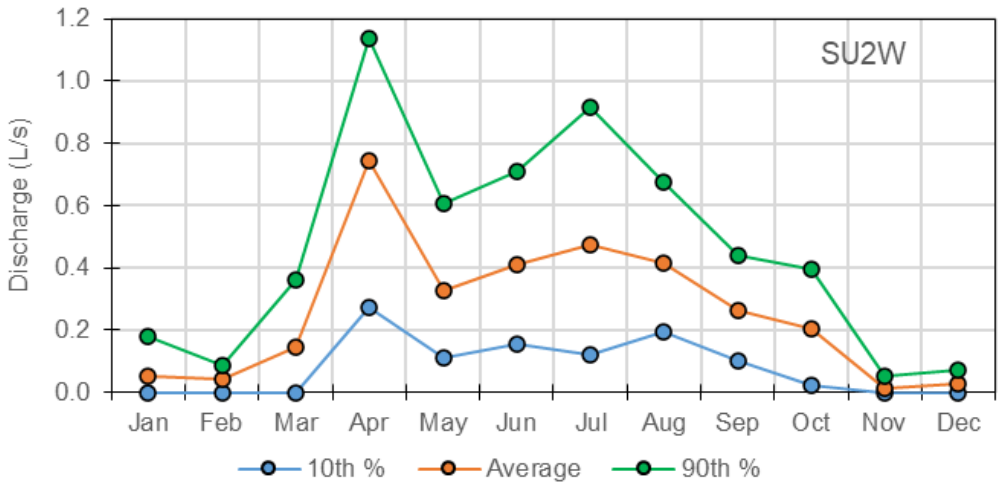

Figure 7-10 SU2W Pit Surface Discharge Rates

SU3W and SU3 Pit Lakes

The SU3W pit lake is located west of the SU3 Pit, and both drain to the YT24 catchment. The SU3W pit lake is predicted to spill by Year 10 to Year 12 (2036 to 2038) and report to YT-24 (Figure 7-11). Monthly average surface flow rates from this pit lake are predicted to range from 0.04 L/s in November to 2.08 L/s in April (Table 7-5 and Figure 7-12). The SU3 pit lake is predicted to reach the spill elevation between Year 36 to Year 37 (2062 to 2063; Figure 7-11). Monthly average surface flow rates from this pit lake are predicted to range from 0.1 L/s in November to 65.7 L/s in April, reporting to YT-24 (Table 7-5 and Figure 7-12).

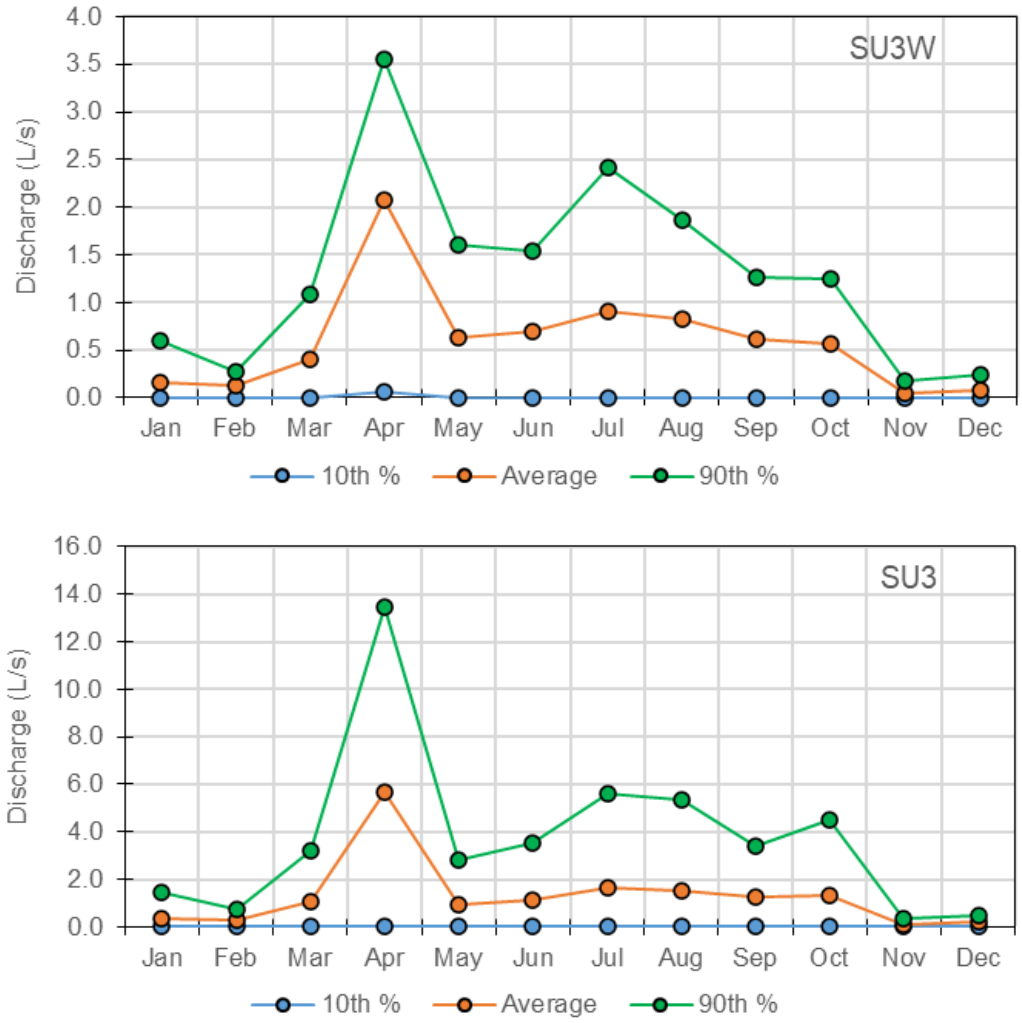

Figure 7-12 SU3W (top) and SU3 (bottom) Pit Lake Surface Discharge Rates

SU4E and SU4W Pit Lakes

The SU4E pit lake, located north of the backfilled Double Double Pit, is predicted to spill by Year 18 to Year 20 (2044 to 2046) and report to the interception ditch that flanks Double Double and drains into the SU1 Pit, and ultimately to Latte Creek (Figure 7-13). Monthly average surface flow rates from this pit lake are predicted to range from 0.04 L/s in November to 2.65 L/s in April (Table 7-6 and Figure 7-14).

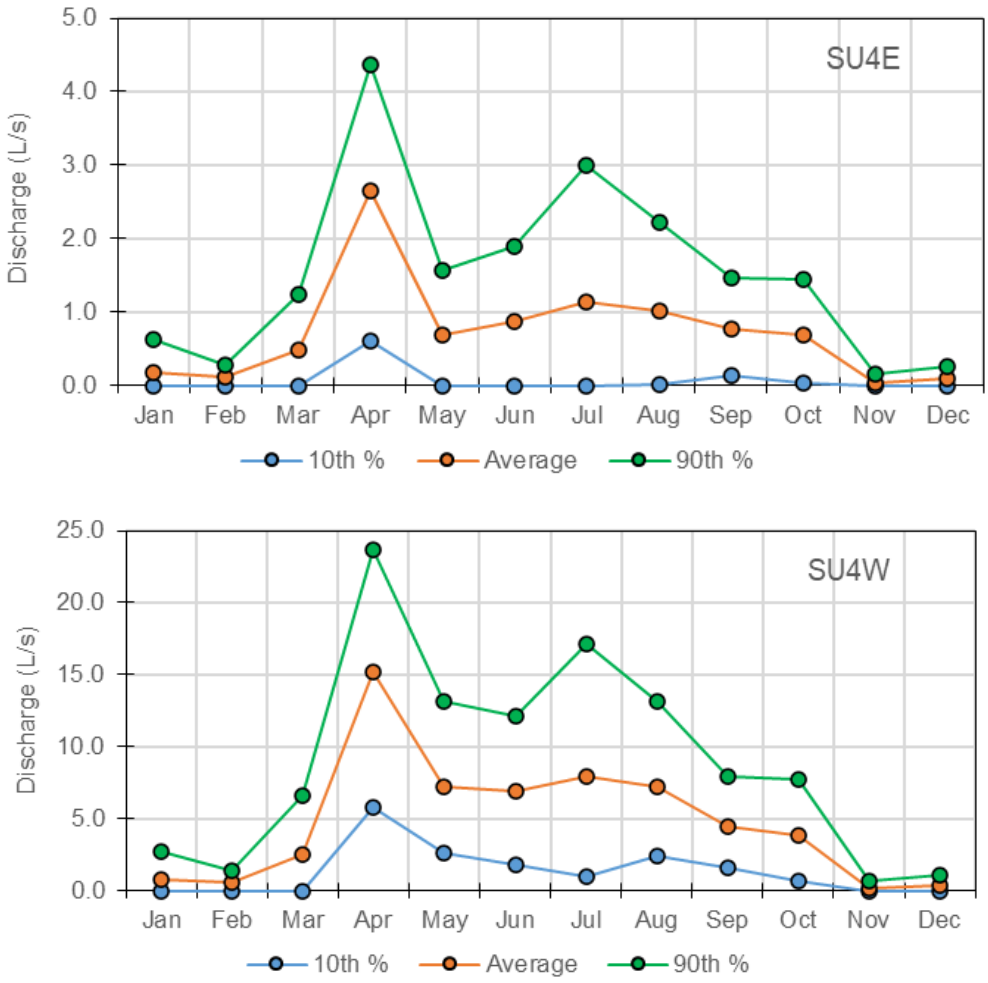

Figure 7-14 SU4E (top) and SU4W (bottom) Pit Lake Surface Discharge Rates

At the SU4W Pit, once the lake is at the spill elevation of 1,105 masl, water will drain passively to the Latte Creek catchment (Figure 7-13). Monthly average surface flow rates from this pit lake are predicted to range from 0.2 L/s in November to 15.2 L/s in April (Table 7-6 and Figure 7-14).

SU5 Pit Lake

The SU5 pit lake is predicted to reach the spill elevation in Year 8 (2034), and surface discharge from this pit lake will to YT-24 (Figure 7-13). Monthly average surface flow rates from this pit lake are predicted to range from 0.07 L/s in November to 3.7 L/s in April (Table 7-7 and Figure 7-16).

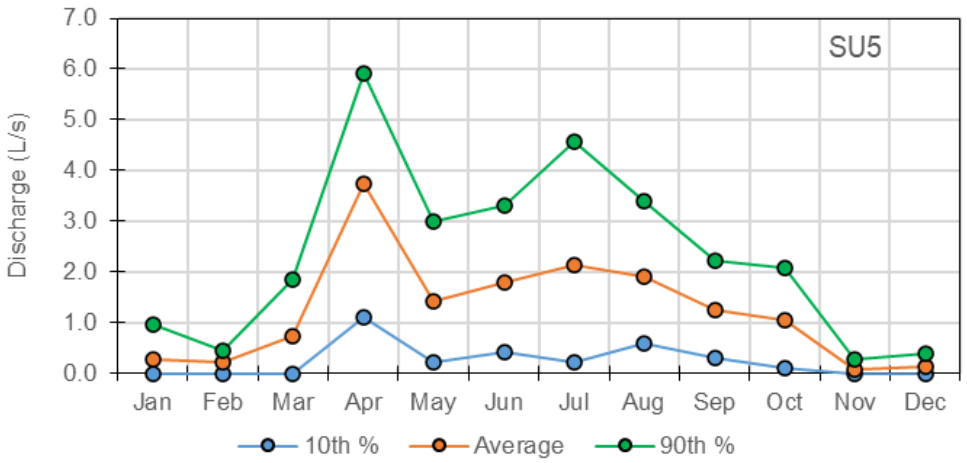

Figure 7-16 SU5 Pit Lake Surface Discharge Rates

7.1.2.3 Backfilled Double Double Pit

The backfilled Double Double Pit will begin to fill with meteoric water during the Operation Phase. By Year 24 near the beginning of the Post-Closure Phase, the pore space within the backfilled waste rock is expected to have filled with water to the 1,044 masl spill point elevation (Figure 7-17) and will passively discharge to the Latte Creek catchment at average monthly rates of 0.01 L/s in December to 2.4 L/s in May (Table 7-8 and Figure 7-18).

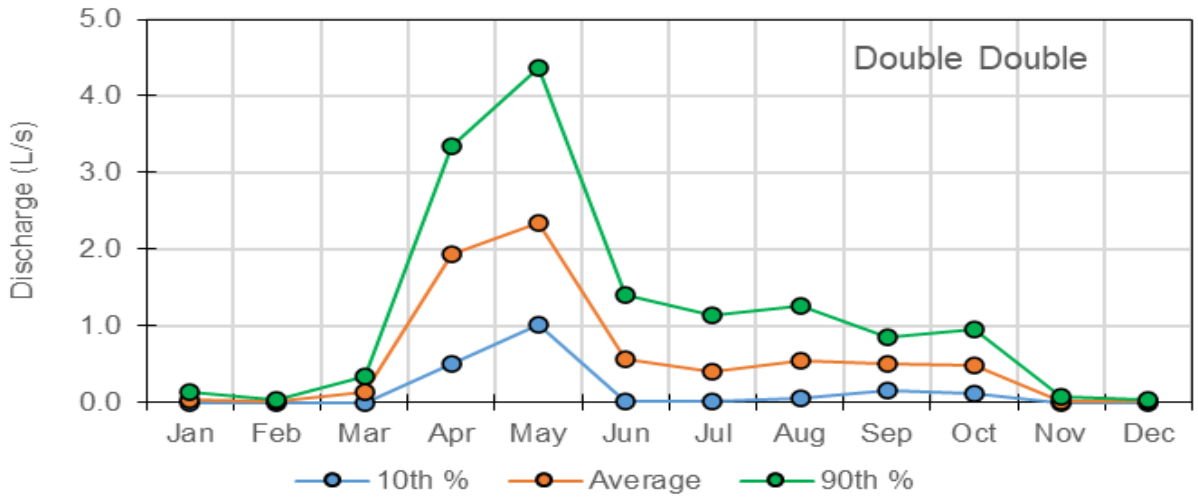

Figure 7-18 Backfilled Double Double Pit Surface Discharge Rates Backfilled Kona Pit

The backfilled Kona Pit will begin to fill with meteoric water during the Operation Phase. By Year 25 to 27, near the beginning of the Post-Closure Phase, the pore space within the backfilled waste rock is expected to have filled with water to the 1,230 masl spill point elevation (Figure 7-19) and will passively discharge to the Halfway Creek catchment via the Alpha WRSF rock drain. The backfilled Kona Pit will discharge at average monthly rates of 0.04 L/s in November to 1.1 L/s in May (Table 7-9 and Figure 7-20). Groundwater discharge is not expected from this backfilled pit.

7.1.3 Groundwater Leakage from Pit Lakes

Pit lake leakage from the pit lakes to the local groundwater system is dependent on the water level, and therefore driving head, in the pit lakes. GW leakage rates from the pit lakes are expected to be minimal. The Latte West and SU2 pit lakes are predicted to leak at rates of 1.7 L/s and 0.6 L/s, respectively, to Halfway Creek, and at rates of 1.0 L/s and 2.4 L/s, respectively, to Latte Creek. The SU1 and SU4W pit lakes are predicted to leak at 0.02 L/s and 0.36 L/s, respectively, to Latte Creek. None of the pit lakes are predicted to develop measurable groundwater flow pathways to YT-24 (Table 7-10).

Table 7-10 Predicted Groundwater Leakage Rates from Pit Lakes to Receiving Catchments

7.1.4 Closure Measures

The Kona and Double Double Pits will be backfilled during the Operation Phase, therefore open pit closure measures described in the proceeding paragraphs pertain to the Latte and Supremo Pits which will have been partially backfilled during operations. Additional backfilling of the Latte and Supremo Pits during the Closure Phase is not currently planned.

Once mining operations in the open pit have ceased, the pit sump pumps and pipelines will be removed using excavators and labour support. Pipelines will be drained fully prior to dismantling. Pumps, pipelines, and fittings will be reused or salvaged, when possible, otherwise they will be placed in the designated landfill if the material is included on the approved landfill item list.

With respect to protecting humans and wildlife from topographic hazards, egress points will be maintained to minimize potential wildlife entrapment within the pits. Boulder fences will be placed, where required, around each open pit as it is mined out. Boulders would be placed with a set-back from the final pit crest to provide a visual warning to indicate a change in landscape for both humans and large mammals. The boulders would be strategically placed to ensure egress from the pit is maintained in the event that wildlife enters the pit. The placement of boulders is not intended to prevent access. Guidance will be sought from the Project's wildlife biologist on strategic placement of boulders, if required. Specific safety requirements for open pit closure will be determined once the pits have been constructed. Open pit closure measures will fulfill the requirements set out in the *Workers' Safety and Compensation Act* and Regulations.

Erosion and sediment control measures will be undertaken in the areas adjacent to the pit perimeters and near the spill points of the pit lake. With respect to surface water management and runoff, engineered spillway channels will be constructed where deemed necessary to prevent erosion at the pit lake spill points and subsequent sedimentation downstream. Processed material may be required to be used for spillway channels, produced using the on-site crushing equipment, immediately following the Operation Phase. Roadside ditches and diversions that were constructed in the Operation Phase will be used as necessary to assist in achieving WQO until such a time that they can be decommissioned. When decommissioned, ditches and diversions will be graded to blend into the surrounding landscape. Built-up sediment in sediment control structures will be excavated and placed within a closure landform, away from running surface water.

Prevention of subsidence will be accomplished by adhering to pit designs that either meet or exceed the acceptable safety factor of 1.3 (additional details on pit stability analyses are provided in Section 5.3.1).

7.1.5 Reclamation Activities

Reclamation activities proposed in areas adjacent to the pit perimeters and near the spill points of pit lakes will focus on erosion and sediment control. As such, once closure measures are completed, disturbed areas will be seeded and/or planted to establish ground cover as soon as possible. Revegetation research programs are currently underway to refine the site-specific revegetation prescriptions as described in Section 2.3.1. No additional reclamation activities for the backfilled and partially backfilled pits are currently proposed.

7.1.6 Remaining Issues and Investigations

Although the waste rock from the Kona Pit is non-PAG (low sulphur granitic rock), it is expected that a small area of ore exposed in the completed pit wall has weak potentially acid generating tendencies. In order to

limit exposure of this ore seam to potential oxidation, the current closure strategy is for the Kona Pit to be backfilled with waste rock from Supremo Pit during winter in order to re-establish permafrost to depth prior to the Closure Phase. With changing climate conditions in the future, it is anticipated that eventually (i.e., in more than 100 years) the backfilled pit could fill with meteoric water and spill to the Halfway Creek catchment. The potential issue that arises with this is that saturated Kona pit-derived granite may be source of arsenic.

The water balance water quality model indicates that the backfilled Kona Pit will fill with meteoric water over an approximately 18-year period from completion of backfill (e.g., Year 9 to Year 27) (Lorax 2023b). The purpose of the backfill with higher neutralization potential gneiss waste rock from Supremo is to limit the potential for acid generation from remaining ore seams on pit walls in Kona. Both the backfilling and eventual saturated conditions will effectively eliminate the ARD potential. However, metal leaching and in particular, arsenic mobility is anticipated due to reductive dissolution of arsenic in the granitic ore material. This process has been accounted for in the geochemical source terms and reflected in the output of the water quality model. Figure 7-21 below illustrates that As concentrations in the Kona Pit backfill are modeled to discharge to Halfway Creek at approximately 0.28 mg/L. This compares to Double Double saturated backfill, which does not contain elevated As or granite material with elevated As, where the predicted concentration of As in Double Double overflow is an order of magnitude lower at approximately 0.02 mg/L (Figure 7-22).

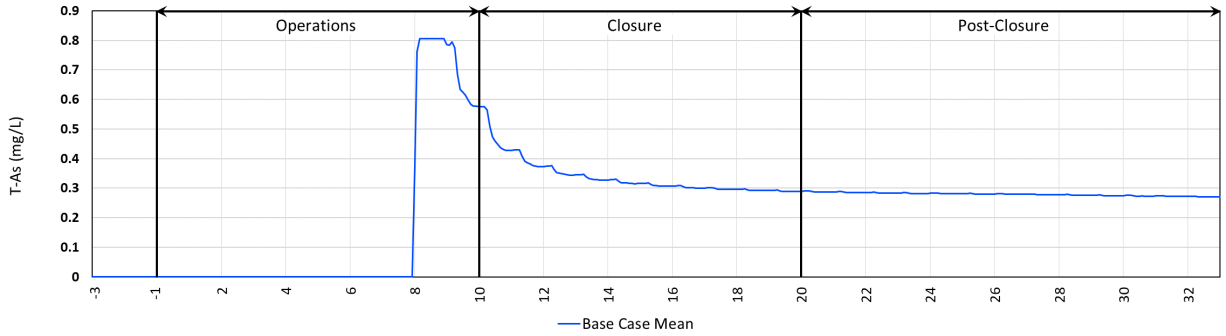

Figure 7-21 Time Series of Predicted Kona Pit Water Quality. Passive Spilling of the Backfill Pit Water is projected to Occur in Year 27

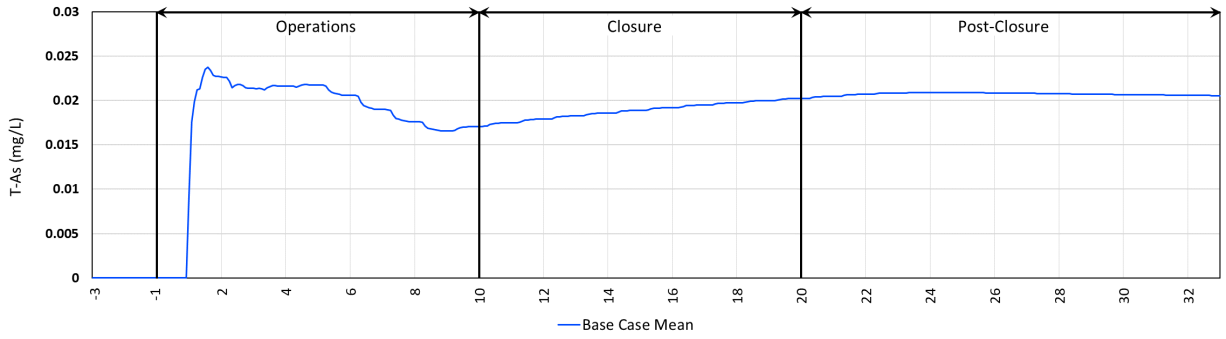

Figure 7-22 Time series of Predicted Double Double Pit Water Quality. Passive Spilling of the Backfill Pit Water is Projected to Occur in Year 24

While elevated As in the Kona backfill porewater is anticipated, the water quality model does not predict exceedances of the As Use-Protection objective in Halfway Creek at HC-1.0 (Figure 7-23). The predicted As concentrations following passive spilling of the Kona Pit in Year 27 show seasonal peaks of just over 0.003 mg/L and below the objective of 0.005 mg/L.

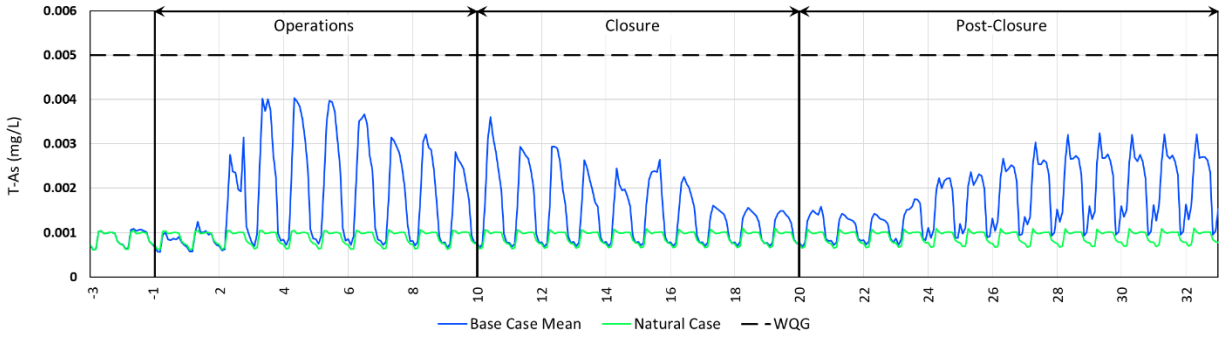

Figure 7-23 Time Series of Predicted As Concentrations in Halfway Creek at Attainment Location HC-1.0

These results notwithstanding, attention will be given to the pit wall exposures in Kona once mining is completed to ensure that backfilling plans minimize any exposure of granite ore material which can generate elevated As concentrations.

With respect to achieving the post-mine vision of returning the site to pre-mining conditions to the extent practical (outlined in Section 3.1.1), an alternatives assessment for pit backfilling was carried out as described in Section 2.3.4. Evaluations were conducted to assess the feasibility of placing additional waste rock in Latte and/or portions of Supremo Pits after they are mined out, using waste rock derived from active mining in other pits. This ultimately determined that it was not feasible to completely backfill Latte and Supremo Pits. Throughout the Operation Phase, in-pit drilling program results will ultimately inform decisions regarding the extraction of additional ore, as well as the timing (either progressively or at the end of mine life) and amount of backfilling to occur in each pit. By Year 6 of mining, a potential plan for additional backfill will be re-evaluated.

7.2 Waste Rock Storage Facilities and Stockpiles

For the Alpha WRSF and stockpiles, the performance targets for closure are to ensure physical stability, avoid unacceptable release of contaminants to the receiving environment, and avoid risks to humans and wildlife (YWB and EMR 2013). In general, these guidelines require information that demonstrates expected performance and/or management measures pertaining to physical and chemical stability, water quality and quantity conditions (including porewater, seepage, and runoff), surface water management and sediment control, and potential safety risks.

As outlined in Sections 5.3.1 and 5.3.2, waste rock will be permanently stored in the Alpha WRSF and in pits. Material contained in the soil stockpiles will be used during the reclamation of other disturbed areas, and ice-rich material placed in the FSSA will be managed depending on its acceptability of use in reclamation. General reclamation and closure measures for the stockpile pad areas are outlined in

Section 7.2.2. Additional information regarding the WRSF and stockpile designs and management are provided in the Waste Rock and Overburden Management Plan.

7.2.1 Alpha WRSF – Closure Measures

The Alpha WRSF will be constructed according to design criteria with progressive re-sloping during the Operation Phase to achieve final slope angles of 3:1 in closure. Operational plans will be developed to manage the placement of material within the Alpha WRSF so that the final surface of the facility contains waste rock with low arsenic concentrations (at or below 60 mg/kg). Once waste rock dumping ceases in Year 9, minor re-sloping may be completed to achieve long-term physical stability criteria and appropriate water conveyance for closure.

It is currently proposed that ice-rich material contained within the FSSA which is not suitable for use in other reclamation activities will be removed and placed in horizontal lifts within the Alpha WRSF progressively throughout operations.

At this time, no additional closure, safety, or reclamation measures are proposed. Based on this closure strategy, predicted water infiltration and seepage rates from the Alpha WRSF and downstream water quality is provided below.

7.2.1.1 Infiltration and Seepage Rates and Water Quality

Based on the current base case closure design of no cover for the Alpha WRSF, infiltration and seepage rates are expected to reach a steady state relative to annual precipitation during the latter part of the Operation Phase (Figure 7-21 and Figure 7-11). On a sub-annual time-scale, the Alpha WRSF is assumed to attenuate streamflow locally, as the high pore space volume and higher than natural proportion of fines acts to slow runoff generation as meteoric water infiltrates the facility, leading to attenuated peak flows and enhanced summer low flows. This process is evident in the monthly distribution of basal seepage, which shows a freshet peak flow condition that extends later in the year, into May and June – relative to the pit lake spill signature. Note that the potential effects of climate change have been incorporated into the site-wide water balance and water quality model (Lorax 2023b), and average annual precipitation is predicted to only marginally increase as the Post-closure Phase progresses (for more information refer to Section 4.1.1).

The Base Case source terms for the Alpha WRSF at closure are presented in Appendix 7-A.

7.2.2 Stockpile Pads – General Closure Measures

Prior to commencing closure works for the stockpile pads, erosion and sediment control measures will be installed at the toes and low points of each stockpile area to minimize sediment-laden runoff outside of the disturbed area. Erosion and sediment control measures will be removed once no longer required.

Once the stockpiled material is depleted during the Post-mining Closure Phase, the disturbance footprint of the soil stockpiles will be scarified, if necessary, and seeded and/or planted to establish ground cover as soon as possible. Site-specific prescription will be developed in the future based on the outcomes of reclamation research that will be advanced during the Construction and Operation Phases as described in Section 2.3.1. Water management infrastructure associated with the pad areas will remain operational until closure WQO are achieved. This supporting infrastructure will then be decommissioned, as outlined in Section 7.7.

7.2.3 Reclamation Activities

Due to uncertainty related to available cover material volume and suitability, no additional active reclamation measures for the Alpha WRSF are currently proposed. The revegetation strategy for the Alpha WRSF is to allow the facility to naturally revegetate. This strategy will be actively researched through the reclamation research program during the Operation Phase to assess its feasibility to meet end land use planning objectives. The revegetation strategy for the Alpha WRSF may be re-evaluated based on the outcomes of the reclamation research and obligation to meet site specific closure objectives refined through end land use planning.

7.2.4 Remaining Issues and Investigations

As part of the alternatives assessment for closure options at the Project (Section 2.3.4), Newmont evaluated cover options for the Alpha WRSF, including conducting a material balance assessment and material prioritization evaluation. The reclamation material prioritization evaluation is included in the 2022 Coffee Mine Heap Leach Facility Cover Design Summary Report (Appendix 7-B). The current material balance identified sufficient suitable material for a WRSF cover; however, the evaluation is preliminary, and an updated material balance will be carried out during the Construction and Operation Phases to confirm that material is available for use as a WRSF cover. If adequate reclamation material is identified throughout construction and operation, a cover system will be designed and constructed for the WRSF based on volume and quality of reclamation material available as well as on end land use planning. The water quality model will then be updated based on the proposed cover design for the WRSF.

Ultimately, the Alpha WRSF reclamation and closure strategy design will focus on achieving the Project-specific closure objectives described in Section 3.1 to the extent practicable. This strategy may evolve as more information becomes available through Construction and Operation Phases (including an updated material balance), as well as from the outcomes of reclamation research.

7.3 Heap Leach Facility and Process Ponds

7.3.1 Heap Leach Pad Closure Measures

Concurrent reclamation of the HLF will occur progressively starting in Year 10 as described in the Heap Leach Facility Engineering Report for Licensing (Forte 2023), and will include the following:

- **Recirculation (rinsing):** recirculation of the leached ore will be carried out using barren solution, which will continue until the chemistry of the heap effluent reaches approximate equilibrium with the rinse solution (estimated timeline: 200 days, actual time driven by water quality measurements). The other determining factor for recirculation durations will be to ensure that CN_{WAD} concentrations have decreased to below 0.5 mg/L in heap effluent. Minor gold recovery will occur during this time.
- **Controlled draindown:** upon completion of recirculation, the HLF solution flow will be reduced to zero until meteoric water inputs become the sole water source to the HLF. Draindown solutions will be actively treated and discharged until all solution within the HLF system is meteoric (estimated timeline for draindown of the HLF: 5 months after the completion of the of recirculation).
- **Passive draindown and cover placement:** Following final rinsing and once heap draindown is complete, a cover system designed to limit meteoric infiltration will be installed on the heap (the cover will be placed progressively over areas as recirculation is completed and will take an estimated 3 months for each recirculation area to be covered). Appropriate water management features to safely convey runoff from the heap cover will also be installed as part of the cover design.

For additional details regarding the HLF design and stability analysis see the Heap Leach Pad Engineering Report for Licensing (Forte 2023).

Progressive regrading will occur near the end of operations to maintain the base case closure design of 2.5H:1V or flatter overall slope, and to prepare the side slopes for a primary leach cycle to recover residual metals. Closure of the heap leach pad will occur progressively during the Closure Phase with preliminary rinsing commencing in Year 10. The recirculation will be carried out progressively in 10 recirculation areas that are sized for optimal recirculation based on flow and application rate of recirculation solution. It is expected that each of the 10 areas will be rinsed with recirculation solution for approximately 200 days but will ultimately be driven by water quality measurements. Progressive closure of HLF will reduce length of time that HLF is at its maximum footprint size.

The final rinse area is expected to be completed in Year 15. Water treatment of surplus recirculation solution and heap seepage will continue during the heap draindown period after active recirculation rinsing has ceased in the Post-mining Closure Phase. Details on the proposed water treatment system are provided in the Heap Leach and Process Facilities Plan and Appendix 5-C of this plan. A sampling program will be developed specifically to determine the success of heap leach recirculation rinsing, which may include physical sampling of the heap. Details of the heap leach rinse sampling program will be provided in future iterations of the RCP.

The cover system will be installed on each rinsed area of the heap once rinsing is complete (starting in Year 11). A plan view of the HLF and cover system is shown on Figure 7-25.

Closure cover designs for the HLF were evaluated through the alternatives assessment (Section 2.3.4) to determine the preferred closure alternative for the HLF. The evaluations included an analytical water balance, numerical water balance, water quality model, slope stability evaluations of the cover material, sediment and erosion stability evaluations, and a trade-off study. In addition, potential failure modes for the HLF alternatives were identified and discussed during an FMEA workshop held in February 2022. Based on outcomes of the assessment and FMEA workshop, the proposed closure cover strategy was selected as the base case closure option for the HLF. Details of the alternative selection process and outcomes of the FMEA are discussed in Section 2.3.4.

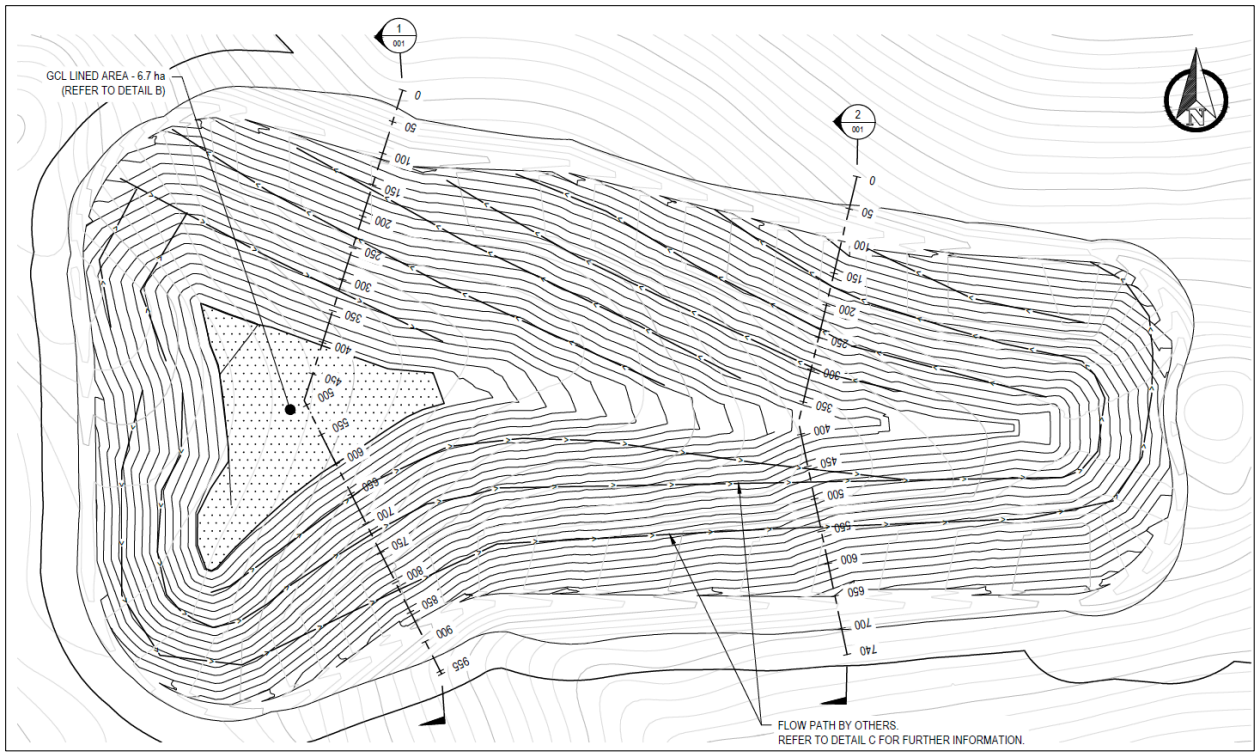

Figure 7-25 Plan View of HLF and Cover System

The closure cover strategy for the HLF includes overall 2.5:1 slopes, store and release cover on the slopes of the HLF and a GCL and store and release cover on the flat surfaces. A surface water drainage system to route runoff water from the cover system is also included in the closure concept for the HLF, as shown in Figure 7-25. Upon completion of active leaching operations, solution management will be maintained until the closure cover is established, and clean runoff is diverted off the facility. Side sloping of the heap during progressive reclamation may need to be scheduled for the warmer months due to freezing. Soils and rock placement will generally be done between May and December. GCL will only be installed immediately before the rock or soil cover is to be installed. GCL installation in May, July, and August will be limited to dry periods. The cover as described in the Heap Leach Facility Cover Design Report (Appendix 7-B) is expected to be completed in Year 16.

The goals of the cover system are as follows:

- Provide for physical stability of the heap, including stable slopes and erosion resistance through development of cover system material specifications to meet erosion criteria, as well as vegetation establishment
- Provide for positive drainage to minimize the creation of saturated zones
- Route runoff away from the heap and into the nearby natural drainage channels in a manner that prevents erosion or other ill effects
- Reduce net infiltration into the HLF from precipitation to approximately 22% of mean annual precipitation (MAP).

From bottom to top, the installation of the cover system on flat areas will entail:

- Compacting the rinsed ore to provide a firm, non-yielding base
- Placing a GCL, compacted low permeability soil, an integral GCL/geomembrane product, or equivalent low permeability infiltration barrier over the compacted base
- Placing a drainage layer (gravel, geonet, or equivalent) over the GCL
- Adding a 0.5 m storage layer comprised of finely-graded waste rock (i.e., confirmed to be of limited metal leaching potential), soil or other suitable material over the drainage layer
- Signage will be placed around the HLF to provide notice to public not to dig or excavate cover material without authorization by Newmont.

For both flat and sloped areas, a revegetation strategy will be developed based on site-specific testing to be performed during the Operation Phase as HLP stages are being progressively reclaimed.

The GCL will be installed by a specialized contractor, using their equipment, ensuring that the layers are keyed-in appropriately at the specified locations. Prior to installation of the GCL, the subgrade will be final graded to fill major voids or cracks. The GCL will be placed on top of the subgrade so that the ends of the panels cover the entire anchor trench floor. The minimum overlap of the GCL panels, as required by the manufacturer specifications and design, will exist at all seam locations. A protective cover will be spread over the GCL with low ground pressure equipment to the minimum cover thickness as indicated by the HLF cover conceptual design.

Groundwater and surface water quality monitoring will be carried out at locations near the HLF as described in Section 7.11.2. Should monitoring results indicate a leak after the facility has been decommissioned, Newmont will conduct a cause-and-effect study of the leakage and perform corrective actions as determined by the study. An example of corrective actions that may be taken include groundwater interception for active remediation.

7.3.2 Heap Leach Facility Pond Closure Measures

Closure of the four HLF ponds are anticipated to be completed in two ways. If deemed feasible and necessary for passive treatment (based on outcomes of future studies), two or three of the ponds will be converted to be part of the PRB system. The remaining pond(s) will be used for the duration of the water treatment period (up to Year 20) for disposal of the likely small volumes of sludge from the water treatment plant. The pond(s) will then be closed by folding down the liner over the sludge, then filling the depression (containing the encapsulated sludge) with suitable material.

7.3.3 Reclamation Activities

Areas that do not require engineered cover systems, such as at the closed HLF ponds, will be seeded and/or planted once closure measures are completed to establish ground cover as soon as possible. Site-specific prescriptions will be developed in the future for the HLF as a whole, based on the outcomes of engineering studies for the HLP, stability analyses, and reclamation research.

7.3.4 Remaining Issues and Investigations

Investigations that will be conducted once the HLF is in operation include a revegetation field trial program and HLF cover systems optimization study.

The requirement for passive treatment following reclamation activities for the HLF will be determined by the water quantities and quality exiting as seepage from the HLF. In the water balance and water quality model (Lorax 2023b), net infiltration into the heap was modeled using the results from the 1D numerical modeling of the combined GCL and store and release cover system as described in Appendix 7-B (i.e., total infiltration of roughly 22% of MAP). Using these cover performance assumptions, the water balance and water quality model was used to estimate effluent quality standards for heap leach seepage in the Post-closure period (e.g., Year 21 onwards). Specifically, the model was used to back-calculate the maximum allowable concentrations of key parameters in heap leach seepage waters that would maintain water quality objectives in Halfway Creek at HC-1.0 under all open water (e.g., April to October) flow conditions.

The back-calculated allowable concentrations were then compared to Upper Case geochemical estimates of late phase heap leach process solutions to provide an indication of which parameters may require treatment through a passive treatment system prior to discharge to Halfway Creek. The comparison was also used to derive passive treatment system (PTS) water quality model input values for estimating long-term water quality in the receiving environment. As illustrated in Table 7-12, there are only five parameters that may require additional passive treatment (e.g., NO_3, NO_2, CN_{WAD}, As and Sb) with the most likely being limited to NO_3 and As given the more significant differences between predicted HLF solution chemistry relative to the respective allowable concentration. Water quality modeling in the Post-Closure period at HC-1.0 for NO_3 and As illustrates that the proposed PTS discharge limits are appropriate for maintaining acceptable water quality in Halfway Creek (Figure 7-26).

Table 7-12 Comparison of Upper Case Late Phase HLF Solution Prediction to Back-Calculated Allowable Concentration in PTS Discharge

Parameter	Units	Upper Case Late Phase HLF Solution	Back-Calculated Allowable Concentration	Value Used for PTS Solution in WQM
$N\text{-}NH_3$	mg/L	0.06	41.3	0.06

Zn	mg/L	0.052	0.563	0.052

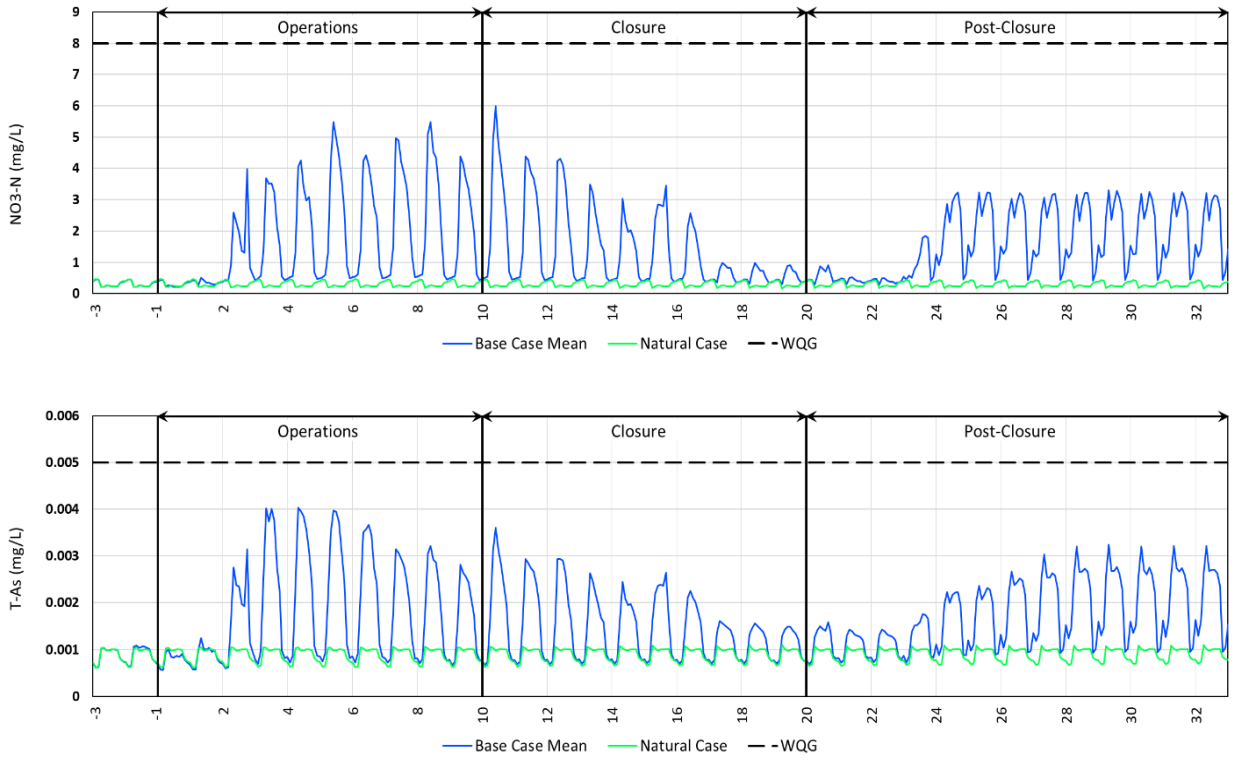

Figure 7-26 Time-series of NO_3 and As Water Quality Predictions at HC-1.0 for all Mine Phases and into Post-Closure Relative to Use Protection Objectives

As noted, nitrate (NO_3^-) and arsenic (As) represent the primary parameters of potential environmental concern from the HLF at closure. Nitrate represents a residual product of cyanide degradation, while As represents leached components from the ore. The use of a passive treatment systems (PTS) employing biological reactors (BR) and permeable reactive barrier (PRB) technology have been a successful passive

treatment technology for treating mine waste solutions and has been considered for this contingency option. All forms of BRs rely on the passage of flow through a permeable matrix (e.g., gravel) amended with materials designed to promote contaminant removal. Common forms of reactive amendments include various sources of organic matter (e.g., hay, sawdust, compost, and peat) and zero valent iron (ZVI). Within the reactive zone, favourable reactions promoted are denitrification and sorption with ZVI corrosion products, most notably for As (Benner et al., 1997; Blowes et al., 2000).

Given that flow paths in BRs are contained below ground, they are influenced to a lower degree by atmospheric conditions in comparison to surface wetlands and have been shown to function well in cold-interior climates (e.g., Benner et al., 1997).

Initial testwork to evaluate this type of semi-passive treatment system was conducted in 2021 at Yukon University and the results are presented in Appendix 2-G.

As Project engineering and closure planning continue and advance, and Project performance is better understood during operations, revisions to water treatment technologies and approaches may be considered.

If the site moves into closure prior to the construction of the active water treatment plant, Newmont will characterize heap seepage, implement appropriate pilot trials to inform water treatment plant design, complete detailed plant design with proof-of-concept, and construct the water treatment plant. Until the water treatment plant is constructed and commissioned, Newmont will manage the HLF seepage water through Event Pond storage and dynamic storage through recirculation of process solution in the heap as described in Section 6.5.2.

7.4 Ore Crushing Facilities

Performance targets for closing ore crushing facilities include ensuring physical stability, removing potential threats to public health and safety, and providing for appropriate future land use (YWB and EMR 2013). This section describes the closure measures that will be implemented to achieve these performance targets and Project-specific closure objectives.

A salvage program will be implemented to reduce the amount of equipment, materials, and items that will require disposal in the on-site landfill. In addition, all equipment, materials, and items will need to be screened and approved for disposal in the onsite landfill prior to disposal. The salvage program will pertain to ore crushing equipment, as well as other equipment and buildings at the Plant Site, Camp Site, bulk explosives storage area, waste management areas, and airstrip. Non-hazardous materials will be separated into three categories:

- Salvageable: materials or items that can be put to use by others as they retain a value equal to or higher than the cost of decommissioning and delivery to the point of sale
- Recyclable: Where materials can’t be salvaged, materials or items can be delivered to a recycling depot, for subsequent processing for use again
- Landfill: inert non-hazardous equipment, items, or materials that have no salvage or recycle value that are on the approved landfill item list will be disposed of in the on-site landfill
- Offsite disposal of non-approved items: equipment, materials or items that are not on the approved items list will be removed from site and landfilled at other approved sites.

7.4.1 Crusher System and Crushed Ore Stockpile Area Closure Measures

At the commencement of the Post-mining Closure Phase, and after any specified processed material for closure has been produced, the two-stage crushing system, overland conveyors, and radial stackers will be dismantled. Additionally, all pad areas (now depleted of materials) will be reclaimed, including the crushed ore stockpile pad and the ROM stockpile pads. Specific activities for each of these components are described below.

The crusher system infrastructure and equipment, except for what can be salvaged or recycled, will be dismantled and disposed of in the landfill if the material is included on the approved landfill item list, or removed from site. Concrete foundations will be demolished to just below ground level while concrete pads will be broken up to allow water infiltration, but otherwise will be left in place. Demolition rubble will be disposed of in the landfill, if approved, and covered with suitable material, based on the priority cover material placement sequence outlined in Appendix 7-B, for subsequent revegetation.

Buried piping and dead electrical cables within the area will be removed to approximately 1 m below grade at surface terminations and ends will be capped. Buried fuel and glycol lines will be flushed with clean water to remove hydrocarbons/glycol prior to capping the ends, or removed entirely and disposed of in the landfill, if approved, or removed from site. Surface piping will be flushed, if necessary, with clean water and removed and disposed of in the landfill, if approved, or removed from site. Surface cables will also be removed and landfilled, if approved, or recycled. Any hazardous wastes and contaminated soils will be managed as per the procedures described in Section 7.9.3.

7.4.2 ROM Stockpile Area Closure Measures

The pad of the ROM stockpile, constructed of waste rock, will remain in place. Prior to reclaiming the pad surface, the pad will be inspected by a qualified person and tested if necessary to ensure that all ore has been removed. Any remaining ore material will be removed and placed in the HLF. The ROM stockpile pad will be sloped to drain pad runoff towards Halfway Creek.

7.4.3 Reclamation Activities

Once closure measures in the ore crushing and stockpile areas are underway, compacted surfaces will be scarified and areas contoured to match adjacent topography. Disturbed areas will be covered with material from the soil stockpiles, based on the priority cover material placement sequence outlined in Appendix 7-B, and seeded and/or planted in order to establish ground cover as soon as possible. Revegetation research programs are currently underway to refine the site-specific revegetation prescriptions. The ore crushing and stockpile areas are anticipated to be revegetated as part of the larger disturbed area (i.e., including the Plant Site, crusher system, stockpile footprints, and areas in between).

7.4.4 Remaining Issues and Investigations

A regrading plan including engineer designs will be developed to outline the activities that will be carried out for closure of the crusher system and crushed ore stockpile area footprints. The regrading plan will include the site-specific revegetation prescriptions as determined through the reclamation research program and will be provided in future iterations of the RCP.

7.5 Plant Site Closure Measures

Performance targets for closure of the Plant Site include ensuring physical stability, removing potential threats to public health and safety, and providing for appropriate future land use (YWB and EMR 2013). This section describes the closure measures that will be implemented to achieve these performance targets and Project-specific closure objectives.

Construction and as-built records (reports, drawings, survey data, etc.) will be kept by Newmont in a secure location electronically and backed up, being available to project team members throughout the operating life of the mine and during closure. These as-built records will be essential for decommissioning, dismantling, demolition, remediation, and reclamation of site infrastructure.

The Plant Site area will be closed during the Active Closure Phase by removing all equipment, buildings, infrastructure, and other materials from the area. Specific measures are as follows:

- Hazardous wastes will be handled and removed from site for offsite disposal, and areas of suspected soil contamination will be assessed and managed as per the procedures described in Section 7.9.3.
- As applicable, utilities and services (air, glycol, power, and water) will be shut off, de-energized, and/or drained to permit safe dismantling and demolition of infrastructure within the Plant Site.
- Equipment, including the modular power plant, will be removed from the area and either transported offsite if it has salvage or recycle value or landfilled on-site if non-hazardous and approved to landfill on site. All contractor-owned equipment will be removed from site by the contractor. At this time, it is premature to indicate which equipment will have resale or salvage value, but equipment (and materials) will be salvaged or recycled to the extent practicable (as outlined in Section 7.4). All equipment will be cleaned thoroughly and drained / flushed of all hydrocarbons using clean water prior to landfilling.
- Storage tanks that support Plant Site processes will be decommissioned and any contents will be drained and placed into suitable drums. The contents will be consumed during closure activities, if practicable. Tanks will be cleaned and decontaminated by a specialized contractor.
- Buildings and structures will be demolished with the resulting steel being recycled or landfilled if the material is included on the approved landfill item list, and other non-hazardous demolition debris landfilled on-site, if approved.
- Concrete foundations will be demolished to just below ground level and concrete pads will be broken up to allow water infiltration but otherwise will be left in place. Demolition rubble from the foundations will be hauled to the on-site landfill, if approved.
- Buried piping or electrical cables within the area will be removed to approximately 1 m below grade at surface terminations and ends will be capped. Buried fuel and glycol lines will be flushed with clean water prior to capping the ends or will be removed entirely and disposed of in the landfill, if approved, or removed from site. At this time, the level of design does not allow for the development of detailed maps showing all buried foundations, equipment or infrastructure that will remain on site (once mine reclamation activities are complete).
- Surface piping will be flushed with clean water, if necessary, removed, and disposed of in the landfill, if on the approved landfill list, or re-purposed for water management use during closure.

- Powerlines and poles will be cut at ground level or removed. Power poles and lines will be shipped off-site if salvageable or not approved for on-site landfill. Otherwise, power poles and lines will be disposed of on-site in the landfill.
- Below-grade depressions (e.g., sump or secondary containment areas) will be backfilled with non-PAG waste rock or other suitable fill to re-establish a level surface. These areas may be contoured with the surrounding topography.

The proposed closure measures for the Plant Site may be altered and/or refined once designs are advanced to show the buried foundations, equipment, and/or infrastructure to remain on-site post-reclamation.

7.5.1 Bulk Fuel and LNG Storage Areas

Remaining fuel will be withdrawn from the fuel storage tanks during the Post-mining Closure Phase. Once empty, large tanks will be cut apart to facilitate their removal. Steel plate sections and distribution system components will be flushed / washed with clean water to remove any hydrocarbons. Wash water will be contained and directed to the oil-water separator used for the truck shop wash bay. Steel will be salvaged or recycled, when possible, removed from site if not approved for on-site landfilling or disposed of in the landfill site, if approved.

The tank farm earthen containment berms will be flattened, and liner materials will be removed and disposed of in the landfill, if approved, or removed from site. Materials underlying the liner will be tested for hydrocarbon contamination. Any contaminated materials encountered will be managed as per the established processes described under Section 7.9.3.1. Depressions within the storage areas will be filled with non-PAG waste rock or other suitable fill material to re-establish a level surface, and the area contoured to blend with surrounding topography.

To support the implementation of final closure measures in other areas after the fuel storage tanks have been removed from the Plant Site, appropriately-sized portable fuel storage tanks will be used to store diesel for equipment and power generation. Lined containment areas will be established for these portable fuel storage tanks as required.

7.5.2 Reclamation Activities

The footprint of the Plant Site will be covered with stockpiled material, based on the priority cover material placement sequence outlined in Appendix 7-B, and seeded and/or planted in order to establish ground cover as soon as possible. Revegetation research programs are currently underway to refine the site-specific revegetation prescriptions. It is anticipated that cover and revegetation plans will be developed considering the larger disturbed area (i.e., including the Plant Site, crusher system, stockpile footprints, and areas in between).

7.5.3 Remaining Issues and Investigations

A regrading plan including engineer designs will be developed to outline the activities that will be carried out for closure of the Plant Site area footprint. The regrading plan will include the site-specific revegetation prescriptions as determined through the reclamation research program and will be provided in future iterations of the RCP.

7.6 Camp Site Closure Measures

The performance targets and general closure measures outlined for the Plant Site are applicable to the Camp Site (see Section 7.5). Once decommissioning of buildings and supporting infrastructure is underway at the Camp Site, the Java camp will be used to house personnel throughout the Post-mining and Active Closure Phases to support closure works and monitoring activities. The Java camp will be decommissioned towards the end of the Active Closure Phase, at which time the Coffee exploration camp may be used. In addition to the closure measures outlined above for the Plant Site, additional measures required to close the Camp Site include decommissioning of the sewage treatment plant and closure of the effluent disposal field.

Prior to decommissioning of the sewage treatment plant, the effluent/treatment tanks and piping will be flushed with clean water to remove residual sludge. Residual sludge will be disposed of in accordance with the procedures established under the Operation Phase. The plant will be disconnected from service connections and transported off-site, where it will either be re-purposed or dismantled and components that cannot be re-purposed either recycled or landfilled (on-site, if on the approved landfill list, or off-site).

Buried piping within the area (including effluent disposal field) will be flushed with clean water, and piping will either be removed to approximately 1 m below grade at surface terminations and ends capped, or removed entirely and disposed of in the landfill, if on the approved landfill list. At this time, the level of design does not allow for development of detailed maps showing buried infrastructure that will remain on site (once mine reclamation activities are complete). Surface electrical cables and surface piping (flushed with clean water, if necessary, prior to removal) will be transported to the landfill, if approved, or off site for disposal.

7.6.1 Reclamation Activities

The footprint of the Camp Site will be covered with stockpiled material, based on the priority cover material placement sequence outlined in Appendix 7-B, and seeded and/or planted in order to establish ground cover as soon as possible. Revegetation research programs are currently underway to refine the site-specific revegetation prescriptions.

7.6.2 Remaining Issues and Investigations

A regrading plan including engineer designs will be developed to outline the activities that will be carried out for closure of the Camp Site footprints. The regrading plan will include the site-specific revegetation prescriptions as determined through the reclamation research program and will be provided in future iterations of the RCP.

7.7 Site Water Management Infrastructure

The end of the Post-mining Closure Phase is primarily dictated by the completion of the HLF recirculation. The water management infrastructure that will be in place at the beginning and end of the Post-mining Closure Phase is shown in Figure 7-2. The water management infrastructure remaining at the end of the Active Closure Phase includes the semi-passive water treatment system (if required), the pit lakes, pit lake outlet structures.

Sedimentation (Facility Pond and Alpha Pond) ponds and water conveyance structures will continue to be operated and monitored during the Closure Phase similar to the Operation Phase. Once pond water quality

has stabilized, decommissioning activities can occur. Stabilization of the water quality within the Alpha Pond is defined as:

- No notable upward trends in the parameters of potential concern (POPCs)
- Sustained reduction in inter-annual variability in POPC concentrations from Operation Phase conditions
- Discharge concentrations for all POPCs are consistently at levels that allow WQOs to be achieved in Halfway Creek.

Decommissioning of the sedimentation ponds will be accomplished by draining the ponds. Sediment that has accumulated in the ponds will be removed and disposed of in dedicated disposal areas in the Alpha WRSF. The base of each pond will be covered with a coarse gravel and revegetated as determined through the reclamation research program, and the base of the Alpha Pond will be reshaped to establish a natural streambed. The sedimentation pond dams may remain in-place to control sediment release during the Active Closure Phase, then will be breached to the pre-mining ground elevations. The plunge pool downstream of Alpha Pond will be left in place to capture sediment following the dam breach. Additional information regarding the design and stability analysis of water management infrastructure can be found in the Water Management Design Basis Report (SRK 2023).

Most of the excavated dam material will be temporarily placed upstream of the dams. Excavated dam materials will be used to backfill pond excavations (if present), to cover the inundation footprint of the ponds, and/or to construct a post-closure drainage pathway through the footprint of the former dam and pond.

The decommissioning of water conveyance structures that are not required in the Post-closure Phase will involve the re-establishment of drainage patterns as determined through the end land use planning for the site. This will be accomplished by breaching diversion and collections ditches in strategic areas to support permafrost protection or at other appropriate locations. Culverts will be removed and ditches and areas where culverts were removed will be re-graded to blend into the surrounding topography.

Closure of the Alpha Dam was evaluated through the alternatives assessment process described in Section 2.3.4, which determined partial decommissioning of the Alpha Dam and construction of a drainage channel as the base case closure measure for this infrastructure. Closure of the West Diversion Ditch was also evaluated through the alternatives assessment process, which determined complete decommissioning (re-grading to slope) as the base case closure measure for this infrastructure.

7.7.1 Reclamation Activities

Where water management infrastructure has been removed, disturbed areas will be covered with stockpiled material, based on the priority cover material placement sequence outlined in Appendix 7-B, and seeded and/or planted in order to establish ground cover as soon as possible. Revegetation research programs are currently underway to refine the site-specific revegetation prescriptions.

7.7.2 Remaining Issues and Investigations

Evaluation and design work will continue on water management structures that are likely to be operational through the Post-closure Phase, such as the Alpha WRSF rock underdrain, the pit lake spillway channels,

and other channels that may be required in the long-term to ensure Project-specific closure objectives are achieved to the extent practicable.

A reclamation research program is currently underway to determine the site-specific revegetation prescriptions and inform the revegetation strategy for the former water management infrastructure areas.

7.8 Mine Site Roads and Other Components

For roads and airstrips, the performance targets for closure are to establish conditions that support future land use objectives, ensure public safety, and eliminate risks to wildlife while providing for long-term operations, monitoring, and maintenance requirements (YWB and EMR 2013). Closure measures and reclamation activities are described below for haul roads and Mine Site roads, the NAR and On-site Access Road, the Project airstrip, laydown areas, and the bulk explosives storage facility. The Coffee exploration camp and airstrip will continue to be used in the Post-closure Phase to support monitoring activities; hence, reclamation and closure measures are not proposed.

7.8.1 Haul Roads and Mine Site Roads

Progressive closure of haul and Mine Site roads will occur throughout the Operation Phase as roads are no longer required to support operations. Roads used for closure works will generally undergo closure in the later portion of the Active Closure Phase when the majority of infrastructure has been decommissioned and key areas have been closed.

The running surfaces of the compacted roads will be scarified, re-graded as per landscape designs, and seeded and/or planted to establish ground cover as soon as possible. It is anticipated the water management infrastructure associated with roads (i.e., ditches and culverts) will be decommissioned at the same time as the road itself is decommissioned. These areas will be re-graded to blend into the surrounding landscape. To minimize the potential of sediment-laden runoff outside of the disturbed footprint, erosion, and sediment control measures (e.g., silt fences) may be temporarily required to minimize sedimentation downslope. Any temporary measures will be removed once monitoring results indicate that water management and revegetation in the area is meeting performance targets.

Revegetation research programs are currently underway to refine the site-specific revegetation prescriptions. Road corridor areas are anticipated to be revegetated as part of the prescribed reclamation for areas that they connect with to blend in with these surrounding areas.

7.8.2 NAR and On-site Access Road

The NAR and On-site Access Road will be operational throughout most of the Active Closure Phase to support closure operations including the transport of equipment, fuel, and consumables to the Mine Site, and the removal of hazardous materials and other wastes and equipment from the Mine Site (further described in Section 8.4). When it is decided that the NAR and On-site Access Road are no longer required for operations in the Closure or Post-closure phases, the On-site Access Road and new sections of the NAR will be decommissioned.

Options for closure of the NAR were evaluated through the alternatives assessment process as described in Section 2.3.4, which determined decommissioning new sections of the NAR constructed to support the Project as the base case closure option. New sections of the NAR and the On-site Access Road will be

decommissioned by removing culverts and bridges to re-establish pre-construction surface drainage patterns, removing the barge landings, scarifying the road surfaces to promote water infiltration and vegetation re-establishment, and contouring of the road surfaces and cut and fill slopes in accordance with landscape designs. Re-contouring works will target minimizing potential hazards for area users and wildlife. Site-specific prescriptions will be developed based on the outcomes of reclamation research. The section of the NAR that are planned for reclamation are shows on Figure 7-27. Newmont will continue to work with Yukon government and placer claim holders (if infrastructure falls within placer claims) on long term maintenance activities for existing sections of the NAR.

The closure measures for decommissioning and reclaiming the new sections of the NAR include:

- Restricting access to areas undergoing decommissioning and reclamation
- All materials installed for the construction of fords, culverts, bridges and barge landings will be removed
- On the road smaller cuts, fills and ditches will be filled in
- Banks will be stabilized and restored to original shape, where practical
- Pre-construction surface drainage patterns at disturbed areas will be established
- Excess rip rap or erosion control structures will be removed
- Re-contouring surfaces, road surfaces, and other disturbed areas (targeted to minimize potential hazards for humans and wildlife
- Scarifying disturbed areas to promote natural revegetation
- Scarifying road surfaces to promote natural revegetation
- Where warranted, temporary erosion protection measures may be used until vegetation is established
- Stabilizing and re-contouring remaining borrow sources
- Stabilizing and scarifying spoil sites
- Revegetation of disturbed areas for erosion protection and reintroduction of native species
- Restoration of shoreline habitat in riparian areas affected by the barge landings
- Specific revegetation methods and vegetation species will be developed based on the reclamation research program for the Mine Site.

Newmont is committed to developing a decommissioning program prior to decommissioning of the NAR. The NAR decommissioning program will be developed in collaboration with affected First Nations. Once the NAR and on-site access roads have been decommissioned, consumables and materials required to support activities conducted in the latter part of the Active Closure Phase and monitoring activities in the Post-closure Phase will be transported to site by air or barge campaigns on the Yukon River.

7.8.3 Project Airstrip

The Project airstrip will be operational during most of the Active Closure Phase to permit the transport of personnel and resupply of consumables to the Mine Site. Upon decision to decommission, reclamation will include removal of lighting, navigation equipment, and water management infrastructure. The compacted runway and apron surfaces will be scarified to promote water infiltration and vegetation re-establishment. Contouring of the surface and cut and fill slopes will be done in accordance with landscape designs, which will consider factors such as minimizing potential hazards for area users and wildlife. Once the Project airstrip is reclaimed, the existing airstrip at the Coffee exploration camp will be used instead.

Once the Coffee exploration airstrip is no longer needed to support Post-closure monitoring activities, reclamation will be undertaken and will involve contouring, scarifying, top-soiling, and seeding.

7.8.4 Laydown Areas

Materials and equipment stored within laydown areas will be consumed prior to reclamation of these areas, shipped offsite, or disposed in the landfill if the material is included on the approved landfill item list. Areas of suspected soil contamination will be assessed and managed as per established processes outlined in Section 7.9.3.1. Upon remediation of any contaminated soils, the laydown areas will be graded in accordance with landscape designs. As per other areas of the Mine Site, it is anticipated that laydown areas will be revegetated to blend in with these surrounding areas. The landfill will be decommissioned following completion of the demolition of site infrastructure. The landfill will be closed as per requirements provided in future *Environment Act* permits for waste management.

7.8.5 Bulk Explosive Storage Area

The inventory of explosives, comprising ammonium nitrate and emulsion product, remaining at the end of mining will either be returned to the supplier or transferred to another licensed user. Areas of suspected soil contamination will be assessed and managed as per established processes outlined in Section 7.9.3.1. Once any contaminated soils have been remediated, the areas will be graded in accordance with landscape designs. Site-specific revegetation prescriptions will be developed based on the outcomes of reclamation research.

7.9 Environmental Management

7.9.1 Air Quality and Dust

Throughout remediation and closure works, dust resulting from earthworks, heavy vehicle traffic, and site light vehicle traffic will be managed using a water truck. The application of water to dry construction surfaces will limit the creation and conveyance of dust particles. Dust management will be the responsibility of Newmont if the work is self-performed, or the Prime Contractor on site.

7.9.2 Spill Management

Spill management on site will begin with good housekeeping. All works areas, laydowns, and maintenance areas will be kept clean and well-organized. Secondary containment will be provided for all fuel storage tanks. Drip trays will be placed under all equipment not in use. Spill kits will be kept on all equipment and

in all work areas as per applicable regulations. Fueling and lubing will only occur in designated areas. All construction waste and waste oil will be disposed of as per the applicable regulations.

In the event of a spill, it will be compulsory to be reported to site management immediately. Personnel will be trained in spill management and reporting procedures. Spill response procedures to be followed during closure are described in the Spill Contingency Plan.

7.9.3 Hazardous Materials Management

As indicated above, hazardous materials will be removed from areas in advance of decommissioning activities occurring, such as demolition or dismantling activities. Evaluations will be conducted early in the Post-mining Closure Phase to determine the type and quantities of hazardous materials that will either need to be consumed during the Closure Phase (e.g., such as during heap leaching or rinsing or water treatment processes, or mobile equipment lubricants), transported to an offsite facility licensed to dispose of such waste materials, or managed on-site (i.e., such as hydrocarbon contaminated soils). Hazardous waste handling and offsite transfer procedures will be conducted according to the Waste and Hazardous Materials Management Plan, which will be updated, if required, prior to the onset of the Post-mining Closure Phase to reflect site conditions at that time.

7.9.3.1 Land Treatment Facility

The locations and extent of hydrocarbon-contaminated soils (or snow) will be determined through a contaminated site investigation early in the Post-mining Closure Phase. Any contaminated soils will be excavated and either treated on site to an acceptable standard or transported off-site for disposal, depending on the volume of material, level of contamination, and anticipated time to remediate such soils.

Prior to closure of the facility, Soils that have successfully undergone bioremediation and have met criteria outlined in the *Contaminated Sites Regulations* numerical soil standards for industrial sites will be removed from the land treatment facility for use as cover material in the landfill or elsewhere on the Mine Site where acceptable. Naturally occurring elevated metals in the material will be considered when placing remediated soils. Once all remediated soil and bedding material have been removed, the HDPE liner will be disposed of in the landfill (if approved and the landfill is still operational) or shipped off-site for disposal. Disturbed areas will be seeded and/or planted to establish ground cover as soon as possible (site-specific prescription will be developed based on the outcomes of reclamation research).

7.9.4 Erosion and Sediment Control

Erosion and sediment control during reclamation and closure works will be the responsibility of Newmont if the work is self-performed, or the Prime Contractor on site. These measures will be implemented prior to and during construction to minimize erosion and sediment discharge into surrounding areas. These measures reduce the potential for erosion by stabilizing exposed soil or by reducing surface runoff and flow velocities. The site will be assessed before and during construction activities to determine the need for various erosion and sediment control provisions. Best practices such as diversion ditches, straw bales, sediment traps, and silt fences will be field-fit with approval from the engineering team. The Erosion and Sediment Control Plan developed for Construction and Operation Phases will be used to guide sediment and erosion control during the Closure Phase.

7.9.5 Revegetation

Construction during reclamation and closure works will generally occur within areas which were disturbed during operations in order to limit the required re-establishment of a natural vegetative cover. Re-vegetation following closure of specific mine components is generally described in the above paragraphs. Disturbed areas will generally be graded to reduce erosion and promote positive surface water drainage. A specified seed mix of native plants will be spread using equipment or by hand over the graded areas. If any areas require quick vegetation growth to achieve erosion control, hydroseeding will be considered. Revegetation research programs are currently underway to refine the site-specific revegetation prescriptions as described in Section 2.3.1.

7.9.6 Soil Salvage

Continuous salvage and stockpiling of reclamation material will be carried out throughout the Construction and Operation Phases to provide reclamation material for the site components that are planned to be covered with material in closure. Effective soil salvage will provide suitable material to restore ecosystems and reduce infiltration. Newmont will develop soil stockpile and salvage guidelines for the Project that will be optimized throughout operations based on material volumes and quantities. The guidelines will include strategic stockpile placement based on source and use locations to reduce costs associated with long haul distances and re-handling, and will also contain the following details:

- Segregate organics rich overburden from mineral overburden to the extent practical. Segregation will be informed by thickness of the organic rich horizon:
  - if greater than 30 cm, can be segregated from mineral overburden below
  - if less than 30 cm, segregation may not be practical using equipment available at the site.
- To not bury soil resources if they can be safely salvaged
- Salvage all salvageable soil as defined in Section 5.3.3.2 and act on opportunities to increase salvage volumes as they arise
- To consider progressive reclamation opportunities, cost-effective handling options, minimizing soil loss, degradation, or contamination
- Progressively update the soil stockpile and salvage guidelines concurrent with updates to the RCP and mine development
- Qualified personnel will be on-site during site preparation activities to guide material segregation and management. Stockpiles may be segregated in multiple lifts if overburden material conditions allow. Maintenance measures to reduce erosion of the stockpiles will be implemented as described in the Erosion and Sediment Control Plan.

7.10 Material Balance

Material balance estimates were prepared in 2018 and 2019 to determine the approximate quantity of material that would be moved during the construction activities for the Project. Overall estimates of available reclamation material range from 2.6 Mm^3 to 2.8 Mm^3 depending on the suitability of the material below the HLF. Overburden is classified as organics, silt layer, gravel layer, and weathered bedrock. Suitable overburden for use as reclamation material includes organics, silt, and the upper 20 cm of gravel, which will be managed to segregate the organics rich overburden from the mineral overburden to the extent practical (Section 7.9.6). The overall volume (including material outside the HLF foundation), and suitability

of frozen material for use as reclamation material remains an uncertainty for the project given depth of refusal for test pitting programs.

7.10.1 Required Materials

A variety of cover system scenarios were evaluated as part of the HLF cover system design to determine reclamation material requirements based on potential cover system thicknesses. The assessment also investigated a variety of options for cover system application across the site to determine reclamation material requirements. A reclamation material priority evaluation was carried out to determine where cover would be established following closure of various site components. The priority list evaluation determined that the HLF including event ponds is the highest priority component to receive reclamation material, followed by the Alpha WRSF, Alpha Pond/Dam, Kona Pit, and the Double Double Pit as described in the Heap Leach Facility Cover Design Report (Appendix 7-B). The priority sequence for cover material application will be refined through collaboration with stakeholders and First Nations.

The base case cover design includes a 0.5 m store and release cover system, based on constructability and likely performance requirements. Figure 7-28 provides an overview of the material required for the base case cover design at the site and indicates sensitivities for the amount of inorganics that are suitable for reclamation. The material balance for the base case design indicates a surplus of suitable material available for reclamation activities.

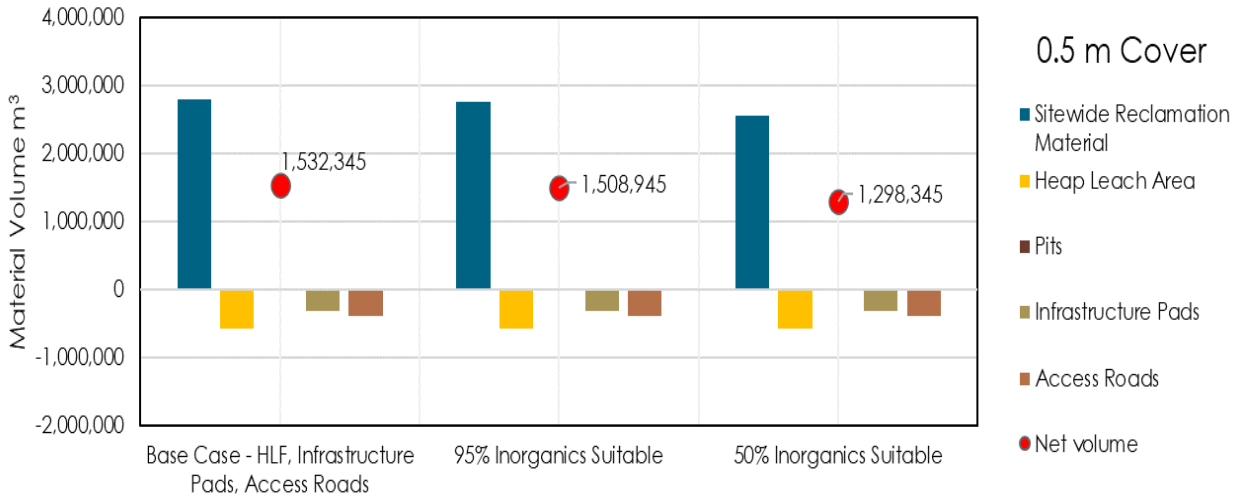

Figure 7-28 Base Case Cover System Material Requirements

7.10.2 Borrow Material and Locations

Table 7-13 shows reclamation material volumes by location and type based on the most recent design work. This represents the overburden material that is estimated to be removed during the Construction and Operation Phases. These volumes will be re-evaluated during construction and operations, and an updated material balance will be developed for confirmation of available reclamation materials. Additional information regarding the estimated material balance is provided in the Surface Material for Reclamation Report (JDS 2018), the Coffee Project Material Balance Report (Appendix 7-C), and the Heap Leach Facility Cover Design Report (Appendix 7-B).

7.11 Maintenance, Monitoring and Reporting Activities

This section describes the monitoring activities that are planned for the Closure Phase and, if relevant, the Post-Closure Phase to confirm the effectiveness of reclamation and closure measures (in accordance with Project-specific closure objectives outlined in Section 3.1.3) and inform adjustments for subsequent RCP iterations. The monitoring activities presented here are conceptual and will be refined as project planning advances. The key objectives that will be informed by monitoring results include:

- All mine-related infrastructure is physically and chemically stable and performing in accordance with designs, which take into consideration longer term risks such as for severe climatic and seismic events.
- Protect and maintain the land, air, and water in a condition that provides for sustainable use.
- Ensure water remains substantially unaltered from pre-mining conditions to the extent practicable with respect to quantity, quality, and rate of flow, including seasonal rate of flow. Pre-mining conditions refers to the state of land, air, water, and resources prior to Project-related activities and disturbances associated with both exploration and mining.
- Protect health and safety of people and area wildlife using and accessing the site by emulating pre-mining conditions to the extent possible.
- Protect or enhance ecological processes and functions in order to maintain ecosystem condition and support diverse, productive, and self-sustaining biological communities, with assemblages and abundances of species that are typical for the geographic area and are consistent with site capabilities that emulate pre-mining conditions.
- Protect and maintain environmental quality (a combination physical and chemical stability as well as ecological processes and functions) consistent with the principle of Sustainable Development. Sustainable Development, as defined in the Umbrella Final Agreement, means beneficial socio-economic change that does not undermine the ecological and social systems upon which communities and societies are dependent.

- Restore lands affected by mining-related activities to allow for future land use similar to surrounding areas to the extent practicable.
- To protect the long-term optimal productivity, quality, and diversity of the traditional economy, including the health and viability of country foods and other harvestable resources.
- Restore views at the site to pre-mining conditions to the extent practicable to facilitate learning and teaching on the land.
- Minimize the need for long-term operations, maintenance, and monitoring after reclamation activities are complete by reducing outstanding liabilities and risks.

The objectives of environmental monitoring, surveillance, and reporting activities with respect to the eventual closure of the Project are to:

- Track the effects of the Project on the environment relative to predicted outcomes.
- Assess the effectiveness of mitigation measures and inform amendments to management and mitigation plans, as necessary.
- Assess the effectiveness of reclamation and closure measures.
- Inform reclamation and closure plan adjustments, as required.

Monitoring of the following environmental components is proposed in order to verify the achievement of the above objectives:

- Meteorology
- Aquatic Conditions
- Hydrology and Surface Water Quality
- Groundwater Quality
- Wildlife
- Vegetation
- Invasive plants
- Fish and Fish Habitat
- Benthic Invertebrate
- Periphyton
- Sediment Quality.

The conceptual monitoring requirements described in this section refer to the period from the commencement of the Post-mining Closure Phase to the end of the Post-closure Phase. The intensity of monitoring is likely to decrease with the progression of the Project into subsequent stages, and in general, monitoring programs will continue until predicted Project-related effects are confirmed or the success of reclamation efforts has been ascertained.

The details of these monitoring programs during the Operation Phase are provided in the EMAMP; however, a summary of the programs as they are to be implemented during the Closure and Post-closure phases is provided below.

7.11.1 Meteorological Monitoring

Meteorological monitoring refers to the collection of high-quality and site-specific climate data, including air temperature, precipitation, wind speed and direction, relative humidity, atmospheric pressure, solar radiation, snow depth, and snow water equivalent. The collection of meteorological data is closely tied to the monitoring of surface water hydrology, surface water quality, groundwater quantity and quality and air quality. The meteorological monitoring program is designed to capture temporal and spatial variability in key climate parameters at the site in such a way that these data can be robustly linked to the data collected by other monitoring programs. For example, short-term trends in water quality at a monitoring location may be caused by wetter or drier than average conditions, and not by changing geochemical factors.

The ongoing monitoring of site climate conditions will be used in the periodic updates of the site-wide water balance and water quality model (WB/WQM) and will aid in the interpretation of the monitoring results from other monitoring programs (e.g., water quality, aquatic biota, etc.).

The meteorological monitoring network consists of two climate stations with full instrument suites, and multiple snow courses situated at various elevations and aspects around the Project site. A Campbell Scientific automated weather station was installed in July 2012 and is located roughly 5 km to the east of the main Project infrastructure (i.e., heap leach, pits, waste rock storage areas) at elevation 975 masl (Table 7-14). This is referred to as the KM 11 climate station, and data is downloaded manually on a monthly basis. A second automated weather station was installed at high elevation (~1,340 masl) and adjacent to the proposed heap leach pad footprint (i.e., ~400 m to the northwest of the HLF) in October 2018. This station is referred to as the Kona climate station, and is equipped with a satellite transmitter, which uploads the climate data to a web server on an hourly basis. This will allow real-time assessment of station performance, battery health and upper elevation climate conditions in support of exploration and mining operations.

Snow courses were also established in 2012 at various elevations/aspects (i.e., low, mid and high elevation), oriented to discern effects of aspect on local snow accumulation and melt (Figure 7-29). Snow courses are surveyed at, or near, peak seasonal accumulation, over a 12-day window centred on Mar. 1 and Apr. 1, at ridgetop, climate station, mid-elevation and valley bottom sites (Figure 7-29).

Table 7-14 Meteorological Monitoring Station Locations

Station	Type	Parameters*	Latitude (°N)	Longitude (°W)	Elevation (m asl)	Sampling Frequency
IC-1.5_SS	Snow Course	SD, SWE, Density	62.915	-139.579	524	Monthly (Feb, Mar, Apr, May)
CC-EAST-1_SS	Snow Course	SD, SWE, Density	62.872	-139.394	1,220	Monthly (Feb, Mar, Apr, May)
KAM-WX_SS	Snow Course	SD, SWE, Density	62.873	-139.180	996	Monthly (Feb, Mar, Apr, May)
Mid-Elev-SS	Snow Course	SD, SWE, Density	62.894	-139.097	638	Monthly (Feb, Mar, Apr, May)
KM 11	Climate Station	TA, RH, WS, WD, BP, SR, PC	62.873	-139.180	975	15-minute, downloaded monthly
Kona	Climate Station	TA, RH, WS, WD, BP, SR, PC, SD	62.874	-139.434	1,340	15-minute, uploaded hourly via satellite

Notes:
TA = air temperature; RH = relative humidity; WS = wind speed; WD = wind direction; BP = barometric pressure; SR = solar radiation; PC = precipitation; SD = snow depth, SWE = snow water equivalent.

The climate stations have wind sensors mounted on the tower at 10 m above the ground surface, with the sensors for other instruments set at 2 m above ground surface. Observations are recorded to a central datalogger, complete with all-weather enclosure, battery pack, solar panel and voltage regulator. The following parameters are measured at 15-minute intervals by the two climate stations:

- Air temperature (◦C) and relative humidity (%) data
- Wind speed (m/s) and direction (0-360 degrees) measurements, including wind gust data
- Incoming solar radiation (W/m^2) and barometric pressure (mb) reading
- Snow depth (Kona station only)
- Measurements of precipitation (mm) at a tipping bucket gauge fitted with Alter shield and solid phase precipitation adaptor (Km 11 station), and a weighing cell all season precipitation gauge at the Kona station.

The full complement of climate monitoring and snow survey stations will be operated throughout the Closure Phase. During the Post-Closure phase, monitoring will likely be carried out remotely, or scaled back to a single climate station located near the HLF (Kona station) and co-located snow course.

7.11.2 Aquatic Conditions Monitoring

The program for water monitoring during the early part of the Closure Phase incorporates hydrology, surface water quality, and groundwater components (including groundwater quality and quantity). Water management activities will strive to separate contact from non-contact water to the extent practical, maximize the use of contact water for heap leach rinsing requirements, and suppress dust in disturbed areas, while the site is being reclaimed, as in the Operation Phase. These practices are expected to reduce both the volume of contact water that must be managed, and the potential of downstream effects on water quality and streamflow volumes.

The Closure Phase water monitoring program will be focused on:

- Meeting Environmental Effects Monitoring (EEM) requirements such that the Coffee Gold Mine becomes a “recognized closed mine” as defined in the Metal and Diamond Mine Effluent Regulations (MDMER)
- Meeting requirements pursuant to permits and approvals issued by the Yukon Government (as per the Quartz Mining License and Water Use Licence, and others that may apply)
- Conducting post-closure phase monitoring to verify that the site is stable.

The surface water and groundwater monitoring programs during the Closure and Post-Closure phases are structured to provide early indication of potential changes in flow sources and chemistry at the Mine Site, and potential effects down-gradient. Efforts will address three types of monitoring:

- **Mine Site** - monitor the quantity and quality of both surface and groundwater that may be potentially affected by the various mine facilities, to confirm that water management systems are effective.
- **Effluent** - monitor the quantity and quality of contact water that accumulates in sediment control ponds located downgradient of mine infrastructure and effluent from the water treatment plant to verify compliance for waters to be discharged to the environment (discharges will be subject to regulatory requirements).
- **Receiving Environment** - monitor the quantity and quality of surface water upstream and downstream of points of discharge in the receiving environment to confirm compliance with applicable regulatory requirements. A system of groundwater monitoring wells will be used to verify groundwater flow paths, and discharge rates and quality within these watersheds.

The surface water and groundwater monitoring programs for these components will be implemented in a systematic manner during the Closure Phase to obtain reliable and consistent data for comparison to previous results.

7.11.2.1 Earthworks Related Water Quality Monitoring

A water quality monitoring program will be implemented in closure to monitor for parameters associated with earthworks and construction activities, providing early warning about the onset of ARD or an increase in contaminant loading due to construction activities. The monitoring locations will focus on areas affected by construction, such as surface run-off over exposed slopes and water collected in temporary sumps and ditches. Construction water quality monitoring will consist of observations, testing, analysis, and recommendation on turbidity, total suspended solids (TSS), and contaminant loading.

Turbidity measuring equipment will be available for use by the Newmont or the contractor's environmental monitors, or as a contingency to be used by the field engineering team if the environmental monitor is not present. Water quality sampling bottles will be available to collect water samples for lab analysis of TSS if required. The senior environmental specialist will determine the specific needs for turbidity sampling equipment and water quality sampling bottles and analysis.

Event-based monitoring will be conducted by the environmental monitors during and/or following any naturally occurring or construction related discharge events that impact or have the potential to impact receiving waterbodies (e.g., if turbidity levels in the receiving environment exceed guidelines). These events include but are not limited to rainfall events, landslides, and failure of erosion and sediment control measures.

Corrective action will be implemented if there is change from background turbidity and/or TSS based on the Yukon water quality guidelines. The corrective action will be determined by the contractor with advice from the environmental monitors. The immediate response will be to identify the source of increased suspended sediment in the receiving waterbody. Corrective action will normally include stopping work and repairing or implementing additional mitigation measures. The environmental monitors will observe and document any non-conformance or environmental incident. If turbidity guidelines continue to be exceeded with the additional mitigation measures the environmental monitor will halt work in the area until turbidity levels meet guidelines.

In the event of failure of sediment or erosion control measures, increased frequency and timed intervals for turbidity sampling will be required. Sampling intervals and duration will vary with site conditions and the severity of the event; intervals may range from five minutes to one hour, with sampling normally terminated once levels have returned to baseline conditions.

7.11.2.2 Hydrology and Surface Water Quality Monitoring

Surface water monitoring is conducted within the area where the Project is reasonably expected to interact with streamflows and surface water quality, including all streams expected to receive effluent from the mine site, up to and including the Yukon River in the immediate vicinity of the confluence with Coffee Creek, YT-24, and Halfway Creek. Surface water monitoring consists of discharge and water quality monitoring at mine site locations (including effluent discharge points), and in the receiving watercourses (including reference sites) (Table 7-15 and Figure 7-30). Hydrometric monitoring includes streamflow and mine site effluent discharges, pond and pit lake levels and discharges (once the end-pit lake has reached the spillpoint elevation), and is directly linked to other aquatic ecosystem components, including surface water quality, groundwater quality and fish and fish habitat. This surface water monitoring program will serve two purposes. First, the data will be used to verify that flows and concentrations of POPCs from the mine site and in the receiving environment remain within the range of predicted outcomes made using the site-wide WB/WQM. Second, the data will allow calculation of loads (flow times measured concentrations for water quality parameters) should this become necessary as part of an investigation into an unanticipated occurrence with respect to surface water quality exceedances of licensed thresholds.

Table 7-15 Summary of Mine Site and Receiving Environment Surface Water Hydrology and Quality Monitoring Stations, Monitoring Parameters, and Frequency

Monitoring during the Post-mining and Closure Phase will be similar to the Operation Phase monitoring program, including the monitoring of the Alpha Pond and Facility Pond discharges. Continuous flow monitoring will be undertaken where continuous gauging data loggers are installed (Table 7-15) with gauging conducted monthly at stations with active discharges. While the open pits are filling with meteoric inputs, pit water levels will be surveyed to determine pit volumes and estimate a range of potential remaining time until the end pit lake reaches the spill point elevation. Pit lake water level surveys will be determined twice per year in June and October by a surveyor (with access to the water surface via pit ramps) to the end of the Closure Phase. Pit discharges to the receiving environment through the spill points (M10 through M16 and M20; Figure 7-30) will be monitored once pits are flooded and spilling by gravity drainage. In the receiving environment, continuous water levels are measured by level logger, and verified by manual gauging to maintain the rating curve for each receiving tributary. Where level loggers are not installed, flows and level are measured manually.

The Kona Tributary is included in the unlikely event that groundwater from the backfilled Kona Pit were to report into this catchment. This is not anticipated to occur, as permafrost is expected to aggrade into the backfilled Kona Pit, and this will be aided by placing waste rock into the pit in winter when the rock is frozen, limiting groundwater discharge to the near-surface active layer in summer and early autumn. The expectation is that any groundwater flow from the Kona Pit will report to the Halfway Creek catchment.

Facilities that will be decommissioned in the Closure Phase are shown as grey boxes in Table 7-15. The Facility Pond and HLF Event and Rainwater Ponds will no longer be required once the plant site and other facilities up-gradient are decommissioned and dismantled, unless deemed necessary during the Operation Phase as required for passive water treatment, and the area reclaimed as described in Section 7.3.2. The HLF will not be fully reclaimed until drain-down is completed. Excess water will be treated to remove residual cyanide, nitrogen, metalloids, and metal concentrations to acceptable concentrations.

The treatment system will make use of the HLF Ponds. Treated water of acceptable quality from the WTP will be released to the Halfway Creek drainage during the Operation Phase and into the Active Closure Phase. Upon cessation of active water treatment, the water treatment plant will be decommissioned and if required, the HLF seepage water will be directed through the HLF ponds that have been converted to passive treatment cells and ultimately into Latte Pit.

All receiving watercourse hydrometric stations are fully instrumented (i.e., staff gauge, stilling well, continuous water level recorder). Hydrologic monitoring will be undertaken on a monthly basis (dataloggers downloaded where they have been installed, and spot flow measurements taken at all stations) in the open water season (May through October). Monitoring will be discontinued in winter, and instrumentation will be removed for the winter months.

The Operation Phase surface water quality monitoring program will be maintained, with the following exceptions:

- Discharge from the Alpha Pond and Facility Pond will continue to be sampled weekly, and annual toxicity testing undertaken, according to the Water Use Licence (WUL) and Quartz Mine Licence (QML) conditions. These ponds will be decommissioned during the Active Closure Phase once water quality has stabilized, and these water management features are no longer required.

- Similarly, pit lake monitoring, including level surveys and water quality sampling, discharge flows and concentrations may be terminated if water quality conditions within the pit lakes stabilize such that there is no anticipated negative residual effect on receiving watercourse water quality.
- Monitoring may be terminated at a small number of receiving environment stations, recognizing that downstream monitoring will not be relevant if water quality is at background concentrations and/or consistently below the applicable water quality guidelines for the protection of aquatic life at stations closer to the mine, and/or higher up in a given catchment.

Surface water quality monitoring will continue at sites downstream of discharge points as per the requirements of the WUL and QML (Table 7-15) but will be discontinued once the site is deemed a "recognized closed mine". Samples will be shipped to an accredited laboratory and are analyzed for physical parameters, major ions, nutrients, total and dissolved organic carbon, weak acid dissociable (WAD) cyanide, and total and dissolved metals. The full list of parameters that are analyzed, and detection limits, are provided in Table 7-16.

7.11.2.3 Groundwater Quality Monitoring

Both groundwater flows and groundwater quality will be monitored during the Post-mining Closure, Active Closure, and Post-closure phases to detect any changes in groundwater pressure (i.e., water table elevations), or groundwater quality that may be caused by mine operation and closure activities.

The groundwater monitoring network includes the following instrumentation:

- Westbay® multi-level monitoring installations to monitor groundwater levels and groundwater quality on a discrete basis

- Vibrating wire piezometers (VWPs) to measure groundwater levels and temperature on a continuous basis
- Shallow and deep conventional groundwater monitoring wells to monitor groundwater levels on a continuous basis and groundwater quality on a discrete basis.

Groundwater monitoring station locations and monitoring frequencies are provided in Table 7-17 and shown on Figure 7-31. Locations were chosen to provide data adjacent to the mine facilities and in down-gradient locations along groundwater flowpaths to surface water surface receptors.

During the Post-mining Closure Phase (Year 10-15), most monitoring wells and Westbay systems will be sampled for water quality on a quarterly basis. The exception is the nested well pair MW14-03A/B, which will be monitored for water levels only as this well pair is not optimally located to detect seepage from the Latte Pit. In its place, a new monitoring station, MW-02WB (well or Westbay, to be determined) will be monitored for water quality. MW-02B will be initiated during operations and will be better positioned to detect seepage from Latte Pit.

During the Post-mining Closure Phase (Year 10-15), a new thermistor will be installed in the backfilled Kona Pit to monitor ground temperatures. This station, plus, other VWP/thermistor stations and conventional monitoring wells equipped with loggers will be downloaded on a quarterly basis.

During the Active Closure Phase (Year 16-20), groundwater quality sampling will decrease in frequency to twice per year, with loggers at monitoring wells and VWP/thermistor installations downloaded during the sampling events. The number and location of monitoring stations will remain consistent with those identified for the Post-mining Closure Phase (Year 10-15).

The Post-closure monitoring program is designed to focus on the receiving environment rather than focus on the areas immediately adjacent to mine facilities. It is assumed that monitoring conducted during Post-mining and Active Closure Phases will establish trends at these facilities. Draindown and progressive reclamation of the HLF is expected to eliminate the need for continued groundwater monitoring adjacent to the facility.

During Post-closure (Year 21+), the monitoring frequency is reduced to one event per year, with the number of monitoring locations streamlined to six sentinel stations located in the four project drainages (Halfway Creek, Latte Creek, YT-24, and Kona Tributary):

- MW15-01WB and MW15-02AZ: the Westbay well and shallow conventional well in overburden will be used to monitor the groundwater flowpath from Supremo and Double Double Pits towards Latte Creek
- MW15-04WB: this Westbay well will monitor groundwater draining Supremo Pit and Alpha WRSF downgradient of the Alpha Pond in Halfway Creek
- MW-05WB: this Westbay well will monitor groundwater potentially draining from the backfilled Kona Pit towards Independence Creek via the Kona Tributary
- MW15-01WB: this Westbay well will monitor groundwater draining from the Supremo Pit towards YT-24.

These monitoring locations listed above are co-located with VWP/thermistor installations. It is suggested that these VWPs continue to be downloaded while they are operational, however, the VWPs need not be replaced if they become non-operational as the adjacent Westbay will provide water level data.

The extensive groundwater monitoring program prescribed in the Construction, Operations, Post-mining Closure, and Active Closure Phases will serve to bolster the groundwater model calibration for the site, which in turn will be used evaluate the appropriateness of the monitoring network through all stages of mine life, including the Post-closure Phase. Alternative or additional Post-closure groundwater monitoring stations may be contemplated should groundwater quality monitoring or groundwater modeling outcomes suggest they are warranted.

Table 7-17 Groundwater Monitoring Well, Thermistor and Vibrating Wire Stations and Monitoring Frequency

7.11.3 Wildlife Monitoring

All project personnel will be responsible wildlife awareness and reporting wildlife encounters. Wildlife monitoring will be conducted under the supervision of the environmental monitor, and a wildlife encounter log will be maintained. All project personnel will be trained on wildlife encounter procedures as per the site-specific safety plan. The environmental surveillance and monitoring programs that will be carried out to monitor the occurrence of wildlife during the Closure Phase include the following:

- Wildlife Observation Monitoring
- Project-related Wildlife Mortality Monitoring.

Table 7-18 and Table 7-19 summarize the wildlife monitoring programs that will be carried out in closure. Based on results of the monitoring programs that are implemented during the Construction and Operation Phases as described in the EMAMP, the monitoring programs in closure may be expanded to include additional monitoring for Project-related effects on wildlife. Details for the wildlife closure monitoring programs will be advanced throughout mine operations and will be provided in future RCP iterations. Outcomes of the closure wildlife monitoring program will inform potential mitigative or adaptive management actions to minimize project-related effects on wildlife.

Table 7-18 Overview of Wildlife Observation Monitoring Program

Monitoring Component	Description
Indicator	Wildlife presence – all species
Monitoring Category	Environmental surveillance
Design	Observational
Measurable Parameter	Occurrence of wildlife use
Key Project Interactions	The Project may result in habitat loss, sensory disturbance, and increased mortality risk for wildlife.
Threshold	N/A - Data will be used to support other monitoring programs and inform adaptive management where applicable.
Objective	To document wildlife presence in the Project area, including interactions with personnel and facilities.
Scope of Monitoring Work	All wildlife sightings within the Project LSA will be documented in the Wildlife Log. Monitoring will be ongoing throughout the life of the Project.
Monitoring Frequency	Wildlife observation monitoring will be ongoing throughout the life of the Project, including through the Closure Phase and the Post-closure Phase. It will be conducted on an opportunistic basis as wildlife are observed by Project personnel on site.

Table 7-19 Overview of Project-related Wildlife Mortality Monitoring Program

Monitoring Component	Description
Indicator	Wildlife mortality – all species
Monitoring Category	Environmental surveillance
Design	Observational
Measurable Parameter	Occurrence of Project-related wildlife mortality
Key Project Interactions	The Project has the potential to increase mortality risk for wildlife directly through vehicle collisions and interaction with mine site infrastructure.
Threshold	Every Project-related mortality involving an ungulate or large carnivore will be reviewed to determine if further action is needed. Other mortalities will be dealt with on a species-by-species basis.
Objective	To document wildlife mortality and determine cause to reduce the risk of similar wildlife mortality in the future.
Scope of Monitoring Work	All Project-related wildlife mortalities within the Project LSA will be documented. Monitoring will be ongoing throughout the life of the Project as mortality occurs.
Monitoring Frequency	All Project-related wildlife mortalities within the Project LSA will be documented. Monitoring will be ongoing throughout the life of the Project as mortality occurs, including during the Closure Phase and the Post-Closure Phase.

7.11.4 Vegetation Monitoring

The vegetation monitoring program that will be implemented during the Closure Phase includes the Habitat Loss/Habitat Reclaimed Monitoring Program and will be an extension of the program that will be implemented during the Construction and Operation Phases. Table 7-20 provides an overview of the closure Habitat Loss/Habitat Reclaimed monitoring program.

In addition to the program described below, closure monitoring for metals uptake in vegetation that has established on bare waste rock will be carried out through an extension of the revegetation reclamation research program as described in Section 2.3.1. Details for the vegetation closure monitoring programs will be advanced throughout mine operations and as results from vegetation monitoring during the Operation Phase are made available. Outcomes of the closure vegetation monitoring program will inform potential mitigative or adaptive management actions to minimize project-related effects on vegetation.

Table 7-20 Overview of Habitat Loss/Habitat Reclaimed Monitoring Program

Monitoring Component	Description
Indicator	Ecological Communities
Monitoring Category	Environmental Effects
Design	Project footprint survey with focus on the mine area and new quarry/borrow sites along the NAR.
Measurable Parameters	Size of the footprint (comparison of proposed footprint and actual area disturbed; ha)
Key Project Interactions	Direct habitat loss in the mine area footprint (either temporary or permanent). Project activities will result in direct loss of ecological communities including wetland habitats, traditional and medicinal plants, and rare plants.
Goal	The Project will not exceed the extent of the proposed footprint; progressive reclamation will take place during operations.
Objective	Ensure that the Project footprint within area of new disturbance (i.e., the mine area and new quarry/borrow sites along the NAR) is within the proposed limit; quantify the amount of habitat loss and habitat reclaimed.
Threshold	Exceedance of proposed mine area footprint
Scope of Monitoring Work	Habitat loss/habitat reclaimed monitoring will be conducted along the boundary of the mine area footprint at the mine area which encompasses the proposed mine site, mine access route, and airstrip up to the boundary of the NAR. It will also be conducted at new quarry/borrow sites along the NAR. Monitoring will be conducted using the most appropriate technology available, (which may include aerial mapping, surveys, handheld GPS or drone) to measure the extent of the mine area footprint by walking the perimeter of the footprint where surface disturbance is observed. Similar methodology will be used to measure the extent of progressive reclamation in the areas. The size of the footprint (ha) will be compared between actual area disturbed and the proposed footprint.
Frequency	The Habitat Loss/Habitat Reclaimed monitoring will be completed during construction, operations, and reclamation and closure. During construction and operations, monitoring will be conducted once annually to capture the direct loss of vegetation from clearing activities and to track locations that are progressively reclaimed. During reclamation and closure, monitoring will be conducted every three years, or as determined by reclamation efforts, to capture on going revegetation activities.

7.11.4.1 Invasive Plant Monitoring

Invasive plants are those that are introduced by humans to areas outside of their natural range of distribution, where they become established and disperse, generating a negative impact on the economy, environment, and social realms (IUCN 2011). Potential Project-related effects include changes to plant composition and possible loss of native plant species, due to the introduction and spread of invasive plants in the Project area through physical disturbance and vehicle transport. Newmont will implement mitigation measures for invasive plant species across the Project area and will actively manage for invasive plants to prevent invasive species spread south of the Yukon River throughout the Project. In addition, Newmont will quantify the presence and abundance of invasive plant species within and adjacent to the Project footprint south of the Stewart River.

The invasive plant closure monitoring program will be a continuation of the invasive plant monitoring program that will be implemented during the Construction and Operation Phases as described in the EMAMP. The results of invasive plant monitoring will be used to:

- Guide the targeted removal of any Rank 1 invasive species identified in the Project area south of the Yukon River (refer to the Vegetation Protection Plan for further details on the methods for invasive plant removal
- Monitor and document any spread of invasive plant species along the southern sections of the NAR (i.e., between the Stewart and Yukon Rivers).
- Document the effectiveness of Project mitigation measures for invasive plants and, if necessary, inform adjustments to mitigation practices.

Table 7-21 provides an overview of the invasive plant monitoring program that will be implemented in during the Closure Phase. Monitoring will be carried out annually in closure, with reduced monitoring frequency as the Project enters advanced stages of closure, which will be determined by results of previous monitoring activities, consideration of adaptive management, or incidental observations. Sample site selection will consider potential entry points and locations where there is a high volume of humans, vehicles, and equipment entering or leaving the mine area footprint south of the Yukon River, including mine infrastructure, laydown areas, access roads, airstrip, and camp facilities. The invasive plant monitoring areas are provided on (Figure 7-32).

Monitoring methods will include roadside driving and walking surveys, as well as observations during other environmental monitoring programs and routine monitoring tasks within the Project footprint. Further details regarding invasive plant species monitoring methods are provided in the EMAMP.

Table 7-21 Overview of Invasive Plant Monitoring

Monitoring Component	Description
Indicator	Invasive plant species
Monitoring Category	Environmental Effects
Design	Project footprint survey; presence and absence sampling
Measurable Parameter	Occurrence of invasive plants in the Project footprint south of the Stewart River; density distribution class
Key Project Interactions	Introduction of invasive plant species causing habitat loss for native plant species and possible change of plant composition
Goal	The Project minimizes the potential introduction and spread of invasive plant species
Objective	1) To quantify the presence and abundance of invasive plant species within and adjacent to the Project footprint south of the Yukon River to aid in the management of invasive plants 2) To document any spread of invasive plant species along the southern sections of the NAR between the Stewart River and the Yukon River.
Threshold	No introduction of invasive plant species within and adjacent to the Project footprint south of the Yukon River as a result of Project activities
Scope of Monitoring Work	Invasive plant monitoring will be conducted in the Project footprint south of the Stewart River. Monitoring will be conducted using presence and absence sampling methods to determine abundance and density distribution of invasive species. A combination of roadside driving at slow speeds in a vehicle or UTV averaging 20 km/hr and walking surveys will be used to monitor linear and non-linear (localized) features. Invasive plant monitoring will be completed annually during construction and operation.

7.11.5 Fish and Aquatic Life Monitoring

7.11.5.1 Fish and Fish Habitat Monitoring

Closure of the Project has the potential to affect the fish and fish habitat VC and/or the periphyton and benthic invertebrates IC by physical disturbance, flow alteration, toxicity, and productivity alteration. The objective of fish and fish habitat monitoring is to assess the key Project interactions and predicted residual effects in comparison to baseline and reference conditions in a quantitative and statistically robust manner (where possible), and to also comprehensively monitor aquatic environments that could potentially be influenced by Project activities. The following Fish and Fish Habitat components will be monitored:

- Fish community (general abundance/diversity)
- Fish condition
- Fish habitat.

Fish community sampling includes assessing fish species diversity, condition, and general catch per unit effort (CPUE) results through sampling efforts[13]. Sampling methods will include electrofishing (open site), minnow trapping, and beach seining, where appropriate.

The fish and fish habitat monitoring program will focus on measurements of fish habitat attributes within fish-bearing locations downstream of the mine infrastructure index areas for each stream. Specifically, stream habitat units (i.e., riffles, pools, and glides) will be delineated and measured (width, length, and depth) and bed materials within each unit will be documented. Wolman Pebble Counts and hourly water temperature data will also be collected. The monitoring locations and timing will be consistent with fish sampling efforts. An overview of the monitoring program for fish community and condition as well as fish habitat quality are provided in Table 7-22.

Monitoring for fish community, condition, and habitat will be at stations on Latte, YT-24, Halfway and Coffee Creeks, with reference sites on upper Carlisle, Independence and an unnamed stream south of YT-24 (SYT; Figure 7-33). During mine operations and during the Closure Phase of the Project, fish and fish habitat monitoring will be conducted at all the same stations as during the construction phase. Fish and fish habitat monitoring locations and frequency throughout the Construction, Operation, and Closure Phases are provided in Table 7-23.

Post-closure, fish and fish habitat monitoring will only be conducted in the event that site-specific water quality objectives are not maintained or if identified thresholds were recently exceeded and monitoring of adaptive management actions are required. Further details regarding fish and fish habitat monitoring are provided in the EMAMP.

13 As reported in EDI (2018), low fish densities in receiving waters do not allow for statistical confidence when evaluating CPUE data.

Table 7-22: Overview of Fish Community, Condition and Habitat Monitoring

Monitoring Component	Description	
	Fish Community Sampling and Fish Condition	Fish Habitat Quality
Monitoring Category	Environmental Effects	Environmental Effects
Design	Before-After-Control-Impact (BACI)	Before-After-Control-Impact (BACI)
Measurable Parameters	Fish CPUE, fish species diversity, Fulton's condition factor, presence of various stages/ages (based on length/weight data).	Number and depth of pools; channel width.
Key Project Interactions	Changes in water quality/quantity, changes in prey item availability and habitat primary productivity.	Changes in water quality (sediment mobilization/deposition) and quantity (erosion).
Goal	The Project will not have a significant adverse effect on fish populations, including community structure or fish condition.	The Project will not have a significant adverse effect on fish habitat when compared to control/reference areas.
Objective	Evaluate how the Project may influence fish use and fish condition in habitat downstream of the Project.	Evaluate how the Project may influence habitat in fish-bearing streams downstream of the Project.
Scope of Monitoring Work	Fish sampling in receiving watersheds, including Latte, Halfway, and YT-24 Creeks and reference sites via electrofishing. Sampling will also be conducted in Coffee Creek via beach seining, electrofishing, and minnow trapping. Monitoring to be conducted annually during Construction and then every three years during Operation, Reclamation and Closure.	Detailed habitat assessment in receiving watersheds, including Halfway, Latte, YT-24, and Coffee Creeks (at fish-bearing monitoring stations) and a matched reference area. Monitoring to be conducted annually during Construction and then every three years during Operation, and Reclamation and Closure.
Mitigation Measures	Erosion and sediment control within the footprint of the Mine Site. Water management within the footprint of the Mine Site to prevent or reduce changes in the downstream aquatic environment.	Erosion and sediment control within the footprint of the Mine Site. Water management within the footprint of the Mine Site to prevent/reduce changes in the downstream aquatic environment.
Project Terms and Conditions	To be determined following YESAA and Yukon Water Board process	To be determined following YESAA and Water Board processes

7.11.5.2 Benthic Invertebrate Monitoring

The benthic invertebrate monitoring program includes benthic invertebrate productivity, benthic invertebrate community, and benthic invertebrate tissue quality. Benthic invertebrate monitoring is focused on Halfway Creek, YT-24 Creek, Latte Creek, and Coffee Creek, with sampling areas located in the upper reaches (considered to be most sensitive to potential Project-related changes due to highest potential for mine-related change) and the lower reaches which are occupied by fish (Figure 7-34). An overview of the benthic invertebrate monitoring program is provided in Table 7-24.

Benthic invertebrate monitoring will be completed through construction, operations, and reclamation and closure, as summarized in Table 7-25. During the Closure Phase of the Project, the benthic invertebrate monitoring program will be conducted every two years (subject to adaptive management). Post-closure, monitoring will only be conducted in the event that site-specific water quality objectives are not maintained or if identified thresholds were recently exceeded and monitoring of adaptive management actions are required. Additional details on benthic invertebrate monitoring are provided in the EMAMP.

Table 7-24 Overview of Benthic Invertebrate Monitoring

Monitoring Component	Description
Indicators	Benthic Invertebrate Productivity, Community Structure, and Tissue Quality
Monitoring Category	Environmental Effects
Design	Multiple Control-Impact Approach (MCI) and Before-After/Control-Impact (BACI)
Measurable Parameters	Biomass (dry weight/m^2), density (organisms/m^2), taxon richness, %EPT[1], %mayflies, %HPG[1], %FFG[1], metal concentrations in composite samples
Key Project Interactions	Changes in surface water hydrology and surface water quality
Goal	The Project will not have a significant adverse effect on benthic invertebrates when compared to baseline and/or reference conditions
Objective	Evaluate how the Project may influence benthic invertebrates
Scope of Monitoring Work	Benthic invertebrate community samples will be collected at five stations per area by Hess sampler (3-grab composites, 500 µm mesh, lowest practical level taxonomy) and analyzed following guidance for MDMER-EEM. Sampling areas will include upper areas on Halfway Creek, YT-24, and Latte Creek and two matched reference creeks. Lower areas on the same creeks (with Coffee Creek replacing Latte Creek) will also be evaluated using a similar design (with separate lower reference creeks). Monitoring of upper creek areas will be conducted at least once during Construction, annually in upper creek stations for the first three years of Operation, and every two years for subsequent years of Operation and during Reclamation and Closure. Monitoring of lower creek areas will be the same as for upper Creek areas, except for every 2 years through all years of Operation. Monitoring will be subject to Surface Water Quality and Aquatic Life AMP triggers for higher frequency based on Fish and Aquatic Life Monitoring Plan (FALMP) findings.
Mitigation Measures	Erosion and sediment control within the footprint of the Mine Site. Water management within the footprint of the Mine Site to avoid/reduce changes to the downstream aquatic environment.
Project Terms and Conditions	To be determined following YESAA and *Yukon Waters Act* licencing processes

[1]EPT = ephemeroptera, plecoptera, trichoptera (mayflies, stoneflies, and caddisflies); HPG = habit preference group; FFG = functional feeding group

[2] Where a significant change is a statistically significant difference of greater than two standard deviations of the reference mean.

Benthic Invertebrate and Periphyton Monitoring Areas, Coffee Project FALMP

Date: March 2022
Project 217202.0040

minnow environmental inc.

Figure 7-34

Document Path: C:\Users\MLaPalme\Trinity Consultants, Inc\Newmont - 217202.0040 - Coffee AEMP and Permitting 2020\D - GIS\AEMP Design\21-40 Figure 4-1 BI and Periphyton Monitoring Areas, Coffee Project FALMP.mxd

7.11.5.3 Periphyton Monitoring

Periphyton represents an important component of aquatic food webs in creeks and consists of a complex matrix of organisms. Periphyton generally includes algae, fungi, bacteria, and protozoa attached to submerged substrate, and are an indicator of primary productivity in creeks. Key Project interactions with periphyton include predicted residual changes in surface water hydrology (flow reductions or increases with changes to the seasonal distribution of low and high flows) and changes in surface water quality (some localized increases in concentrations of sulphate, nitrate, arsenic, and/or aluminum) in Latte Creek, YT-24 Creek, and/or Halfway Creek. The design of the periphyton monitoring program is similar to that for benthic invertebrates and includes periphyton productivity and periphyton community. As with benthic invertebrate monitoring, periphyton monitoring is focused on Halfway Creek, YT-24 Creek, Latte Creek, and Coffee Creek (Figure 7-34). An overview of the periphyton monitoring program is provide in Table 7-26.

Periphyton monitoring will be completed through construction, operations, and reclamation and closure, as summarized in Table 7-27. During the Closure Phase of the Project, the periphyton monitoring program will be conducted every two years. Post-closure, monitoring will only be conducted in the event that site-specific water quality objectives are not maintained or if identified thresholds were recently exceeded and monitoring of adaptive management actions are required. Further details regarding periphyton monitoring are provided in the EMAMP.

Table 7-26 Overview of Periphyton Monitoring

Monitoring Component	Description
Indicators	Periphyton Productivity and Community Structure
Monitoring Category	Environmental Effects
Design	Multiple Control-Impact Approach (MCI) and Before-After/Control-Impact
Measurable Parameters	Biomass (ash free dry mass/m^2), chlorophyll-a (mg/m^2), taxon richness, %green algae, %blue-green algae, %diatoms
Key Project Interactions	Changes in surface water hydrology and surface water quality
Goal	The Project will not have a significant adverse effect on periphyton when compared to baseline and/or reference conditions
Objective	Evaluate how the Project may influence periphyton
Scope of Monitoring Work	Periphyton samples will be collected at five stations per area by scraping carefully recorded surface areas to provide three samples, one for ash free dry mass, one for chlorophyll-a, and one for taxonomy. Sampling areas will include upper areas on Halfway Creek, YT-24, and Latte Creek and two matched reference creeks. Lower areas on the same creeks (with Coffee Creek replacing Latte Creek) will also be evaluated using a similar design (with separate lower reference creeks). Monitoring of upper creek areas will be conducted at least once during Construction, annually in upper creek stations for the first three years of Operation, and every two years for subsequent years of Operation and during Reclamation and Closure. Monitoring of lower creek areas will be the same as for the upper Creek areas except that it will be every 2 years throughout Operation.
Mitigation Measures	Erosion and sediment control within the footprint of the Mine Site. Water management within the footprint of the Mine Site to avoid/reduce changes to the downstream aquatic environment.
Project Terms and Conditions	To be determined following YESAA and *Yukon Waters Act* licencing processes.

Table 7-27: Periphyton Monitoring Areas and Frequency

Station	Area	Mean* Coordinates (UTM Zone 7)		Rationale for Inclusion	Frequency		
		Easting	Northing		Construction	Operation	Reclamation and Closure
Halfway Creek Watershed							
HF6.8	Upper Halfway Creek	584040	6976554	Downstream of influence	Annually	Annually**	Every 2 Years
HF0.2	Lower Halfway Creek	588708	6980454	Downstream of influence	Annually	Every 2 Years	Every 2 Years
Latte Creek Watershed							
LC10.2	Upper Latte Creek	586245	6971292	Downstream of influence	Annually	Annually**	Every 2 Years
Coffee Creek Watershed

Upstream Reference Area 2							
CF23.7	Coffee Creek	597045	6961892	Reference Area	Annually	Annually**	Every 2 Years
Downstream Reference Area 1							
XE0.2	Creek East of Excelsior	605198	6974086	Reference Area	Annually	Every 2 Years	Every 2 Years
Downstream Reference Area 2							
SYT0.6	Stream South of YT-24 Creek	590395	6978316	Reference Area	Annually	Every 2 Years	Every 2 Years

*Mean of n = 5 stations per area
**Sampling will be conducted annually for first three years of the Operation phase. Sampling will be conducted every two years after year three if that change in sampling effort is deemed appropriate. Annual frequency is the maximum recommended for temporal comparison and both annual and bi-annual frequencies are appropriate to detect potential changes and meet or exceed standard recommended frequencies AEMP and/or EEM biological studies.

7.11.5.4 Sediment Quality Monitoring

Key Project interactions with sediment include predicted residual changes in surface water hydrology (flow reductions or increases with associated changes to the seasonal distribution of low and high flows that can affect levels of suspended solids) and changes in surface water quality (some localized increases in concentrations of sulphate, nitrate, arsenic, and/or aluminum that could affect sediment quality) in Latte Creek, YT-24 Creek, and/or Halfway Creek. The objectives of stream sediment quality monitoring are to assess the key Project interactions in comparison to baseline and reference conditions and sediment quality guidelines for the protection of aquatic life (CCME 2000b). Sediment quality monitoring is an independent monitor of potential Project-related influence and provides supporting data for the interpretation of benthic invertebrate monitoring data.

An overview of the sediment monitoring program is provided in Table 7-28. The design of the monitoring program includes physical characteristics (particle size distribution and organic carbon content) and chemical characteristics (nutrients and metal concentrations). Sediment quality monitoring will be completed through construction, operations, and reclamation and closure as summarized in Table 7-29.

During the Operation Phase and during the Closure Phase, sediment quality monitoring will be conducted every two years. Post-closure, sediment quality monitoring will only be conducted in the event that water quality objectives are not maintained or if identified thresholds were recently exceeded and monitoring of adaptive management actions are required. Sediment quality monitoring will be undertaken in the late summer to ensure comparability over time. To simplify monitoring logistics and to facilitate linkages among monitoring components, sediment monitoring will be completed at the same time as benthic invertebrate and periphyton monitoring, although the actual location of the stations will differ to accommodate the requirement for in-creek sediment deposition. Stream quality monitoring locations are shown on Figure 7-34. Further details regarding the sediment monitoring program are provided in the EMAMP.

Table 7-28 Overview of Sediment Monitoring

Monitoring Component	Description
Indicator	Sediment Quality
Monitoring Category	Environmental Effects
Design	Before-After
Measurable Parameters	Particle size distribution, total organic carbon content, total nitrogen, total metals scan (ICP-MS[1] on < 63 µm fraction)
Key Project Interactions	Changes in surface water hydrology and surface water quality
Goal	The Project will not have a significant adverse effect on sediment quality when compared to baseline conditions
Objective	Evaluate how the Project may influence sediment quality
Scope of Monitoring Work	Sediment samples will be collected at five stations per area. Sampling areas will include locations of sediment deposition on Latte Creek, Coffee Creek, lower YT-24 Creek, and Halfway Creek. No sampling will be undertaken at reference areas. Monitoring will be conducted at least once during Construction and every two years during Operation and during Reclamation and Closure
Mitigation Measures	Erosion and sediment control within the footprint of the Mine Site. Water management within the footprint of the Mine Site to avoid/reduce changes to the downstream aquatic environment
Project Terms and Conditions	To be determined following YESAA and *Yukon Waters Act* licencing processes

[1] ICP-MS = inductively couple plasma - mass spectrometry

Table 7-29 Sediment Quality Monitoring Areas and Frequencies

Station	Area	Mean* Coordinates (UTM Zone 7)		Rationale for Inclusion	Frequency**		
		Easting	Northing		Construction	Operation	Reclamation and Closure
Halfway Creek Watershed							
HF0.2	Lower Halfway Creek	588708	6980454	Downstream of influence	Once	Every 2 Years	Every 2 Years

LC10.2	Upper Latte Creek	586245	6971292	Downstream of influence	Once	Every 2 Years	Every 2 Years
Coffee Creek Watershed							
CF5.6	Coffee Creek	596860	6974237	Downstream of influence	Once	Every 2 Years	Every 2 Years
YT-24 Watershed							
YT0.2	Lower YT-24 Creek	589471	6979077	Downstream of influence	Once	Every 2 Years	Every 2 Years

*Mean of n = 5 stations per area
**Annual frequency is considered appropriate to detect potential change over time

7.11.6 Physical Inspections

Annual physical inspections of remaining infrastructure and facilities in closure will be carried out by a qualified engineer licensed to practice in Yukon. An annual review of the physical monitoring program results (including inspections and instrumentation data) by a qualified engineer will be conducted in accordance with Project permits and licences. Table 7-30 provides a summary of the physical inspection program that will be implemented early in the Closure Phase.

The frequency of inspections is likely to decrease with the progression of the Project into subsequent Closure Phases until determined to be no longer required, or until the success of reclamation efforts has been ascertained. The closure physical monitoring program will be advanced through detailed project planning stages.

Table 7-30 Closure Physical Inspection Program

Mine Component	Type of Inspection	Frequency			Responsible Party	Deliverable
		Post-mining Closure Phase	Active Closure Phase	Post-closure Phase		
Open Pits	Water Level and General Visual Inspection	Quarterly until reaches spillway then annually	Quarterly until reaches spillway then annually	Every two years for first ten years then as recommended	Care and Maintenance Personnel	Weekly Log, included in Monthly and Annual Reports
Heap Leach Facility	Geotechnical / Detailed	Annual	Annual	Every two years for first ten years then as recommended	Geotechnical Engineer (Yukon P.Eng)	Inspection Report
Facility and Alpha Ponds	Water Samples	As per permitting requirements	As per permitting requirements	N/A	Environmental Monitors	Daily Log, included in Monthly and Annual Reports
Waste Rock Storage Facility	Geotechnical	Every two years	Every two years	Every two years for first ten years then as recommended	Geotechnical Engineer (Yukon P.Eng)	Inspection Report
Water Management Infrastructure	Inspection of Ice, Blockages	Annual, prior to freshet	Annual, prior to freshet	Every two years for first ten years then as recommended	Care and Maintenance Personnel	Inspection Report
	Water Samples	As per permitting requirements	As per permitting requirements	As per monitoring plan	Environmental Monitors	Daily Log, included in Monthly and Annual Reports
Site Roads (including the NAR)	General Visual Inspection	Quarterly	Quarterly	N/A	Care and Maintenance Personnel	Inspection Reports
Pumps / Pipelines	Confirmation of Operation	Daily for operating pumps	Daily for operating pumps	N/A	Care and Maintenance Personnel	N/A
	Check for Flow and Absence Leaks	Weekly for operating pipelines	Weekly for operating pipelines	N/A	Care and Maintenance Personnel	N/A

7.11.7 Reporting

Reporting will be conducted in accordance with Project permit and license conditions. At a minimum, Newmont anticipates the submission of an annual interpretive report to satisfy regulatory requirements. The annual report will include:

- Summaries of Project activities completed, and mitigation measures implemented within the previous calendar year
- Results of monitoring programs and interpretation of findings related to the inspection and monitoring programs outlined above
- Details of any additional investigations that were conducted and any corrective actions taken
- A summary of engagement with regulators, Project-related working groups, First Nations, or Project stakeholders regarding that status of monitoring programs
- A description of any proposed changes to mitigation and monitoring plans.

Every three years, or as appropriate based on data collection, Newmont will review the results of annual monitoring and develop a detailed report that evaluates monitoring indicator trends. This interpretive report will include a retrospective analysis of monitoring data from baseline to current conditions to assess trends and compliance with Project-specific objectives and thresholds. Statistical analysis of the monitoring results will be performed where appropriate.

7.12 Socio-Economic Aspects of Permanent Closure

This section describes closure aspects for socio-economic components. Because the socio-economic environment is dynamic and interconnected, some closure-related measures described below may include components of, or references to, other reclamation and closure measures. As part of monitoring associated with the SEMP, Newmont will manage and monitor the implementation of socio-economic mitigation measures throughout the Construction and Operation phases and iteratively revise these measures as needed based on community feedback and other influencing factors. Results of the SEMP will be incorporated into the RCP to accurately reflect the socio-economic conditions of the community through the Closure and Post-closure Phases. These updates will include potential Project-related impacts that may be observed through the SEMP as well as through community consultation, and a social closure impact assessment and plan will be developed to present and guide mitigation of these impacts. The SEMP will be updated as the Project advances and will describe the socio-economic monitoring program that will be carried out in the Closure and Post-closure Phases. A key objective informed by results of the closure and post-closure socio-economic monitoring program includes protecting the quality and diversity of the traditional economy, including the health and viability of country foods (e.g., fish, wildlife, plants) and other harvestable resources (e.g., furs, medicinal plants).

Socio-economic measures to address potential effects on socio-economic valued component described in Section 4.3 are presented below and will become more prescriptive as the Project advances.

7.12.1 Education and Training Measures

Preparing for the Closure and Post-closure Phases, Newmont is committed to:

- Supporting information sharing with local education institutions to plan for a decrease in student enrollment numbers associated with families or workers leaving the area

- Providing appropriate training opportunities that align with transferrable skills to support workers and the local/regional economy toward a post-mining transition.

Table 7-31 summarizes the proposed education and training measures that will be implemented during the Closure and Post-closure Phases, expected timeframe for the start of implementation, and the anticipated roles and responsibilities for involved parties or groups in their implementation.

Table 7-31 Education and Training Measures Associated with Closure

Action	Role(s) &/or Responsibilities	Timeframe	Link to Other Newmont Plans or Initiatives
Support local elementary and secondary educational institutions to plan for changes in student enrollment numbers			
Engage with Yukon Education and local elementary and secondary schools to communicate anticipated population-driven changes in enrollment.	**Newmont**: Responsible for communicating workforce and corresponding population decreases anticipated during the Closure and Post-closure Phases. **Yukon Department of Education**: Responsible for broad communication across all Yukon schools, including Whitehorse, and ensuring local schools have support to manage potential changes to enrollment. **Robert Service School (City of Dawson), Eliza Van Bibber School (Pelly Crossing), J.V. Clark School (Mayo), and Nelnah Bessie John School (Beaver Creek)**: Responsible for communicating changes in enrollment to Yukon Department of Education.	Initiate engagement specific to closure approximately Project Year 8	**SEMP:** Describes measures to be implemented during Construction and Operations to manage potential Project related effects on educational services (primary, secondary and post-secondary) and community-based training, including on-going engagement with local education and training institutions. On-going SEMP monitoring will inform Closure and Reclamation Strategy.
Provide appropriate training opportunities that are available and focus on skills transferrable to the local and regional economy			
Engage with local education and training organizations and institutions to discuss how transferrable skills and other closure-supporting activities will be included in Newmont and partners training programs.	**Newmont**: Responsible for engaging with local education/training institutions on necessary education and/or training requirements for all identified positions required for each Project Phase, including specific training opportunities associated with reclamation and closure, and working with partners to identify training needs that prepare for closure. **Yukon University and other training providers**: Responsible for providing feedback to Newmont regarding available training programs and/or needs to develop new training programs. **TH Human Resources & Education Department, SFN Citizen Development Department, WRFN Employment and Training Department, and FNNND Education and Training Department**: Responsible for providing feedback to Newmont regarding available training programs and/or needs to develop new training programs.	Design training initiatives that may begin during Construction and Operation phases to consider skills that are relevant post-mining. Initiate engagement on job transition training specific to closure at approximately Year 8.	**Engagement Plan(s) Newmont will engage with relevant training or education organizations**

7.12.2 Local Employment, Procurement, and Economic Measures

Newmont is committed to:

- Supporting education, training, and career development opportunities through a Workforce Transition Strategy
- Supporting career planning, financial management, and financial literacy training through an Employee Assistance Program that plans for post-Project careers for the Project's workforce
- Supporting supply chain changes by communicating proactively with suppliers with respect to the Project schedule and future supply requirements for the Closure Phase
- Supporting local governments to absorb potential changes to communities by communicating proactively on the Project schedule
- Supporting financially sustainable partnerships and agreements
- Establishing and contributing to investment opportunities through Community Investment planning that anticipates closure.

Table 7-32 summarizes the proposed measures associated with local employment, procurement, and the economy to be implemented to address closure-related Project effects, along with the expected timeframe for the start of implementation, and the potential roles and responsibilities for other involved parties or groups.

Table 7-32 Local Employment, Procurement, and Economic Measures Associated with Closure

Action	Role(s) &/or Responsibilities	Timeframe	Link to Other Newmont Plans or Initiatives
Supporting education, training, and career development opportunities through a Workforce Transition Strategy			
Reduce potential adverse economic effects of closure by exploring options to reduce the Project's direct workforce gradually and retain local staff as long as possible.	**Newmont:** Prioritize current employees for reclamation and closure positions, where possible, and facilitate training, if necessary. Work with key suppliers and contractors to define possibilities for staging a reduction of the workforce in preparation for closure. Provide management/leadership training and career advancement for employees who have a demonstrated interest and aptitude. Consider employees for corporate positions locally if available, or at other mine/development sites, where possible.	Initiate during Operation phase. More focused recruitment beginning approximately Year 8	**Human Resources plans and documents**
Fulfill all obligations identified in employment contracts	**Newmont:** Fulfill all conditions for terminations as defined in employment contracts, including severance payments. The Proponent will offer an Employee Assistance Program to support employees during transition to permanent closure. Identify and provide a local workforce transition contact to respond to questions and concerns regarding temporary or permanent closure status, schedule, and activities.	Initiate pre-Construction, carries forward through Construction, Operation and Closure Transition Contact identified approximately Year 12	**Human Resources plans and documents**
Focus on transferrable skills and career opportunities that are relevant to workers and the economy post-closure	**Newmont**: Convene a planning process toward the Workforce Transition Strategy that includes up-to-date information on Newmont's commercial plans and workforce needs. Emphasize transferable skills for on- and off-the-job training opportunities to maximize workers' "job-ready" status for potential positions in other mining projects and industries. Connect workers with relevant jobs that are local, where possible. Define approach to incentivizing retention of existing staff, to avoid a "brain drain" near the end of mine life. Engage with First Nations and other parties to gather input for the Workforce Transition Strategy **The Project's direct workforce:** Provide input into the Workforce Transition Strategy, as requested.	Initiate engagement with external groups specific to closure at approximately Year 8. Define approach to retention incentives (approximately Year 8)	**Workforce Transition Plan; Workforce Mobilization Plan**

Action	Role(s) &/or Responsibilities	Timeframe	Link to Other Newmont Plans or Initiatives
	Other mining firms in Yukon: Contribute information about their potential workforce needs, to maximize the transfer of jobs and skills to current and future mines and mining projects in Yukon. **Yukon Government Department of Energy and Mineral Resources:** Contribute information about potential industry needs and plans that connect to workforce and skills demand. **Yukon Bureau of Statistics:** Contribute data on jobs and skills to support a Workforce Transition Strategy. **Yukon University:** Participate in identifying up-to-date training needs and opportunities that bridge the Project's workforce with other career opportunities. **Other groups or organizations that may have partnered with Newmont on education, training, and career development:** Contribute information, insights, or identification of opportunities to bridge the Project's workforce into new career opportunities.		
Supporting career planning, financial management, and financial literacy training through an Employee Assistance Program that plans for post-Project careers			
Support the Project's direct workforce in their long-term careers and financial outcomes over the post-Project transition period	**Newmont**: Design workforce training initiatives to focus on long-term (Post-closure) career and financial planning. Provide resources and initiatives focused on career transitioning such as financial planning, job-search techniques, career fairs, and others under the Employee Assistance Program. **Project's direct workforce:** Participate in Employee Assistance Program initiatives, as desired. **Newmont's key suppliers:** Share information related to the Employee Assistance Program, and how it could implement something similar for their own workers (the Project's indirect workforce). **Other partners TBD**: Contribute information, insights, or identification of opportunities to bridge the Project's workforce into new careers and/or income sources.	Refresh career and financial planning initiatives at approximately Year 8	**Education and Training Strategy** **Employee Assistance Program**

Action	Role(s) &/or Responsibilities	Timeframe	Link to Other Newmont Plans or Initiatives
Supporting supply chain changes by planning proactively with suppliers on Project timeframes, including Closure			
Engage key suppliers and contractors about Project timeframes (including Closure), to inform and support their businesses' long-term planning Share information with the business community at large that may be interested in the secondary effects of Project-related changes to purchasing	**Newmont**: Convene a planning process for and with key contractors that focuses on planning for closure. Provide updates on Project timeframes. **Suppliers:** Participate in a planning process. Share information with Newmont and peers, as desired. Raise questions and concerns for Newmont's awareness and response, as needed. **Chambers of Commerce (e.g., Dawson, Whitehorse, Yukon First Nation Chamber of Commerce, Yukon Chamber of Mines):** Participate in closure-related supply chain planning and/or receive informed on Project timeframes. Share information on Project timeframes with Chamber membership, if appropriate. **Other groups or organizations that may have partnered with Newmont on business development:** Contribute information, insights, or identification of opportunities to bridge the Project's supply chain into new economic opportunities.	Initiate engagement specific to closure at approximately Year 8	**Local Contracting and Procurement Strategy, Engagement Plan**
Supporting local governments to absorb potential changes to communities by communicating proactively on Project timeframes			
Share information with local municipal and Indigenous government to allow them to plan for post-Project futures	**Newmont**: Initiate information-sharing with local governments related to Closure and overall Project timeframes. Remain engaged with governments and contribute actively to their revenue planning. Engage regularly on a determined schedule to develop strategies that will support communities through the period of revenue change once closure dates confirmed. **Local governments in Dawson, Pelly Crossing, Mayo, Beaver Creek, Whitehorse**: Share information on Project timeframes to their communities (i.e., available on website, community offices, project events, etc.). Raise questions and concerns for Newmont's awareness and response, as needed.	Information sharing, government engagement, and engagement reporting will occur throughout Project Revenue change engagement will occur at approximately Year 10	**Engagement Plan**

Action	Role(s) &/or Responsibilities	Timeframe	Link to Other Newmont Plans or Initiatives
Supporting financially sustainable partnerships and agreements			
Support First Nations and/or other partners with whom Newmont has financially-based partnerships and agreements in transitioning beyond the Project's LOM (and revenue stream)	**Newmont**: Engage First Nations partners in conversations about Project timeframes and how these affect agreements. **First Nations with whom Newmont has signed agreements that include revenue or other financial components:** Raise questions or concerns related to long-term financial sustainability of partnerships, if desired. **Other supports or resources, as requested:** Provide advice or services on long-term financial planning, if needed.	Design and/or renew agreements so that Project timeframes such as Closure are considered, if this is appropriate and mutually agreeable to Newmont and First Nations partners. Initiate engagement specific to closure at approximately Year 8	**Impact-Benefit Agreements**
Establishing and contributing to investment opportunities through Community Investment planning that anticipate Closure			
Support Newmont's Community Investment partners in transitioning beyond the Project's LOM (and revenue stream)	**Newmont**: Include exit and/or financial sustainability strategies in Community Investment commitment decisions that Newmont makes during Construction and Operations. Prefer Community Investment opportunities in which Newmont is not the only financial contributor. Communicate financial sustainability objectives with Community Investment partners when commitments are made. Engage Community Investment partners to clarify and update exit/sustainability strategies. **Community Investment Partners:** Share information during the detailed closure-planning process. Raise questions and concerns, if desired.	Exit strategies determined and communicated as Community Investment decisions are made during Construction and Operation phases. Initiate engagement specific to closure at approximately Year 8	**Community Investment Protocol**

7.12.3 Community Infrastructure and Services Measures

Newmont is committed to:

- Supporting users of the Northern Access Road in understanding changes in access and/or maintenance of the road post-Closure
- Supporting local governments and service providers in understanding potential changes in demand for municipal and social services related to Closure.

Table 7-33 summarizes the proposed measures associated with community infrastructure and services to be implemented to address closure-related Project effects, along with the expected timeframe for the start of implementation, and the potential roles and responsibilities for other involved parties or groups.

Table 7-33 Community Infrastructure and Services Measures Associated with Closure

Action	Role(s) &/or Responsibilities	Timeframe	Link to Other Newmont Plans or Initiatives
Support road users in understanding access to the NAR post-Closure			
Engage users of the NAR on long-term use post-Closure	**Newmont**: Engage with road users and governments. Describe options for road access post-Closure. Incorporate feedback and concerns, as appropriate. **TH and SFN governments:** Participate actively in conversations about road access post-Closure. Share information on traditional use and other interests related to the road. **Other road users**: Participate in conversations about road access. **Yukon Government Department of Public Works and Highways, and EMR:** Participate in conversations with road users, as needed.	Initiate engagement specific to closure at approximately Project Year 10	**NAR management agreements and/or governance instruments (leases, permits, closure objectives, etc.)**
Support governments and providers of long-term and short-term accommodations in Whitehorse in a transition toward lower demand for accommodation post-Closure			
Engage property market players to contribute to their plans for sustainable long-term housing options	**Newmont**: Engage members of affected communities. Communicate Project timelines and describe the potential to affect the property market. Share information about workforce planning, including closure timeframes. **Property market players in Dawson**: Contribute information, insights, or identification of opportunities to bridge the Project's accommodation supply into new opportunities. **Yukon Bureau of Statistics, Canada Mortgage and Housing Corporation, Statistics Canada**: Contribute data and reporting on housing demand, prices, and other factors related to housing supply at the time of closure. **City of Dawson, Pelly Crossing, Mayo, Beaver Creek, City of Whitehorse:** Participate in conversations with Newmont about long-term sustainable housing options. **Direct project workforce**: Actively contribute to closure planning by sharing information about where they plan to live post-Closure.	Initiate engagement specific to closure at approximately Project Year 8	**SEMP:** Includes the Community Infrastructure and Services Management Strategy, which describes measures to be implemented during Construction and Operations to manage potential Project related effects on housing. On-going SEMP monitoring will inform Closure and Reclamation

Action	Role(s) &/or Responsibilities	Timeframe	Link to Other Newmont Plans or Initiatives
Support local governments and service providers in responding to changes in demand for municipal and social services related to closure			
Engage local governments and service providers on Project timeframes, to contribute to their long-term plans	**Newmont**: Share information about timeframes for closure, including workforce transitions. Brief local governments and service providers about any workforce well-being-related topics that may have arisen during Construction and Operation Phases that may be relevant to Closure. **City of Dawson, Pelly Crossing, Mayo, Beaver Creek, City of Whitehorse:** Participate in conversations with Newmont related to Closure. Identify specific local government departments or other partners who may be incorporated into Closure-related conversations related to services. **Service providers in Dawson, Pelly, Mayo, Beaver Creek, and Whitehorse, as needed:** Participate in conversations with Newmont related to Closure. Ask clarifying questions and request data from Newmont, if needed, to allow service providers to adapt to closure-related changes. Troubleshoot solutions, as needed.	Initiate engagement specific to closure at approximately Year 8	**SEMP** **Engagement Plans**

7.12.4 Traditional Knowledge and Lands and Resource Use Measures

Newmont is committed to:

- Communicating the results of post-mining environmental monitoring to increase confidence in safely consuming traditional and non-traditional foods from the Project area and to support the traditional economy
- Communicating areas that will be open to (or excluded from) traditional and non-traditional use activities
- Ensure that First Nations have an opportunity to participate in end land-use planning for the site that are consistent with traditional land use values for the area, including future uses.

Table 7-34 summarizes the proposed measures associated with traditional knowledge and lands and resources use to be implemented to address closure-related Project effects, along with the expected timeframe for the start of implementation, and the potential roles and responsibilities for other involved parties or groups.

Table 7-34 Traditional Knowledge and Lands and Resource Use Measures Associated with Closure

Action	Role(s) &/or Responsibilities	Timeframe	Link to Other Newmont Plans or Initiatives
Support traditional land use activities within the project area to the extent possible and perception of safe land and resource use			
Engage with key users of land and resources post-closure on environmental monitoring results to maximize confidence in the Project's environmental management measures. Communicate areas that will be open to (or excluded from) traditional and non-traditional use activities. Maintain legacy hiking trails.	**Newmont**: Convene a process that builds on initiatives established by Newmont during construction and operations (see SEMP) so that First Nations and key land and resource users can continue to feel comfortable and confident in the environmental quality parameters post-Closure. Establish a feedback process so that information can be shared transparently on agreed environmental quality parameters (physical and biophysical environments) and quality or harvesting resources. Respond to questions and concerns in a forthright and timely fashion. Consider input from First Nations and other land users into reclamation programs (e.g., use of traditional plans for revegetation) and in the definition of end land use planning for the site. **First Nations lands departments and technical experts on environmental quality topics**: Represent their respective Nations in participating in conversations and problem-solving around closure-related environmental quality. Represent the interests of land and resource users through providing technical information and First Nations governance support. **Hunters, gatherers, other land and resource users, users of legacy hiking trails:** Provide key information on expected and actual land and resource use post-closure.	Construction, Operation, and Closure	**Engagement Plan(s)** **Environmental monitoring programs during Construction, Operation, and Closure Phases**

7.12.5 Community Health and Well-Being Measures

Newmont is committed to:

- Engaging with service providers (YG, municipalities, hospitals, and clinics) on changes in demand for health services, including the potential for additional requirements and changes in demand for mental health supports
- Engaging with local RCMP regarding changes in workforce and/or scheduled layoffs
- Including in the Workforce Transition Strategy connections to social support services, information on food security, and health and well-being information.

Table 7-35 summarizes the proposed measures associated with community health and well-being to be implemented to address closure-related Project effects, along with the expected timeframe for the start of implementation, and the potential roles and responsibilities for other involved parties or groups.

Table 7-35 Community Health and Well-Being Measures Associated with Closure

Action	Role(s) &/or Responsibilities	Timeframe	Link to Other Newmont Plans or Initiatives
Engagement with service providers (Yukon Government, municipalities, hospitals, and clinics) on changes in demand for health services, including additional requirements and mental health			
Support service providers in anticipating, planning for, and responding to potential changes in demand for services related to closure.	**Newmont**: Share information about timeframes for closure, including workforce transitions to support service delivery planning. Brief local governments and service providers about any workforce well-being-related topics that may have arisen during Construction and Operation Phases that may be relevant to Closure. **City of Dawson, Pelly Crossing, Mayo, Beaver Creek, City of Whitehorse, Yukon Government:** Participate in conversations with Newmont related to Closure. Identify specific local government departments or other partners who may be incorporated into Closure-related conversations related to services. **Hospitals, clinics, and mental health service providers, addictions support providers:** Participate in conversations with Newmont related to Closure. Ask clarifying questions and request data from Newmont, if needed, to allow service providers to adapt to closure-related changes.	Initiate engagement specific to closure at approximately Project Year 8	**Engagement Plan(s)**
Including in the Workforce Transition Strategy connections to social support services, information on food security, and health and well-being information			
Connecting the Project's direct workforce with social, health, and well-being supports to ease the transition into post-Closure life and work	**Newmont**: Share information about timeframes for closure, including workforce transitions. Brief local governments and service providers about any workforce well-being-related topics that may have arisen during Construction and Operation Phases that may be relevant to Closure. Provide information and training to employees on resources available to them regarding social support and services through extended health and public health. **Social support service providers**: Participate in conversations with Newmont related to Closure. Ask clarifying questions and request data from Newmont, if needed, to allow service providers to adapt to closure-related changes. **Direct Project workforce:** Engage with Newmont on social, health, and well-being issues for inclusion in the Workforce Transition Strategy, as needed. **Newmont's key suppliers:** Adopt Newmont's approaches to social, health, and well-being topics at the time of workforce transition, as needed.	Initiate engagement specific to closure at approximately Project Year 8	**Engagement Plan(s)**

7.12.6 Heritage Resources

During reclamation and closure activities, it is not anticipated that there will be increases in the potential to affect tangible heritage resources (i.e., archaeological, and historical resources, as well as paleontological resources). Nevertheless, should additional ground disturbance occur to support reclamation and closure activities, mitigation to be implement in areas of new ground disturbances would involve the same measures in place for the Construction and Operation phases of the Project, including:

- Completing a Heritage Resources Impact Assessment (HRIA) for any areas of new disturbance not previously assessed
- Consulting on appropriate mitigation measures
- Avoiding known archaeological and historical resources
- Conducting systematic data recovery
- Implementing Project-specific Heritage Resources Protection Plan, including a Chance Find Procedure (CFP)
- Following monitoring plans
- Implementing Project-specific Heritage Resources Protection Plan, including a CFP.

Regardless of new ground disturbances, Newmont will implement the following measures during the Closure Phase to restore historical features:

- Consult with First Nations on the preferred approach to historical features restoration
- Cover disturbed areas to the extent practicable with materials from areas already disturbed
- Restore the character of the Coffee Creek camp area for cultural gatherings
- Maintain and restore historical cabins and features
- Revegetate with native vegetation including berry producing shrubs, medicinal plants, etc.

7.13 Performance Uncertainty and Risk Management

Project-related risks will continue to be assessed as the Project advances. Once the site has ready steady-state operating conditions, it will be possible to re-evaluate closure-related risks, based on lessons learned during early operations, as especially those learned from progressive reclamation measures that have been implemented. Management and monitoring plans will continue to evolve as the Project advances and continual refinements and improvements will reduce uncertainties associated with perceived or potential risks. As the Project will gradually transition from operations to closure (i.e., operating activities such as heap rinsing and water treatment will start in the Operation Phase and continue into the Closure Phase), there will be further opportunity to refine plans and incorporate changing site conditions when relevant.

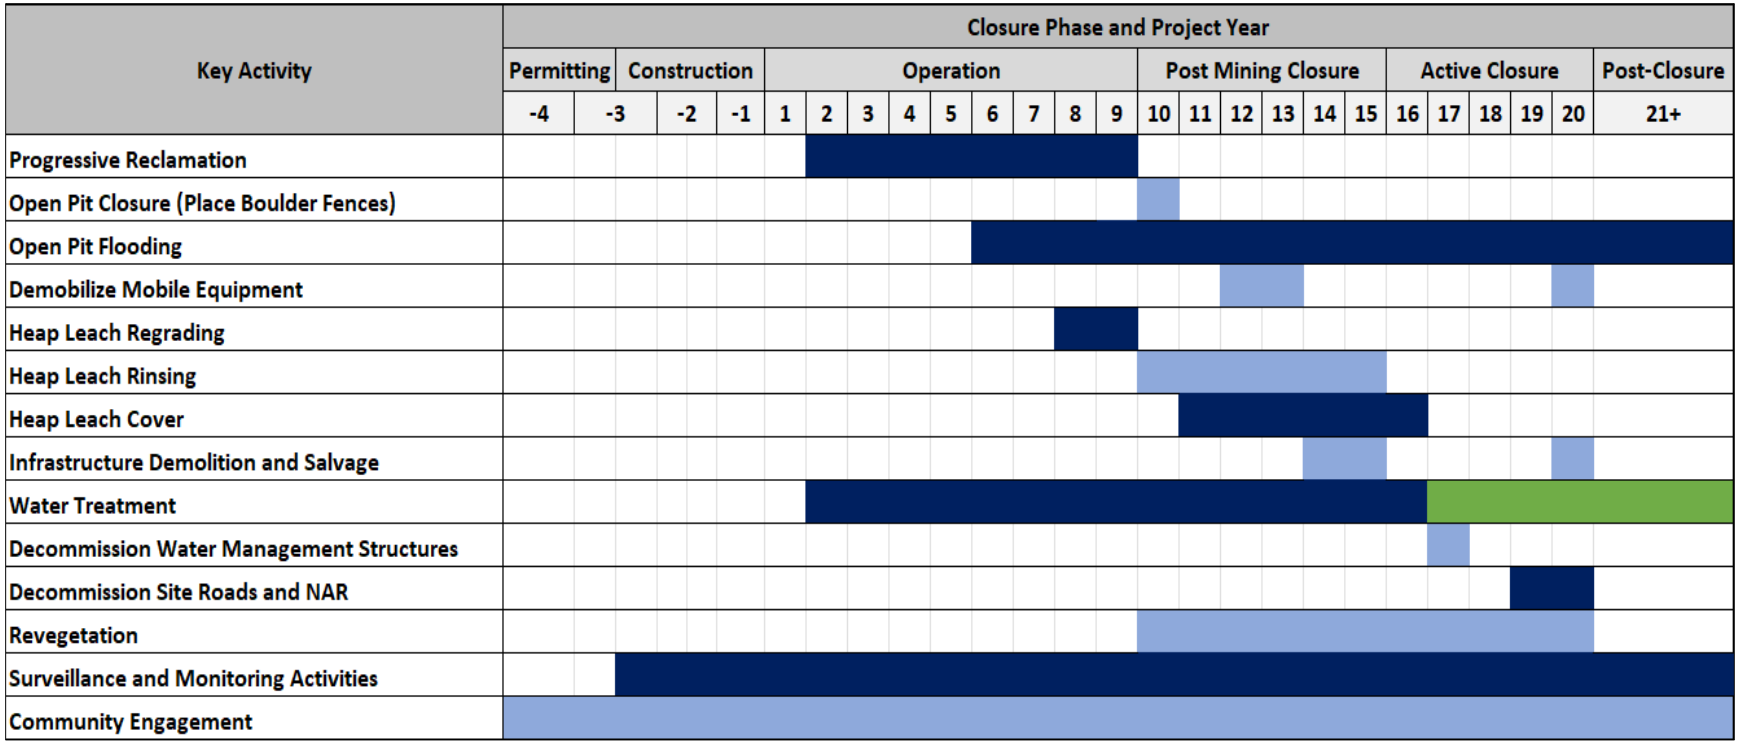
Risks will also be managed adaptively, as outlined in Section 5.8.2. An AMP for the Closure Phase will be developed during the Operation Phase, and it is expected that the approach will largely follow the plan implemented for the Operation Phase. The Operation Phase plan would have been tested under actual conditions and/or refined throughout this period in response to gaining a better understanding of actual site conditions.

8.0 RECLAMATION AND CLOSURE SCHEDULE AND EXECUTION STRATEGY

8.1 Schedule Overview

Throughout the Operation Phase, closure activities will be undertaken in a progressive manner from Year 2 to the end of Year 9 when open pits, the Alpha WRSF and FSSA, and stages of the HLF are no longer required to support mine operations. Activities planned during the Operation Phase are detailed in Section 2.3.2.

The Closure Phase will commence at the start of Year 10 and is projected to end at the end of Year 21. The Closure Phase is categorized into Post-mining Closure (Year 10 – 15) and Active Closure (Year 16 - 21) Phases based on site water quality associated with the HLF draindown and rinsing. Activities within the Post-mining Closure Phase are focused on water treatment, as well as decommissioning and reclamation of site areas that are no long in use and are not required for closure. Activities within the Active Closure Phase are focused on decommissioning water management infrastructure as well as site components that are not required for the Post-closure Phase. The Post-closure Phase activities include long-term monitoring and site maintenance, and passive water treatment, if determined to be required. Figure 8-1 presents the estimated time period for key closure activities as they occur during each Project phase. The time period for the activities will be refined through further Project planning and evaluations.



*Green highlighted cells indicate years that passive water treatment will be in effect, if required.

Figure 8-1 Key Closure Activities Estimated Time Period

Certain tasks will be performed simultaneously or overlap preceding or subsequent tasks to ensure that closure works remain on schedule.

Routine monitoring in accordance with the conditions of the mine operating licenses and permits will be ongoing throughout the Operation Phase and Closure Phase as described in Section 7.11. Additionally, monitoring of reclaimed areas to observe progress towards achieving site-specific closure objectives will be ongoing throughout the Closure Phase.

8.2 Reclamation Execution Strategy

During the Closure Phase, reclamation of disturbed areas within the Mine Site footprint will be undertaken when those areas are no longer required to support closure activities. The following items will be considered when planning and executing final closure:

- Reclamation activities will incorporate suitable surface preparation techniques that will contribute to long-term stability, reduced erosion, and success of revegetation. A combination of re-grading, scarification, and rough and loose surfacing will be utilized. Based on reclamation research during operations and from other analogous sites, landscaping such as the creation of hummocks or mounds may be utilized.
- Stockpile management during operations and closure will be imperative to ensure that suitable reclamation material is available. Strategic stockpile placement will reduce also costs associated with long haul distances and reduce requirements to re-handle material.
- Overburden materials used for reclamation will be sourced from stockpile locations proximal to the area to be reclaimed, unless direct placement opportunities exist (direct dozing).
- Proper construction and maintenance of water management structures (channels, ditches, berms, settling basis, etc.) during reclamation and closure activities will be important to ensure success. Water management and erosion and sediment control around reclaimed areas will be carefully planned to maximize reclamation success, limit the need for future disturbance, and divert clean water away from areas still being used.
- The mining fleet will be used to support progressive reclamation during operations and will be available during the beginning of the closure period to support final reclamation and closure activities. Utilizing the remaining mining fleet to support reclamation, specifically those activities that require large amounts of material movement will contribute to operational efficiencies and lower costs.
- Site infrastructure will be decommissioned, and sites will be reclaimed as the closure phase progresses and the infrastructure is no longer required to support closure activities. The infrastructure that will remain on-site to support closure activities includes the Exploration Camp, site office and labs, emergency response building, fuel storage tanks, waste management facility, land treatment facility, truck shop and warehouse, and power plant. This infrastructure will be decommissioned by the end of the Active Closure Phase once they are no longer required.
- Post closure monitoring will be completed as per the schedule provided in Section 7.0 using helicopter access and third-party consultants. Post closure maintenance will occur on as needed basis based on outcomes of monitoring and recommendations of qualified professionals. Post closure maintenance may require mobilization of equipment and supplies using barges and will be carried out by a third-party contractor.

8.3 Equipment Fleet

The anticipated mining equipment on-site prior to the Closure Phase includes the following:

Table 8-1 Major Mining, Support, and Ancillary Equipment Count by Year (Start, Peak, LOM)

Major Equipment List[1]	End of Construction	Peak of Operation Phase	End of LOM
Komatsu - PC3000 - Shovel	3	4	4
Komatsu - WA900 - FEL	1	2	2
Sandvik - D55SP - Production Drill	3	4	3
Sandvik - DX800 - Presplit Drill	1	2	2
Komatsu - D275 - Track Dozer	5	6	5
Komatsu - WD500 - Wheel Dozer	2	3	3
Komatsu - GD825 - Grader	3	3	3
Komatsu - HD785 - Water Truck	2	2	2
Komatsu - D275 - Track Dozer - ROM STK	1	1	1
Komatsu - HD1500 - Haul Truck	12	27	12
Total Units Required	34	54	37
Ancillary Equipment List[1]	**End of Construction**	**Peak of Operation Phase**	**End of LOM**
Drilling			
Caterpillar - 236D - Skid Steer	2	2	2
Loading & Hauling			
Caterpillar - 415 - Backhoe	1	1	1
Caterpillar - 236D - Skid Steer	2	2	2
Komatsu - HD785 - Rock Spreader	1	1	1
Service / Materials			
Lowboy - TowHaul - Trailer (100t Float)	1	1	1
Komatsu - HD785 for Lowboy Trailer (100t Float)	1	1	1
Hyster - 700HD - Tire Manipulator	2	2	2
Western Star - 6900 - Fuel / Lube Truck	2	2	2
Ford - F550 Custom - Explosives Box Truck	1	1	1
Ford - F550 Custom - Mechanic Truck	2	2	2
Lifting			
Gehl - D12-40 - Fork Lift Zoom-Boom (5t)	2	2	2
Grove - Rough Terrain Crane (65t)	1	1	1
Personnel Transport			
Ford - F350 - Light Vehicles	10	10	10
Freightliner - Custom - Passenger Bus (44 ppl)	1	1	1
Crew Van	1	1	1
Fixed			
Pit Dewatering Pumps (Diesel)	4	4	4
Noram - LTN20WL - Portable Light Plants (Diesel)	11	12	8
Mobile Wash Car	1	1	1
Dispatch Equipment	1	1	1

Source: Stantec (2019)

[1] Equipment brand is subject to change; however, the equipment listed in the table is the anticipated size to be available post mining.

It is anticipated that contractor equipment will be required to be mobilized to support the existing fleet of mining equipment to be used for reclamation and closure activities. The following equipment is anticipated to be required. This equipment list may be updated or modified based on required capacity.

- Pickups & Vans (x 4)
- Telehandlers
- 345 Excavator
- 330 Excavator
- 40T Articulating Trucks (x 4)
- D6T Dozer
- D8 Dozer
- 140M Grader
- 992K Loader
- 980 Loader
- Small roller compactor
- Rubber-tired backhoe (for GCL installation only)
- Cranes
- Manlifts (x 2).

It is not anticipated at this time that a portable crushing spread consisting of a jaw crusher, cone crusher, screen deck(s), and a wash plant will be required for the Closure Phase. If processed material is required for reclamation and closure activities, it is preferred to produce it using on-site stationary equipment immediately following the Operation Phase.

8.4 Site Access and Haul Roads

Site access during the Closure Phase will be achieved via the NAR. The NAR and on-site access road, including barge crossings, will be kept in place to support Closure including Operation Phase equipment demobilization, infrastructure demobilization as appropriate, and mobilization of supplementary equipment for closure activities. Site access control, access road requirements, and security will be maintained to the same level as during operations, as described in Access Route Operation Management Plan, until NAR access is no longer required.

Progressive closure of haul and Mine Site roads will occur throughout the Operation Phase as roads are no longer required to support operations. Roads used for closure works will generally undergo closure in the later portion of the Closure Phase. Light vehicle roads will be maintained to support monitoring activities as required, although the preference will be to use small vehicles such as snowmobiles and ATVs to support monitoring.

8.5 Site Security

Site security will be maintained at all times throughout the Closure Phase as per the procedures set up during operations. Security will be tailored to protect equipment and assets on site and operations security requirements associated with gold production may be reduced / removed. Site security and traffic management responsibilities will be shared by security personnel.

Security personnel will maintain a logbook of all site visitors, including check-in and check-out times, name, company, vehicle details. Security personnel will utilize radio communication to assist with access control, safety, incident command, and traffic management as required.

8.6 Site Infrastructure

8.6.1 Site Camp

Once the Mine Camp has been decommissioned in the Post-mining Closure Phase, the Exploration Camp will be utilized to house mine site personnel to support closure works and monitoring activities throughout the Post-mining and Active Closure Phases. The capacity of the Exploration Camp will be 245 persons and will include single rooms with shared washrooms. The camp will contain five dorm wings, which contains eight 3.4 x 18 m trailers. In addition to the dorms, the camp will include a kitchen, diner, and recreation hall. The construction camp will be powered by a generator. The Exploration Camp will be decommissioned towards the end of the Active Closure Phase, at which time the Coffee Exploration Camp may be used.

8.6.2 Site Offices and Labs

The site office complex and site laboratory will be utilized during the Closure Phase. The office complex will include a large open office area, private offices, a main boardroom, and a meeting room. Construction management, administrative, and QA/QC personnel will be headquartered in these offices, which will be equipped with high-speed internet. The offices will also serve as a location for site visitors to report to and to receive site orientations.

8.6.3 Emergency Response Team Building

The emergency response building located adjacent to the mine dry and office complex will house an ambulance and fire truck throughout the Closure Phase. An emergency medical responder will be on site 24 hours a day to provide emergency care. For additional information regarding emergency response infrastructure and equipment, refer to the Emergency Response Plan.

8.6.4 Bulk Fuel Storage

Four 4-million litre fuel tanks with dispensing systems will be constructed in Year -2 and are planned for use during the initial portion of the Closure Phase. The bulk fuel storage is planned to be located at least 30 m away from any water bodies, and in an area where it can be frequently supervised. The construction plans for the bulk storage area include a geomembrane liner covered by aggregate materials to ensure any spills are contained at the source. Emergency response equipment will be available at the bulk storage area.

To support the implementation of final closure measures in other areas after the bulk fuel and LNG storage areas have been decommissioned and the fuel storage tanks have been removed from the Plant Site,

appropriately sized portable fuel storage tanks will be used to store diesel for equipment and power generation. Lined containment areas will be established for these portable fuel storage tanks as required.

8.6.5 Waste Management

The waste management facility, non-hazardous waste landfill within the waste management area, and the land treatment facility for storage and treatment of hydrocarbon-contaminated soil and snow located east of the Supremo Pit will continue to be used for waste management throughout the Closure Phase. All work will adhere to site waste management procedures which will be procured for the Operation Phase. At this time, no additional waste streams not accounted for during the Operation Phase will be generated. Washcars will be pumped at least once a week by a septic truck.

8.6.6 Maintenance Areas and Laydowns

The truck shop and warehouse will be utilized for maintenance and repairs to site vehicles and equipment until demolished. It is then anticipated that a fabric structure building would be used as a maintenance shop for contractor equipment. Existing laydowns will be used selectively until reclaimed. When the final laydown areas are due to be reclaimed, the final equipment on site will be staged / parked on tertiary roads to ensure that laydowns can be appropriately reclaimed.

8.6.7 Power Generation

The power plant utilized throughout the Operation Phase will be utilized as the power source throughout the Closure Phase. The power plant will be able to generate 9 megawatts (MW) of peak gross electrical power. Further details on the construction and capacity of the power plant are provided in Section 5.3.6.4.

8.7 Labour Requirements

Table 8-2 shows the anticipated labour requirements during the Closure Phase. Equipment operator and supervision requirements will increase and decrease according to the amount and size of reclamation and closure activities being completed on site. The following table shows the manpower required to conduct earthworks reclamation activities with some supplementary demolition activities but does not include specialized subcontractors such as the decommissioning crew. Post closure monitoring and maintenance activities will be completed using applicable consultants and contractors.

Table 8-2 Personnel Required for Closure Phase

Position	Total Compliment	Shift Rotation (Weeks in x Weeks out)
Administration		
Site Manager	1	4x3 (days)
Health and Safety Officer	2	2x2
General Administrator	2	2x2
Environmental		
Environmental Superintendent	1	4x3 (days)
Environmental Monitors	2	2x2
Environmental Technician	2	2x2
Operations / Maintenance		
Surface Foreman	2	2x2
Demolition Foreman	2	2x2
Electrician	2	2x2
Facilities Maintenance - Tradesman	2	2x2
Mobile Equipment Operator	24	2x2
Labourers/Apprentices/ADR Operators	4	2x2
Survey	2	2x2
QA/QC	4	2x2
Operations Foreman	1	2x2
Power Plant Operator	2	2x2
Millwright	2	2x2
Barge or ice bridge	4	2x2
Camp Support Services		
Camp Manager	1	4x3 (days)
Catering	6	2x2
Housekeeping	6	2x2
Nurse / Paramedic	2	2x2
Total Closure Staff	76	

9.0 RECLAMATION AND CLOSURE LIABILITY

9.1 Basis of Estimate

Based on Newmont internal policies, the Standard Reclamation Cost Estimator (SRCE) Version 2.0 was used to develop both the Two Year Forward and Life of Mine Reclamation Liability Cost Estimates. Third party rates were used to simulate a contractor performing reclamation activities. Third party rates were established by increasing standard Newmont Nevada equipment and labour rates for third party contractors by 25%. These rates were checked against standard contractor rates in Yukon and BC to ensure continuity. This approach is in alignment with previous reclamation liability cost estimates developed for the Coffee Project. A cost model summary is provided in Appendix 9-A. The complete SRCE cost model is provided as a supplementary information package.

Using SRCE, indirect and overhead costs were added directly to the estimate following buildup of direct costs.

The following percentages were used for indirect and overhead costs:

- Engineering, Design and Construction Plan 5.0%
- Contingency 15.0%
- Contractor Overhead and Profit 13.0%
- Contract Administration 2.0%

Both cost estimates consider the costs of closure activities over a period of 50 years following operations. A discount rate of 4.0% is used to calculate the NPV in 2023 dollars. In the absence of prescriptions for Yukon, this discount rate is in alignment with BC guidance for major mines. An inflation rate of 2.1% was used, representing the 10-year average of Yukon CPI increase between 2013 and 2022. The difference between discount rate and inflation rate (1.9%), was used as the actual SRCE input “Discount Rate”. Furthermore, Active Closure activities were not discounted when reporting the total NPV in 2023 dollars. Therefore, the aggregate discount rate of 1.9% was only applied to long-term monitoring and maintenance costs.

9.2 SRCE Model

The closure cost estimates for the Site were developed using the SRCE model, a tool which was developed to improve the consistency and accuracy of reclamation and closure cost estimates. The model standardizes user input requirements, productivity calculations, and volume and area calculations in a consistent format while allowing flexibility to incorporate site-specific conditions. Since its development in 2006, the model has been accepted and is currently used in world-wide applications to develop costs for Financial Assurance (FA), Life of Mine (LOM), and Asset Retirement Obligation (ARO) cost estimates for countless mines through North and South America, and Asia.

Equipment productivities used by the model are derived from readily available published resources such as CAT Handbook or RS Means, which compare against actual field conditions. The model includes rates based on published sources for equipment and labor crews to complete reclamation activities, but also allows incorporation of site-specific contractor rates and fuel costs.

Descriptions of calculation methods and assumptions on which calculations found in the model are based on are presented in the SRCE User's Guide available on the web at NVbond.org.

9.3 Two Years Forward Liability Estimate

The Two Years Forward Liability Estimate assumes a closure scenario immediately following Construction. In this scenario, metal prices, or other market factors would push the mine into temporary closure and then final closure.

The estimate considers a two-year interim care and maintenance period following Construction. This can also be thought of as temporary closure and would include re-circulation of the heap leach solution.

This two-year interim care and maintenance period consists of $10,601,602 of undiscounted costs, broken down into the following:

- Road Maintenance $ 1,162,483
- Monitoring $ 1,420,000
- Site Management $ 881,906
- Closure Planning $ 431,346
- G&A $ 3,957,303
- Engineering, Design and Construction Plan $ 392,652
- Contingency $ 1,177,956
- Contractor Overhead and Profit $ 1,020,895
- Contract Administration $ 157,061

If the mine moves to final closure, as simulated in this scenario, a three-year period of active closure would follow, which would include one year of heap leach rinsing followed by covering of the heap leach facility. Other reclamation activities carried out in this scenario include regrading, scarifying, and revegetating the Alpha WSRF, partial removal of the Alpha Dam, open pit closure of any pits developed during construction (anticipated at this time to be Latte and Supremo), demolition of infrastructure and buildings, reclamation of laydowns, pads, and roads, and revegetation of disturbed areas.

Active water treatment is required for heap leach rinsing. As the active water treatment plant has not been constructed by this time, the capital and operating costs are included in this estimate.

Capital costs of $13,377,500 are considered to retrofit the ADR plant into an active Water Treatment Plant (WTP) capable of treating the HLF drain-down. An operating cost of $10.09/$m^3$ is considered.

Activities conducted during Post-Closure are limited to surveillance and monitoring.

Table 9-1 Two Years Forward Closure - Undiscounted Costs

Total Cost	
CA$	
Waste Rock Dumps	806,257
Heap Leach	541,606
Solution Mgmt	16,577,318

Total Cost	
CA$	
Pits	18,567
Roads	6,335,651
Process Ponds	1,959,996
Yards, etc.	1,801,506
Landfills	1,015,008
Foundations & Buildings	12,320,351
Other Demo & Equip Removal	168,720
Sediment & Drainage Control	366,634
Waste Disposal	783,718
Monitoring	5,970,000
Reclamation Maintenance	378,805
Construction Management	2,204,766
Closure Planning	678,965
G & A	10,037,058
Subtotal – Direct Costs	**61,964,925**

Engineering, Design and Construction Plan	**3,098,246**
Contingency	**9,294,739**
Contractor OH and Profit	**8,055,440**
Contract Administration	**1,239,299**
Total – Undiscounted Costs	**83,652,649**

The NPV (2024) of the Two Years Forward Liability Estimate is CDN $92,902,637.

9.4 Life of Mine Liability Estimate

The Life of Mine Liability Estimate assumes a closure scenario in line with the mine plan and current regulatory submissions.

This scenario considers a six-year period of “Post-Mining Closure” following Operations. This is followed by a five-year period of “Active Closure” before “Post-Closure”.

Activities conducted during Post-Mining Closure include open pit closure, demobilization of any mobile equipment not required for closure, heap leach closure, demolition of infrastructure and buildings, and active water treatment.

Heap leach closure consists of regrading, rinsing, and progressive covering over a total period of nine years. Active water treatment is required during Post-Mining Closure and heap leach closure, however the active water treatment plant is already built in this scenario, so only operating costs are considered in the liability estimate.

As Post-Mining Closure moves to Active Closure, water treatment is transitioned from Active to Passive. The capital and sustaining capital costs for passive water treatment are considered during Active Closure and Post-Closure.

An operating cost of $10.09/m^3 is considered for the Active WTP. Capital costs of $5,200,000 are considered to construct the passive water treatment facility. Sustaining capital costs of $17,533,773 over a period of 44 years (to the end of the closure duration estimated) are considered for replacement of the passive water treatment media.

Activities completed during Active Closure include construction of the passive water treatment facility, decommissioning of water management structures, decommissioning of site roads and the NAR, and final revegetation of disturbed areas.

Activities conducted during Post-Closure are maintenance of the passive water treatment facility and surveillance and monitoring of the site.

Table 9-2 Life of Mine Closure - Undiscounted Costs

Total Cost	
CA$	
Waste Rock Dumps	262,229
Heap Leach	2,282,078
Solution Management	61,131,590
Pits	121,015
Roads	9,213,420
Process Ponds	2,047,448
Yards, etc.	1,881,520
Landfills	477,259
Foundations & Buildings	11,694,297
Other Demo & Equip Removal	168,720
Sediment & Drainage Control	385,447
Waste Disposal	783,718
Monitoring	10,170,000
Construction Management	3,527,626
Closure Planning	678,965
G & A	21,500,407
Subtotal – Direct Costs	**126,325,738**
Engineering, Design and Construction Plan	**6,316,287**
Contingency	**18,948,861**
Contractor OH and Profit	**16,422,346**
Contract Administration	**2,526,515**
Total – Undiscounted Costs	**170,539,747**

The NPV (2024) of the Life of Mine Liability Estimate is CDN $209,852,847.

APPENDIX 1-A

Reclamation and Closure Plan
YWB and EMR Table of Concordance

Table of Concordance for RCP Sections – YWB and EMR (2013) Reclamation and Closure Planning for Quartz Mining Projects: Annex 1 – Annotated Outline for Reclamation and Closure Plans

YWB and EMR (2013) Annex 1 Annotated Outline for Reclamation and Closure Plan		RCP Section(s)
1.0 INTRODUCTION		
Provide a brief project summary including the closure philosophy and guiding principles for the reclamation and closure plan (RCP).		1.1, 1.2
Summarize the project schedule from the current status through to completion of reclamation and closure.		1.1.1
2.0 RECLAMATION AND CLOSURE PLANNING		
Summarize the processes and approaches used to develop the RCP.		2.0
Describe the sequence and phases of reclamation and closure planning for the mine, and where this RCP fits in a continuum of reclamation and closure planning.		2.2
Identify the extent of additional research, planning and design required to complete a final, detailed plan ready for construction.		2.3
Describe processes for integrating reclamation and closure planning into development and operational decision-making.		1.2, 2.3
Summarize reclamation research completed to date. Include results from reclamation research programs as appendices if appropriate. Provide a summary of any plans for additional reclamation research. Include a detailed reclamation research plan as an appendix if appropriate.		2.3.1, Appendices 2-B to 2-J
Summarize community (e.g., governments, local communities, regulatory agencies, and non-government organizations) engagement activities undertaken to support the development of the RCP.		2.1, Appendix 2-A
Describe methods used to identify, characterize, evaluate, and select closure alternatives. Include descriptions of specific tools like risk assessment, failure modes effects analysis, multi-attribute analysis, etc. that were applied, and why these approaches were selected.		2.3.4, Appendices 2-K to 2-M
3.0 CLOSURE OBJECTIVES AND DESIGN CRITERIA		
3.1 Reclamation and Closure Objectives	Describe specific reclamation and closure objectives, including objectives that meet or exceed the fundamental objectives described in Section 5.1 of the *Plan Requirements and Closure Costing Guidance (YWB and EMR (2013).* Describe any constraints to achieving the fundamental objectives.	3.1; Appendix 3-A
	Provide rationales for selection of specific objectives. Describe how the objectives address community (e.g., governments, local communities, regulatory agencies, and non-government organizations) expectations.	3.1
3.2 Design Criteria	Provide the design criteria that guide the design for the reclamation and closure activities, including project constraints, regulatory and guidance-based criteria and other criteria. These are the criteria that will define the effectiveness of the design.	3.3
	Identify and describe design criteria for all components of the project and RCP, recognizing that criteria may vary depending on risks associated with specific components or processes. Include rationales for selection of all criteria. Where criteria are developed in accordance with regulatory requirements or guidance documents, rationales must clearly demonstrate how the proposed criteria meet these requirements or guidance.	3.3
	Design criteria must be supported with data and analyses that quantify the criteria for the site. For example, summarize seismic analysis, flood-frequency analysis and site-specific water quality analysis. Provide detailed reports as appendices.	3.3; 5.3
4.0 ENVIRONMENT DESCRIPTION		
Summarize environmental conditions for areas that are, or will be, affected by the mine. This should include footprint areas as well as environmental components that will be affected (e.g., watersheds, airsheds – the geographical area affected by air from the mine site, wildlife ranges). Address both pre-disturbance and existing conditions and include descriptions of relevant reference areas. Provide references for supporting data and analyses that demonstrate a suitable understanding of site-specific environmental conditions.		4.1; 4.2
4.1 Climate	Describe climate conditions at the site, including but not limited to temperature, rainfall, snowfall, snow accumulation and evaporation. Describe the climate change scenarios that will be considered in designing closure features.	4.1.1
4.2 Surface Water	Describe the hydrology of the site including high, low and mean flows for various seasonal conditions. Describe the water quality in water courses affected by mining, including the seasonal variability. Identify contaminants of concern as well as any parameters that may be appropriate indicators.	4.1.6; 4.1.7
4.3 Groundwater	Describe the groundwater conditions at the site, including a summary of elevations, flow directions, permeabilities, water quality, and interactions with surface water.	4.1.8
4.4 Vegetation and Wildlife	Describe the vegetation and wildlife in the area. Characterize species distributions and habitats.	4.2.2; 4.2.3
4.5 Soil and Bedrock	Describe soil and bedrock conditions, including both surface and subsurface conditions. Summarize the site data from geotechnical testing, site investigation programs, and overburden investigations. Include a discussion of the geology of the area, including geomorphic features, bedrock composition and thermal conditions.	4.1.5
4.6 Seismicity	Summarize seismic hazard conditions for the project site.	4.1.2

YWB and EMR (2013) Annex 1 Annotated Outline for Reclamation and Closure Plan		RCP Section(s)
5.0 PROJECT DESCRIPTION		
Provide a description of the project that includes the project location, history of the site, mining activities, and the operational phases. Describe the facilities and features that have already been constructed and the activities that have been undertaken. Also describe facilities, features and activities that are proposed as part of the mine plan and provide a schedule for their completion. Descriptions of all facilities and features should include both narratives and design drawings showing plan views, layouts, cross-sections, and profiles. For the purpose of liability estimates, discrete descriptions are required for current, two-years forward, and end-of-mine conditions.		5.0
5.1 Mine Features, Facilities and Equipment	Provide detailed descriptions of mine features, facilities, and equipment for current, two years hence and end-of-mine conditions. This should include information on the quantity and size of all components with narrative descriptions and/or design drawings showing plan views, layouts, cross-sections and profiles. Descriptions require sufficient detail to estimate reclamation and closure liability for all mine components.	5.3, 5.4, 5.5, 5.6
	Provide maps and drawings, at appropriate scales and contours for the information displayed, showing all features and facilities identified in the mine plan, including related and off-site facilities that are associated with the mine plan or reclamation. The maps should include, or be accompanied by, information about each feature such as area, volume, tonnage, slope angles, and other dimensions as needed to quantify reclamation and closure tasks.	5.3
	Describe mine-related land disturbance in detail, to accompany and explain the information provided on maps and drawings. Describe any current or potential stability issues or other issues affecting on-site features and facilities.	5.4, 5.5, 5.6
5.2 Mining Operations	Describe the mining operations including rates, types of equipment, processing, metal recovery, material segregation, hauling, waste disposal, tailings disposal, heap leaching, concentrate storage, etc. Describe how mining activities and decisions have considered reclamation needs. Quantify mining activities that have occurred as well as those that are proposed within the next two years, and by the end-of-mine.	5.3.1; 5.5; 5.6; Mine Operations Plan; Waste Rock and Overburden Management Plan; Heap Leach and Process Facilities Plan
5.3 Water Management	Describe the current and proposed management of surface water and groundwater at the site. Include narratives and design drawings for all water management facilities and activities including diversions, ponds, intake structures, dams, storage facilities, pumps, water collection wells, sumps, pipelines, etc. Describe management of solutions used for processing or metal recovery. Address quantities, flow rates and paths, quality, storage requirements, groundwater/surface water interactions, etc.	5.3.12; Water Management Plan; Heap Leach and Process Facilities Plan
	Characterize geochemical effects associated with mining activities. Describe results from monitoring and testing programs. Provide predictions of geochemical loading and effects from mine-related sources, using appropriate modeling tools (e.g., water balance models, groundwater models, contaminant load models, conceptual site models). Modeling tools should be of sufficient granularity to evaluate seasonal conditions.	7.1; Water Management Plan
	Describe water treatment operations and facilities, including the types of processes used (physical, chemical, biological), nominal and maximum capacity, maintenance and availability requirements, and any unique or special operating features. If the water treatment system is currently operating, provide monitoring results to demonstrate performance. If the treatment system is proposed, describe the results of water treatment testing programs that demonstrate performance of the proposed treatment methods for site-specific water quality, flow rate, climate and receiving environment conditions.	2.3.1.2; 5.3.5.4; Heap Leach and Process Facilities Plan
5.4 Monitoring	Describe monitoring activities and results, including monitoring schedules and analytical requirements for surface water quality and flow, groundwater quality and flow, physical stability, vegetation, wildlife and air.	5.7
5.5 Risk Assessment, Contingency Planning and Adaptive Management	Describe any risk assessment or contingency planning processes undertaken to support decision making for mine development and operations. Include risk assessment results or contingency plans as appendices as appropriate.	5.8
	Provide details about any adaptive management plans that are being implemented to address uncertainties about mine development or operation.	5.8.2; Environmental Monitoring and Adaptive Management Plan
6.0 TEMPORARY CLOSURE		
The Temporary Closure Plan section of a RCP must describe the measures and activities that will be undertaken in the event of a temporary closure. During any temporary closure, facilities on site must remain substantially intact and maintained in good working order. Site maintenance and monitoring and reporting must continue uninterrupted throughout temporary closure.		6.0
In general, temporary closure plans must focus on ensuring public health and safety, protecting the environment, and managing risks associated with potential abandonment of a site. To demonstrate how these objectives will be achieved, each temporary closure plan must include at a minimum the following information.		6.0
6.1 Site Security, Monitoring and Maintenance	Describe the locations where equipment will be stored, storage methods for chemicals, reagents, and fuel, and how infrastructure will be maintained during temporary closure.	6.3
	Summarize the ongoing monitoring and maintenance activities that will be required and any processes that will be used to make decisions about these requirements. Provide an environmental monitoring, management and reporting plan that will be implemented to ensure that the site remains secure and stable, and to demonstrate that the site continues to meet performance expectations.	6.6
	Describe how site access will be restricted, the onsite security that will be in place, how access to open pits and underground working will be restricted, and how buildings and infrastructure will be secured.	6.3
	Describe how all landfills, waste management areas, tailings facilities, ore stockpiles, heap leach pads, and impoundments will be geochemically and physically stabilized and secured. Describe how increased durations of exposure during temporary closure may affect acid rock drainage or metal leaching predictions for ore or waste materials. Describe measures that will be taken to minimize exposure of susceptible materials.	6.4
	Quantify labour, materials, energy, and other requirements to conduct temporary closure activities and provide details that will be required to estimate costs of temporary closure activities.	6.2

YWB and EMR (2013) Annex 1 Annotated Outline for Reclamation and Closure Plan		RCP Section(s)
6.2 Interim Water and Solution Management Plan	Describe plans for the management of clean water, contaminated water, and process solutions during any temporary closure.	6.5
	Describe water and solution management processes, protocols and activities including managing water levels in open pits, underground workings, tailings impoundments, heap leach pads, pregnant and barren solution ponds, storm water ponds, or other water holding, conveyance or treatment facilities on-site. Include a description of ongoing water treatment processes and management of discharge streams.	6.5
	Include descriptions of the facilities and processes for conveyance of clean water through or around the site, including their maximum capacities. Address any special requirements for maintaining or operating these during temporary closures.	6.4.4
	Provide flow diagrams and drawings for water management programs including control or shut off switches for all tanks, pumps, pipelines, and ponds. Include an equipment list of essential fluid management system components and describe spare parts and backup systems that will be maintained on site.	5.3; 6.5
	Provide schedule of water management activities to be undertaken during periods of temporary closure. Describe inspections needed to ensure suitable water and solution management performance and outcomes.	6.5; 6.6
	Provide an emergency fluid management protocol that includes by-pass procedures if over-topping of water holding facilities may occur, and by-pass or containment procedures if water treatment facilities are damaged or unable to keep up with demand.	6.5.2
7.0 FINAL RECLAMATION AND CLOSURE MEASURES		
The Final Reclamation and Closure Measures section of the RCP should provide details on proposed reclamation and closure for all components of the mine site. Each section should describe the disturbance on site, the proposed closure methods, and alternative closure options associated with that closure aspect. Provide designs and detailed descriptions for reclamation and closure measures and activities that will be undertaken for all mine features and facilities.		2.3.4; 7.0
Describe what will be done to achieve the reclamation and closure objectives and meet the design criteria. Provide sufficient detail and supporting analyses to demonstrate how the proposed measures and activities will meet the performance expectations.		7.0
Also provide sufficient detail to support accurate estimates of reclamation and closure liabilities. A table that shows the total area of disturbance for all project components must be provided, addressing current, two-years forward, and end-of-mine conditions.		5.4; 5.5; 5.6
Identify and describe any alternatives that were considered for reclamation and closure of specific mine components or to address specific issues. Provide details about the characterization, evaluation, and selection of alternatives, including the use of tools like risk assessment, failure modes effects analysis, multi-attribute analysis, etc. Describe the benefits and drawbacks associated with the alternatives and provide rationale for the options selected.		2.3.4, Appendices 2-K to 2-M
7.1 Underground Workings and Openings to Surface	Describe how all surface openings to underground workings (raises, shafts, excavations, tunnels, chutes) will be blocked utilizing a suitable method as designed by a qualified professional engineer and capped to meet requirements specified in the Occupational Health and Safety Regulations of the *Occupational Health and Safety Act*.	N/A
	Where there is a demonstrated risk, and potentially significant consequence, that mine water pressures are likely to build to dangerous levels, describe how long-term drainage of excess mine water will be achieved.	
	Describe long-term water management for underground workings. Identify expected long-term water levels and describe any management requirements for discharge. Quantify any potential discharges including those to both surface and groundwater. Characterize interactions between underground workings and local groundwater. Provide predictions of underground water quality, based on monitoring data and geochemical analyses. Describe water treatment requirements associated with long-term drainage or water management from underground facilities. Identify any contingency treatment facilities to address uncertainty about water quality or underground water levels. Provide predictions of water quality, based on monitoring data and site-specific testing programs. Include predictions of loading to receiving water, using water quality and contaminant loading models.	
	Provide stability analyses for underground workings and demonstrate how workings are designed to minimize any surface expression of underground subsidence. Describe any underground support structures that are to remain in place to provide long-term structural stability. Provide analysis to demonstrate how the support structures will sustain anticipated loads for the long term, including static and dynamic loading. Stability calculations must be based on current standards and designs certified by qualified professional engineers must be provided.	
	Identify areas where safety issues may arise and describe how access to areas of unsafe drop-offs will be blocked and notices will be appropriately posted. Include measures to address requirements of the Workplace Health and Safety Regulations as set out in the *Occupational Health and Safety Act*.	
	If underground backfill will be used, describe how the mine workings will be backfilled, what materials will be used, and the timing of the backfill. Include a description of any material or equipment that will be left underground and how it will be decontaminated. Provide schematics of underground workings, including ramps, adits and other openings to surface and any remaining related structures, equipment or materials to be left in place.	
	Describe reclamation and re-vegetation activities that will be taken at any surface openings.	
7.2 Open Pits	Provide stability analyses for pits and describe any measures to stabilize open pits, including any re-sloping, grading, buttressing, etc. Provide designs to demonstrate expected performance. Stability analysis reports may be provided in appendices.	5.3.1.1; Appendix 5-A; Mine Operations Plan
	Describe any pit backfilling, including quantities and types of materials, handing and transportation methods, placement methods, and criteria for final fill. If pits will be left to fill with water, prepare a pit water balance that predicts pit filling conditions and timing.	5.3.1; 7.1.2; Waste Rock and Overburden Management Plan
	Identify areas where safety issues may arise and describe how access to areas of unsafe drop-offs will be blocked and posted appropriately. Include measures to address requirements of the Occupational Health and Safety Regulations as set out in the *Occupational Health and Safety Act*.	7.1.4
	Provide predictions of pit water quality based on monitoring data, operational uses of the pit and materials stored in pits. Address both transitional and long-term water quality. Provide a characterization of interactions between pits and local groundwater. Include groundwater model reports as appendices. Describe water treatment requirements associated with pit water, for both transitional and long-term conditions. Describe transitional and long-term management of pit water including both water levels and water quality based on monitoring data and site-specific testing programs. Include long-term predictions of loading to receiving water, using water balance analysis and contaminant loading models. Address water storage requirements for both normal and emergency circumstances and identify conditions in which pit storage may be used for site water management. Quantify any potential discharges including those to both surface and groundwater.	7.1.2; 7.1.3; Water Management Plan
	Provide designs for surface water management and sediment control facilities at pits and infrastructure including layout, sizing, material and construction specifications, and erosion control.	5.3.12; Erosion and Sediment Control Plan
	Describe reclamation and re-vegetation activities for pit areas. Provide details about landscape design, describing how the area will provide long-term ecosystem services once mine activities are complete.	7.1.4

YWB and EMR (2013) Annex 1 Annotated Outline for Reclamation and Closure Plan		RCP Section(s)
7.3 Heap Leach Pads and Process Ponds	For heap leach pads and process ponds, RCPs should contain the following information.	
7.3.1 Detoxification, Rinsing and Solution Management	Describe proposed processes, sequences and scheduling for any residual leaching, rinsing, detoxification and/or neutralization of heap materials. The proposed processes should be supported by site-specific test work that demonstrates the effectiveness of proposed rinsing, detoxification, and neutralization methods.	7.3.1
	Provide a complete physical and chemical characterization of the residual heap leach materials, providing evidence that rinsing will be physically practical and can achieve neutralization. Include predictions of water quality from the heap leach pad, based on monitoring data, and/or site-specific testing programs. Include long-term predictions of loading to receiving water, using water quality and contaminant loading models.	5.3.5; 7.3.1; Heap Leach and Process Facilities Plan
	Identify water quality criteria that will be used to start and end rinsing, detoxification and/or neutralization activities.	7.3.1; Heap Leach and Process Facilities Plan
	Provide a solution management plan that describes expected flows, storage and handling of process and rinsing solutions. Describe the water balance for the heap leach facility, including leaching and rinsing sequences, areas and volumes of ore under leach/rinse, application rates, and percolation characteristics of the ore. Provide test results to demonstrate ore performance at the neutralization stage, considering multiple leach cycles and full heap depth. Describe the overall solution storage capacity, and how the capacity will be used during detoxification, rinsing and draindown. Include the sequence and plan for final draindown of the heap leach facility, considering the total quantity of solution, expected draindown rate, and the capacity of proposed water treatment systems. Provide designs for the pumping and piping facilities for conveying leach solution to and from the heap leach pad, including layout and sizing.	5.3.5; Heap Leach and Process Facilities Plan
	Describe water treatment processes that will be used during rinsing, detoxification, and post-closure. Provide as appendices the results of water treatment test programs that demonstrate expected performance of treatment systems. Provide designs for water treatment facilities including flow sheets, sizing, capacities, process controls, containment systems, reagent use and discharge conditions. Describe amounts and characteristics of any water treatment sludge and provide designs for containment facilities/approaches, both temporary and permanent. Describe scheduling for construction of water treatment facilities, including any variations or additions that may be required for specific closure phases.	5.3.5.4; Appendices 2-D to 2-G; Heap Leach and Process Facilities Plan
7.3.2 Physical Stability and Reclamation	Describe the results of stability analyses for the heap leach pad and any reclamation measures required to meet long-term stability requirements. Analyses must be supported by site-specific sampling and testing of materials, providing realistic and defensible material strengths and properties. Provide stability analyses and design reports as appendices.	Heap Leach and Process Facilities Plan; 7.3.1
	Provide designs for cover systems that will be used for heap leach pads. Include detailed descriptions and specifications for proposed covers and provide modeling to demonstrate how the proposed covers will achieve infiltration criteria, to support water balance and contaminant load modeling. Identify materials and sources for cover construction. Describe any proposed re-grading of heap surfaces.	7.3.1; Appendix 7-B
	Provide designs for surface water management and sediment control facilities and infrastructure for heap leach pads, including layout, sizing, material and construction specifications, and erosion control.	5.3.5.2; Erosion and Sediment Control Plan
	Describe how liner systems for heap leach pads and process ponds will be decommissioned. Demonstrate measures to ensure that liners do not remain as long term containment facilities unless designed for this purpose.	7.3.2
	Identify areas where safety issues may arise, and describe methods for addressing safety issues by reclamation, controlling access or posting notice.	7.3.3
	Describe reclamation and re-vegetation activities for heap leach pads and pond areas. Provide details about landscape design, describing how the area will provide long-term ecosystem services once mine activities are complete.	7.3; Appendix 7-B
7.4 Tailings Facility Areas	Describe the materials that will be contained in any tailings facilities on site, including sample selection, mineralogical analyses, static testing, and kinetic testing. Also describe the water quality and quantity conditions associated with the tailings, including porewater, seepage and runoff. Provide results of monitoring and site-specific testing programs. Include long-term predictions of loading to receiving water, using water quality and contaminant loading models. Describe the results of stability analyses for tailings facilities and any reclamation measures required to meet long-term stability requirements. Analyses must be supported by site-specific sampling and testing of materials, providing realistic and defensible material strengths and properties. Provide supporting reports for characterization of tailings conditions as appendices.	N/A
	Provide designs for covers that will be used to reclaim tailings surfaces. Include detailed descriptions and specifications for proposed covers and provide modeling to demonstrate how the proposed covers will achieve infiltration criteria, to support water balance and contaminant load modeling. Identify any requirements for water covers, saturation of tailings materials, or maintenance of dry tailings, and provide designs for achieving these outcomes.	
	Provide detailed designs for the closed tailings facility, along with management approaches for long-term maintenance and monitoring. Describe how the proposed closure measures will achieve the overall closure objectives. Identify specific design components and operational requirements that will affect or constrain closure options. Include the results of stability analyses for any proposed upgrades or changes to tailings facilities and any reclamation measures required to meet long-term stability requirements.	
	For any permanent structures that will remain as part of a tailings facility, describe long-term care and maintenance activities required to ensure the integrity of the tailings facility.	
	Describe any tailings relocation activities, including where the tailings will be placed, how they will be moved, and reclamation requirements for both existing and new storage locations. Identify any water management implications of tailings relocation and describe how these have been incorporated into water management strategies.	
	Describe water treatment requirements associated with tailings storage facilities and locations including surface water, seepage, and groundwater. Identify any contingency treatment facilities to address uncertainty related to tailings water quality or flows. Provide predictions of seepage, runoff and groundwater quality, based on monitoring data and site-specific testing programs. Include long-term predictions of loading to receiving water, using water balance analysis and contaminant loading models.	
	Describe the requirements for surface water management for tailings areas including transitional and long-term surface water management and sediment control. Provide designs for surface water management and sediment control facilities and infrastructure, including layout, sizing, material and construction specifications, and erosion control. Include descriptions and diagrams of the pipelines, diversion ditches, spillways, and seepage recovery systems, including those that will be removed or decommissioned at closure and those that will remain permanently.	
	Identify areas where safety issues may arise, and describe methods for addressing safety issues by reclamation, controlling access or posting notice.	
	Describe reclamation and re-vegetation activities for tailings areas. Provide details about landscape design, describing how the area will provide long-term ecosystem services once mine activities are complete.	

YWB and EMR (2013) Annex 1 Annotated Outline for Reclamation and Closure Plan		RCP Section(s)
7.5 Waste Rock and Overburden Dumps	Describe the materials that will be contained in each waste rock and overburden storage facility on site, including sample selection, mineralogical analyses, and the results of other testing programs. Also describe the water quality and quantity conditions associated with the waste rock and overburden materials including porewater, seepage and runoff. Provide results of monitoring and site-specific testing programs. Include long-term predictions of loading to receiving water, using water quality and contaminant loading models.	5.3.2; 7.2.1.1; Waste Rock and Overburden Management Plan
	Describe the results of stability analyses for the waste rock and overburden dumps, and any reclamation measures required to meet long-term stability requirements. Analyses must be supported by site-specific sampling and testing of materials, providing realistic and defensible material strengths and properties.	5.3.2; Appendix 5-B; 7.2.1
	Describe proposed reclamation methods for waste rock and overburden dumps, including re-grading, covering and re-vegetation. Include figures and drawings that show plan views, layouts, cross-sections and profiles. Describe how the proposed closure measures will achieve the overall closure objectives. Also provide designs for covers that will be used for waste rock and overburden materials. To support water balance and contaminant load modeling, include detailed descriptions and specifications for proposed covers and provide modeling to demonstrate how the proposed covers will achieve infiltration criteria. Identify materials and sources for cover construction. Identify any requirements for water covers, saturation of waste materials, or maintenance of dry conditions, and provide designs for achieving these outcomes.	5.3.2; 7.2
	Describe any waste rock or overburden relocation activities, including where the materials will be placed, how they will be moved, and reclamation requirements for both existing and new storage locations. Identify any water management implications of waste relocation and describe how these have been incorporated into water management strategies, water balance and contaminant load predictions.	7.2; 7.9.6
	Describe water treatment requirements associated with waste rock and overburden storage facilities and locations, including surface water, seepage, and groundwater. Identify any contingency treatment facilities to address uncertainty related to waste rock and overburden water quality or flows. Provide predictions of seepage, runoff and groundwater quality, based on monitoring data and site-specific testing programs. Include long-term predictions of loading to receiving water, using water balance analysis and contaminant loading models.	7.2.1.1
	Provide designs for any contaminated water collection and conveyance facilities, including details about how the designs have addressed foundation conditions and requirements for long-term performance if needed.	5.3.12; 7.7
	Describe the requirements for surface water management for waste rock and overburden areas including transitional and long-term surface water management and sediment control. Provide designs for surface water management and sediment control facilities and infrastructure including layout, sizing, material and construction specifications, and erosion control. Include descriptions and diagrams of the pipelines, diversion ditches, spillways, and seepage recovery systems, including those that will be removed or decommissioned at closure and those that will remain permanently.	7.7; 7.9.4; Water Management Plan
	Identify areas where safety issues may arise, and describe methods for addressing safety issues by reclamation, controlling access or posting notice.	7.2.1
	Describe reclamation and re-vegetation activities for waste rock and overburden areas. Provide details about landscape design, describing how the proposed design will provide long-term ecosystem services once mine activities are complete.	7.2.3
7.6 Ore Stockpiles and Pads	Describe the materials that will be contained in each ore stockpile or the remaining pads. Include details about sample selection, mineralogical analyses, and the results of other testing programs. Provide predictions of seepage, runoff and groundwater quality, based on monitoring data and site-specific testing programs. Include long-term predictions of loading to receiving water, using water balance and contaminant loading models.	5.3.3.3; Waste Rock and Overburden Management Plan
	Describe any plans for milling of ores stockpiles and the costs associated with the milling activities. Provide test work that demonstrates feasibility of milling the materials.	5.3.4; Heap Leach and Process Facilities Plan
	Provide designs for any re-grading, covering and re-vegetation of ore stockpiles or pads. Include figures and drawings that show plan views, layouts, cross-sections and profiles. Describe how the proposed closure measures will achieve the overall closure objectives.	5.3.3; 7.4.2
	Provide designs for covers that will be used for ore stockpiles and pads. Include detailed descriptions and specifications for proposed covers and provide modeling to demonstrate how the proposed covers will achieve infiltration criteria. Identify materials and sources for cover construction. Performance of covers should be incorporated into water balance and water quality modeling, to predict long-term contaminant effects. Identify any requirements for water covers, saturation of ore materials, or maintenance of dry conditions, and provide designs for achieving these outcomes.	N/A
	Describe ore stockpile relocation activities, including where the materials will be placed, how they will be moved, and reclamation requirements for both existing and new storage locations. Identify any water management implications of stockpile relocation and describe how these have been incorporated into water management strategies.	5.3.3; 7.4.3
	Describe the requirements for surface water management for ore stockpile areas, including transitional and long-term surface water management and sediment control. Provide designs for surface water management and sediment control facilities and infrastructure including layout, sizing, material and construction specifications, and erosion control. Include descriptions and diagrams of the pipelines, diversion ditches, spillways, and seepage recovery systems, including those that will be removed or decommissioned at closure, and those that will remain permanently.	5.3.3.3; 7.9.4; Erosion and Sediment Control Plan
	Describe water treatment requirements associated with ore stockpiles and pads, including surface water, seepage, and groundwater. Identify any contingency treatment facilities to address uncertainty related to ore stockpiles water quality or flows. Provide predictions of seepage, runoff and groundwater quality based on monitoring data and site-specific testing programs. Include long-term prediction ns of loading to receiving water, using water balance analysis and contaminant loading models.	N/A
	Describe reclamation and re-vegetation activities for ore stockpile areas. Provide details about landscape design, describing how the area will provide long-term ecosystem services once mine activities are complete.	7.4.3

YWB and EMR (2013) Annex 1 Annotated Outline for Reclamation and Closure Plan		RCP Section(s)
7.7 Water Management Structures and Systems	Provide detailed geotechnical and hydraulic designs for all water management structures and facilities including dams, diversions, ponds, passive treatment systems, spillways, collection systems, etc. Include designs for any upgrades or changes required during reclamation and closure. Demonstrate how the proposed facilities meet the design criteria.	5.3.12; Water Management Plan
	Describe the results of stability analyses for the water management structures, and any reclamation measures required to meet long-term stability requirements. Analyses must be supported by site-specific sampling and testing of materials, providing realistic and defensible material strengths and properties. Analyses should also address permafrost conditions and long-term performance.	7.7; Water Management Plan
	Provide an overall water management plan that addresses surface water, groundwater and seepage, the management of clean water and contaminated water, water treatment requirements, and sediment and erosion control. This management plan must address regular conditions, flood events, and low-flow events. Provide description and diagrams of closure period water management processes and protocols. Include decision diagrams if relevant.	Water Management Plan
	Provide designs for any contaminated water collection and conveyance facilities, including the location and capacity of water collection wells, pumps, slurry walls, pipelines, etc. Describe how these facilities will operate in a variety of climatic and flow conditions.	Heap Leach and Process Facilities Plan; Water Management Plan
	Describe treatment systems that will be used during reclamation implementation or long-term closure to address contaminated water from all sources at the site. Provide results of water treatment test programs that demonstrate expected performance of treatment systems, whether passive or active. Provide designs for water treatment facilities, including flow sheets, sizing, capacities, process controls, containment systems, reagent use and discharge conditions. Describe amounts and characteristics of any water treatment sludge and provide designs for containment facilities/approaches, both temporary and permanent. Describe scheduling for construction of water treatment facilities, including any variations or additions that may be required for specific closure phases.	5.3.5.4; 2.3.1.2; Appendices 2-D to 2-G; Appendix 5-C
	Describe the requirements for overall site surface water management, including transitional and long-term surface water management and sediment control. Provide designs for surface water management and sediment control facilities and infrastructure including layout, sizing, material and construction specifications, and erosion control. Include descriptions and diagrams of the pipelines, diversion ditches, spillways, and seepage recovery systems, including those that will be removed or decommissioned at closure and those that will remain permanently.	5.3.12; Water Management Plan
	Describe long-term monitoring and maintenance requirements for water management structures that will remain on site (e.g., dams, diversions). Describe the role of professional engineers in the long-term management of these structures. If dams will be removed, provide detailed designs for dam removal. Dams that are to remain in place must meet the provisions of the Canadian Dam Safety Guidelines and must be certified by a qualified professional engineer with respect to their long-term physical and chemical stability.	7.11
	Describe proposed methods for reclaiming and closing any water storage, water treatment or process ponds on site. Characterize any sediments remaining in the ponds (e.g., ABA, ICP-MS, XRD, TCLP, SWEP, etc.). Describe relocation or reclamation of sediments contained in ponds. Address any water management implications associated with pond or sediment reclamation.	7.3.2; 7.7
	All aspects of the water management plan should be based on the results of water balance analyses and contaminant load modelling. Provide an overall site water balance with at least a monthly time step that incorporates water balances from all major site components and predicts water deficits and surpluses. Provide an overall site contaminant load balance that integrates source loading from all mine related sources and predicts interactions with local groundwater and surface water. Document or predict past, present or future predicted discharges from individual source facilities including location, volume, and water quality.	Water Management Plan
7.8 Mine Infrastructure	Describe how mill and processing buildings and facilities will be dismantled and how the foundation will be removed. Describe plans for revegetation. Include details for the removal of processing equipment, presses, crushing and ore handling facilities, concentrate storage sheds and any other ancillary structures that are used in the milling process.	7.4
	Describe how machinery, equipment, and storage tanks will be cleaned and removed from the mine site. Provide a list of all fixed and mobile equipment that will be removed from the site for sale or salvage.	7.4; 7.5
	Provide the proposed measures for reclamation and closure of buried support infrastructures (tanks, pipes, underground services, etc.). Provide detailed maps that show all buried foundations, equipment or infrastructure that will remain on site once mine reclamation activities are complete.	7.5; 7.6
	Describe how the camp will be dismantled, including how sewage treatment facilities, water supply wells, and pump houses will be decommissioned. Include the proposed measures for reclamation and closure of airstrips, power transmission lines, pipelines, and railways.	7.6
	Describe in detail how all landfills, land treatment facilities, and waste storage areas will be decommissioned and reclaimed. Provide a figure that shows the locations of all landfills and waste storage areas.	7.8.4; 7.9.3.1; Waste and Hazardous Materials Management Plan
	Describe how any power generation facilities, transmission towers and poles' right of way will be decommissioned and dismantled.	7.5
	Describe reclamation and re-vegetation activities for infrastructure sites. Provide details about landscape design, describing how the area will provide long-term ecosystem services once mine activities are complete.	7.5.2; 7.6.1
7.9 Hazardous Materials	Provide an inventory of hazardous materials on the site, including reagents, explosives, fuels, lubricants, etc. Include estimates of expected hazardous material quantities to be addressed during reclamation and closure and describe plans for completion of environmental site assessments to be conducted early in the reclamation and closure implementation phase to confirm quantities and types. Also provide estimates of hydrocarbon contaminated soils that will require reclamation and provide designs and operation plans for any contaminated soil treatment facilities.	7.9.3; Waste and Hazardous Materials Management Plan
	Describe how explosives, reagents and other hazardous materials will be removed from site and/or disposed of in an approved facility. Describe reclamation plans for operational storage areas and facilities.	7.8.5; 7.9.3
	Describe the investigation, reclamation and revegetation activities that will be required at all areas where fuel was stored. Include in this description how all waste fuel or unused fuel will be removed from the site.	7.5.1
7.10 Roads and Other Access	Describe access requirements for site operations, monitoring and maintenance, including any measures for control of access to the site during reclamation and closure, and the expected duration of any restrictions on access.	5.3.13.2; 5.3.13.3; 8.5
	Provide a detailed description of methods and timing for reclamation of access roads, site roads, airstrips and other access. Include methods and timing for removal of bridges, culverts and drainage ditches, including re-establishment of streambeds. Provide designs for long-term erosion and sediment control, demonstrating how the closed facilities will handle flood events.	7.7; 7.8; 7.9.4
	Describe scarification, re-grading, landscape design and re-vegetation activities, including areas where specific prescriptions will be applied. Identify any indicators that will be used to determine if revegetation is warranted.	7.7; 7.8; 7.9.4

YWB and EMR (2013) Annex 1 Annotated Outline for Reclamation and Closure Plan		RCP Section(s)
	Describe any measures to address specific requirements for reclamation of access that is subject to an easement, right of way or lease under the *Lands Act*. Also describe any specific reclamation requirements for access that is located on First Nation settlement land.	7.8
7.11 Borrow Materials Planning	Provide a site wide compilation of borrow requirements for the RCP, identifying quantities, material specifications, and proposed locations for use.	7.10
	Provide an inventory of available borrow materials (e.g., overburden, growth media, granular, rip-rap, low permeability), showing sources for the required borrow materials. Provide quantities and properties of available materials, including site-specific test work to demonstrate that the proposed sources will meet the required specifications and quantities. Provide detailed borrow source investigation reports as appendices.	7.10.2; Appendix 2-I
	Describe any measures that will be required to refine or amend borrow materials so that they will achieve specifications.	N/A
	Mining activities often produce materials that can be used for implementation of reclamation works – e.g., overburden for covers. If mined materials are needed for reclamation activities, describe how the mine plan will be implemented to segregate appropriate materials and place them in easily accessible locations.	7.9.6
7.12 Monitoring and Maintenance	Describe maintenance and monitoring programs that will be undertaken during reclamation and closure. Monitoring may include water quality, water quantity, vegetation performance, terrestrial contamination, wildlife usage, physical integrity, air quality, etc. Include detailed schedules that describe monitoring locations, parameters, frequencies and analytical requirements. Describe how schedules may change during different stages of reclamation and closure, including any monitoring triggers for adjustments to monitoring locations, parameters or frequencies. Describe the access requirements for operation, maintenance, and monitoring.	7.11
	Describe re-vegetation maintenance requirements and expectations. Fertilization, weed control, and replanting or additional planting schedules should be provided. Include cover repair activities and decision-making protocols for evaluating cover performance and making decisions about maintenance needs. Describe any constraints on expected cover life, especially for synthetic covers. Include measures and schedules for replacing or repairing covers.	2.3.1; 7.9.5; Appendix 7-B
	Describe expected life for passive or active water treatment facilities, and measures and schedules for replacing or repairing those facilities.	7.3.1; 8.1
	Describe other site maintenance requirements such as storm water conveyances, water storage facilities, passive treatment facilities, and dams.	7.11.6
7.13 Performance Uncertainty and Risk Management	The RCP should identify and characterize key risks and uncertainties, and provide measures for addressing them where possible, while recognizing the reclamation and closure principle that adaptive managements must not form the basis of the RCP.	5.8.2; 7.13
7.13.1 Risk Assessment	Describe processes undertaken to identify and characterize risks associated with the site and the reclamation and closure plan. Describe how these processes have incorporated perspectives of various parties with different perspectives about mine related risks. Provide results of these risk assessment processes.	2.3.4; 5.8
	Describe mitigation measures and contingency plans established to address risks identified in the risk assessment.	5.8.2; 7.13
7.13.2 Adaptive Management Plans	Describe any proposed adaptive management plans that are designed to address unexpected performance of the mine closure facilities and systems. Describe specific events associated with uncertain performance, identify appropriate indicators for measuring performance. Describe monitoring requirements, defining specific thresholds for responding to unexpected performance. Outline processes for evaluating monitoring results and comparing to thresholds and provide descriptions of specific actions that will be taken in response to the threshold exceedances. Decision diagrams should be included for adaptive management protocols.	5.8.2; 7.13
8.0 RECLAMATION AND CLOSURE SCHEDULE AND EXECUTION STRATEGY		
The Reclamation and Closure Schedule and Execution Strategy section of the RCP describes when and how the reclamation and closure measures will be conducted. The schedule should address all reclamation and closure activities from progressive reclamation through to long-term monitoring and maintenance. The execution strategy should identify how the reclamation and closure activities will be completed - who is expected to carry them out, and how they will be funded.		8.0
8.1 Reclamation and Closure Schedule	Provide a detailed reclamation and closure schedule, describing the timing, sequencing, and duration for all reclamation and closure activities.	7.0; 8.1
	Describe the current design status for the RCP and provide schedules for completion of remaining reclamation research and design activities required to prepare a for construction RCP.	2.3; 2.3.1.4; 8.1
	Describe any progressive reclamation activities that have been completed or are proposed.	2.3.2
8.2 Execution Strategy	Describe the human resource requirements for completion of the RCP. Provide a table which summarizes the number and type of personnel required to implement each of the reclamation and closure activities. Include personnel requirements for the initial (i.e., with active work underway) closure phase and the long-term post-closure phase.	8.7
	Describe any institutional controls necessary to protect human health and environment (e.g., prohibition on excavation into cap/cover, prohibition on use of ground water, closure of all open adits/shafts, limitation of site access to treatment process units and reclaimed area).	8.5
	Describe who will carry out each stage of reclamation and closure activities. Identify plans for conducting any long-term operations, maintenance and monitoring activities, including who will carry out these activities and how they will be funded.	8.2
9.0 RECLAMATION AND CLOSURE LIABILITY		
The RCP must summarize estimates of liability associated with completion of reclamation and closure measures and activities. Quantify liabilities for current conditions, two-years hence and end-of-mine. Describe the approach and assumptions for estimating liabilities, including demonstrating how the approaches have addressed the principles described in this guide. Details of costs estimation methods and models must be provided as appendices, in accordance with direction provided in Annex 2 of this guide.		9.0

APPENDIX 1-B

Reclamation and Closure Plan
Decision Document and Proponent Commitments
Table of Concordance

Decision Document Mitigation Measures				
Mitigation Number	**Proposed Mitigation**	**Management Plan**	**Project Phases**	**Notes**
		Wildlife and Wildlife Habitat		
1	The Proponent shall apply for a lease or another form of regulatory approval under the Territorial *Lands Act* that will provide the Proponent with the authority and ability to control access between Maisy May Creek and the Stewart River. The point of access control shall be the beginning of new road connecting the existing road network with the Stewart River barge landing. Access shall be restricted through means such as a gatehouse or equivalent access restriction until the road is decommissioned such that this section of new road not become a public road.	**Access Route Construction Management Plan** Section 2.0: Authorizations for Construction; Section 7.0: Access Tie-in, Access Control, and Staging Area	Construction / Operation	
		Access Route Operational Management Plan Section 3.1: Access Control		
		Wildlife Protection Plan Section 4.2.4.1: Access Management		
2	The Proponent shall restrict public access to the Coffee Creek barge landing and roads connected to the barge landing that it maintains. Access shall be restricted through means such as a gatehouse, as near the barge landing as possible, until such time the road network attached to the barge landing is decommissioned such that these roads not become public roads.	**Access Route Construction Management Plan** Section 7.0: Access Tie-in, Access Control, and Staging Area	Construction / Operation	Access restricted through operation of the barge landings and through a gatehouse located approximately 2.8 km northeast of the north Stewart River barge landing.
		Access Route Operational Management Plan Section 3.1: Access Control		Access restricted through operation of the barge landings and through a gatehouse located approximately 2.8 km northeast of the north Stewart River barge landing.
		Wildlife Protection Plan Section 4.2.4.1: Access Management		
2.1	The Proponent shall ensure that all new road sections do not become public roads and that all new road sections be decommissioned by the conclusion of project activities. New barge landings shall be obstructed in a manner to prevent unloading of vehicles by barge.	**Access Route Construction Management Plan** Section 9.13: Decommissioning and Reclamation	Closure	
		Access Route Operational Management Plan Section 3.1: Access Control	Construction / Operation / Closure	
		Reclamation and Closure Plan Section 7.8.2: NAR and On-site Access Road	Closure	
3	The Proponent shall not use the NAR, except for maintenance purposes, when caribou migrations are expected to intersect the NAR or caribou are persistently crossing the NAR over a period of three days. Normal road use shall not resume until caribou are considered to have cleared the road corridor.	**Access Route Operational Management Plan** Section 4.5: Interaction with Wildlife	Construction / Operation / Closure	
		Wildlife Protection Plan Section 4.3.1: Species Specific Mitigation: Caribou		Phased approach to caribou mitigation: Response Level 3.
4	Snowbanks along the Northern Access Route shall be maintained at a level of less than 50 cm above the roadbed. Flowthrough breaks should be included at appropriate intervals and locations along the Northern Access Road.	**Wildlife Protection Plan** Section 4.1: Project Design; Section 4.2.4: Manage Road Operations	Construction / Operation	Snowbanks will be managed and maintained to 0.5 m high where safe to do so and allowed by other design considerations and will include periodic breaks to allow wildlife to move across the road, spaced between 500 m and 1 km apart on alternating sides of the road.
		Access Route Operational Management Plan Section 4.3: Snow Removal and Snow Management		Snowbanks will be managed and maintained to 0.5 m high where safe to do so and allowed by other design considerations and will include periodic breaks to allow wildlife to move across the road, spaced between 500 m and 1 km apart on alternating sides of the road.
5	The proponent shall retain an individual qualified in caribou behavior who will, in consultation with Government of Yukon, implement design features to reduce the likelihood of entrapment within project infrastructure as well as design features that reduce noise, visual, and light stimuli in alpine and subalpine habitats of high importance to caribou that are within line of sight of the mine site's activities to assist in reducing stimuli that may cause an expansion of the zone of influence (ZOI) for the mine site.	**Noise Management Plan** Section 5.0: Environmental Protection Measures	Construction / Operation / Closure	
		Wildlife Protection Plan Section 4.0: Wildlife Protection Measures Framework; Section 4.2: General Wildlife Protection Measures		
		Access Route Construction Management Plan Section 7.0: Access Tie-in, Access Control, and Staging Area; Section 8.0: Borrow Sources		
6	Between May 1 and August 31, the minimum cruising altitude for project-related aircraft shall be 600m. This window will be extended as necessary based on seasonal caribou presence documented in the Wildlife Monitoring Plan and decision criteria in the Adaptive Management Plan.	**Wildlife Protection Plan** Section 4.2.5: Manage Aircraft Operations	Construction / Operation / Closure	

Decision Document Mitigation Measures				
Mitigation Number	**Proposed Mitigation**	**Management Plan**	**Project Phases**	**Notes**
		Water and Aquatic Resources		
7	In evaluating whether the non-degradation threshold for Coffee Creek is met, the Proponent shall be subject to performance evaluation criteria that incorporate a suitable method to determine if the Coffee Gold Project is the primary or most substantial cause of any exceedance of the non-degradation threshold. The Proponent's non-degradation thresholds shall be revised to require that the Project not be the primary or most substantial cause of any exceedance of a non-degradation threshold.	**Surface Water Quality and Aquatic Life Adaptive Management Plan** Section 2.3.2: Non-Degradation Water Quality Objectives - Coffee Creek and Yukon River	Construction / Operation / Closure	
8	The proponent shall revise water quality objectives prior to licensing, as necessary, dictated by the current relevant science and using the same level of protection assessed during the Screening. That is, use-protection objectives in Halfway, Latte and YT-24 creeks, and performance evaluations that reflect non-degradation objectives in Coffee Creek and the Yukon River downstream of Halfway, Latte and YT24 creeks.	**Water Management Plan** Section 1.4.2: Territorial Regulations	Construction / Operation / Closure	
9	Prior to licencing, the Proponent shall revise use-protection water quality objectives to ensure they incorporate the most recent toxicological information and guidance from CCME, Government of Canada, and BCMoE for the protection of freshwater aquatic life.	**Water Management Plan** Section 1.4.2: Territorial Regulations	Construction / Operation / Closure	
10	Reclamation and closure plans required under the Quartz Mining Act will include, at a minimum, the same use protection and non-degradation objectives as during operations. Water quality early warning triggers for reclamation and closure will be developed and applied for all watercourses as part of the Environmental Monitoring and Adaptive Management Plan.	**Reclamation and Closure Plan** Section 3.1.5: Water Quality Objectives **Reclamation and Closure Plan** Section 5.8.2: Contingency Planning and Adaptive Management Approach	Closure	
11	The Proponent shall develop water related adaptive management plans in accordance with Government of Yukon's 2021 guidance document, including any future revisions, "Guidelines for developing adaptive management plans in Yukon: water-related components of quartz mining projects".	**Environmental Monitoring and Adaptive Management Plan** Section 2.2: Adaptive Management Approach **Surface Water Quality and Aquatic Life Adaptive Management Plan**	Construction / Operation / Closure	
12	Ore shall not remain on the ROM ore pad at the end of operations, during scheduled or unscheduled closure, without prior confirmation of long-term attenuation capacity of the schist pad for the key COPIs, arsenic and uranium that has been reviewed and accepted by the relevant regulator.	**Reclamation and Closure Plan** Section 6.4.1: Heap Leach Facility and ROM Stockpile; Section 7.4.2: ROM Stockpile Area Closure Measures	Temporary Closure	
13	The proponent shall provide to the relevant regulator all iterative water balance and water quality model runs generated in support of future licensing applications based on project updates, additional water quality mitigation measures proposed during screening and licensing, and new information. During operations, the proponent shall provide results of monitoring data to allow comparison with predictions with relevant regulators and affected First Nations.	**Water Management Plan** Section 7.0: Reporting **Water Management Plan** Section 8.0: Annual Water Management Planning	Construction / Operation / Closure	
14	Prior to licensing, the proponent shall summarize the results of all test work completed for the development of the proposed bioreactor treatment system (EBR system), identify treatment performance objectives for the EBR, provide timelines to complete the remaining test work and develop the detailed design of the EBR system.	**Heap Leach and Process Facilities Plan** Section 4.5: Water Treatment of Heap Leach Solutions **Heap Leach and Process Facilities Plan** Appendix D: Coffee Mine Water Treatment Design for Permitting	Construction / Operation	
15	The overall timeline for development of the EBR system must meet the conditions evaluated during the Screening, such that detailed plans for the EBR are submitted, reviewed and accepted by the responsible regulator, and the EBR is operational prior to the HLF water balance reaching a threshold that requires discharge of treated excess water to Halfway Creek or the Latte Pit.	**Heap Leach and Process Facilities Plan** Section 4.4: Solution Management **Heap Leach and Process Facilities Plan** Section 4.5 Water Treatment of Heap Leach Solutions	Construction / Operation	
16	The proponent shall provide contingency plans contemplating scenarios where timelines or effluent quality objectives cannot be met prior to licensing. Contingency plans shall include a proof of concept, an estimated implementation time, and water quality early warning triggers which will be developed and applied for all affected watercourses as part of the Environmental Monitoring and Adaptive Management Plan.	**Water Management Plan** Section 4.3.8.1: Alpha Pond Performance Targets and Mitigation Measures **Water Management Plan** Appendix A: Coffee Gold Project Contingency Water Management Measures - Memo	Construction / Operation	
		Heap Leach and Process Facilities Plan Section 4.5.3.3 and Appendix E: Contingency Water Treatment Plan	Construction / Operation	
17	The proponent must define acceptable performance conditions for the Alpha Pond in terms of water quantity and quality for seepage from the Pond as part of the adaptive management for the Alpha Pond.	**Water Management Plan** Section 4.3.8.1: Alpha Pond Performance Targets and Mitigation Measures	Construction / Operation	
18	The proponent shall provide contingency plans contemplating scenarios where the management of surface effluent discharged from Alpha Pond fails to meet water quality objectives in Halfway Creek.	**Water Management Plan** Section 4.3.8.1: Alpha Pond Performance Targets and Mitigation Measures	Construction / Operation	

Decision Document Mitigation Measures				
Mitigation Number	**Proposed Mitigation**	**Management Plan**	**Project Phases**	**Notes**
Traditional Land Use and Heritage Resources				
18.1	The Noise Management Plan shall include the following measures to reduce the effects on traditional land uses: a) The plan shall include an objective to mitigate noise from a traditional land use perspective. b) In collaboration with affected First Nations, mitigations measures shall be identified that achieve the above objective. This may include reducing the timing and frequency of noise-related activities during critical times for traditional land use, such as fall harvesting. c) The Proponent shall develop a system for tracking, recording, and responding to complaints related to noise in collaboration with Environmental Health Services. Complaints are to be submitted to Environmental Health Services for recording purposes. d) The Proponent shall establish, in discussion with affected First Nations and communities, a means by which to communicate and inform individuals and communities who may be affected by Project-related noise in advance of any changes in sound levels that may occur, including when planned blasts are predicted to occur or deviations in the blasting plans. e) This aspect of the plan shall be adaptive and be based on inputs from the Noise Monitoring Plan and/or through the Socio-economic Management Plan undertaken in collaboration with affected First Nations.	a) **Noise Management Plan** Section 1.2: Scope and Objectives b) **Noise Management Plan** Section 5.0: Environmental Protection Measures c) **Noise Management Plan** Section 5.1.5: Noise Complaint Procedure d) **Noise Management Plan** Section 5.1.3: Blasting e) **Noise Management Plan** Section 5.2: Adaptive Management	Construction / Operation / Closure	
19	The Proponent shall facilitate and support traditional land use activities within the project area to the extent possible (that is, within the limits of safety and in areas under the control of the Proponent). Facilitation and support shall include, but not be limited to: a) Making all or a portion of the Coffee Creek camp available for traditional uses; b) Funding suitable infrastructure at the Coffee Creek camp for traditional uses; c) Funding and supporting culture camps for affected First Nations; d) Ensuring staff are provided with information regarding traditional land uses they may encounter.	**Socio-economic Monitoring Plan** Appendix B: SEMP Management Strategies - Traditional Knowledge and Lands and Resource Use Management Strategy	Construction / Operation / Closure	
20	The Proponent shall establish an elder-in-residence program in order to better: a) improve cross cultural awareness; b) increase First Nations physical presence at the mine site; c) improve First Nation knowledge of project development, and improve the Proponent's understanding of First Nation perspectives regarding the Project's development; d) ensure First Nation workers can access elders at the mine site.	**Socio-economic Monitoring Plan** Appendix B: SEMP Management Strategies - Cultural Awareness and Diversity Management Strategy	Construction / Operation / Closure	
21	The Proponent shall include the following in the scope of the Socio-Economic Management Plan: a) A management objective to continue to identify effects on each affected First Nation's Traditional Land Use in the Coffee Creek Area b) A commitment to carrying thorough effectiveness monitoring and adaptive management of measures intended to mitigate impacts from construction until post-closure; c) A commitment to ensure that all affected First Nations have an opportunity to participate in developing end land use objectives for the site that are consistent with traditional land use values for the area, including future uses. d) Development of a Terms of Reference with each affected First Nation for the methodology to undertake studies under the umbrella of the SEMP relating to effects to Traditional Land Use, including roles and responsibilities of Proponent and First Nation contributors; and e) Capacity funding to ensure the affected First Nations' full participation in the SEMP management and monitoring components that are relevant to the affected First Nations interests, if they so choose.	a) **Socio-economic Monitoring Plan** Section 6.0: Monitoring b) **Socio-economic Monitoring Plan** Section 6.0: Monitoring c) **Socio-economic Monitoring Plan** Section 1.6.2: Potentially Affected First Nations' Role and Responsibility d) **Socio-economic Monitoring Plan Section** 1.6.2: Potentially Affected First Nations' Role and Responsibility e) **Socio-economic Monitoring Plan** Section 1.6.2: Potentially Affected First Nations' Role and Responsibility	Construction / Operation / Closure	

Decision Document Mitigation Measures				
Mitigation Number	**Proposed Mitigation**	**Management Plan**	**Project Phases**	**Notes**
		Traditional Land Use and Heritage Resources		
22	The Proponent shall fund efforts of affected First Nations (TH, WRFN, SFN and FNNND) to collect traditional knowledge with respect to the Coffee Creek area for the purposes of supporting a First Nation-developed culture program aimed at transmitting knowledge about the area to future generations.	**Socio-economic Monitoring Plan** Appendix B: SEMP Management Strategies - Traditional Knowledge and Lands and Resource Use Management Strategy	Construction / Operation / Closure	
23	The Proponent shall provide capacity funding for each affected First Nation to retain Indigenous Project Monitors, if they so choose, which shall have the following functions in relation to reducing effects to traditional land use; a) To identify, document and develop mechanisms to support resolution of potential conflict between mining activities and First Nation cultural values and practices in the Coffee Creek area. b) The monitors shall be involved in the collection of information on matters on-site related to harvestable resources in the project area and surrounding landscape and ways in the accessibility to those resources or quality of experience in harvesting those resources may be diminished. c) The monitors shall be on-site during mining activities but also be given means for community-based outreach work. This may include but not be limited to travel to First Nation primary communities and/or accommodating First Nation elders and land users at the site. d) The monitors shall also be involved in data collection for other culturally important land uses. Data collection shall include but not be limited to land user perceptions, regarding compatibility of traditional activities and adjacent industrial activities (e.g. user tolerance for noise, visual scarring, or other "sense of place" determinants). e) The Monitors shall be provided authority and resources to scope traditional knowledge and traditional use studies aimed at documenting mining / land use conflicts (actual or potential), and ways in which those conflicts could be mitigated. For greater clarity, this condition envisions that the Monitor may, from time to time, employ supporting staff of their choosing to support special projects. f) Funding for the Monitors shall be sufficient to enable the above functions, if so desired by each affected First Nation. The Indigenous Project Monitors act as a liaison between the affected First Nations and the Proponent and are a mechanism to implement the adaptive management framework outlined in the SEMP to address effects to traditional land uses. The Indigenous Project Monitors may act in conjunction with, or replace, the Environmental Monitors as committed to by the Proponent, depending on the needs and preferences of each affected First Nation. The Indigenous Project Monitors are intended to be independent of the Proponent and represent the interests of the affected First Nations.	**Socio-economic Monitoring Plan** Appendix B: SEMP Management Strategies - Traditional Knowledge and Lands and Resource Use Management Strategy	Construction / Operation / Closure	
24	The proponent shall only landfill inert substances at the project site. The Proponent shall work with affected First Nations and regulatory agencies to develop an Approved Landfill Materials list and mechanism for establishing suitably low leachability risk for proposed landfill materials.	**Waste and Hazardous Materials Management Plan** Section 1.3: Incorporation of Traditional Knowledge and Consultation Feedback, Section 5.0 Waste Management and Appendix B: Waste Materials List	Construction / Operation	
		Health and Safety		
25	The Proponent shall develop mandatory, regular harassment prevention training, in consultation with a qualified expert, to be delivered to all the Proponent's employees, contractors and consultants working on the Project. The qualified expert must also be proficient in cross-cultural awareness training.	**Socio-economic Monitoring Plan** Appendix B: SEMP Management Strategies - Community Health and Well-Being Management Strategy **HR Policy**	Construction / Operation / Closure	
26	The Proponent shall ensure that human resource staff complete training to enable them to effectively support employees who disclose workplace harassment. In order to support reporting of sexual harassment and assault, human resource staff shall provide all new staff members with information about ways in which they can record and provide evidence of harassment or bullying, what happens after they make a disclosure, and how they will be protected from reprisals.	**Socio-economic Monitoring Plan** Appendix B: SEMP Management Strategies - Community Health and Well-Being Management Strategy **HR Policy**	Construction / Operation / Closure	
27	The Proponent shall ensure that all HR staff complete training to effectively support employees who disclose sexualized or gender-based violence, as well as harassment and discrimination against Indigenous people in their workplace or at home. It is recommended that a counsellor be available on site for support through this as well.	**Socio-economic Monitoring Plan** Appendix B: SEMP Management Strategies - Community Health and Well-Being Management Strategy **HR Policy**	Construction / Operation / Closure	

Decision Document Mitigation Measures				
Mitigation Number	**Proposed Mitigation**	**Management Plan**	**Project Phases**	**Notes**
		Health and Safety		
28	The Proponent shall create a mentor program for Yukon First Nation employees to achieve three goals: a) ensure that First Nation women have access to a mentor or supervisor who has the authority to and regularly checks in to address any negative experiences related to the male-dominated work environment, and who pays special attention to potential cases of abuse; b) develop a formal feedback process to ensure that enquiries are regularly made of First Nation employees to ensure that they are able to voice their concerns and address any negative experiences; and c) involve TH, SFN, FNNND and WRFN in further developing the program to ensure that it meets the needs of First Nation employees.	**Socio-economic Monitoring Plan** Appendix B: SEMP Management Strategies - Community Health and Well-Being Management Strategy	Construction / Operation / Closure	
29	The Proponent shall, in consultation with a qualified expert and with TH, SFN, FNNND and WRFN, develop gender appropriate and gender- and sexuality-specific policies and processes that promote a safe, respectful, and inclusive environment for women and gender and sexual minorities.	**Socio-economic Monitoring Plan** Appendix B: SEMP Management Strategies - Community Health and Well-Being Management Strategy **HR Policy**	Construction / Operation / Closure	
30	The Proponent shall ensure that HR staff administer confidential exit surveys with explicit questions about whether workplace harassment occurred, if disclosures were made, and what supports were provided. The proponent shall use this information to track trends and inform hiring, policy, and other initiatives at the mine site, and shall provide an annual report to Health and Social Services and the Women's Directorate detailing the Proponent's efforts to prevent workplace harassment as well as statistics on reported incidences of harassment, disclosures, etc.	**Socio-economic Monitoring Plan** Appendix B: SEMP Management Strategies - Community Health and Well-Being Management Strategy **HR Policy**	Construction / Operation / Closure	
31	The Proponent shall ensure that the on-site First Aid Technician or Emergency Medical Technician is trained in Mental Health First Aid and/or has formal mental health training to provide short-term or crisis support at the mine site and has referrals to other mental wellness supports or navigation to other systems.	**Socio-economic Monitoring Plan** Appendix B: SEMP Management Strategies - Community Health and Well-Being Management Strategy	Construction / Operation / Closure	
32	The Proponent shall ensure that on-site employees have the ability to utilize the Employee Assistance Plan (EAP) services available (i.e., make available a private phone line or Internet connection so employees can discreetly reach EAP services)	**Socio-economic Monitoring Plan** Appendix B: SEMP Management Strategies - Community Health and Well-Being Management Strategy	Construction / Operation / Closure	
33	The Proponent shall retain professional services in the appropriate field to help their on-site mental health first aid staff develop the methods and tools that are appropriate to provide support to perpetrators of violence and harassment to help end cycles of abuse.	**Socio-economic Monitoring Plan** Appendix B: SEMP Management Strategies - Community Health and Well-Being Management Strategy	Construction / Operation / Closure	
34	The Proponent shall consider gender equity/diversity in hiring processes.	**Socio-economic Monitoring Plan** Appendix B: SEMP Management Strategies - Community Health and Well-Being Management Strategy **HR Policy**	Construction / Operation / Closure	
35	To address and mitigate impacts to employees who are or become victims of domestic abuse, the Proponent must create a policy that: a) outlines clear procedures for the workplace to deal with affected employees and provide appropriate resources and support; b) plans for and addresses the safety concerns of the affected employees while at work to ensure that all workers are safe from threats of domestic violence; and c) includes a personal safety plan for employees suffering from domestic violence.	**Code of Conduct**		Additional detail will not be provided
36	The Proponent shall provide access to the EAP for the eligible dependents of employees and inform all employees of this.	**Socio-economic Monitoring Plan** Appendix B: SEMP Management Strategies - Community Health and Well-Being Management Strategy **HR Policy**	Construction / Operation / Closure	

Decision Document Mitigation Measures				
Mitigation Number	**Proposed Mitigation**	**Management Plan**	**Project Phases**	**Notes**
		Health and Safety		
37	The Proponent shall develop clear standards for behaviour at work and codes of conduct against sexual harassment and gender-based violence on the job site and in the broader community, including standards/codes of conduct in relation to the sex trade, and shall distribute education and awareness campaign materials on gender-based violence. Refer to Unlocking Opportunities for Women and Business: Actions and Strategies for Oil, Gas and Mining Companies Tool Suite 4: Addressing Gender Based Violence in the Workforce (2018) for information and resources.	**Code of Conduct**		Additional detail will not be provided
38	The Proponent's Noise Management and Monitoring Plans submitted at licensing should incorporate all recommendations outlined in Appendix 10-A Noise Intermediate Component Analysis Report 2017, s.43.3. In addition, the Proponent must implement the following measures based on industry best-practice guidelines: a) Workers' living quarters shall be designed to limit noise, with mitigating features such as high-quality soundproofing for windows and seals on doors. b) Physical barriers shall be used to maximize shielding and reduce noise transmission. Physical barriers shall be of an appropriate height and thickness to break the line-of-sight between the project related noise sources and the dormitory and other sensitive receptors at the permanent camp, to reduce noise levels to lower than 30 dBA (Leq) indoors to be protective of sleep. c) Optimization of operations shall include notifying workers of the schedule for loud procedures or particularly annoying noise events. Periods of respite shall be provided in the case of unavoidable maximum noise level events.	a) **Noise Management Plan** Section 5.1.4: Design of Permanent Camp b) **Noise Management Plan** Section 5.1.1: Heavy Equipment c) **Noise Management Plan** Section 5.1.3: Blasting	Construction / Operation / Closure	
39	If thresholds under YAAQS are being approached at the sites of the monitoring stations, or where CACs have exceeded thresholds, activities involving sources of emission be reduced or have additional emission mitigations applied. In this way, air quality and adaptive management may reduce or prevent further increases in CACs, and reduce the risk to employees during non-working hours. The Proponent shall notify workers traversing areas that have elevated outdoor concentrations and require them to use appropriate PPE. Off-duty workers will be advised to reduce exposure by remaining indoors to the extent possible and closing windows in camp residences at times of peak emissions.	**Air Quality and Greenhouse Gas Monitoring Plan**	Construction / Operation / Closure	Emission sources determined to cause excursions of or approaches to CAC thresholds will be reduced, curtailed and/or have additional emission mitigations applied.
40	The Proponent shall incorporate an adaptive management plan in collaboration with First Nations and regulators, that establishes concrete actions for approaching and exceeding thresholds. The following adaptive management actions and corresponding triggering thresholds are to be used until such time as a detailed project specific approach is jointly developed to operationally target the reduction of CAC's and particulates and management of air quality at, and in proximity to, the Project site.	**Air Quality and Greenhouse Gas Monitoring Plan**	Construction / Operation / Closure	
41	The Proponent shall ensure that impacts on employee health (both on and off-duty, on-site) are considered in assessing the need for adaptive measures. The Proponent shall ensure that ambient air quality in camp buildings meets indoor air quality guidelines through various means including the use of adequate ventilation and air filtration systems, effective insultation, seals on windows and doors, bans on vehicles idling in the immediate vicinity. Indoor air monitoring will occur to ensure that emissions are not accumulating in indoor environments.	**Air Quality and Greenhouse Gas Management Plan** Section 7.1.4: Design of Camp Accommodations **Health and Safety Program**	Construction / Operation / Closure	
		Community and Economics		
42	The Proponent shall maintain a transition fund, as a component of the Workforce Transition Strategy, of an amount sufficient to ensure, in the event of unscheduled closure: a) the funding of programs and other financial commitments outlined in the Socio-Economic Monitoring Program for a period of 12 months, b) maintenance of the Employee Assistance Program for a minimum of 6 months.	**Socio-economic Monitoring Plan** Appendix B: SEMP Management Strategies - Local Employment and Procurement Management Strategy	Construction / Operation / Closure	
43	The Proponent will promptly notify Health and Social Services of unscheduled closures, the supports and services the Proponent has in place for impacted employees and their families, and any forecasted implications beyond the scope of what the Proponent can address. Health and Social Services will assess the need to coordinate or deploy health and social resources to support impacted communities, in alignment with mandate(s) and scope.	**Reclamation and Closure Plan** Section 6.7.1: Management of Socio-economic Aspects of Temporary Closure	Temporary Closure	

Decision Document Mitigation Measures				
Mitigation Number	**Proposed Mitigation**	**Management Plan**	**Project Phases**	**Notes**
		Community and Economics		
44	The Proponent shall provide staff with access to online information and resources for money management and budgeting.	**Socio-economic Monitoring Plan** Appendix B: SEMP Management Strategies - Local Employment and Procurement Management Strategy **EAP**	Construction / Operation / Closure	
45	Recruitment for care and maintenance positions shall follow the same process used for hiring mine employees, prioritizing local hire, with preference given to former qualified mine employees.	**Socio-economic Monitoring Plan** Appendix B: SEMP Management Strategies - Local Employment and Procurement Management Strategy	Construction / Operation / Closure	
46	Security requirements shall take into consideration the potential for early unscheduled closure and the need for care and maintenance requirements to maintain environmental safeguards prior to decommissioning.	**Reclamation and Closure Plan** Section 9.0: Reclamation and Closure Liability	Closure	
47	The Proponent shall match the current Government of Yukon incentive for secondary suite renovation ($10,000). Residents in Dawson and its environs will be eligible, with the number of Proponent grants capped at 30 approved and matched incentives.	**Socio-economic Monitoring Plan** Appendix B: SEMP Management Strategies - Community Infrastructure and Services Management Strategy	Construction / Operation / Closure	
48	The Government of Yukon shall work with the City of Dawson and Tr'ondëk Hwëch'in Government to identify and make available suitable lands for housing development.	**Yukon Government**		Additional detail will not be provided

Decision Document Monitoring Requirements				
Mitigation Letter	**Proposed Mitigation**	**Management Plan**	**Project Phases**	**Notes**
Wildlife and Wildlife Habitat				
A	The Government of Yukon shall implement a monitoring program for linear development (i.e. roads) and surface disturbance (i.e. mined areas) in the White Gold area in relation to effects to moose and other wildlife (i.e. caribou). The program shall be scoped with the following considerations: 1. Monitoring shall include past developments and disturbances as well as reclamation efforts. 2. Monitoring shall seek to consolidate the quantity and quality of data submitted by Proponents into a consistent format for intended use in this program. 3. The program shall aspire to define significant cumulative linear and surface disturbance thresholds in the White Gold area for moose and caribou prior to issuance of any new Quartz Mining Land Use approvals, or expansion by more than 5% of the disturbance area for existing approvals. 4. The program shall be developed collaboratively with First Nations with traditional territory overlapping the area. First Nation participation in the monitoring program shall be funded by Government of Yukon. 5. The program shall be guided by a Terms of Reference (ToR), developed by consensus with Government of Yukon and First Nation government representatives. The ToR shall define temporal and spatial scopes, roles and responsibilities, and overall mandate. 6. Monitoring shall reflect and complement priorities identified in and work undertaken for the Dawson Land Use Plan.	**Yukon Government**		
B	The Government of Yukon shall implement monitoring of the overall abundance of moose in the Dawson Gold Fields MMU using a variety of methods that allow for tracking of population abundance and spatial distribution, such as aerial surveys and tracking of licensed harvest data, and which are performed consistently throughout the Project's lifecycle. Surveys should be conducted in early winter, commencing prior to construction, with subsequent surveys at five-year intervals, where possible, and include involvement of monitors from affected First Nations. The subsequent effects monitoring shall be informed by survey results and annual monitoring of all licensed moose harvest in game management subzones adjacent to, and intersecting the Northern Access Route.	**Yukon Government**		
C	The Proponent shall, in coordination and consultation with Government of Yukon, undertake effects monitoring of moose populations for areas of direct overlap with mine infrastructure, including the Northern Access Route, and for areas determined to be in the ZOI for moose within the Dawson Gold Fields MMU, Lower Stewart MMU and White Gold MMU.			Newmont is currently in negotiations with Yukon Government regarding the effects monitoring program for wildlife. Program details will be provided when finalized as the negotiations are ongoing.
D	Within 5 years of commencing operations, Government of Yukon shall conduct regional surveys, focusing on the interactions between the Fortymile and Klaza caribou herds and the Project. These surveys shall be conducted for the purposes of understanding the direct effects of the Project as well as the effects of the Project's induced development on herd movements and populations, establishing adaptive management thresholds and determining if additional measures are required should the evidence indicate there are negative project-related effects on caribou, either directly or indirectly.	**Yukon Government**		

Decision Document Monitoring Requirements				
Mitigation Letter	**Proposed Mitigation**	**Management Plan**	**Project Phases**	**Notes**
Water and Aquatic Resources				
E	The proponent shall develop and implement a plan to monitor seepage quality downgradient of the ROM ore pad to serve enable detection of any arsenic or uranium breakthrough from the pad to the underlying groundwater. Monitoring data shall be compared to triggers developed under the proponent's Environmental Monitoring and Adaptive Management Plan.	**Groundwater Monitoring Plan** Section 2.3.5: Seepage Monitoring	Construction Operations Closure	GW Monitoring Plan includes a visual survey once a month during the non-frozen season to confirm the presence of persistent seepage around facility perimeters (ROM).
		Surface Water Quality and Aquatic Life Adaptive Management Plan Section 4.5.3: Indicators, Performance Thresholds and Responses		Latte Creek thresholds tied to completing an evaluation of the ROM stockpile pad seepage.
F	The proponent's Environmental Monitoring and Adaptive Management Plan (EMAMP) plan shall include: 1. Water management goals defined as use-protection in Halfway, Latte and YT-24 creeks, and non-degradation in Coffee Creek and the Yukon River downstream of Halfway, Latte and YT-24 creeks; 2. For the purpose of non-degradation performance evaluation for the Yukon River extend monitoring spatially to the Yukon River downstream of Halfway, YT-24 and Coffee creeks, in areas directly affected by each creek's plume. This is in addition to water quality for the purpose of non-degradation performance evaluation in the fully mixed areas of the Yukon River downstream of Coffee Creek. 3. The rationale for the scope of the monitoring programs; 4. Descriptions of how the Project effects assessments informed the development of the monitoring programs; and 5. Descriptions and rationales for which programs require an adaptive management component. 6. Include AMP events for Halfway Creek closer to the site than HC1.0, which is located in the lower reaches of Halfway Creek upstream of the Yukon River, where use-protection WQOs can be proposed; 7. Include annual assessments to confirm non-degradation of surface water quality in Coffee Creek downstream of Latte Creek and the Yukon River downstream of Halfway, Latte and YT-24 creeks; such assessments will include comparison to a reference watershed; 8. Thresholds for arsenic and uranium levels in downgradient seepage of the ROM ore pad and triggers for adaptive measures 9. And shall develop Adaptive Management initiatives to address areas of uncertainty relevant to: i. Performance of the Alpha Rock Drain; ii. Performance of the Alpha Pond(s) (water quality and seepage quantity and quality); iii. Performance of the bioreactor treatment system for HLF seepage (EBR system); and iv. NORM/TENORM for long-term storage of uranium-rich materials (EBR materials) 10. Define stabilization of water quality in the Alpha Pond (during the Closure phase, as a pre-condition for decommissioning of the Alpha Pond in Post-Closure) as: i. No notable upward trends in the COPIs ii. A sustained reduction in inter-annual variability in COPI concentrations from Operations phase conditions iii. Discharge concentrations for all COPIs are consistently at levels that allow WQOs to be achieved in Halfway Creek.	1) **Water Management Plan** Section 1.4.2: Territorial Regulations 1) **Surface Water Quality and Aquatic Life Adaptive Management Plan** Section 1.2: Adaptive Management Plan Objectives	Construction Operations Closure	
		2) **Surface Water Quality Monitoring Plan** Section 2.0: Monitoring Locations and Frequencies		
		3) **Environmental Monitoring and Adaptive Management Plan**		
		4) **Environmental Monitoring and Adaptive Management Plan** Section 2.0: Environmental Monitoring Approach		
		5) **Environmental Monitoring and Adaptive Management Plan** Section 2.2: Adaptive Management Approach		
		6) **Water Management Plan** Section 4.3.8.1: Alpha Pond Performance Targets and Mitigation Measures		
		7) **Surface Water Quality and Aquatic Life Adaptive Management Plan**		Will not include a comparison to a reference watershed.
		8) **Surface Water Quality and Aquatic Life Adaptive Management Plan** Section 4.5.3: Indicators, Performance Thresholds and Responses		Latte Creek thresholds tied to doing an evaluation of the ROM stockpile pad seepage.
		9i) **Water Management Plan** Section 4.3.7: Alpha Rock Drain		
		9ii) **Water Management Plan** Section 4.3.8.1: Alpha Pond Performance Targets and Mitigation Measures

		9iv) **Heap Leach and Process Facilities Plan**, Section 4.5.3.1 Process Descriptions		
		10) **Reclamation and Closure Plan** Section 7.11.2: Aquatic Conditions Monitoring, Section 5.8.2 Contingency Planning and Adaptive Management Approach		

Decision Document Monitoring Requirements				
Mitigation Letter	**Proposed Mitigation**	**Management Plan**	**Project Phases**	**Notes**
		Health and Safety		
G	The Proponent shall include the following parties in the development of a monitoring program to ensure that the Project's effects on personal safety are adequately monitored: Government of Yukon, the Yukon Status of Women Council, and the Yukon Aboriginal Women's Council.	**Socio-economic Monitoring Plan** Appendix B: SEMP Management Strategies - Community Health and Well-Being Management Strategy		
H	To position Government of Yukon with adequate information to act on recommendations and preparation of services within communities, data collected in the monitoring program must be shared and used by parties in the development of response and resources to address effects as they occur. To support that, information relating to the amount and percentage of workforce that is transient to the Yukon will be required. The Proponent shall provide a quarterly report detailing the numbers and percentage of workforce that is transient (i.e. fly-in/fly-out and non-resident to the Yukon) to the Government of Yukon.	**Socio-economic Monitoring Plan** Section 6.0: Monitoring **Socio-economic Monitoring Plan** Appendix B: SEMP Management Strategies - Community Infrastructure and Services Management Strategy and Community Health and Well-Being Management Strategy		
I	The Proponent shall develop an Air Quality and Dust Management and Monitoring Plan which incorporates the following: 1. Long-term Monitoring stations o Long-term monitoring stations will be operated throughout the phases of the Project. The long-term monitoring stations: o Shall be placed at the permanent camp facilities, mine dry and office complex); the truck shop/warehouse; and at the Yukon River foreshore, east of the existing Coffee Creek camp. These are sites of predicted exceedances and worker presence (including off-duty workers) and likely exposure. The aim of establishing these stations is to redress the insufficient number of monitoring stations suggested by the Proponent for the mine site area. o Employ continuous monitoring, as opposed to the periodic and volumetric monitoring currently proposed. 2. Apply the use of MicroPulse LiDAR technology to monitor and track dust and particulates throughout the Project and adjacent areas. 3. At the commencement of Project Operations, Government of Yukon (YG) shall develop a repository for the monitoring data collected by the Proponent under the Air Quality and Dust Management Plan, and which it will provide on a timely (quarterly) basis. This repository will be accessible to First Nations, industry parties, regulators and the general public. YG shall review repository data and ensure compliance with the Adaptive Management Measures outlined under Mitigations 40 and 41. 4. A system for implementing additional monitoring and/or mitigation measures in the event of: o Changes to overall air quality, particularly increases in particulates, dust and contaminant concentrations approaching thresholds; o Complaints o Such a plan is required for submission during the Quartz Mining Licence phase for the Project. 5. A system for tracking, recording and responding to complaints related to air quality in collaboration with Environmental Health Services. Complaints are to be submitted to Environmental Health Services for recording purposes.	1. **Air Quality and Greenhouse Gas Monitoring Plan** Section 2.0: Monitoring Locations, Section 3.0: Monitoring Methodology 2. **Air Quality and Greenhouse Gas Monitoring Plan** Section 4.0 Data Analysis and Interpretation; Yukon Government 3. **Air Quality and Greenhouse Gas Monitoring Plan** Section 6.0 Reporting and Annual Review 4. **Newmont Coffee Grievance Mechanism** 5. **Newmont Coffee Grievance Mechanism**	Construction Operations Closure	1. Continuous monitoring for PM10, PM2.5, NOx and SO2 and discrete monitoring for dustfall with metals analysis is proposed for the mine dry and office complex. Passive monitoring for dustfall fall with metals analysis and NOx and SO2 is proposed for the Yukon River Foreshore. The Yukon river foreshore location is only inhabited for part of the year and will likely have unreliable power, therefore, passive monitoring is proposed for this site. The truck shop/warehouse and the existing Coffee Creek Camp are not expected to produced statistically different results than the mine dry and office complex and may have reliable power and/or equipment interference effects. 2. MicroPulse LiDAR is not a currently available and accepted practice.
		Community and Economics		
J	A working group shall be formed consisting of Government of Yukon, City of Dawson, Tr'ondëk Hwëch'in Government and the Proponent. This working group will monitor project-induced population growth and housing demand across project life. Project monitoring must involve the collection of data on the population of Dawson, rental and homeownership rates, availability of rental and market housing and associated prices. The Proponent shall provide an annual report on workforce numbers and place of worker residence, made publicly available, to establish clear reporting of inmigration trends.	**Socio-economic Monitoring Plan** Appendix B: SEMP Management Strategies - Community Infrastructure and Services Management Strategy		

Proponent Commitments - Reclamation and Closure Plan

FSR Plan	Mitigation Name	Reference	Proponent Committed Mitigation	Management Plan	Commitment Incorporated	Section Location	Notes
Access Route Construction Management Plan (ARCMP)	ARCMP	SIR7-R7-4 (YOR 2017-0211-2174)	The NAR will be decommissioned at the end of the Post-mining closure stage, unless otherwise directed by First Nations or regulators. Decommissioning of the new portions of the NAR that are purpose-built for the Project will entail the removal of culverts and bridges to maintain pre-construction surface drainage, removal of the barge landings, and general grading of the road surface to promote runoff shedding. Once grading is complete, the road surface will be scarified. All culverts and bridges installed on currently undisturbed or unconstructed sections of the NAR are proposed to be removed unless Yukon Government or Yukon Water Board specifically authorizes otherwise during approval of the Project's Reclamation and Closure Plans (updated every two years during Project operation). As existing road falls on crown land, Newmont will continue to work with Yukon government and placer claim holders (if infrastructure falls within placer claims) on long term maintenance activities.	RCP	Yes	**RCP** Section 7.8.2: NAR and On-site Access Road	New sections of the NAR will be decommissioned near the end of the Active Closure Phase. All culverts and bridges installed on the new sections of road will be removed.
Access Route Construction Management Plan (ARCMP)	Project and Exploration Airstrip Access Management	SIR1-21.1-R281 (YOR 2017-0211-326-2)	• The Project airstrip will be reclaimed near the end of the Post-closure Phase, when lighting, navigation equipment, and culverts will be removed. Reclamation will involve contouring, scarifying, top-soiling, and seeding. Once the Project airstrip is reclaimed, the existing airstrip at the exploration camp will be used instead.	RCP	Yes	**RCP** Section 7.8.3: Project Airstrip	The project airstrip will be decommissioned near the end of the Active Closure Phase.
Access Route Construction Management Plan (ARCMP)	Project and Exploration Airstrip Access Management		Once the exploration airstrip is no longer needed to support Post-closure monitoring activities, reclamation will be undertaken and will involve contouring, scarifying, top-soiling, and seeding.	RCP	Yes	**RCP** Section 7.8.3: Project Airstrip	
Conceptual Reclamation and Closure Plan (CRCP)	CRCP	PP Table 32-2 (YOR 2017-0211-027-1)	• Develop a detailed closure Adaptive Management Plan (AMP) to support Project licensing.	RCP	Yes	**RCP** Section: 5.8.2: Contingency Planning and Adaptive Management Approach	
Conceptual Reclamation and Closure Plan (CRCP)	CRCP		• Consult and work with communities for subsequent versions of the reclamation and closure plan, which will include mitigation measures activities related to socioeconomic aspects of closure (e.g., community contributions, partnerships).	RCP	Yes	**RCP** Section 2.1 : Consultation and Engagement Activities	
Conceptual Reclamation and Closure Plan (CRCP)	CRCP		• Salvage suitable soil material from areas that will be disturbed by the Project footprint where appropriate.	RCP	Yes	**RCP** Section 7.9.6: Soil Salvage	
Conceptual Reclamation and Closure Plan (CRCP)	CRCP		• Undertaken progressive reclamation and closure. Revegetate inactive areas as soon as practical.	RCP	Yes	**RCP** Section 2.3.2: Progressive Reclamation	
Conceptual Reclamation and Closure Plan (CRCP)	CRCP		• Implement erosion and sedimentation mitigation associated with reclamation and closure activities.	RCP	Yes	**RCP** Section 7.9.4: Erosion and Sediment Control	
Conceptual Reclamation and Closure Plan (CRCP)	CRCP		• Ensure that reclaimed ponds and conveyance structures are graded, as required, for proper drainage. Implement a care and maintenance program during seasonal closures or temporary closure.	RCP	Yes	**RCP** Section 6.4.4 Water Management Infrastructure - Diversion Ditches, Alpha and Facility Pond; Section 7.7: Site Water Management Infrastructure	
Conceptual Reclamation and Closure Plan (CRCP)	CRCP		• During temporary closure, conduct regular inspections to confirm compliance with applicable permits and licenses.	RCP	Yes	**RCP** Section 6.6: Reporting and Monitoring Requirements	
Conceptual Reclamation and Closure Plan (CRCP)	CRCP		• Maintain an egress point out of Open Pits during Reclamation and Closure and Post-closure phases, to reduce potential wildlife entrapment.	RCP	Yes	**RCP** Section 7.1.4: Closure Measures	
Conceptual Reclamation and Closure Plan (CRCP)	CRCP		• Develop a Revegetation Reclamation Research Program where reclamation protocols will be developed and tested on-site. Apply the most successful treatments more broadly during the reclamation phase.	RCP	Yes	**RCP** Section 2.3.1.1: Revegetation Reclamation Research	
Conceptual Reclamation and Closure Plan (CRCP)	CRCP		• Decommission and close Project facilities as described in this plan.	RCP	Yes	**RCP** Section 7.0: Final Reclamation and Closure Measures	
Conceptual Reclamation and Closure Plan (CRCP)	CRCP		• Continue the Operation Phase monitoring programs until no longer required or have been adapted for closure.	RCP	Yes	**RCP** Section 5.7: Monitoring Activities	
Conceptual Reclamation and Closure Plan (CRCP)	CRCP	SIR2-14-R2-73 (YOR 2017-0211-411-1)	• A Social Reclamation and Closure Plan will be developed as an effort to minimize potential negative effects to local communities and individuals.	RCP	Yes	**RCP** Section 2.3.3: Minimizing Project Effects	Socio-economic monitoring and mitigation measures to minimize potential negative effects to local communities and individuals will be described in the SEMP as well as in future iterations of the RCP.

Proponent Commitments - Reclamation and Closure Plan							
FSR Plan	**Mitigation Name**	**Reference**	**Proponent Committed Mitigation**	**Management Plan**	**Commitment Incorporated**	**Section Location**	**Notes**
Conceptual Reclamation and Closure Plan (CRCP)	CRCP	SIR1-2.12-R49 (YOR 2017-0211-323-1)	During the active Reclamation and Closure Phase, numerous personnel will be on site year-round as required, as key activities will include the following:	RCP	Yes	**RCP** Section 7: Final Reclamation and Closure Measures	
Conceptual Reclamation and Closure Plan (CRCP)	CRCP		• Continue water treatment until HLF effluent is of suitable quality for discharge.	RCP	Yes	**RCP** Section 7: Final Reclamation and Closure Measures	
Conceptual Reclamation and Closure Plan (CRCP)	CRCP		• Continue operation of conveyance structures and sedimentation ponds until water quality in the ponds meets discharge requirements.	RCP	Yes	**RCP** Section 7: Final Reclamation and Closure Measures	
Conceptual Reclamation and Closure Plan (CRCP)	CRCP		• Continue decommissioning of roads, pads, processing equipment, and other mine infrastructure, then decommissioning of water management infrastructure toward the end of the active Reclamation and Closure Phase.	RCP	Yes	**RCP** Section 7: Final Reclamation and Closure Measures	
Conceptual Reclamation and Closure Plan (CRCP)	CRCP		• Reclaim remaining disturbed areas within the Mine Site footprint.	RCP	Yes	**RCP** Section 7: Final Reclamation and Closure Measures	
Conceptual Reclamation and Closure Plan (CRCP)	CRCP		• Continue routine monthly, annual, and event-driven monitoring at conveyance structures and sedimentation ponds and their dams for stability, signs of seepage, blockage due to ice or foreign debris and significant erosion, or damage to any geosynthetic components.	RCP	Yes	**RCP** Section 7: Final Reclamation and Closure Measures	
Conceptual Reclamation and Closure Plan (CRCP)	CRCP		• Continue monitoring of surface water quality and infrastructure in accordance with conditions of mine licences and monitoring to observe progress toward the return of the Mine Site to pre- mining conditions.	RCP	Yes	**RCP** Section 7: Final Reclamation and Closure Measures	
Conceptual Reclamation and Closure Plan (CRCP)	CRCP		Annual physical inspections of engineered facilities will be carried out by a qualified engineer licensed to practice in Yukon. An annual review of the monitoring program results (including inspections and instrumentation data) by a qualified engineer will be a requirement of internal protocols and expected in Project licenses.	RCP	Yes	**RCP** Section 7.11.6: Physical Inspections	
Conceptual Reclamation and Closure Plan (CRCP)	CRCP	SIR7-R7-16 (YOR 2017-0211-2174)	Certain components of the site will be buried in place at closure, this includes items that are not salvageable, (e.g., pond liners, concrete foundations, piping).	RCP	Yes	**RCP** Section 7.3.2: Heap Leach Facility Pond Closure Measures; Section 7.4.1: Crusher System and Crushed Ore Stockpile Area Closure Measures; Section 7.5: Plant Site Closure Measures; Section 7.6: Camp Site Closure Measures	
Conceptual Reclamation and Closure Plan (CRCP)	CRCP	TH Proposed Conditions (March 2020) (YOR 2017-0211-3971)	Description of the approach for determining End Land Use objectives that explicitly considers; i. Pre- and post-mining traditional use; ii. Pre-mining ecosystems and habitats in comparison with the projected postmining landscape. iii. How affected communities and First Nations will be engaged in the development of the End Land Use objectives.	RCP	Yes	**RCP** Section 3.2: End Land Use Planning	
Conceptual Reclamation and Closure Plan (CRCP)	CRCP		Specific closure objectives for major mine components and analysis of cover options based on the closure objectives. These specific objectives must then be incorporated into a workplan clearly illustrating how the closure objectives are considered in the development of the closure concepts and detailed closure plans proposed for each of the major mine components.	RCP	Yes	**RCP** Section 3.1.4: Component-specific Closure Objectives	
Conceptual Reclamation and Closure Plan (CRCP)	CRCP		These objectives should include consideration of the following: i. Minimizing infiltration / contact water; ii. opportunities to mitigate pathways for metal uptake in vegetation and wildlife; and iii. supporting target ecosystems and habitats. iv. Measures to ensure arsenic concentrations within the top metre of waste rock storage locations will not exhibit an arsenic concentration greater than 60 mg/kg, on average.	RCP	Yes	**RCP** Section 3.1.4: Component-specific Closure Objectives	
Conceptual Reclamation and Closure Plan (CRCP)	CRCP		Description of continuous improvement measures or research to reduce loading of contaminants into the environment through ongoing evaluation and implementation of mine planning, mine development, mitigation, and remedial options in order to meet the long-term protection goals for waterbodies downstream of the mine components, including but not limited to enhancing the level of use-protection in Halfway Creek.	RCP	Yes	**RCP** Section 2.3.1: Reclamation Research	
Conceptual Reclamation and Closure Plan (CRCP)	CRCP		A reclamation research program that is designed to test proposed reclamation and closure activities in order to reduce uncertainty or answer specific questions in order to develop detailed reclamation and closure plans that support achieving closure objectives. This program must consider: i. Specific closure objectives of major mine components; ii. a detailed implementation schedule tied to life of mine milestones.	RCP	Yes	**RCP** Section 2.3.1: Reclamation Research; Section 2.3.1.4: Reclamation Research Implementation Schedule	
General Mine Development Plan (GMDP)	Failure Modes and Effects Analysis and Risk Register	SIR1-2.1-R1 (YOR 2017-0211-323-1)	The Failure Modes and Effects Analysis (FMEA) and associated Risk Register are to be updated and refined during Project design and planning, including during the development of the detailed Reclamation and Closure Plan (RCP) for Project licensing.	RCP	Yes	**RCP** Section 2.3.4.4: Step 4: Failure Modes and Effects Analysis	

Proponent Commitments - Reclamation and Closure Plan							
FSR Plan	**Mitigation Name**	**Reference**	**Proponent Committed Mitigation**	**Management Plan**	**Commitment Incorporated**	**Section Location**	**Notes**
General Mine Development Plan (GMDP)	Phased Mine Development and Progressive Reclamation	PP Table 32-1 (YOR 2017-0211-027-1)	In addition to providing flexibility in the schedule, maximizing ore grade, and allowing the HLF to be maintained at full production capacity, phased development of the mine will reduce pre-stripping requirements in the early years. Progressive reclamation and closure activities will begin as soon as mining is completed and will continue throughout the mine life.	RCP	Yes	**RCP** Section 2.3.2: Progressive Reclamation	Phased development of the mine is incorporated into the mine plan. Progressive reclamation activities will commence at the beginning of the Operations Phase (Years -1 to 9).
Heap Leach and Process Facility (HLPF)	Heap Leach Solutions	SIR1-5.7-R98 (YOR 2017-0211-324-1)	Upon completion of active leaching operations, solution management will be required until the closure cover is established, and clean runoff is diverted off the facility.	RCP	Yes	**RCP** Section 7.3.1: Heap Leach Pad Closure measures	
Heap Leach and Process Facility (HLPF)	Heap Leach Solutions	SIR1-9.4-R207 (YOR 2017-0211-325-1)	Water treatment of HLF draindown waters will continue until both seepage volumes and seepage chemistry are reduced sufficiently such that additional polishing measures (e.g., biological passive treatment) are demonstrated to meet post-closure discharge limits. An extensive testing and piloting program is planned for post-closure water management using biological passive treatment. Results of this program, along with results from the progressive rinsing and in situ reclamation proposed for the HLF, will dictate the timing of post-closure water treatment.	RCP	Yes	**RCP** Section 5.3.12: Site Water Management Infrastructure; Section 2.3.1: Reclamation Research	
Heap Leach and Process Facility (HLPF)	Heap Leach Solutions	SIR2-2.6-R2-14 (YOR 2017-0211-411-1)	The EBR will be operating year-round for treatment of rinse waters for the heap, but only during the open water period of May to September for treatment of excess heap leach rinse waters that are to be discharged to the environment. Phase 2 testing will optimize the EBR system to include and test any needed pre-and/or post-treatments required to achieve site water treatment objectives.	HLPF Plan; RCP	Yes	**HLPF Plan** Section 4.5.2: Chemistry of HLF Solutions **RCP** Section 2.3.1.2: Treatment Technologies Reclamation Research	The WTP will be available for treatment of site impacted water year round, but is planned to be used for excess heap leach solution during the open water period.
Heap Leach and Process Facility (HLPF)	Management of Non-Contact Water	PP Table 32-1 (YOR 2017-0211-027-1)	• Progressive closure of HLF will reduce length of time that HLF is at its maximum footprint size.	HLPF Plan; RCP	Yes	**HLPF Plan** Apppendix B: Heap Leach Pad Engineering Report for Licensing; **RCP** Section 7.3.1: Heap Leach Pad Closure Measures	
Heap Leach and Process Facility (HLPF)	Management of Non-Contact Water	SLR4-R4-2 (YOR 2017-0211-4259)	• Progressive reclamation of the heap leach pad will entail rinsing individual sections of the heap leach ore once they have undergone the complete gold recovery cycle. The heap will be rinsed (via solution from the rinse pipelines) and capped in stages; as each stage is capped, the raincoats for that area will be removed and used in other areas or incorporated as part of the closure capping.	HLPF Plan; RCP	Yes	**HLPF Plan** Apppendix B: Heap Leach Pad Engineering Report for Licensing; **RCP** Section 7.3.1: Heap Leach Pad Closure Measures	Partially incporporated. The heap solution will be recirculated for rinsing and not through specific "rinse pipelines", and reliance on raincoats is not included in current design.
Heap Leach and Process Facility (HLPF)	Management of Non-Contact Water	SIR6-R6-14 (YOR 2017-0211-7131)	The diversion channel along the western edge of the Alpha WRSF will be decommissioned in the Post-Closure phase once the water quality in the Alpha Pond has stabilized. The Facility Ponds will be decommissioned in the Post-Closure phase.	RCP	Yes	**RCP** Section 7.7: Site Water Management Infrastructre	Diversion channels and and Facility Pond will be decommissioned during the Active Closure Phase, once water quality in the Alpha Pond has stabilized.
Heap Leach and Process Facility (HLPF)	Heap Leach Pad Liner System	SIR1-9.3.2-R183 (YOR 2017-0211-325-1)	• Should groundwater and/or surface water monitoring indicate a leak after the facility has been decommissioned, an investigation will be undertaken to determine the size and extents of the leak and if natural attenuation processes are active. If warranted, active remediation such as groundwater interception, may be undertaken as appropriate.	RCP	Yes	**RCP** Section 7.3.1: Heap Leach Pad Closure Measures	
Heap Leach and Process Facility (HLPF)	HLF Cover System	SIR1-2.11-R44 (YOR 2017-0211-323-1)	Most of the HLF cover will be composed exclusively of geologic materials of rock and soil. In a small portion of the Coffee heap, the crest, and benches, a GCL will be included beneath the rock and soil layers.	RCP	Yes	**RCP** Section 7.3.1: Heap Leach Pad Closure Measures	
Heap Leach and Process Facility (HLPF)	HLF Cover System	SIR1-2.12-R52 (YOR 2017-0211-323-1)	Field trials with a minimum of two to three years of monitoring of the selected capping system is envisioned for the Project. For example, beginning in the fourth year of operation, the oldest portion of the heap will be rinsed, graded, and capped. This area will produce 15 years of data before final closure is completed. Even the last portions of the heap to be capped will undergo several years of monitoring.	RCP	Yes	**RCP** Section 2.3.1.3: Site Characterization Reclamation Research	
Heap Leach and Process Facility (HLPF)	HLF Design to Facilitate Progressive Closure	SIR1-2.12-R48 (YOR 2017-0211-323-1)	Side sloping may need to be scheduled for the warmer months due to freezing. Soils and rock placement will generally be done between May and December. GCL will only be installed immediately before the rock or soil cover is to be installed. GCL installation in May, July, and August will be limited to dry periods.	RCP	Yes	**RCP** Section 7.3.1: Heap leach Pad Closure Measures	
Heap Leach and Process Facility (HLPF)	HLF Design to Facilitate Progressive Closure	SIR1-2.12-R51 (YOR 2017-0211-323-1)	The RCP will also be frequently updated and reviewed (every two years) as part of the licensing conditions, and this will allow adaptations to the design based on field experience.	RCP	Yes	**RCP** Section 2.2: Sequences and Phases of Reclamation and Closure Planning	

Proponent Commitments - Reclamation and Closure Plan

FSR Plan	Mitigation Name	Reference	Proponent Committed Mitigation	Management Plan	Commitment Incorporated	Section Location	Notes
Heap Leach and Process Facility (HLPF)	HLF Design to Facilitate Progressive Closure	SIR1-Appendix 9-B (YOR 2017-0211-368-1)	Progressive reclamation and closure of the HLF includes measures designed to improve heap seepage water quality. Specifically, the addition of microbes, carbon, and nutrients to the heap during progressive rinsing and reclamation will foster reducing conditions within 368-1) the heap pore waters allowing for in situ denitrification and ultimately reductive precipitation of metals.	RCP	No	RCP Section 2.3.1.2: Treatment Technologies Reclamation Research	The HLF will be recirculated for rinsing and final gold recovery during early Post-mining Phase (Year 10-15). The addition of amendments during rinsing remains an option that may be considered. As part of treatment technologies reclamatio research, a pre-feasibility study evaluating permeable reactive barrier and biological reactor technologies has been completed, and a full feasibility study is being considered.
Socio-economic Management Plan (SEMP)	Workforce Transition Strategy	SIR1-12.1-R254 (YOR 2017-0211-326-2)	• Mine activities leading up to and during temporary mine closure or reduced scale of operation will be associated with ensuring that the site is secure and safe to minimize health and safety risks and ensuring compliance with all regulatory and licensing requirements to manage risks associated with reduced activity at the site.	RCP / Health and Safety Program	Yes	**RCP** Section 6: Temporary Closure **SEMP:** Section 4.2.1 Local Employment and Procurement Management Strategy - Mitigation Measure Category #3: Workforce Transition and Training	
Water Management Plan	Water Management Plan	SIR7-R7-4 (YOR 2017-0211-2174)	Stabilization of water quality in the Alpha Pond will be defined as follows: • No notable upward trends in the COPCs. • A sustained reduction in inter-annual variability in COPC concentrations. • All discharge COPC concentrations are consistently at levels that allow WQOs to be achieved in Halfway Creek.	RCP	Yes	**RCP** Section 7.7: Site Water Management Infrastructure	Reference for this commitment is for SIR7-R7-40. This is defined in the RCP during the closure phase, as a pre-condition for decommissioning of the Alpha Pond.
Water Management Plan	Water Management Plan		The proposed water treatment system is a two-stage process. The first stage of the treatment process will oxidize residual cyanide using hydrogen peroxide. The products of this process will be cyanate and/or ammonia and carbon dioxide. The second stage of the process will utilize a biological reactor system termed Electrochemical Biological Reactor or EBR.	HLPF Plan	No	HLPF Plan Section 4.5: Water Treatment of Heap Leach Solutions; Appendix D: Coffee Mine Water Treatment Design for Permitting (WesTech 2023) **RCP** Section 2.3.1.2: Treatment Technologies Reclamation Research	Cyanide destruction will occur through the SO_2/air method. Chlorination will be evaluated as an alternative. The water treatment system includes a 6 stage process, with cyanide destruction and EBR being two of the stages.
Water Management Plan	Water Management Plan	SIR4-R4 (YOR 2017-0211-4259)	Meteorological monitoring will include: • Operation of the existing weather stations, which are located at KM 11 of the mine access road (record period 2012-present; 975 m), and between the proposed HLF and Kona Pit locations (record period 2018-present; 1,300 m). • Continued monitoring of baseline snow courses to quantify snow water equivalent accumulation. All conveyance structures (drainage ditches, collection channels) and both sedimentation ponds and their dams will be inspected for stability (slumping or failure), signs of seepage, blockage due to ice or foreign debris and significant erosion or damage to any geosynthetic components. Monitoring by a qualified professional in accordance with the requirements of the CDA guidelines will be required. Monitoring of surface water during the Operation Phase, Reclamation and Closure and Post-closure Phases, in support of water management, will include both hydrologic (flow) monitoring and water quality sampling. A generic hydrologic monitoring program will focus below on monitoring concepts as they relate to: Mine Site Monitoring; Effluent Monitoring; and Receiving Environment Monitoring.	EMAMP; RCP	Yes	**EMAMP - Appendix D: Meteorological Monitoring Plan** Section 2.0: Monitoring Locations and Frequencies **EMAMP - Appendix K: Physical Monitoring Plan** Section 5.0: Water Management Infrastructure **EMAMP - Appendix B: SWQ Monitoring Plan** Section 3.0: Monitoring Methodology **EMAMP - Appendix A: Hydrology Monitoring Plan** Section 4.0: Monitoring Methodology **RCP** Section 7.11: Maintenance, Monitoring and Reporting Activities **EMAMP - Appendix C: Groundwater Monitoring Plan** Section 2: Mine Site Groundwater Monitoring Reporting and Annual Review sections of all above reports.

FSR Plan	**Mitigation Name**	**Reference**	**Proponent Committed Mitigation**	**Management Plan**	**Commitment Incorporated**	**Section Location**	**Notes**
Water Management Plan	Water Balance and Water Quality Model	TH Proposed Conditions (March 2020) (YOR 2017-0211-3971)	The Site-wide Water Balance and Water Quality and Heap Leach Facility models will be updated annually and include the following components: a) Updated water quality predictions for downstream receiving environment waterbodies, including expected-case and worst-case scenarios; b) Updated year-by-year capacity for emergency available storage in mined pits including consideration of storage that would or would not affect access to ore and impede mining; c) Discussion of the timeframe of water storage available prior to release of environment in the event of a loss in pumping ability; d) Updated schedule for water treatment implementation that includes engineering, procurement, construction, and commissioning; e) An annual water treatment discharge volume plan/goal for the upcoming year; and f) Reassessment of reoccurrence interval analyses and precipitation trends. g) Assessment of amount of raincoat deployment necessary to manage water in the event of the mine entering temporary closure (in order to set raincoat inventory requirements).	Water Management Plan; HLPF Plan; RCP	Yes	**WMP** Section 8.0: Annual Water Management Planning **HLPF MP** Section 4.5.7: Additional Design Testwork and Schedule	Precipitation and snowmelt recurrence interval analyses are not expected to be completed on an annual basis but will be reviewed in the case that large precipitation events are measured on-site that indicate potential exceedances of the design storm events used in water management infrastructure design.
Water Management Plan	Active Water Treatment Testwork	TH Proposed Conditions (March 2020) (YOR 2017-0211-3971)	The Proponent shall provide licensing bodies the results of any bench-scale electro bioreactor testwork. The Water Management Plan must include a water treatment section that describes the workplan and schedule for any pilot-scale and/or full-scale treatment plant design, construction, and operation. At a minimum, the workplan will include a discussion of the preliminary schedule covering kick-off of pilot design through operation of full-scale water treatment plant including key milestones such as: • kickoff of pilot design (should a pilot plant be determined to be required) • pilot deployment to site • pilot operation at site • pilot reporting • design of full-scale system • construction of full-scale system • beginning of full-scale operation The proponent shall provide licensing bodies the results of the passive treatment testing that assesses the use of passive bioremediation treatment of heap leach rinse solutions prior to authorization this treatment method at closure.	HLPF Plan; RCP	Yes	**HLPF Plan** Section 4.5: Water Treatment of Heap Leach Solutions; Appendix D: Coffee Mine Water Treatment Design for Permitting (WesTech 2023) **RCP** Section 2.3.1: Reclamation Research	
Water Management Plan	Passive Water Treatment Testwork	TH Proposed Conditions (March 2020) (YOR 2017-0211-3971)	The proponent shall provide licensing bodies the results of the passive treatment testing that assesses the use of passive bioremediation treatment of heap leach rinse solutions prior to authorization this treatment method at closure.	RCP	Yes	**RCP** Section 2.3.1.2: Treatment Technologies Reclamation Research	
Water Management Plan	Temporary Closure	TH Proposed Conditions (March 2020) (YOR 2017-0211-3971)	In the event of temporary closure, the Proponent shall: a) Within 3 months, provide regulators with a short term HLF water balance for solution recirculation, contingency volume, and time available and volume and quality of water required for HLF rinsing; b) Within 3 months, provide regulators with an implementation plan for the Water treatment plant (if not operational); c) If, while in temporary closure, the decision is made to enter permanent closure, the proponent shall provide regulators with an updated Reclamation and Closure Plan.	RCP	Yes	**RCP** Section 6: Temporary Closure; Section 6.5.2: Heap Leach Facility	
Wildlife Protection Plan (WPP)	Wildlife Protection Plan		• Reclaim riparian vegetation in areas affected by barge landing construction (restore shoreline habitat).	RCP	Yes	**RCP** Section 7.8.2: NAR and On-site Access Road	

APPENDIX 2-A

Summary of Consultation and Engagement Activities Related to Reclamation and Closure

1.0 Document Sharing Summary

Table 1-1 includes a summary of the timeline for Newmont's distribution of the Reclamation and Closure Plan (RCP) to First to support the Environmental and Socio-economic Assessment process and in preparation for Project licencing submission. Table 1-1 also includes the timeline for when subsequent comments/feedback were received by Newmont. Newmont incorporated the comments/feedback into the RCP where possible, and follow-up meetings between Newmont and First Nations were held when necessary to further discuss issues that arose following the document review process.

Table 1-1 Document Sharing Timeline

Date	Outgoing/Incoming	Details
28-Jan-19	Outgoing	NEM shared draft with TH, SFN, WRFN.
03-Jul-19	Incoming	TH shared comments with NEM.
27-April-21	Outgoing	NEM shared draft with WRFN
02-Nov-22	Outgoing	NEM shared draft with TH.
03-Nov-22	Outgoing	NEM shared draft with SFN and WRFN.

TH - Tr'ondëk Hwëch'in; SFN – Selkirk First Nations; WRFN – White River First Nation; NEM – Newmont.

2.0 Engagement Details

This section presents an overview of the key topics that were discussed during engagement events between Newmont and First Nations. The events highlighted below are those that were held outside of the regular biweekly meetings between Newmont and TH, and monthly meetings between Newmont and WRFN, and involved RCP-specific topics. General discussion topics for the ongoing engagement events are not included below.

Table 2-1 Key Engagement Events Between TH and NEM

Date	Meeting Topic	Details
30/31 August 2018	Technical Reclamation and Closure Workshop	NEM and TH met over a two-day workshop to review site-specific closure objectives and definitions from the Socioeconomic Closure Workshop from May 30, 2018. Recommendations to NEM on the draft RCP included refining closure objective evaluation criteria. NEM and TH evaluated closure alternatives for the pits with NEM committing to including alternative assessment in the RCP. NEM committed to arranging a teleconference to discuss adaptive management and environmental monitoring.
21/22 February 2019	Heap Leach Test Pad Design, Water, and Reclamation and Closure Workshop	NEM provided an overview of the Heap Test Cells Design Report and Heap Test Pad Program and Water Management Plans. NEM committed to considering snow as an insulator in the next iteration of the Heap Leach plan. Discussion on Phase I of water testing and the planned test work for Phase II. NEM committed to arranging a teleconference to discuss TH comments on the water monitoring plans.

Date	Meeting Topic	Details
17 December 2021	Reclamation and Closure	NEM presented the Alternatives Assessment Evaluations Overview. TH requested NEM re-examine the Evaluations in consideration of current gold prices. NEM stated additional work (further alternatives assessment, failure modes effects assessment (FMEA)) would be completed in January 2022 and that the results would be shared with TH and other First Nations for discussion. The type of habitat characteristics for end land use was discussed with TH raising the importance of considering the 40-mile caribou. Follow-up items included NEM providing a copy of the HLF Water Treatment Plant Treatability Assessment Report (2016) with TH, and sharing figures developed for the alternatives ranking exercise. NEM committed to re-examining the Alternatives Overview Assessment with consideration of current gold prices.
20 June 2022	Reclamation and Closure Meeting	NEM provided a presentation on the status of the RCP, reclamation research program approach, alternative assessment and FMEA, End Land Use Planning approach, temporary closure scenario, and next steps.

Table 2-2 Key Engagement Events Between SFN and NEM

Date	Meeting Topic	Details
26-28 September 2018	Closure, Site and Water Workshop	NEM and SFN met for a two-day workshop to discuss Project updates, site/mine refinements, mine closure, water quality and treatment, environmental monitoring, and adaptive management. SFN provided suggestions for inclusion in the RCP.

1.0 INTRODUCTION

1.1 Project Summary

The proposed Coffee Gold Mine (the Project) is an open-pit gold mine owned by Goldcorp Kaminak Ltd, a subsidiary of Newmont, located in the White Gold District of west-central Yukon, approximately 130 km south of the City of Dawson, 140 km west of Pelly Crossing, 95 km south-west of Beaver Creek, and 330 km northwest of Whitehorse. The Project is located wholly within the traditional territory of Tr'ondëk Hwëch'in, partially within the traditional territory of Selkirk First Nation and First Nation of Na-cho Nyäk Dun, and partially within the asserted territory of White River First Nation. The Project contains several gold occurrences within an exploration concession covering an area of more than 600 km^2. The Mine Site will be accessed by road from Dawson via a 214-km all-season, gravel road with pull-outs, referred to as the Northern Access Route (NAR) (Figure 1-1). The NAR includes upgrades to 177 km of existing road and construction of 37 km of new single-lane, forestry-type access road. The NAR includes seasonal barge crossings on both the Stewart and Yukon rivers, with ice bridges in the winter months.

The Project is comprised of open pits named Latte, Double Double, Supremo and Kona, and one permanent Waste Rock Storage Facility (WRSF) named Alpha. The ore production rate is proposed to be up to approximately 9.0 million tonnes (Mt) per year, producing an estimated total of 67 Mt of heap leach feed over the 10-year Operation Phase. The conceptual-level estimate for waste material to be moved over the life of mine (LOM) is 330 Mt based on an average strip ratio of 5.0:1. The ore will be crushed and transported to the Heap Leach Facility (HLF) via overland conveyor or trucks for nine months of the year. During the three coldest months of winter, run-of-mine (ROM) ore will be stockpiled in the ROM stockpile. Gold will be extracted from gold-bearing leach solution by a six tonnes per day (t/d) adsorption, desorption, recovery carbon plant with mercury retorting to produce a final gold doré product. A total of 2.6 million ounces of gold is planned to be recovered over a 10-year mine life.

The Project phases are defined as follows:

- Construction Phase: Q2 Year –3 to end of Year –1 (30 months)
- Operation Phase: Year 1 to end of Year 9 (10 years)
- Reclamation and Closure Phase: Year 10 to end of Year 21, including a 6-year Post-Mining Closure Stage and a 5-year Active Closure Stage (11 years)
- Post-Closure Phase: Year 21 onwards as determined to be required.

These phases broadly describe the activities occurring within a particular time period; however, some activities will continue from one phase to another as mine site development advances with operational activities (e.g., Open Pits, WRSF). When areas that support mine operations are no longer required, they will be progressively reclaimed. The overall Project schedule is the general expected scenario for mine construction and operation; detailed activities are subject to change depending on detailed mine planning and the timing of receipt of authorizations.

1.2 Scope and Objectives

Construction, operation, and closure of the Project have the potential to negatively impact vegetation within or near the project area which may affect the environment. This Revegetation Reclamation Research and Monitoring Report (the Report) is intended to summarize research concerning revegetation and reclamation and identify and demonstrate how appropriate management techniques will reduce the potential for any vegetation-related adverse effects to the environment and describes the measures that will be undertaken to reclaim adverse affects generated by Project activities.

This Plan has been written to meet the guidance provided in the *Plan Requirement Guidance for Quartz Mining Projects* (YWB and EMR 2013).

This Report is provided in conjunction with several other plans to meet the requirements for quartz mine applications for a Quartz Mining License and a Water Use Licence under the *Quartz Mining Act* and the *Waters Act*, respectively. Other applicable regulations related to vegetation management and monitoring are detailed in Section 2.0.

1.3 Incorporation of Traditional Knowledge and Consultation Feedback

Consultation during preparation of the Project Proposal (2017-0211) identified vegetation as a valued component that should have a range of mitigation measures implemented in order to minimize change (Goldcorp 2017). Specific concerns included habitat loss, change in vegetation health due to dust deposition, and risk of introduction and spread of invasive plant species.

This draft Report is provided for review and feedback by stakeholders to address the above concerns. Once reviewed, any further concerns, and where they have been addressed in the revised plan will be summarized here.

1.4 Synergies with Newmont Standards and Requirements and Other Project Documents

As an important part of Newmont's internal governance process, Newmont has implemented Global Policies and Standards (Global Standards) that are reviewed and preliminarily approved by a Global Policies & Standards Committee. The Global Standards provides the framework and standards for Newmont sustainability management and ensures a consistency of approach for implementing these global policies across the Company.

The Standards apply to all directors, officers and employees of Newmont Corporation, its subsidiaries, and any other entities that it controls. A variance request process for existing or future conditions is in place. The process provides an alternative mechanism for those instances where a Newmont site/operation cannot logistically or feasibly conform to a requirement established in a Standard due to special conditions or unique hardships. The Standards are intended to be fully integrated into all core business functions, and they emphasize sustainability, responsibility, and accountability at all organizational levels.

The list of Standards is provided in Table 1-1.

Table 1-1 Newmont Standards

Standard	
Air Emissions Management Standard	Land Acquisition and Involuntary Resettlement Standard
Biodiversity Management Standard	Local Procurement and Employment Standard
Closure and Reclamation Management Standard	People Policy
Code of Conduct	Product Stewardship Standard
Community Investment and Development Standard	Social Baseline and Impact Assessment Standard
Cultural Resource and Management Standard	Stakeholder Relationship Management Standard
Drug and Alcohol Policy (Coffee-Specific)	Tailings Storage Facility and Heap Leach Facility Environmental Standard
Hazardous Materials Management Standard	Tailings Storage Facilities Technical and Operations Standard
Health and Safety Policy	Waste Management Standard
Human Resources Standard	Waste Rock and Ore Stockpile Management Standard
Human Rights Standard	Water Management Standard
Indigenous Peoples Standard	

While this Report can be reviewed in isolation to inform a review of the specific actions for vegetation management and monitoring, this report should be viewed in concert with the following additional management plans in order to attain a holistic understanding of the Project:

- Access Route Construction Management Plan
- Access Route Operational Management Plan
- Reclamation and Closure Plan
- Explosives Management Plan
- Emergency Response Plan
- Spill Contingency Plan
- Vegetation Protection Plan
- Vegetation Monitoring and Adaptive Management Plan
- Water Management Plan
- Wildlife Protection Plan.

1.5 Roles and Responsibilities of Key Personnel

The Proponent has committed to providing the necessary human, material, and financial resources to implement and maintain the Revegetation Reclamation Research and Monitoring Report. Key Project personnel responsible for being familiar with the contents of this Report are shown in Table 1-2.

Table 1-2 Key Project Personnel

Role	Responsibility
Mine General Manager	Overall responsibility for Mine Site management.
Operations Manager	Responsible for mine planning and production, mine technical monitoring, and mine regulatory compliance.
H&S Manager	Responsible for conducting regular safety site inspections and implementing the appropriate controls in a timely manner. The H&S Manager shall maintain records of all safety inspections as well as any actions taken because of these inspections throughout the life of the Project. Where safety inspections show the potential for environmental effects, the H&S Manager will work in collaboration with the Environment Department.
CSR Department	Responsible for recording and addressing any complaints received from nearby land users, or other interested parties regarding vegetation-related impacts off-site. The CSR department shall maintain records of all complaints received as well as any actions taken because of these complaints.
Environmental Manager	Responsible for permitting, environmental monitoring, and regulatory compliance.

2.0 RECLAMATION RESEARCH AND MONITORING

Since the inception of mine exploration associated with the Project, areas disturbed for drilling have been mechanically restored using machinery to replace the vegetation mat. From 2013 to 2015, Kaminak initiated progressive reclamation research alongside exploration activities to test the effectiveness of various reclamation techniques under different site conditions.

2.1 Plants for Reclamation

Not all species have equal weight in providing ecosystem services to the environment (Lawton 1994); therefore, identifying northern plant species that promote effective ecosystem processes is crucial for reclamation. Effective ecosystem processes include below-ground processes, such as nutrient cycling, water cycling, decomposition, and energy flow that support the production of plant matter. In consideration of this, a preliminary list of potential native species for reclamation at the Project was developed by looking at the local availability of plant species recommended for use in the Yukon by the Yukon Revegetation Manual (Matheus & Omtzigt 2013).

Field investigations were conducted in conjunction with baseline rare plant surveys carried out by EDI from July 5 to 9, 2014. Native species considered for reclamation studies were selected based on moderate to high distribution and abundance within the Project area. Abundance was rated on a scale from 1 to 9 based on the British Columbia Ministry of Forests Weed Density Distribution Classes (Luttmerding et al. 1990). These guidelines provide a density distribution for plants growing in a 20 m x 20 m area and take into consideration continuous occurrence and clumped distribution. Locations were marked with a GPS and categorized into broad regional areas.

Candidate native species for reclamation studies identified as having moderate or high abundance included grasses, nitrogen-fixing forbs, and shrubs. Table 2-1 and Table 2-2 provide a preliminary list of native grass species and native forb and shrub native grass species, respectively, that may be considered for reclamation and studies.

Table 2-1 Native Grass Species Considered for Coffee Gold Mine Reclamation Studies

Common Name	Species Name	Ecotype	Abundance[a]	Latitude	Longitude
Alpine bluegrass	*Poa alpina*	Subalpine	4	62.8743	-139.4360
Alpine sweetgrass	*Hierochloe alpina*	Subalpine	7	62.7664 62.8743 62.8878	-139.0063 -139.4360 -139.3299
Bluejoint reedgrass	*Calamagrostis canadensis*	Boreal	8	62.9142	-139.0837
		Subalpine	4	62.8878	-139.3299
Fowl bluegrass	*Poa palustris*	Boreal	7	62.8882 62.9142	-139.0784 -139.0837
		Subalpine	4	62.8878	-139.3299
Glaucous bluegrass	*Poa glauca*	Boreal	7	62.8882 62.8804	-139.0784 -139.1018
Northern rough fescue	*Festuca altaica*	Subalpine	7	62.7986 62.8743 62.8878	-139.0282 -139.4360 -139.3299
Ticklegrass	*Agrostis scabra*	Boreal	5-7	62.8806 62.9084	-139.1002 -139.0697
Tufted hairgrass	*Deschampsia cespitosa*	Boreal	7	62.9144	-139.0868

Note: a. Abundance was rated on a scale from 1 to 9 based on the British Columbia Ministry of Forests Weed Density Distribution Classes to provide a baseline value for abundance and distribution (Luttmerding et al. 1990).

Table 2-2 Native Forb and Shrub Species Considered for Coffee Gold Mine Reclamation Studies

Common Name	Species Name	Notes
Alpine bearberry	*Arctous alpina*	Found in open subalpine not dominated by high shrubs > 2 m tall, such as scrub birch.
Alpine sweet-vetch	*Hedysarum alpinum*	Found in the low boreal forest along the Yukon River. Nitrogen fixing plant.
Arctic lupine	*Lupinus arcticus*	Found in open subalpine not dominated by high shrubs > 2 m tall, such as scrub birch. Nitrogen fixing plant.
Arctic willow	*Salix arctica*	Found in open subalpine not dominated by high shrubs > 2 m tall, such as scrub birch.
Bog bilberry	*Vaccinium uliginosum*	Found in moist subalpine and boreal forest
Canada buffalo-berry	*Shepherdia canadensis*	Found in dry subalpine and boreal forest. Nitrogen fixing plant.
Dwarf birch	*Betula glandulosa*	Widespread in subalpine
Gray-leaved willow	*Salix glauca*	Widespread in subalpine
Lowbush cranberry	*Vaccinium vitis-idaea*	Widespread at all elevations
Mountain avens	*Dryas* spp.	Found in open subalpine not dominated by high shrubs > 2 m tall, such as scrub birch.
Northern bedstraw	*Galium boreale*	Found in subalpine and boreal forest

2.2 Reclamation Demonstration Sites

Mine exploration involves surface disturbance where the vegetation mat is removed for drilling core samples. The outcome of drilling activities is commonly referred to as drill sites/fences. As exploration activities progress, these disturbances create a need for progressive reclamation and revegetation. Additional disturbances which present an opportunity to test methods of reclamation and revegetation onsite are cut slopes along the existing access road between the Coffee exploration camp and the deposit (i.e., Java Road). These areas are prone to erosion; therefore, various methods of reclamation and revegetation (i.e., site prescription) must be tested to determine the most effective solution to reduce erosion and stabilize slopes. Kaminak Environmental Monitors conducted preliminary research at reclamation demonstration sites in 2013. In 2014, Kaminak, in collaboration with Arctic Alpine Reclamation Group, expanded reclamation demonstration sites to include data collection and monitoring, as well as new sites).

2.2.1 Year 2013

In 2013, reclamation studies tested basic site prescriptions at existing drill sites/fences. The objective was to test natural regeneration through mechanical reclamation and seeding. To conduct mechanical reclamation, machinery is commonly used to replace the original vegetation layer from where it was removed. A combination of machinery and manual labor was used to conduct this work. Kaminak Environmental Monitors used shovels and rakes to replace soil, vegetation, and boulders in an effort to emulate a well-known reclamation technique referred to as “rough and loose”. Rough and loose surface treatments provide ecosystem benefits by minimizing compaction, controlling erosion, and creating conditions that promote revegetation of the site (Polster 2009). The rough and loose approach promotes a diversity of habitats by creating topographic heterogeneity, which supports early and successful establishment of pioneering species (Holling 1973).

In 2013, sites were seeded with native seed from Arctic Alpine Reclamation Group, including 20% tickle grass (*Agrostis scabra*) 20% alpine bluegrass (*Poa alpina*), 20% glaucous bluegrass (*Poa glauca*), 20% Rocky Mountain fescue (*Festuca saximontana*), and 20% tufted hairgrass (*Deschampsia caespitosa*) at a rate of 1500 pure live seeds per square metre (PLS/m^2). The seed was applied with a manual seed spreader and raked into the soil materials.

2.2.2 Year 2014

In 2014, reclamation studies expanded to include long-term monitoring plots at existing and new reclamation demonstration sites including drill sites/fences and cut slopes.

The objective was to test and monitor various site prescriptions at reclamation demonstration sites to determine which prescriptions are most effective for reclamation and revegetation for the Project. The following site prescriptions were applied to new disturbed sites in 2014 including drill sites/fences, and cut slopes along the Java Road:

1. Mechanical Reclamation (MR).
2. Mechanical Reclamation + Seeding (MRS).
3. Mechanical Reclamation + Raking + Seeding + Raking (MRRSR).

4. Mechanical Reclamation + Bio-engineering + Seeding + (MRBS).

Drill sites/fences were treated with site prescriptions one (MR), two (MRS) or three (MRRSR) which included mechanical reclamation, seeding, and/or raking. For those site prescriptions that included seeding, in 2013, seed was sourced from Arctic Alpine Reclamation Group. In 2014 and 2015, seed was locally collected onsite and included a mixture of grasses, nitrogen-fixing forbs, and shrubs (for details on seed collection refer to Section 3.0 Seed Collection, Inventory, and Mapping**)**.

Site prescription four (MRBS) was only applied at selected cut slopes along the Java Road and tested local seed mixtures and bio-engineering techniques. Bio-engineering techniques involved staking and bundling cuttings from local shrubs including willow (*Salix* spp.), alder (*Alnus viridis*), balsam poplar (*Populus balsamifera*), and birch (*Betula glandulosa*). Native seed was also applied to the cut slopes; the seed mix included alpine bluegrass (*Poa alpina*), glaucous bluegrass (*Poa glauca*), Rocky Mountain fescue (*Festuca saximontana*), tufted hairgrass (*Deschampsia caespitosa*), and boreal wormwood (*Artemisia norvegica* ssp. *saxatilis*). Seed was applied at a rate of 1500 PLS/m^2.

Demonstration sites along the Java Road focused on cut slopes. Cut slope site prescription trials focused on three main sites located at KM 1.6, 3.2, and 7.2. Cut slope sites were different in size; site one at KM 1.6 was 35 m x 2.5 m (87 m^2), site two at KM 3.2 was 195 m x 3 m (585 m^2) and site three was 285 m x 90 m (25,650 m^2). Site three was further divided into eight, 30 m plots. For all sites, native species cuttings were inserted horizontally (bundles) and vertically (stakes) into the soil. Willow, alder, balsam poplar, and Labrador tea (*Rhododendron groenlandicum*) were used as cuttings for bioengineering. All erosion sites were treated with site prescription four (MRBS), which included soil bioengineering techniques. Soil bioengineering is the use of living plant materials to perform specific engineer functions (Schiechtl 1980). To test the effectiveness of site prescriptions at demonstration sites, four 1 m^2 long-term monitoring plots were established at selected demonstration sites.

2.2.3 Year 2015

Reclamation demonstration sites established in 2013 and 2014 were monitored in 2015. To determine the effectiveness of site prescriptions at drill sites/fences, the percent cover of germinating plants were measured at all four 1x1 m plots within a site. At cut slope sites, the percent cover of vegetation was also recorded, as indicated by the percent of live stakes and bundles. Results for the reclamation demonstration sites will be provided following future onsite monitoring activities that will be undertaken by Randy Lewis and Environmental Monitors.

2.3 Yukon Research Centre Studies

In 2015, the Yukon Research Centre (YRC) established seeding trials to test various reclamation techniques in different ecotypes present onsite at the Project site. In addition, greenhouse trials were conducted to test the relationship between soil amendments and the recovery of ecosystem processes (i.e., nitrogen-fixation). Seeding trials were conducted onsite at the Project site in conjunction with the NTR course. Greenhouse trials were conducted at the YRC by trained staff, as a laboratory experiment. Both trials support reclamation research and monitoring activities as part of the Project.

2.3.1 Seeding Trials

Seeding trials were conducted to determine germination rate and percent cover of native seed applied to different ecotypes using various reclamation techniques. Using a randomized block design, trials were established at both boreal low and subalpine sites. At each site ten blocks each with seven different reclamation techniques were installed for a total of 140 plots. The reclamation techniques were applied in 1 m² plots and randomly assigned within each block. At a minimum, all plots were situated 1 m apart and 1 m from the edge of the site. The following seven reclamation techniques were tested:

- Boreal low, organic matter and seed (BOS)
- Subalpine, organic matter and seed (SOS)
- Boreal low, organic matter, fertilizer and seed (BOFS)
- Subalpine, organic matter, fertilizer and seed (SOFS)
- Fertilizer and seed (FS)
- Seed only (S), and
- Control, no addition (C).

The two types of organic matter applied as a soil amendment were Boreal low (BO) and Subalpine (SO). The BO amendment was harvested from a low-lying bog underlain by permafrost at approximately 50 to 100 cm located near the airstrip. The SO amendment was harvested from the top 50 cm of the soil profile in subalpine birch heath located adjacent to a subalpine drill site/fence. Kaminak Environmental Monitors, NTR students, and YRC researchers applied organic matter at 5% (v/v) to the top 5 cm of soil and fertilizer (19:19:19 NPK) was added at 160 kg/ha. A native seed mix was applied at a rate of 1500 PLS/m². The native seed mix included alpine bluegrass (*Poa alpina*), glaucous bluegrass (*Poa glauca*), Rocky Mountain fescue (*Festuca saximontana*), tufted hairgrass (*Deschampsia caespitosa*) and boreal wormwood (*Artemisia norvegica* ssp. *saxatilis*). Plots were seeded from June 15 to 16, 2015 and measured for germination and percent cover from August 17 to 18, 2015. Although the seed used in this initial trial was not from site, all species in the mix were found to occur naturally on-site and was sourced from the Alaska Seed Bank to maintain regional continuity. For additional information on local seed collections that were carried out concurrently to this trial please refer to Section 3.0 Seed Collection, Inventory and Mapping**.**

2.3.2 Greenhouse Trials

To test the relationship between soil amendments and the recovery of ecosystem processes a greenhouse trial was conducted at the Yukon Research Centre (YRC) using a common native species found at the Project site. Arctic lupine (*Lupinus arcticus*) is an understory species that possesses natural nitrogen-fixing abilities. Through a symbiotic relationship with a strain of bacteria known as rhizobia, lupine can fix nitrogen to assist growth, development and reproduction of plants in the surrounding soil and promotes ecosystem processes. This process occurs in tiny, round nodules on the roots and is a good indication of site conditions that will support natural regeneration.

In a controlled growth chamber, eight treatments were tested to determine ethylene production in lupine after three months of growth. Ethylene is a natural plant hormone that is produced as a by-product during

all stages of tissue development. It is produced from all parts of higher plants, including leaves, stems, flowers, fruits, roots, tubers and seeds. The amount of ethylene produced (ppm/h) by individual lupine plants growing in a medium was measured for each of the following treatments:

- Inoculum peat and seed (IP-S)
- pH adjusted, inoculum peat and seed (pHIP-S)
- Inoculum seed (IS)
- Peat and seed (P-S)
- pH adjusted, peat and seed (pHP-S)
- Seed only (S)
- Inoculum peat and inoculum seed (IP-IS), and
- pH adjusted, inoculum peat and inoculum seed (pHIP-IS).

Lupine root nodules were harvested onsite June15–16, 2015. Root nodules were kept in a cool, dark fridge until processing on June 26, 2015. Both roots and nodules were washed with a small brush to remove soil, rinsed with deionized (DI) water, sterilized with ethanol by submersing it in the liquid for 30 seconds then rinsed by DI water six times. Nodules were separated from the roots using a sterile scalpel, weighed and then ground with a mortar and pestle. Ground nodules were added to a yeast sucrose broth (YSB; Vincent 1970). The YSB was made by mixing 100 g of baker's yeast with one litre of cold DI water. The mixture sat at room temperature for one hour then was autoclaved at 120°C for 40 min. Following this it was left to settle before adjusting the pH to 6.10 with calcium carbonate (CaCO3). The mixture was left to stand for 24 hours at room temperature, then was diluted to 1500 ml with DI water to create enough broth for all treatments.

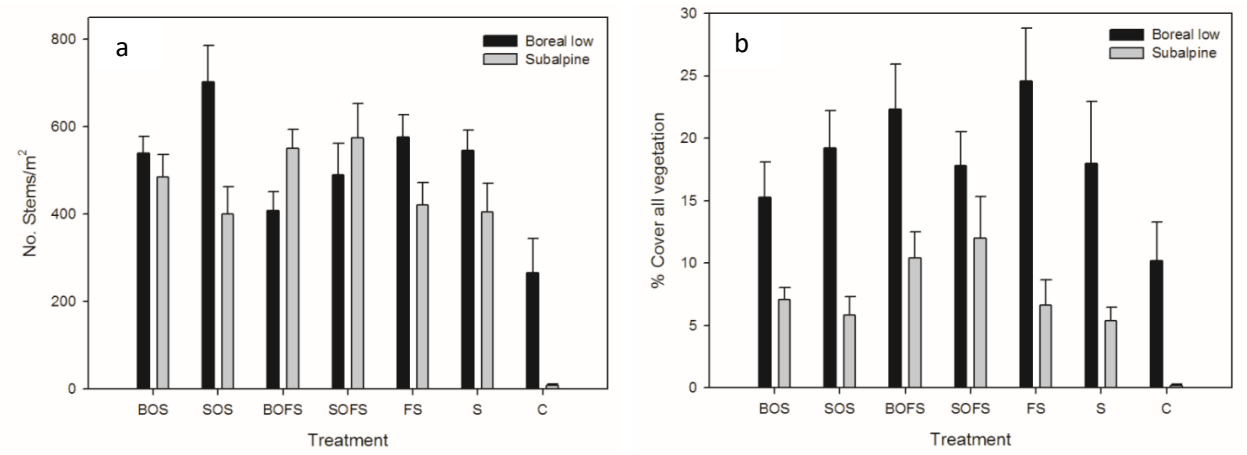
Potting soil and organic peat were collected from two locations onsite June 14, 2015, from the boreal low (62˚54.267', -139˚04.666') and subalpine (62˚53.043', -139˚17.429') areas. The peat was processed for the potting trials by sieving, air drying, sterilizing in an autoclave at 120 ° C for one hour, then grinding the material in a food processor. It was neutralized with $CaCO_3$ at a rate of 10 km/m^3 (12 g added to 1200 ml of peat). Sterilized peat was then mixed with the YSB to achieve 50% moisture v/v (700 ml peat was mixed with 700 ml YSB). Finally, both peat and lupine seeds were soaked in the YSB for 24 hours or DI water. Two lupine seeds were planted per tube of 150 ml of soil and watered to field capacity with DI water. After approximately three months soils were measured by ARAs-acetylene reduction assays to determine amount of ethylene produced (ppm/h).

2.3.3 Results: 2015 Yukon Research Centre Studies

Seeding Trials

Overall organic matter and fertilizer amendments had little to no effect on germination rates of the native seed mix for either the boreal low or subalpine ecotypes (Panel a in Figure 2-1); However, the addition of fertilizer either alone or in addition to organic matter affected the percent cover of vegetation found growing at sites within these ecotypes (Panel b in Figure 2-1). In general, aboveground cover was higher in all plots with fertilizer amendments in both the boreal low and subalpine ecotypes. This suggests that at least in the

first growing season aboveground biomass production can be promoted by the use of commercial fertilizers. Further research is needed to determine the long term effectiveness of fertilizer addition on plant growth. Total percent cover for all species was three times higher in the boreal low (18%) than the subalpine (6%), which was in part driven by the recruitment of native local volunteer species (6%) establishing in the research plots (see Table 2-3). While further monitoring is needed to determine the effectiveness of these amendments over time it is evident that different approaches will likely be required in different ecotypes. High recruitment from the seed bank at the boreal low site indicates that natural revegetation will likely occur with minimal interventions; however, the low aboveground cover and lack of recruitment from the seed bank at the subalpine ecotype indicates that a more extensive revegetation strategy will likely need to be developed.



Note: Germination rate (number of stems/m^2) is on the left (a) and percent cover (%) is on the right (b);

Figure 2-1 2015 Seeding Trial Results from Boreal Low and Subalpine Ecotypes at the Coffee Gold Mine Project

Table 2-3 Total Percent Cover for all Species in Boreal Low and Subalpine Ecosites

Ecotype	Total Cover (%)	Grass Cover (%)	Volunteer Species (%)
Boreal low	18	12	6
Subalpine	6	6	0

Greenhouse Trials

Ethylene production (i.e., nitrogen-fixation) from lupine was significantly different between boreal low and subalpine soils within some treatments (Figure 2-2). Nitrogen fixation was higher in subalpine than boreal low soils for the following treatments: IP-S (Inoculum peat and seed), pHIP-S (pH adjusted, inoculum peat and seed, IS (Inoculum seed) and IP-IS (Inoculum peat and inoculum seed). There was no difference in nitrogen fixation between subalpine and boreal low soils for the following treatments: P-S (Peat and seed), pH-S (pH adjusted, peat and seed), S (Seed only), and pHIP-IS (pH adjusted, inoculum peat and inoculum seed).

Between treatments, pH adjustment of peat led to higher rates of nitrogen-fixation. This may be due naturally low acidic/high alkaline subalpine soil or a naturally high number of rhizobium in the soil. Quantification of the rhizobium associated with each treatment could determine if rhizobium colonization rates were higher in the above treatments or if higher alkaline conditions only increased nitrogen-fixation activity, while maintaining similar colonization rates.

3.0 SEED COLLECTION, INVENTORY AND MAPPING

In 2014, Kaminak initiated onsite seed collection and inventory for use in reclamation studies based on the preliminary list of potential species for reclamation (see Section 2.1 Plants for Reclamation**)**. This was expanded in 2015 through the work with the Yukon Research Centre. Disturbed and undisturbed vegetation communities in the boreal low, boreal high and subalpine ecotypes were surveyed to identify species naturally recolonizing disturbed areas. Due to higher rates of natural recovery and the reduced adverse effects expected in the boreal low ecotype (i.e., no Project mining operations in the boreal low), seed collection sites were selected in the boreal high and subalpine ecotypes. Seed collection sites also considered the availability of native species for bio-engineering bundles and stakes. Native seed was collected during the fall of 2014 and 2015 from KM zero (i.e., old airstrip) to KM 20 (i.e., Java Road). Detailed locations are provided online as part of an interactive seed source map available at:

http://yrc-c.maps.arcgis.com/apps/MapJournal/index.html?appid=30b9ade6ce39467d8bb503fbfe4147b5

More than 30 candidate species were collected from 26 locations including grasses, nitrogen-fixing forbs, and shrubs. Seed collection considered plant phenology according to species. Plant phenology refers to the timing of plant growth and development. This can vary by season and is dependent on factors such as climate, elevation, and aspect. All seed was harvested by hand then dried and stored in the temporary nursery located onsite at the Coffee exploration camp.

Early successional species colonizing disturbed areas within the boreal high and subalpine ecotypes included prickly rose (*Rosa acicularis*), red raspberry (*Rubus idaeus*; boreal high only), fireweed (*Chamerion angustifolium*), bitter fleabane (*Erigeron acris*), tall lungwort (*Mertensia paniculata*; boreal high only), blue-joint reedgrass (*Calamagrostis canadensis*) and *Poa* grass species. This suggests that these species are good indicators of disturbed areas in these ecotypes and may be appropriate candidates for reclamation and revegetation.

4.0 NURSERY PLANNING

Using native species for northern reclamation is a challenge due to lack of available seed stock. In 2014 and 2015, Kaminak initiated preliminary plans to examine the basics of operating a nursery onsite. As part of this pilot project, Environmental Monitors and students from the NTR program established a temporary nursery at the Coffee exploration camp and participated in native seed potting trials and target species transplants. To prepare seeds for planting in nursery pots all seeds were cleaned by sieving to separate the seed from the husk and outer covering and then dried on a mesh rack. Following this, seeds were planted in nursery pots with soil collected onsite and watered to examine survival. Target species transplants were potted as soon as possible to prevent drying or damage to the root system.

Newmont will seek opportunities to work with local or Yukon First Nation businesses who are interested in establishing a nursery to grow native species for use in reclamation research and ultimately to cultivate seed and plants for use in reclamation activities (i.e., species that are adapted to the growing and climatic conditions that occur at the Mine Site).

5.0 FUTURE WORK

Newmont has committed to continue reclamation research and monitoring as part of reclamation and closure planning. Future work aims to increase the scope and depth of research to find innovative restoration techniques that are Project specific. One way that this can be achieved is by understanding rhizosphere (i.e., plant-root interface) properties of boreal plants and their potential to restore belowground processes (Iversen et al. 2015). This is important because understanding how these plant species interact with soil is fundamental to the development of sound and successful restoration practices that not only promote predictability of plant community assemblages, but also ensure restoration of key ecosystem processes in soils that support these communities over the long-term (Kardol and Wardle 2010; Quideau et al. 2013). It has been identified that more knowledge is needed on the use of local peat as a soil amendment during restoration and to address the management of a large ice-rich peat deposit overlying one of the major proposed pits onsite (i.e., Supremo). In addition, understanding the relationship between soil biological community development, carbon and mineral nutrient availability, and ecosystem function will provide important information for the reclamation and closure plan. To fulfill these knowledge gaps, Newmont has committed to a three-year (2016 to 2018) reclamation research program with Katherine Stewart (Assistant Professor, University of Saskatchewan) to:

1. Characterize the rhizosphere of northern native plants that are potential candidates for restoration to understand the relationship between the diversity and abundance of plant roots, soil bacteria, fungi, and archaea with ecosystem functions (i.e., soil nitrogen and carbon cycling and storage).
2. Examine the use of local peat as a soil amendment during restoration and the potential impact of stockpiling on above and belowground plant-soil systems.
3. Investigate the interaction of peat soil amendments with northern plant species and rhizospheres.
4. Establish a three-year field trial to evaluate the restoration of plant-soil materials on existing disturbance (e.g., drill fences) in subalpine areas.

This work will result in the training of two technicians, two masters' students, and three undergraduate student assistants. It will also engage Newmont's environmental monitoring team by involving the Environmental Monitors in field trial establishment and monitoring.

Yukon University

Revegetation research at Minto Mine

Year 1 Progress Report | November 2021

UNIVERSITY OF ALBERTA

Acknowledgements:

Dr. Simon Landhäusser at the University of Alberta was instrumental in study design and provided long-distance guidance as needed – thank you for your continued support despite Covid-19 travel restrictions! Thank you to Minto Explorations Ltd. for providing a research location and logistical support when our research team was on site. The authors would also like to thank field assistants Amanda Eskridge, Taylor Belanksy, Ben McGrath and Kirsten Reid for their invaluable support setting up the experiment. Thank you to Brittany Hynes for organizing and sending field equipment from the University of Alberta. Seed collection support from Maria Ledergerber, Brett Isbister, Bonnie Burns and Jared Gonet was greatly appreciated.

Funding for this research was generously provided by Natural Science and Engineering Research Council of Canada, Mitacs, Yukon University's Innovation and Entrepreneurship, Weston Family Foundation and the Yukon Mining Research Consortium: Minto Explorations Ltd., Newmont Corporation, BMC Minerals Ltd., Victoria Gold Corp., Casino Mining Corp., Selwyn Chihong Mining Ltd., and Alexco Resource Corp.

Introduction

Revegetation is a key process in reclamation as it ultimately determines future land uses by people and wildlife (Guittony 2020). The majority of boreal reclamation research focuses on oil sands mining in the Boreal Plains Ecoregion of Alberta with a strong emphasis on soil amendments of peat and forest floor materials, as well as extensive tree planting (Dhar et al. 2018). Forest floor salvage and peat amendments can reintroduce plant propagules and improve soil characteristics; tree planting reduces the time to canopy closure and can limit establishment of weedy species (Macdonald et al. 2015). In the Yukon, most mines are in remote locations without significant peat or topsoil resources. Access to locally sourced tree seedlings is also limited. Best practice in revegetation is to optimize the use of local resources (Guittony 2020) and thus exploring alternative techniques for northern regions is warranted.

Facilitation by woody shrubs in restoration projects has been documented in dry, arid climates, but not tested in northern systems (Gómez et al 2004; Castro et al. 2004; Gómez -Aparacio et al. 2005). Research studying shrub encroachment in arctic and alpine tundra provides evidence that tall shrubs have a strong, year-round influence on northern non-forested community dynamics (review by Myers-Smith et al. 2011). Plants can facilitate the survival and growth of their neighbors by providing more favorable environmental conditions such as reduced soil and air temperature extremes, nitrogen fixation, attracting pollinators and providing physical protection from herbivory (Castro et al. 2004 Baraza et al. 2006; Padilla and Pugnaire 2006; Dona and Galen 2007; Brooker et al. 2008). In cold climates, vertical structure such as a shrub canopy can increase the capture of snow which dramatically alters both summer and winter soil conditions (Kreyling 2019). Vertical structure can also reduce the loss of soil and seeds to wind erosion (Peterson 2001).

Figure 1. Green alder seedling facilitating the “capture” of windblown seeds.

Facilitation between plants is most common in harsh environments, especially during the establishment and early growth life stages (Maestre et al. 2009). Growth of shrubs alters abiotic and biotic conditions in non-forested northern ecosystems; in a reclamation setting, the presence of shrubs may facilitate establishment and growth of other species. The strength of facilitation effects from the physical characteristics of vertical structure versus biological characteristics of shrubs is unclear.

The main objectives of this study are to evaluate the usefulness of vertical structure in facilitating the arrival, establishment and growth of northern plants and compare the effects of living vs. non-living structure.

More specifically, the hypothesizes investigated in this study are:

1) Vertical structures improve growing season soil moisture by increased wind protection, snow capture and soil shading.
    a. The magnitude of effect is proportional to structure height and distance from structure
    b. Living structures increase soil moisture more than inert structures as litter increases soil organic matter and thus water holding capacity
2) Living vertical structures improve growing season plant available nitrogen by nitrogen fixation and litter deposition
    a. The magnitude of effect is species specific
    b. The magnitude of effect is proportional to structure height and distance from structure
3) Increases in soil moisture and plant available nitrogen provided by woody shrubs improves plant growth under harsh, northern conditions
    a. Facilitation by woody shrubs is stronger than competition during establishment and early growth of target species
4) Vertical structure increases natural deposition of seeds
    a. From animal/bird dispersal using the perches/cover
    b. From wind dispersal, slowing wind currents to deposit seeds

Experimental design

The study design is a randomized complete block experiment with biotic and abiotic structures of three different heights for a total of four blocks of six treatments (Table 1.). Treatments are in rows perpendicular to the dominant wind direction. Spacing between rows is based on the tallest treatment in each row to avoid interference between treatments; main effects of treatments are expected between two and seven times structure height (AAFC 2010). See the Experiment Layout Section for more details on actual site layout.

Table 1. Summary of experiment treatments

Treatment Height	Biotic Structure	Abiotic Structure
Tall	Green alder	0.65 m snow fence
Medium	Soapberry	0.35 m snow fence
Short	Smooth-leaf mountain avens	0 m control

To determine whether vertical structure facilitates seed capture, three 0.25 m wide transects with a smooth, uniform seedbed will be installed straddling each treatment from -1 to 7x the treatment height (Figure 2.). In Blocks 1-3, soil moisture and temperature sensors will also be installed along the centre transect at -1, 1, 3, and 7x the treatment height.

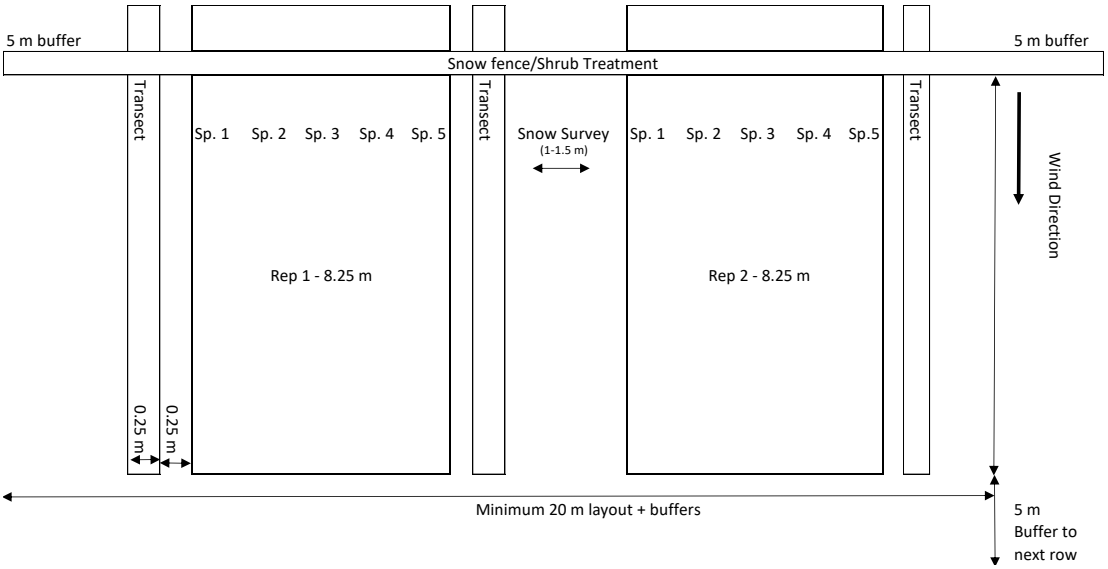

Figure 2. Within block layout of transects and germination/seedling plot replicates. See Figure 3. for detailed layout of each replicate.

In Year 3 (2023), small plots will be established at -1, 1, 3, and 7x the height of the shelter to evaluate the effect of vertical structure on the germination, establishment and growth of target northern plants (Figure 3.). Shrub heights in each treatment will be averaged from measurements in Year 3 to determine the treatment height. For each target species, paired comparisons of spring vs. fall seeding/planting will be tested. Germination trials of 100 seeds will be installed in 0.15 m^2 plots; protection from herbivory will be provided if required. Plant performance will be tested by planting six seedlings in 0.5 x 0.15 m plots. A minimum distance of 0.25 m between plots will be maintained. Germination percentages, seedling survival, seedling height will be sampled in September of Year 4 (2024).

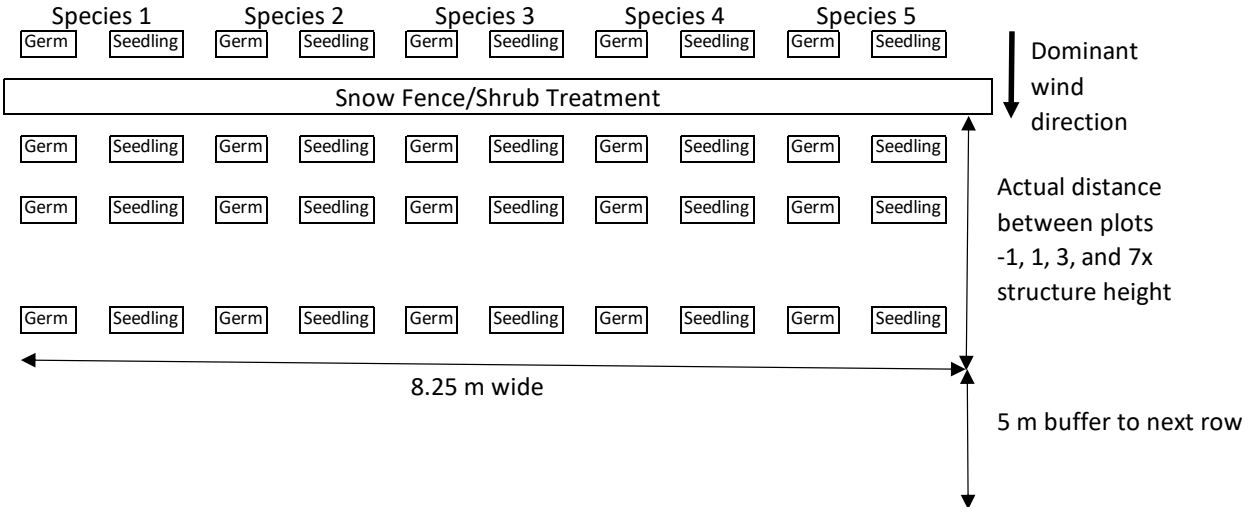

Figure 3. Replicate layout for germination/seedling plots. Target species will be selected in 2022.

Experiment set-up in 2021

Project area description

The research will be located at the Minto Mine in central Yukon, Canada (62.620097°N, 137.276705°W). The site is within the Yukon Plateau-Central Ecoregion of the Boreal Cordillera Ecozone and is characterized by long, cold winters and short, warm summers (Smith et al. 2004). The ecoregion was almost entirely glaciated three million years ago, but the Minto Mine site remained unglaciated during the last glacial maximum (Smith et al. 2004). The northernmost Holocene volcano in Canada, Nelruna (Volcano Mountain), is located about 30 km northeast of the mine and last erupted between 5,000-10,000 years ago (name from Ritter et al. 1977; Smith et al. 2004). Historical annual average temperature was -4°C, though average temperatures in Yukon have risen by 2°C in the past 50 years and increased precipitation is expected in the future (Streiker 2016). Currently, Minto Mine has limited precipitation (<300 mm/year) due to the rain shadow effect of the St. Elias-Coast Mountains (Smith et al. 2004). Wildfire is common due to low precipitation and has resulted in various successional stages of plant communities surrounding the mine (Access Consulting 2013).

The mine footprint is within the Boreal Low Bioclimate Zone-Yukon Plateau North Subzone, with potential for Boreal High Bioclimate Zones at the uppermost elevations (McKenna and Flynn 2017). Most of the surrounding area is forested with pure or mixed stands of trembling aspen (*Populus tremuloides*), white spruce (*Picea glauca*) and lodgepole pine (*Pinus contorta*) depending on drainage, aspect and fire history. Black spruce (*Picea mariana*) forests are found on cool, north facing slopes that have not burned within the last 100 years (Access Consulting 2013). Shrub dominated plant communities (*Salix* spp. and *Betula glandulosa*) are found on the edges of wetlands and riparian areas, and grassland communities are located on dry, warm and nutrient-poor slopes (Access Consulting 2013).

The mine is located within the Traditional Territory of the Selkirk First Nation: Northern Tutchone peoples who share a language and close ties with the First Nation of Na-cho Nyäk Dun and Little Salmon Carmacks First Nation. The majority of Yukon-based citizens live in the community of Pelly Crossing (TPWG 2021), on the banks of Ts'éki Netú (Pelly River), about 60 km upstream of the confluence with Tagé Cho (Yukon River) (Ritter et al. 1977). The Minto Mine area is about 40 km southwest of Pelly Crossing and, prior to the mine, was known as Marten Hill due to a high marten population in the area (Selkirk First Nation 2018).

The mine is also close to Łútsäw Dachäk (Minto Landing), an important gathering and harvesting site beside Tagé Cho and at one point a small settlement (Selkirk First Nation 2018). Łútsäw Dachäk is actively used and the location where Selkirk First Nation representatives signed Self-Government and Final Agreements with the Governments of Canada and Yukon in July of 1997. Included in these agreements was 4,740 km^2 Category A and B Settlement Lands. Minto Explorations Ltd. was in the process of developing the Minto Mine prior to the Final Agreement and is situated in Category A Settlement Land Parcel R-6A. Selkirk First Nation owns the land though the mine is regulated under federal and territorial legislation through special conditions in the Final Agreement (GC, SFN and YG 1997).

Site selection and preparation

A site visit to Minto Mine was completed May 27th, 2021 to identify a location for the research. Site criteria were a 1.5 ha area with minimal slope, final soil cover in place, minimal existing vegetation, and significant wind exposure. The site would need to remain undisturbed for a minimum of four years. A suitable site was identified on the Southwest Waste Dump (see Figure 4.). The waste rock was capped with 0.5 m of overburden in 2014-2015 and the overburden ripped east-west to 30 cm by a Caterpillar 16G grader in early June of 2021.

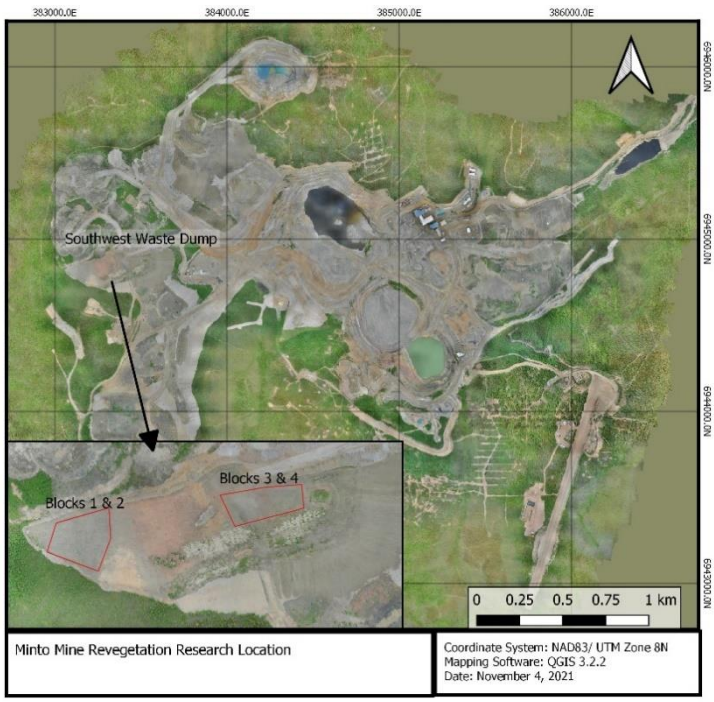

Figure 4. Minto Mine revegetation research location on the Southwest Waste Dump.

Experiment layout

The dominant wind direction (300° W/NW) was determined from Minto Exploration Ltd.'s 2020 weather data. Treatments were laid out in rows along a bearing of 120° with one to three treatments per row. Rows with tall treatments were spaced at 15 m, medium treatments at 10 m and short treatments at 7.5 m (Figure 5.). Treatments were 25-35 m long depending on the length of each row with two exceptions: control treatments in block two (18.5 m) and block four (23.5 m).

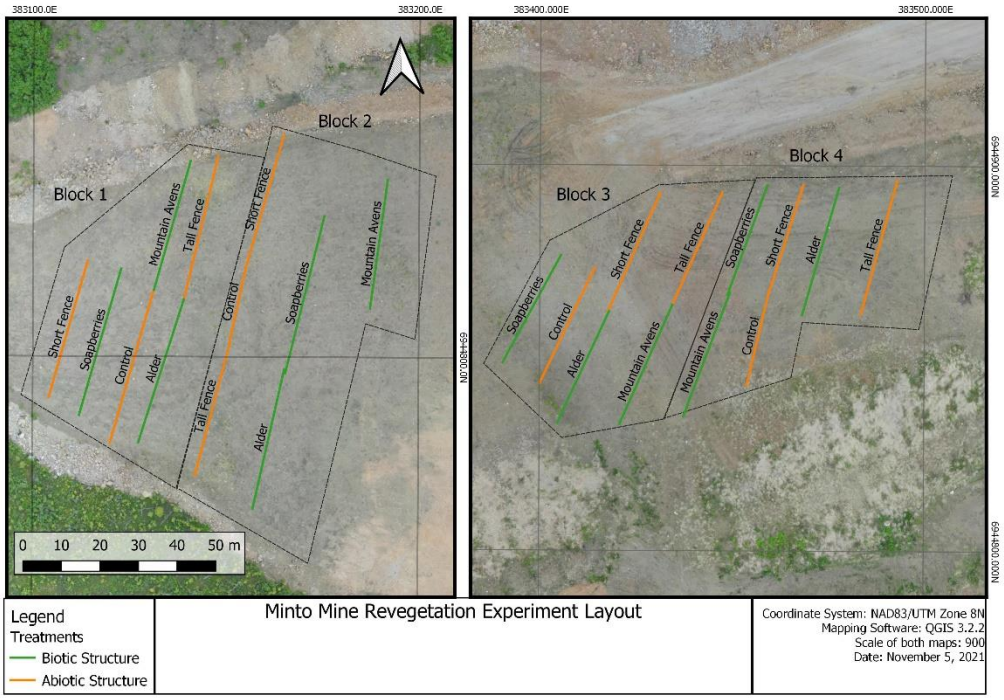

Figure 5. Minto Mine revegetation experiment layout

Biotic structure establishment

Species selection for shrub shelters

Green alder (*Alnus viridis* subsp. *crispa*), soapberry (*Shepherdia canadensis*) and smooth-leaf mountain avens (*Dryas integrifolia*) were selected for tall, medium and short biotic structures. Primary succession processes in northern systems indicate shrubs, especially nitrogen fixers, have a prominent role. Nitrogen fixation by shrubs in early seral stages is a primary determinant of total nitrogen within the climax system though legumes can also contribute (Jacobson and Birks 1980; Chapin et al. 2006; Buma et al. 2017). Green alder and soapberry are well known nitrogen fixers; the evidence is inconclusive for smooth-leaf mountain avens though yellow mountain avens (*D. drummondii*) are capable (Kohls et al. 1994; Rhoades et al. 2008; Callender et al. 2016). Mat-forming shrubs, especially *Dryas* spp., and erect shrubs also capture wind-blown soil fines which stimulates soil development on glacial moraines and outwash (Viereck 1966; Birks 1980; Buma et al. 2017). These species are native to the Yukon and tolerate poorly developed soils and harsh conditions associated with mine sites.

Seedling procurement

Green alder seeds were collected from five populations in late September and early October of 2019 (Table 2.). Seeds were air dried and shipped to NATS Nursery in Abbotsford, BC. Seedlings were grown over the summer of 2020, hardened and frozen for overwinter storage. Alder was shipped frozen by air in February 2021. Soapberry and smooth-leaf mountain aven seeds were each collected from a single population near Whitehorse. Aven seeds were air dried and soapberries kept moist in the fridge until shipping to NATS Nursery in August. Both aven and soapberry seedlings were grown over the summer of 2021, however delayed germination of soapberries meant they were not ready for outplanting in September. Soapberries are expected to be ready in the spring of 2022.

Table 2. Seed source locations for shelter species

Species	Ecoregion	Landmark	Coordinates
Green alder	Yukon Plateau Central	Cabin Gulch	62°16'26"N, 137°9'32"W
Green alder	Yukon Plateau Central	Freegold Road	62°20' 46"N, 137°14'10"W
Green alder	Pelly Mountains	Little Salmon Lake	62°12'21"N, 134°47'24"W
Green alder	Yukon Southern Lakes	Copper Haul Road	60°42'44"N, 135°10'7"W
Green alder	Yukon Southern Lakes	Grey Mountain	60°39'50"N, 134°54'26"W
Soapberries	Yukon Southern Lakes	Deep Creek	61° 4'34"N, 135°12'30"W
Mountain avens	Yukon Southern Lakes	Grey Mountain	60°39'34"N, 134°53.81"W

Green alder seedlings were removed from freezer storage June 13th and planted 0.3 m apart on June 14-16th, 2021 (Figure 6.). Boxes of seedlings were kept in the adjacent forest for shade and covered with a Silvicool Tarp (Bushpro) until planting. Each replicate received 100 L of water the day of planting and another 100 L of water 24 hrs after planting. Alder replicates received 50 L of water June 24th and 70 L of water July 1st. An additional 20 L mixed with 30 mL of soluble 10-40-25 fertilizer (GardenPRO Water Soluble Superbloom) was applied to each alder replicate June 24th and July 20th.

Twenty alder seedlings were randomly selected during planting to determine seedling characteristics (Table 3.). Alder height, root collar, shoot count and presence of nodules was determined in the field. Seedlings were kept cool during transport and frozen at the Yukon Research Centre Lab.

Root to shoot ratios were determined by separating the root and shoot at the root collar, washing the roots thoroughly and drying samples at 70°C for 24 hrs before weighing to the nearest 0.1 mg.

Table 3. Alder seedling characteristics from twenty randomly selected seedlings.

Characteristic	Mean	SE (n=20)	Min	Max
Height (cm)	1.28	± 0.92	1	16.8
Root Collar Diameter (mm)	0.98	± 0.14	2.54	4.65
Shoot #	1.11	± 0.39	2	9
R:S Ratio (g)	1.22	± 0.13	1.02	3.38

Avens were hardened at NATS Nursery, shipped by air to Whitehorse, and planted September 14-16th, 2021. Boxes of seedlings were stored at the research site and covered with a Silvicool tarp (Bushpro) until planting. Avens were planted 0.1 m apart and each replicate was watered with 20 L to improve seedling-soil contact. Twenty-five seedlings were randomly selected for characterization. Seedlings are currently in the freezer and will be processed this winter following the same procedure as the alders.

Soapberries will be planted in spring 2022 at 0.2 m apart.

Abiotic structure installation

Orange snow fencing with 50% porosity was cut into 0.6 and 0.3 m strips. Medium duty steel T-rails were cut into 1.4 m and 0.75 m posts. The tall and medium snow fencing was installed June 12-17, 2021. Posts were spaced at 2 m and pounded in with a mallet or post pounder to the height of the treatment. Snow fencing was installed with the factory edge up, raised 5 cm above the ground to account for variation in microtopography for a final height of 0.65 and 0.35 m respectively. Controls were marked with a wooden stake at each end, but no further structure added.

Figure 6. Planting rows of alder along a stringline in Block 2. The short fence (left) and tall fence (right) are already installed.

Transect Installation

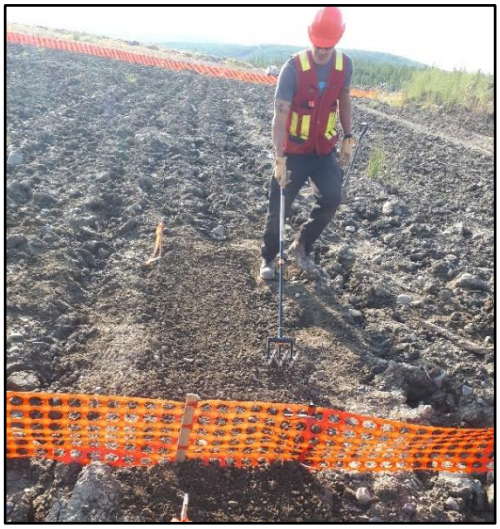

Figure 7. Seedbed preparation with a hand-held cultivator along a transect.

Three uniform seedbeds perpendicular to each abiotic treatment replicate were established July 20-24th, 2021 (Figure 7.). Smooth 0.35 m wide belt transects were created with shovels, mattocks and Fiskars Extended Reach Cultivators. Transect lengths straddled the centerline and were based on the height of the treatment: -0.65 to 4.55 m (tall), -0.35 to 2.45 m (medium) and -0.25 to 1.75 m (short) (Figure 7.). Four Hobo EC-5 Soil Moisture Smart Sensor or Decagon 5TM Soil Moisture Sensors and four Maxim Integrated iButton Thermochron F5 temperature data loggers were installed at intervals along the centre transect in each replicate based on treatment height. Soil moisture sensors log hourly and temperature sensors log every three hours. Seedbeds at biotic treatments will be established in 2023 once the final shrub heights for the experiment are known.

Baseline sampling and environmental monitoring

A weather station was installed in June 2021 near Block 2 to monitor climate conditions (Figure 8.). Data is logged by a HOBO USB Microstation outfitted with an Onset Photosythetic Light Smart Sensor, Davis Wind Speed and Direction Smart Sensor, Davis Rain Gauge Smart Sensor, Decagon EC-5 Soil Moisture Sensor and Onset Smart Temperature Sensor. An additional HOBO External Temperature and Relative Humidity logger was also installed. Two Reconyx HP2X Hyperfire 2 Professional Covert IR Cameras were set up overlooking the site to monitor overall conditions with a daily photo at 1 pm.

Figure 8. Amanda and Taylor celebrating successful weather station installation.

A vegetation inventory of the waste dump surrounding the research site was conducted June 16th and confirmed July 24th (Appendix 1.). Baseline soil samples were collected June 15-16th. Three composite samples were collected in each block and treatment for a total of 12 samples. A separate composite sample was taken of the red residuum material that occurs around the research site and sporadically in Block 3. Each sample was analyzed for pH, electrical conductivity, soil texture, total carbon, total organic carbon, total nitrogen, % organic matter, plant available NPK and trace metals. Copper was the only metal above CCME guidelines and only in Block 3 replicate; the red residuum sample confirmed this material as the source. Select soil sample results are summarized in Table 4.

Table 4. Mean soil characteristics and standard error (n=3) from baseline sampling in June 2021 and single red residuum sample results. TOC=total organic carbon and TIN=total inorganic nitrogen.

Block	pH	Texture	TOC (w/w%)	TIN mg/kg	PO4-P mg/kg	K mg/kg	Cu mg/kg
B1	8.43 ± 0.05	Clay Loam	0.27 ± 0.03	2.83 ± 0.47	0.66 ± 0.08	64.84 ± 6.56	40.12 ± 1.11
B2	8.47 ± 0.05	Clay Loam	0.35 ± 0.09	2.33 ± 0.38	0.69 ± 0.16	60.90 ± 3.83	40.38 ± 2.32
B3	8.73 ± 0.09	Loam	0.17 ± 0.05	1.50 ± 0.19	0.66 ± 0.16	51.14 ± 2.83	92.85 ± 2.56
B4	8.67 ± 0.02	Clay Loam	0.17 ± 0.01	2.07 ± 0.03	1.05 ± 0.31	68.52 ± 2.19	52.63 ± 0.54
Resi-duum	8.7	Sandy Clay Loam	0.12	2.40	0.68	62.9	214.8

The above ground structure and biomass of green alders were sampled July 20-24th, 2021, following the Tall Shrub Monitoring Protocol for Arctic Canada and Alaska (Myers-Smith et al. 2012). Ten randomly selected alders within each replicate were tagged and sampled for stem count, stem diameter, annual growth, maximum canopy height, and canopy area.

Heights of 10 randomly selected mountain avens and previously tagged alders in each replicate were measured September 14th-17th, 2021 (Table 5.). Weather station, transect sensors and time lapse photo data were also downloaded at this time. A full series of photopoints was taken September 16th, 2021 (Appendix 2.).

Table 5. Shrub seedling heights (n=10) in September 2021

	Alder		Mountain Avens	
Block	Mean Height (cm)	SE	Mean Height (cm)	SE
B1	25.29	± 2.17	4.33	± 0.42
B2	12.5	± 0.80	4.96	± 0.28
B3	13.14	± 1.23	4.66	± 0.46
B4	13.48	± 1.54	4.31	± 0.39

Remaining experiment set-up activities

Characterization of mountain avens

Twenty-five seedlings are currently frozen and seedling height, root collar diameter, presence of nodules and root to shoot ratio will be measured over the winter.

Soapberry establishment

Soapberry seedlings are growing at NATS Nursery in Abbotsford, BC and will be shipped frozen to Whitehorse in the spring of 2022. Seedlings will be planted with 0.2 m spacing shortly after receipt.

Transects for living shelters

Transects along alder, soapberry and mountain aven treatments will be established in 2023 once final height for the experiment is known.

Species selection for target species

Species selection for the target species remains unknown. The plan is to follow up with the Mining Manager at Selkirk First Nation about whether there is interest in collaborating on species selection. Seeds need to be collected in 2022. If there's either limited interest or Covid prevents engagement, species selection can be done with existing written material. Selkirk First Nation has published several in-depth heritage reports and Minto Mine's Reclamation and Closure Plan does include Selkirk First Nation's high level reclamation objectives (Minto Exploration Ltd. 2020).

Once species are selected, seeds will be collected from wild populations in Yukon, cleaned and either stored at the Yukon Research Centre or shipped to NATS Nursery for propagation.

EXECUTIVE SUMMARY

WesTech Engineering (formerly Inotec) was contracted to develop a conceptual water treatment system for the Coffee Mine's heap leach rinse waters. In order to increase confidence in the proposed treatment, reduce uncertainty and risks, and develop a site-specific approach for the treatment of the Coffee waters, the testing was designed in three phases. This report conglomerates the results of Phase I feasibility evaluations and Phase II bench-scale laboratory testing and summarizes the feedback obtained from the stakeholders (Newmont, Tr'ondek Hwech'in, and the Canadian regulatory agencies). Once the mine is operational, and heap waters are available, the system design and expected performance will be demonstrated during the Phase III pilot-scale trial.

The Phase I feasibility testing successfully demonstrated the removal of nitrate, arsenic, and uranium from Coffee Gold leach waters. Even though arsenic removal was demonstrated with the biological treatment, the feasibility testing proved that long retention times and high nutrient doses would be required to meet the required discharge levels. The Phase I recommendation was to investigate phys-chem arsenic removal options.

Upon completing Phase I feasibility testing, WesTech and Newmont sought out feedback from the stakeholders through a series of water-treatment-focused workshops. The consultations yielded positive feedback, identified additional contaminants of interest, and resulted in the addition of several analytical parameters to the monitoring list, strengthening the testing design and outcomes. Sulfate and antimony were identified as potential additional contaminants of interest. Thiocyanate, sulfide, arsenic and selenium speciation, and radiochemistry were added to the analytical schedule.

The Phase II bench-scale testing removed all contaminants of interest to below their respective discharge targets. The best approach for the Coffee Mine water treatment was confirmed to be a multi-stage treatment train, consisting of a phys-chem pretreatment for arsenic and sulfate precipitation, biological EBR treatment for denitrification and metals polishing, and a small aerobic post-treatment for removal of residual nutrients and reintroduction of dissolved oxygen. **The demonstrated benefits of the tested treatment train included:**

1) **a significantly smaller biological EBR system footprint;**
2) **no need for complex organic nutrient addition;**
3) **lower organic carbon requirement, thus lower residual nutrient concentrations; and**
4) **continuous removal of some radioisotopes in the pretreatment, which resulted in little to no accumulation of gross radiation within the EBR bioreactor matrix.**

Arsenic was removed to below the discharge target of 0.035 mg/L using ferric co-precipitation. Barium precipitation of sulfate was demonstrated to be dose-dependent and was optimized to target sulfate discharge target of 1,500 mg/L. The limited evaluation of only two barium salts resulted in residual chloride concentrations; further jar tests will be required once the mine is operational and actual site waters are available to establish the most suitable reagent dose to avoid generating excess chlorides.

The EBR treatment successfully removed nitrate-N to below the detection limit of 0.3 mg/L and uranium to less than 0.1 mg/L (its discharge target) with ethanol as a sole nutrient source and a hydraulic retention time of 7 to 11 hours. Once optimized to target only nitrate and uranium, the EBR system was demonstrated to allow residual arsenic and sulfate to pass through without further reducing either one. The speciation results showed that the EBR system did not produce any methylated arsenic species, even during the preliminary testing stages, when residual arsenic was biologically removed. Several other metals (Sb, Cu, Hg, Mo, and Ni) were reduced by the EBR system from elevated levels to below

their discharge targets, while some multivalent metals (Fe and Mn) were not targeted and passed through the EBR system unchanged. Hardness minerals (Ca, Mg) were shown to be present at elevated concentrations in the Coffee waters and will likely need to be removed by a water softening pretreatment to meet their discharge limits. The EBR system also polished WAD cyanide to below the detection limit of 0.006 mg/L.

Once the pretreatment was optimized, ethanol was used as a sole nutrient source for the EBR treatment, resulting in a low residual nutrient generation. BOD and ammonia were removed in the aerobic post-treatment step, but a spike of phosphate and manganese was experienced in the aerobic column effluent, which can only be attributed to the leaching of these metals from the pumice support matrix. Quality control will be conducted on the media used in pilot-scale tests and the full-scale installation to ensure no unexpected leaching of metals occurs.

A set of preliminary design and operational parameters was developed for a pilot-scale trial based on the results obtained from bench-scale testing. Conducted over a minimum of three months, the on-site demonstration trial is a required last step before the preliminary engineering of the water treatment plant can be completed. The testwork and analytical plan will include, at the minimum, the same level of detail as the Phase II bench-scale program.

INTRODUCTION

TIMELINE OF EVALUATIONS, TESTING, CONSULTATIONS, AND PROCESS DESIGN

The proposed Coffee Gold project is located in the west-central Yukon Territory, approximately 130 km south of Dawson City. Acquired in 2016 by Goldcorp (subsequently, Newmont), Coffee is a high-grade potential open pit and heap leach development project that lies within the traditional territory of Tr'ondek Hwech'in (TH).

WesTech Engineering (formerly Inotec) was contracted to develop a treatment system for the Coffee Mine's heap leach rinse waters. In order to increase confidence in the proposed treatment, reduce uncertainty and risks, and develop a site-specific treatment approach for the treatment of the Coffee waters, the testing was designed in three phases.

Phase I - Treatability assessment and proof-of-concept, conducted in 2016, consisted of laboratory assessment tests and evaluation of site water chemistry. Tests included column heap leach to generate water for treatment, site water chemistry evaluation, microbial screening tests, and treatment effectiveness assessment.

Phase II - Continuous flow laboratory column tests, conducted in 2020, were used to develop an overall treatment approach for the Coffee Gold heap leach rinse waters and to develop operational parameters for on-site pilot-scale tests.

Phase III – On-site pilot tests, to be conducted once mine is operational, are needed to validate the selected unit processes for treatment of all the contaminants of interest in the actual Coffee Gold heap leach rinse waters and to develop operational parameters, design criteria, and preliminary CAPEX/OPEX estimates for a full-scale facility.

This tiered approach was developed based on the EPA's Guide for Conducting Treatability Studies Under CERCLA: Biodegradation Remedy Selection (EPA/540/R-93/519b). The specific characteristics of each phase are provided in Table 1.

WesTech has worked with the project since 2015. Our main objective has been to design a water treatment system that meets the discharge limits using a phased feasibility testing approach that de-risks the process and considers input from all the stakeholders. Several treatment methods have been considered to meet the treatment objectives, and the resulting treatment train utilizes multiple unit processes, including phys-chem and biological methods. The overall timeline of feasibility testing and consultations is summarized in Figure 1. Ample time was allocated after each testing phase for consultations with Tr'ondek Hwech'in and the Canadian regulatory agencies to identify areas of concern and develop appropriate protocols for future testing to address them.

Table 1. Criteria for a three-phase water treatment technology selection process.

Phase/Scale	Phase I: Feasibility Study (completed)	Phase II: Lab Bench-Scale Test (completed)	Phase III: On-Site Pilot Demo (to be completed)
Goal	Process screening	Process selection	Process design
Degradation of the contaminant of interest	Positive degradation	Meets effluent compliance standards under test conditions	Meets compliance standards under site conditions
Extent of treatment	Estimate/ Qualitative	Measure/ Quantitative	Measure/ Quantitative
Biodegradation rate	Crude estimate	Defensible estimate	Quantified
Process control and reliability	Not available	Assess potential	Demonstrate
Process optimization	Not available	Estimate	Refined estimate/ Demonstrate
Study time	2-8 weeks	2-6 months	2-6 months
Full-scale cost estimate	Not available	Rough	Detailed/ Refined

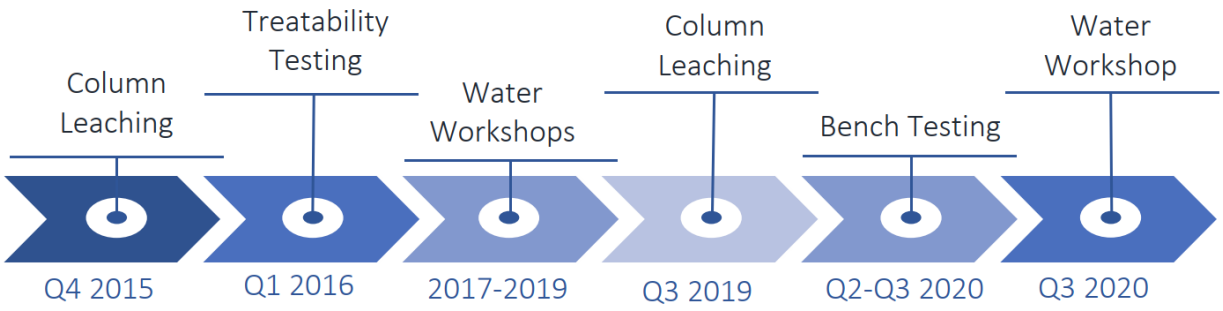

Figure 1. Feasibility testing and consultations timeline.

Predicted Water Quality and Treatment Needs

Developing a conceptual water treatment design for a prospective mine is challenging as without an operational mine, no heap leach rinse waters exist for treatment evaluations. Predicting water quality generated by the heap leach facility (HLF) during rinsing is crucial for identifying the parameters of concern and developing a treatment system with appropriate unit processes. Water modeling, performed by Lorax Environmental Services, identified the target parameters for Phase I treatability testing as nitrate/nitrite, arsenic, and uranium (Table 2). Additionally, sulfate and antimony were added to the list of target parameters for Phase II bench-scale testing based on the input from TH. The treatment targets were based on a back-calculation approach to arrive at allowable concentrations in the discharge to achieve Use-Protection water quality objectives in Halfway Creek.

Table 2. Water quality predictions of the HLF rinse solutions.

Parameter [mg/L]	HLF Rinse Modeling	Treatment Target
NH_3-N	0.025-0.06	8

Zn	0.02-0.052	0.02

TREATMENT PROCESSES

ELECTRO-BIOCHEMICAL REACTOR

Microbes mediate the removal of metal and inorganic contaminants through electron transfer (redox processes). For example, denitrification can be described by the following redox reaction:

$$NO_3^- + 5e^- + 6H^+ \rightarrow \frac{1}{2}N_2 + 3H_2O \quad (1)$$

The biotransformation shown in Reaction 1 occurs under anaerobic, reductive conditions, requiring low dissolved oxygen (DO) levels and a negative oxidation-reduction potential (ORP) environment. Five electrons are needed to reduce one molecule of nitrate to nitrogen gas. Other constituents, such as dissolved oxygen, nitrite, arsenate, selenate, chromate, sulfate, etc., add to the electron demand.

In conventional biological treatment systems, the electrons required for contaminant transformation are supplied in the form of excess nutrients added to the system. Conventional biotreatment systems require excess nutrients/chemicals to compensate for inefficient and variable electron availability to adjust reactor ORP chemistry and for contaminant removal (electron release from organic nutrients requires nutrient metabolism that proceeds at a variable rate). Excess nutrients used to compensate for system sensitivity lead to significantly increased biomass production, resulting in additional CAPEX and OPEX (higher nutrient consumption and management of the excess biomass production).

The Electro-Biochemical Reactor (EBR) technology overcomes these shortcomings by decoupling the electron provision from organic carbon metabolism. The electrons are directly supplied to the reactor and microbes, using a low applied potential (1-3V) across the bioreactor at low milli-Amp levels. The current of 1 mA provides 6.2×10^{15} electrons per second. In contrast, one molecule of acetic acid, commonly used as a nutrient in the water treatment processes, provides only eight electrons under complete metabolism. These electrons replace and supplement the electrons customarily supplied to the conventional bioreactor system by excess nutrients, with considerable savings and multiple reactor, microbial, and environmental benefits. The directly supplied electrons are readily available to the microbes in a consistent, controllable manner without metabolic energy expenditure. Moreover, these "free electrons," from the microbes' standpoint, make the EBR bioreactors more robust and less sensitive to wide fluctuations in water chemistries than the past generations of conventional biotreatments.

ARSENIC REMOVAL BY FERRIC COAGULATION/PRECIPITATION

Even though the EBR technology was validated for arsenic removal to concentrations of less than 0.015 mg/L from initial values in excess of 1.0 mg/L (i.e., > 98.8% removal), evaluation of other arsenic removal methods and integration into the proposed treatment train was recommended. The initial bench-scale treatability assessments indicated that a relatively long retention time and high nutrient loading would be required to target arsenic biologically.

Ferric-based coagulation and flocculation is a widely used arsenic removal method in wastewater and drinking water treatment. It uses a metal-based coagulant, such as ferric chloride ($FeCl_3$), which hydrolyzes in water to form positively charged ferric hydroxide [$Fe(OH)_3$]. Dissolved arsenic oxyanions are negatively charged and readily sorb to the positively charged ferric hydroxide particles. The process is sensitive to the oxidative state of arsenic; if any reduced arsenic oxyanions, such as arsenite, are present, they must be oxidized to arsenate first for the ferric coagulation step to be effective.

Sulfate Precipitation

In contrast to contaminants such as nitrate, arsenic, and heavy metals, sulfate has no primary standard for drinking water or aquatic life. Numerous treatment technologies for efficient sulfate removal exist, including biological and physical processes. As an alternative option for biological sulfate removal, sulfate precipitation using physicochemical methods was evaluated. The most commonly used technology for reducing high sulfate concentrations is lime precipitation, which generates calcium sulfate (gypsum). This method is effective for sulfate concentrations higher than the gypsum solubility limit of 1,500-2,000 mg/L. As a polishing step for sulfate removal, barium sulfate precipitation can be applied. Barium sulfate has very low solubility in water (~ 2.5 mg/L), with the final sulfate concentration limited only by the amount of barium added and reaction time.

In-Situ Bioremediation

The basic premise of bioremediation is to accelerate microbial activity using nutrients (carbon, phosphorus, nitrogen, etc.) to create conditions conducive to biodegradation of target contaminants. In general, in-situ bioremediation is designed to modify the environmental conditions, typically through oxidation/reduction manipulation, to create an environment that stimulates the growth of indigenous and added microbes and the subsequent degradation of the target contaminants via microbial catalyzed reactions.

This testing focused on in-situ denitrification (nitrate reduction). Nitrate is an important co-contaminant because it is a preferred electron acceptor that needs to be reduced or removed before metal removal is effectively targeted. Nitrate is the most ubiquitous groundwater contaminant in North America and is common at many mining sites due to the use of ammonium nitrate in blasting. Nitrate is non-sorptive and does not exchange on many surfaces. It has a very low probability of retardation onto soil colloids. Nitrate reduction occurs during anaerobic respiration; in the absence of oxygen (<2 mg/L dissolved oxygen) and the presence of a carbon source, bacteria utilize nitrates as electron acceptors during respiration.

In mining waters, nitrate-N is typically found at tens or hundreds ppm levels as compared to ppb concentrations most metals like arsenic and uranium are present at. Since nitrate is a preferred electron acceptor and is typically present in mining waters several orders of magnitude higher than dissolved metals, the majority of the retention time required for an active biological treatment is spent on denitrification. Longer retention times require larger bioreactors, which in turn means higher CAPEX (capital expenditures). A holistic mine site water management and treatment should include in-situ denitrification within the heap followed by a smaller active treatment for metals removal.

TESTWORK

TESTING PHASES AND OBJECTIVES

WesTech has completed Phases I and II of feasibility and system design stages. The objectives of the two phases were as follows:

Phase I:

Provide **a proof-of-concept** for removal of nitrate, arsenic, and uranium from the Coffee Mine heap leach rinse waters.

- Task 1 – Spent Ore Column Leaching Tests. Task 1 was used to generate leach waters for Tasks 2 through 4.
- Task 2 – Microbial Screening and Treatability Assessment. The goal of Task 2 was to develop microbial consortia for Tasks 3 and 4.
- Task 3 – EBR Validation Testing. The goal of Task 3 was to provide a proof-of-concept evaluation of the EBR technology for the treatment of the Coffee Gold leach waters.
- Task 4 – In-Situ Testing. The goal of Task 4 was to evaluate microbial in-situ denitrification of the Coffee Gold spent ore materials.

Phase II:

Develop and **optimize a systems approach** to treating all parameters present above the discharge standards in the Coffee Mine heap leach rinse waters

- Task 1 – Side-by-side evaluations of two treatment approaches. The goal was to determine the optimal process design for nitrate, uranium, sulfate, and arsenic removal to below the discharge objectives.
- Task 2 – System stress-testing to determine the optimal system configuration and operational conditions (including required chemical doses and hydraulic retention times).
- Task 3 – Treatment train design to meet all discharge requirements (including required pretreatment, e.g., for cyanide destruction, and any needed post-treatment, e.g., for aeration and BOD and ammonia oxidation).
- Task 4 – Development of the required design information for Phase III testing.

Experimental Design and Procedures

Microbial Screening

Microbial isolation and screening tests were conducted on solutions received and initial column materials at 5ºC and 20 ºC. Microbes isolated from the Coffee Mine waters and spent ore materials were tested for their ability to remove arsenic, uranium, nitrate, sulfate, and antimony. These isolates were tested in direct comparative screening tests alongside WesTech's repository microbes to select a site-specific inoculum for the removal of contaminants of interest.

These tests provided the microbes for Phase I and Phase II testing. A microbial population screened to be effective at removing arsenic, uranium, nitrate, sulfate, and antimony was grown into an inoculum for feasibility and bench-scale testing.

Phase I Feasibility Testing

The process flow diagram for the feasibility testing is shown in Figure 2. The feasibility setup consisted of a two-stage, up-flow, fixed bed EBR system. The tests were conducted under continuous flow conditions, i.e., the water was treated 24 hours per day, seven days per week. The system was operated using a total hydraulic retention time (HRT) of 44 hours. The bioreactors were provided with laboratory-grade nutrients (tryptic soy broth) rich in macro- and micro-elements. The long HRT and laboratory-grade nutrients were chosen to ensure that no limiting conditions (e.g., nutrient-limited) occurred that could affect the proof-of-concept testing.

The column tests were conducted continuously for two months for process assessment and validation testing. The goal of validation testing was to generate sufficient compliance data (i.e., nitrate, arsenic, and uranium concentrations in the treatment effluent below desired levels). The system initially treated leach waters pumped twice through the Coffee Gold spent ore columns. However, since uranium concentrations have decreased after the second pass through the spent ore columns, it was decided to treat first pass leach solutions instead.

Prior to the biological EBR treatment, cyanide destruction in the leachate solutions was performed using hydrogen peroxide treatment; nitrate-N was readjusted to at least 150 mg/L, and pH of the water was dropped to about 6.5.

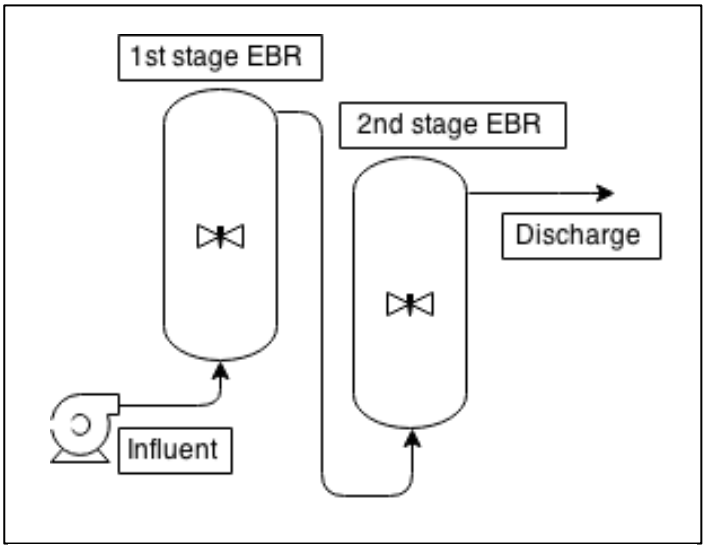

Figure 2. Process flow diagram of the Phase I feasibility test system.

Phase I In-Situ Feasibility Testing

Two 100-kg test columns were constructed, each containing three lithologies and two weathering zones of mined materials that represent thoroughly mixed Coffee Gold leach pad materials in the following percentages: 80% Supremo, 18% Latte, and 2% Kona. The columns went through a series of conditioning steps to ensure the effluent water chemistries from both columns were similar. One of the constructed columns was used as a test column; the other one was used as a control (baseline) column. The in-situ testing progressed in two testing stages:

1. Application of the EBR effluent spiked with 150 mg/L nitrate-N at a flowrate of 1L per day. The in-situ column influent was supplemented with nutrients, while the control column influent was filtered to remove microbial cells and residual nutrients. The process flow diagram is shown in Figure 3.
2. Application of DI water spiked with 150 mg/L nitrate-N at a flowrate of 1L per day. The in-situ column influent was supplemented with nutrients, but the control column was not. The process flow diagram is shown in Figure 4.

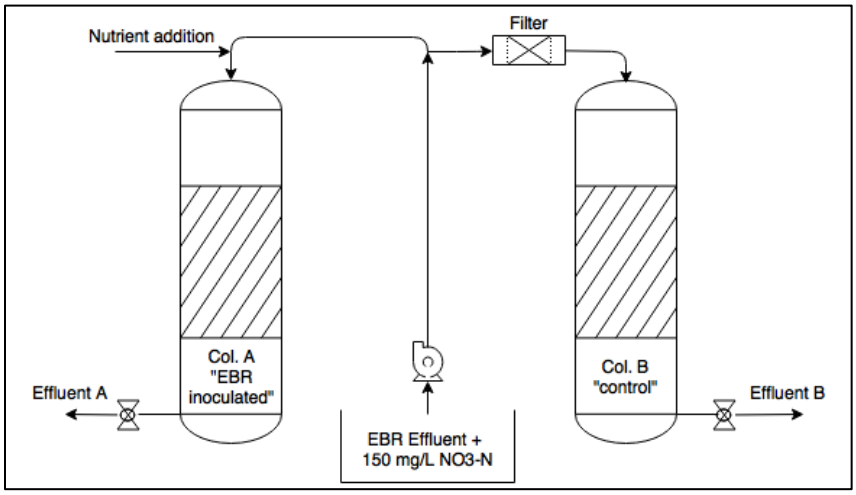

Figure 3. Process flow diagram of a Phase I feasibility in-situ testing; test stage #1.

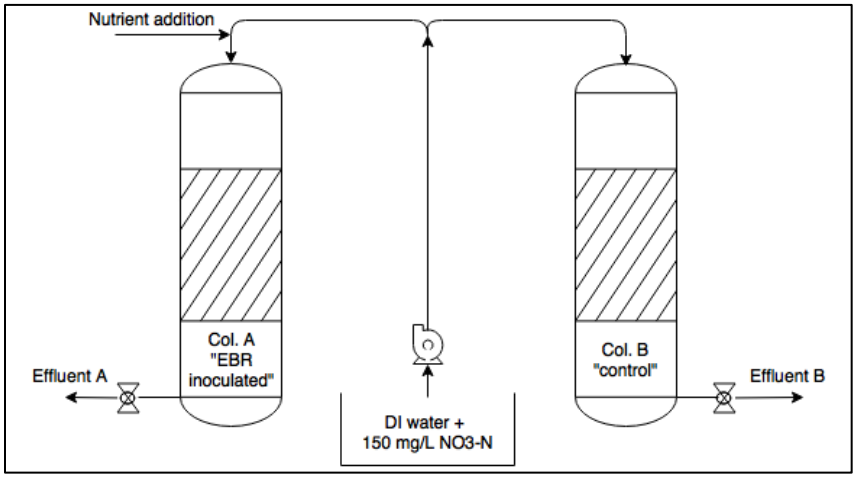

Figure 4. Process flow diagram of a Phase I feasibility in-situ testing; test stage #2.

Phase II Bench-Scale Testing

Leach and rinse waters were generated by Kappes, Cassiday & Associates at their metallurgical laboratory in Reno, NV, and shipped to WesTech. The process flow diagram for the bench-scale setup is shown in Figure 5. The required pretreatments included cyanide destruction and pH adjustment; both were performed as batch treatments. Two treatment trains were evaluated concurrently as a core treatment. In system A, chemical precipitation methods (ferric coagulation for arsenic removal and barium precipitation of sulfate) were tested in conjunction with a two-stage EBR system for denitrification, uranium reduction, and metals polishing. System B targeted all contaminants with the EBR treatment alone. Following the core treatments, aerobic post-treatments were tested for the removal of residual nutrients.

Both treatment trains utilized up-flow, fixed bed EBR bioreactors. Each EBR column was equipped with sampling ports halfway up the column and at the effluent point. The tests were conducted under continuous flow conditions, and the systems were initially operated using a 24-hr HRT per reactor, with samples collected from sampling ports correlating to 12-hr HRT intervals. The bench-scale EBRs had an empty bed volume of 1,610 mL (per reactor). The activated carbon used to fill the columns had a pore space of 42%.

The photograph in Figure 6 shows the bench-scale setup for treatment train A. Not pictured are the chemical pretreatments that were performed in batches. The system was initially designed to use only one pump and gravity flow between the reactor stages (as can be still seen in Figure 6 from the differences in elevation between the test columns). However, since large sample volumes were required for the routine internal and external analyses, and the forward flow was only 1.0 - 1.5 mL/min, an intermediary sample storage jug was placed between the reactor stages and a second pump was installed.

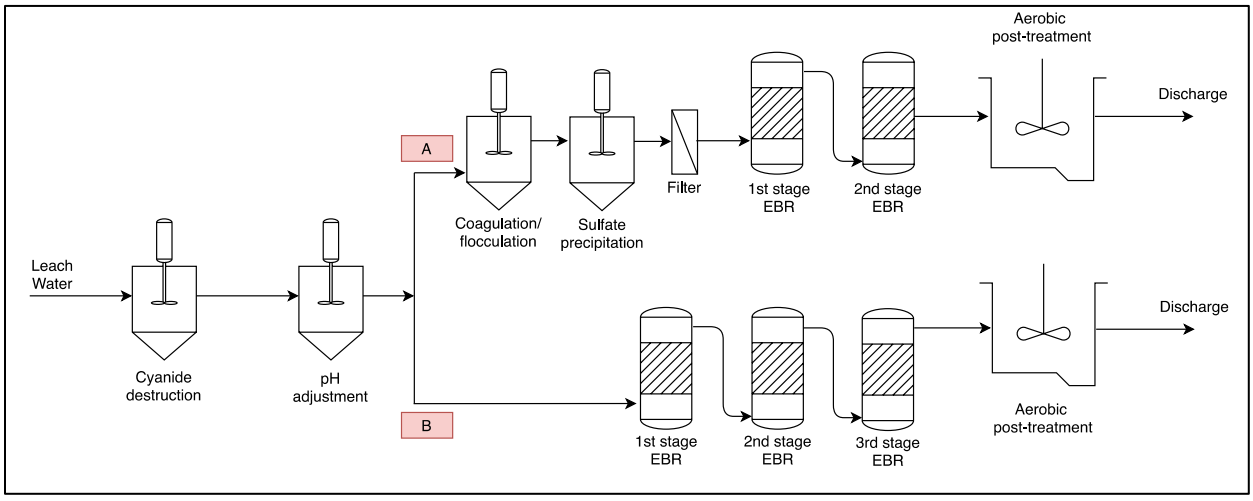

Figure 5. Process flow diagram of the Phase II bench-scale Coffee treatment systems.

Figure 6. Phase II bench-scale setup of treatment train A.

SAMPLING AND ANALYSIS

Feasibility Testing

Daily in-house measurements included flowrate, pH, ORP, DO, temperature, nutrient addition, conductivity, and nitrate-N. Influent and EBR effluent samples were collected in 5-day intervals and sent out to ALS Analytical Laboratories in Vancouver, Canada, for a complete suite analysis (Table 3).

Table 3. Analytes and analytical methods used in the EBR bench-scale tests.

Analyte	Method	Method Number
Hardness	EDTA Titration	APHA 2340B
pH	Automated pH meter	APHA 4500-H pH Value
TDS	Gravimetric	APHA 2540 C
Alkalinity	Titration	APHA 2320 Alkalinity
Bromide	Ion Chromatography (IC)	EPA 300.1
Chloride	Ion Chromatography (IC)	EPA 300.1
Fluoride	Ion Chromatography (IC)	EPA 300.1

Analyte	Method	Method Number
Total Nitrogen	Colorimetric	APHA Method 4500-P (J) / NEMI 5735
Ammonia-Nitrogen	Fluorescence	J. ENVIRON. MONIT., 2005
Nitrite-Nitrogen	Ion Chromatography (IC)	EPA 300.1
Nitrate-Nitrogen	Ion Chromatography (IC)	EPA 300.1
Total Phosphorus	Colorimetric	APHA 4500-P Phosphorus
Orthophosphate	Colorimetric	APHA 4500-P Phosphorus
Sulfate	Ion Chromatography (IC)	EPA 300.1
Total Cyanide	Continuous Flow Analyzer (CFA)	ISO 14403:2002
WAD Cyanide	Continuous Flow Analyzer (CFA)	APHA 4500-CN CYANIDE
Total Metals	Collision/Reaction Cell – Inductively Coupled Plasma (CRC-ICP)	EPA 200.2/6020A
Total Mercury	Cold Vapor Atomic Absorption Spectrophotometry (CVAAS)	EPA 1631E

Bench-Scale Testing

Sampling locations are marked in Figure 7. For process assessment, raw waters, pretreated waters, EBR sampling locations, and post-treatment were analyzed. The in-house analysis included pH, ORP, DO, conductivity, temperature, nitrate, nitrite, sulfate, and COD. These measurements were taken three times a week. Routine metals analyses were performed by a certified independent analytical laboratory, American West Analytical Labs (AWAL) in Salt Lake City, UT, using Ion-Coupled Plasma/Mass-Spec (ICP-MS), method EPA 200.8. In addition to these frequently monitored parameters, a chemistry suite analysis was performed on system influents and effluents once per month by AWAL. Samples for arsenic and selenium speciation were submitted once per month to Brooks Applied Labs in Bothell, WA. Upon completion of testing, the system was taken apart, and any accumulated or generated solids, including the activated carbon media, were sampled and sent to AWAL for TCLP analysis and Pace Analytical Laboratories for rad-chemistry analysis.

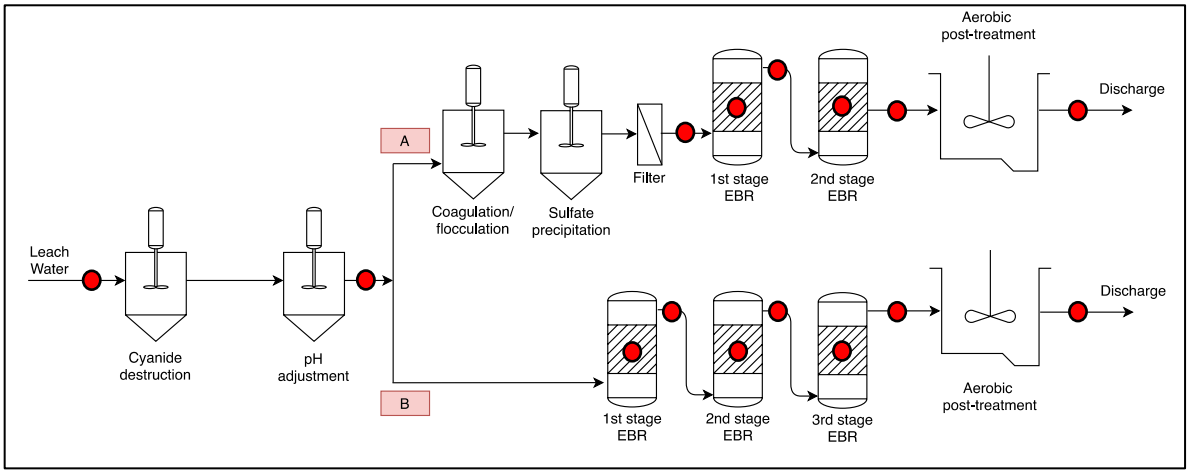

Figure 7. Phase II bench-scale sampling locations.

Data Analysis, Interpretation, and Quality Control

The influent and effluent nitrate, sulfate, uranium, and arsenic concentrations were measured, which allowed the calculation of percent removals and treatment efficiencies. A 30-day continuous operation was required to demonstrate the repeatability of results and reliability of the treatment process. Taking measurements at different sampling points (corresponding to different retention times) determined the removal kinetics.

Quality control was performed on all analyses. As part of the internal quality control testing, AWAL Laboratories performed method blanks (MB), laboratory control samples (LCS), matrix spikes (MS), and matrix spike duplicates (MSD) on the submitted samples. The recoveries of the spiked analyte are evaluated to determine the accuracy in a given matrix, while the comparison between the MS and MSD shows how precise the procedure is in a given matrix.

RESULTS

PHASE I FEASIBILITY RESULTS

Chemistry and Treatability Assessment

The leachate solution chemistry treated by the feasibility test system is shown in Table 4. Nitrate-N (105 mg/L) and uranium (144 µg/L) concentrations were within the biological treatability range. Arsenic levels of 1.1 mg/L were at the upper limit of biological treatability. Compounds that often compete with nitrate, arsenic, and uranium for electrons during biotreatments, e.g., nitrite, and other metal oxyanions, such as selenate or chromate, were not present at concentrations that would impact the biological treatment performance.

Inorganic parameters that often have an inhibitory effect on microbial metabolism, such as chlorides, were present at low levels. Total and WAD cyanides were elevated and needed to be destroyed prior to the biological treatment. Due to the nature of the spent ore, the generated leach solutions had pH of about 8.7 and needed to be adjusted to 6.5 for optimal denitrification and As/U removal.

Water chemistry assessment strongly suggested that the biological treatment would be effective at removing the contaminants of concern. Additionally, the EBR technology also reduced the concentration of some other metals, such as aluminum, antimony, cadmium, chromium, copper, mercury, molybdenum, nickel, and tin.

Microbial Screening and Assessment Results

Nitrate-, arsenic-, and uranium-reducing microorganisms were isolated from the Coffee Gold waters and spent ore materials received and screened with WesTech's repository strains to examine their bioremediation potential in the site waters at 5°C and 20°C. The microbial screening is used to 1) determine whether a given contaminant is easy or difficult to remove in given water chemistry using the EBR technology; 2) identify a best performing microbial population in the given water chemistry (contaminant transformation, temperature dependence, performance robustness); 3) select an adjusted/enhanced microbial consortium that is the most compatible with the unadjusted native population; and 4) condition the selected microbial consortia for optimal biological performance.

With an evaluation of the obtained wastewater chemistry, good positive denitrification and microbial arsenic/uranium reduction screening results were obtained. Selected microbes were further screened, conditioned, and characterized to develop the inocula for the feasibility tests. From the various consortia tested in the Coffee Gold waters, the best inoculum was selected based on:

- Nitrate/As/U reduction potential at low and high temperatures.
- Robustness in the Coffee Gold waters at low and high temperatures.
- Compatibility with indigenous microbes present in the Coffee Gold waters.
- The ability to maintain an integrated biofilm with desired contaminant removal characteristics.

Table 4. Water chemistry of Coffee Gold leach solutions used during feasibility testing.

Parameter	Concentration
Metals	
Aluminum	1.5 mg/L
Antimony	30.8 µg/L
Arsenic	1.1 mg/L
Barium	70.5 µg/L
Cadmium	3.7 µg/L
Calcium	37.5 mg/L
Chromium	10.3 µg/L
Cobalt	239 µg/L
Copper	0.5 mg/L
Iron	0.5 mg/L
Lead	1.1 µg/L
Magnesium	5.9 mg/L
Manganese	32 µg/L
Mercury	3.7 µg/L
Molybdenum	75 µg/L
Nickel	118 µg/L
Potassium	83 mg/L
Selenium	2.1 µg/L
Silver	5.2 µg/L
Sodium	234 mg/L
Strontium	186 µg/L
Thallium	0.88 µg/L
Tin	7.7 µg/L
Titanium	9.3 µg/L
Uranium	144 µg/L
Vanadium	1.2 µg/L
Zinc	187 µg/L
Inorganics	
pH	8.7
Hardness, Total (as $CaCO_3$)	118 mg/L
Alkalinity, Total (as $CaCO_3$)	188 mg/L
Ammonia as N	13 mg/L
Chloride	6.8 mg/L
Fluoride	0.35 mg/L
Cyanide, Total	24 mg/L
Cyanide, WAD	25 mg/L
Nitrate as N	105 mg/L
Nitrite as N	0.3 mg/L
Total N	130 mg/L
Sulfate	160 mg/L
Dissolved Orthophosphate	0.13 mg/L

Feasibility Treatment of Contaminants of Interest

The feasibility testing validated the biological treatment for the removal of nitrate, arsenic, and uranium from Coffee Gold heap leach rinse waters. Figure 8 and Figure 9 show the reduction of nitrate-N and nitrite-N by the feasibility test system. Nitrate-N concentrations were spiked to a minimum of 150 mg/L in the influent waters and averaged 188 mg/L during the 2-month test period. **The feasibility EBR system consistently removed both nitrate-N and nitrite-N to below detection limits** (0.19 mg/L and 0.04 mg/L, respectively).

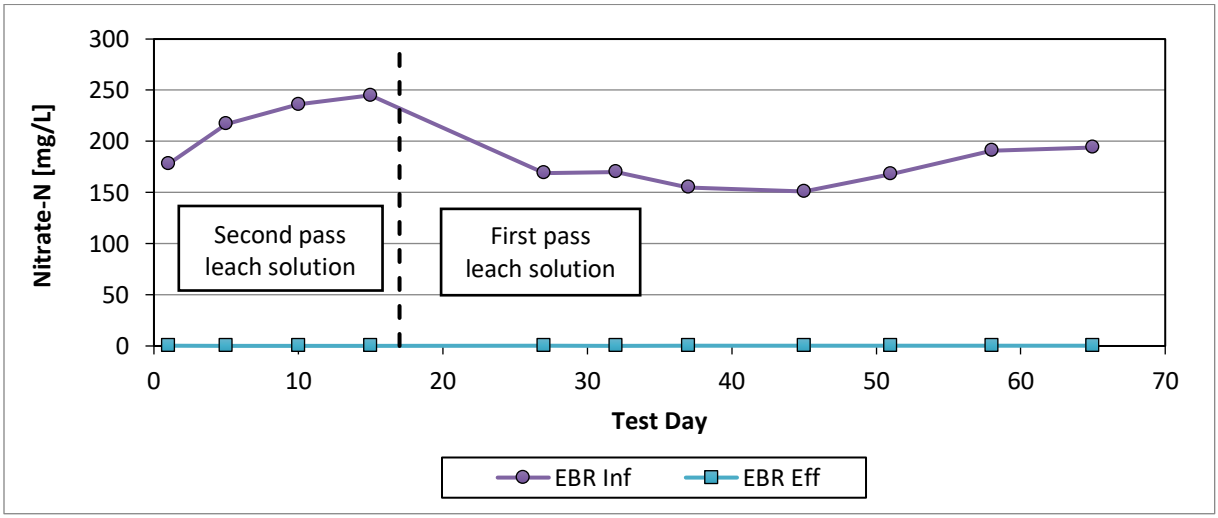

Figure 8. Phase I feasibility EBR nitrate-N removal from Coffee Gold leach waters. The dashed vertical line corresponds to the day when the EBR system influent was changed from leach waters pumped through the spent ore columns twice to the leach waters that were pumped through the spent ore columns once.

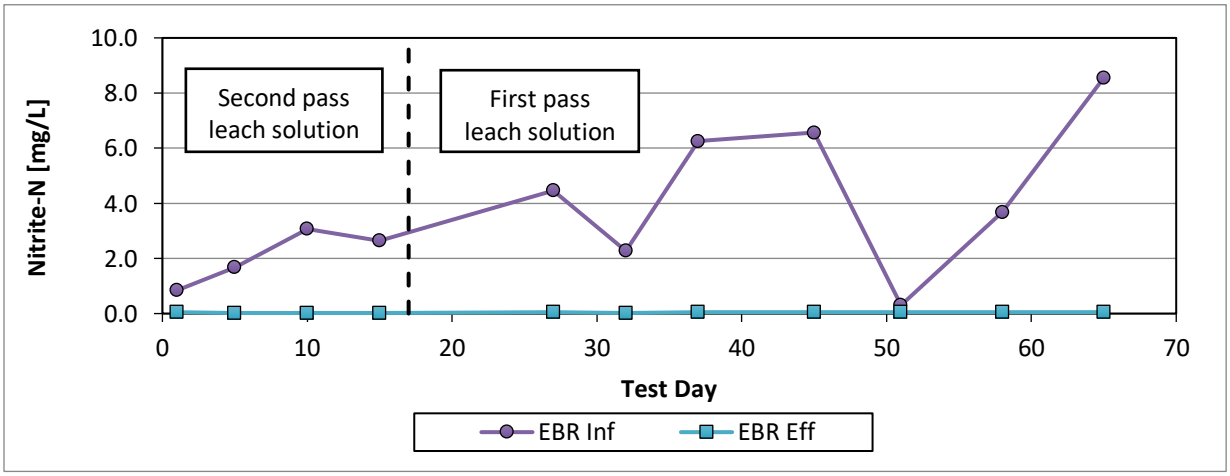

Figure 9. Phase I feasibility EBR nitrite-N removal from Coffee Gold leach waters. The dashed vertical line corresponds to the day when the EBR system influent was changed from leach waters pumped through the spent ore columns twice to the leach waters that were pumped through the spent ore columns once.

Arsenic removal for the initial two weeks averaged 60% (Figure 10). Process and bioreactor operation were adjusted to improve the EBR performance. **After system modifications were implemented, arsenic removal increased to an average of 98.8%.** Total arsenic was removed from the average of 1,113 µg/L in the leach waters to an average of 12.9 µg/L in the EBR system effluent.

Uranium removal averaged 99.1%, with the EBR system effluent concentrations averaging 0.8 µg/L (Figure 11). Influent uranium levels varied between 34 µg/L and 154 µg/L, with the average concentrations of 92.5 µg/L. Table 5 summarizes the feasibility performance.

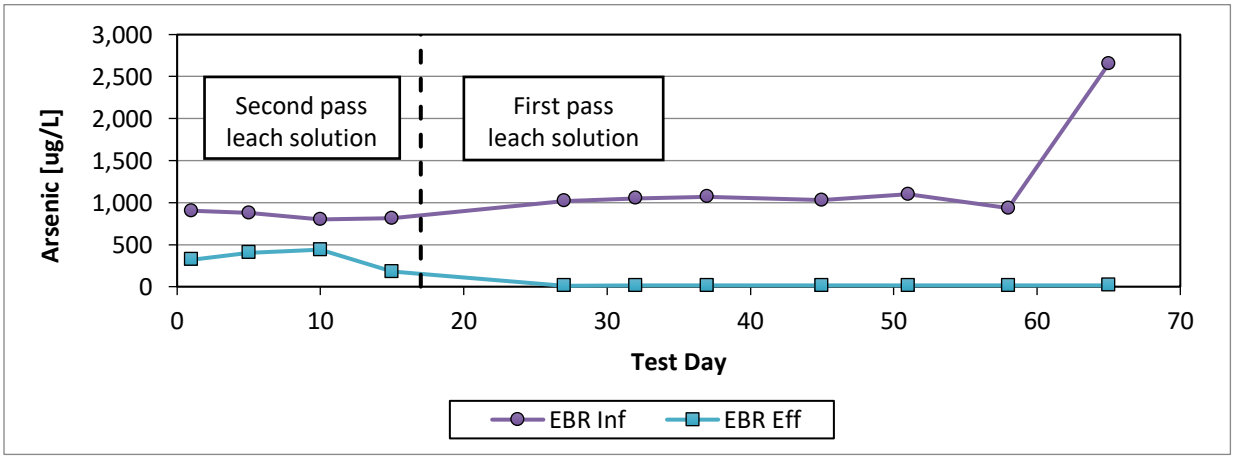

Figure 10. Phase I feasibility EBR arsenic removal from Coffee Gold leach waters. The dashed vertical line corresponds to the day when the EBR system influent was changed from leach waters pumped through the spent ore columns twice to the leach waters that were pumped through the spent ore columns once.

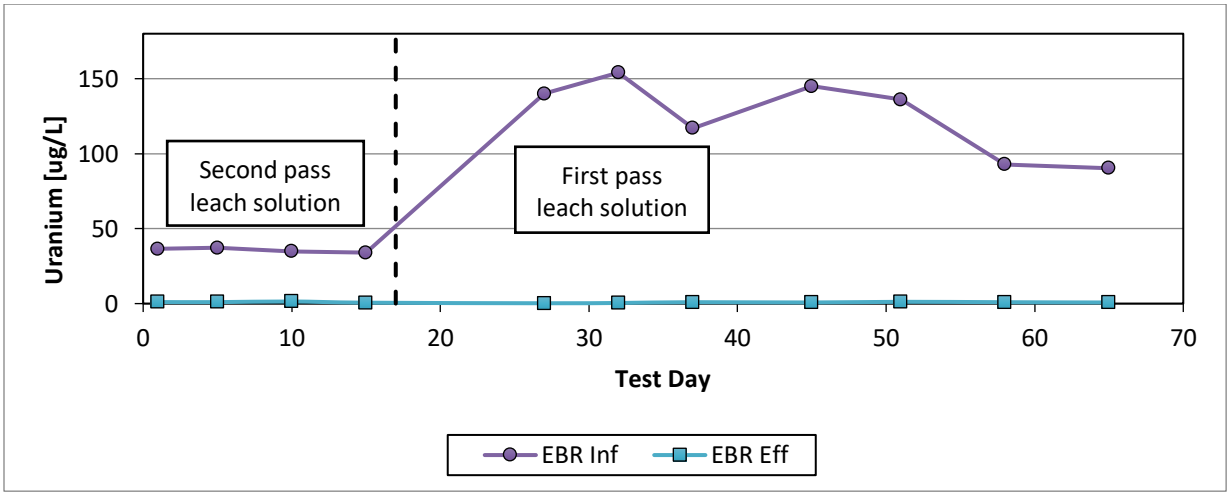

Figure 11. Phase I feasibility EBR uranium removal from Coffee Gold leach waters. The dashed vertical line corresponds to the day when the EBR system influent was changed from leach waters pumped through the spent ore columns twice to the leach waters that were pumped through the spent ore columns once.

Table 5. Average Phase I feasibility treatment performance.

Parameter	Average Influent	Average Effluent	% Removal
Nitrate-N [mg/L]	188	< 0.19	> 99.9%
Nitrite-N [mg/L]	3.7	< 0.04	> 98.9%
As [µg/L]	1,113	12.9*	98.8%
U [µg/L]	92.5	0.8	99.1%
Al [µg/L]	737	< 35.8	> 95.1%
Sb [µg/L]	33.2	< 0.35	> 98.9%
Cd [µg/L]	1.3	< 0.02	> 98.5%
Cr [µg/L]	10.7	< 0.66	> 93.8%
Co [µg/L]	269	122	54.6%
Cu [µg/L]	267	< 2.4	> 99.1%
Fe [µg/L]	2.2	0.23	89.5%
Pb [µg/L]	1.9	< 0.17	> 91.0%
Hg [µg/L]	1.6	0.03	98.1%
Mo [µg/L]	59.5	< 6.9	> 88.4%
Ni [µg/L]	75.1	< 2.3	> 96.9%
Se [µg/L]	2.9	1.2	58.6%
Ag [µg/L]	3.9	< 0.06	> 98.5%
Tl [µg/L]	0.8	< 0.03	> 96.2%
Sn [µg/L]	32.5	0.8	97.5%
Zn [µg/L]	76.1	38.1	49.9%

NA – not applicable

Feasibility Treatment of Other Contaminants and By-Product Formation

Besides arsenic and uranium, the feasibility test system removed other metals to various degrees (Table 5). **Over 90% average removal efficiencies were achieved for Al, Sb, Cd, Cr, Cu, Pb, Hg, Ni, Sn, Ag, and Tl.** Total and WAD cyanide were still present in the leach waters after cyanide destruction with peroxide, albeit at much lower concentrations (0.48 mg/L and 0.03 mg/L, respectively). The EBR system degraded WAD cyanide to below the detection limit of 0.007 mg/L and total cyanide to average levels of 0.16 mg/L (Table 5).

As expected in this preliminary treatability evaluation, nutrient levels (e.g., ammonia-N and orthophosphate) were elevated in the test system effluent. The scope of work for the feasibility phase was focused on the initial validation of the biological process for removal of contaminants of interest (i.e., proof-of-concept) and not on process optimization. In field applications, minimum nutrient additions to the biological system are established and balanced, often resulting in minimal (if any) increases in residual nutrients in the system effluent. However, if ultra-low levels of ammonia or BOD are required in the system effluent, a conventional aerobic bioreactor polishing step can be used. Aerobic bioreactors are a well-established technology for nutrient removal from municipal wastewaters, where they have been successfully implemented for over a century. Phase II bench-scale testing will investigate the optimal nutrient composition and dosage to more accurately define what levels of residual nutrients can be expected in the full-scale plant effluent.

Feasibility of In-Situ Denitrification

Table 6 summarizes average nitrate-N concentrations during two in-situ testing phases. Figure 12 shows the results of in-situ denitrification in the Coffee Gold spent ore materials.

For the initial three weeks of operation, both columns were irrigated with 1 L/day of the EBR effluent spiked with about 150 mg/L nitrate-N; the influent to the control column was filtered before it was applied to the top of the column. During test stage 1, the average in situ test column effluent contained 13.9 mg/L NO_3-N, while the average control column effluent was 103 mg/L NO_3-N. It should be noted that nitrate-N concentrations in the control column decreased with time to about 50 mg/L, which can be explained by the fact that the EBR effluent applied to the top of this column, although filtered, still contained excess nutrients in the form of organic carbon, nitrogen, and phosphorus, that allowed the native denitrifying population to carry out partial denitrification.

For the following four weeks, both columns were irrigated with 1 L/day of deionized (DI) water spiked with about 150 mg/L nitrate-N. The in-situ test column was provided with the required nutrients daily. During test stage 2, the average in-situ test column effluent contained 26.4 mg/L NO_3-N, while the average control column effluent was 146 mg/L NO_3-N. The negligible nitrate removal in the control column as compared to the in-situ column demonstrated the effectiveness of in-situ denitrification.

The feasibility testing proved the in-situ treatment to be a feasible approach to controlling nitrates within the heap environment. Lowering the nitrate concentrations in the heap leach rinse solutions in-situ would significantly impact the size, capital cost, and operating expenditures of the active water treatment system.

Table 6. Average Phase I feasibility in-situ denitrification performance.

	Control	In Situ	Control	In Situ
	EBR Effluent + 150 mg/L NO_3-N		DI Water + 150 mg/L NO_3-N	
NO_3-N [mg/L]	103	13.9	146	26.4

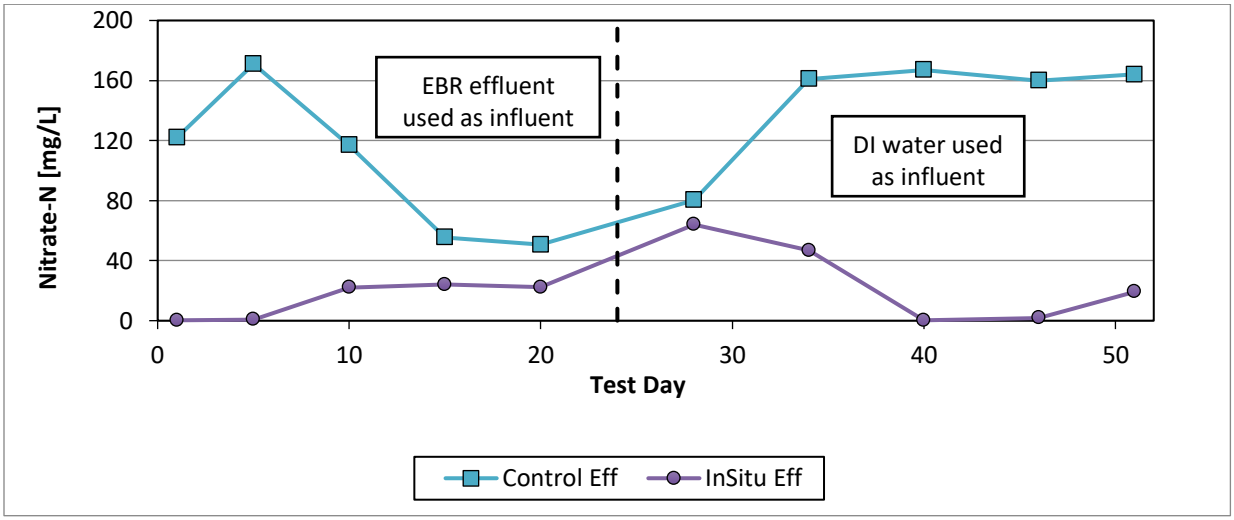

Figure 12. Phase I feasibility in-situ denitrification from Coffee Gold spent ore and water. The dashed vertical line corresponds to the day when the column influent was switched from the EBR effluent to deionized water.

PHASE I FEASIBILITY CONSULTATIONS, FEEDBACK, AND INFORMATION REQUESTS

The feasibility testing concluded with a final report submitted to Newmont (then Goldcorp) in August 2016. Following the report submittal, Newmont elicited feedback from the stakeholders, most notably the First Nations and their representatives (Tr'ondek Hwech'in and Source Environmental Associates) in 2017, as well as the Canadian and local regulatory agencies through the YESAB review process in 2018. Several technical meetings and workshops were held for consultations. WesTech participated in the meetings to provide clarifications and adjust the planned Phase II testwork based on the feedback. Table 7 lists the feedback and action items identified through the process.

Table 7. Feedback and information requests, obtained through consultations with the stakeholders.

Requested by/ Reference	Issue and Rationale	Feedback and Information Request	Solution & Action Item
Source Environmental Associates/ Tr'ondek Hwech'in, Technical Memorandum, 06/2017	Will the Heap Leach Facility pose a concern for long-term water quality downstream of the proposed project? Are water treatment plans for the active closure phase and the post-closure phase sufficient?	The information provided is not adequate to assess the short-term and long-term water quality associated with the Heap Leach Facility. Additional information is required. The descriptions of the active and passive treatment design plans in the submission are not sufficient for EA-level review.	Phase I Feasibility was a "proof-of-concept" test focused on establishing whether or not the waters can be treated and on identifying suitable treatment options. Phase II testing will define the required treatment train in more detail.

Source Environmental Associates/ Tr'ondek Hwech'in, Technical Memorandum, 06/2017	Residual Ammonia and Ortho-phosphate across Active Treatment. Appendix A of the EBR feasibility report shows the change in concentrations of a variety of constituents across the system.	What level of residual orthophosphate and ammonia could be expected in the EBR effluent after nutrient dosage has been optimized?	The goal of Phase I Feasibility testing was not to evaluate the nutrient requirements, and thus, a laboratory-grade nutrient was used. It ensured that nutrient limitations would not affect the evaluated treatment approach. Data from other testing were shared to show what residual nutrient levels were generated in the past by the EBR system. Phase II testing will use commercial-grade nutrients and will optimize nutrient addition to demonstrate what residual nutrient levels can be expected from a full-scale treatment system at the Coffee Mine.
Source Environmental Associates/ Tr'ondek Hwech'in, Technical Memorandum, 06/2017	Active Treatment Residue Characterization and Management. The EBR system is a biological system and so biosolids waste residue will be generated. No information on the characterization and handling of this waste is presented in the documentation.	Elaborate on the residue characterization, geochemical stability, disposal/handling plan, and long-term management plan.	The preliminary residue characterization will be performed in the form of TCLP testing of the reactor's support media upon the completion of Phase II testing. On-site Phase II pilot-scale demonstration testing will define the volume and inform a long-term management plan.
Source Environmental Associates/ Tr'ondek Hwech'in, Technical Memorandum, 06/2017	Active Treatment Adaptability. Three things must be achieved for the water treatment to be a success - denitrification with no residual ammonia/other	The level of nitrate in the plant feed will decrease over time as CN is washed out of the HLF as there is a finite load of N on site. On the other hand, As and U will persist on a longer time scale. As such, it is likely that later in the	From the ORP-ladder perspective, uranium bioreduction occurs at similar if not more energetically favorable ORP ranges than denitrification. The process will be staged, and the denitrification reactor-stage will never be driven to low

	nutrients, metal reduction, and conversion of sufficient sulphate to sulphide to precipitate metals without leaving residual sulphide in solution.	project, the influent concentration of NO3 will be low while influent As and U will be high. Can the EBR system effectively achieve the three goals described with only a single lever of control, ORP?	enough ORPs to generate ammonia. After cyanides/nitrates are washed out from the HLF, the redundant denitrification reactors can either be taken offline, adapted to treat more volume for uranium removal, or used for other metals polishing. Phase II bench-scale testing will also evaluate alternative treatment options for Arsenic removal.
Source Environmental Associates/ Tr'ondek Hwech'in, Technical Memorandum, 06/2017	Residual Chloride from Active Treatment. Appendix A of the EBR feasibility report shows an increase in chloride.	Why is chloride being added across the circuit? Can this addition be mitigated in some way? Is there a minimum level of chloride that must be present for the EBR system to be effective?	Chlorides are not required for the bioreactors and were a byproduct of a laboratory-grade nutrient mixture used. The goal of Phase I Feasibility testing was not to evaluate the nutrient requirements, and thus, a laboratory-grade nutrient was used. It ensured that nutrient limitations would not affect the evaluated treatment approach, but it resulted in increases in parameters, such as chlorides, that will not be present in commercial-grade nutrients. Phase II bench-scale testing will use commercial-grade nutrients to demonstrate that no chloride increases are expected from the full-scale facility.
Source Environmental Associates/ Tr'ondek Hwech'in, Technical Memorandum, 06/2017	Sulphur Deportment across Active Treatment. Appendix A of the EBR feasibility report shows sulphate removal of 100-150 mg/L across the system	What is the form of the sulphur removed from the system using the SBR?	Sulfur undergoes a number of biochemical transformations within the bioreactor, depending on the treatment conditions, with hydrogen sulfide gas generation as the most dominant pathway. Phase II bench-scale testing will evaluate two options for

	and simultaneous generation of 3-4 mg/L of sulphide. Given that only trace levels of metals are removed by the system, there is a gap between the influent and effluent total sulphur.		sulfate removal: 1) EBR treatment with expected H_2S gas generation, and 2) chemical precipitation pre-treatment.
Source Environmental Associates/ Tr'ondek Hwech'in, Technical Memorandum, 06/2017	Bioavailability of Metals across Active Treatment. The bioavailability of dissolved metals can be enhanced through contact with reductive biological treatment systems which generate species such as methylated arsenic species. These organic-metal complexes can be significantly more bioavailable than their inorganic counterparts.	Has Inotec analyzed the speciation of residual metal that is not removed through the EBR for this project or any others? Particularly arsenic, as this is a key constituent of concern in the project.	Arsenic and selenium speciation will be included in the Phase II bench-scale testing analytical plan. Methylated arsenic species have never been observed in our past testing.
Environmental Associates/ Tr'ondek Hwech'in, Technical Memorandum, 06/2017	Deportment of Cyanide Residue across Active Treatment. Oxidative treatment of cyanide can lead to the formation of cyanate, and reductive treatment of cyanide and cyanide degradation products can lead to formation of thiocyanate.	How do cyanate/thiocyanate behave in the EBR system? Are either removed/generated in the process? Given the amount of sulphate reduction occurring in the system (see previous point about sulphur deportment), the formation of thiocyanate may be occurring simultaneously.	Thiocyanate analysis will be included in the Phase II bench-scale testing analytical plan.

Environmental Associates/ Tr'ondek Hwech'in, Technical Memorandum, 06/2017	Active Treatment Startup/Shutdown. The EBR system is a biological system that is to be run seasonally for 6 months of the year. The startup/shutdown of biological processes can be lengthy.	How long is the startup period before the EBR is system is generating effluent meeting discharge targets? Does plant shutdown have an impact on effluent discharge quality?	Generally, the EBR system has been shown to require 5-14 days to reach steady-state during the initial start-up of a new facility and less than an hour to 7 days after long-term shutdowns. Shutdowns are not expected to have an impact on the effluent discharge quality
Environmental Associates/ Tr'ondek Hwech'in, Technical Memorandum, 06/2017	Active Treatment Variability with Flow. The rate of EBR treatment is expected to vary between 4 and 10 L/s. The Inotec document describes a 44h hydraulic retention time (HRT) in the system.	How sensitive to HRT is the discharge quality of the plant? Will performance change if HRT varies because there is excess water on site (or not enough)? If this risk is significant, is a surge pond available to modulate variability in water availability?	Phase I Feasibility was a "proof-of-concept" test focused on establishing whether or not the waters can be treated and on identifying suitable treatment options. The HRTs used were far from optimized and were long enough as not to affect the treatment efficacy. Phase II bench-scale testing will optimize the HRT range, which we expect to be several times shorter. Based on the variable flow expectations, an equilibration basin or tank is expected to be required for a full-scale facility.
Environment and Climate Change Canada – YESAB, 02/2018	The Proponent states that for heap leach solutions only, cyanide destruction followed by an Electrochemical Biological Reactor (EBR) will be employed to treat water to discharge quality. EBRs have not typically been proposed nor used for Yukon projects and their suitability	Clarify whether the proposed water treatment system has been tested (bench-scale) using a synthesized heap leach solution (of the characteristics expected for this project) to proof of concept level and its applicability in a Northern context. If this has yet to be demonstrated, provide clarification whether the Proponent is planning on conducting bench-scale	The proposed phased testing approach includes feasibility (proof-of-concept) testing and bench-scale testing on heap leach solutions generated from the Coffee Project ore materials. The on-site pilot-scale demonstration will be conducted as a final step of a full-scale water treatment design. The phased testing and process development approach minimizes the risks associated with technology

	/ performance in a Northern context remains uncertain. It is not clear what testing has been conducted to suggest suitability for this aspect of the project in particular.	testing as part of the water treatment system finalization, as well as characterizing the resulting effluent prior to implementation.	selection and treatment implementation.
Environment and Climate Change Canada – YESAB, 02/2018	Elevated uranium concentrations in both groundwater quality and surface water quality baseline have been identified. Radium 226 (Ra226) is a daughter isotope resulting from the radioactive disintegration series (decay) of uranium. Given that uranium is a parameter of concern and has been shown to be present and in exceedance as per the above-mentioned, it is not without reason to assume that Ra226 concentrations may end up in the receiving environment throughout the life of the project.	Ra226 is a deleterious substance as set out in Schedule 4 of the MMER. Predictions for Ra226 have been generated by the water quality model for pit lakes and settling ponds. Demonstrate that a non-acutely toxic effluent as required by the MMER will be met throughout the life of the project (i.e. construction, operation, and closure).	Radium-226, as well as other radiochemistry parameters, will be included in the Phase II bench-scale testing analytical plan.
BQE and Source Environmental Associates/ Tr'ondek Hwech'in,	The test work for the biological treatment proposed (EBR) shows a very significant increase in phosphate,	The Inotec EBR work plan authored Oct 30, 2017 included an objective in Phase 2 of determining the optimal dosage of nutrients to minimize	The goal of Phase I Feasibility testing was not to evaluate the nutrient requirements, and thus, a laboratory-grade nutrient was used. It ensured that nutrient limitations

Technical Memorandum, Coffee Gold Upcoming Water Treatment Workshop Discussion, 05/2018	ammonia and chloride across the treatment system. These increases are not accounted for in the WQ model. These will be ecologically significant because of the low nutrient levels in northern water courses. The increase in chloride across the system is relevant both because of the direct toxicity of salinity on freshwater species and the corrosive impact for metal release in the rock drain.	residual nutrients in the effluent. Phase 2 also includes development of an integrated treatment train include pre-treatment (ex. cyanide destruction) and post-treatment (nutrient polishing). The minimum residual nutrient levels in EBR effluent while still reaching nitrate/arsenic/uranium levels can be assessed. Following this, the requirement of nutrient polishing systems can be evaluated and supported through testing or other reference sites.	would not affect the evaluated treatment approach, but it resulted in increases in parameters, such as chlorides, that will not be present in commercial-grade nutrients. Phase II testing will use commercial-grade nutrients to demonstrate ammonia, phosphate, and chloride levels more representative of the proposed full-scale treatment system.
BQE and Source Environmental Associates/ Tr'ondek Hwech'in, Technical Memorandum, Coffee Gold Upcoming Water Treatment Workshop Discussion, 05/2018	The active water treatment system will produce some quantity of waste biomass and carbon, likely both as a periodic bleed from the system and during the final reclamation of the system after shutdown of the EBR. Plans for characterizing this material were not covered in the EBR workplan.	The upcoming Phase 2 EBR test work is a good opportunity to characterize waste and help inform disposal plans. TCLP is one option for characterization, but depending on residue disposal options that are on the table and the amount of material generated during Phase 2 testing, different characterization could be done.	TCLP analysis will be added to the Phase 2 test work, but the pilot test materials would provide better data as they would represent testing conducted with actual wastewaters. TCLP tests will be done on both sets of test materials.
BQE and Source Environmental Associates/ Tr'ondek Hwech'in,	Arsenic speciation in the feed	The Phase II work plan describes use of ferric coagulation to remove arsenic from water. Arsenic removal in this way will depend on	Arsenic speciation of the influent waters will be included in Phase II testing.

Technical Memorandum, Coffee Gold Upcoming Water Treatment Workshop Discussion, 05/2018		arsenic speciation – As(V) is more amenable to ferric than As(III). Arsenic in the HLF water may be more reduced (from the reductive conditions in the heap) or more oxidized (from use of peroxide to destroy cyanide upsteam of the EBR) or a mix of the two. Consideration of speciation in the test plan/analytics is recommended.	
BQE and Source Environmental Associates/ Tr'ondek Hwech'in, Technical Memorandum, Coffee Gold Upcoming Water Treatment Workshop Discussion, 05/2018	Organo-arsenic complexes in EBR effluent	The EBR systems involve biological activity and therefore have the potential to convert inorganic arsenic species to organic species. Organic arsenic species can be more bio-accumulative. It is recommended that arsenic speciation analysis be conducted on treatment effluent in future testing campaigns so as to better evaluate the impact of the project on biota in the receiving environment.	Arsenic speciation of the effluent waters will be included in Phase II testing.
BQE and Source Environmental Associates/ Tr'ondek Hwech'in, Technical Memorandum, Coffee Gold Upcoming Water Treatment Workshop Discussion, 05/2018	Cyanate formation potential	Cyanate is a likely byproduct of cyanide destruction with peroxide and so should be expected in the EBR feed. It is recommended that cyanate assay be incorporated into the Phase 2 laboratory program (in addition to the thiocyanate as was noted in the Oct 30, 2017 Phase 2 EBR workplan).	Thiocyanate analysis will be included in Phase II testing. Cyanate analysis is not available through the selected analytical laboratory. Cyanate will be added to the pilot-scale analytical plan.

PHASE II BENCH-SCALE TESTING RESULTS

Preliminary Assessments

The Obtained Leach Water Chemistry and Experimental Implications

The chemistry of the waters generated by Kappes, Cassiday & Associates in the leach testing differed from the water modeling performed by Lorax Environmental (Table 8), as was discussed by WesTech and Lorax when deciding how to best approach the needed chemistry adjustments. Limitations of an accelerated leaching procedure, as well as scaling issues of a small-scale leach column, likely contributed to the discrepancies.

Batches of the waters delivered to WesTech's laboratories were spiked with the parameters of concern (NO_3, SO_4, As, U, and Sb) to match the upper modeling predictions. These parameters are highlighted in blue in Table 8. Counter ions were chosen with a goal to balance the major ion chemistry and included Ca, Mg, Na, and Cl.

Certain other influent water chemistry parameters exceeded the predicted levels by up to several orders of magnitude (NH_3, alkalinity, Al, Ag, and Cu). They are highlighted in yellow in Table 8. Except for alkalinity, **these concentrations in the generated waters exceeded their respective treatment targets. Water chemistry was not adjusted to lower their concentrations.**

Table 8. Water chemistry comparison of the modeling predictions and the received solutions. Treatment targets are provided as a reference.

Parameter [mg/L]	HLF Rinse Modeling	Coffee Waters	Treatment Target

Chemistry Assessment

Evaluation of the chemistries suggested that most of the parameters of interest were well within the treatability range. A discussion of the treatability assessment and the identified potential issues are presented below.

Nitrate-N, uranium, and sulfate concentrations of 300 mg/L, 600 μg/L, and 2,500 mg/L, respectively, were within the biological treatability range. Inorganic parameters, such as chlorides and cyanides, which often have an inhibitory effect on microbial metabolism, were present at low levels. Additionally, the elevated alkalinity and presence of nitrates would benefit the biological treatment approach, maintaining an optimum pH of the system. No microbial inhibitory parameters were identified.

In terms of potential issues, as demonstrated in the Phase I feasibility testing, arsenic concentrations were present at the upper margin of biological treatability. What is more, the compounds that often compete for electrons during biotreatments, e.g., nitrate, nitrite, sulfate, and other metal oxyanions, such as arsenate, were present at elevated concentrations, complicating the treatment approach. Finally, from the system design perspective, due to the concentrations of sulfate, aluminum, calcium, and other water hardness parameters, bioreactor operation must be conducted within design specifications to prevent the potential for excessive precipitation formation. **The chemistry assessment concluded that, while treatable, the complexity of the Coffee waters presents a challenging scenario for full-scale system design based solely on biological treatment.**

Jar Testing

The generated waters contained only 0.5 mg/L total As. The solutions were spiked with sodium arsenite to reach the forecasted As levels of 2 mg/L. Arsenite is the less oxidized species of As, and it is more difficult to remove using ferric co-precipitation. **Arsenite was chosen for this testing as "the worst-case scenario" for chemical pretreatment.** The actual As speciation in the future Coffee waters is uncertain, but arsenate is generally a more prevalent species in mining environments.

Ferric co-precipitation tests demonstrated the impact of arsenic speciation on the performance (Figure 13). When no oxidizing agent was present, negligible arsenic removal was achieved. **Once arsenic was oxidized, ferric co-precipitation decreased As concentrations to at or below the treatment target.** Permanganate was used in the jar testing procedure as a strong oxidizer. Since the proposed treatment includes the destruction of cyanide by oxidation with hydrogen peroxide, it is expected that most of arsenic present will be converted to arsenate, rendering the ferric co-precipitation a suitable option for As pretreatment.

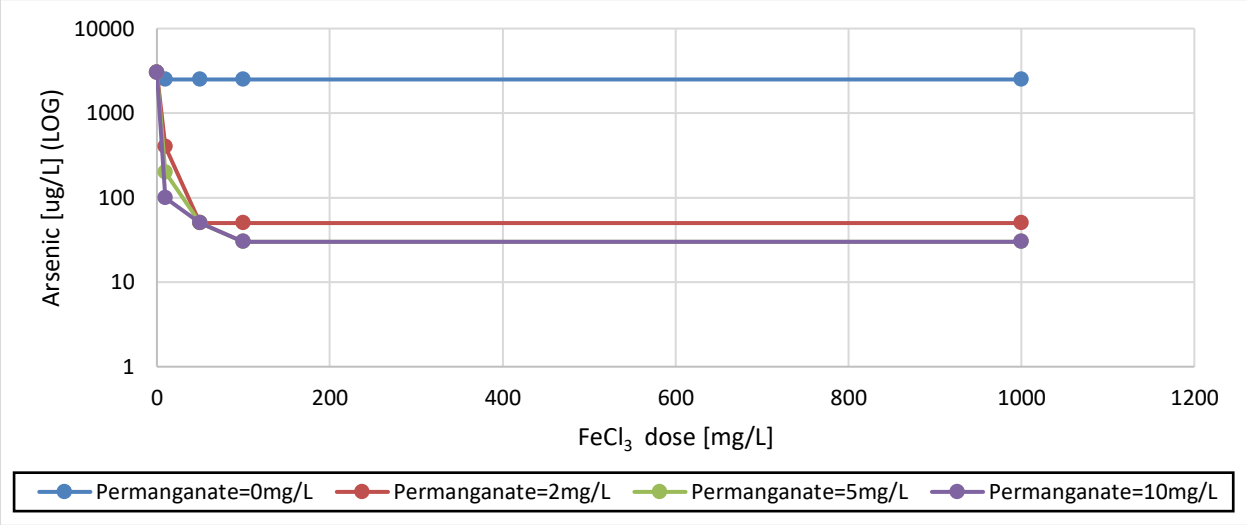

Figure 13. Arsenic ferric co-precipitation jar test results.

Sulfate is forecasted to be present at approximately 2,300-2,500 mg/L in Coffee Mine waters, which is a threshold of gypsum solubility. At such high concentrations, under specific conditions, a portion of sulfate might be expected to precipitate out of solution within the bioreactor – a scenario that should be avoided.

Sulfate precipitation pretreatment with barium salts (barium chloride and barium hydroxide) was investigated in the absence and presence of lime additions (Figure 14).

- **Treatment efficiency was shown to be directly proportional to the barium dose.**
- **Lime additions improved sulfate precipitation, but only at higher Ba doses. With the sulfate treatment target of 1,500 mg/L, lime addition was shown not to be needed.**

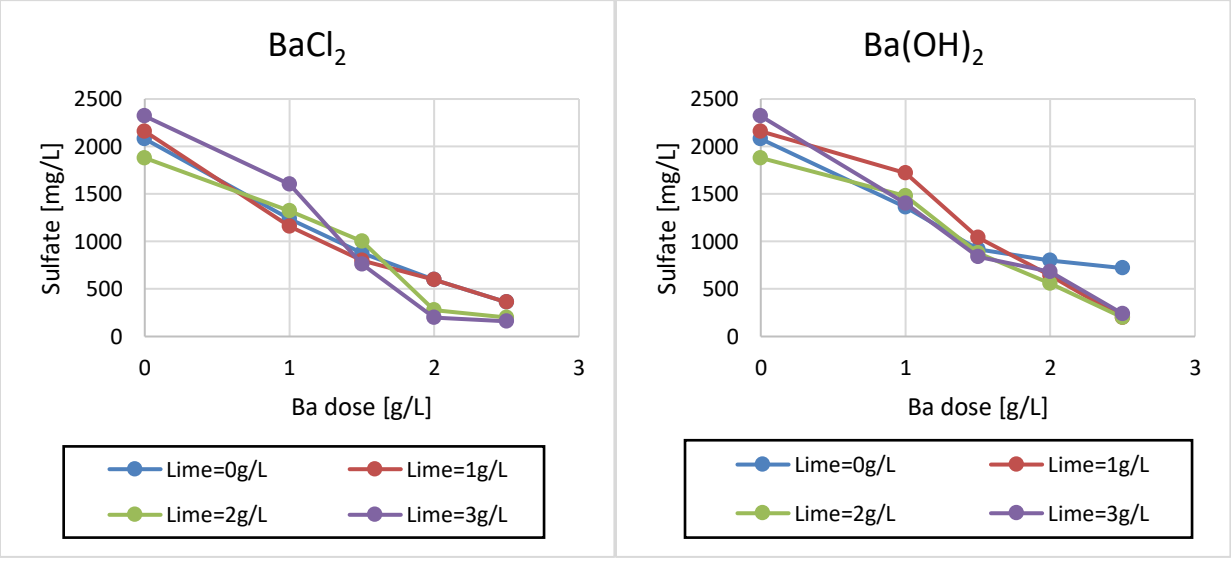

Figure 14. Sulfate precipitation jar tests with barium chloride and barium hydroxide salts.

As both evaluated barium salts proved to be effective for sulfate precipitation from the Coffee waters, other treatment parameters were considered (Table 9). Precipitated sludge resulting from barium hydroxide addition was more amorphous, took longer to settle, and generated more sludge volume than barium chloride treatment. **Barium chloride was initially chosen as a precipitation reagent for the bench-scale testing** because it yielded better results per Ba dose than $Ba(OH)_2$, the produced sludge had more beneficial characteristics, and barium chloride addition would not require an additional pH adjustment step.

Table 9. Sulfate precipitation with barium salts. Reagent dosage, sludge volume, and water loss comparison.

	$BaCl_2$	**$Ba(OH)_2$**
Min. Ba dose to meet discharge target	0.72 g/L	0.83 g/L
Equivalent reagent dose	1.28 g/L	1.91 g/L
Sludge volume	10 mL/L treated	23 mL/ L treated
Sludge volume (extrapolated)	10 L/m^3 treated	23 L/m^3 treated
Sludge weight (extrapolated)	12.6 kg/m^3 treated	25.6 kg/m^3 treated
Dry sludge weight (extrapolated)	3.5 kg/m^3 treated	4.2 kg/m^3 treated
Water loss (extrapolated)	9.1 kg/m^3 treated	21.5 kg/m^3 treated

Microbial Screening and Assessment

Microbes present in the received water samples were cultured. This task provided information about concentrations and colony types of microbes present (i.e., microbial diversity). Understanding the native population is as crucial as understanding water chemistry since indigenous microbes can either hinder or enhance the biotreatment.

The microorganisms isolated from the waters received were screened with WesTech's repository strains to examine their contaminant-reducing potential in the site waters. The microbial screening was performed as a batch, qualitative assessment toward a selection of a robust microbial population. It was used 1) to determine whether a given contaminant was easy or difficult to remove in the given water chemistry using biological treatment; 2) to identify the best performing microbial population in the given water chemistry (contaminant transformation, performance robustness, etc.); 3) to select an adjusted/enhanced microbial consortium that was the most compatible with the unadjusted native population; and 4) to condition the selected microbial consortia for optimal EBR performance.

The microbes screened included denitrifiers, uranium reducers, arsenic reducers, antimony reducers, and sulfate reducers, matched with the indigenous microbial population. **With an evaluation of the obtained water chemistry, microbial screening tests demonstrated favorable biological treatment of all contaminants of concern.** Figure 15 shows a snapshot of the screening results of denitrification and sulfate reduction. Only a few microbial strains tested are shown in the figures to help with legibility. Out of dozens of microbial strains tested, selected few were further screened to develop the inocula for bench-scale tests.

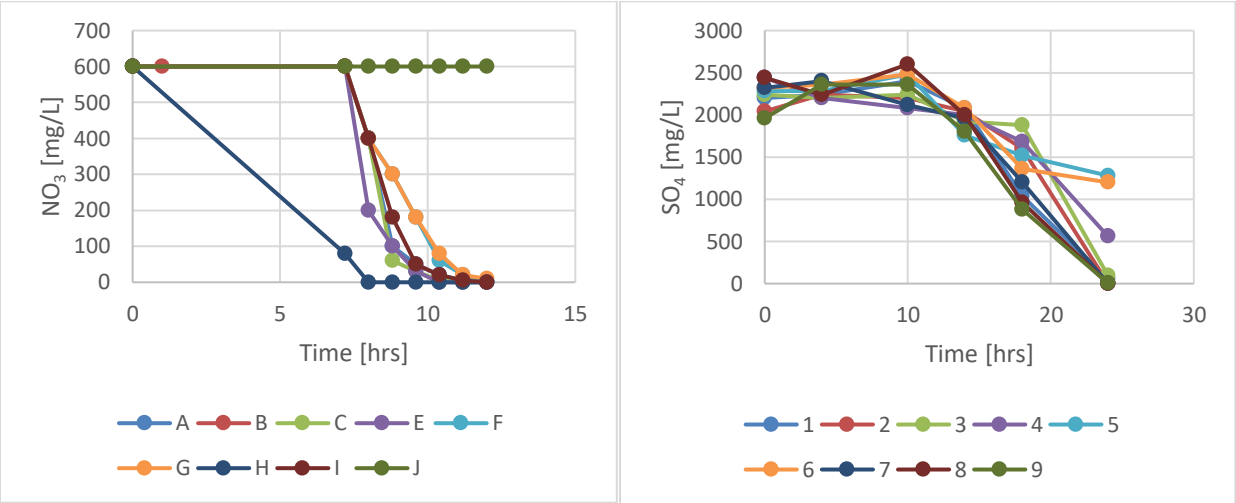

Figure 15. Selected snapshots of denitrification and sulfate reduction microbial screening tests using various denitrifying (A – J) and sulfate-reducing (1 – 9) strains.

Bench-Scale Testing

System A: Validation Results of Contaminants of Interest

The validation phase of the bench-scale EBR testing with System A was completed successfully for all contaminants of concern. Nitrate-N was consistently removed to below the detection limit of 0.5 mg/L within the first EBR stage and remained nondetectable throughout the treatment (Figure 16).

Sulfate was successfully removed to below the discharge target of 1,500 mg/L in the phys-chem pretreatment stage and remained within compliance throughout the treatment (Figure 17). Sulfate removal in the pretreatment can be adjusted further based on Ba dose. The increase in sulfate concentration observed in the aerobic column during the post-treatment optimization was expected. The post-treatment's main goal was residual COD/BOD oxidation; once that goal was achieved, system optimization in terms of the HRT and the required aeration was performed to avoid re-oxidizing reduced species.

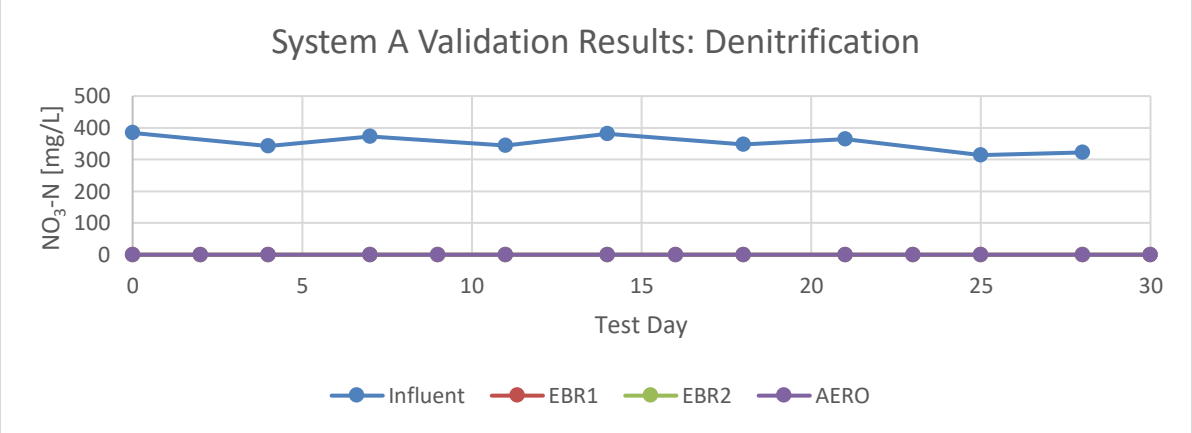

Figure 16. Phase II bench-scale denitrification results: System A validation.

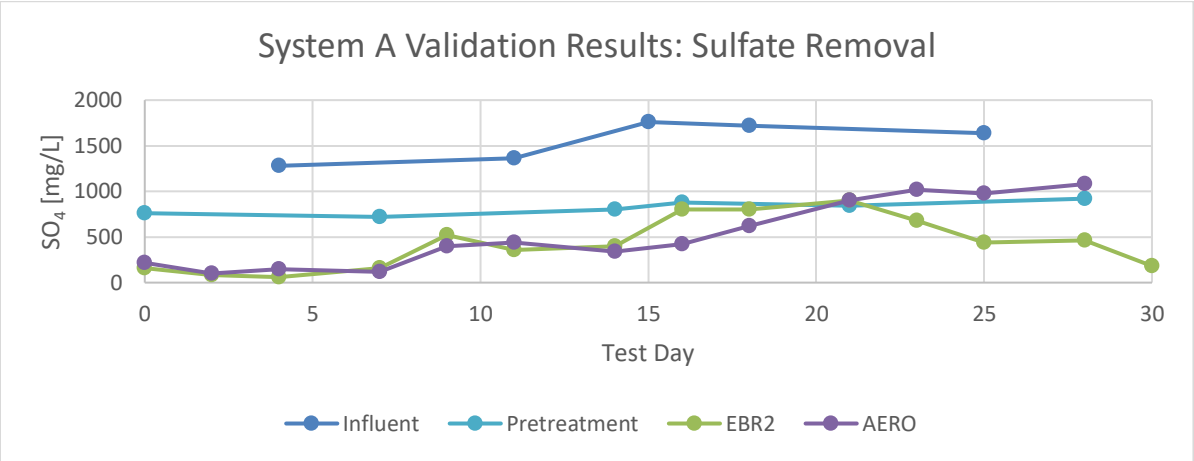

Figure 17. Phase II bench-scale sulfate results: System A validation.

A 30% total uranium reduction was achieved in the phys-chem pretreatment. The EBR system further reduced uranium to below the detection limit of 0.002 mg/L (Figure 18). Uranium removal kinetics followed linear fit in the first-stage EBR, designed for denitrification, and an exponential fit in the second-stage EBR, designed for metals removal.

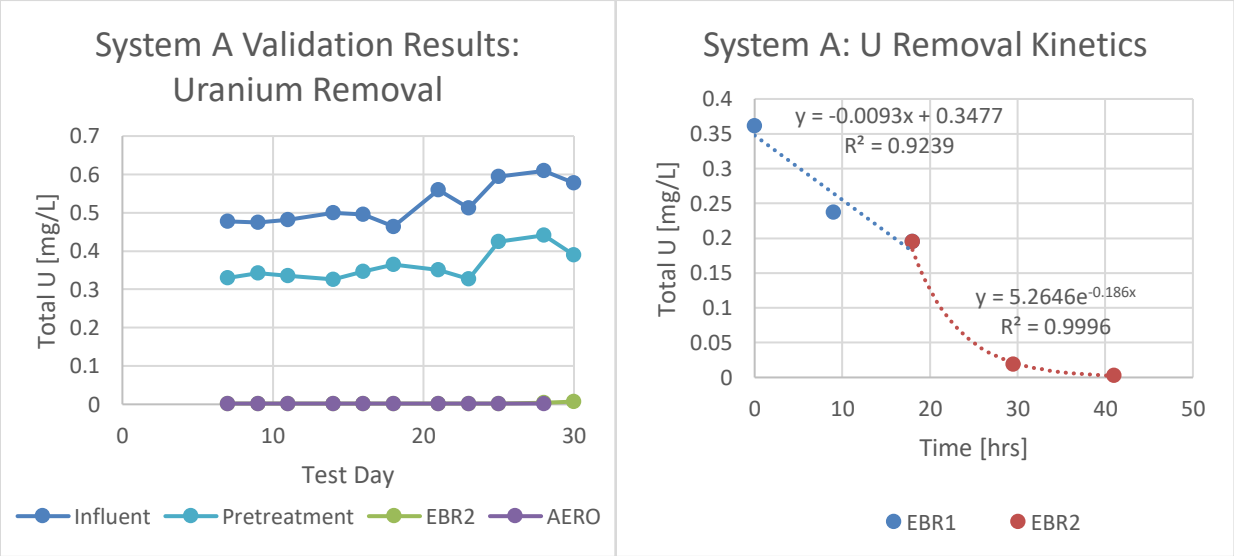

Figure 18. Phase II bench-scale uranium results: System A validation.

Total arsenic was removed to an average of 0.4 mg/L in the phys-chem pretreatment using a 20 mg/L $FeCl_3$ dose (Figure 19). Further pretreatment optimization was needed to lower the As level in the pretreatment step. The goal of the optimization was to demonstrate that the arsenic discharge target can be achieved with the ferric co-precipitation alone, without the need for a biological polishing step. The EBR system polished arsenic levels to an average of 0.009 mg/L.

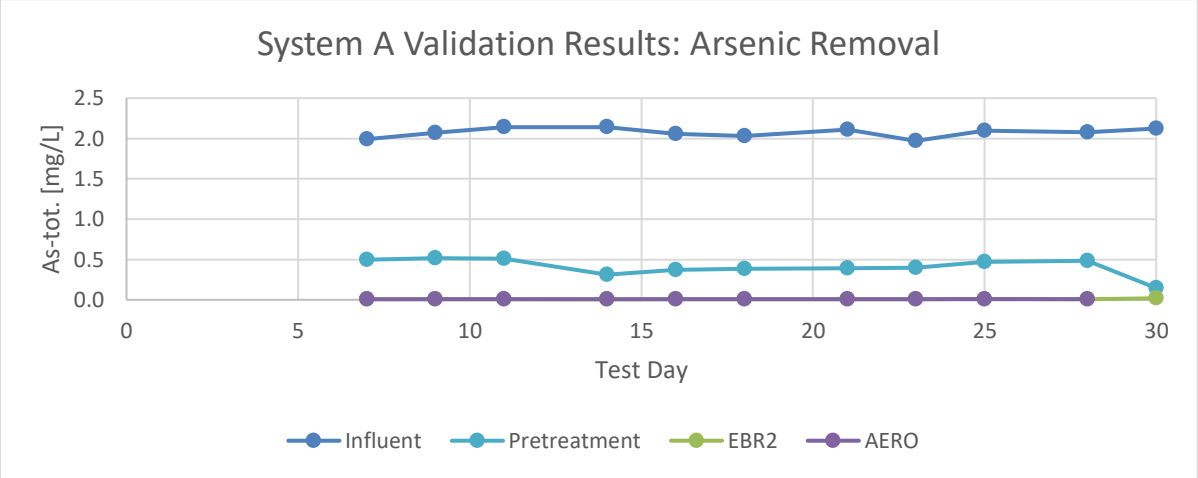

Figure 19. Phase II bench-scale arsenic results: System A validation.

System B: Validation Results of Contaminants of Interest

The validation phase of the bench-scale EBR testing with System B was completed successfully for nitrate, sulfate, and uranium removal. Successful arsenic removal was achieved during start-up and the first couple of weeks of steady-state operation, but a troubling upward trend in As concentrations was observed with time.

Nitrate-N was removed on average to 1.6 mg/L within the first EBR stage (average 16-hr HRT) and remained nondetectable throughout the rest of the treatment (Figure 20).

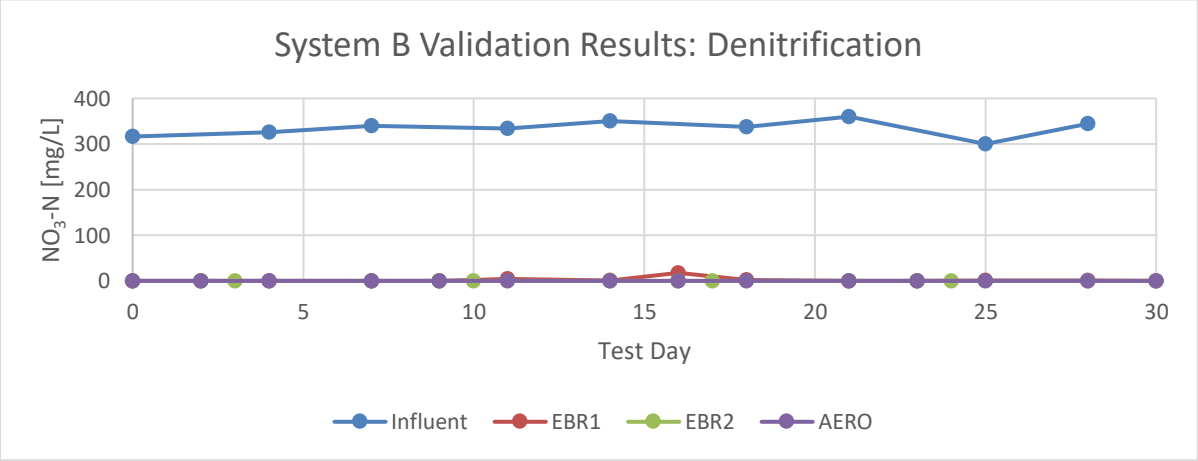

Figure 20. Phase II bench-scale denitrification results: System B validation.

Sulfate was successfully removed to below the discharge target of 1,500 mg/L in the second EBR stage (average 30-hr HRT) and remained within compliance throughout the treatment (Figure 21). Based on the first month of data, the influent's sulfate spike was adjusted further to match the upper modeling predictions.

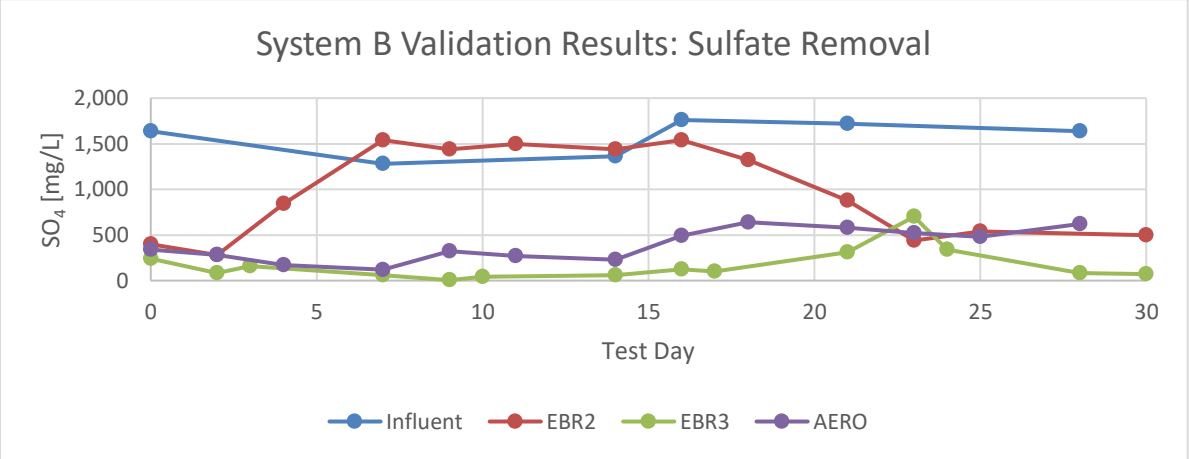

Figure 21. Phase II bench-scale sulfate results: System B validation.

The EBR system consistently reduced total uranium to below the detection limit of 0.002 mg/L (Figure 22). Average U-total concentrations of 0.14 mg/L, 0.007 mg/L, and <0.002 mg/L were achieved in the consecutive EBR reactor stages.

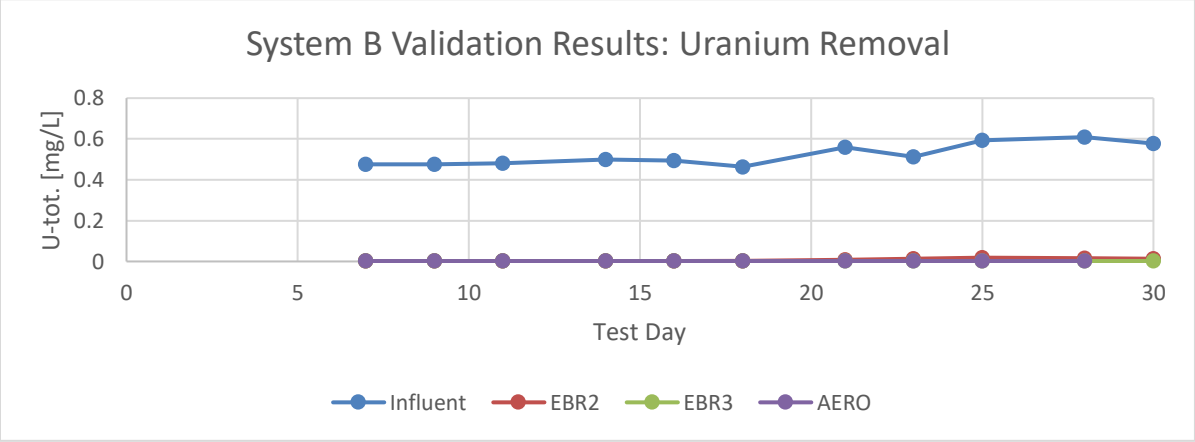

Figure 22. Phase II bench-scale uranium results: System B validation.

Total arsenic was removed to an average of 0.03 mg/L in the EBR system effluent; however, As concentrations had steadily increased throughout the validation phase (Figure 23). Arsenic levels in the system effluent during the last week of validation testing averaged 0.048 mg/L.

Based on the chemistry assessment results indicating a high load of oxyanions acting as competing electron-acceptors and the degrading As removal performance in the continuous-flow bench tests, System B treatment approach was deemed unsuitable for the Coffee Gold waters. Testing of System B was discontinued, and further testing focused on optimization and stress-testing of System A.

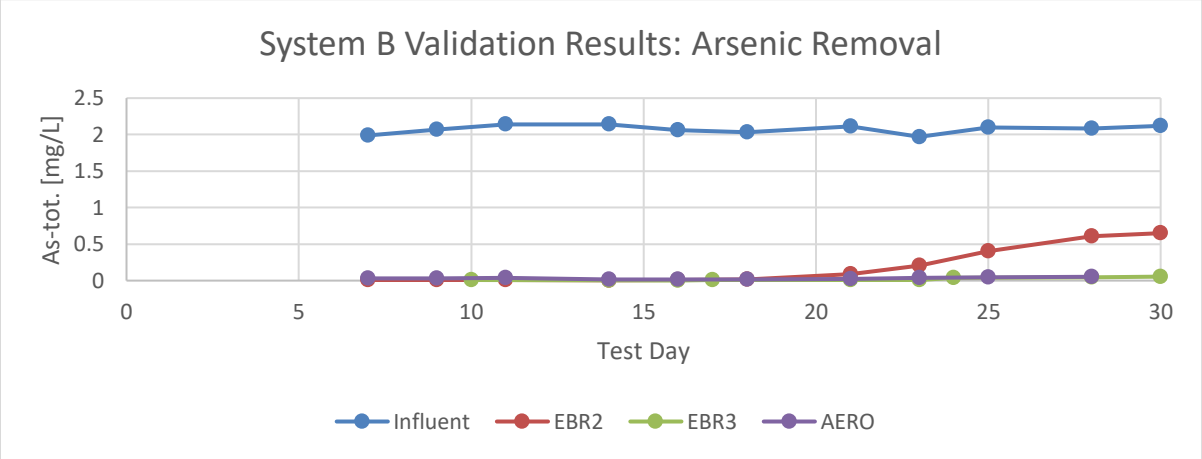

Figure 23. Phase II bench-scale arsenic results: System B validation.

System A: Stress-Testing Results of Contaminants of Interest

System stress-testing included changing the nutrient type and concentration (from the mixture of molasses and ethanol to ethanol alone) and increasing flowrates to evaluate different hydraulic retention times.

The stress-testing events yielded observable responses in nitrate concentrations in the mid-point sampling port of the first-stage EBR but had little to no effect on EBR1 effluent concentrations (Figure 24). Even though the denitrification performance was not driven to failure during stress-testing, the obtained data is sufficient to aid the pilot-scale system design. During the final four weeks of testing, the first stage EBR was operated at an average HRT of 7-hours and provided with average ethanol (nutrient) concentration of 0.6 mL/L. **Except for a stress response on test day 88, the average resulting nitrate-N concentrations in EBR1 effluent were non-detectable (<0.3 mg/L), meeting the discharge target of 3 mg/L.**

Each EBR stress-testing event affected the aerobic post-treatment performance and required system optimization (bottom graph in Figure 24). For example, as nutrient additions were lowered, the BOD loading into the aerobic column decreased as well, rendering it oversized. With extra dissolved oxygen no longer consumed by residual organics, the intermediary denitrification by-products (e.g., NO_2^-, NO, N_2O) were oxidized back to nitrate. Since reducing the aerobic post-treatment size was not feasible on the bench-scale once the columns were constructed, the post-treatment was optimized by balancing the frequency and intensity of oxygen gas additions. At the end of the testing, the aeration was only turned on for one minute every three hours instead of running continuously, meaning that the aerobic post-treatment column was significantly oversized.

Nitrite removal followed a similar trend to nitrate (Figure 25). **While the samples collected from the mid-point EBR1 showed elevated nitrite-N concentration in response to stress-testing events, the average EBR1 effluent was 0.037 mg/L, and the EBR2 effluent was non-detectable (<0.01 mg/L).** During the final four weeks of testing, after the required oxygen gas addition optimization, the average nitrite-N discharge from the aerobic post-treatment column was 0.02 mg/L. The treatment target for NO_2-N is 0.09 mg/L.

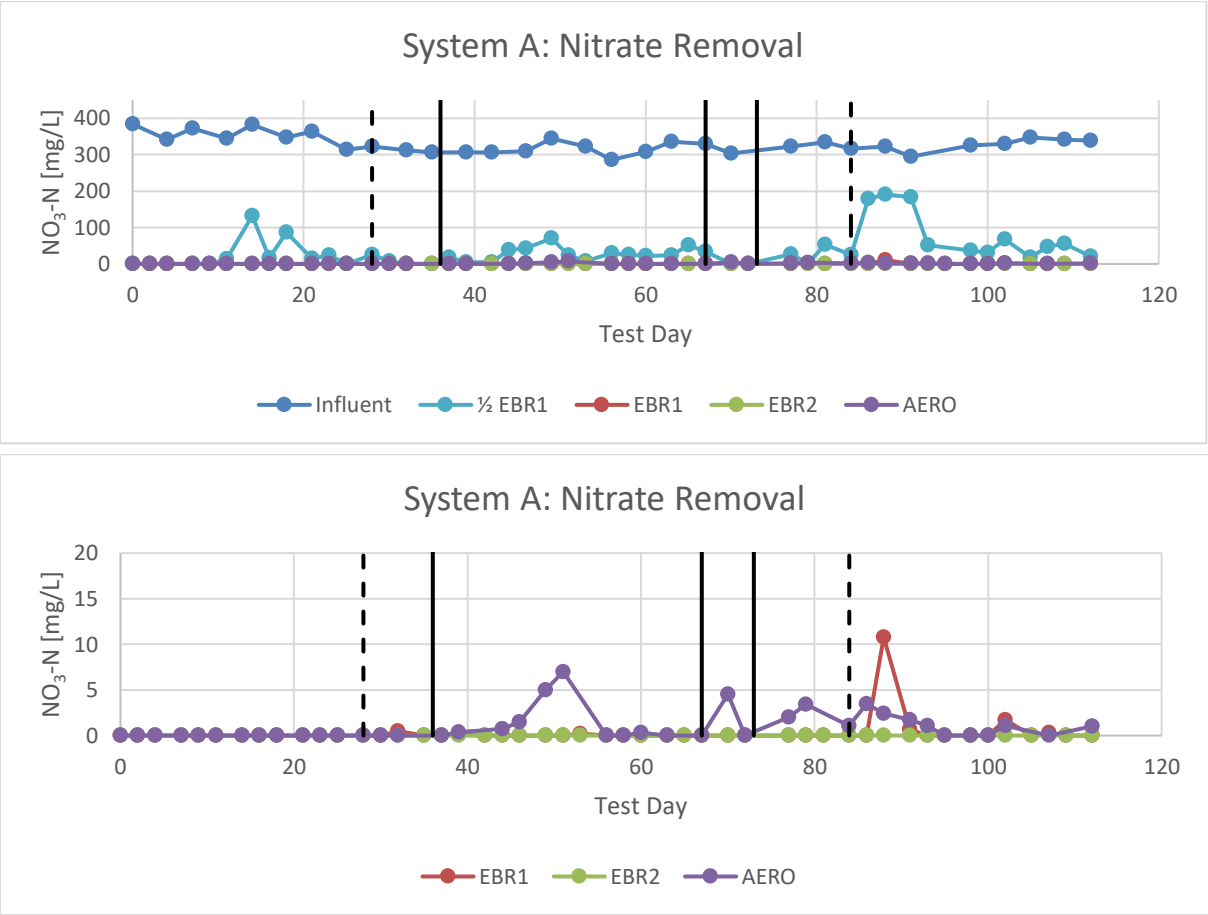

Figure 24. Phase II bench-scale denitrification results: System A overall results. Dashed vertical lines represent the major HRT reduction events, while solid vertical lines indicate the major nutrient adjustments. The bottom graph focuses on nitrate-N results below 20 mg/L.

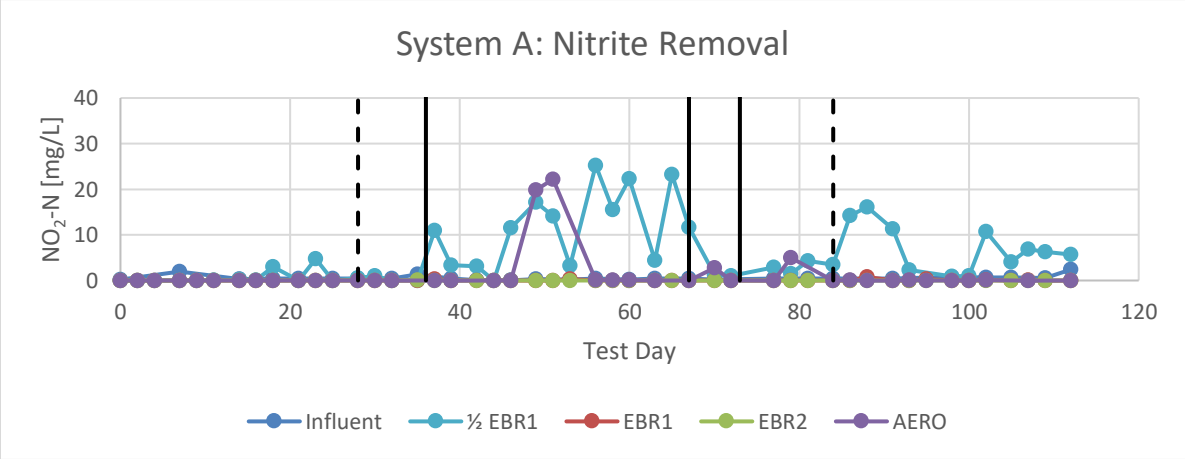

Figure 25. Phase II bench-scale nitrite results: System A overall nitrite results. Dashed vertical lines represent the major HRT reduction events, while solid vertical lines indicate the major nutrient adjustments.

The sulfate spike in the influent waters was increased after the initial 30-day operation period to match the upper modeling predictions. After the adjustment, influent sulfate levels varied between 2,340-3,350 mg/L. The average influent concentration of 2,820 mg/L slightly exceeded the upper modeling prediction of 2,500 mg/L.

Barium precipitation pretreatment target was set at 1,500 mg/L - the treatment target. **The average sulfate concentration in the pretreatment effluent was 1,513 mg/L** (Figure 26). The preliminary jar test experiments showed that the final sulfate concentration was directly correlated to the barium dose, i.e., lower sulfate concentrations can be achieved with higher barium doses if needed.

During stress-testing, various operating conditions were evaluated to establish the optimal conditions to ensure that the EBR system reduced no or little additional sulfate. Short HRT, lack of complex nutrient additions, and balanced nutrient concentrations were found to be the most optimal operating conditions to limit sulfate bioreduction. **Since both arsenic and sulfate were removed to below their respective discharge limits in the chemical pretreatment steps, biological EBR treatment could be maintained at higher ORP ranges without using excess nutrients and thus limiting the creation of problematic by-products, such as hydrogen sulfide or methyl-arsonic acids.**

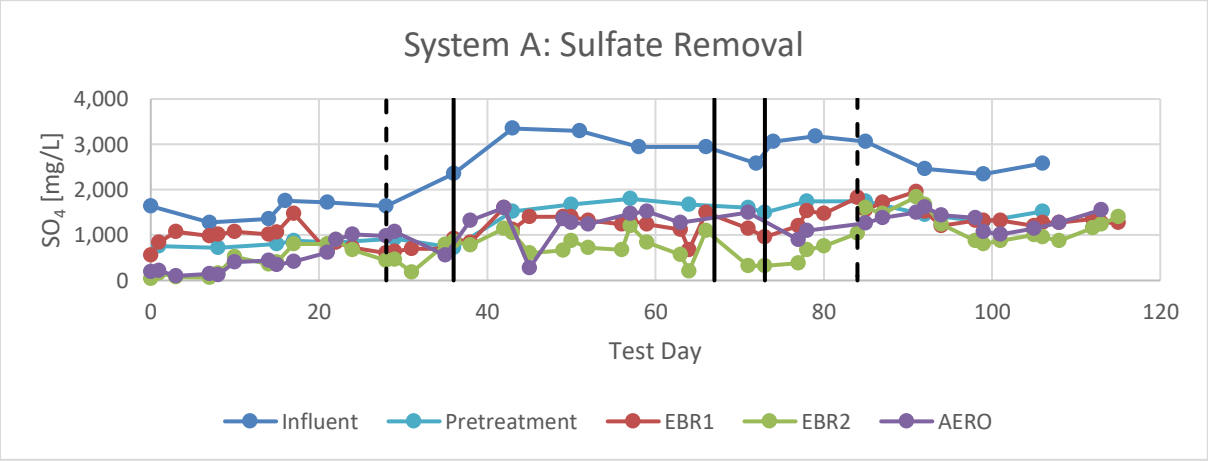

Figure 26. Phase II bench-scale sulfate results: System A overall results. Dashed vertical lines represent the major HRT reduction events, while solid vertical lines indicate the major nutrient adjustments.

An average total uranium removal of 39% was achieved with the chemical precipitation pretreatment alone (Figure 27). The average total uranium influent concentrations were reduced from 0.56 mg/L in the raw Coffee water (after spiking) to an average of 0.34 mg/L in the pretreatment effluent. Uranium co-precipitation with barium sulfate has been known and studied for decades. The proposed chemical structure of the resulting precipitate is a double potassium sulfate complex of U(IV) or $K_2Ba[U(SO_4)_4]$. That is supported by a decrease in potassium concentrations in the pretreatment effluents. Since the co-precipitation mechanisms depend on uranium speciation, the actual pretreatment efficiency for uranium removal will be determined during on-site pilot-scale testing of the Coffee Mine waters.

Further removal of total uranium to below the discharge target 0.1 mg/L was achieved with the first-stage EBR treatment during test days 37 through 79 (Figure 27). The average HRT of EBR1 during that time was 11 hours, and the average ethanol nutrient concentration was 0.9 mL/L. Once the nutrient

additions to EBR1 were lowered to 0.6 mL/L and the HRT of the system was reduced to 7 hours, the resulting EBR1 effluent contained, on average, 0.17 mg/L total uranium. The second EBR stage maintained total uranium concentrations at or below the discharge target throughout the test's entire duration. The aerobic post-treatment did not affect total uranium concentrations.

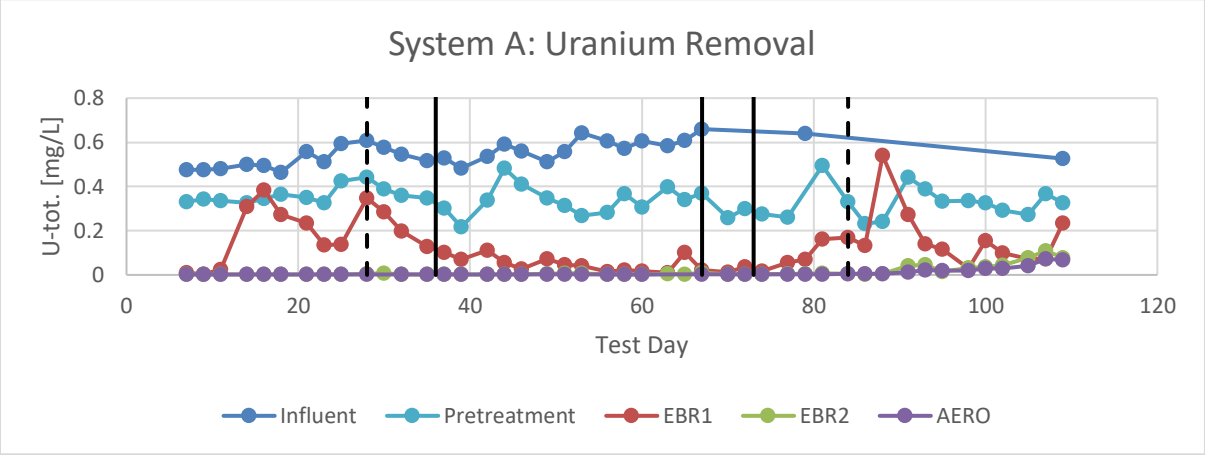

Figure 27. Phase II bench-scale uranium results: System A overall results. Dashed vertical lines represent the major HRT reduction events, while solid vertical lines indicate the major nutrient adjustments.

Ferric arsenic co-precipitation pretreatment was optimized after the first four weeks of operation (Figure 28). **On average, the initial 79% removal efficiency was improved to 98.4%, removing total arsenic to 0.035 mg/L.** The factors affecting the pretreatment efficiency were the ferric chloride dose, as well as the type of barium pretreatment used for sulfate precipitation since barium sulfate sludge acted as coagulant/flocculant for arsenic co-precipitation. Increasing ferric chloride dose from 20 mg/L to 30 mg/L on test day 30 improved the system efficiency; the resulting total arsenic concentrations in the pretreatment effluent decreased from 0.43 mg/L to 0.077 mg/L. When barium hydroxide was used for sulfate precipitation instead of barium chloride, starting on test day 50, total arsenic concentrations dropped further to 0.029 mg/L. A short-lived evaluation of barium carbonate between test days 77 and 82 showed to be detrimental to both arsenic and uranium removal in the pretreatment; total arsenic concentrations peaked at 0.411 mg/L during that test.

Whenever arsenic concentrations spiked in the pretreatment effluent, a similar spike was observed later in the first-stage EBR effluent. Once the pretreatment was optimized, the EBR configuration and operating conditions were to specifically not target any arsenic reduction.

Arsenic speciation was performed three times throughout the bench trial – at the end of validation testing (day 28), early on during stress-testing when arsenic removal was still in steady-state operation (day 70), and at the end of stress-testing (day 113). The predominant arsenic species in the influent water was arsenate, as expected due to the use of hydrogen peroxide for cyanide destruction (Table 10). After arsenic precipitation pretreatment, arsenate remained the predominant species. The EBR system generated progressively more reduced arsenic species but never produced any methylated arsenic by-products. Depending on the operating conditions, the aerobic post-treatment re-oxidized most of the arsenic remaining in the system into the least bioavailable and less toxic As(V).

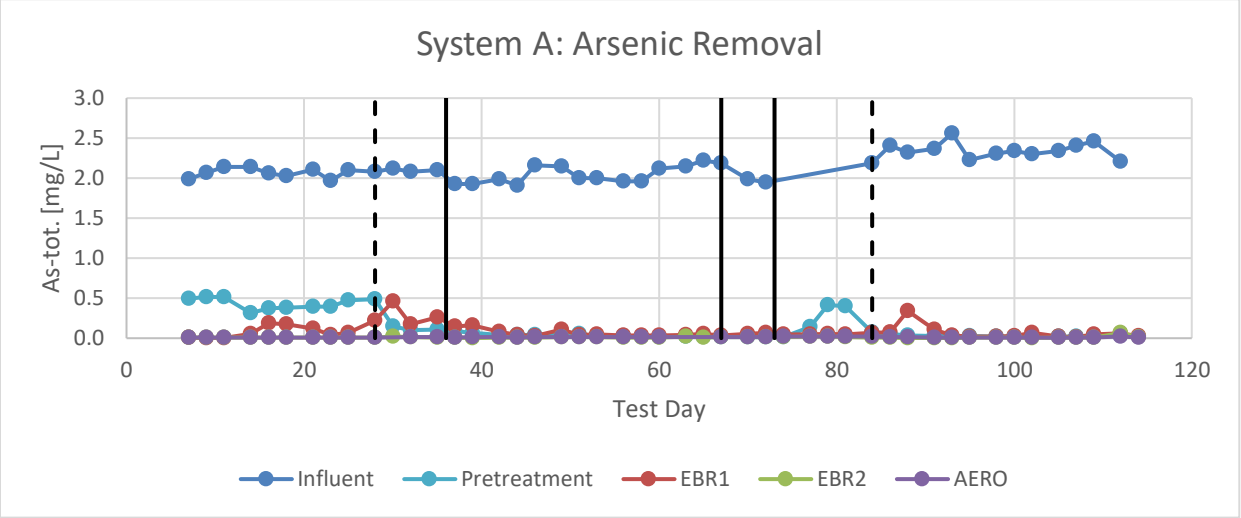

Figure 28. Phase II bench-scale arsenic results: System A overall results. Dashed vertical lines represent the major HRT reduction events, while solid vertical lines indicate the major nutrient adjustments.

Table 10. Arsenic speciation results, including the following arsenic species: As(V) – arsenate, As(III) – arsenite, MM-As – monomethylarsonic acid, DM-As – dimethylarsonic acid, and a sum of unknown species.

Test Day	As Species	Influent	Pretreatment	EBR1	EBR2	Aerobic

Arsenic species concentrations varied between testing stages and operating conditions. To illustrate the speciation transformations, Figure 29 shows average arsenic species concentrations across the treatment system.

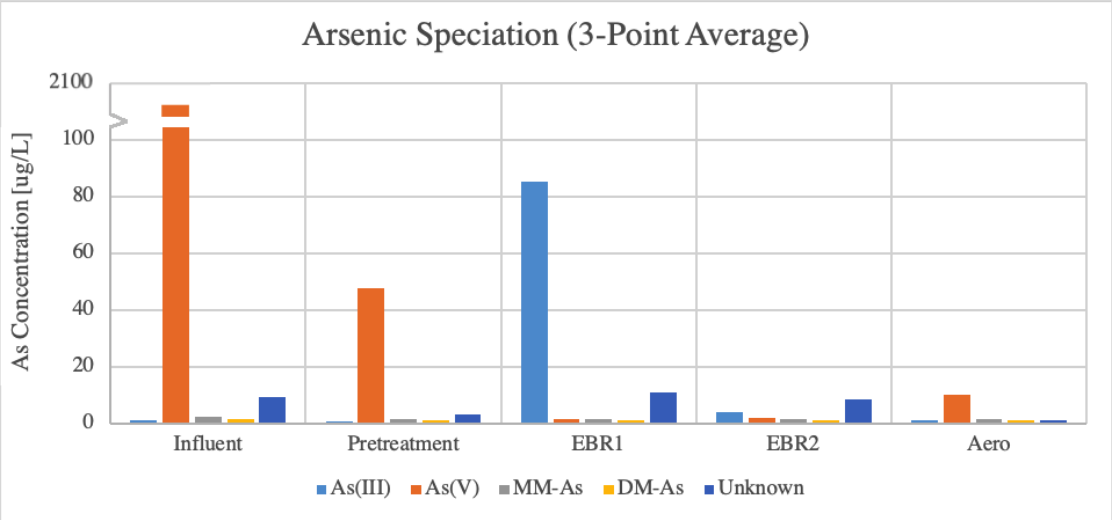

Figure 29. Phase II bench-scale arsenic speciation results: System A. Values averaged over three data points.

System A: Anions

Analytical suite chemistry scans were performed three times throughout the test – at the end of validation testing (day 28), early on during stress-testing when arsenic removal was still in steady-state operation (day 70), and at the end of stress-testing (day 113). **Because of the different testing-stage goals and changing operating conditions across all the treatment units, many of the evaluated parameters were never in a true steady-state. Drawing conclusions based on a limited set of three data points collected during various operating conditions has a number of limitations.**

Table 11 summarizes the results of major ions analysis. Nitrate-N, nitrate-N, and sulfate concentrations obtained from the analytical laboratory support the routine in-house analysis performed at WesTech's labs.

Table 11. The average concentration of anions throughout the Phase II bench-scale testing. Three-point average.

	Influent	Pretreatment	EBR1	EBR2	Aerobic	Target
Nitrate-N [mg/L]	335	303	0.034	<0.01	<0.01	3.0
Nitrite-N [mg/L]	1.04	1.57	<0.04	<0.02	<0.02	0.09
Sulfate [mg/L]	2,703	1,530	1,397	902	1,237	1,500
Sulfide [mg/L]	<0.016	<0.01	0.38	0.24	<0.01	N/A
Chloride [mg/L]	138	577	665	648	695	290

The average sulfide concentrations remained nondetectable in the influent and chemical pretreatment effluent, increased to 0.38 mg/L and 0.24 mg/L in the EBR stages, and were oxidized to below the detection limit of 0.01 mg/L in the aerobic post-treatment. While higher than the odor threshold of 0.5 μg/L, the average sulfide concentrations generated within the EBR reactors were orders of magnitude lower than the US OSHA health and safety standards. US OSHA defines sulfide exposure ranges as 100 mg/L (immediately dangerous to life or health), 50 mg/L (maximum peak for 10 minutes), 30 mg/L (maximum concentration below which it is believed that nearly all individuals could be exposed for up to one hour without experiencing or developing irreversible or serious health effects).

Because of the reagents used in the chemical precipitation steps, chloride levels spiked in the pretreatment effluent and remained elevated throughout the system. The highest chloride concentration in the pretreatment (836 mg/L) was detected when barium chloride was used as a sulfate precipitation reagent. Due to that high concentration, an adjustment was made to use barium hydroxide as a sulfate precipitant instead. However, since hydrochloric acid was used twice in the treatment train following this change (once to adjust the pH after cyanide destruction and the second time to neutralize the pH after barium hydroxide addition), chloride levels remained elevated at 307 mg/L. **We recommend performing additional sulfate precipitation jar tests with different barium salts that would not cause chloride increases (such as barium carbonate) once the mine is operational and actual site waters are available.**

System A: Metals

The average concentrations of metals collected throughout the individual treatment units are summarized in Table 12. For ease of interpretation, these results can be divided into five categories:

1. **Metals present in the influent waters within the forecasted ranges that were already below the discharge targets.**
    - Lead: present below the detection limit of 0.002 mg/L in the influent and throughout the treatment stages.
2. **Metals present in the influent waters within the forecasted ranged but exceeding the discharge targets.**

    2.1. Metals treated to below their respective discharge targets.
    - Molybdenum: present at 0.048 mg/L in the influent, removed to 0.04 mg/L in the pretreatment. The discharge goal of 0.033 mg/L was met within the first-stage EBR.
    - Nickel: present at 0.0053 mg/L in the influent, removed to less than 0.003 mg/L in the chemical pretreatment. The discharge goal of 0.002 mg/L was met within the first-stage EBR.
    - Calcium: present at 261 mg/L in the influent, removed to less than 90 mg/L in the final effluent. Calcium treatment target is 180 mg/L.

    2.2. Metals not treated to below their respective discharge targets.
    - Manganese: present at 0.029 mg/L in the influent. The initial spike of manganese concentrations observed throughout the EBR system was attributed to the addition of molasses as a nutrient source. Stress-testing with ethanol as the sole nutrient demonstrated that manganese could be maintained at or below the influent concentrations throughout the EBR treatment. Since no nutrients or reagents were added to the aerobic post-treatment column, a further spike discovered in the aerobic system effluent can only be

attributed to the microbial support media – in this case, pumice was used as a cost-effective alternative to activated carbon. Quality control will be conducted on media used in pilot-scale tests and the full-scale installation to ensure no unexpected leaching of manganese occurs.

Table 12. The average concentration of metals throughout the Phase II bench-scale testing. Three-point average.

3. Metals present in the influent waters outside of the forecasted ranges.

3.1. Metals present in the influent waters at higher concentrations than forecasted and removed by the treatment to below their respective discharge targets.

- Antimony: influent concentrations of 0.61 mg/L reduced to 0.38 mg/L in the chemical pretreatment and reduced further by the biological treatment to 0.06 mg/L and 0.02 mg/L in the consecutive EBR stages. The discharge target of 0.07 mg/L was met in EBR1.
- Copper: present at 0.018 mg/L in the system influent, reduced by 66.7% in the pretreatment, and removed further biologically to below the detection limit of 0.003 mg/L. The discharge goal of 0.004 mg/L was met in the first EBR stage.

- Mercury: present at 0.0034 mg/L in the influent, reduced to 0.00013 mg/L in the chemical pretreatment. The discharge limit of 0.0001 mg/L was met within the first-stage EBR.

3.2. Metals present in the influent waters at higher concentrations than forecasted and not removed by the treatment to below their respective discharge targets.

- Magnesium: present at 195 mg/L in the influent, removed in the chemical pretreatment to 121 mg/L. It remained at a similar level throughout the biological treatment, exceeding the discharge limit of 50 mg/L. Water softening pretreatment step should be added to remove excess hardness minerals during pilot-scale testing.
- Potassium: present at 16.2 mg/L in the influent, removed to 12.1 mg/L in the pretreatment, and varied between 13.7-14.7 mg/L in the biological treatment. The upper-level prediction for potassium in Coffee waters is 11 mg/L. The discharge target is 8 mg/L.
- Sodium: present at 1,500 mg/L in the influent and not removed by any treatment stages. The upper-level prediction for sodium in Coffee waters is 1,168 mg/L.

3.3. Metals present in the influent waters at lower concentrations than forecasted.

- Iron: present in the influent at 0.105 mg/L. The initial spike of iron concentrations observed throughout the EBR system was attributed to the addition of molasses as a nutrient source. Stress-testing with ethanol as the sole nutrient demonstrated that iron remained at or below the influent concentrations.
- Zinc: present in the influent below the detection limit of 0.008 mg/L. Remained nondetectable throughout the treatment.

4. Metals with analytical detection limits higher than the discharge target.

- Aluminum: present below the detection limit of 0.1 mg/L.
- Cadmium: present below the detection limit of 0.0005 mg/L.
- Chromium: present below the detection limit of 0.002 mg/L.
- Selenium: present below the detection limit of 0.002 mg/L. Selenium speciation results are shown in Table 13, indicating that the influent concentrations averaged about 1 μg/L, with a somewhat even distribution between selenate and selenite. The EBR system removed both selenate and selenite below the detections limits. No other (often more bioavailable and/or more toxic) species of selenium were detected throughout the treatment.
- Silver: present below the detection limit of 0.002 mg/L.
- Thallium: present below the detection limit of 0.002 mg/L.

5. Metals with no specified discharge targets.

- Dissolved arsenic: present at 2.05 mg/L in the influent, reduced to 0.16 mg/L in the pretreatment, and further reduced biologically to 0.02 mg/L in the EBR treatment.
- Barium: present at 0.17 mg/L in the influent, reduced to 0.10 mg/L in the pretreatment, remained at similar levels throughout the rest of the treatment.
- Dissolved uranium: present at 0.61 mg/L in the influent, removed to 0.35 mg/L in the pretreatment. Reduced biologically to 0.004 mg/L.

Table 13. Selenium speciation results, including the following arsenic species: Se(VI) – selenate, Se(IV) – selenite, Se-CN – selenocyanate, MeSe(IV) – methylselenic acid, Se-Met – selenomethionine, $SeSO_3$ – selenosulfate, and a sum of unknown species.

Test Day	Se Species	Influent	Pretreatment	EBR1	EBR2	Aerobic

System A: Cyanides

The average concentrations of cyanides are summarized in Table 14. The biological treatment removed total cyanide from 0.35 mg/L to 0.16 mg/L. WAD cyanide's elevated levels in the influent (0.04 mg/L), while lower than the predicted levels of 0.09-0.2 mg/L, exceeded the discharge target of 0.025 mg/L; **the EBR system removed WAD cyanide to below the detection limit of 0.006 mg/L. Thiocyanates remained relatively stable throughout the treatment.**

Table 14. The average concentration of cyanides throughout the Phase II bench-scale testing. Three-point average.

	Influent	Pretreatment	EBR1	EBR2	Aerobic	Target
Total CN [mg/L]	0.35	0.40	0.22	0.17	0.16	N/A
WAD CN [mg/L]	0.041	0.038	<0.015	<0.006	<0.006	0.025
Thiocyanate [mg/L]	0.40	0.33	0.24	0.40	0.22	N/A

System A: Residual Nutrients

While Table 15 provides a summary of residual nutrients results from the entire duration of bench-scale testing, some of the averaged data might be misleading. The residual nutrient parameters were monitored throughout the testing, and their concentrations changed depending on the operating

conditions and the goals of a given testing stage. All residual nutrient parameters, except for total organic carbon (TOC), were monitored twice a week.

Ammonia-N and organic carbon were present in the Coffee waters at significantly higher concentrations than the modeling had forecasted for the on-site chemistry. This was likely caused by natural cyanide bio-attenuation in Coffee solutions during storage since several biochemical metabolic pathways of cyanide biodegradation produce organic carbon and ammonia. When received at WesTech's Labs in October 2019, WAD cyanide concentration in the leach solution was 0.691 mg/L; by the time the rinse solutions were delivered in February 2020, WAD cyanide concentration in the leach solution dropped to 0.116 mg/L, indicating that natural biodegradation was occurring in the barrels. In the same period, ammonia-N increased in the leach solution from 68 mg/L to 83.4 mg/L.

Such high ammonia and organics concentrations are not expected to be present during normal operation of the mine and only occurred because of the prolonged storage of the generated leach waters. Ammonia-N is expected to be found at 0.025-0.06 mg/L in the heap leach rinse solutions, which is considerably lower than the discharge target of 8 mg/L. Even though the average ammonia-N concentrations in the system effluent were at 27.9 mg/L, the EBR system removed it to less than 20 mg/L through cell assimilation, while the aerobic post-treatment decreased it further to 7 mg/L. Conditions in the aerobic post-treatment had to be closely controlled to limit available oxygen that could lead to nitrate/nitrite production.

Organic carbon indicators, i.e., biological oxygen demand (BOD), chemical oxygen demand (COD), and total organic carbon (TOC), all followed the same trend. Medium concentrations of organics were found in the system influent, then increased in the biological EBR system before being oxidized to CO_2 and removed in the aerobic post-treatment. The average organics concentrations given in Table 15 can be misleading since they disregard a bench-scale project's optimization, adjustments, and stress-testing conditions. Figure 30 and Figure 31 illustrate the organics loading changes throughout the testing stages, using BOD and COD as examples. During the first month of operation, both the anaerobic and aerobic unit processes were in start-up and equilibration modes; the elevated nutrient levels in the EBR system were expected during start-up. The aerobic post-treatment needed time to establish a high-density biofilm on the support media to sustain the needed oxidation kinetics. **When the aerobic biofilm was well-established in the last 45 days of operation, the effluent BOD concentrations were typically below the detection limit of 5 mg/L.**

Table 15. The average concentration of nutrients throughout the Phase II bench-scale testing.

	Influent	Pretreatment	EBR1	EBR2	Aerobic	Target
BOD [mg/L]	21.7	17.3	312	517	582	N/A
COD [mg/L]	104	112	307	704	498	N/A
TOC [mg/L]	5.2	4.0	96	69	116	N/A
Ammonia-N [mg/L]	27.9	22.3	21.2	19.7	7.0	8
Phosphate-P [mg/L]	0.41	0.33	0.54	1.93	5.85	0.14

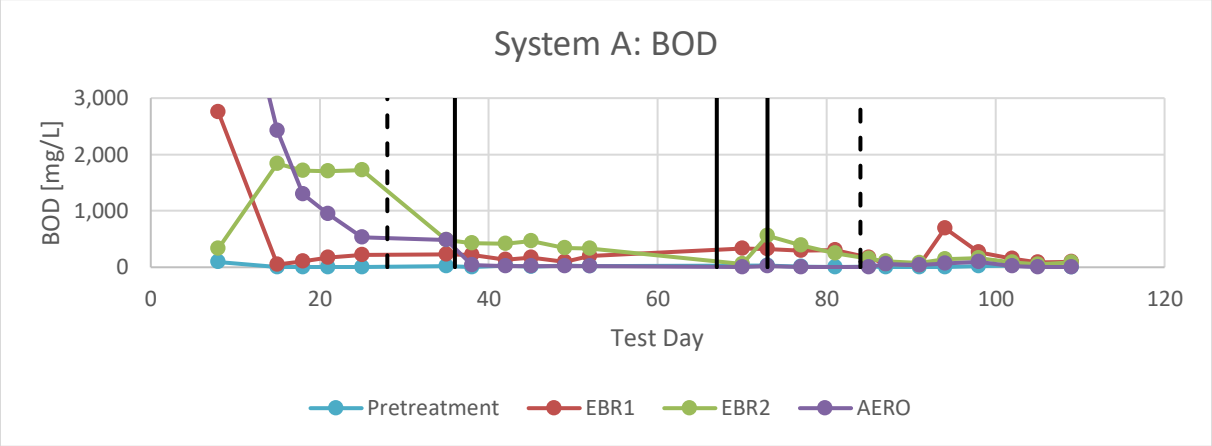

Figure 30. Phase II bench-scale results: System A overall BOD data. Dashed vertical lines represent the major HRT reduction events, while solid vertical lines indicate the major nutrient adjustments.

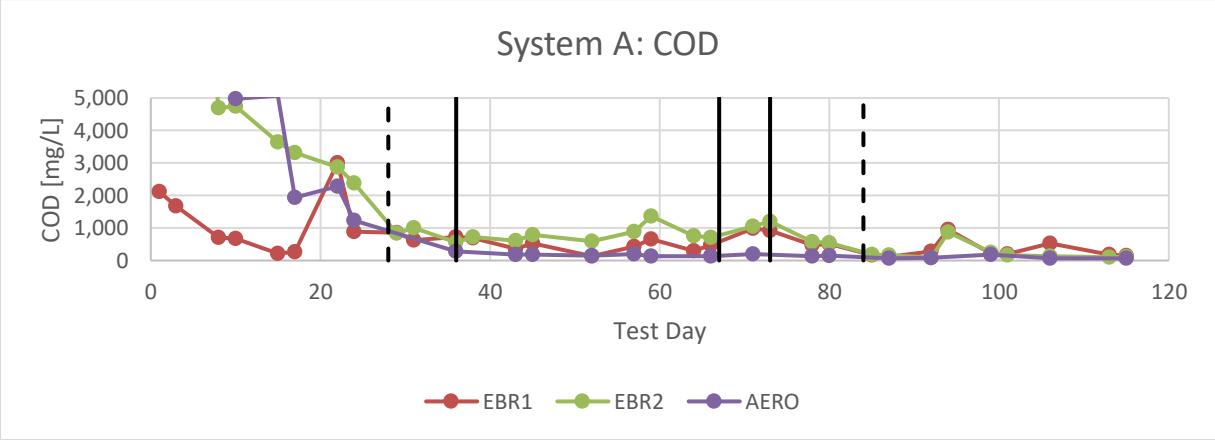

Figure 31. Phase II bench-scale results: System A overall COD data. Dashed vertical lines represent the major HRT reduction events, while solid vertical lines indicate the major nutrient adjustments.

Total phosphate-P was present in the influent waters at 0.41 mg/L – a level twice as high as the water quality modeling had forecasted. As a residual nutrient, phosphate followed a similar trend throughout the EBR treatment system as the residual organics (Figure 32). Initial elevated concentrations can be attributed to start-up and steady-state operation using molasses/ethanol mixture as a nutrient. During the last two weeks of operation, once the system was stabilized and ethanol was used as a sole carbon source, the average EBR effluent PO_4-P concentrations were 0.18 mg/L for EBR1 and 0.35 mg/L for EBR2, when the average system influent carried 0.25 mg/L PO_4-P. With no external source of phosphorus, the slightly elevated levels detected in the second-stage EBR as compared to the system influent can only be explained by residual concentrations still being rinsed out from the preliminary testing stages. **A pilot- and full-scale installation is expected to not require any external phosphate additions and that the EBR system would remove some of the PO_4-P present in the influent waters through assimilatory pathways.**

Since no nutrients or reagents were added to the aerobic post-treatment column, the continuously elevated phosphate levels discovered in the aerobic system effluent can be attributed to the microbial support media – in this case, pumice was used as a cost-effective alternative to activated carbon. Quality control will be conducted on media used in pilot-scale tests and the full-scale installation to ensure no unexpected leaching of phosphate occurs.

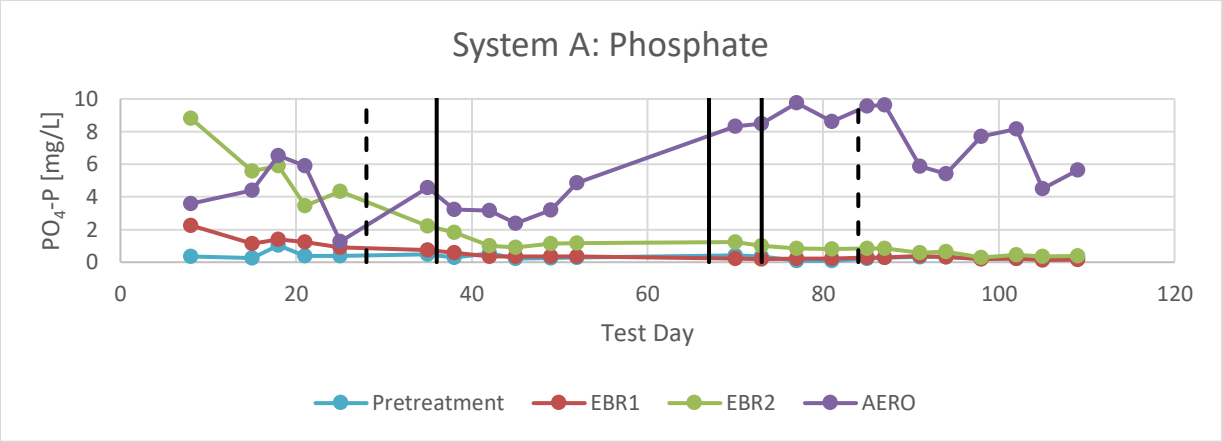

Figure 32. Phase II bench-scale results: System A overall phosphate-P data. Dashed vertical lines represent the major HRT reduction events, while solid vertical lines indicate the major nutrient adjustments.

System A: Radiochemistry

Water samples from System A were sent for radiochemistry analysis to Pace Analytical Laboratories. The general trend can be illustrated by the gross radiation graph, shown in Figure 33. Table 16 shows the detailed results of the radiochemical analysis. Most of the analyzed radioisotopes were present at concentrations lower than their respective uncertainty errors. Gross alpha and beta radiation spiked in the pretreatment effluent waters before dropping back down in the biological treatment effluents.

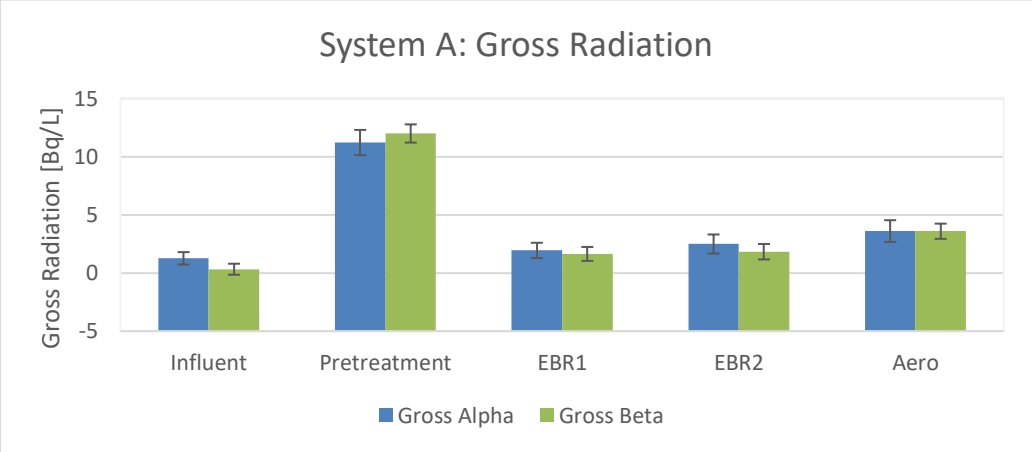

Figure 33. Phase II bench-scale results: System A gross radiation results.

In terms of compliance with the proposed water discharge standards, Figure 34 shows radium-226 analysis results. Ra-226 has a discharge target of 0.016 Bq/L (corresponding to 0.432 pCi/L), which was met throughout all treatment stages, except for the pretreatment effluent.

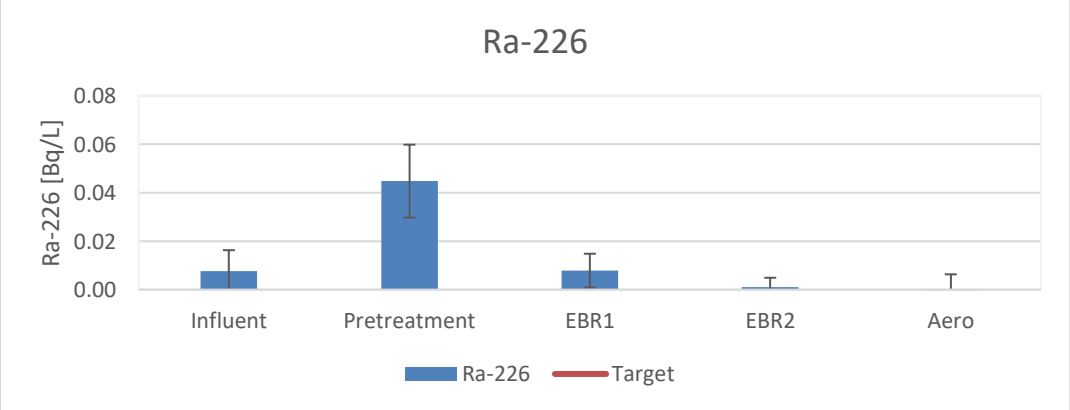

Figure 34. Phase II bench-scale results: System A radium-226 results.

At the conclusion of bench-scale testing, the columns were taken apart, and solids were collected from each treatment stage. This included the dewatered pretreatment sludge, activated carbon support media with any residual precipitates and microbial biofilm from the EBR columns, and the pumice support media with any residual precipitates and microbial biofilm from the aerobic post-treatment. **Except for Pb-214, Tl-208, U-235, and U-238, most of the analyzed radioisotopes were present at concentrations lower than their respective uncertainty errors (Table 17).**

Table 17. Phase II bench-scale results: Radiochemistry analysis of solids samples collected from all the treatment stages. One data point.

	Pretreatment Sludge	EBR1 Solids	EBR2 Solids	Aero Solids

U-238 [pCi/g]	5.05 ±2.26	3.79 ±1.54	4.27 ±1.62	0.193 ±0.487

As a point of reference, the US EPA does not consider radium as a "source material," and therefore, it would not be considered a by-product if present in the water treatment residuals. Uranium, however, is considered a "source material." The US EPA classifies any waste (solid or liquid) containing more than 0.05% by weight uranium, a low-level radioactive waste. That weight percentage corresponds to approximately 335 pCi/g for uranium.

The low concentration of radioisotopes in the Coffee waters implies a risk that they might be concentrated in one or multiple stages of the treatment, producing a radioactive by-product or waste that will be difficult to dispose of. Utilizing an optimized chemical pretreatment step removes both uranium isotopes (U-235 and U-238) from the influent waters continuously without generating even low-level radioactive sludge. U-238 concentrations in the influent waters were reduced from 155 ±84.6 pCi/L to levels below the uncertainty errors in the pretreatment step (Table 16), while only generating 5.05 ±2.26 pCi/g of U-238 in the sludge (Table 17). This point is also illustrated by the gross radiation detected in solids collected from the treatment stages (Figure 35). **A low-level peak of gross radioactivity in the pretreatment sludge suggests a concentration of the radioisotopes that can be safely disposed.**

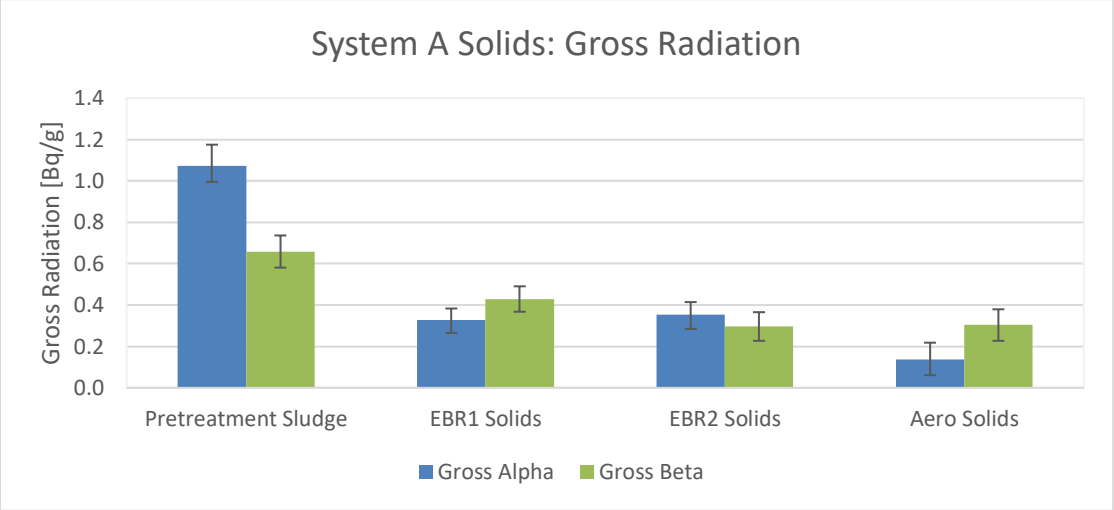

Figure 35. Phase II bench-scale results: System A solids radiation results.

System A: Toxicity Characteristic Leaching Procedure

At the conclusion of bench-scale testing, the columns were taken apart, and solids were collected from each treatment stage. This included the dewatered pretreatment sludge, activated carbon support media with any residual precipitates and microbial biofilm from the EBR columns, and the pumice support media with any residual precipitates and microbial biofilm from the aerobic post-treatment. The solids were submitted to AWAL laboratories for toxicity characteristic leaching procedure (TCLP) analysis.

All the collected solids passed the TCLP analysis (Table 18). Most metals were not leached in detectable quantities from any generated solids. The only exceptions were arsenic (leached out of the pretreatment sludge at 0.128 mg/L – well below the allowable limit of 5 mg/L) and barium (leached out of the EBR1 solids at 0.34 mg/L – well below the allowable limit of 100 mg/L). Since the ferric co-precipitation is a one-pass system, similar TCLP results from the pretreatment sludge can be expected from the pilot-scale test and full-scale installation. The EBR system has the potential of concentrating the contaminants with time. Assuming a linear accumulation and leachability of barium in the first-stage EBR, it would take 33,823 days of continuous operation (or about 93 years) to reach the allowable limit of 100 mg/L in the EBR solids.

Table 18. Toxicity characteristic leaching procedure (TCLP) results.

	Pretreatment Sludge	EBR1 Solids	EBR2 Solids	Aero Solids	Limit
As [mg/L]	0.128	<0.02	<0.02	<0.02	5.0
Ba [mg/L]	<0.3	0.34	<0.3	<0.3	100.0
Cd [mg/L]	<0.0035	<0.0035	<0.0035	<0.0035	1.0

Quality Control Results

As part of the internal quality control testing, AWAL Labs performed method blanks (MB), laboratory control samples (LCS), matrix spikes (MS), and matrix spike duplicates (MSD) on the submitted samples. Method blanks use an analyte-free matrix, such as deionized water, through the complete procedure; it is used to evaluate contamination potential due to sample preparation and analytical procedure. Laboratory control sample uses the same analyte-free matrix as MB but is spiked with a known concentration of the analyte of interest; it is used to determine if the procedure is working within the established control limits, without the interference from the sample matrix. Finally, matrix spike uses an aliquot of the sample spiked with a known concentration of the analyte of interest; it is used to determine whether the procedure works within the established control limits, including sample matrix interferences. The matrix spike is routinely performed in duplicate as the MSD. The recoveries of the spiked analyte are evaluated to determine the accuracy in a given matrix, while the comparison between the MS and MSD shows how precise the procedure is in a given matrix.

For total metals analysis, the acceptable recovery control limits for the QC samples must be within 75%-125%. The recoveries of both total arsenic (Figure 36) and total uranium (Figure 37) were well within the acceptable recovery limits. Based on the standard deviations obtained from matrix spikes and matrix spike duplicates, the precision of total arsenic measurements was defined as ±0.0028 mg/L, while the accuracy was ±0.0068 mg/L (Table 19). For total uranium, the precision and accuracy were ±0.0061 mg/L and ±0.0111 mg/L, respectively. **The established precisions and accuracies of the total metals analyses were an order of magnitude lower than their respective discharge targets, giving us high confidence in the obtained results.**

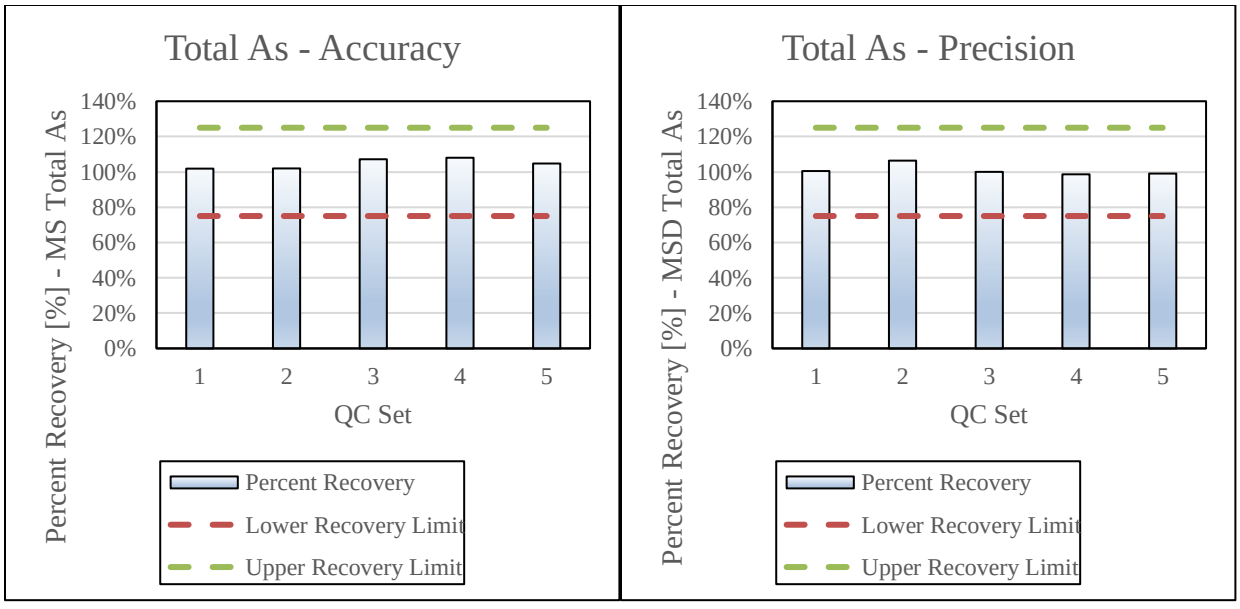

Figure 36. Quality control results for total arsenic analysis.

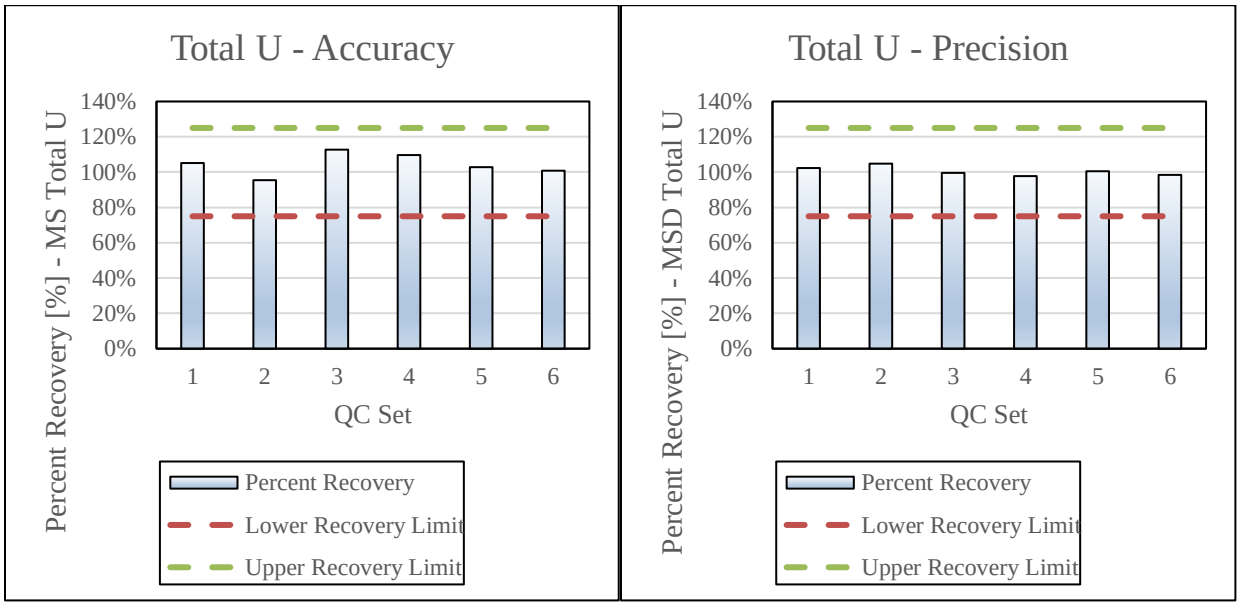

Figure 37. Quality control results for total uranium analysis.

Table 19. Analytical precision and accuracy during bench-scale testing of Coffee waters.

	Average Precision [mg/L]	Average Accuracy [mg/L]
Arsenic-tot.	±0.0028	±0.0068
Uranium-tot.	±0.0061	±0.0111
Nitrate-N	±0.01	±0.04
Sulfate	±11.7	±61.9

For anions, the acceptable recovery control limits must be within 90%-110%. The recoveries of nitrate-N and sulfate were shown to be within these limits (Figure 38 and Figure 39). Very high precision (±0.01 mg/L) and accuracy (±0.04 mg/L) were established for nitrate-N analysis (Table 19). Sulfate analysis carried a ±11.7 mg/L precision and ±61.9 mg/L accuracy, providing very high confidence in the obtained results compared to the 1,500 mg/L discharge target.

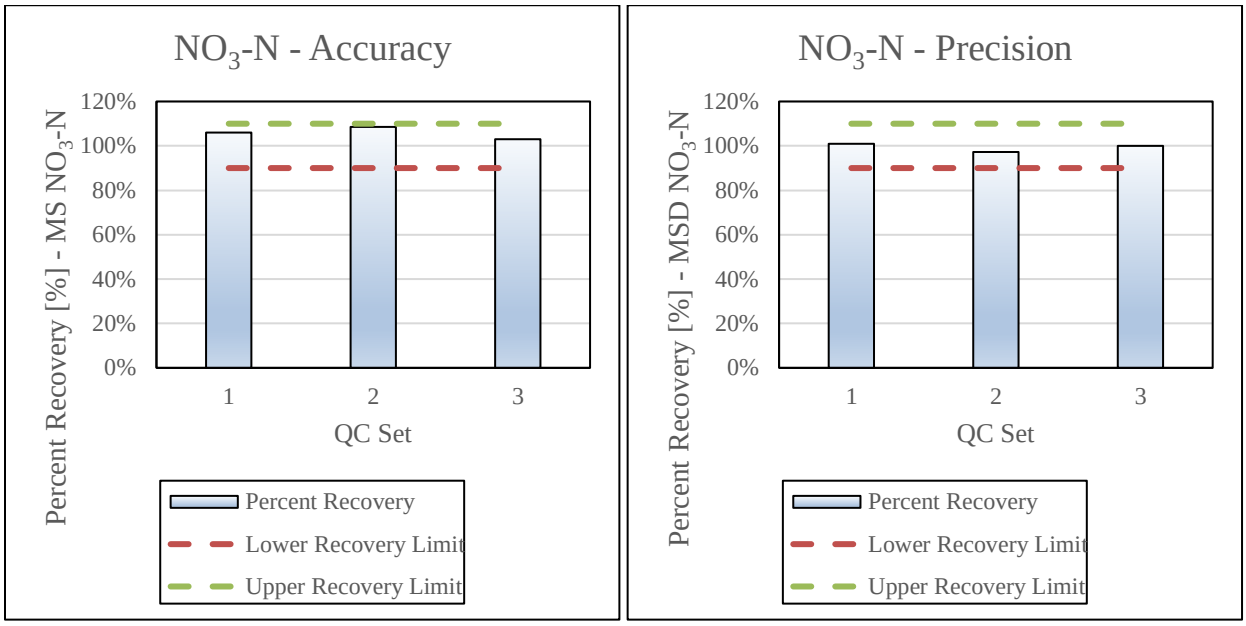

Figure 38. Quality control results for nitrate-N analysis.

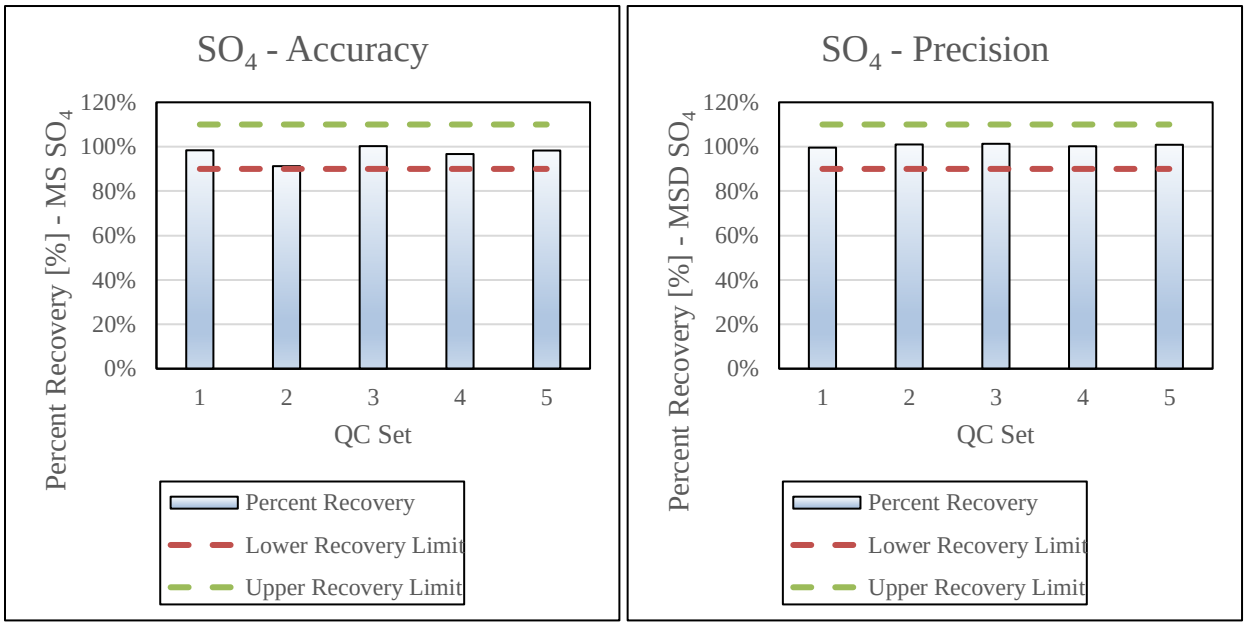

Figure 39. Quality control results for sulfate analysis.

Preliminary Design and Operational Parameters

Based on the results obtained from bench-scale testing, a set of preliminary design and operational parameters was developed for a pilot-scale demonstration trial (Table 20). It is recommended that the pilot be conducted once the Coffee Mine is operating and actual leach waters are generated.

The pilot demonstration is a required last step before preliminary engineering of the water treatment plant can be completed. The on-site demonstration will be conducted over at least a three-month period with a seasonal temperature change. The testwork and analytical plan will be developed prior to the pilot demonstration and will include at the minimum the same level of detail as the Phase II bench-scale program.

Table 20. Summary of the design and operational parameters for pilot-scale testing.

Unit process	Retention time	Reagent dose
Ferric Co-precipitation	~ 1hr	~ 30 mg/L $FeCl_3$
Sulfate Precipitation	~1 hr	~ 2 g/L Ba
EBR Treatment	7-10 hrs	0.6-0.9 mL/L ethanol
Aerobic Post-treatment	< 1hr	Continuous air addition

CONCLUSIONS

The Phase I feasibility testing successfully demonstrated the removal of nitrate, arsenic, and uranium from Coffee Gold leach waters. Nitrate-N was removed from an average of 188 mg/L to below the detection limit of 0.19 mg/L. After process adjustments, average removals of 98.8% and 99.1% were achieved for arsenic and uranium, respectively. Furthermore, sixteen other metals, as well as total and WAD cyanides, were removed by the EBR system.

Even though arsenic removal was demonstrated with the biological treatment, the feasibility testing proved that long retention times and high nutrient doses would be required to meet the required discharge levels. The Phase I recommendation was to investigate phys-chem arsenic removal options.

The in-situ feasibility tests demonstrated enhanced denitrification upon inoculation with the EBR effluent and nutrient additions. Natural nitrate reduction occurred in the control column upon nutrient additions due to the presence of a native denitrifying microbial population. However, inoculation with the EBR microbial population enhanced the denitrifying performance. Nitrate-N was reduced in the in-situ test column from approximately 150 mg/L to 13.9 mg/L when the EBR effluent was used to irrigate the columns, and it was reduced to 26.4 mg/L when DI water was used as column influent.

In line with the Phase I findings, the Phase II bench-scale testing demonstrated that the best approach for the Coffee Mine water treatment is a multi-stage treatment train that consists of a phys-chem pretreatment for arsenic and sulfate precipitation, biological EBR treatment for denitrification and metals polishing, and a small aerobic post-treatment for removal of residual nutrients and reintroduction of dissolved oxygen. The list below presents the detailed findings pertaining to each unit process.

1. Chemical pretreatment

- **The pretreatment design took advantage of combining three steps to benefit the overall system performance.** The cyanide destruction step aided the oxidation of more reduced arsenic species and converted them into arsenate, which is the most amenable form of arsenic to ferric co-precipitation. Instead of further reagent additions after ferric dosing, barium salts that were used to precipitate sulfate also acted as coagulants and flocculants for the already formed arsenic precipitates.
- **System optimization demonstrated that arsenic could be removed to below the discharge target of 0.035 mg/L with ferric co-precipitation alone.**
  - Arsenic analysis had an accuracy of ±0.0068 mg/L.
- **Sulfate was shown to be removed from the Coffee waters to below the discharge target of 1,500 mg/L with barium precipitation alone.** Jar tests demonstrated that barium dose is directly proportionate to the amount of sulfate precipitated; greater or lower sulfate removal can be achieved with an adjusted Ba dose.
  - Sulfate analysis had an accuracy of ±61.9 mg/L.
  - The evaluated barium salts (barium chloride and barium hydroxide) resulted in elevated chloride concentrations passing through the treatment system. A jar test examination of

different barium salts alone and in combination is recommended once the mine is operational and actual site waters are available to establish the most suitable reagent dose to avoid generating excess chlorides.

  - **The implications of the successfully demonstrated pretreatment of both arsenic and sulfate include the need for a significantly smaller biological EBR system, no requirement for the addition of complex organic nutrients, and a lower organic carbon addition, resulting in lower residual nutrient concentrations.**
- **A 39% removal of total uranium was achieved on average with the chemical precipitation pretreatment.**
  - The pretreatment sludge removed the radioisotopes, rendering the following EBR treatment less likely to accumulate them. The average gross alpha radiation in the pretreatment sludge was 29 ±2.76 pCi/g, while gross beta radiation was 17.8 ±2.10 pCi/g.
- **Sludge generated in the pretreatment passed the TCLP analysis.**

2. EBR treatment

- **A single-stage EBR treatment operated with a 7-hr HRT and a 0.6 mL/L ethanol dose removed nitrate-N to below the detection limit of 0.3 mg/L.**
  - Nitrate-N analysis had an accuracy of ±0.004 mg/L.
  - Average nitrite-N concentration (an intermediary denitrification by-product) in EBR1 was 0.037 mg/L, meeting the discharge target of 0.09 mg/L.
- **Total uranium removal to below the discharge target 0.1 mg/L was achieved with the first-stage EBR treatment using an 11-hour HRT and 0.9 mL/L ethanol dose.**
  - Total uranium analysis had an accuracy of ±0.0111 mg/L
- Once optimized to target only nitrate and uranium, the EBR system was demonstrated to allow residual arsenic and sulfate to pass through without further reducing either one.
  - The speciation results show that the EBR system did not produce any methylated arsenic species, even during the preliminary testing stages, when residual arsenic was removed biologically.
- **In addition to the contaminants of interest, the EBR system removed the following metals from elevated concentrations in the influent waters to below their respective discharge targets: antimony, copper, mercury, molybdenum, and nickel.**
  - The EBR system removed all selenium species to below detection, including organo-selenium species that are more bioavailable in the natural environment.
  - Iron and manganese were present in the influent waters above their discharge targets and passed through the EBR system largely unchanged after the system was provided with ethanol as a sole nutrient source.
  - If present above their respective discharge targets, magnesium and calcium will need to be removed through an additional softening pretreatment step prior to EBR treatment. Although possible, removing hardness minerals in the EBR system is not advised because their elevated concentrations would load the bioreactor bed with solids and blind the activated carbon media in a relatively short amount of time (a few years).

- Monovalent cations, such as potassium and sodium, were present at higher levels than forecasted by the water quality models and exceeded their respective discharge targets. The EBR system cannot be used to target them.

- **The EBR system polished WAD cyanide to below the detection limit of 0.006 mg/L.**
- **Once the pretreatment was optimized, ethanol was used as a sole nutrient source for the EBR treatment, resulting in low residual nutrient generation.**
  - Ammonia-N concentrations of several mg/L were removed through an assimilatory pathway in the EBR treatment. However, since the influent NH_3-N concentrations were 465-times higher than forecasted (27.9 mg/L, instead of 0.06 mg/L), elevated ammonia still passed through the EBR system.
  - Average BOD concentrations stabilized at about 100 mg/L in the EBR system effluent.
  - Phosphate concentrations of 0.18 mg/L and 0.35 mg/L were generated from EBR1 and EBR2, respectively, when the average system influent carried 0.25 mg/L PO_4-P. A pilot- and full-scale installation is expected to not require any external phosphate additions and that the EBR system would remove some of the PO_4-P present in the influent waters through assimilatory pathways.
- **Neither the EBR treated effluents nor the EBR solids, including the activated carbon matrix as well as any precipitated residues and biofilm, accumulated gross radiation.**
- **EBR solids, including the activated carbon matrix as well as any precipitated residues and biofilm, passed the TCLP test.**

3. Aerobic post-treatment

- **Once optimized, the aerobic post-treatment removed BOD to below the detection limit of 5 mg/L.**
- **On average, the aerobic column removed ammonia-N to 7 mg/L, meeting the discharge goal of 8 mg/L while not generating excess nitrate/nitrite species.** The influent ammonia-N concentrations are forecasted to be present at 465-times lower concentrations (up to 0.06 mg/L) in the Coffee waters.
- **A significant spike of phosphate-P (5.85 mg/L on average) detected in the aerobic post-treatment effluent is attributed to phosphorus leaching out of the microbial support media (pumice) since no nutrients or reagents were added to the system.**
  - Quality control will be conducted on media used in pilot-scale tests and the full-scale installation to ensure no unexpected leaching of phosphate occurs.
- The aerobic post-treatment did not negatively affect any parameters removed by the EBR treatment upstream, except for manganese.
  - Manganese concentrations spiked in the post-treatment effluent to an average concentration of 0.271 mg/L – over 4.2x increase from the EBR system effluent. Since no nutrients or reagents were added to the post-treatment, the source of manganese can only be attributed to the pumice used as a support matrix inside the column.

APPENDIX 2-E

Work Plan to Demonstrate Feasibility of Passive Bioremediation Treatment of Heap Leach Rinse Solutions at Closure

TECHNICAL MEMORANDUM

To:	Jennie Gjertsen, Goldcorp
From:	Alan Martin Jane Nieuwenburg David Flather (Lorax Environmental Services Ltd.)
Date:	October 31, 2017
Subject:	**Coffee Gold Project: Work Plan to Demonstrate Feasibility of Passive Bioremediation Treatment of Heap Leach Rinse Solutions at Closure**

1. Introduction

The Coffee Gold Project (the Project) is evaluating the use of semi-passive treatment at closure to treat drain down from the decommissioned heap leach facility (HLF). Parameters of potential concern (POPCs) have been identified as arsenic, nitrate and uranium. Nitrate represents a residual product of cyanide degradation while As and U represent leached components from the ore. A semi-passive treatment system based on the principles of permeable reactive barrier (PRB) technology is being considered for the closure phase of the Project. In PRB systems, a permeable matrix (*e.g.*, gravel) is amended with one or more materials to create a reactive medium for contaminant removal. For example, zero-valent iron (ZVI) and/or carbon-based organic materials (*e.g.*, straw, sawdust, wood chips, etc.) have been successful in treating arsenic, nitrate and uranium (USEPA, 2005).

PRBs have been used for the treatment of groundwater contaminants since the 1980s, and have been documented in numerous reports and publications that summarize extensive research, field trials and full-scale implementations (*e.g.*, USEPA, 1998, 2005; Blowes *et al*., 2000; ITRC, 2005, 2011). There are numerous examples of successful full-scale PRB installations that have been operating for more than five to ten years. In this regard, PRBs are acknowledged as an appropriate and cost-effective technology for the treatment of mine-influenced water (ITRC, 2013). Given that PRBs are contained within the subsurface environment, they are minimally influenced by atmospheric temperature, and have been shown to function well in cold-interior climates (Benner *et al*., 1997).

To assess the potential application of PRB technology at the Project, a literature review was conducted (Lorax, 2017). The Lorax (2017) memorandum includes a general description of PRB systems, an overview of the biogeochemical processes responsible for the removal of arsenic, nitrate, and uranium, and a description of case studies summarizing the application of PRB systems designed to treat these parameters. Overall, the memorandum concluded that all Project POPCs have the potential to be treated using a common treatment design. Potential risks were also identified, including the potential for the generation of potentially-harmful by-products (*e.g.*,

ammonia, nitrite, ferrous Fe) as well as the performance of passive treatment systems in cold-interior climates.

Development of a final passive treatment system design will be dependent on the outcome of pre-feasibility level (lab-scale) and feasibility level (on-site pilot scale) studies. This memorandum, prepared by Lorax Environmental Services Ltd. (Lorax), provides a description of the proposed work plan in support of the lab-scale and on-site pilot-scale assessments. Ultimately, these components will be used to evaluate the merits and risks associated with passive treatment at the Project, and provide the input for final design.

2. Conceptual Design for Post-Closure Passive Treatment

During operations and the early stages of closure of the HLF, geomembrane covers (raincoats) will be used to reduce the amount of meteoric water infiltrating into the heap and entering the process solution. The heap will be rinsed and capped in stages (progressive closure), and as each stage is capped, the raincoats for that area will be removed and used in other areas or incorporated as part of the closure capping. Rinsing will be completed in two phases.

Phase I – Preliminary Rinsing

Preliminary rinsing of the heap will occur using process solution with the pH adjusted to below about 8 to facilitate the removal of cyanide through volatilization. The high vapor pressure of HCN causes free cyanide to volatilize where conditions favor a significant concentration of this species (pH below approximately10) and therefore volatilization increases with decreasing pH. The preliminary rinsing will continue until the chemistry of the heap effluent reaches approximate equilibrium with the rinse solution. Preliminary rinsing will begin in project Year 4 or 5 and then occur annually until about two years after cessation of active leaching for gold recovery, or until about project Year 13. Preliminary rinsing will advance along the heap in the same direction as ore stacking (east to west) and, once started, will progress at approximately the same rate as the westward advancement or stacking of the heap;

Phase II – Final Rinsing

Final rinsing is designed to dramatically reduce contaminant levels in heap solutions with the ultimate objective of reducing contaminant concentrations to levels acceptable for direct discharge to the environment. Final rinsing of the heap will be performed using fresh water (stored in the rainwater pond during or following the spring freshet or the mid-summer rainfall events), and treated process solution from the electrochemical bioreactor (EBR) or a combination of the two. The effluent from final rinsing will then be used as either rinse water from preliminary rinsing, or makeup water for the process circuit until active leaching for gold recovery is completed. Under the current HLF water balance, discharge of excess rinse water from the HLF to the receiving environment will be required beginning in approximately Year 9; this excess rinse water will require active treatment. Active treatment will involve the addition of hydrogen peroxide to

remove residual cyanide followed by biological treatment using electrochemical biological reactor technology (EBR) to remove nitrate (via denitrification) and reduce metals/metalloids to below discharge limits. Details on the workplan proposed for advancing the design of the EBR system for Coffee is presented under a separate memorandum.

As indicated above, some treated water from the EBR system will be used in Final Rinsing of heap leach cells. Final rinsing will begin one year after preliminary rinsing (project Year 5 or 6) and will continue until the entire heap has been rinsed, approximately Year 15. Rinsing with treated heap leach solutions is designed to foster *in situ* treatment of the heap and reduce the overall time for chemical stabilization of the heap leach pad. The concept is to rinse with EBR treated solutions as this water will be both free of contaminants and contain microbes from the bioreactor adapted to treating heap chemistry. Nutrients and soluble carbon (e.g. methanol, molasses, other soluble sugar and phosphate) will likely be added to the treated solutions prior to rinsing and application on the heap.

The addition of microbes, carbon and nutrients to the heap will foster reducing conditions within the heap pore waters allowing for *in situ* denitrification and the potential for reductive precipitation of metals and metalloids within the heap. This phase of *in situ* treatment is designed to treat constituents within the heap, as well as decreasing metals concentration to sufficient levels to either directly discharge, or at least provide water that is of sufficiently good quality to only require polishing in a passive treatment system.

The current conceptual design for this passive treatment system entails the conversion of one or more event ponds into bioremediation cells (Figure 2-1). A total of three events ponds could be available at closure for conversion to bioremediation cells. The total storage volume of the three events ponds combined is on the order of approximately 430,000 m^3. The proposed passive treatment system will ultimately be designed to collect heap leach seepage originating from the decommissioned facility and convey the solution through events ponds that have been converted to bioremediation treatment cells. To improve system performance and robustness under the climatic conditions experienced at Coffee, treatment will occur in the subsurface to minimize the potential influence of freezing temperatures during the spring and fall shoulder periods of open water. Seepage flow from the HLF will be conveyed to the subsurface through permeable coarse rock drains constructed along the upstream slope of the events ponds (Figure 2-2).

This design illustrates a two-stage treatment system, with the first cell serving to facilitate denitrification (using organic matter) and the second cell serving to reduce arsenic and uranium concentrations (using a combination of organic matter and ZVI) (Figure 2-2). Currently, it is not clear if a one-stage or two-stage system will be required. However, the two-stage conceptual design provides an example of how the system may be tailored to maximize the potential for nitrate reduction to proceed to nitrogen gas, and minimize the generation of ammonia.

In the presence of organic carbon (*e.g.*, wood chips), reduction of nitrate to nitrogen gas (N_2) under anaerobic conditions is thermodynamically favoured (Robertson and Cherry, 1995; Robertson *et al.*, 2000), as per Equation 1:

$$5CH_2O_{(s)} + 4NO_3^- \rightarrow 2N_{2(g)} + 5HCO_3^- + 2H_2O + H^+ \quad \text{Equation 1}$$

Reduction of nitrate to nitrogen gas is the preferred reaction pathway, since the nitrogen is removed from the system via release of N_2 gas to the atmosphere. In contrast, the reduction of nitrate to ammonia is not preferred, since the ammonia may be re-oxidized at some point downstream with no net loss from the system. Reduction of NO_3^- by ZVI, for example, may generate ammonia instead of nitrogen gas (Cheng *et al.*, 1997; Zhu and Getting, 2012), as per Equation 2.

$$4Fe(0) + NO_3^- + 10H^+ \rightarrow 4Fe^{2+} + NH_4^+ + 3H_2O \quad \text{Equation 2}$$

Although the final treatment configuration will be based on the results of the lab-scale and pilot-scale testwork, the basic principles are illustrated in Figure 2-2. In this design, seepage from the HLF will be conveyed to the pond bottom via a coarse gravel drain and permit upward vertical flow through the permeable reactive matrix. The reactive medium will comprise a mixture of gravel and amendments (*e.g.*, organic carbon and/or ZVI) to promote conditions conducive to the removal of nitrate, arsenic and uranium. Wood chips represent an ideal source of organic carbon given their local availability and successful application in bioremediation systems (USEPA, 1998). Baffles may be used to lengthen the flow pathways and maximize HRT. A 1 to 2 m layer of granular material will be placed on top of the reactive matrix to provide an insulating barrier to cold temperatures, thereby maximizing treatment potential during the winter months (Figure 2-2).

The conceptual design illustrated here deviates from traditional PRBs in terms of how flow is delivered and conveyed through the treatment system. In PRBs, flow is governed by the local groundwater flow field, and is placed to intercept a contaminated groundwater flow path. In the conceptual design described here, flow through the permeable reactive matrix is driven by upward hydraulic gradients imposed by the conveyance of the HLF effluent to the bottom of a lined pond (*i.e.*, imposition of upward flow).

Ultimately, the discharge from the passive treatment system will drain to the Latte pit, prior to release to the receiving environment. The long residence time afforded by the Latte pit will allow for final polishing processes if necessary, that may include particle settlement, oxidation of reduced species (*e.g.*, ammonia, nitrite, ferrous iron), and nutrient uptake by algae.

3. Proposed Work Plan

Based on the conceptual design for closure, a combination of lab-scale and on-site pilot-scale testwork is proposed. Pre-feasibility work will include lab-based column experiments, while feasibility testwork will entail the construction of a pilot-scale system at site. Each of these components is described in turn below.

3.1 Pre-Feasibility Column Testwork

As part of the pre-feasibility testwork program, column experiments will be conducted at the University of Waterloo (UW), under the oversight of Dr. David Blowes and Jeff Bain. David Blowes is one of the original pioneering scientists behind PRB technology, and together with Jeff Bain, bring considerable experience to the project. The column experiments will be used to:

- Demonstrate proof of principle (*i.e.*, can the technology reduce POPC concentrations to acceptable levels?);
- Determine POPC removal rates, which in turn have relevance to hydraulic retention time (HRT) requirements and treatment system dimensions;
- Evaluate the risks and merits associated with various reactive media, including wood chips and ZVI;
- Identify the nature of secondary minerals that may clog the system over time (relevance to the potential for hydraulic failure and system longevity); and
- Identify any potentially-problematic by-products that may be generated within the treatment system (*e.g.*, nitrite, ammonia, ferrous iron, hydrogen sulfide).

To address these objectives, three column configurations are proposed (Figure 3-1). The first configuration will encompass two columns in series, as per the conceptual design for the full-scale system illustrated in Figure 2. The first column (gravel + wood chips) will be used to promote denitrification (reduction of nitrate to nitrogen gas), while the second column (gravel + wood chips + ZVI) will be designed to reduce arsenic and uranium concentrations. Some arsenic and uranium removal may also occur in the first column in the presence of wood chips alone (Figure 3-1).

Column configurations #2 and #3 comprise single reaction cells, containing gravel + wood chips + ZVI (Figure 3-1). In the presence of ZVI, the reduction of nitrate to nitrogen gas can be favoured with sufficient organic carbon present, which is required to nourish denitrifying microbial assemblages (David Blowes, Pers. Comm.). In other words, the potential for ammonia generation can be theoretically minimized. Accordingly, it is possible that desired treatment outcomes may be achieved with a singular bioremediation design (i.e., single stage). To test this combined matrix, column configurations #2 and #3 have been designed with varying proportions of gravel + wood chips + ZVI (Figure 3-1).

Columns will be operated under fully saturated conditions over a period of 6 to 12 months, commencing in the first quarter of 2018. The columns will be configured to accommodate HRTs on the order of 4-7 days. Effluents will be monitored on a bi-weekly basis for a full suite of parameters including:

- General parameters: pH, redox potential, EC, temperature
- Major ions: Ca, Mg, Na, K, F, Cl, Br, HCO_3, SO_4
- Nitrogen and phosphorus (P) species: ammonia, nitrite, nitrate, phosphate-P, total-P

- Trace elements: As, Cd, Co, Cr, Cu, Fe, Mn, Ni, Pb, Sb, Se, Ti, Tl, V, U, Zn
- Organics: DOC, propionate, acetate (as indicators of carbon reactivity)
- Other: H_2S

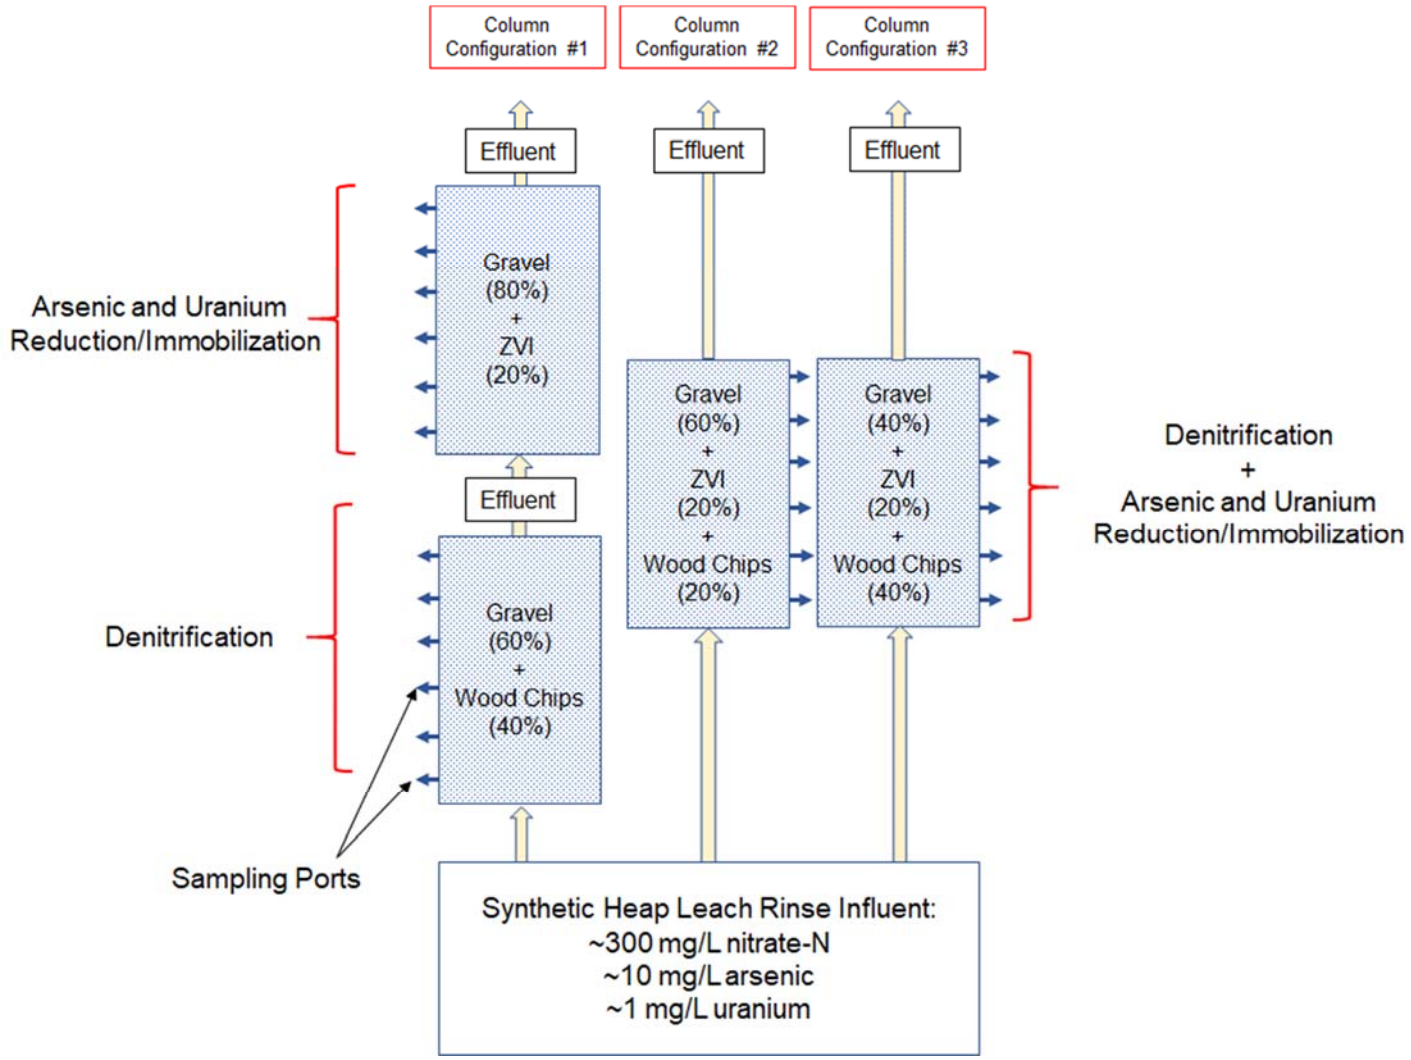

Figure 3-1: Conceptual schematic of proposed lab-based passive treatment experiments. ZVI = zero valent iron.

In addition to the column effluents, water quality samples will be periodically collected at multiple points within each column (sample ports shown in Figure 3), to quantify the spatial distribution of POPCs along the length of the column. These profile data are used to better quantify reaction rates.

The UW column experiments will require the generation of a synthetic HLF seepage. A representative solution will be generated by cyanide leaching of representative Coffee Gold ore. In order to produce representative nitrate concentrations, leaching solutions will be spiked with 300 mg/L nitrate-N.

3.2 Feasibility On-Site Pilot Scale Testwork

Feasibility testwork will be conducted on a pilot-scale under site climate conditions at the mine. This will involve the construction of a small-scale passive treatment system similar to the conceptual configuration shown in Figure 2-2. To permit acquisition of the most valuable data, pilot-scale experiments will be implemented with similar materials and construction methods as would be used for a full-scale application. The spatial dimensions of the pilot-scale test have not been finalized, and will be informed by the results of the lab-scale work. Overall, the results of pilot- scale testwork will be used to better quantify:

- Reaction rates under site conditions;
- Limits of system performance;
- Longevity;
- HRT requirements;
- System dimensions and footprint;
- Potential failure modes (hydraulic failures, generation of problematic parameters); and
- Construction and operational costs.

Effluents representative of the HLF will become available in the early closure period (Year 4) owing to progressive reclamation. This will provide an invaluable opportunity to conduct the pilot-scale studies with actual effluent, which will increase the confidence in the resulting data and the final design recommendations.

4. Closure

We trust that this memorandum meets your expectations at this time. Please contact the undersigned with any questions or comments.

Respectfully submitted,

1. Introduction

The mine life cycle, from exploration to mine closure can be fast-paced and volatile, therefore careful consideration should be given to remediation planning of mine sites. Ensuring strategies are developed which are both cost effective, and appropriate to the climate and biome of which the mine site is located, are essential. Of particular concern to gold-mining operations in Northern climates are waste by-products of cyanide degradation; metal leaching (ML) and acid mine drainage (AMD); and extreme cold conditions which have potential to hamper biological processes involved in bioremediation methods.

Exposure of mine tailings to water and oxygen cause acid-generating reactions to occur and the now-reactive tailings become a source of the effluent commonly known as AMD in ground and surface water (Johnson 2003). Generally, AMD is characterized by low pH and high concentrations of sulphate, iron, and dissolved metals (Blowes et al. 1994).

Due to the acidic conditions created by AMD, arsenic sulfidic ore such as arsenopyrite (FeAsS) leaches arsenic from gold heap leaches (Roussel et al. 2000). Arsenic (As) in aquatic environments usually exists in inorganic forms as arsenate (As(V)) and arsenite (As(III)). As (III) is usually more mobile and toxic then As (V) although As (III) can also become immobilized in the presence of sulfide (Bissen and Frimmel 2003; Stauder et al. 2005). However, ML of As from arsenic minerals at neutral pH due to oxidation can occur in heap leach waste (Mend 10.1).

Cyanide leaching is used in 90% of gold ore beneficiation (Yarar 2002). The cyanide used in ore processing degrades into a combination of ammonia, carbonate, and sulfate, wherein ammonia

converts to nitrate (NO_3^-) through the 2-step nitrification process, leaving nitrate as a by-product in the surrounding groundwater and waterways (Akcil 2003). High levels of NO_3^- in waterways, and consequently drinking water, can potentially cause methemoglobinemia in infants and gastrointestinal cancer in adults (Kundu et al. 2008). As well, excessive nutrients, such as phosphate and NO_3^-, can lead to eutrophication of waterways (Boeykens et al. 2017).

Many methods of removing and/or reducing As and NO_3^- from mine waste have been studied. Engineered denitrification systems with woodchips used as a carbon source have been studied and implemented in agricultural settings for the removal of nitrate. These engineered dentrification systems provide an environment that supports the growth of denitrifying bacteria. Denitrifying bacteria utilize nitrate to oxidize woodchip carbon, and in the process reduce NO_3^- to N_2 gas (Blowes et al. 1994; van Driel et al. 2006; Christianson et al. 2010, 2011a,b; Schipper et al. 2010; Woli et al. 2010).

Zero-valent iron (ZVI) has been successfully deployed as a reactive material for the treatment of arsenic (Su and Puls 2001). ZVI immobilizes As by adsorption of As (V) or As (III) onto iron corrosion products in the shell surrounding the elemental iron core and this is sometimes accompanied by reduction As (V) to As (III) (Rao et al. 2009; Manning et al. 2002; Kanel et al. 2006; Bang et al. 2005). Adsorption contributes to the collection of molecules by the internal surface or the external surface of solid matter or by the surface of liquids. Absorption, with which it is often confused, refers to processes in which a substance enters the very interior of crystals, blocks of amorphous solids, or liquids. Adsorption is characterized by the ability of all solid substances to attract molecules of gases or solutions with which they are contacted to their surfaces.

Successful use of ZVI as a reactive material, in conjunction with the development of biological denitrification systems within a permeable reactive barrier (PRB) for the reduction of As and NO_3^- have been observed (Lee et al. 2009; Johnson et al. 2008). In spite of successful use of PRBs to treat these contaminants, there is very little data available on the efficacy of PRBs utilizing ZVI and denitrification under cold conditions.

In this bench-scale column experiment, the efficacy of a PRB at low temperature (4°C) was tested. The PRB consisted of ZVI for arsenic adsorption, woodchips for the facilitation of denitrifying bacterial activity to reduce nitrate, and gravel to create an insulating effect. Two columns with varying ratios of woodchips, gravel and ZVI (Tab. 1) were tested. The ratio of amendments and hydraulic residence time (HRT) were adapted from an experiment designed by Lorax Environmental Services Ltd. and implemented by YukonU Research Centre's Industrial Research Chair in Northern Mine Remediation for Newmont Corporation's proposed Coffee Gold Mine.

2. Materials and Methods

2.1. Synthetic Mine Water Preparation

A synthetic mine water (SMW) stock solution was prepared by adding specific heavy metals into deionized water to reach the concentrations similar to mean concentrations found in mine wastewater analyzed from Golden Predator's Brewery Creek mine located in Yukon. Due to the location's proximity to Coffee Gold mine and similar processing used, Brewery Creek mine was

chosen by Lorax Environmental Services Ltd. as an analog site to model predicted post-closure heap leach waste solution metal concentrations. The SMW stock solution was prepared using the following metal salts: KNO_3, $MgSO_4 \cdot 7H_2O$, As_2O_5, and $FeCl_3 \cdot 6H_2O$ (Tab. 1). Mass of each metal salt used calculated based on target metal ion concentration (App. A).

Table 1. Metal salts used to reach target concentrations of target metal ions in SMW solution.

Metal Salt	**Target Metal Ion**	**Target Concentration (mg/L)**
Potassium Nitrate (KNO_3)	Nitrate (NO^-_3)	300
Magnesium Sulphate Septahydrate ($MgSO_4 \cdot 7H_2O$)	Magnesium (Mg)	200
Arsenic Pentoxide (As_2O_5)	Arsenic (As^{+5})	20
Iron (III) Chloride Hexahydrate ($FeCl_3 \cdot 6H_2O$)	Iron (III) (Fe^{+3})	0.5

A total of 16 litres of SMW was prepared for the duration of the experiment based on the calculations of HRT and flow rates (App. B). The SMW was tested for pH, electrical conductivity (EC) and oxidation reduction potential (ORP). pH measurements were performed using a pH meter (650 PCD, Oakton, Vernon, IL, USA) equipped with a double junction Ag/AgCl electrode (Cole Parmer Canada, Montréal, QC, Canada). Calibration of the pH meter was performed before testing using certified buffer solutions (buffer solution pH 10.00; pH 7.00; pH 4.00, Fisher Scientific, Montréal, QC, Canada). Oxidation reduction potential (ORP) measurements were performed using a double junction electrode ORP (ORP Electrode tested. 59001-77, Cole Parmer, Montréal, QC, Canada). Calibration of the ORP meter was performed using a certified solution (ORP Standard, Thermo Fisher Scientific, Waltham, MA, USA). Electrical conductivity (EC) measurements were performed using an EC metre (650 PCD, Oakton, Vernon, IL, USA). Calibration of the EC metre was performed using a certified solution (Conductivity Standard, Thermo Fisher Scientific, Waltham, MA, USA). Two samples were taken of the SMW for metals and nitrate analysis. The metals sample was acidified with HNO_3

and analyzed via CRC ICPMS by ALS Environmental (Vancouver, BC). The NO_3^- sample was acidified with H_2SO_4 and analyzed via ion chromatography by ALS Environmental (Vancouver, BC).

2.2. Column Construction

Two cylindrical columns (Fig. 1) made of 1.1 cm thick Plexiglas™ were used for this experiment. The internal diameter of these columns was 6.4 cm, and the length was 63 cm. Each column was sealed closed at the bottom by bolting a Plexiglas™ plate to it with the same external diameter. Between the column and end plate, a rubber gasket was used to ensure an air-tight seal was achieved. Each end plate was fitted with an outlet port with ~ 1 mm opening hole and sealed additionally with epoxy. L/S Masterflex 16 ID tubing (Cole-Parmer Canada Company, Montreal QC) was attached to the outlet port.

0.45 μm cellulose acetate filter cut to the diameter of the column opening was wetted with deionized water and placed inside of the column against the end plate. To ensure equal distribution of SMW into each column, 139.58 g of Ottawa Sand (Fisher Scientific, Ottawa ON) was placed on top of the filter paper measuring ~ 1 cm in height in each column. The experimental setup was placed in a laboratory refrigerator (Fisher Scientific Isotemp Refrigerator, Ottawa, CA) to ensure a temperature of 4°C was maintained throughout the experiment.

(b)

Figure 1. (a) Schematic of column design and experimental setup. (1) influent (SMW); (2) peristaltic pump; (3) column; (4) effluent. Schematic is not to scale. (b) Picture of actual experimental setup located in the Yukon U Research Centre Laboratory.

2.3 Column Substrates

Each column had a unique mixture of reactive materials. The reactive materials used in this experiment were wood chips, gravel and ZVI. The different percentages of each material were chosen based on a design by Lorax Environmental Services Ltd. (Tab. 2). The ratio was chosen to design a column system which would allow for the treatment outcomes desired through a single-stage system.

The woodchips were sourced from Wiley Mill (Vancouver, BC) and were not representative of available woodland found near the Coffee mine. Gravel was sourced from the City of Whitehorse gravel pit (Whitehorse, YT). The gravel contained limestone and was not

characteristic of the geology found at Coffee Mine. The ZVI was -8 +50 mesh screened and sourced from Connelly GPM (Chicago, IL).

The mass of each substrate was calculated based on the density of each material. Each substrate mixture was amalgamated prior to packing into each column.

Table 2. Substrate (ZVI, gravel and woodchips) ratios of column 1 and column 2.

Substrate	Column 1	Column 2
Woodchips	20%	40%
Gravel	60%	40%
ZVI	20%	20%

2.4. Hydraulic Residence Time

A target HRT of 4 days was pre-determined by Lorax Environmental Services Ltd. (Vancouver, BC) in consultation with Dr. David Blowes (University of Waterloo, Waterloo ON). The flow rate was calculated by the pore volume for each column. The pore volume was determined by completely filling each packed column with deionized water (DIW). The volume of DIW used to fill each column was determined to be the pore volume.

2.5. Experimental Design

The SMW, Column 1 and 2 were placed in a refrigerator (Fisher Scientific Isotemp Refrigerator, Ottawa, CA) which was maintained at 4 C° for the duration of the experiment (Fig. 1b). SMW was fed via Masterflex peristaltic pumps (Cole-Parmer Canada Company, Montreal QC) from below the columns into the bottom port of each column. The SMW was fed continuously throughout the experiment with the exception of sampling days, wherein flow was stopped temporarily. Volume levels of effluent collected over each 4-day cycle was monitored to ensure target flow rates were maintained. On the 4th day of each cycle, flow was stopped, and samples

were taken for nitrate and metals analysis, as well as pH, EC and ORP measurements of the effluent. The effluent was then discarded, and flow was reinitiated into the columns to start the next 4-day cycle.

3. Results and Discussion

3.1. Porosity and flow rate calculation

The pore volumes were determined to be 834.9 mL for column 1 and 960.1 mL for column 2. To achieve the target HRT of 4 days the flow rates were back calculated using an HRT of 4 days and the pore volumes using the following formula:

Flow rate (m^3/day) = pore volume (m^3) / HRT (days) **Equation 1**

The flow rates were determined to be 0.14 mL/min for column 1 and 0.17 mL/min for column 2 (App. B).

3.2. Arsenic

The experiment began with an expected high concentration of As in the SMW influent, at 19.0 mg/L (target As concentration = 20 mg/L (table1)). Once SMW influent passed through each column, dramatic reduction As concentrations decreased dramatically. In column 1, the As concentration decreased to 6.43×10^{-2} mg/L after the initial 12-day period, and in column 2, the As concentration decreased to 1.12×10^{-3} (Fig. 2). Over time, As concentrations continued to trend downward in column 1, eventually reaching a concentration of 8.10×10^{-4} mg/L in effluent collected on the final (28th) day of the experiment. In column 2, the As concentration reached its lowest concentration on the 24th day at 9.50×10^{-4} mg/L. The As concentration began to rise in

the effluent of column 2 after the 24th day, rising from 9.50 x 10^{-4} mg/L to the final concentration of 1.81 x 10^{-2} mg/L.

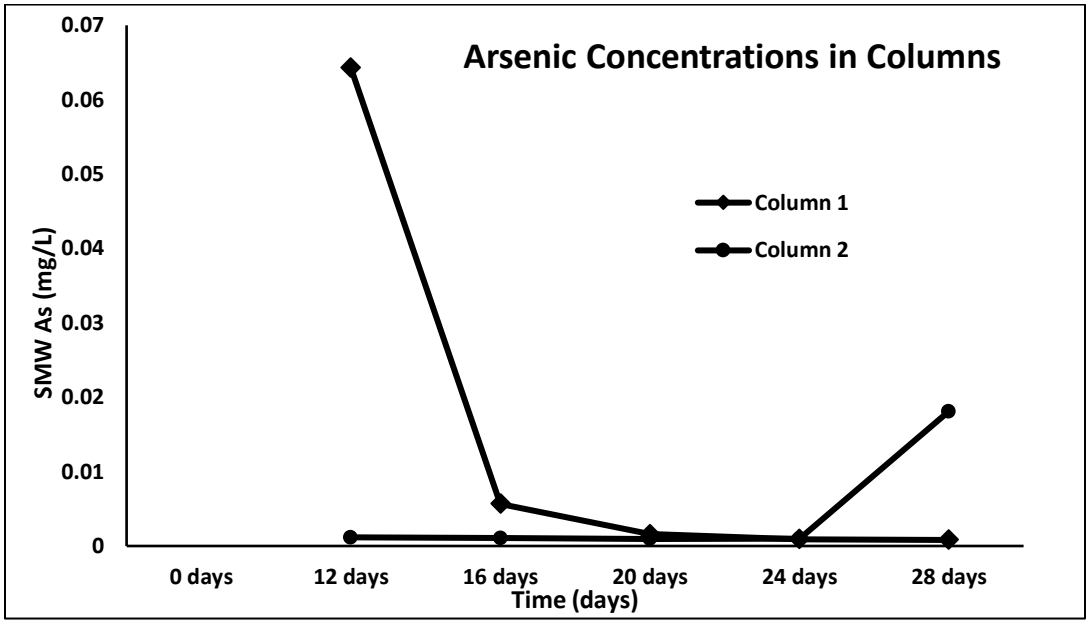

Figure 2. Graph of As concentrations (mg/L) over time throughout the experiment in column 1 and 2.

Overall, there was a high As removal rate of >99.0% observed in both column 1 and column 2 throughout the experiment (Fig. 3). A slight decrease in the removal rate of As in column 2 was observed on the final day, decreasing from 99.99% to 99.92%.

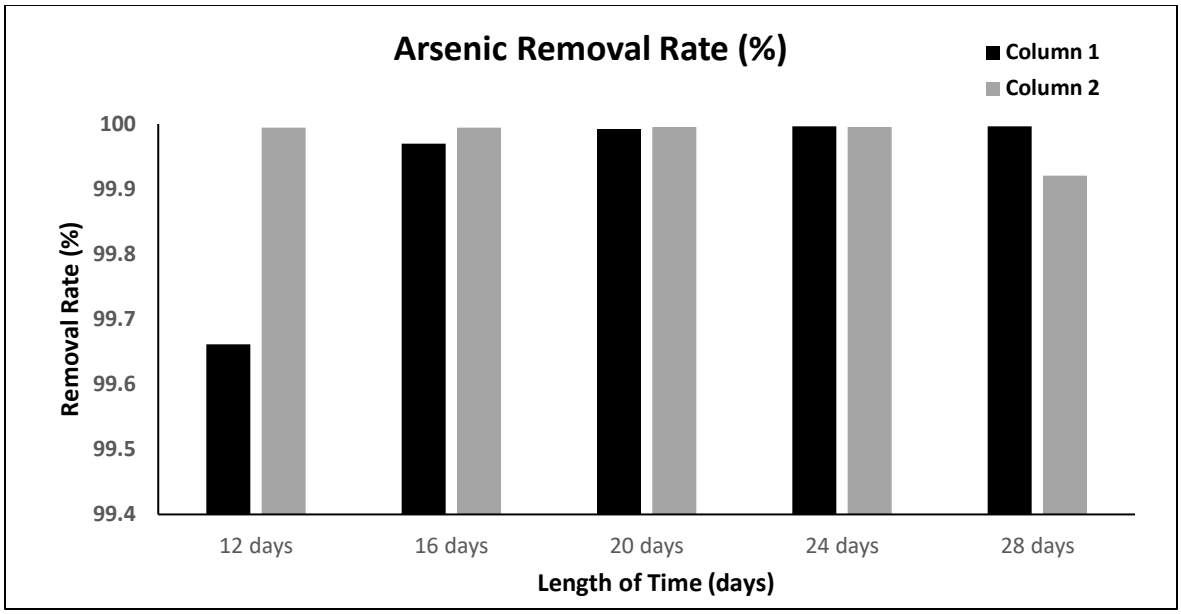

Figure 3. Removal rates (%) of As analyzed in the effluent of column 1 and 2 over time.

The decreased of As concentrations in the SMW throughout the experiment are consistent with the adsorptive qualities of ZVI. Over time, Iron (Fe) concentrations within effluent samples decreased over time in tandem with a decrease in As concentrations (Fig. 4). These findings suggest Fe corrosion products, such as ferrous hydroxide; mixed valence Fe oxides and hydroxides; and ferric oxyhydroxides formed.

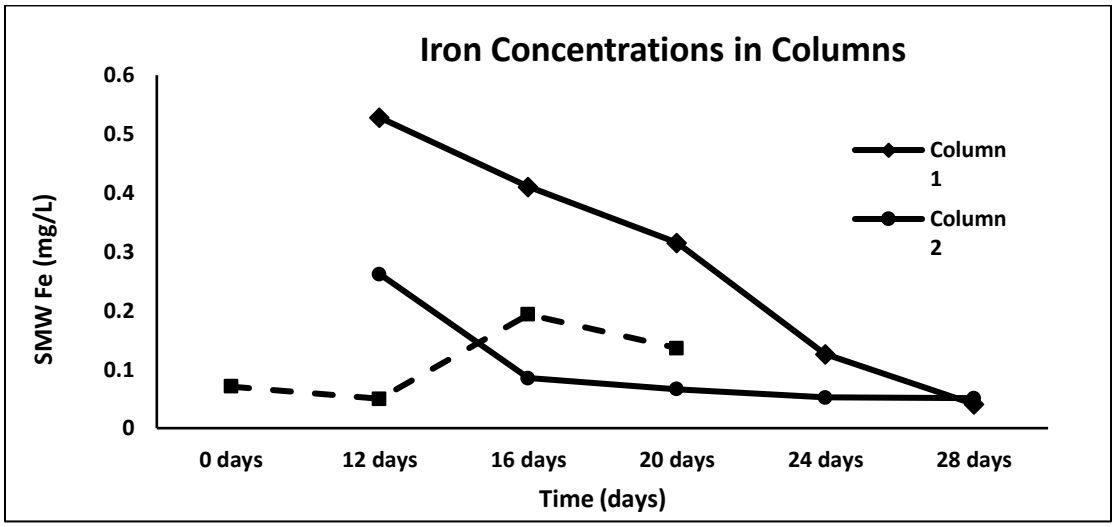

Figure 4. Graph of Fe concentrations over time throughout the experiment of column 1 and 2.

This was further demonstrated by visible greenish deposits, which were likely evidence of iron oxide formation (Fig. 5). Likely, As was adsorbed to ZVI within the columns, and Fe corrosion products complexed with the adsorbed As (Rao et al. 2009).

Figure 5. Green coloured deposit found in columns at end of experiment.

It is unknown whether the As (V) present in the SMW was reduced to As (III) within each of the columns. However, reducing conditions were observed through ORP readings of the effluent from each column throughout the experiment, ranging between -72 mV to -8 mV and -49.5 mV

to -0.3 mV, for Column 1 and 2 respectively. It is possible reduction of As (V) to As (III) occurred.

3.2. Nitrate

The target NO_3^- concentration of the SMW was 300 mg/L, however, upon analysis, the NO_3^- concentration was found to be 68.7 mg/L (Fig. 4). To exclude the possibility of faulty measurement of the original metal salt (KNO_3) in the creation of the SMW, back-calculation of the expected concentration of potassium based on the called for weight of KNO_3, was found to be 191.26 mg/L. The metals analysis of the SMW showed a potassium concentration of 191.0 mg/L (not shown). It is likely the NO_3^- decomposed to various nitrogenous products in solution, such as HNO_3, HNO_2, NO, NO_2, etc. (Stern 1972).

Each column produced a reduction of NO_3^- of varying concentrations in the first samples of effluent collected. Column 1 NO_3^- concentration decreased from 68.7 mg/L to 8.43 mg/L and in column 2 NO_3^- concentration decreased from 68.7 mg/L to 22.4 mg/L at day 12. After day 12, NO_3^- concentrations continued to be lower than SMW concentrations, however, removal rates lessened for the rest of the experiment (Fig. 6).

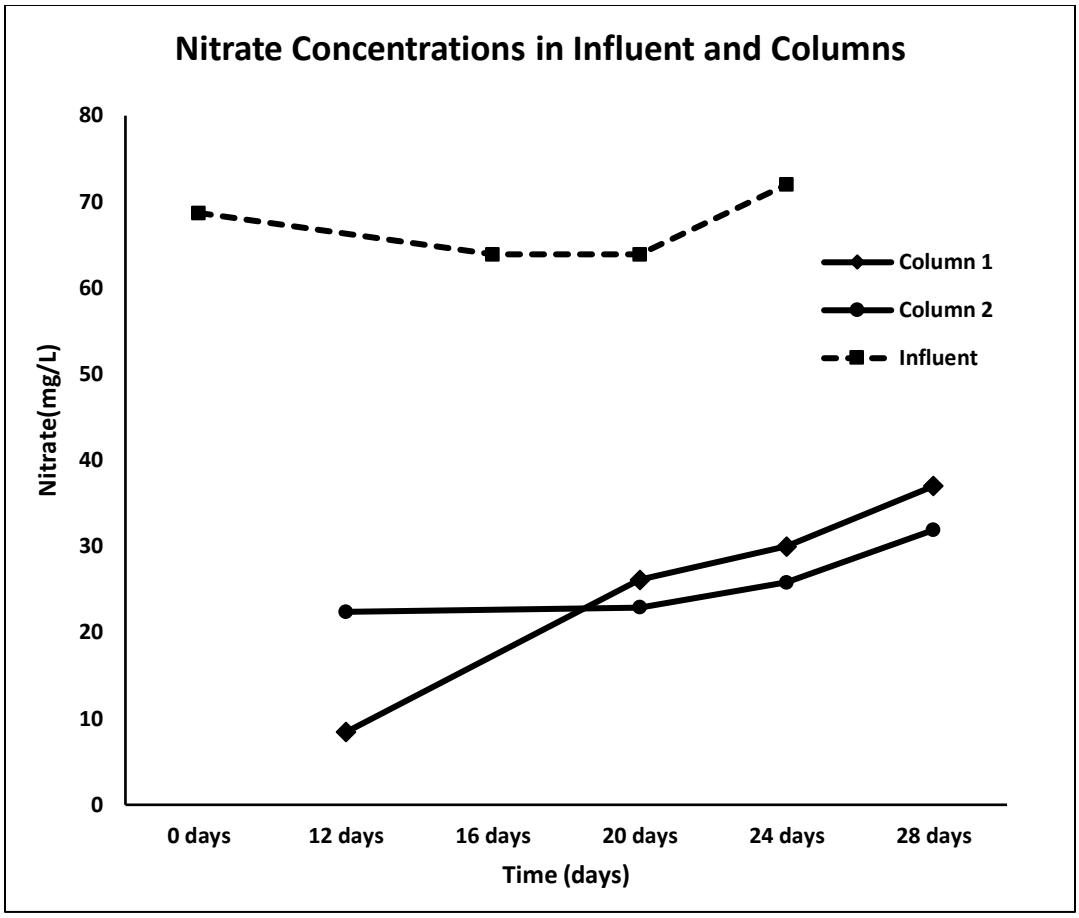

Figure 6. Graph illustrating the concentrations of NO_3^- in influent samples and effluent samples of column 1 and 2 over time.

Broadly, removal rates of NO_3^- in column 1 decreased from 87.7% to 48.6% over the course of the experiment. Removal rates of NO_3^- in column 2 decreased from 67.4% recorded at the beginning of the experiment to 55% removal rate recorded at the end of the experiment.

The concentrations of NO_3^- analyzed in the effluent of each column seem to indicate that denitrification is not the mechanism by which NO_3^- concentrations decreased in the columns. Although denitrifying bacteria are known for slow growth in culture (Koike and Hattori 1974), as well as the inhibiting effect cold temperatures can have on growth rates of denitrifying bacteria (Palacin-Lizarbe et al. 2018), the total length of the experiment, 4 weeks, is typically enough time for growth of denitrifying bacteria colonies. If substantial denitrifying bacteria colonies existed, i.e. if the columns were inoculated with bacteria from the gravel and woodchips

amendments, constant NO_3^- removal rates throughout the experiment would be observed. In contrast, a declining removal rate in each column was observed (Fig. 7).

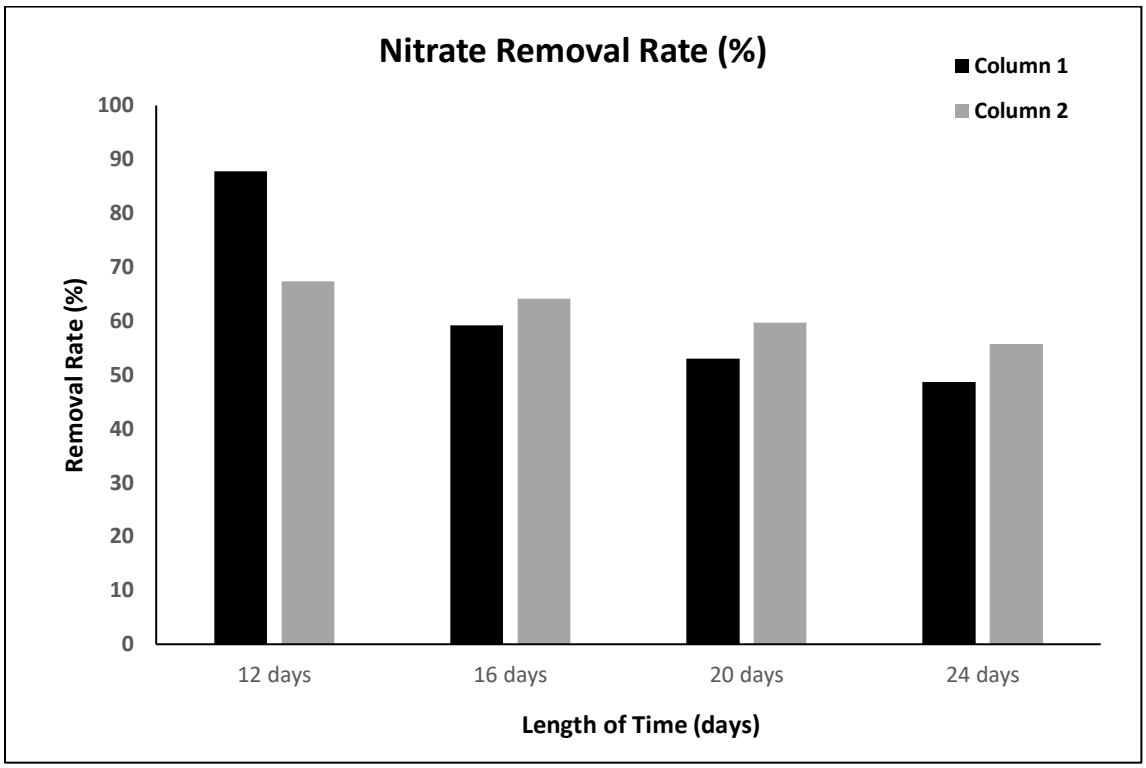

Figure 7. Graph showing NO_3^- removal rates in column 1 and 2 over time.

Total organic carbon (TOC) was analyzed in the SMW influent and effluent samples throughout the experiment. TOC analyzed from the effluent samples, had starting concentrations of 205.15 mg/L and 415.58 mg/L, for column 1 and 2 respectively. As no extraneous carbon source was added to the SMW, it is assumed TOC comes from woodchips. This aligns with the ratio percentage of woodchips in each column, as column 1 had 20% woodchips, and column 2 had double, at 40%. Over time, the TOC concentrations in the effluent of each column decreased with rates consistent of natural release of dissolved organic carbon from woodchips in bioreactors (Abusallout and Hua 2017). For this reason, it is unlikely the decrease in carbon over time can be attributed to denitrifying bacteria metabolic processes.

3.3. pH

pH analyzed in both the SMW influent, and effluent of each column, showed a progression of very acidic conditions in the SMW influent, pH 3.80 ± 0.03, to 8.86 ± 0.25 and 8.06 ± 1.47 for columns 1 and 2 respectively (Fig. 8). As the gravel used in the PRB had a makeup that included limestone, it is assumed the dissolution of $CaCO_3$ from the limestone created alkaline conditions within the columns, raising the pH overall (Cravotta and Traham 1999).

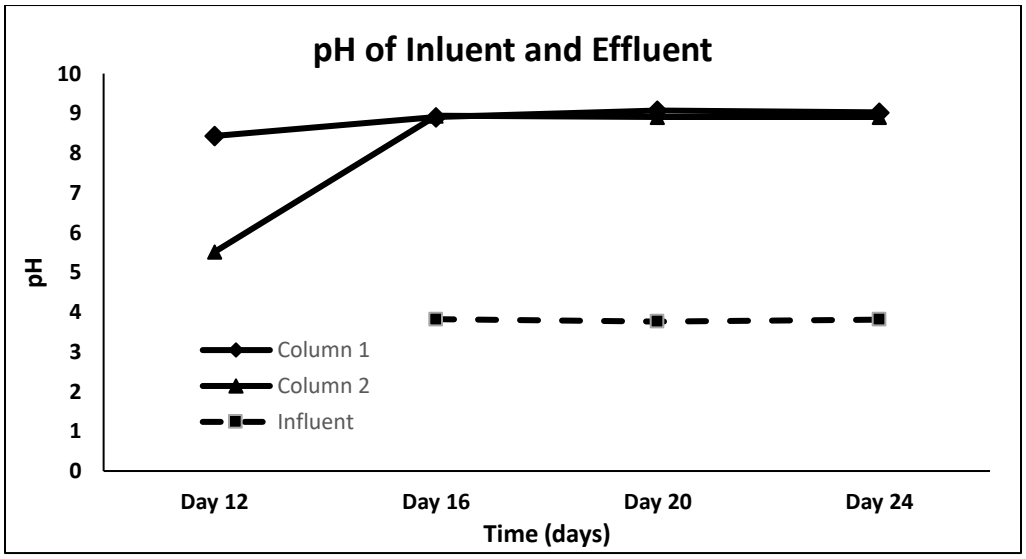

Figure 8. Progression of pH over time in influent and effluent of column 1 and 2.

4. Conclusions

Due to possible negative environmental and public health impacts, mitigating excessive metals and nutrient discharge, such as As and NO^{3-} from heap leach pads is of critical importance to the gold mining industry when considering mine waste management. While mitigation strategies need to be effective, Industry also seeks to reduce costs whenever possible. Bioremediation methods, such as PRBs, may potentially meet these demands. However, there is currently a dearth of research of the use of these methods in cold climates.

The results of this experiment demonstrated, under laboratory conditions, the capability of PRBs in reducing As and NO^{3-} concentrations to concentrations within the target concentrations for heap leach/passive treatment discharge during closure and water quality objectives (Lorax 2019).

This is especially true for multivalent metals such as the metalloid As, where reactive materials such as ZVI can be used as an adsorbent to remove As under cold climate conditions, as was demonstrated in this experiment.

Although there was a reduction in NO^{3-} overall, it cannot be determined if this was completed by adsorption or denitrification. Further study is needed to determine the efficacy of reducing NO^{3-} via denitrification within PRBs in cold climate conditions. Specifically, the use of analyses of parameters such as the progression of NO^{2-} concentrations, bacteria enumeration assays and genetic identification of existing bacterial colonies within PRBs.

Although there is a large body of literature on the efficacy of PRBs in mining activity, there is still a lack of data on their use in cold climate conditions. Of particular importance, and relevant to the parameters of concern in this experiment, is the ability to cultivate denitrifying bacteria in cold conditions typically found at mine sites in Yukon. Lastly, in light of effects of climate change, varying weather conditions, e.g. high vs low precipitation patterns, should also be considered in future cold climate PRB studies.

Appendix A

Calculation of Target Metal Ion Concentrations in SMW

Arsenic

Metal salt used: As_2O_5, 229.8402 g/mol
Target metal ion concentration: 20.0 mg/L*

% Ratio

As = 149.8 g/mol / 229.8402 g/mol = 65.18%

20 mg = 0.02 g

$$\frac{0.02\ g}{x\ g} \times \frac{65.18\%}{100\ \%}$$

x = 0.0307 g/L of As_2O_5

Nitrate

Metal salt used: KNO_3, 101.1032 g/mol
Target metal ion concentration: 300.0 mg/L

% Ratio

NO_3 = 62.006 g/mol / 101.1032 g/mol = 61.33%

300 mg = 0.30 g

$$\frac{0.30\ g}{x\ g} \times \frac{61.33\%}{100\ \%}$$

x = 0.4892 g/L of KNO_3

Magnesium

Metal salt used: $MgSO_4 \cdot 7H_2O$, 246.48 g/mol
Target metal ion concentration: 200.0 mg/L

% Ratio

Mg = 24.3 g/mol / 246.48 g/mol = 9.86%

200 mg = 0.20 g

$$\frac{0.20\ g}{x\ g} \times \frac{9.86\%}{100\ \%}$$

x = 2.03 g/L of $MgSO_4 \cdot 7H_2O$

Iron

Metal salt used: $FeCl_3 \cdot 7H_2O$, 270.30 g/mol
Target metal ion concentration: 0.5 mg/L

% Ratio

Fe = 55.8 g/mol / 270.30 g/mol = 20.64%

0.5 mg = 0.0005 g

$$\frac{0.0005\ g}{x\ g} \times \frac{20.64\%}{100\ \%}$$

x = 0.0024 g/L of $FeCl_3 \cdot 7H_2O$

*20 mg/L was used as the target concentration for arsenic due to a misreading of projected heap leach solution arsenic concentrations for Coffee Gold mine. The actual projected concentration is 2.0 mg/L of arsenic.

Appendix B

Calculation of Flow Rates in Column 1 and 2

Equation: Flow rate (m^3/day) = pore volume (m^3) / HRT (days)

Column 1

Pore volume = 834.9 mL or 8.35 x 10^{-4} m^3

HRT target = 4 days

Flow rate (m^3/day) = 8.35 x 10^{-4} m^3 / 4 days

Flow rate = 2.087 x 10^{-4} m^3 / day

Flow Rate = 208.73 mL / day

Flow Rate = 0.14 mL/min

Column 2

Pore volume = 960.1 mL or 9.60 x 10^{-4} m^3

HRT target = 4 days

Flow rate (m^3/day) = 9.60 x 10^{-4} m^3 / 4 days

Flow rate = 2.40 x 10^{-4} m^3 / day

Flow Rate = 240.025 mL / day

Flow Rate = 0.17 mL/min

1. Background and Objectives

Newmont™

1. Background and Objectives

The Coffee Gold Project (the Project) is evaluating the use of semi-passive treatment at closure to treat drain down seepage water from the decommissioned heap leach facility (HLF). Parameters of potential concern (POPCs) in heap leach seepage waters have been identified as nitrate, arsenic and uranium. Nitrate represents a residual product of cyanide degradation while As and U represent leached components from mined ore.

A semi-passive treatment system, based on the combined principles of permeable reactive barrier (PRB) technology and biological reactor (BR) technology, is being considered for the closure phase of the Project. In PRB/BR systems, a permeable matrix is amended with one or more materials to create a reactive medium for contaminant removal. As part of the pre-feasibility testwork program, column experiments were conducted using varying compositions and configurations of gravel, wood chips and zero valent iron (ZVI) to evaluate treatment performance of the aforementioned POPCs. All column testwork was conducted at the Yukon Research Center, Yukon University with the support of Lorax Environmental Services Ltd. (Lorax).

The specific objectives of the column study include the following:

- Demonstrate proof of principle for the proposed technology to reduce POPC concentrations in heap leach seepage solutions to acceptable levels;
- Determine POPC removal rates, which are relevant to hydraulic residence time (HRT) requirements and treatment system dimensions;
- Assess the risks and merits associated with the reactive media;
- Evaluate the applicability of a carbon amendment to enhance nitrate removal; and,
- Identify any potentially problematic by-products that may be generated within the treatment system.

2. Methods

Newmont™

2. Methods

2.1 Experimental Design and Material Characterization

The reactive medium for the column study comprises a mixture of gravel, wood chips and ZVI to promote chemical conditions conducive to the removal of nitrate, As and U. The selection of column materials was informed by the current literature on PRB/BR as well as relevant considerations regarding the local availability of source materials. A rationale for the inclusion of each material as a component of the treatment columns is provided below.

- Gravel provides a permeable matrix for structural support and to enhance flow; additionally, the presence of mineral surface areas can faciliate contaminant removal via adsorption.
- Wood chips provide a carbon source (an electron donor) which can stimulate microbial activity to reduce contaminant species to less soluble forms.
- Zero valent iron (ZVI), in addition to or as an alternative to carbon, is an electron donor which can stimulate chemical reduction of contaminant species.

Specifications and photographs for column materials are presented in Table 2-1 and Figure 2-1 respectively. Note that these materials are not intended to be directly representative of the components that will ultimately be utilized for a semi-passive bioreactor at the Coffee site. Rather, selection was based on fulfillment of experimental design requirements with the primary objective of providing proof of principle for the use of a ZVI mixture for treatment of enriched contaminants in the HLF drain down seepage.

Table 2-1:
Sources and Specifications for Column Materials

Column Material	Source	Specifications
Gravel	City of Whitehorse, YT	The gravel is of mixed composition, containing roughly equal portions of an intrusive granite and mixed, fine-grained clastic sedimentary rocks. The gravel composition is decidedly heterogenous and derived from surficial materials. Grain sizes range from 8 mm to 16 mm.
Wood Chips	City of Whitehorse YT	50% wood chunks shredded by the Wiley Mill + 50% splintered wood (< 25 mm)
Zero Valent Iron (ZVI	Connelly GPM Inc. (Chicago, United States)	ETI CC-1004 (<2.4 mm)

Figure 2-1: Photographs of gravel, wood chips and ZVI (from left to right).

Analytical procedures applied for characterization of solid phase materials are described in the report: *Updated Work Plan and Standard Operating Procedures for Passive Treatment Column Study* (Lorax , 2020) and provided in full in Appendix A. Solid phase analytical testing of post-test column residues is planned for 2022 which will include supplementary mineralogy characterization.

2.2 Column Experiment

2.2.1 Treatment Configurations

Three column configurations were investigated in the bench-scale study (Figure 2-2). For all configurations, the composition of ZVI is maintained at 20%. Column Configuration #1 (C1) encompasses two columns in series:

- *Initital column C1A* - containing gravel and wood chips (and no ZVI) is intended to initially promote denitrification (the reduction of nitrate to nitrogen gas) prior to treatment via the secondary column (C1B)
- *Secondary Column C1B* - containing gravel and ZVI, and designed to reduce As and U concentrations.

Some degree of As and U removal may also occur in the primary column in the presence of wood chips alone. Column Configuration #2 (C2) and Column Configuration #3 (C3) comprise single reaction cells, containing a mixture of gravel, wood chips and ZVI (Figure 2-2). These experiments were designed to evaluate whether the desired treatment outcomes may be achieved with a single stage bioremediation design. To test the performance of this combined matrix, C2 and C3 have been designed with varying proportions of gravel (40% and 60%) and wood chips (20% and 40%) as noted in Figure 2-2.

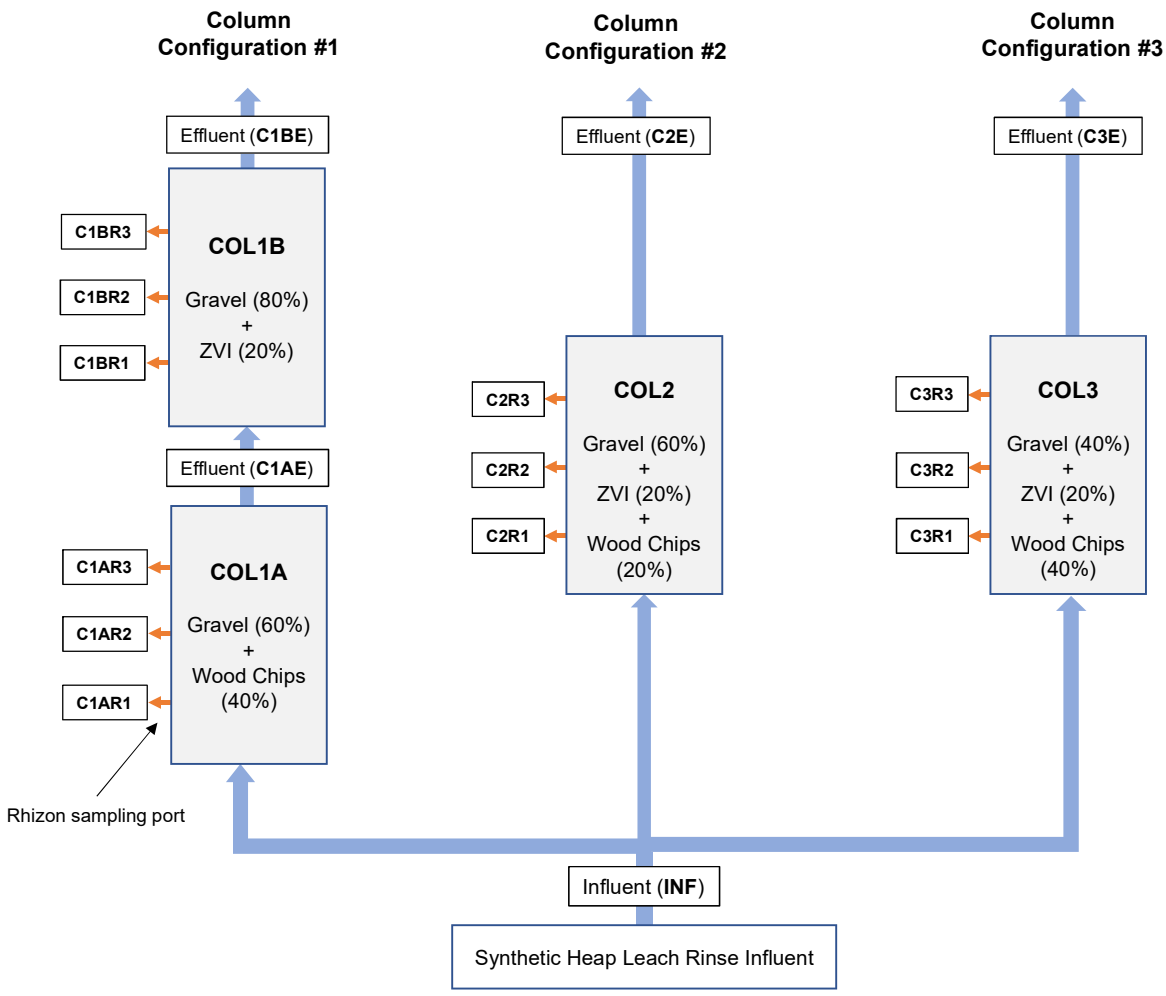

Figure 2-2: Treatment column configurations showing sampling locations for effluent and rhizon chemistry.

2.2.2 Construction and Operation

All columns were constructed and operated at the Yukon Research Center laboratory, Yukon University, Whitehorse YT. Complete descriptions related to column specifications, construction, operation and sampling procedures are provided in Appendix A.

Columns are composed of Plexiglass cylinders (total volume = 2.36 L) with an inlet at the base and terminus (top) of each column. Influent enters from the base of the column and flows upward to reduce the potential for the formation of preferential pathways. Three rhizon ports (*in situ* water quality samplers) are located equidistant along the length of each column with R1, R2 and R3 corresponding to 25%, 50% and 75% of the vertical treatment length, respectively (Figure 2-2).

During construction, materials were coned and quartered, homogeneously mixed in the designated proportions (% by volume) and packed in 2-3 cm lifts to minimize segregation. The composition of each column is summarized in Table 2-2.

Table 2-2:
Composition and Estimated Porosity of Each Column

Column	Mass of Gravel	Mass of ZVI	Mass of Wood Chips	Total Mass of Column Substrates	Total Water Added for Saturation	Estimated Porosity
	kg	kg	kg	kg	L	%
C1A	2.3	-	0.17	2.5	1.1	47
C1B	3.0	1.4	-	4.5	0.90	38
C2	2.3	1.4	0.087	3.8	1.0	42
C3	1.5	1.4	0.17	3.1	1.2	51

The experiment was initiated on July 1st, 2020 with the addition of influent to saturate the solid mixture in each column. Specifications for operation were informed by the selection of a target HRT representative of the treatment period required to achieve a specified removal performance. The selection of a target HRT was informed by several considerations including: i) the rate limiting step for POPC treatment which was predicted to be denitrification; ii) the volume of synthesized influent available (~350 L); and iii) a minimum operational period of six months to evaluate treatment performance. Based on these considerations, an HRT of 4 days was selected.

Flow was initiated on July 3, 2020 for column configurations C1, C2 and C3 at 21 mL/hr, 11 mL/hr and 13 mL/hr, respectively, to achieve the target HRT and was maintained throughout the duration of the experimental period. Columns were operated inside a fridge at 4˚C to more closely reflect site conditions (Figure 2-3).

Weekly flow monitoring and weekly to monthly water quality sample collection and analysis were performed according to the procedures outlined in Section 4 and Appendix A of Lorax (2020). All samples were collected under suboxic conditions, filtered (only for effluent samples) and preserved and submitted to ALS Laboratories.

Column operation was terminated on March 19, 2021 (week 37). Throughout the experimental period, 64 to 177 L (equivalent to 55 to 61 pore volumes) of synthesized drain down seepage water was treated within each configuration with >94% efficiency (Table 2-3).

Figure 2-3: Photograph of column set-up at the Yukon Research Center laboratory.

Table 2-3:
Total Influent and Effluent Volumes During 37 Weeks of Testing

Column Treatment System	Total Influent Volume	Total Effluent Volume	Percentage of Volume Treated	Number of Pore Volumes Treated
	L	L	%	#
C1	117	110	94	55
C2	64	61	95	61
C3	74	72	98	59

2.2.3 Influent Chemistry

The chemistry of influent used for column testwork represents a synthesized solution of expected drain down seepage water from the HLF which was modified to reflect the Upper Case predicted concentrations as detailed in Lorax (2022).

Table 2-4:
Seepage Water Chemistry Estimate for HLF prior to Treatment

		HLF Seepage Quality Estimate (Feed to Active and PTS)	
		Upper Case	**Base Case**
pH	s.u.	8.4	8.0
N-NH_4	mg/L	0.06	0.025
N-NO_3	mg/L	307	275
N-NO_2	mg/L	1.9	1.6
Cl	mg/L	123	115
Sulphate	mg/L	2516	2300
Total Alk	mg/$CaCO_3$/L	87	47
WAD-CN	mg/L	0.2	0.09
TDS	mg/L	4100	3000
Al	mg/L	0.2	0.06
Ag	mg/L	0.00125	0.00009
As	mg/L	2.0	0.66
Ca	mg/L	350	204
Cd	mg/L	0.00013	0.00004
Cr	mg/L	0.014	0.004
Cu	mg/L	0.014	0.004
Fe	mg/L	0.5	0.15
Hg	mg/L	0.00026	0.0001
Mg	mg/L	155	117
Mn	mg/L	0.06	0.016
Mo	mg/L	0.105	0.0330
Na	mg/L	1168	890
K	mg/L	11	8
Ni	mg/L	0.006	0.002
Pb	mg/L	0.0013	0.00032
Sb	mg/L	0.5	0.17
Se	mg/L	0.005	0.0015
Tl	mg/L	0.004	0.0015
U	mg/L	0.685	0.300
Zn	mg/L	0.052	0.02
Ra-226	Bq/L	0.07	0.05

The key parameters targeted for treatment for the study are summarized in Table 2-5. Sulphate is included as concentrations are predicted to be elevated, but treatment of this parameter is not an expected outcome of this study.

Table 2-5:
Synthesized Influent Chemistry Relative to Target Concentrations

Parameter	Unit	HLF Seepage Base Case	HLF Seepage Upper Case	SYN TEST 1	SYN TEST 2
				28-May-20	28-May-20
SO_4	mg/L	2,300	2,516	2,460	2,420
NO_3-N	mg/L	275	307	338	335
D-As	mg/L	0.66	2.0	2.1	2.1
D-U	mg/L	0.30	0.69	0.44	0.44

The synthesized solution was prepared by Inotec in March 2020 and shipped in HDPE drums to be stored at the Yukon Research Center laboratory for the duration of column testwork. Analytical samples were collected in May 2020 from each drum and was compared to the target concentrations prior to commencing with the column experiments. The results show that with the exception of U, concentrations of other POPCs were within >90% of the Upper Case target values; however, the test U influent concentration was well above the Base Case seepage prediction concentration (Table 2-5).

2.2.4 Carbon Amendment

During the first 16 weeks of operation, a minimal decline in nitrate concentrations was observed across all treatment configurations. Although dissolved organic carbon (DOC) was detectable in column effluents at a relatively stable concentration of ~30 mg/L, it was hypothesized that carbon released from the wood chips were not present in a readily labile form to support microbial denitrification.

Experiments of various scales and applications have utilized organic carbon amendments to stimulate anaerobic bacteria, including bench-scale reactor studies of mine waters. Sodium-acetate was chosen as the DOC source for this work since studies of similar scale have successfully used this reagent as an organic-carbon source in denitrification experiments (Cuervo and Lopez, 1999). Further, acetate has been cited as a suitable and favourable electron donor to stimulate microbial growth compared to other organic carbon sources such as ethanol, acetic acid, propionate and lactate (Srinandan *et al*., 2012; Calderer *et al*., 2010) and as a readily useable carbon source for denitrification (Flather, 1989).

Based on the literature review, a 2:1 carbon to nitrogen dose of Na-acetate ($NaCH_3COO$) was used to amend the influent throughout weeks 20 to 32. This amendment increased the DOC content in the influent water from <10 mg/L to ~590 mg/L.

2.2.5 Quality Assurance/Quality Control

QA/QC practices are conducted at various stages of sample collection through to analytical testing. Validated-clean sample bottles and preservatives are received from the analytical laboratory and are stored in a clean environment prior to use. Once samples are submitted to ALS, internal laboratory QC procedures are performed, which include analysis of method blanks, blank spikes, matrix spikes, reference standards and method duplicates at a minimum frequency for each analytical batch (*i.e.,* 1/20 samples). Results from these QC samples are not discussed in this report; however, the data quality objectives for laboratory QC samples need to be met by the analytical laboratory before a final report is issued.

In addition to the internal QC procedures performed at the analytical laboratory, monthly sampling of a method blank column (Col100-3.0) operated at the Lorax Laboratory (in Vancouver, B.C.) is conducted. Complete results are provided in Appendix C. Method blank samples are collected from a column constructed with similar materials as the treatment columns but containing only distilled water sourced from ALS Laboratories. This procedure is used to assess contamination associated with leaching from column materials and with the sample collection procedure, as the procedures used at Yukon Research Centre are based on practices developed at the Lorax Laboratory. A caveat of this approach is that it does not capture variability associated with the laboratory environment.

With respect to method blank results, parameters which show median concentrations within 5x the median levels observed in the treatment column leachates include TD-P and dissolved Al, Ba, Cd, Mn and Si. Although, there is some uncertainty associated with the concentrations of these parameters, it is not expected to considerably alter the interpretation of leachate chemistry.

3. Results and Discussion

Newmont™

3. Results and Discussion

3.1 Solid Phase Characteristics

The results of the static testwork conducted on the column materials are presented in the following sections with regards to acid-base accounting (ABA), elemental abundance, nutrient content and shake flask extractions (SFEs). Laboratory reports for these analyses are provided in Appendix B.

3.1.1 Acid-Base Accounting

Acid-base accounting was performed to ensure materials used in the column experiments were non-acid generating. Acid base accounting results for the gravel and ZVI samples are presented in Table 3-1.

Table 3-1:
Acid-Base Accounting Results of Column Materials

Parameter	Unit	Gravel	ZVI
Paste pH	s.u.	8.4	7.4
Total S	wt.%	0.16	0.10
Sulphate S	wt.%	<0.01	<0.01
Sulphide S	wt.%	0.11	0.01
AP	kg $CaCO_3$/t	3.4	3.1
Total C	wt.%	0.52	3.0
Total Inorganic C	wt.%	0.46	<0.01
CaNP	kg $CaCO_3$/t	38	<0.8
Modified NP	kg $CaCO_3$/t	49	66
NPR (CaNP/AP)	ratio	11	<0.25
NPR (Mod NP/AP)	ratio	14	21

Notes:
AP: Acid Potential in kg $CaCO_3$/t (Gravel- Sulphide-S wt.% x 31.25; ZVI- Total S wt.% x 31.25)
CaNP: Carbonate Neutralization Potential in kg $CaCO_3$/t (Total Inorganic Carbon wt. % x (100/12) x 10)
Modified NP: determined using the method outlined in Lawrence and Wang (1996)
NPR = net potential ratio, calculated by dividing NP by AP

Paste pH provides information on the availability of neutralization potential (NP) by indicating whether a sample is actively producing acidity. Both the gravel and ZVI samples show slightly alkaline pH values of 8.4 and 7.4, respectively. Total sulphur is low in both test samples and less than 0.2 wt.%. Sulphide S is the dominant sulphur species in the gravel sample and, thus will be used to estimate acid potential (AP). Conversely, the ZVI sample shows a sulphur inventory primarily comprised of acid insoluble S, the remaining

sulphur fraction not characterized as sulphide S or sulphate S. Since the sulphide S content of this sample is equivalent to the detection limit (0.01 wt.%), AP is conservatively calculated from the total S value.

Estimates of NP are provided in Table 3-1 including carbonate neutralization potential (CaNP) calculated from TIC content and bulk (modified) NP which measures the contribution of NP from carbonate and non-carbonate sources (*e.g.*, aluminosilicates). Although there is a lack of detectable TIC (<0.01 wt.%) in the ZVI sample indicating negligible CaNP, the modified NP value (66 kg $CaCO_3$/t) suggests there may be a considerable non-carbonate source of NP in ZVI. By comparison, the gravel sample shows general consistency between the CaNP and modified NP measurements (38 kg $CaCO_3$/t and 49 kg $CaCO_3$/t, respectively) suggesting that the NP contribution is dominantly from carbonate minerals and any NP from aluminosilicates is relatively minor.

Estimates of net potential ratio (NPR), calculated as NP/ AP, are determined using both CaNP and modified NP values. The classification scheme outlined by Price (2009) is applied to evaluate ARD potential, with samples showing NPR values ≥2 being designated as non-potentially acid generating (non-PAG) while samples showing NPR values <2 are considered potentially acid generating (PAG). NPRs for the gravel sample are both >2 indicating that this sample is considered non-PAG. For the ZVI sample, there is uncertainty associated with the NPR calculated by CaNP due to the TIC being below the detection limit. However, the NPR measured using modified NP strongly suggests that the ZVI sample is also non-PAG.

3.1.2 Elemental Abundance

Elemental abundances for column test materials were compared to average upper continental crust concentrations (AUCCC; Rudnick and Gao, 2014) to evaluate the magnitude of solid-phase enrichment (Table 3-2). For the purpose of this assessment, enrichment is defined as being at least three times greater than the AUCCC. Metal enrichment does not necessarily indicate that the element will become problematic, since the leaching rate is highly dependent on other factors, including the metal-phase associations, grain size, the geochemistry of infiltrating waters and the depositional environment.

The ZVI sample shows the greatest metal enrichment relative to the other test materials. Specifically, metal concentrations for Ag, As, Cd, Co, Cr, Cu, Fe, Mn, Mo, Ni, Sb, Sn and W were found to be enriched relative to the AUCCC. The greatest magnitude of enrichment (at least 10x > AUCCC) was observed for Cd, Cr, Cu, Fe, Mo, Ni, Sb and Sn. By comparsion, only Cd was found to be notably above the AUCCC for the wood chip sample, while no metal parameters showed enriched levels in the gravel sample. Since the detection

limit for Se is greater than the AUCCC value, enrichment for this parameter cannot be confirmed.

Table 3-2:
Elemental Abundance by Aqua Regia Digestion of Column Materials

Parameter	Unit	*AUCCC*	Gravel Rock	Zero Valent Iron	Wood Chips
Ag	ppm	*0.053*	0.08	0.36	0.02
As	ppm	*4.8*	8	37	4
Cd	ppm	*0.09*	0.14	***1.4***	0.40
Co	ppm	*17*	10	62	0.3
Cr	ppm	*92*	100	***1,564***	15
Cu	ppm	*28*	27	***4,236***	9.6

3.1.3 Carbon, Nitrogen, Phosphorus and Sulphur

The composition of nutrient parameters, including total C, N, P and S are determined for the wood chip sample and presented in Table 3-3. Expectedly, the organic carbon content present in the wood chips sample far exceeds the composition of any other column materials. The C:N ratio is a common indicator used for characterization of organic material to determine its capacity to support nutrient mineralization as the biogeochemical cycling of C and N tend to be closely coupled in terrestrial ecosystems. A stochiometric C:N ratio of 3:1 to 24:1 is generally measured in soil microbial biomass across grassland and forest ecosystems, consistent with the typical range of nutrient requirements (Cleveland and Liptzin, 2007). A C:N ratio of 187:1 was measured for the wood chip sample, indicating a greater proportion of C and a relative deficit of N. With regard to P, the content measured in the wood chip sample is within the range of values observed for gravel (0.1 wt.%) and ZVI (0.03 wt.%), while total S content is up to two times greater than measured for the other column materials.

Table 3-3:
Carbon, Nitrogen, Phosphorus, Sulphur Content of Wood Chips

Parameter	Unit	Wood Chips
Total Organic C	wt.%	48
Total N	wt.%	0.30
Total P	wt.%	0.03
Total S	wt.%	0.26

Notes:
Total organic carbon derived as total carbon – total inorganic carbon
Total nitrogen and sulphur determined by infrared combustion
Total phosphorus determined by Aqua Regia digestion

3.1.4 Shake Flask Extractions

SFE leachate results for the column materials are presented in Table 3-4. Leachate quality are compared to the Canadian Council of Ministers of the Environment (CCME) water quality guidelines (WQG) for the protection of aquatic life. When available short-term guidelines were used, otherwise values represent long-term guidelines. Water quality guidelines generally apply at designated water quality monitoring stations in the receiving environment (*e.g.*, streams, lakes) and not to treated effluent chemistry. Therefore, guideline exceedances of SFE leachates are primarily useful for the preliminary evaluation of potential drainage chemistry associated with the column test materials.

Leachate results show circumneutral pH for gravel and zero valent iron (pH 7.4 and 6.6, respectively) and an acidic pH (4.5) for the wood chip sample. There is relatively limited alkalinity contributed by the gravel or ZVI with leachate for these samples showing concentrations <25 mg $CaCO_3$/L. Leachate for the wood chip sample notably shows elevated conductivity up to 20x greater than observed for the other test materials, owing to elevated K, Ca, Cl and sulphate levels. The discrepancy in the ion balance for this sample suggests that the sulphate concentration reported for this sample is likely an underestimation. Based on the leachable sulphur detected, the sulphate concentration is estimated to be an order of magnitude higher than the reported value. This sample could not be retested; however, these results are not expected to significantly alter the interpretation of results since the influent solution is the dominant source of elevated sulphate concentrations.

In general, the wood chip sample shows the highest concentrations of water-soluble parameters. For the gravel and ZVI samples, only Al and F show values above the WQGs, respectively. By comparison, the wood chip sample shows concentrations of Al, As, Cd, Cr, Cu, Fe, Pb and Zn above the CCME WQGs. Other parameters including Co and Ni also show elevated concentrations in the wood chip sample relative to the other test materials. The enhanced leachability of metal cations observed for wood chips is attributed to the

acidic nature of this sample. Although no guideline is presented for P, the wood chip sample also shows a particularly elevated concentration of 15 mg/L well above levels observed for the gravel and ZVI samples, which are below the detection limit (<0.003 mg/L).

Table 3-4:
Shake Flask Extraction Results of Column Materials

Parameter	Units	*CCME*	Gravel Rock	Wood Chips	Zero Valent Iron

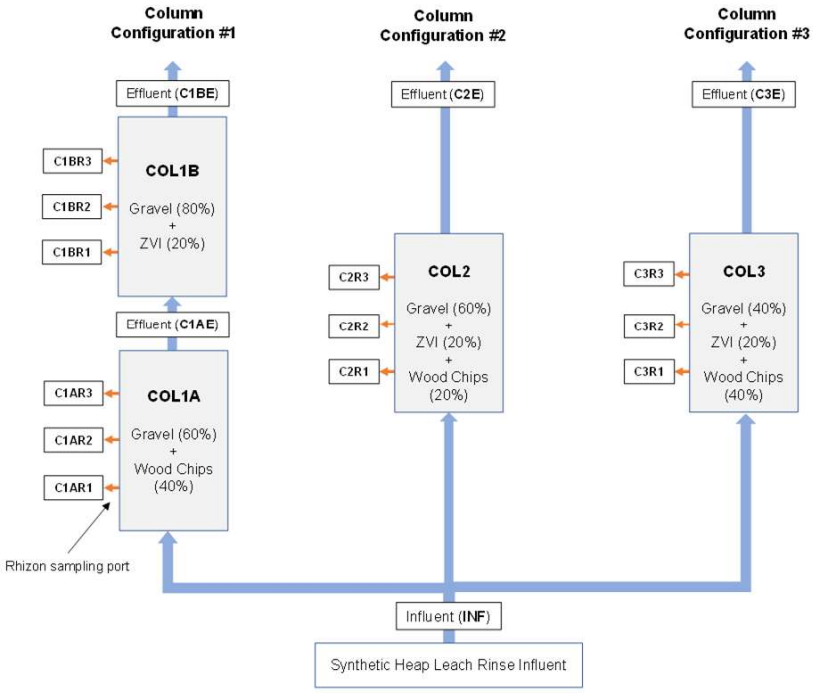
Notes:
Values highlighted in blue are above the Canadian Council of Ministers of the Environment (CCME) water quality guidelines for the protection of aquatic life. Short-term guidelines are presented for Cl, NO_3-N, B, Cd, U and Zn; other values presented reflect long-term guidelines. Guidelines are for total metals with the exception of Zn. Hardness or pH dependent criteria are applicable for Al, Cd, Cu, Pb, Ni and Zn. Minimum hardness (13 mg $CaCO_3$/L), average pH (6.2) and an assumed DOC value of 2 mg/L was used to calculate guidelines values for conservatism.
*Based on the calculated discrepancy in the ion balance for this sample, it is inferred that the sulphate result (4 mg/L) underestimates the actual concentration in this sample

3.2 Column Effluent Results

The following sections present the results of the column experiments. Complete tabulated analytical results for column effluents are provided in Appendix C. Results are described for each column and the column configuration described in Section 2 is reproduced below for ease of reference when reviewing results discussion.



3.2.1 Flow Rates and Hydraulic Retention Time (HRT)

Effluent flow rates and corresponding HRTs are illustrated in Figure 3-1. The time series demonstrates that with few exceptions, a mean HRT of 4 days was maintained throughout the experimental period for all columns. Operational issues were occasionally encountered which contributed to fluctuations in flow rate resulting in inconsistencies in the frequency of sample collection. These issues were commonly related to blockage of or leakage from the rhizon samplers; cessation of flow to change tubing; and increasing flow rates during sample collection.

Greatest variability was observed for the C1 treatment configuration with HRTs ranging from 1.6 to 28 days. Specifically, in weeks 25 to 29, HRTs are notably extended ($\geq$ 10 days), resulting in distinct leachate chemistry for nitrogen species which will be discussed in Section 3.2.5.1. Flow rates in C2 remained relatively consistent with the exception of a peak HRT of 13 days observed in week 25. The target HRT was slightly exceeded for C3 during the first half of the test period, potentially due to overestimation of the pore volume

of this column. Higher HRTs were observed in weeks 18, 19 and 27 reaching a maximum of 8.3 days. In the latter half of the test period (weeks 20 to 37), the target HRT was achieved over most periods for C3.

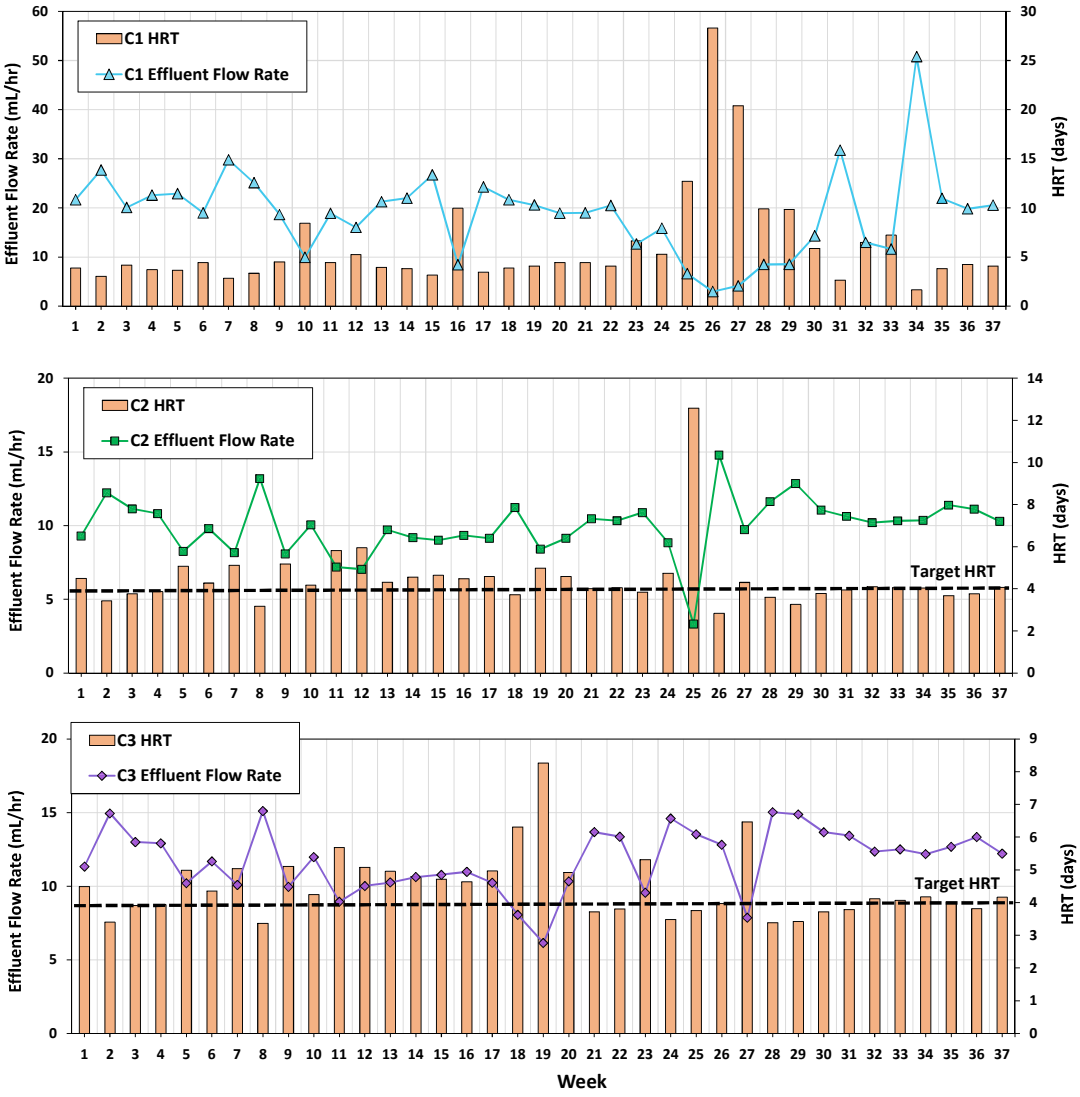


Figure 3-1: Weekly effluent flow rates and corresponding hydraulic retention times

3.2.2 Dissolved Organic Carbon

A time series for DOC concentrations in column leachates is presented in Figure 3-2. At the beginning of the test period, DOC levels show a flushing tendency in all columns, presumably associated with the rinsing of labile C from the wood chips to reach relatively stable levels of ~ 30 mg/L (Figure 3-2). Influent was amended with Na-acetate commencing in week 20 to help foster denitrification. In week 20, leachate concentrations in all columns initially reflect the composition of the DOC amended influent (~590 mg/L) but decline over weeks 20 to 32 to reach a minimum of 220 mg/L in week 26 in the effluent

from Column 1A (C1AE). DOC concentrations are mostly similar or lower in C1AE samples relative to corresponding C1BE samples which suggest that consumption of DOC is primarily occurring in the primary column (COL1A) containing no ZVI. Leachate from the mixed configurations (C2E and C3E) overall show lower carbon consumption reaching a minimum of 430 mg/L in week 24. Following termination of the DOC amendment, DOC levels readily decline in all column leachates to ~10 mg/L.

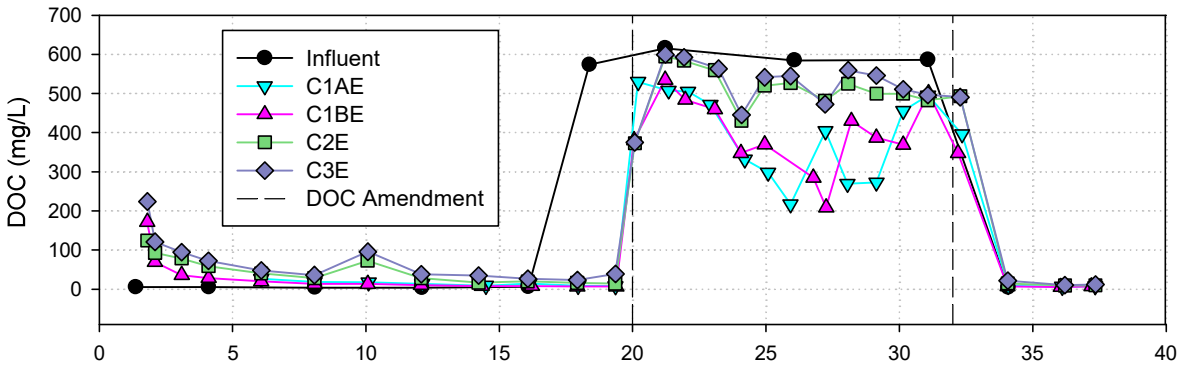

Figure 3-2: Time series profiles for DOC in column effluents over 37 weeks of operation. Note that a sample was collected for analy

3.2.3 pH

The influent water is characterized by circumneutral pH with values ranging from pH 6.6 to 8.1 over the experimental period (Figure 3-3). Fluctuations in influent pH may be partly associated with chemical artifacts from changes in sample storage conditions (*i.e.,* temperature) which can result in changes in CO_2 dissolution.

COL2 and COL3 containing ZVI had consistently higher pH effluent during the first 20 weeks of testing prior to the addition of Na-acetate amendment. COL2 and COL3 effluents (C2E and C3E) were ranged from 8.5 to 9.0 and reflect an increase in pH observed to occur through the iron corrosion process (Blowes *et al*., 2000). Leachate pH for C1AE (pH 6.5 to 8.4) are mostly below the pH observed in the ZVI columns. The SFE results indicated that the wood chips are a source of acidity and thus may account for the slightly lower pH observed in this column, as it lacks any ZVI.

Following the DOC amendment, pH measurements increase in all treatment columns particularly from week 25 to 32 reaching a peak of pH 9.2. C1AE and C1BE overall show the greatest variation in pH conditions. The increase in pH observed is postulated to result from increased alkalinity produced during decomposition of added DOC within the columns. Following termination of the DOC amendment (post week 32), pH levels return to previously observed conditions (pH 7.0 to 8.5).

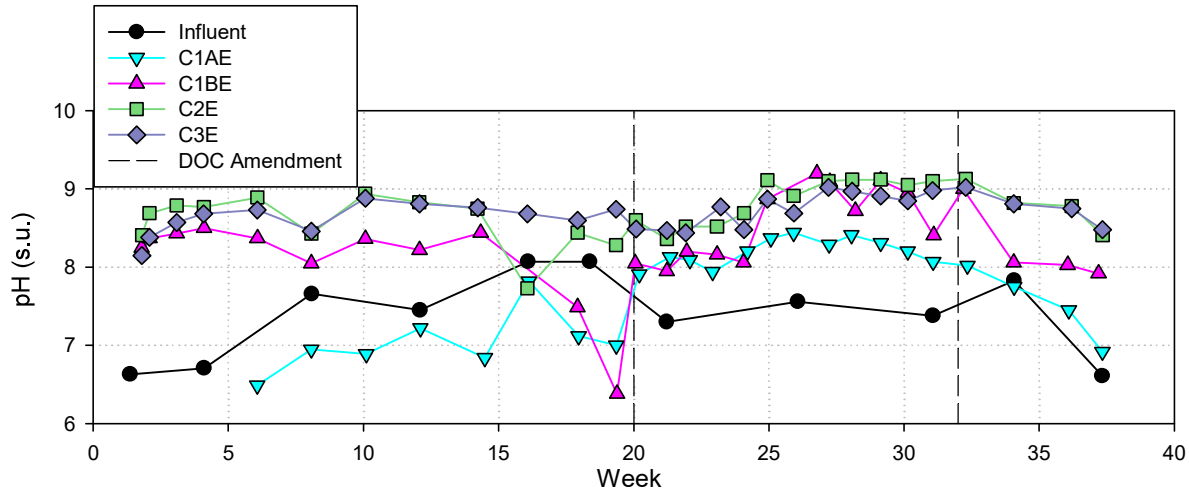

Figure 3-3: Time series profiles for pH in column effluents over 37 weeks of operation.

3.2.4 Major Ions

Conductivity and major ion concentrations remained relatively invariant with exception to leaching behaviour observed during the DOC amendment period. The addition of Na-acetate to the influent solution resulted in an increase in Na concentrations from 1,300 mg/L to 1,900 mg/L, as well as an increase in conductivity from ~6,600 µS/cm to ~7,400 µS/cm (Figure 3-4).

As noted above, during the DOC amendment period, alkalinity levels in column leachates show a 6x increase from approximately 150 mg $CaCO_3$/L to 900 $CaCO_3$/L due to the alkalinity generation during organic carbon decomposition (Figure 3-4). C1AE distinctly shows alkalinity levels above the influent composition (up to 1,600 mg/L), inferred to be related to the decomposition of added influent carbon, as illustrated by the associated decline in DOC concentrations in this column.

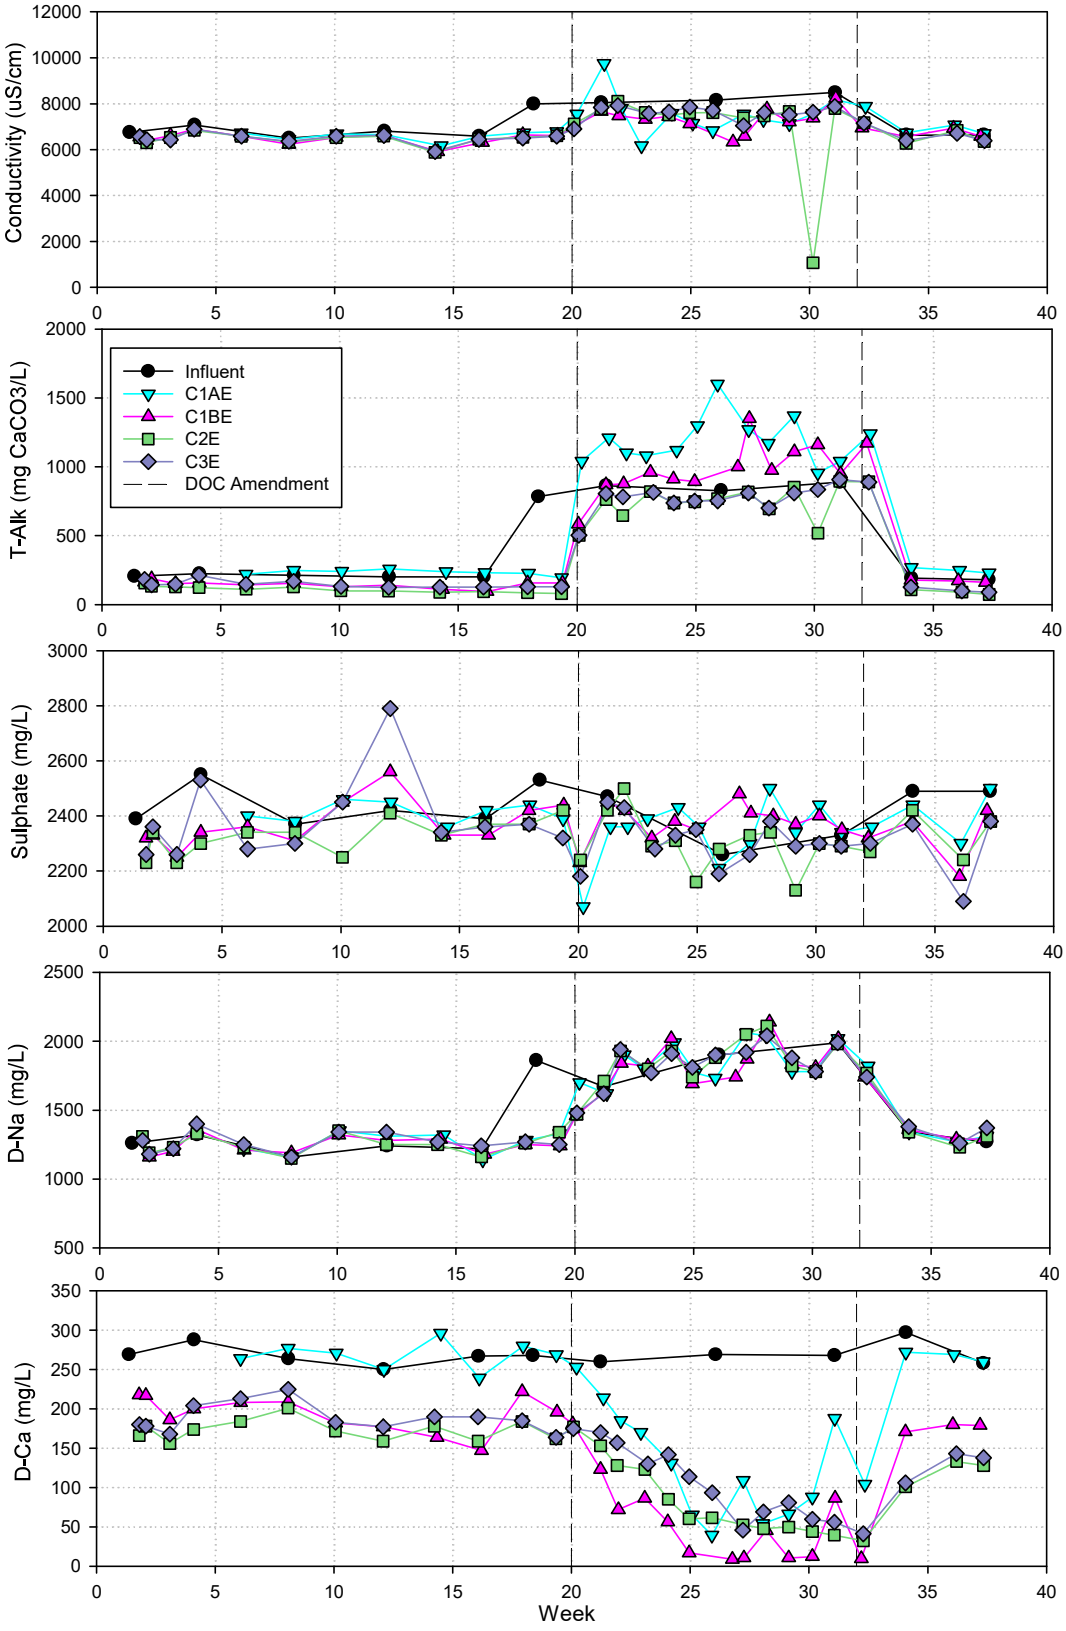

Figure 3-4: Time series profiles for conductivity, total alkalinity, sulphate and dissolved Na and Ca in column effluents over 37 weeks of operation.

Sulphate concentrations fluctuate throughout the experimental period, ranging from 2,100 mg/L to 2,800 mg/L. Sulphate removal is not expected as part of the treatment outcomes of this experiment given the redox state maintained in the columns. With the availability of a more optimal electron acceptor (*i.e.*, NO_3), denitrification rather than sulphate reduction is favoured to occur. Correspondingly, there is no evident removal of sulphate as sulphide concentrations are consistently non-detectable (<0.20 mg/L).

Calcium is consistently attenuated in columns containing ZVI, as demonstrated by lower leachate concentrations relative to the composition of the influent solution. For C1AE, Ca attenuation is only observed during the DOC amendment period. Overall, Ca levels decline from ~200 mg/L to ~100 mg/L, which is attributed to enhanced calcite formation ($CaCO_3$). Blowes *et al*., (2000) noted that waters moving through zero-valent iron, the precipitation of Ca and Mg carbonates and Fe and Al oxyhydroxides may occur due to the large decrease in Eh and increase in pH that results from the iron corrosion reaction. Alkalinity generation and precipitation of $CaCO_3$ during organic carbon decomposition also likely accounts for the decrease in dissolved Ca in all columns during week 20 to 32 while Na-acetate was amended to the column influent.

3.2.5 Parameters of Potential Concern

3.2.5.1 Nitrate

All treatment configurations show minimal nitrate removal prior to DOC amendment, with leachate concentrations ranging from 300 to 380 mg/L (Figure 3-5). At best, leachate concentrations show a <15% decline relative to influent composition (~350 mg/L). Relatively low temperatures of column operation likely inhibited microbial denitrification processes influencing both ZVI performance and the likelihood of microbial denitrification.

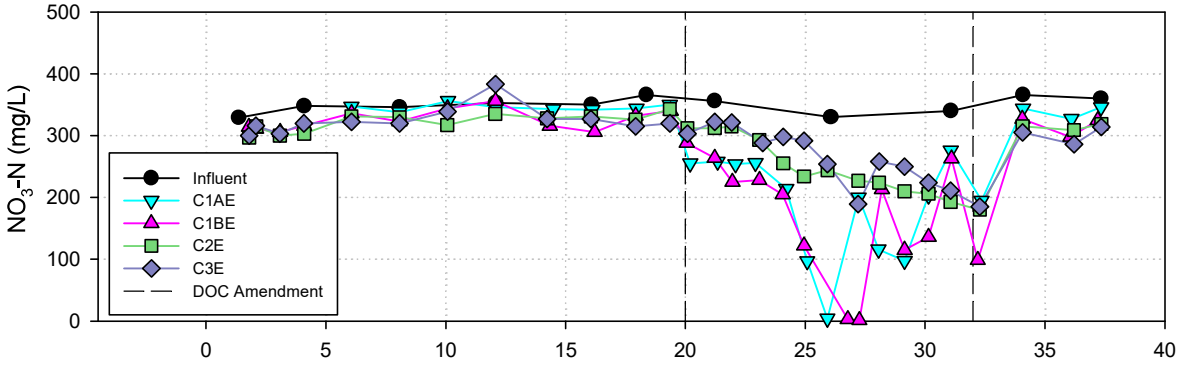

Figure 3-5: Time series profile for NO_3-N in column effluents over 37 weeks of operation.

In response to the observed limitations on treatment performance, Na-acetate was introduced to the columns to stimulate microbially-facilitated electron donating (oxidation of carbon) and accepting (denitrification) processes, illustrated by the equations below.

$$CH_3COO^- + 4H_2O \rightarrow 2HCO_3^- + 9H^+ + 8e^-$$

$$8e^- + 8/5NO_3^- + 48/5H^+ \rightarrow 4/5N_2 + 24/5H_2O$$

Based on the effluent chemistry observed, these redox reactions are inferred to be variably occurring in all treatment configurations. In particular, nitrate concentrations for the mixed treatment configurations, C2E and C3E, show a progressive decline reaching a minimum concentration of ~185 mg/L in week 32 (Figure 3-5). The greatest magnitude of nitrate removal was observed in C1AE with levels reaching <5 mg/L in week 26. Of note, the C1AE time series profile for DOC shows a decreasing trend (Figure 3-2) which parallels the reduction in nitrate concentrations through denitrification (Figure 3-5). Nitrate concentrations are relatively unchanged in C1BE, indicating minimal to no additional removal of nitrate in the presence of ZVI for the sequential treatment configuration.

The effective removal of nitrate in C1AE was also found to be notably influenced by HRT. In Figure 3-6, a proportional decline in nitrate concentrations during weeks 25 to 29 coinciding with elevated HRTs ranging from 10 to 28 days is illustrated. Specifically, nitrate levels only decline below 100 mg/L (in week 26) when the target treatment HRT (*e.g.,* 4 days) was increased 7-fold to roughly 28 days.

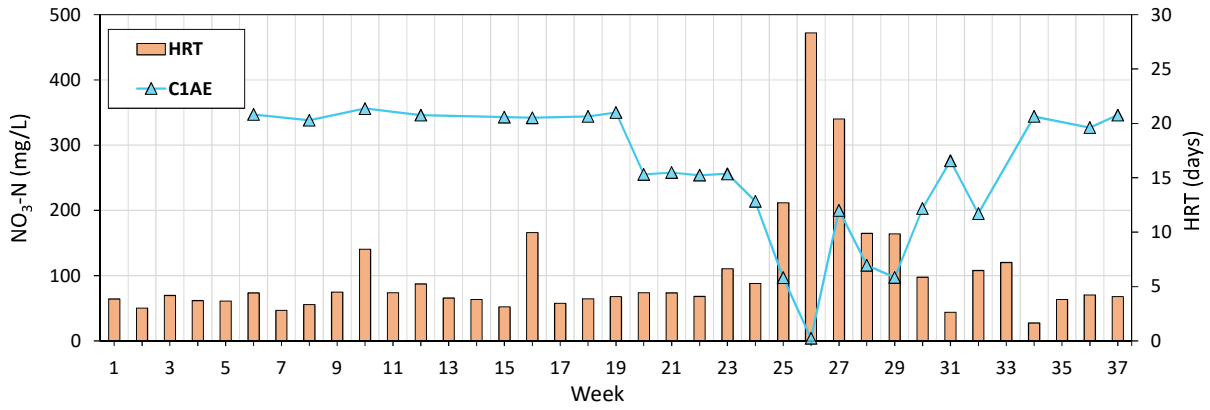

Figure 3-6: Time series profile for NO_3-N in C1AE and HRT for the C1 configuration over 37 weeks of operation.

Elevated HRTs are also observed for Column C2 and C3 during this period (13 and 6.5 days for C2E and C3E, respectively) but are not sustained over several weeks (refer to Figure 3-1). As such, a proportional decline in nitrate levels corresponding to HRT was not observed for these column experiments. These results demonstrate that the provision of a

labile carbon source at the operational temperature tested (4ºC) was insufficient for significant nitrate removal without greatly increasing the treatment HRT.

3.2.5.2 Arsenic

Arsenic is a redox sensitive parameter typically present in two valence states in aqueous environments, As(III) and As(V). Under more oxidizing conditions, As(V) is dominant and present in various hydrated forms (*i.e.,* H_3AsO_4, $H_2AsO_4^-$, $HAsO_4^{2-}$, AsO_4^3). In its reduced form, As (0), As is insoluble. Owing to its sensitivity to redox conditions, manipulation of the As redox state can reduce its overall solubility.

Figure 3-7 provides time series profiles for As in all columns. These data demonstrate immediate and effective removal in all columns containing ZVI throughout 37 weeks of testing. No removal is observed in C1AE, providing clear indication that removal is facilitated by the ZVI. Column effluents show As concentrations ranging from <0.003 to 0.097 mg/L reflecting >96% reduction in concentration relative to influent levels (median of 2.2 mg/L).

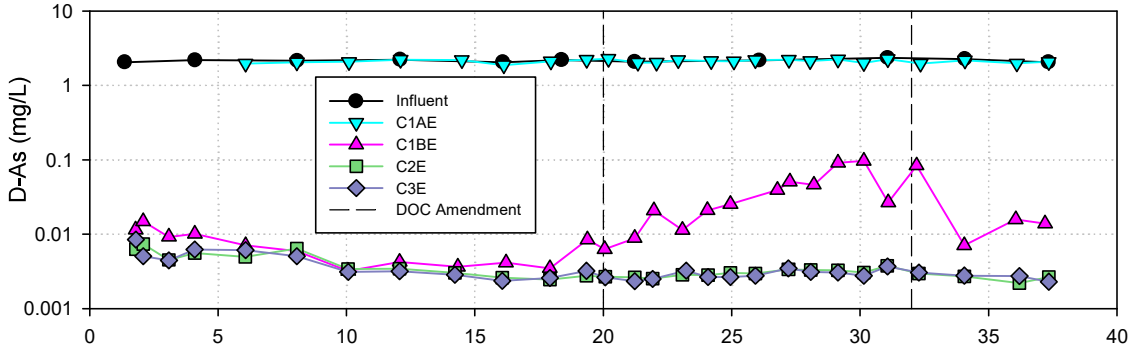

Figure 3-7: Time series profile for nitrate in column effluents over 37 weeks of operation. (Note that results are presented on a logarithmic scale).

Reduced attenuation of As in C1BE is observed during the DOC amendment period, with concentrations reaching a peak in week 32 and declining shortly after. Note that the magnitude of increased concentrations is relatively minor compared to the attenuation observed. Leachates for C2E and C3E, contrastingly, show no change in As concentrations during this period. There is no obvious discernable explanation for the decreased attenuation observed in C1BE; however, pH conditions in this column show greater fluctuations than in C2E and C3E, (Figure 3-3), which may indirectly contribute to variability in As solubility.

The exact mechanism for As attenuation in these columns remains to be investigated. Potential mechanisms for As removal which may be singularly or co-occurring include:

- reduction of oxidized As species to As(0) resulting in immobilization;

- complexation or co-precipitation of As with the ZVI surface; and
- adsorption onto corrosion products of ZVI, including iron hydroxides, oxyhydroxides, and mixed valance Fe(II)-Fe(III) green rusts (USEPA, 2008; Lien and Wilkin, 2005; Su and Puls, 2001).

3.2.5.3 Uranium

In aqueous environments U may be present in three valence states: U(IV), U(V) and U(VI). For oxic waters within a pH range of 5.0 to 9.0, U is dominantly present as U(VI) and may speciate as uranyl $(UO_2)^{2+}$, UO_2OH^+ or U complexed with carbonate and/or hydroxide depending on the availability of these compounds and the pH range observed (Markich, 2002; Gorman-Lewis et. al., 2008; Stewart *et al*., 2010).

The time series profiles for dissolved U shows progressive removal in all columns containing ZVI with maximum removal observed in weeks 10 to 20 (Figure 3-8). Prior to week 10, U concentrations ranged from 0.0016 mg/L to 0.035 mg/L. During the optimal treatment period, U concentrations consistently declined to <0.002 mg/L. Similar to As, the exact mechanism of U attenuation, while not determined, is inferred to be related adsorption or precipitation of U(VI) onto the ZVI surface resulting in immobilization. For example, Fiedor, *et al*., (1998) observed, in a groundwater treatment study using ZVI to remove U, that under aerobic conditions U(VI) was rapidly and strongly sorbed to hydrous ferric oxide particulates on the surfaces of ZVI.

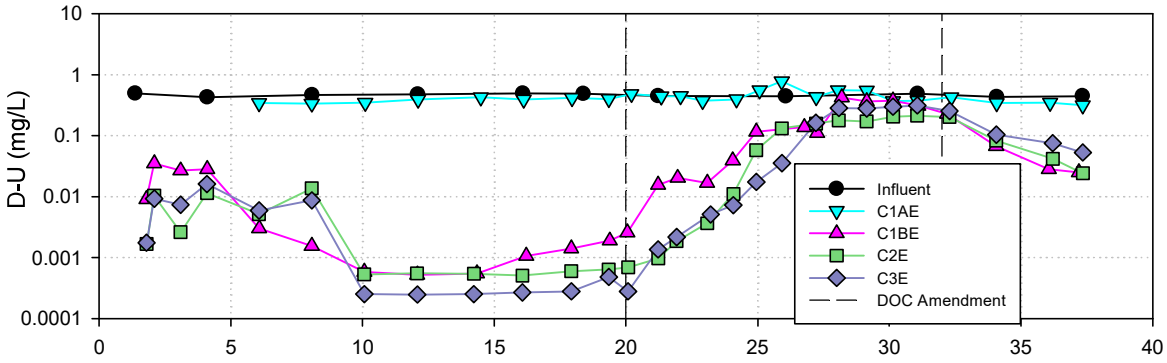

Figure 3-8: Time series profile for U in column effluents over 37 weeks of operation. (Note that results are presented on a logarithmic scale).

Interestingly, upon addition of DOC, there was an immediate decline in U attenuation within those columns containing ZVI as concentrations increased to approach influent levels (0.46 mg/L), reaching a maximum concentration of 0.42 mg/L in C1BE in week 28. Due to the nature of U species complexation, it is postulated that the reduced attenuation observed in weeks 20 to 32 is associated with the increase in alkalinity generated from carbon decomposition and the attendant increase of carbonate ions in solution. Carbonate

ions act as a competing complexing agent to ZVI. Uranyl carbonate complexes ($UO_2(CO_3)_2^{2-}$, $UO_2(CO_3)_3^{4-}$) are known to be stable and soluble in aqueous environments across the neutral to slightly alkaline pH range (8 to 9) observed during this period (Markich, 2002; Gorman-Lewis et. al., 2008; Stewart *et al*., 2010). Results for U and alkalinity in the ZVI columns provide some supporting evidence for this hypothesis as the occurrence of elevated U concentrations (>0.10 mg/L) in column effluent are only observed at alkalinity levels >500 mg $CaCO_3$/L (Figure 3-9). Moreover, U attenuation was observed following termination of the DOC amendment which resulted in a reduction in alkalinity levels and a concomitant decrease in dissolved U in all columns to <0.05 mg/L by the end of the test period (Figure 3-8).

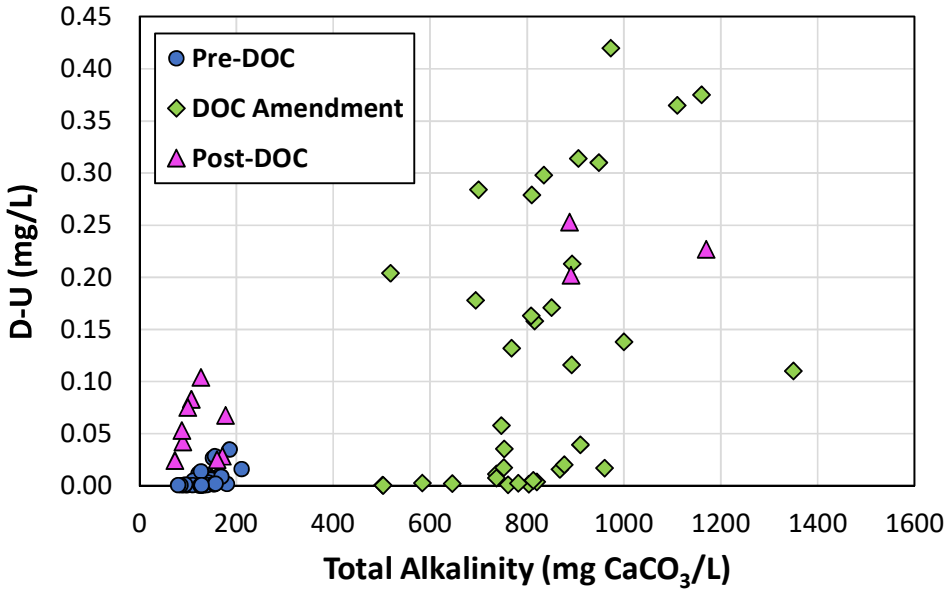

Figure 3-9: Dissolved U versus alkalnity measured in C1B, C2 and C3.

3.2.6 Contaminant Removal

3.2.6.1 Removal Rates

Water quality measured at the rhizon samplers demonstrate contaminant removal along the vertical flow path in the treatment columns (Figure 3-10, Figure 3-11, Figure 3-12). The greatest magnitude of decline in nitrate, As and U concentrations was observed between the inlet to the column and R1. Generally, there is an additional decline in concentrations between R1 and R2 and only minor additional removal observed at R3 despite the availability of reactive media (see Figure 3-11 for As).

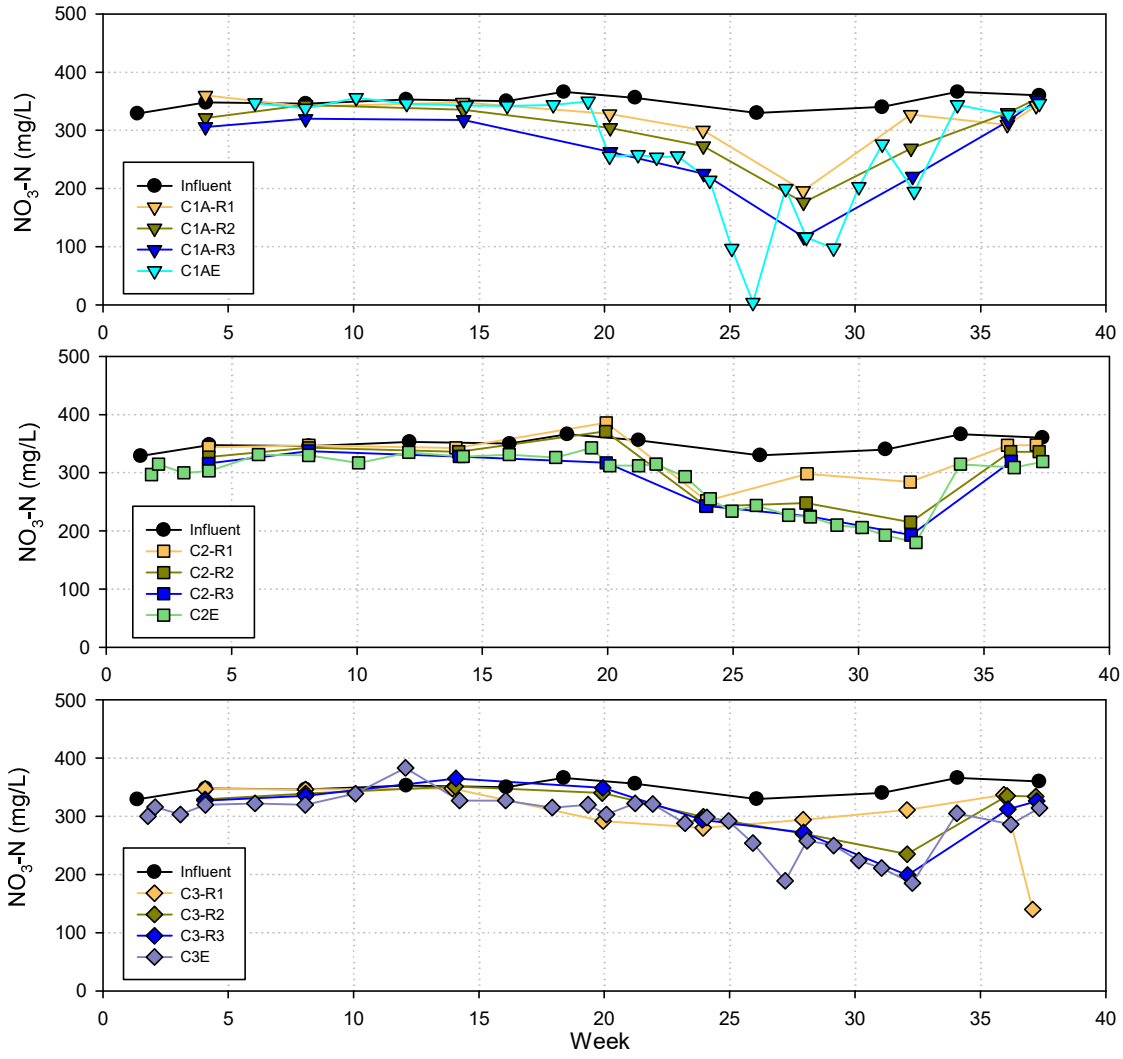

Figure 3-10: Time series profiles for NO_3-N measured in rhizon samples in C1A, C2 and C3 (top to bottom) over 37 weeks of operation.

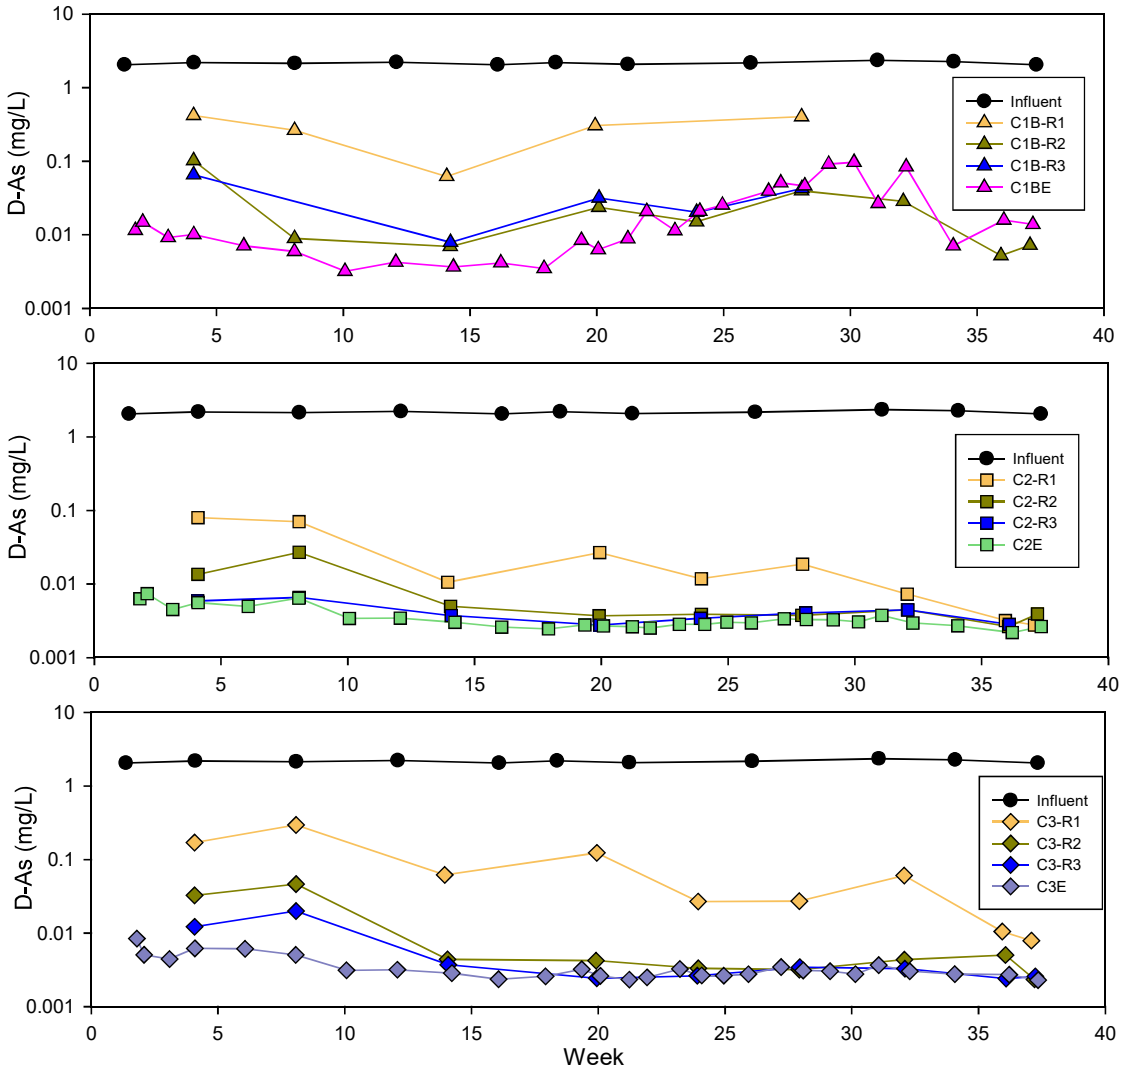

Figure 3-11: Time series profiles for dissolved As measured in rhizon samples in C1B, C2 and C3 (top to bottom) over 37 weeks of operation. (Note that results are presented on a logarithmic scale).

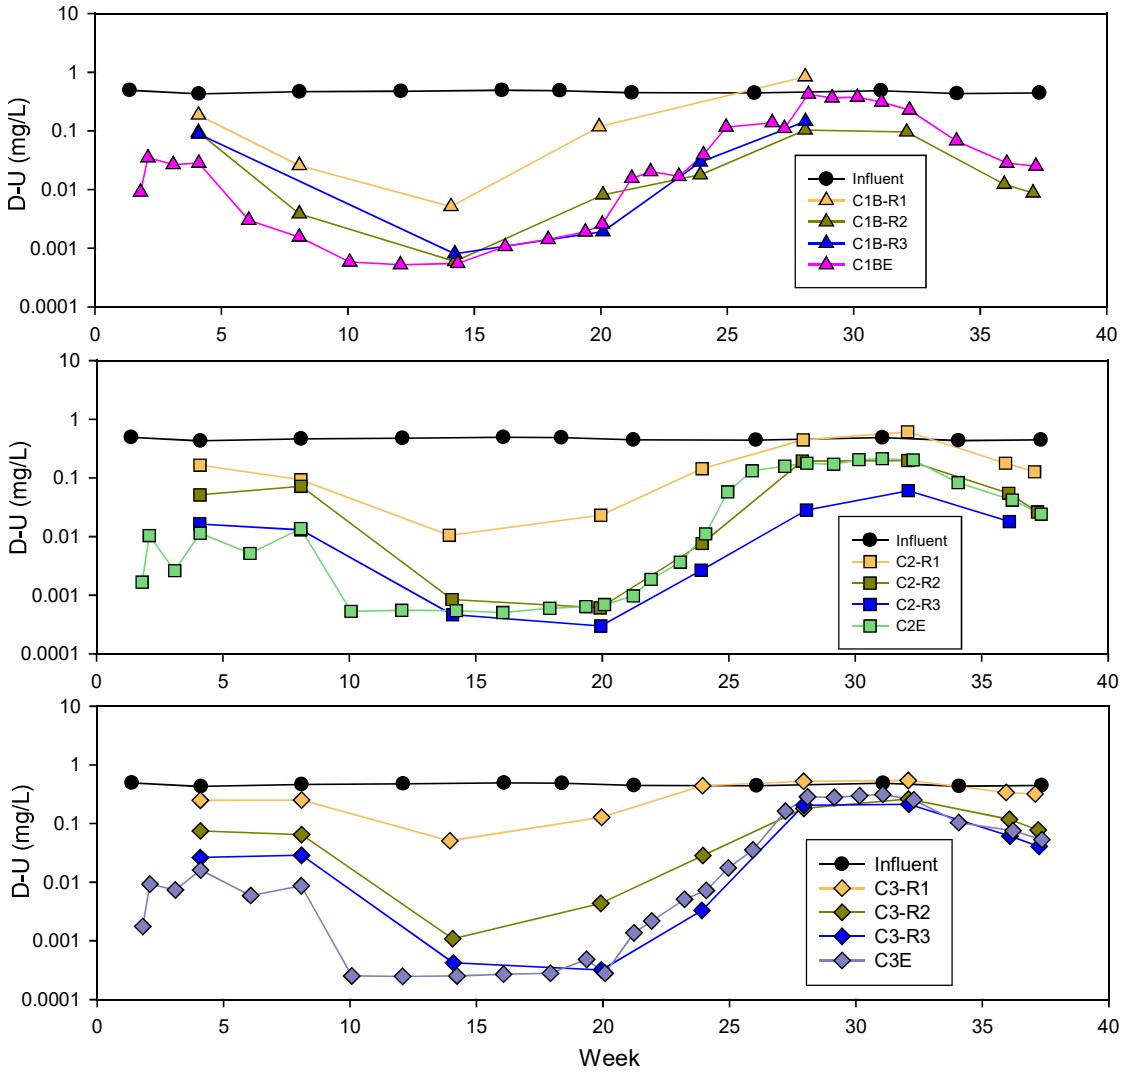

Figure 3-12: Time series profiles for dissolved U measured in rhizon samples in C1B, C2 and C3 (top to bottom) over 37 weeks of operation. (Note that results are presented on a logarithmic scale).

Removal rates for POPCs were calculated based on the dominant removal observed between the inlet and R1 for weeks during which rhizon samples were collected. The equation used to calculate removal rates presents an example for nitrate below.

(Influent [NO_3-N *mg/L*] - R1[NO_3-N *mg/L*]) x [Weekly effluent flow rate *L/day*] / [Volume of column material between inlet and R1 m^3]

Time to removal was then estimated based the equation below.

[Pore volume between inlet and R1 m^3]/ ([Weekly effluent flow rate *L/day*]/ 24,000)

Due to the sequential nature of the C1 configuration, these calculations were applied to removal observed in C1A for nitrate and to C1B for As and U. The rationale for this is to provide a direct comparison with rates observed in the mixed configurations.

Calculated weekly removal rates are shown for NO_3-N, As and U in Figure 3-13, Figure 3-15 and Figure 3-16, respectively.

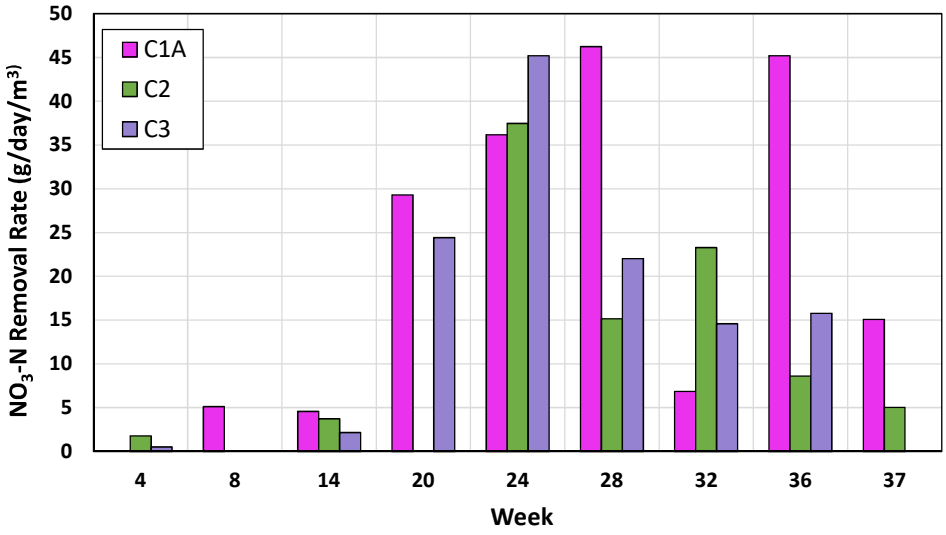

Figure 3-13: NO_3-N removal rates measured between the column inlet and R1 for weeks corresponding to rhizon sample collection

Nitrate removal rates were low in all column configurations during the initial 15 weeks of testing and generally were less than 5 g/day/m^3 (Figure 3-13). Removal rates increase upon introduction of DOC in week 20 but remain variable between configurations. Peak removal rates for C1 (*e.g.*, >35 g/day/m^3) were observed in week 24, 28 and 36. Observed removal rates during week 24 and 28 appear to be explainable by the increased HRT during this period in C1 (Figure 3-14) although the peak rate in week 36 does not appear to be related to HRT.

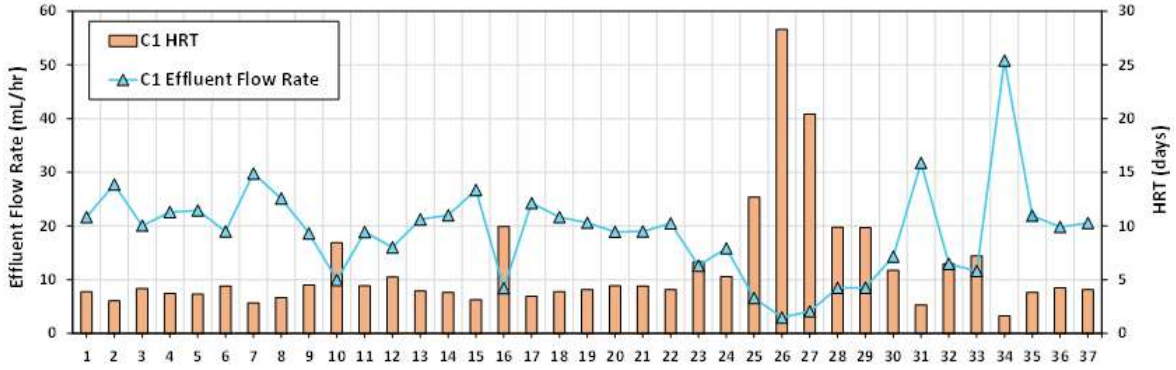

Figure 3-14: Weekly effluent flow rates and corresponding hydraulic retention time for C1.

Similar peak rates occurred only in week 24 for C2 and C3 (Figure 3-13).

For As and U, the data are incomplete C1 for the period after week 20. Greater removal rates are measured for C1 relative to C2 and C3 in weeks 4 to 20 and removal rates remain relatively stable throughout the entire test period. Conversely, U removal rates decline by up to a factor of 2 lower for C3 in week 32 relative to pre-DOC conditions. This is consistent with the reduced U attenuation observed in all ZVI columns during this period. In week 36 and 37, U removal rates approach pre-DOC conditions in C2 and C3.

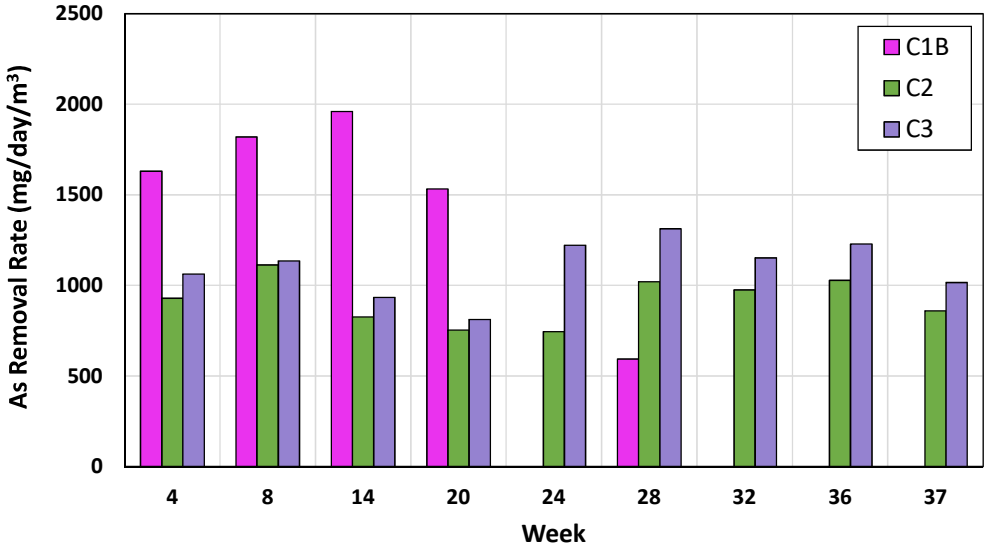

Figure 3-15: Arsenic removal rates measured between the column inlet and R1 for weeks corresponding to rhizon sample collection.

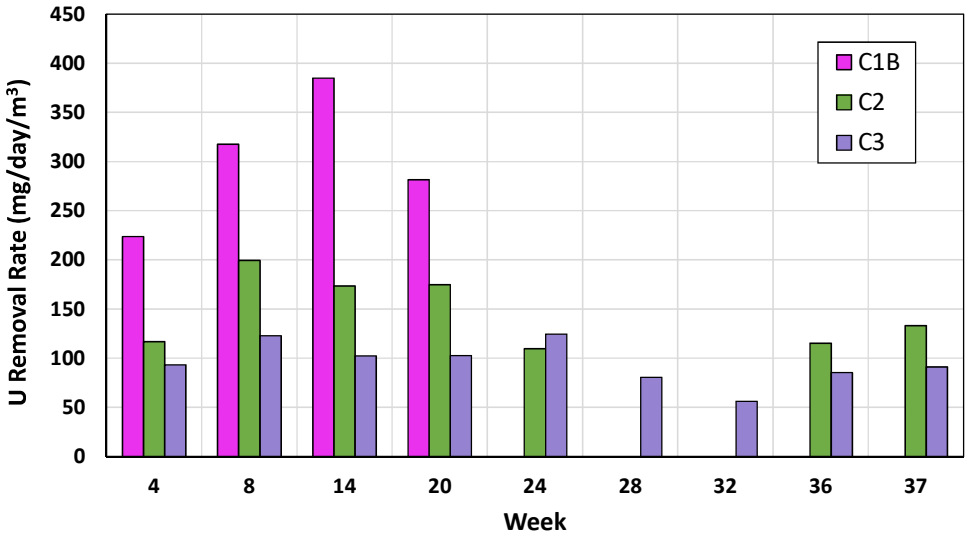

Figure 3-16: Uranium removal rates measured between the column inlet and R1 for weeks corresponding to rhizon sample collection.

Median removal rates and time to removal were calculated for each column configuration over the entire treatment period (*e.g.,* 37 weeks) as summarized in Table 3-5. Across

treatment configurations, median removal rates for nitrate range from 8.6 to 28 g/day/m^3. Nitrate removal rate for C1A is approximately 3x and 2x higher than in C2 and C3, respectively, and occurs in nearly half the time. The results also demonstrate that for similar treatment durations, nitrate removal rates were nearly 2x higher in C3 relative to C2.

Table 3-5:
Median Removal Rates and Time to Removal for Nitrate, As and U

Treatment Column	Median NO_3-N Removal	
	Removal Rate	Time to Removal
	g/day/m^3	Hours
C1A	28	14
C2	8.6	24
C3	16	23
Treatment Column	Median As Removal	
	Removal Rate	Time to Removal
	mg/day/m^3	Hours
C1B	1,630	9.9
C2	930	24
C3	1,136	23
Treatment Column	Median U Removal	
	Removal Rate	Time to Removal
	mg/day/m^3	Hours
C1B	300	9.9
C2	133	24
C3	95	23

Median removal rates for As range from 930 to 1630 mg/day/m^3 and from 95 to 300 mg/day/m^3 rates for U. Due to the limited rhizon data available for C1B, the rate presented is biased high as it primarily reflects pre-DOC conditions. Specifically, C1B shows removal rates for As and U up to 1.8x and 2.3x greater than observed for C2 and C3 as well as a shorter time to removal. The median removal rate for As and U are similar for mixed configurations, C2 and C3.

3.2.6.2 Contaminant Mass Removal

A summary of POPC mass removal during various periods of experimental testing is presented in Table 3-6. The results reflect minimum and maximum percentages of weekly mass removal calculated for the three treatment configurations.

For nitrate, contaminant mass removal was low (<15%) in all configurations in weeks 0 to 19 and prior to the addition of labile DOC. Once carbon was added to the system, % removal improved in all configurations and was highest in C1, reaching a maximum value

of ~100% in weeks 26 and 27 and remaining below 49% in C2 and C3. After week 32, % removal approached pre-DOC levels, with a greater range of removal observed in C1.

Table 3-6:
Minimum and Maximum Percentages of Contaminant Mass Removal

Period of Column Testing	Week	Median Effluent (mg/L)	Statistic	C1	C2	C3
				% mass removed	% mass removed	% mass removed
NO_3						
Pre-DOC	0 to 19	350	Min	0%	2%	0%
			Max	13%	15%	14%
DOC Amendment	20 to 32		Min	18%	10%	8%
			Max	100%	49%	47%
Post-DOC	33 to 37		Min	7%	9%	10%
			Max	72%	49%	47%
As						
Pre-DOC	0 to 19	2.17	Min	99%	100%	100%
			Max	100%	100%	100%
DOC Amendment	20 to 32		Min	96%	100%	100%
			Max	100%	100%	100%
Post-DOC	33 to 37		Min	96%	100%	100%
			Max	100%	100%	100%
U						
Pre-DOC	0 to 19	0.46	Min	92%	97%	97%
			Max	100%	100%	100%
DOC Amendment	20 to 32		Min	9%	54%	32%
			Max	99%	100%	100%
Post-DOC	33 to 37		Min	51%	56%	45%
			Max	95%	95%	89%

Notes:
Removal rates for C1 are based on final effluent chemistry observed for C1BE

Compared to nitrate, removal of As and U was effective for all treatment configurations throughout the entire treatment period. Arsenic was negligibly influenced by differences in column configuration and/or changes to treatment conditions (*e.g.*, DOC addition), showing consistently >96% removal across all columns. Alternatively, % removal for U declined to a minimum of 9% for C1 in week 28. By comparison, % removal during this period remained greater than 54% and 32% for C2 and C3, respectively. Following termination of the DOC amendment, % removal increased for C1 and C3 to greater than 45%. A similar range of % removal is observed for C2 during and post DOC amendment; however, the median value shows an increase from 72% to 82%, consistent with observations for the other treatment configurations.

3.2.7 Treatment By-Products

3.2.7.1 Nitrite and Ammonia

Nitrite and ammonia are undesirable reduced nitrogen species produced throughout the experimental period, as illustrated by the stepwise equations below for the denitrification of nitrate by ZVI.

$$Fe^0 + NO_3^- + 2H^+ \rightarrow Fe^{2+} + NO_2^- + H_2O$$

$$3Fe^0 + NO_2^- + 8H^+ \rightarrow 3Fe^{2+} + NH_4^+ + 2H_2O$$

Nitrite, prior to the DOC amendment, was consistently detected in all columns at concentrations <3.5 mg/L (Figure 3-17). Starting in week 20, levels in C2E and C3E progressively increase to reach a peak of 45 mg/L in week 32. For C1BE, nitrite levels fluctuate and mostly remain <20 mg/L. The overall increased production of nitrite is likely a response to enhanced denitrification as nitrite is an intermediary reduction product. Considerably lower nitrite concentrations (mostly < 3 mg/L) are observed in C1AE during this period, which is consistent with more complete denitrification (to N_2) occurring in this column. Following termination of the DOC amendment, nitrite levels decline by nearly 10x to < 5 mg/L by week 36.

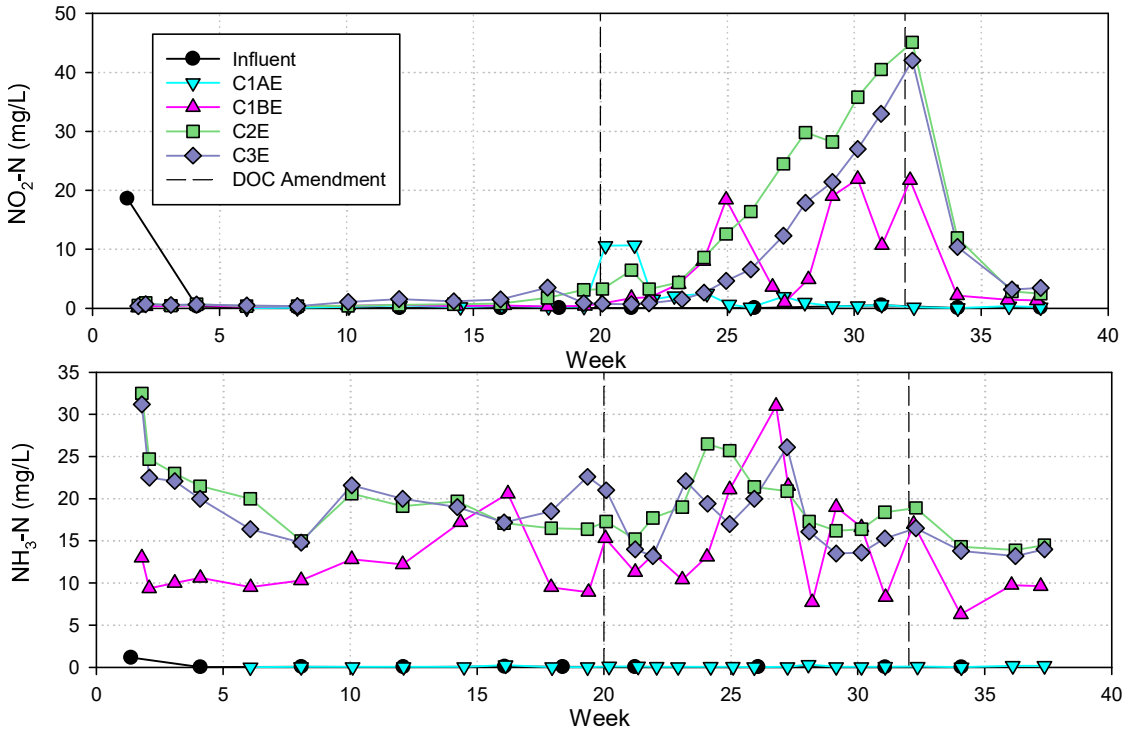

Figure 3-17: Time series profiles for NO2-N and NH3-N in column effluents over 37 weeks of operation.

For ammonia, concentrations are consistently detected in leachates from columns containing ZVI at levels ranging from 6.3 to 33 mg/L (Figure 3-17). Conversely, ammonia was observed at much lower (*e.g.*, <0.30 mg/L) in the absence of ZVI in C1AE, which indicate that ammonia production is associated with the presence of ZVI. Apart from the DOC amendment period when ammonia concentrations are similar across all leachates from ZVI columns, levels observed in the C1BE column are generally lower compared to the mixed configurations (C2E and C3E).

Poor nitrate removal by ZVI coincides with the production of ammonia in the treatment columns. Under the circumneutral conditions observed (pH 6.4 to 9.2), studies have shown that formation of iron oxides on the surface of ZVI tends to inhibit electron transfer from ZVI to nitrate, thus constraining the efficacy of chemical denitrification (Liu and Wang, 2019; Westherhoff and James, 2003; Cheng *et al*., 1997). As a result, in these instances, ammonia has been found to be the dominant reduction product.

3.2.7.2 Cyanide

Throughout the experimental period, weak acid dissociable cyanide (WAD-CN) was consistently detected at low levels (<0.15 mg/L) in leachates from all columns containing ZVI, while concentrations of WAD-CN were generally below the detection limit (<0.02 mg/L) in the influent solution and in C1AE (Figure 3-18). The SFE testwork conducted on the individual column test materials (Section 3.1.4) showed that total and WAD-CN levels in gravel and wood chips were below the detection limit (0.01 mg/L) and were at or below the detection limit for ZVI (0.002 mg/L). Overall, the results suggest that CN production may be associated with the presence of ZVI.

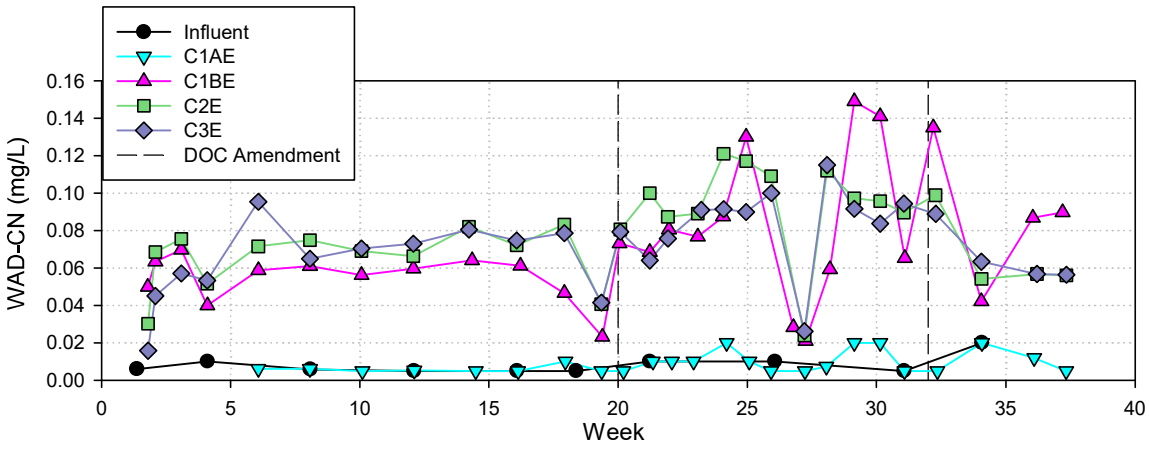

Figure 3-18: Time series profiles for WAD-CN in column effluents over 37 weeks of operation.

In response to the column results, an additional independent bench-scale leach test was performed on the ZVI material at the liquid to solid ratio (0.64:1) measured in the column tests to evaluate the leaching potential of WAD-CN. Leachate samples were collected periodically from 48 hours to 14 days from a sample containing ZVI and the synthesized drain down solution and a corresponding control with ZVI and deionized water. For the entirety of the batch test, concentrations of WAD-CN remained below the detection limit (<0.02 mg/L) in all samples.

Although the bench scale test have not been able to elucidate the source of CN detected in column leachates, the results provide supporting evidence that the chemical conditions unique to the column experiments facilitate the release of CN. Review of literature on other ZVI column studies were unable to provide a supporting hypothesis for CN release.

3.2.7.3 Trace Metals

Apart from the POPCs, other trace elements introduced via the influent solution or released from the column materials were also found to be influenced by the treatment process. Metal parameters which demonstrated a tendency for attenuation or release are presented in Figure 3-19 and Figure 3-20, respectively.

Trace metals including Al, Co, Cu, Sb and Se show attenuation primarily in the ZVI columns with concentrations declining by up to 5x relative to levels observed in the influent (Figure 3-19). Attenuation may be facilitated directly by adsorption onto the ZVI and enhanced as the ZVI undergoes corrosion and Fe oxides form on the surface of the material. Presumably, the gravel present in all columns could also provide supplemental adsorption capacity, and thus may account for parameters which show attenuation in C1AE namely Al and Cu. Since Se is a redox sensitive parameter, attenuation may be partially related to the formation of less soluble reduced species as Se reduction occurs at a similar redox potential to nitrate.

Lower attenuation was observed during the DOC amendment period, particularly for Al, Co and Cu, which reached maximum concentrations of 0.018 mg/L, 0.060 mg/L and 0.028 mg/L, respectively. Increased solubility of Cu and Co may be related to the formation of metal-organic complexes during excess DOC additions which limited their sorption to ZVI surfaces. For Al, the increased concentrations observed in all columns during DOC addition could be a function of the increase in pH that occurred during that period and the amphoteric behaviour of Al (*e.g.,* increased solubility at both low and high pH). The metalloid Sb exhibited somewhat reduced attenuation during DOC amendment and may also be associated with more alkaline pH conditions and lower sorption of Sb onto Fe-oxide surfaces of the ZVI.

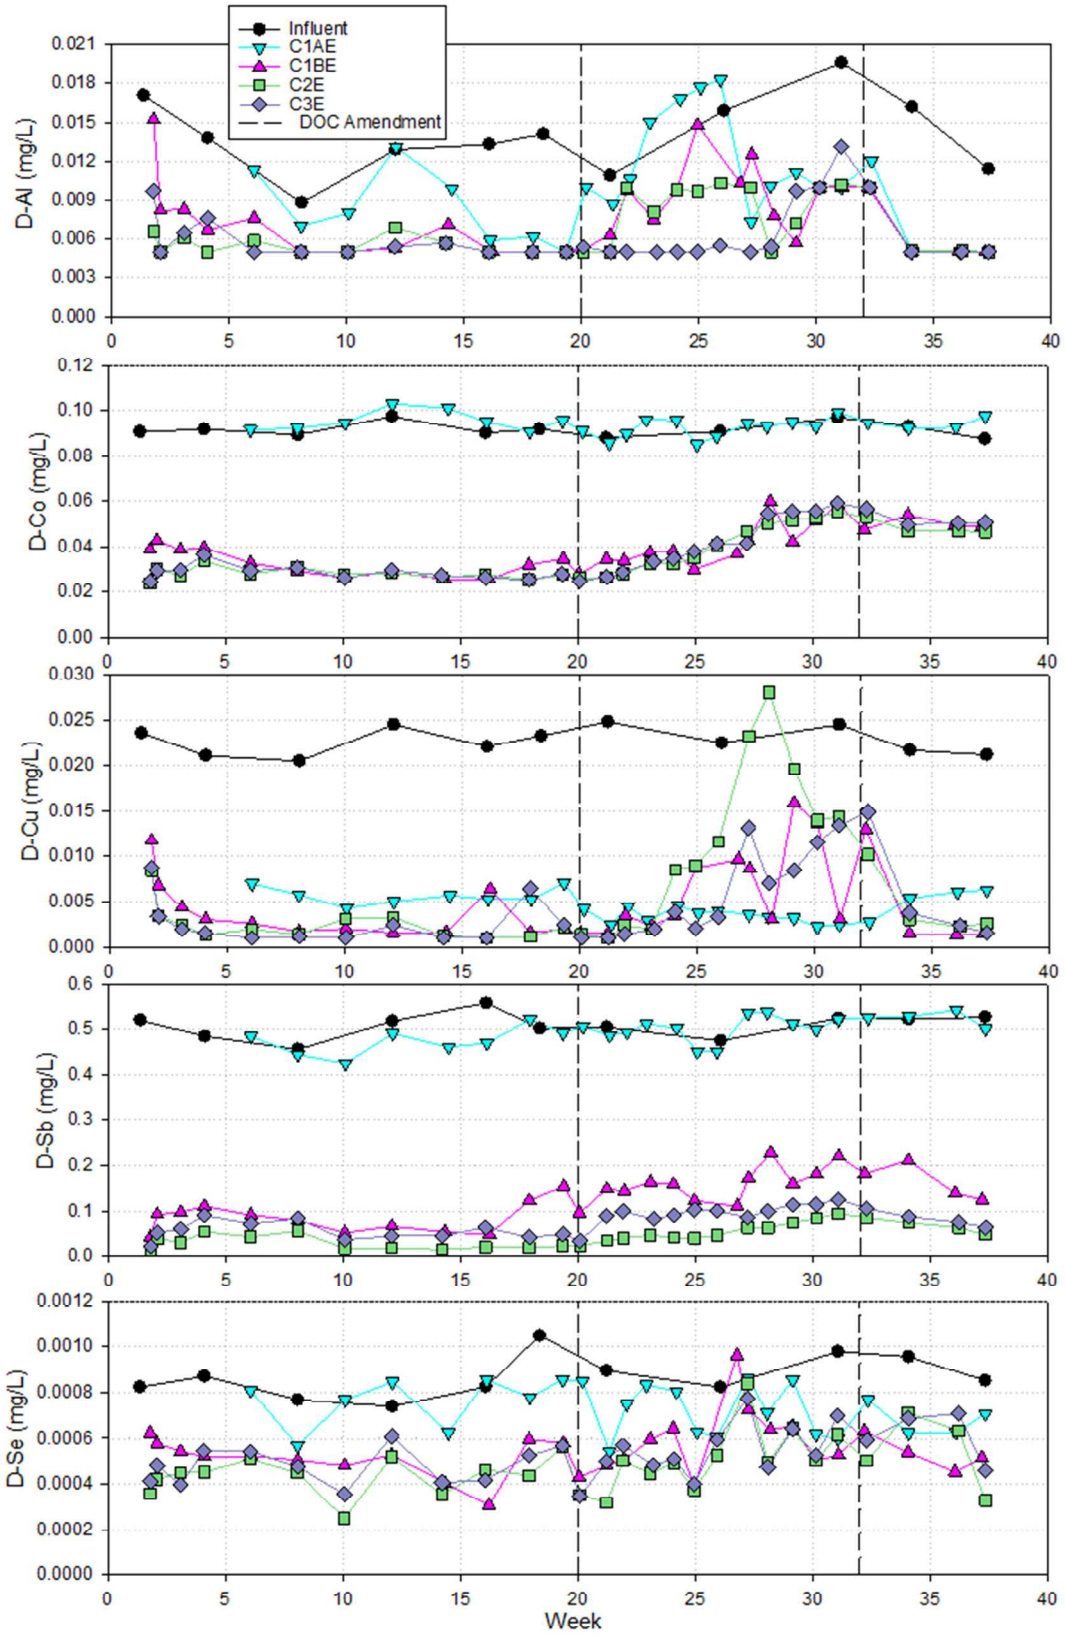

Figure 3-19: Time series profiles for dissolved Al, Co, Cu, Sb and Se in column effluents over 37 weeks of operation.

As a result of the treatment process, release of Fe, Mn, Mo, Ni and Zn are also observed primarily in columns containing ZVI (Figure 3-20) and were measured at concentrations in excess of that present in the influent prior to treatment. Concentrations of Fe are initially elevated reaching a peak of 5.9 mg/L, consistent with the rinsing of ZVI surfaces, and reach relatively stable levels (<0.5 mg/L) by week 10. The other metal parameters similarly show a flushing tendency followed by relatively stable concentrations approaching or remaining above influent levels by weeks 5 to 10.

Zn concentrations elevated above influent levels persist in CIAE until week 20, with concentrations ranging between 0.014 to 0.026 mg/L. Given that Zn was observed to be leachable from the wood chip sample (Section 3.1.4), this along with the absence of ZVI may account for the persistence of detectable levels in C1AE. By comparison, following the initial flush, Zn is slightly attenuated in all columns containing ZVI.

During the DOC amendment period, release of Mo and Ni is enhanced in C1BE to a maximum of 2.5 mg/L and 0.030 mg/L, respectively. Similar to previous observations, the enhanced solubility of Mo and Ni may be influenced by the increased presence of dissolved organic species or by the change in pH conditions. For Mn, the opposite is observed as concentrations decrease particularly for C1AE which show levels below the influent composition.

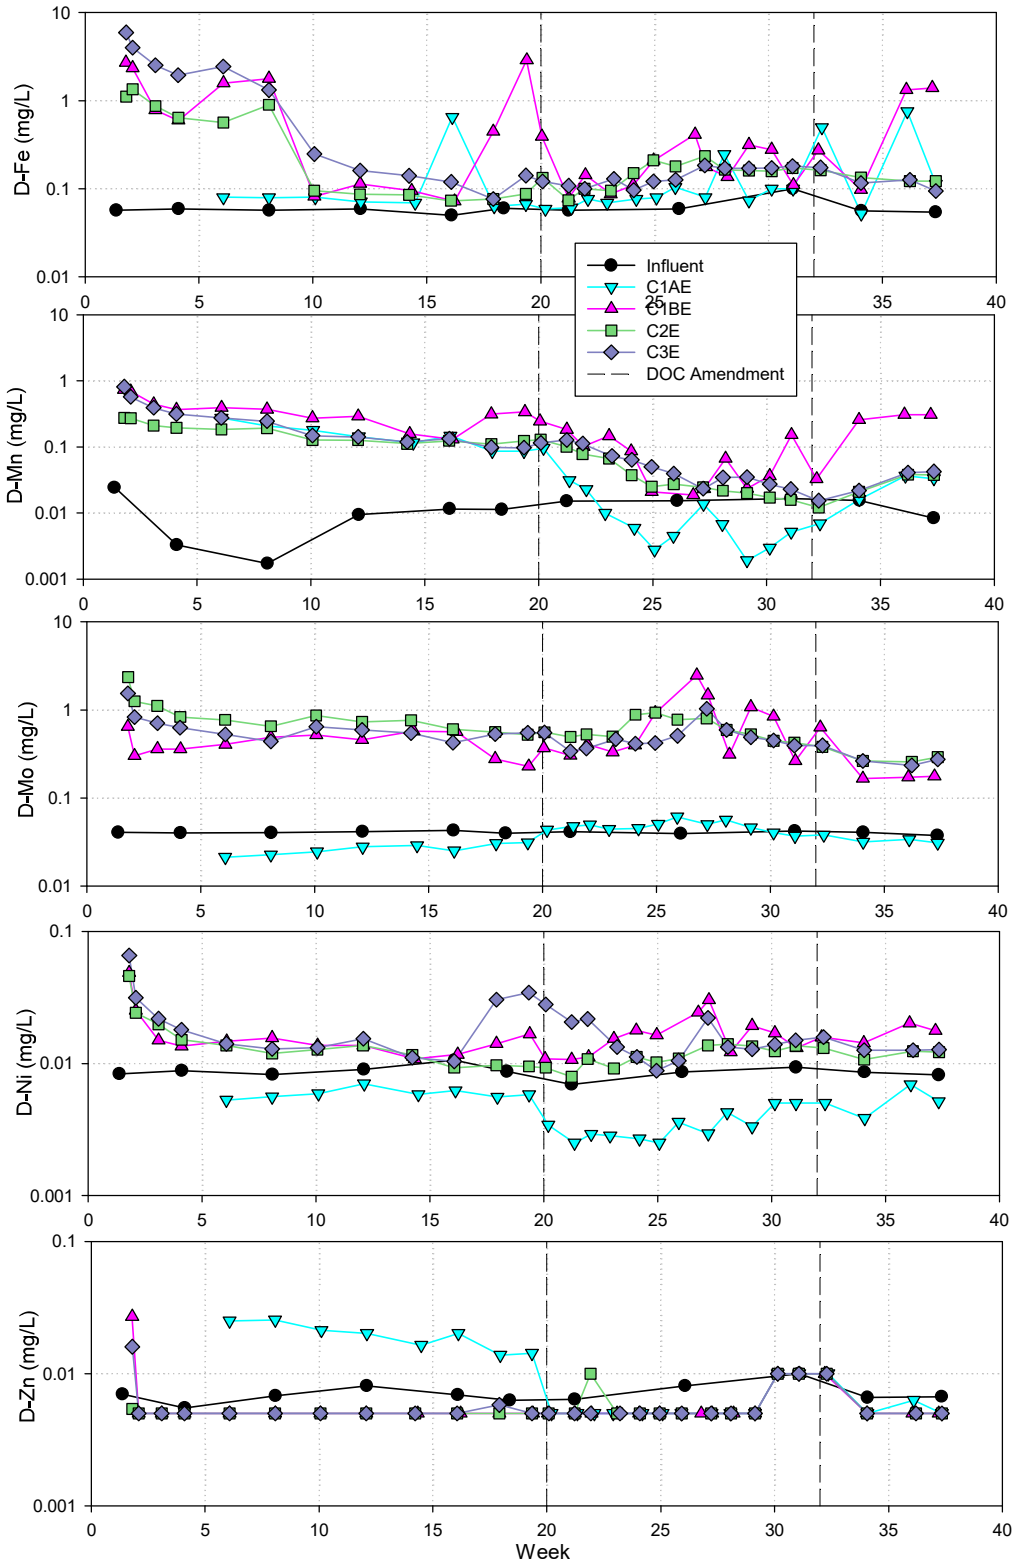

Figure 3-20: Time series profiles for dissolved Fe, Mn, Mo, Ni and Zn in column effluents over 37 weeks of operation. (Note that results are presented on a logarithmic scale).

4. Conclusions and Recommendations

Newmont™

4. Conclusions and Recommendations

4.1 Summary of Key Findings

The following outlines the most salient conclusions from the ZVI column testwork.

- Leachate results show circumneutral pH for gravel and ZVI and an acidic pH (4.5) for the wood chip sample. The latter exhibited the highest concentrations of water soluble parameters in SFE with Al, As, Cd, Cr, Cu, Fe, Pb and Zn levels above the CCME. By comparison, the gravel and ZVI samples show Al and F values above the WQGs, respectively.
- With few exceptions, a median HRT of 4 days was maintained throughout the operational period. Greatest variability was observed for C1 with HRTs ranging from 1.6 sto 28 days. A peak HRT of 13 days observed in week 25 for C2, while the target HRT was slightly exceeded for C3 during the first half of the test period, and reached a maximum of 8.3 days.
- Denitrification and nitrate removal did not occur to any significant extent in all columns during the first 19 weeks of testing.
- In response to the poor nitrate removal observed in week 0 to 19, a DOC amendment of Na-acetate (2:1 dose of C:N) was initiated in weeks 20 to 32. Microbial decomposition of added DOC is inferred from the decline of influent DOC in the columns and concomitant increases in alkalinity measured in effluents during the DOC amendment period. Similarly, Ca concentrations were observed to decrease during this period and is attributed to calcite precipitation.
- Sulphate concentrations remained elevated (>2,000 mg/L) throughout the test period as removal is not expected as part of the treatment outcomes of this experiment. Correspondingly, sulphide concentrations are consistently non-detectable (<0.20 mg/L).
- Initially (in weeks 0 to 19), leachate concentrations show a <15% decline in nitrate relative to influent concentration. It is postulated that temperature (maintained at 4ºC) was a key limiting factor influencing microbial denitrification.
- Nitrate concentrations declined following DOC addition, reaching minimum concentrations of ~185 mg/L for C2E and C3E and <5 mg/L for C1AE. Maximum denitrification only occurred with addition of more labile carbon and a significant increase in the treatment HRT from 4 days to 28 days.
- Arsenic demonstrated immediate removal in all columns containing ZVI throughout the test period. Column effluents show As concentrations ranging from <0.003 to 0.097 mg/L reflecting >96% reduction in concentration relative to influent levels.

- Uranium showed progressive attenuation in all columns containing ZVI with maximum removal to <0.002 mg/L observed in weeks 10 to 20. Upon addition of DOC, U concentrations increased to approach influent levels; however, concentrations declined after week 32 to <0.05 mg/L.
- Due to the nature of U species complexation, it is posited that the reduced attenuation observed in weeks 20 to 32 is associated with the enhanced presence of carbonate ions which acts as a complexing agent to form stable soluble uranyl carbonate complexes.
- Ammonia was consistently detected in leachates from columns containing ZVI at levels ranging from 6.3 to 33 mg/L and is consistent with observations in the literature that nitrate is reduced to ammonia in the presence of ZVI.
- Nitrite concentrations increased in all columns containing ZVI during the DOC amendment period from <3.5 mg/L to a peak of 45 mg/L and indicate incomplete denitrifiation during this period in the presence of ZVI. Conversely, considerably lower nitrite concentrations (mostly < 3 mg/L) were observed in C1AE throughout the entire experimental period including during DOC amendment and consistent with more complete denitrification (to N_2) occurring in this column.
- WAD-CN was consistently detected at low levels (<0.15 mg/L) in leachates from all ZVI columns. Independent bench scale testing of the ZVI sample did not show detectable WAD-CN levels. No plausible explanation for the release of CN in the ZVI columns is available at this time.
- Trace metals including Al, Co, Cu, Sb and Se were attenuated relative to influent concentrations, primarily in the ZVI columns. This is attributed to adsorption by the ZVI surface.

4.2 Conclusions and Future Work

The bench-scale column testing of a semi-passive treatment system for the Coffee Mine Project highlighted some successful treatment strategies as well as challenges. It is clear from the bench-scale testing that a semi-passive treatment configuration would require an initial denitrification step to remove nitrate from heap leach effluent and prior to passing through the proposed ZVI-matrix for arsenic and uranium removal. In the absence of nitrate removal, the ZVI-matrix has shown that reduction of nitrate to ammonium occurs and produces elevated ammonium in post-ZVI effluent which is undesirable. These findings are consistent with results described in the primary literature.

With the wood chips used in this bench-scale testwork, and the low temperatures (*e.g.*, 4ºC) employed throughout the testing, denitrification did not proceed at a sufficient rate to effect complete nitrate removal without the addition of a more labile carbon source and an

extended hydraulic residence time, at least within the denitrification treatment step. The carbon addition favoured microbial decomposition but with a concomitant generation of excess alkalinity resulting in increased uranium solubility and poor removal efficiency. Conversely, increased alkalinity had no effect on As removal which was effectively >99% in all materials tested and throughout the duration of testing. Future testing of semi-passive treatment configurations will need to evaluate a balance between improving carbon availability - to support microbial decomposition - without generating excess alkalinity in the treated effluent as this results in poor uranium removal. Therefore, the areas of future focus will include:

- Identification of a natural carbon source capable of supporting sufficient microbial decomposition to supply electrons for nitrate reduction via denitrification;
    - Possible carbon sources to evaluate would be:
        - Composted wood chips and bark – composting could provide for breakdown of cellulitic material and generation of more readily available carbon by-products. It may be possible to generate this material as part of clearing conducted during construction phase;
        - Hay or grasses – these materials are used in other semi-passive treatment systems (*e.g.,* Biochemical Reactors) used to promote denitrification of mine contact waters. This material would need to be imported to Coffee.
- Optimization of the hydraulic residence time for denitrification. The target HRT of less than 5 days was not sufficient for denitrification; however, As and U removal occurred rapidly and the removal was satisfactory with the relatively short HRT.

Further bench-scale testing is not recommended at this time given the constraints on the availability of representative heap leach solution and quantities necessary to support test durations required to address the questions outlined above.

There is an opportunity to capitalize on reclamation research that is being proposed for Coffee, commencing once Phase 1 of heap leach stacking and leaching has concluded in Yr-5 of the mine life. Specifically, a test pad is contemplated using Coffee ore, leaching the ore and rinsing the ore in order to generate heap leach material to assess cover options and revegetation strategies. The heap leach rinsing period on the test pad can likely generate representative solution as well as sufficient volumes to support further evaluations of viable carbon sources and optimum hydraulic retention times to support acceptable denitrification rates while limiting excessive alkalinity production. A detailed testing program will be provided in Yr-3 and circulated to First Nations and regulators for review and comment. External review will serve to refine the experimental design well in advance of testwork initiation.

1. Introduction

The Coffee Gold Project (the Project) is evaluating the use of semi-passive treatment at closure to treat drain down seepage water from the decommissioned heap leach facility (HLF). Parameters of potential concern (POPCs) have been identified as arsenic (As), nitrate (NO_3) and uranium (U). Nitrate represents a residual product of cyanide degradation while As and U represent leached components from the ore. A semi-passive treatment system, based on the combined principles of permeable reactive barrier (PRB) technology and biological reactor (BR) technology, is being considered for the closure phase of the Project. In PRB/BR systems, a permeable matrix (*e.g.*, gravel) is amended with one or more materials to create a reactive medium for contaminant removal.

As part of the pre-feasibility testwork program, column experiments will be conducted at the Yukon Research Center, Yukon College, under the oversight of Guillaume Nielsen, Ph.D. The column experiments will be used to:

- Demonstrate proof of principle (*i.e.*, can the technology reduce POPC concentrations in heap leach seepage solutions to acceptable levels?);
- Determine POPC removal rates, which in turn have relevance to HRT requirements and treatment system dimensions;
- Evaluate the risks and merits associated with various reactive media, including wood chips and ZVI;
- Identify the nature of secondary minerals that may clog the system over time (relevance to the potential for hydraulic failure and system longevity); and
- Identify any potentially-problematic by-products that may be generated within the treatment system (*e.g.*, nitrite, ammonia, ferrous iron, hydrogen sulfide).

To address these objectives, three column configurations are proposed (Figure 1-1). The first column configuration encompasses two columns in series. The first column (gravel + wood chips) is used to promote denitrification (reduction of nitrate to nitrogen gas), while the second column (gravel + ZVI) is designed to reduce arsenic and uranium concentrations. Some arsenic and uranium removal may also occur in the first column in the presence of wood chips alone (Figure 1-1).

Column configurations #2 and #3 comprise single reaction cells, containing gravel + wood chips + ZVI (Figure 1-1). In the presence of ZVI, the reduction of nitrate to nitrogen gas can be favoured (*i.e.*, the potential for ammonia generation can be theoretically minimized) with sufficient organic carbon present, which is required to nourish denitrifying microbial

assemblages (David Blowes, Pers. Comm.). Accordingly, it is possible that desired treatment outcomes may be achieved with a singular bioremediation design (*i.e.*, single stage). To test this combined matrix, column configurations #2 and #3 have been designed with varying proportions of gravel + wood chips + ZVI (Figure 1-1).

Columns will be operated under fully saturated conditions over a period of 6 to 12 months, commencing in the first quarter of 2020.

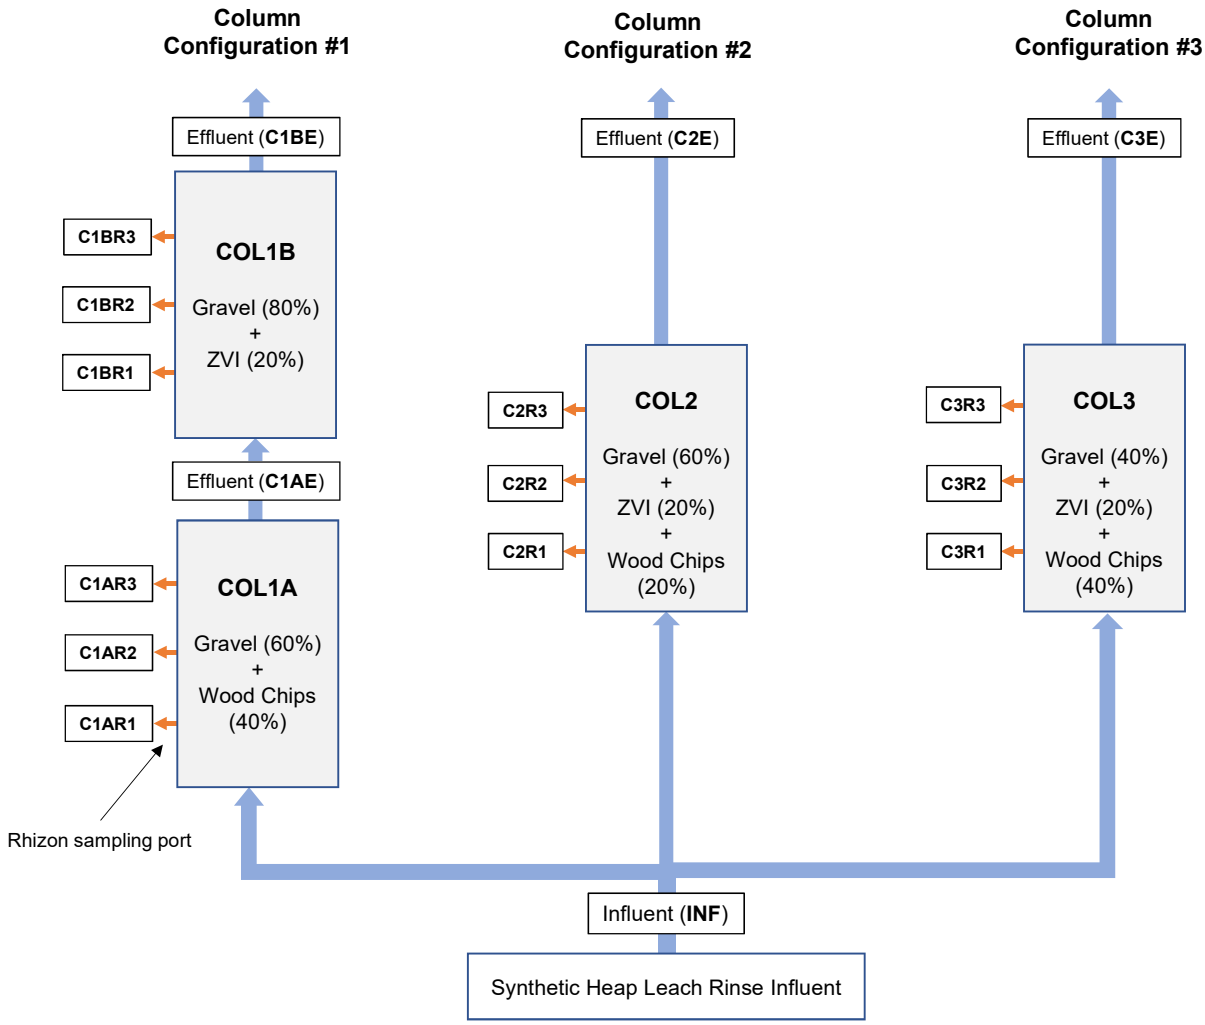

Figure 1-1: Column Study Configuration

This updated work plan presents information regarding column substrates and their characterization (Section 2), column construction and start-up activities (Section 3), the operational monitoring plan (Section 4), and record-keeping activities (Section 5). Equipment and materials required for the column study are outlined in Appendix A. Standard operating procedures (SOPs) for operating the columns are provided in Appendix B.

2. Substrate Specifications and Solid-Phase Test Work

The reactive medium for the column study will comprise a mixture of gravel and amendments (*e.g.*, organic carbon and/or ZVI) to promote conditions conducive to the removal of nitrate, arsenic and uranium. Wood chips represent an ideal source of organic carbon given their local availability and successful application in bioremediation systems. Specifications for these column substrates are presented in Table 2-1 below.

Table 2-1:
Substrate Material Specifications

Column Substrate	Specifications
Wood Chips	50% wood chunks shredded by the Wiley Mill + 50% splintered wood collected directly from the bucket
Gravel	¼"to ½" grain size
Zero Valent Iron	Connelly-GPM ETI CC-1004 (-8 + 50 mesh)

All substrate materials (gravel, wood chips, zero valent iron) will be characterized for solid-phase properties. Sample analysis will be conducted at SGS Laboratories in Burnaby, B.C. and will include:

- Acid-base-accounting (ABA), which includes neutralization potential, total-sulfur (S), sulfate-S, total inorganic carbon and total carbon (C).
    - Total S and C will be determined by infrared (IR) combustion (LECO).
    - Sulfate-S will be determined by acid leach (25% HCL) and analysis by inductively coupled mass spectrometry (ICP-MS).
- Aqua regia digestible metals analysis, which will determine solid-phase metal abundance by ICP-MS.
- Shake flask extraction (SFE) will be conducted using a 24-hour NanoPure water leach extraction test at a 3:1 liquid:solid ratio to provide a measure of readily soluble metals that will be immediately available for leaching upon exposure to infiltrating water.
- Total nitrogen (N) and phosphorus analysis (wood chips only).
    - Total N will be determined by infrared (IR) combustion (LECO).
    - Total phosphorus content will be determined by sodium peroxide flux and analysis by ICP-MS.

3. Column Construction and Start-Up

3.1 Column Construction

The columns will be constructed and operated at the Yukon Research Center laboratory in Whitehorse. The columns are Plexiglass cylinders (inner diameter = 10 cm, length = 30 cm, total volume = 2.36 L) with an inlet at the base and terminus (top) of each column. Three outlet ports for rhizon installation are pre-drilled along the length of each column (6-7 cm apart) and reinforced with 1 inch of plexiglass. The columns are designed such that influent enters from the bottom of the column and flows upward to reduce the potential of preferential pathway formation.

Saturated columns will be constructed with varying combinations of wood chips and gravel and a constant proportion of zero valent iron (Figure 1-1). Prior to packing the columns with the substrates, the bottom of each column is lined with a dispersion plate (*i.e.*, perforated disk), a sheet of non-reactive polyester fabric, and a layer of silica sand to allow for the even distribution of influent over the bottom of the column. Gravel will be rinsed with deionized water prior to use in column construction to remove fines or other residue on material surfaces. The density of wood chips, gravel and zero valent iron will be determined to convert column proportions to equivalents in substrate mass. Substrates will be manually mixed and transferred to the columns in 2-3 cm lifts to minimize heterogeneity and segregation. Each lift will be packed by hand to a similar density.

Rhizon samplers will be installed at intermediate distances along the columns by placing the packed columns on their side and inserting rhizons into the pre-drilled outlet ports. Outlet ports will be sealed with two-part epoxy and left to cure for one week. Epoxy will only be applied to the acrylic exterior of the column to ensure that effluent chemistry is not affected.

A list of equipment and materials for column construction and operations is presented in Appendix A.

3.2 Column Start-Up

Columns will be operated in the fridge at 4˚C. Influent to be used for column operation will be stored in in the fridge (at 4˚C) at least 3 days prior to being added to the influent container for refill; this will ensure that the temperature of influent is consistent with the temperature of the water within the columns to limit any potential disturbance to microbial populations.

The porosity of each column must be verified to determine the operational flow rate (based on a target hydraulic residence time of 4 days at the start of the experiment). The flow rate will be calculated by dividing the porosity by the target HRT. The porosity of the columns will be determined by measuring the volume of influent added to saturate the column substrates upon initiation of the experiment. This volume is subject to change slightly as the materials absorb water and slowly degas over the subsequent 7 days.

4. Operational Monitoring

4.1 Monitoring Plan and Sample Collection

The monitoring plan for the column study is presented in Table 4-1. Specific details regarding column operation and effluent and rhizon sampling procedures are outlined in SOP A through J (Appendix B).

4.2 Quality Assurance and Quality Control

Quality control protocols include monthly method blank samples collected from a blank column operated at the Lorax laboratory in Vancouver, and one blank sample collected during each sample collection week at the Yukon College laboratory. The method blank column is a column built with identical materials to the one used for this experiment and filled with deionized water. The corresponding sample is a full-suite analysis which captures leaching from column construction materials. The blank sample collected during a sampling week will be analyzed for only dissolved metals and anions to capture environmental variability or subsampling error as these parameters are most commonly subject to contamination.

Table 4-1:
Column Monitoring Plan

Parameter Group		Flow	General Chemistry	Dissolved Metals	Dissolved Mercury	Anions	Cyanide	Sulphide	Nutrients
Parameters		Flow Rate (Q)	EC, pH, Total Alkalinity	Full Suite (*e.g.*, D-Al, D-Sb, D-As, D-Se, D-Cd, D-Cr, D-Co, D-Cu, D-Fe, D-Pb, D-Mn, D-Mo, D-Ni, D-Se, D-S, D-U, D-Zn)	D-Hg	F, Cl, Br, SO_4, NO_3, NO_2	WAD-CN	H_2S	DOC, NH_3, TD-P

Notes:
1. INF = influent; EFF = effluent; RHZ = rhizons
2. When applicable, effluent and rhizons should be sampled as close together as possible (*i.e.*, on consecutive days
3. Flow rate is measured by the change in influent and effluent volumes during influent refill events, to be conducted at least once per week. Flow rates should closely align with the rate set on the pump.
* Influent addition marks experiment start time. Substrates should be saturated (without flow into columns) for 7 days.
** A planned flow rate change will occur in Week 16. Sample should be collected before the flow rate is increased.
*** End date of experiment to be finalized as it proceeds.

4.3 Leachate Analytical Testwork

Saturated column leachate and influent samples will be sent to ALS Environmental Laboratories (ALS) in Burnaby, B.C. for analysis in accordance with Table 4-2 below.

Table 4-2:
Summary of Analytical Methods

Parameter Group	Standard Method	Method Description
Dissolved Metals	APHA 3030B/6020A (mod)	Analysis by CRC ICP-MS.
Dissolved Mercury	APHA 3030B/EPA 1631E (mod)	Cold-oxidation using bromine monochloride prior to reduction with stannous chloride, and analysis by CVAAS or CVAFS.
Anions (nitrate, nitrite, sulphate, chloride, bromide, fluoride)	EPA 300.1 (mod)	Ion chromatography with conductivity and/or UV detection.
Cyanide (WAD only)	APHA Method 4500-CN I	In-line sample distillation with final determination by colourimetric analysis.
Sulphide	APHA 4500 -S E-Auto-Colorimetry	A continuous flow manifold adds HCl to the sample which converts sulphide to a gas, then the sulphide is separated from the flow using a gas dialysis membrane. A Colorimetric reaction produces a methylene blue compound which is measured at 660 nm.
Dissolved Organic Carbon (DOC)	APHA 5310B TOTAL ORGANIC CARBON (TOC)	High temperature combustion to convert carbonaceous material to CO_2 which is then analyzed by IR spectroscopy.
Ammonia (NH_3)	J. ENVIRON. MONIT., 2005, 7, 37-42, RSC	Flow-injection analysis with fluorescence detection.
Total Dissolved Phosphorus (TD-P)	APHA 4500-P Phosphorous	Persulphate digestion followed by colourimetric analysis .

Alkalinity, pH and conductivity will be measured in-house at the Yukon Research Center laboratory.

5. Record-Keeping

A summary of required record-keeping activities is presented in Table 5-1 below.

Table 5-1:
Summary of Required Record-Keeping Activities

Record Type	Purpose	Frequency of Record Collection and Submission to Lorax	Information to be Included
Daily Records (hard copy only)	Daily records are collected in a notebook to be shared with lab analysts managing the columns. This is where information regarding column operation, refill events, and observations regarding appearance, odours, and incidents should be noted.	Notes will be collected regularly and reviewed as column operation progresses. Complete records do not need to be digitized but notable events *(i.e.*, incidents or any changes to column operation) should be summarized and relayed to Lorax to aid interpretation of effluent results.	• The time when flow is stopped • The time when flow is initiated • The time when nitrogen purge is initiated • The time when nitrogen purge is completed • The time and change in flow rate during sample collection • The time and change back to the regular column operation flow rate • The time when sample collection is initiated • The time when sample collection is completed • Observations of changes in column appearance or odours • A detailed account of any occurrence of incidents and steps taken to troubleshoot the issue • Mass of effluent before refill • Mass of influent before refill • Mass of influent after refill
Sampling Records (hard copy and digital)	Sampling records contain information on the general chemistry of effluent and rhizon samples. These parameters are measured in-house as indicators of changes to chemical conditions (*i.e.*, redox state) that may be occurring in the columns.	Information will be collected following each sampling event. A digital version of the sampling records should be submitted to Lorax within one week after sample collection.	• Mass of sample collected • pH and conductivity calibration results • Conductivity measurement • pH measurement • Alkalinity measurement
Flow Records (digital only)	Flow records are collected to ensure that the intended flow rate is being achieved, and to track total influent and effluent volumes going through the columns. If there are (substantial) losses from the columns, this should also be included as estimates to best account for the total volume treated by the columns.	Information from the daily records relevant to flow records will be digitized and reviewed weekly. Digitized records should be submitted to Lorax on a biweekly basis.	• The time that flow is stopped before refill • The time that flow is initiated after refill • Mass of effluent before refill • Mass of influent before refill • Mass of influent after refill
Photos (digital only)	Photos of the columns should be collected on a biweekly basis to monitor physical changes occurring in the column substrates.	Photos should be submitted to Lorax on a monthly basis, or sooner if a notable observation is made.	• An indication of when the photos were taken • A description of changes documented by the photos (*i.e.*, precipitate formation)

Templates for record-keeping (*i.e.*, Daily Records, Sampling Records and Flow Records) and the Chain of Custody (COC) form to be used for sample submissions will be provided by Lorax in Excel format.

Appendix A: Equipment & Materials List for Column Study

Quantity	Item	Supplied By
Column Construction and Maintenance		
4	Acrylic columns (including dispersions plates, screws, nuts, gaskets)	Lorax
4	Polyester filter	Lorax
As required	Ottawa sand	Lorax
Extras to be included for maintenance	Tubing (PTFE and C-flex), valves, adapters, luers, port caps for column and sample bottle construction	Lorax
	Macrorhizon samplers (0.15 µm pore size) and two-way valves	Lorax
3	2-part epoxy for rhizon installation	Lorax
8	HDPE sample bottles (for bulk sampling)	Lorax
As needed	Plumber's (thread sealing) tape	Lorax
As needed	Cable zip-ties	Lorax
1	Power drill with bits	Lorax
1-2	Screwdriver and bits	Yukon College
1	Wrench (7/16")	Lorax
2	X-Acto (utility) knife	Yukon College
2	Lighter	Yukon College
1	Mallet	Lorax
2 packs	Nitrile gloves for column construction	Lorax
As needed	Plastic sheets for cone and quartering of column substrates	Yukon College
As needed	Equipment to mix the substrates before packing the column (*i.e.*, buckets or heavy-duty clear plastic bags)	Yukon College
Substrates for Column Construction		
1.5 kg	Wood chips	Lorax
12.3 kg	Gravel	Yukon College
4.6 kg	Zero Valent Iron	Yukon College
Column Operation		
As needed	HDPE drums (~200 L) to store bulk influent water	Yukon College
1	Peristaltic pump (high flow) to pump influent from drum containing bulk supply during refill events	Yukon College
6	HDPE influent and effluent containers with lids (4 L to 8 L capacity)	Yukon College
1-3	Peristaltic pump (low flow) for column operation	Yukon College

Quantity	Item	Supplied By
Extras to be included	Tubing for pump head	Yukon College
1	Scale (precision to at least 1 g) for influent refill and general sample collection	Yukon College
Effluent and Rhizon Sampling Equipment		
As needed	Nitrogen gas (industrial quality)	Yukon College
As needed	Regulator for nitrogen gas	Yukon College
As needed	Tubing to connect gas regulator to bulk sample bottles	Yukon College
As needed	0.45 µm cellulose acetate filter	ALS to YC
As needed	Sample containers (subsamples) for each suite of parameters	ALS to YC
As needed	Preservatives for each suite of parameters	ALS to YC
1	pH probe and meter	Yukon College
1	EC probe and meter	Yukon College
As needed	pH and EC calibration solutions to cover the range of effluent chemistry expected; recommended pH 4, 7 and 10 for pH measurements, and 84 and 1413 µS/cm for EC measurements	Yukon College
As needed	pH probe filling and storage solutions	Yukon College
1	Magnetic stirrer (for pH measurements)	Yukon College
2	Magnetic bars	Yukon College
As needed	Materials needed for alkalinity measurement (conducted by titration or using an indicator dye); standard method to be used throughout experimental period	Yukon College
1	Portable filter or in-situ ventilation *(TBD)*	Yukon College
General Labware and Other Materials		
As needed	Distilled water	ALS to YC
As needed	Mild acid (nitric or hydrochloric) for acid wash of non-disposable sampling equipment, according to standard method used in lab; recommended at least 0.1 M HCl and 3x rinse with DI water	Yukon College
2-3	Spray bottles	Yukon College
As needed	Standard labware/glassware (*i.e.*, clean weigh boats, beakers, volumetric flasks, burettes, *etc.*)	Yukon College
1-2	Pipettor (50 to 200 µL)	Yukon College
As needed	Pipette tips (clean but not sterile)	Yukon College
As needed	Vinyl gloves (for wet chemistry work)	Yukon College
As needed	Kimwipes (large size)	Yukon College
As needed	Parafilm	Yukon College
10 to start	Luer-lock syringes (50 mL)	ALS to YC
As needed	Pens and sharpie markers	Yukon College

Quantity	Item	Supplied By
As needed	Notebook(s)	Yukon College
As needed	Labels for columns and sample bottles	ALS to YC
1	Fridge to store in-house test samples for 1 month and potentially also influent water	Yukon College
As needed	Paper towels	Yukon College
As needed	Plastic bags for sample submission	Yukon College
As needed	Bubble wrap	ALS to YC
As needed	Coolers for sample submission	ALS to YC
As needed	Ice packs	ALS to YC
As needed	Packing tape	Yukon College

Appendix B:
Standard Operating Procedures for Column Study

A	**Initiating Flow through the Columns**
Purpose	To describe when and how flow through the columns should be initiated or re-initiated after a short- or long-term stop of flow.
Context	Initiating flow to the columns must be completed after stop of flow. When flow to the columns is stopped, valves along the tubing are closed off to prevent exposure of the column to oxidative conditions. Stop of flow is regularly conducted during influent refill or maintenance events (*i.e.*, replacement of tubing/luers/adapters/valves). The schematic shows the orientation of valves after flow has been initiated to the columns.
Procedure	1. Open the valve between the **Influent Container** and **Pump** (**Valve 1**) to allow flow through the tubing. 2. Start flow on the peristaltic pump at the designated pump rate. 3. Flush the valve after the **Pump** (**Valve 2**) by letting the influent overflow through the side port (the port not connected to the tubing), while the valve remains closed off in the direction of the column. This will allow any bubbles or precipitate built up in the lines to be flushed out and not introduced to the columns. Flow can be "maxed out" on the pump during flushing periods. 4. Once ~ 10 mL has been flushed through **Valve 2**, open the valve to allow flow in the direction of the column. 5. Flush **Valve 3** below the column. Once ~10 mL has been flushed through the side port, open **Valve 3** to allow flow into the column. 6. Once **Valves 1-3** have been opened, open **Valve 4** to allow effluent to collect in the **Effluent Container**. 7. Record the time when flow to the columns was initiated, and the flow rate applied in the daily records.
Schematic	 ***Three-way valve: Black indicates the direction to which flow is closed off***

Record-Keeping	• Daily records:
	  ○ The time when flow was initiated to the columns.
	  ○ The flow rate applied to operate the columns.

B	**Stopping Flow through the Columns**
Purpose	To describe when and how flow to the columns should be stopped for an extended period of time (>5 minutes).
Context	Stopping flow to the columns will be done during influent refill events and if any column maintenance is needed. This is different from *pausing* the flow as this will be for an extended period of time, which will require valves along the tubing to be closed off to ensure that air is not introduced to the column. (If flow to the columns is stopped for <5 minutes, this can be achieved by pausing flow on the pump without closing off valves to the columns.) The schematic depicts the orientation of valves after flow to the columns has been stopped.
Procedure	1. Close off the valve between the column and the **Effluent Container** (**Valve 4**) in the direction of the column. 2. Close off **Valve 3** below the column in the direction of the column. 3. Close off **Valve 2** after the **Pump** in the direction of the column. 4. Pause flow on the **Pump**. 5. Close off **Valve 1** in the direction of the **Influent Container**. 6. Record the time when flow was stopped to the columns in the daily records.
Schematic	 ***Three-way valve: Black indicates the direction to which flow is closed off***
Record-Keeping	• Daily records: ○ The time when flow to the columns was stopped.

C	**Nitrogen-Purge of Sample Bottles**
Purpose	To describe how a nitrogen-purge of sample bottles is conducted prior to initiating effluent and rhizon sample collection. The nitrogen purge can be done on a single sample bottle, or on multiple bottles connected in sequence.
Context	The nitrogen-purge is conducted to remove oxygen from the sample bottles to limit the formation of oxidation artifacts during collection of effluent and rhizon samples from the columns. The schematic shows the orientation of the valves after the nitrogen purge has been initiated and terminated.
Procedure	<u>Initiation:</u> 1. Connect the long-tubing valve of the **Primary Bottle** in the sequence to the **Regulator**, as indicated in the schematic below. 2. Open the long-tubing valve of the **Primary Bottle** to allow gas into the bottle. 3. If the nitrogen purge is conducted for only one sample bottle, connect the short-tubing valve of the **Primary Bottle** to the **Water Bottle**, and open the valve. This will limit the introduction of oxygen through the short-tubing valve while allowing oxygen from the sample bottle to be vented as nitrogen gas is filling the bottle. If the nitrogen purge is conducted for multiple sample bottles, proceed to Step 4. Otherwise, proceed to Step 9. 4. Connect the long-tubing valve of the **Secondary Bottle** in the sequence to the short-tubing valve of the **Primary Bottle**. 5. Open the short tubing valve on the **Primary Bottle** to allow gas flow in the direction of the **Secondary Bottle.** 6. Open the long-tubing valve on the **Secondary Bottle** to allow gas flow into the sample bottle. 7. Repeat Steps 4 to 6 with all proceeding sample bottles connected in sequence. 8. Connect the short-tubing valve of the **Last Bottle** in the sequence to the **Water Bottle** and open the valve. 9. Check that all valves are opened in the right direction. 10. Open the **Regulator** to allow a steady stream of gas into the sample bottles. 11. Ensure that there are no leaks from the valves or lids of the sample bottles. Consistent bubbling from the **Water Bottle** will indicate that there is sufficient pressure coming through the sample bottles. 12. Continue the nitrogen-purge for 15 minutes per sample bottle 13. Record the start time of the nitrogen purge in the daily records. <u>Termination:</u> 1. Once the nitrogen purge is complete, disconnect the sample bottles from one another before closing off the **Regulator**. 2. Start with closing off the short-tubing valve of the **Last Bottle** in the sequence to the sample bottle. 3. Next, close off the long-tubing valve of the **Last Bottle** in the sequence to the sample bottle. Both short and long- tubing valves should be closed off to the bottle before disconnecting from the sequence. 4. Disconnect the long-tubing valve of the **Last Bottle** from the short-tubing valve of the preceding sample bottle. 5. Repeat Steps 2 to 4 until all sample bottles have been disconnected from each other, and the **Primary Bottle** has been disconnected from the **Regulator**.

C	**Nitrogen-Purge of Sample Bottles**
	6. Close off the **Regulator**. 7. Record the end time of the nitrogen purge in the daily records.
Schematic	***Initiation: configuration of valves on sample bottles connected in sequence***  ***Termination: Configuration of valves on a sample bottle, before it is disconnected from the sequence***  ***Three-way valve: Black indicates the direction to which flow is closed off***
Record-Keeping	• Daily records: o Start time of the nitrogen purge for the sample bottle(s). o End time of the nitrogen purge for the sample bottle(s).

D	**Effluent Sample Collection**
Purpose	To describe how effluent samples are to be collected through in-line filtration using a 0.45 µm cellulose acetate filter.
Context	If influent is already flowing through the columns, proceed with the following steps. If influent is not flowing through the columns, initiate flow per SOP A. Effluent sample collection should only be done following a nitrogen-purge of sample bottles as described in SOP C. The mass of the sample bottles are recorded on the bottles, allowing for the mass of the sample to be calculated by difference. Note that mass is used as a proxy for volume measurement. The schematic shows the orientation of valves after effluent sample collection has been initiated.
Procedure	1. If needed, increase the flow rate on the **Pump** during effluent sampling. Record the time for the change in flow rate along with the sampling flow rate in the daily records. 2. Once sample bottles have been disconnected from each other, following a nitrogen purge, take a **Sample Bottle** and 0.45 µm cellulose acetate **Filter** to the **Effluent Container** of the column designated for effluent collection. 3. Connect the **Filter** to the side port of the effluent valve (**Valve 4,** Schematic for SOP A). (The side port is the port that is not connected to the column or to the effluent container.) The filter should be attached ensuring that the reactive side of the filter is facing the direction that effluent will be passing into the **Sample Bottle**. 4. Turn **Valve 4** to allow flow from the column to enter the **Filter**, and closing off flow to the **Effluent Container**. 5. Connect the other side of the filter to the long-tubing valve of the **Sample Bottle**. 6. Connect the short-tubing valve of the **Sample Bottle** to the **Water Bottle** to allow nitrogen gas venting out of the sample bottle (during sample collection) to be released in water rather than open air to limit introduction of oxidation artifacts. 7. Repeat the set-up of **Filter** and **Sample Bottle** for all effluents to be sampled. 8. After set-up of the **Filter** and **Sample Bottle** are complete, wait until effluent has passed through the filter and the side port of the long-tubing valve of the sample bottle. This can take up to 10-20 minutes depending on the flow rate. 9. Once effluent is consistently passing through the side port of the long-tubing valve on the **Sample Bottle**, depressurize the sample bottle by first opening the short-tubing valve to allow gas to pass from the sample bottle to the **Water Bottle**. Then, open the long-tubing valve to allow effluent to enter the **Sample Bottle**. There is potential for filters to get clogged, particularly during the first few weeks of sampling when the columns have not reached equilibrium conditions. Troubleshooting a clogged filter is described in detail in SOP J. 10. Record the time when sample collection is initiated in the daily records. 11. Monitor the progress of effluent collection to ensure that the volume collected is consistent with the rate set by the pump. 12. Once sufficient volume of effluent has been collected (per the monitoring program in Table 4-1), disconnect the **Sample Bottle** by first closing off the short-tubing valve to the bottle, followed by closing off the long-tubing valve to the bottle. 13. Disconnect the **Sample Bottle** and **Filter** from **Valve 4.** Open up **Valve 4** to allow effluent to flow into the **Effluent Container**. Discard the filter. 14. Record the time when sample collection is completed in the daily records.

D	**Effluent Sample Collection**
	15. If the flow rate was changed during sampling, decrease the flow rate as needed for regular column operation. Record the time for the change in flow rate along with the column operation flow rate in the daily records. 16. Weigh the mass of sample bottle + effluent collected. Record the mass of effluent collected in the sampling records.
Schematic	 ***Three-way valve: Black indicates the direction to which flow is closed off***
Record-Keeping	• Daily records: o Start time of flow rate change and sampling flow rate. o End time of flow rate change and column operation flow rate. o Start time sample collection initiated. o End time sample collection completed. • Sampling records: o Mass of effluent sample collected.

E	**Rhizon Sample Collection**
Purpose	To describe how rhizon samples are to be collected without in-line filtration. The rhizon samplers are designed with porous glass fiber with a pore size of 0.15 µm.
Context	If influent is already flowing through the columns, proceed with the following steps. If influent is not flowing through the columns, initiate flow per SOP A. Rhizon sample collection should be conducted sequentially from the bottom to the top of the column. Rhizon sample collection can only be done following a nitrogen-purge of sample bottles as described in SOP C. The mass of the sample bottles are recorded on the bottles, allowing for the mass of the sample to be calculated by difference. Note that mass is used as a proxy for volume measurement. The schematic shows the orientation of valves on Rhizon 1 after sample collection has been initiated, while valves for Rhizons 2 and 3 remain closed.
Procedure	1. If needed, increase the flow rate on the **Pump** during effluent sampling. Record the time for the change in flow rate along with the sampling flow rate in the daily records. 2. Once sample bottles have been disconnected from each other, following a nitrogen purge, take a **Sample Bottle** to the rhizon port to be sampled. 3. Connect the (two-way valve) on the bottom-most rhizon (**Rhizon 1**) of the column to the long-tubing valve of the **Sample Bottle**. Open the two-way valve to allow flow out of the rhizon port. 4. Connect the short-tubing valve of the **Sample Bottle** to the **Water Bottle** to allow nitrogen gas venting out of the sample bottle (during sample collection) to be released in water rather than open air to limit introduction of oxidation artifacts. 5. Repeat the set-up for **Sample Bottle** for all Rhizons (on other columns) to be sampled. 6. After set-up of the **Sample Bottle** is complete, wait until effluent has passed through the side port of the long-tubing valve on the sample bottle. This can take up to 10-20 minutes depending on the flow rate. 7. Once effluent is consistently passing through the side port of the long-tubing valve on the **Sample Bottle**, depressurize the sample bottle by first opening the short-tubing valve to allow gas to pass from the sample bottle to the **Water Bottle**. Then, open the long-tubing valve to allow effluent to enter the **Sample Bottle**. 8. Record the time when sample collection is initiated in the daily records. 9. Monitor the progress of rhizon sample collection to ensure that the volume collected is consistent with the rate set by the pump. 10. Once sufficient volume of effluent has been collected (per the monitoring program in Table 4-1), disconnect the **Sample Bottle** by first closing off the short-tubing valve to the bottle, followed by closing off the long-tubing valve to the bottle. 11. Disconnect the **Sample Bottle** from the two-way rhizon valve. Close off the two-way valve. 12. Record the time when sample collection is completed in the daily records. 13. Weigh the mass of sample bottle + rhizon sample collected. Record the mass of rhizon sample collected in the sampling records. 14. Conduct a nitrogen purge of sample bottles for the next set of **Rhizon x** samples to be collected (per SOP C). 15. Repeat Steps 2-11 to collect **Rhizon x** samples. 16. At the end of the sampling event, if the flow rate was changed during sampling, decrease the flow rate as needed for regular column operation. Record the time for the change in flow rate along with the column operation flow rate in the daily records.

E	**Rhizon Sample Collection**
Schematic	 ***Three-way valve: Black indicates the direction to which flow is closed off*** ***Two-way valve: Vertical position of navy bar indicates that valve is closed*** ***Horizontal position of navy bar indicates that valve is open***
Record-Keeping	• Daily records: o Start time of flow rate change and sampling flow rate. o End time of flow rate change and column operation flow rate. o Start time sample collection was initiated (for set each Rhizon x). o End time sample collection was completed (for each set of Rhizon x). • Sampling records: o Mass of rhizon sample collected.

<table>
<tr><th>F</th><th>Subsampling and Sample Preservation</th></tr>
<tr><td>Purpose</td><td>To describe how effluent and rhizon samples should be subsampled and preserved prior to submission to ALS Laboratories.</td></tr>
<tr><td>Context</td><td>Subsampling is the process of portioning out the bulk volume collected from the columns to smaller volumes for analysis of specific groups of parameters. The subsamples are grouped according to the container and preservative needed to properly store the sample prior to analysis. These include dissolved metals, dissolved mercury, anions, cyanide, sulphide and nutrients.</td></tr>
<tr><td>Procedure</td><td>
1. Prepare sample labels with information regarding the sample ID, sample collection date, parameter(s) to be analyzed, and preservative added.
2. Prepare sample containers as advised by ALS. (Note that orders for sample containers should be done at least one week in advance as limited stock is available at ALS Whitehorse).
3. The following table describes the parameter groups, minimum volumes, sample container and preservative to be used for subsampling. It is recommended that preservatives be added to sample containers right before subsampling is conducted . Note that there are two parts to the sulphide preservative; the second part is to be added after the sample has been poured into the container.
<table>
<tr><th>Parameter Group</th><th>Minimum Volume</th><th>Sample Container</th><th>Preservative</th><th>Volume of Preservative (µL)</th></tr>
<tr><td>General Chemistry (pH, EC, alkalinity)</td><td>25</td><td>60 mL HDPE</td><td>None</td><td>N/A</td></tr>
<tr><td>Dissolved Metals</td><td>25</td><td>60 mL HDPE</td><td>Nitric Acid</td><td>100</td></tr>
<tr><td>Dissolved Mercury</td><td>15</td><td>40 mL glass vial</td><td>Hydrochloric Acid</td><td>100</td></tr>
<tr><td>Anions</td><td>15</td><td>60 mL HDPE</td><td>None</td><td>N/A</td></tr>
<tr><td>Cyanide (WAD only)</td><td>15</td><td>60 mL UV-inhibited HDPE</td><td>Sodium Hydroxide</td><td>200</td></tr>
<tr><td>Sulphide</td><td>15</td><td>60 mL HDPE</td><td>Zinc Acetate (first) + Sodium Hydroxide (second)</td><td>100 of each</td></tr>
<tr><td>Nutrients (DOC, NH_3, TD-P)</td><td>20</td><td>120 mL amber glass bottle</td><td>Sulfuric Acid</td><td>100</td></tr>
</table>
4. To set-up sample containers prior to subsampling, the following are recommended:
   - Order the samples in a consistent sequential manner to reduce chances of error.
   - Order the parameter groups in a consistent sequential manner to reduce chances of cross-contamination of preservatives.
   - Remove all lids for sample containers prior to subsampling to be able to subsample as quickly as possible. Cap the lids to the containers right after subsampling for an individual sample is completed.
5. Once preservative has been added to all sample containers, initiate subsampling. Invert the bulk sample bottle twice and pour out the recommended volume for each parameter group, ensuring that this process is completed within ~ 1 minute.
6. Pipet sodium hydroxide into the sulphide container. Close all sample containers.
7. Once subsampling has been completed, collect all General Chemistry subsamples and set them aside for in-house testing of pH, conductivity and alkalinity. This will be described in greater detail in SOP H.
</td></tr>
</table>

F	Subsampling and Sample Preservation
	8. Prepare all other parameter group subsamples to be packed up in coolers for submission to ALS. Ensure that all lids have been capped firmly, and that glass vials are wrapped in bubble wrap. The process of sample submission to ALS will be described in greater detail in SOP G. 9. Clean the sample bottles by using a mild acid rinse (hydrochloric or nitric) followed by three rinses of deionized water. Ensure that the long-tubing valve is also thoroughly rinsed. Air-dry the sample bottles. If any discolouration or precipitation is observed on the sample bottle, tubing or valves, replace the item prior to using the sample bottle for sample collection. Replacement of the sample bottle should be done every three months regardless of any observation of discolouration.

G	**Sample Submission to ALS Laboratories**
Purpose	To describe how samples and documentation should be prepared for sample submission to ALS Laboratories.
Context	A chain of custody form (COC) releases samples to ALS Laboratories upon submission and allows the client to track the samples submitted and analytical testwork requested. A complete and updated COC form is needed for each sample submission and is followed up with a Sample Receipt Confirmation (SRC) form once the samples have been logged into the ALS system.
Procedure	1. Prepare a Chain of Custody (COC) form to submit to ALS. The COC form should be updated as needed for the sampling event (*i.e.*, sample IDs, sample collection date and time, parameters to be analyzed, lab analyst ID, and release times, etc.). 2. Email the ALS Account Manager to schedule a time for sample pick-up. Note that samples should be picked up as soon as possible following preservation, as nutrient parameters (*i.e.*, nitrogen species) have short hold times of three days. It is recommended that samples be submitted to ALS Whitehorse on the same day that they are collected. Samples need to be in the lab by 3 pm to make the flight to YVR for pick-up the following morning. If this cut-off time is missed, samples can be dropped at the airport and the waybill and information regarding ETA to YVR can be relayed to the Account Manager. 3. If samples need to be kept for some time prior to submission, this should be done following preservation in the fridge at 4°C. 4. Once samples have been subsampled and preserved (per SOP F), place the COC form and samples in a cooler with ice packs. Double-check that the total number of sample containers to be submitted matches the COC form. 5. Ensure that samples are picked up by ALS at the scheduled time. 6. A Sample Receipt Confirmation (SRC) form will be emailed to you once the samples are formally logged into the ALS system. This may take 1-2 business days to receive. Review the SRC form to ensure that there are no issues with sample integrity—this will be explicitly indicated in the email and SRC form.
Record-Keeping	• A digital copy of the COC form

H	In-House Tests for pH, Conductivity and Alkalinity
Purpose	To describe how in-house tests for pH, conductivity (EC) and alkalinity should be conducted on the General Chemistry subsample.
Context	Measurements for pH, conductivity and alkalinity are done in-house to best capture effluent chemistry at the time of collection as these parameters are known to change quickly over time. Prior to measurement of these parameters, all equipment and glassware should be properly cleaned and calibrated for use. A specific procedure has not been included for alkalinity measurement as this can be done multiple ways, depending on whatever method is standard practice in the lab. It is recommended that whatever method is selected to measure alkalinity stay consistent throughout the duration of the experiment.
Procedure	1. Calibration of the pH and EC probes should be completed prior to every instance of conducting in-house tests. A three-point calibration at pH 4, 7 and 10 is recommended, and (at least) a two-point calibration for EC at 84 and 1413 µS/cm. 2. After calibration has been completed, take a pH and EC reading of one of the respective calibration solutions. Record the pH and EC readings in the sampling records. 3. If applicable, collect an alkalinity sample from the General Chemistry subsample prior to measuring pH and EC. 4. Conduct the EC measurement on the sample first by placing the probe into the effluent sample and waiting until a stable reading is shown on the meter. Record the EC measurement of the sample in the sampling records. 5. Measure pH on the sample by placing a magnetic stir bar into the container and waiting for a stable reading on the meter while the sample is stirred on the magnetic plate. Record the pH measurement of the sample in the sampling records. 6. Measure total alkalinity of the sample. Record the alkalinity measurement of the sample in the sampling records. 7. Repeat Steps 2-5 for all samples to be measured for in-house tests. 8. After all samples have been tested, collect the samples in a plastic bag and label the bag with the date and sample IDs. Place samples in the fridge at 4°C. Keep samples until the analytical results have been reviewed by Lorax. 9. Clean all glassware and equipment used to conduct the testwork. This can be done by using a mild acid rinse (hydrochloric or nitric) followed by three rinses of deionized water. Air dry the materials.
Record-Keeping	• Sampling records: o pH and EC calibration results. o EC measurement. o pH measurement. o Alkalinity measurement.

I	**Influent Refill and Flow Records**
Purpose	To describe how influent is refilled for column operation.
Context	Influent refill should be conducted at least once per week to ensure there is sufficient influent for column operation, and to have at least one flow rate measurement per week. Flow records are based on the volume of influent treated and on the volume of effluent generated over a set period of time. Accurate flow records are necessary to evaluate column performance and ensure that the design HRT is being met. The mass of influent and effluent containers are recorded on the containers prior to initiating the experiment, allowing for the mass of the sample to be calculated by difference. Note that mass is used as a proxy for volume measurement.
Procedure	1. Thoroughly mix the bulk influent supply prior to collecting the volume needed for refill to ensure that water chemistry of the influent collected is representative. 2. Collect the volume of influent needed and keep this volume in the fridge at the same temperature as the columns for at least three days prior to use. 3. Operation of columns will be stopped during a refill event. This should be done according to SOP B. Record the time that flow through the columns was stopped in the daily records. 4. Collect all effluent containers and weigh the mass of the container + effluent collected. Record the mass of effluent collected in the daily records. 5. Toss the collected effluent down the sink followed by copious amounts of tap water. Return the effluent containers. 6. Collect the influent container for a column and weigh the mass of the container + influent remaining. Record the mass of influent remaining in the daily records. 7. Fill the influent container to the top and weigh the mass of the container + total influent. Record the total mass of influent in the daily records. Return the influent containers. 8. Repeat Steps 6-7 for all columns. 9. Once the refill is complete, re-initiate flow to the columns per SOP A. 10. Record the time when flow was re-initiated to the columns in the daily records.
Record-Keeping	• Daily records to be used for calculation in flow records: o the time when flow to the columns was stopped. o the time when flow to the columns was re-initiated. o mass of effluent before refill. o mass of influent before refill. o mass of influent after refill.

<table>
<tr><th>J</th><th colspan="3">Column Maintenance and Troubleshooting</th></tr>
<tr><td>Purpose</td><td colspan="3">To outline common column maintenance issues and options for troubleshooting.</td></tr>
<tr><td>Context</td><td colspan="3">Column maintenance involves visual inspection of how flow is passing through the column and tubing to determine whether replacement of equipment is needed over time. As the experiment progresses, precipitate can form in the tubing and impede flow to the columns, influencing the design HRT for the experiment. Further, leaks and inadvertent introduction of air to the columns can occur if not carefully and actively prevented.</td></tr>
<tr><td>Procedure</td><td colspan="3">1. Make observations on column performance and note anything that may be occurring out of place. This includes regularly using pictures to document any visible changes to column substrates (i.e., the formation of precipitate or discolouration).
2. If a problem is encountered, locate the specific blockage or leak.
3. Address the problem by referring to the table below which lists common problems and corresponding options for troubleshooting:
<table>
<tr><th>Problem</th><th>Observation</th><th>Steps for Troubleshooting</th></tr>
<tr><td>Filter Clogging During Sample Collection</td><td>Effluent sample not passing through the filter after a significant amount of time has passed. Effluent volume collecting at a much slower rate in the sample bottle compared to the rate set on the pump.</td><td>Close off the short-tubing valve on the sample bottle, followed by the long-tubing valve on the sample bottle. Remove the filter and if effluent gushes out due to back pressure, this affirms that the filter was clogged. Replace the filter as quickly as possible and reconnect the filter to the long-tubing valve. Wait for effluent to pass through the side port of the long-tubing valve before opening the short-tubing valve to the water bottle, and opening the long-tubing valve to allow effluent to collect in the sample bottle.</td></tr>
<tr><td rowspan="2">Leaking</td><td>Effluent seeping through the sides of the column lid or ponding at the base of the adapter on the top of the lid.</td><td>Tighten the screws and adapter on the lid of the column.</td></tr>
<tr><td>Effluent dripping along the side of the column or at the tip of the rhizon port.</td><td>Ensure that the seal (between the rhizon and the column) made by the epoxy is holding. If not, flow will have to be stopped (per SOP B) and the column will have to be taken offline, placed on its side and epoxy will be applied and left to set for 24 hours. If the seal is holding, ensure that the lid of the rhizon port is capped tightly. If the lid has been compromised, replace it with a spare.</td></tr>
<tr><td>Kinking of the HDPE Tubing</td><td>Leaking or flow being impeded at a connection between the HDPE tubing and a luer.</td><td>Stop the flow per SOP B, cut off the section of tubing that is kinked and replace the luer as quickly as possible.</td></tr>
<tr><td>Influent Tubing Slipped out of Solution</td><td>Headspace filled with air may be evident in the column, or effluent volume generated</td><td>Stop flow per SOP B and fix placement of influent tubing or add more influent (depending on what is needed). Re-initiate</td></tr>
</table></td></tr>
</table>

<table>
<tr><td></td><td>
<table>
<tr><td></td><td>may be much less than typically observed.</td><td>flow to the column per SOP A after flushing air out of the lines.</td></tr>
<tr><td>Clogging in Valves/ Luers/ Adapters/ Tubing</td><td>Effluent volume may be less than typically observed. Leaking may also occur due to back pressure building up at the connectors.</td><td>Stop flow per SOP B, replace the column part as quickly as possible, and re-initiate flow per SOP A.</td></tr>
</table>
4. Record observations on the problem/incident in the daily records noting the time it occurred; a description of the problem/incident; potential impacts on the columns; the time when flow was stopped or initiated (if applicable); and an estimate of the volume of water lost from the system (if applicable).
</td></tr>
<tr><td>Record-Keeping</td><td>

Daily records:

The time when the issue or incident occurred or was noticed.
A description of the issue or incident and steps taken to troubleshoot the problem.
A description of any potential impact(s) on the column(s).
The time when flow stop and/or start occurred (if applicable).
Estimate of volume of water lost (if applicable).

Photos:

An indication of when the photos were taken.
A description of changes documented by the photos.

</td></tr>

Note:

AP = Acid potential in tonnes CaCO3 equivalent per 1000 tonnes of material. AP is determined from the measured sulphide sulphur content.

NP = Neutralization potential in tonnes CaCO3 equivalent per 1000 tonnes of material.

NET Modified NP = Modified NP - AP

Carbonate NP is calculated from TIC originating from carbonate minerals and is expressed in kg CaCO3/tonne.

Sulphate Sulphur determined by 25% HCl Leach with S by ICP Finish.

Sulphide Sulphur determined by Sobek 1:7 Nitric Acid Leach with S by ICP Finish.

Insoluble S is acid insoluble S (Total S - (Sulphate S + Sulphide S)).

Notes

Effluent samples are denoted by "E" following the column ID (C1A, C1B, C2 and C3)

Rhizon samples are denoted by "-R1/R2/R3" following the column ID (C1A, C1B, C2 and C3)

Appendix C: Water Quality Results for Influent, Effluent and Rhizon Samples

Notes

Effluent samples are denoted by "E" following the column ID (C1A, C1B, C2 and C3)

Rhizon samples are denoted by "-R1/R2/R3" following the column ID (C1A, C1B, C2 and C3)

EXECUTIVE SUMMARY

Tetra Tech Canada Inc. was retained by JDS ENERGY & MINING INC. to provide geotechnical consulting services for Phases 1 and 2 of a testpitting program in the Coffee Mine site area. Phase 1 of the testpitting program focused on excavation of testpits with a CAT 336E excavator and description of surficial materials within various proposed mine site infrastructure footprints. Representative samples were collected for analysis during Phase 1. Phase 2 involved testpitting in the proposed open pit areas, with accompanying overburden logging, but no sample collection.

Surficial materials exposed in the testpits at the Coffee Mine Site revealed several surficial units which were described in detail and sampled. The testpits were infilled immediately following logging and sampling. A total of fifty seven testpits were logged and representative samples of various overburden types were collected during Phase 1 for analysis in Tetra Tech Canada Inc.'s geotechnical laboratory in Whitehorse. Thirty additional samples of surficial deposits and fractured bedrock from selected testpits were taken during Phase 1 for Lorax Environmental Services Ltd. These were sent to ALS laboratories in Vancouver, B.C., for geochemical analysis. Phase 2 commenced upon completion of Phase 1.

Various types of overburden were identified within the testpits. These include loess, weathered bedrock, colluvium, peat, and surface moss cover. Approximate volumes of each were calculated for various site facilities. Permafrost conditions, including ground ice, were identified in many of the testpits.

GLOSSARY

Acronyms/Abbreviations	Definition
Active Layer	The top layer of ground subject to annual thawing and freezing in areas underlain by permafrost.
Aggregate Resource	Sand, gravel, or crushed stone used for construction and other industrial purposes.
Clast	An individual constituent or fragment of a sediment or rock, produced by the weathering of a larger rock mass. Synonyms include stone and fragment.
Colluvium	Materials deposited as a result of downslope movements due to gravity, such as rock fall and debris slides.
Cryoturbation	Heaving, churning, and sorting of soil and surficial materials due to repeated freezing and thawing (frost action); results in the development of convoluted structures in the soil, and patterned ground such as stone stripes and sorted polygons.
Debris Slide	A shallow slide consisting of a mass of soil, vegetation, and surficial material; initial displacement is along one or several surfaces of rupture. Composed of comparatively dry and largely unconsolidated earthy material and results in an irregular, hummocky deposit.
Eolian	Well sorted materials, predominantly silt and fine to medium sand, which have been eroded, transported, and deposited by wind.
Fibric	The least decomposed state of organic materials – large amounts of weakly decomposed fibres whose botanical origins are readily identifiable are visible. Fibric material has 40% or more by volume of fibre that retains its character upon rubbing.
Frost Jacking	Cumulative upward displacement of objects embedded in the ground, caused by frost action.
Humic	The greatest decomposed state of organic materials. It has the lowest amount of fiber, the highest bulk density, and the lowest saturated water-holding capacity of the organic materials. It is physically and chemically stable over time, unless drained. Fibres can be easily destroyed by rubbing.
Loess	A homogeneous massive deposit formed by wind, consisting mainly of silt.
Mesic	Organic material in a stage of decomposition that is intermediate between fibric and humic. Fibre remaining after rubbing constitutes greater than 10% and less than 40% of the volume of the material.
Peat	Unconsolidated compressible material consisting largely of undecomposed, or slightly decomposed, organic matter accumulated under water-saturated conditions. Peat is commonly formed by the slow decay of successive layers of aquatic and semi-aquatic plants in swampy or water-logged areas, where oxygen is absent.
Permafrost	Ground, soil, or rock that remains at or below 0˚C for at least two consecutive years.

Acronyms/Abbreviations	Definition
Rock Fall	The process, associated deposits or resultant landform characterized by very rapid downslope movement of newly detached pieces of bedrock that fall freely from a cliff or cascade down a steep slope.
Weathered Bedrock	The chemical and physical decomposition and disintegration of bedrock due to exposure to air, moisture, organic matter, and temperature change.

ACRONYMS & ABBREVIATIONS

Acronyms/Abbreviations	Definition
4WD	Four wheel drive
ALT	Active Layer Thickness
JDS	JDS ENERGY & MINING INC.
WRSF	Waste Rock Storage Facility

SITE INVESTIGATION WAIVER STATEMENT

To minimize the risk of damage to underground utilities, locating and marking of all underground services will be completed by an independent utility locator service, along with any information provided by the property owner (or their representative) prior to any intrusive field investigation operations. The property owner (or their representative) is responsible for ensuring that any private utilities, such as storm sewers or buried power and gas lines, are identified and located within the investigation areas before the start of any field investigation program. Because Tetra Tech cannot verify or rely on the accuracy of this information, Tetra Tech will not accept responsibility for damage, or cause for delay, to any party for private or public utilities not properly identified and or located. Any and all costs resulting from the damaged utility, and/or utilities, as a result of our investigation will be the responsibility of JDS ENERGY & MINING INC.

LIMITATIONS OF REPORT

This report and its contents are intended for the sole use of JDS ENERGY & MINING INC. and their agents. Tetra Tech Canada Inc. (Tetra Tech) does not accept any responsibility for the accuracy of any of the data, the analysis, or the recommendations contained or referenced in the report when the report is used or relied upon by any Party other than JDS ENERGY & MINING INC., or for any Project other than the proposed development at the subject site. Any such unauthorized use of this report is at the sole risk of the user. Use of this document is subject to the Limitations on the Use of this Document attached in the Appendix or Contractual Terms and Conditions executed by both parties.

1.0 INTRODUCTION

Tetra Tech Canada Inc. (Tetra Tech) was retained by JDS ENERGY & MINING INC. (JDS) to provide geotechnical consulting services for Phases 1 and 2 of a testpitting program in the Coffee Mine site area. A location map is shown in Figure 1.The objective of the testpitting program was to investigate the composition, diggability, and thickness of the overburden in the mine site area.

Phase 1 of the testpitting program focused on excavation of testpits, and logging and sampling of surficial materials overlying bedrock throughout various mine site infrastructure footprints. Representative samples of overburden were collected for index testing in Tetra Tech's geotechnical laboratory in Whitehorse.

The data acquired is intended to aid in developing a material inventory and a plan for storage and management of excavated materials. The data can also be used to manage surficial materials during the pre-stripping program.

After the field program commenced, Mr. John Dockrey of Lorax Environmental Services Ltd. (Lorax) requested that additional samples of overburden and bedrock be taken for geochemical analysis at particular testpit locations. This was approved by Mr. James Scott of Goldcorp Inc. (Goldcorp) and additional samples of surficial deposits and fractured bedrock were collected from selected testpits during Phase 1. The samples were sent to ALS laboratories in Vancouver, B.C., for geochemical analysis.

Phase 1 of the program was finished earlier than initially planned, allowing Phase 2 to be completed as well. Phase 2 consisted of testpitting in the proposed open pit areas with no sample collection.

After submission of the initial Issued for Review report, JDS requested volume calculations for the various types of overburden surficial materials. These calculations have been included in this Issued for Use report.

2.0 METHODS

2.1 Fieldwork

To achieve the objectives of the testpitting program, surficial materials were exposed in testpits with a CAT 336E excavator (Photo 1). The surficial material (overburden) units were described in detail by Dr. Shirley McCuaig, Ph.D., P.Geo., Senior Terrain Geologist, between October 6 and 14, 2017. A side by side all-terrain vehicle was used to access the testpit areas from the mine laydown area and to scout out locations of testpits to determine the least environmentally damaging path to be taken by the excavator to mobilize to the pit locations. Mr. Dan Tulp of JDS provided assistance for a number of testpits, mainly in areas where travelling by side by side all-terrain vehicle to the site was more treacherous than usual. Mr. Jason Thompson, Mr. Dan Tulp, and Mr. Larry Berg of JDS all provided excellent operation of the excavator on various days as per their availability. Accommodation for all was provided at Goldcorp's Coffee camp and access to the mine site area was provided by JDS by 4WD pickup.

The testpits were infilled immediately following logging and sampling. Organic cover was removed first and set aside; it was replaced last to help insulate the disturbed overburden material and prevent permafrost thaw. Photos were taken of the soils and bedrock encountered, as well as of the infilled excavations to record the reclamation efforts.

Information recorded included bedrock and clast general rock types, depth to bedrock, presence of peat/organic soil, grain size and composition of deposits, frozen/unfrozen state, diggability, groundwater level where encountered, active layer thickness (ALT), and amount and type of ground ice, if present.

Testpit TP17-14 was not completed as it was expected to be very similar to TP17-13 and TP17-15. The ground was too bouldery for the excavator to access TP17-03 (some of the boulders in this area are large enough to be seen on the air photos).

Phase 2 commenced upon completion of Phase 1. No samples were collected during this phase. This program was completed with the exception of three testpits in distant parts of the proposed open pit areas, and the testpits in the Alpha WRSF, which must be completed at a later date, when the soft ground of that slope is frozen.

Daily Field Reports were compiled at the end of each field day and sent to interested parties at Goldcorp, JDS, and Tetra Tech. Weather, work undertaken, names and numbers of testpits described and samples taken, preliminary information acquired from the testpits, safety and environmental information, and delays/breakdowns were described in the daily reports.

Laboratory testing of a limited number of representative soil samples of various overburden types were taken during Phase 1 for analysis in Tetra Tech's geotechnical laboratory in Whitehorse. Particle size distribution and moisture contents were determined.

Thirty additional samples of surficial deposits and bedrock from selected testpits were taken during Phase 1 for Lorax. These were sent to ALS laboratories in Vancouver, B.C., for geochemical analysis. Additional information on level of bedrock weathering was recorded for these samples. Results of these analyses will be reported under separate cover by Lorax.

Testpit locations were plotted in ArcGIS and overlain on the previously completed permafrost mapping (Figure 2). The permafrost mapping was updated with the frozen/unfrozen and ice content information obtained from the testpits, and also from the summer 2017 drilling program.

Peat and thick organics were also plotted (Figure 3) to see if there were any relationships to the permafrost mapping.

2.2 Overburden Material Volumes

Overburden material volumes were estimated by taking unit thickness values from the testpit logs, importing that data into AutoCAD Civil 3D software, and performing both computed and hand calculations of volumes. The overburden materials were separated into the main overburden types described in Section 3.1, but with peat and surface moss cover combined into a single organics layer. The remaining layers for which volumes were calculated are the upper silt/gravel, the lower gravel/sand, and weathered bedrock. Volumes were calculated for each mine facility site where testpits were dug: the Heap Leach facility, Kona Pit, the Organics Stockpile, the Event Ponds, the Plant Site, the Crusher area, the Frozen Soil Stockpile, and the Pit Areas (Supremo, Double Double, and Latte Open Pit Areas).

Ground contour data, provided by Mr. Joel Griffen of JDS, was used where possible to help determine the most accurate three dimensional material volumes. In smaller locations like Kona Pit, hand volume calculations were used by multiplying the surface area by average material thickness from the testpits. For larger facilities, material volumes were calculated by taking the surveyed testpit point elevations and adjusting them to the corresponding elevations of the top and bottom of each unit at each testpit. The observed unit thicknesses measured at each testpit were used to determine these elevations. Interpolated hand-drawn contours were completed for each unit at each pit. This information was used for areas between and outside of the testpits, which were used to fill in data gaps that were required to complete the calculations in AutoCAD Civil 3D, so that the most accurate surfaces could be built.

Unfortunately, the provided existing ground contour data has much finer detail than the surfaces which can be created using the testpit unit elevation data and the interpolated hand-drawn thickness contours. As a result, the AutoCAD software linearly interpolates the spaces between the testpit location points and the hand-drawn contours when creating surfaces, which creates holes or errors in the data. This makes it difficult to accurately compare the existing ground surface with the created surfaces at some locations. The volume calculations provided herein therefore should be considered to be the best estimates obtainable by the method described above, and not necessarily a true depiction of the material volumes at all locations. Local topographic features such as depressions, outcrops, and rockfall areas will all affect actual material volumes.

3.0 RESULTS

Various types of overburden were identified within the testpits. These include loess, weathered bedrock, colluvium, peat, and surface moss cover. Permafrost conditions were evident and ground ice was encountered in many areas. The materials encountered in all testpits (both Phase 1 and Phase 2 testpits) are summarized below. The data is shown in detail in the testpit logs provided in Appendix B and the locations of the testpits are shown in Figure 2. Phase 1 testpits include TP17-01 to TP17-30, while Phase 2 testpits range from TP17-49 to TP17-79.

3.1 Surficial Materials

3.1.1 Loess

The Coffee Creek Mine Site lies within the unglaciated portion of the Dawson Range. According to Bond and Lipovsky (2011), loess was blown into the area from terraces flanking the Donjek, White, and Yukon Rivers. Loess generally forms uniform, unstratified silt deposits of eolian origin. However, in the project region, it tends to infill and become mixed with weathered bedrock, and it is generally thicker on the southwest (windward) side of the mountains (Bond and Lipovsky 2011). The testpit data confirms the latter – on average, the upper silt-rich deposits are 30 cm thicker on slopes of southwesterly aspect[1].

Silt in the testpits was generally observed in the uppermost portion of the overburden units, but it is mixed with varying amounts of pebbles, cobbles, and boulders, as well as trace amounts of clay, forming a well graded or gap graded unit (hereafter referred to as the upper silt/gravel unit) (Photos 2 and 3). Silt is also present in the underlying surficial materials, but in much smaller quantities, and is more likely a product of long-term physical weathering at these levels within the overburden.

Taken together, these data are consistent with a surficial geology history for the mine site area comprising bedrock weathering to gravel and sand over long periods of time and later becoming infilled with wind-blown loess.

3.1.2 Weathered Bedrock

In general, the mine site infrastructure and pit areas are covered with weathered bedrock, represented by schist in the east and granitoid rocks in the west. These range from slightly to completely weathered, the completely weathered varieties forming a soft mica sand in schist areas and an easily crumbled sand to pea-size gravel in granitic areas (Photos 4, 5a, 5b, 6, and 7). Refusal commonly occurred on more competent bedrock, but it was generally fractured by frost shattering (Photo 8).

[1] Testpits where the excavator met refusal on frozen ground were excluded from these calculations, as the deposits are likely thicker than recorded at these locations.

The frost-shattered bedrock is overlain by gravel or gravel/sand made up of bedrock that has been more physically and/or chemically weathered (and contains small amounts of silt), hereafter referred to as the lower gravel/sand. The granitoid rocks break down to angular fragments of all sizes, but these are more equidimensional than the elongated or slab-like blocks of schist (Photos 4, 5a, 5b, 9, and 10).

3.1.3 Colluvium

Colluvium is present on steeper slopes. It was confirmed in several testpits by the presence of void spaces between angular cobbles and boulders and a lack of finer material, both occurring in the uppermost portions of the surficial units (Photo 11). Inversion of the upper silt/gravel and lower gravel/sand (forming an upper gravel/sand and lower silt/gravel) may also indicate that colluvium is present, as these stratigraphic relationships are found in some of the testpits located on colluvial slopes. A buried soil at Testpit TP17-32 confirms a colluvial origin for the granular material overlying the soil at that location (Photo 12), despite the gentle slope (the material may have been moved by solifluction or soil creep). Colluvium can probably be assumed to be present on steeper slopes, no matter what their aspect, but it may also be present on some of the gentler slopes, where creep or solifluction may be occurring or may have happened in the past.

3.1.4 Peat

A thin peat layer 10 cm to 35 cm thick is present locally (Photo 13). Its distribution is very patchy – as a rule, it was identified within the overburden on one side of a testpit, but not the other (it forms lenses of limited extent). The insulation value of peat is high – frozen ground and visible ice were commonly found 0 to 50 cm below it in testpits where peat was present (Photo 14). The peat is dark brown and generally fibric to mesic. Charcoal was identified within the peat at Testpit TP17-29 (Photo 15).

Frost-jacked granitic boulders overlying the peat in the western part of the mine site (see testpit logs for TP17-05 and TP17-10, Appendix B), indicate that the peat is very old. The boulders obscure the peat from view at surface, both in the field and on the air photos. This makes its presence or absence very difficult to determine. However, if peat is encountered, it is highly likely that frozen ground with visible ice is present below it.

3.1.5 Surface Moss Cover

Moss and rootlets cover the deposits and range from 10 cm to 30 cm thick (Photos 2, 3, and 8). Moss is generally thicker over peat deposits (Photo 13).

3.2 Testpit Data Summary

A total of 57 testpits were excavated and logged. The coordinates, depth to bedrock, permafrost condition observed, and completion depth for each of the testpits are summarized in Table 1 below and are shown in greater detail on the testpit logs in Appendix B. Testpit locations are also presented on Figure 2.

Table 1: Testpit Information Summary

Site Infrastructure	Testpit	UTM ZONE 7			Depth to Weathered Bedrock (m)	Completion Depth (m)	Permafrost Condition
		Easting (m)	Northing (m)	Elevation (m)			
Organics Stockpile	TP17-01	580,141	6,972,769	1,226	-	1.2	Vc, Vr 5-10%

Weathered bedrock is considered to be bedrock broken into large and small blocks by physical weathering as described in Section 3.1.2. It may or may not be diggable. Where it was not diggable, it formed the base of the testpit and a thickness was generally not obtained. No unweathered bedrock was encountered.

The geotechnical laboratory soil testing results are summarized in Table 2 below, are shown on the testpit logs in Appendix B, and are presented fully in Appendix C.

Table 2: Summary of Offsite Geotechnical Laboratory Results

Testpit	Depth		Moisture Content (%)	Clay (%)	Silt (%)	Sand (%)	Gravel (%)	Cobble (%)

3.3 Overburden Material Volumes

Table 3 summarizes the estimated material volumes at each facility. Note that weathered bedrock volumes must be considered minimum estimates only due to diggability issues.

Table 3: Summary of Overburden Material Volumes

Mine Facility	Surface Area (m^2)	Organic Material Volume (m^3)	Upper Silt/Gravel Volume (m^3)	Lower Sand/Gravel Volume (m^3)	Weathered Bedrock Volume (m^3)	Total Overburden Volume (m^3)
Heap Leach Facility	886,800	236,500	473,700	475,000	341,900	1,527,100
Kona Pit	100,600	22,800	101,900	110,700	15,100	250,500
Organics Stockpile	159,800	47,900	159,800	60,000	8,900	276,600
Event Ponds	101,500	20,300	50,700	53,300	6,400	130,700
Plant Site	77,900	15,600	47,500	59,500	47,800	170,400
Crusher	12,300	5,000	-	7,400	-	12,400
Pit Areas	1,820,100	364,000	445,100	985,300	263,400	2,057,800
Frozen Soil Stockpile	208,300	48,600	187,500	125,000	-	316,100

3.4 Permafrost

Frozen ground was encountered in many of the testpits. Ice lenses, coatings, and crystals (Vs, Vc, and Vx on the testpit logs) were identified in several testpits and frozen overburden material well-bonded by nonvisible pore ice (Nbn) was present in a few more testpits (Appendix B, Photos 16 to 18).

The active layer averages 1.3 m thick, except where peat is present. Beneath peat, the ALT was 0.7 m on average.

Cryoturbation has likely played a role in mixing some of the non-colluvial materials. However, the contact between upper silt/gravel and the lower gravel/sand is generally sharp or gradational, so there is a limit to the amount of mixing that occurs between the two over most of the study area.

Frost jacking of boulders over millennia has resulted in a layer of boulders at the surface in many areas (Photos 3 and 10). The boulder layer is especially common in the areas underlying the Proposed Heap Leach Facility, Organics Stockpile, Event Ponds, and Plant Site footprints.

Permafrost mapping completed by Tetra Tech in 2016 for the mine site was updated using the testpit information. The updated locations of unfrozen ground, ice-poor and ice-rich terrain are shown on Figure 2. The same information is given as point data for each testpit[2]. Some interpolation was necessary to update the mapping, so not every testpit point is a perfect match for the mapping. This shows that there is some minor variability within the mapped permafrost units, as explained on the legend of Figure 2.

The locations of peat and organics (peat, moss, organic soil) greater than 30 cm thick were also plotted to see if there were any relationships between organics, peat, and permafrost. Drilling data from 2017 was added and the results are shown on Figure 3. It is evident from Figure 3 that peat and thick organics are generally, but not always, associated with frozen ground. 67% of these are associated with ice-rich terrain, 25% with ice-poor terrain, and 8% with unfrozen ground. It does not appear to matter whether the organic cover is peat or thick organics.

3.5 Diggability

JDS requested a measure of diggability for the testpits, to help with future overburden removal and construction planning. To this end, a diggability range of 1 to 10 was established to compare testpit materials, with 10 being the most difficult to dig and 1 being the easiest.

Refusal occurred either on frozen ground or fractured bedrock, but the excavator was generally able to rip 20 cm to 50 cm into these materials, despite a lack of ripping teeth. The upper silt/gravel units almost always had a diggability rating of 1, the lower gravel/sand units 1 to 3, and frozen ground and fractured bedrock were rated at 9 to 10. There were some variations across the study area, but these diggability relationships are the most common. For details on diggability, please refer to the testpit logs in Appendix B.

3.6 Aggregate Potential

Granitoid rocks produce a reasonable quality sand composed mainly of feldspar, quartz, and granite, but the pebble/cobble gravel in these areas is likely too weak to be considered a good aggregate source. Completely weathered granite crumbles to sand in the hand. Schist gravel is a better, albeit not good, potential aggregate source.

[2] Testpits where bedrock was found close to surface or that met refusal at depths of less than 1.4 m are considered to have uncertain active layer depths. The frozen/unfrozen condition is mapped as “Uncertain” on Figure 2.

In the schist zone, potentially good aggregate was identified at Testpit TP17-18. Here, at least 1.7 m of moderately well graded gravel with some sand, trace silt, and trace clay underlies a thin layer of the upper silt/gravel (Photo 19). Pebbles and cobbles dominate and the material is very diggable. Two testpits were dug nearby to assess the size of the potential aggregate resource. Unfortunately, the gravel is only 30 cm thick at TP17-18a. Testpit TP17-18b is more promising, containing 1 m of sandy gravel with some silt and trace clay, but the micaceous sand derived from completely weathered schist may be problematic (Photo 20). However, the fractured bedrock at all three sites is quite diggable and could potentially provide more aggregate with some crushing (Photo 21).

4.0 CLOSURE

We trust this document meets your present requirements. If you have any questions or comments, please contact the undersigned.

LIMITATIONS ON USE OF THIS DOCUMENT

GEOTECHNICAL

1.1 USE OF DOCUMENT AND OWNERSHIP

This document pertains to a specific site, a specific development, and a specific scope of work. The document may include plans, drawings, profiles and other supporting documents that collectively constitute the document (the "Professional Document").

The Professional Document is intended for the sole use of TETRA TECH's Client (the "Client") as specifically identified in the TETRA TECH Services Agreement or other Contractual Agreement entered into with the Client (either of which is termed the "Contract" herein). TETRA TECH does not accept any responsibility for the accuracy of any of the data, analyses, recommendations or other contents of the Professional Document when it is used or relied upon by any party other than the Client, unless authorized in writing by TETRA TECH.

Any unauthorized use of the Professional Document is at the sole risk of the user. TETRA TECH accepts no responsibility whatsoever for any loss or damage where such loss or damage is alleged to be or, is in fact, caused by the unauthorized use of the Professional Document.

Where TETRA TECH has expressly authorized the use of the Professional Document by a third party (an "Authorized Party"), consideration for such authorization is the Authorized Party's acceptance of these Limitations on Use of this Document as well as any limitations on liability contained in the Contract with the Client (all of which is collectively termed the "Limitations on Liability"). The Authorized Party should carefully review both these Limitations on Use of this Document and the Contract prior to making any use of the Professional Document. Any use made of the Professional Document by an Authorized Party constitutes the Authorized Party's express acceptance of, and agreement to, the Limitations on Liability.

The Professional Document and any other form or type of data or documents generated by TETRA TECH during the performance of the work are TETRA TECH's professional work product and shall remain the copyright property of TETRA TECH.

The Professional Document is subject to copyright and shall not be reproduced either wholly or in part without the prior, written permission of TETRA TECH. Additional copies of the Document, if required, may be obtained upon request.

1.2 ALTERNATIVE DOCUMENT FORMAT

Where TETRA TECH submits electronic file and/or hard copy versions of the Professional Document or any drawings or other project-related documents and deliverables (collectively termed TETRA TECH's "Instruments of Professional Service"), only the signed and/or sealed versions shall be considered final. The original signed and/or sealed electronic file and/or hard copy version archived by TETRA TECH shall be deemed to be the original. TETRA TECH will archive a protected digital copy of the original signed and/or sealed version for a period of 10 years.

Both electronic file and/or hard copy versions of TETRA TECH's Instruments of Professional Service shall not, under any circumstances, be altered by any party except TETRA TECH. TETRA TECH's Instruments of Professional Service will be used only and exactly as submitted by TETRA TECH.

Electronic files submitted by TETRA TECH have been prepared and submitted using specific software and hardware systems. TETRA TECH makes no representation about the compatibility of these files with the Client's current or future software and hardware systems.

1.3 STANDARD OF CARE

Services performed by TETRA TECH for the Professional Document have been conducted in accordance with the Contract, in a manner consistent with the level of skill ordinarily exercised by members of the profession currently practicing under similar conditions in the jurisdiction in which the services are provided. Professional judgment has been applied in developing the conclusions and/or recommendations provided in this Professional Document. No warranty or guarantee, express or implied, is made concerning the test results, comments, recommendations, or any other portion of the Professional Document.

If any error or omission is detected by the Client or an Authorized Party, the error or omission must be immediately brought to the attention of TETRA TECH.

1.4 DISCLOSURE OF INFORMATION BY CLIENT

The Client acknowledges that it has fully cooperated with TETRA TECH with respect to the provision of all available information on the past, present, and proposed conditions on the site, including historical information respecting the use of the site. The Client further acknowledges that in order for TETRA TECH to properly provide the services contracted for in the Contract, TETRA TECH has relied upon the Client with respect to both the full disclosure and accuracy of any such information.

1.5 INFORMATION PROVIDED TO TETRA TECH BY OTHERS

During the performance of the work and the preparation of this Professional Document, TETRA TECH may have relied on information provided by persons other than the Client.

While TETRA TECH endeavours to verify the accuracy of such information, TETRA TECH accepts no responsibility for the accuracy or the reliability of such information even where inaccurate or unreliable information impacts any recommendations, design or other deliverables and causes the Client or an Authorized Party loss or damage.

1.6 GENERAL LIMITATIONS OF DOCUMENT

This Professional Document is based solely on the conditions presented and the data available to TETRA TECH at the time the data were collected in the field or gathered from available databases.

The Client, and any Authorized Party, acknowledges that the Professional Document is based on limited data and that the conclusions, opinions, and recommendations contained in the Professional Document are the result of the application of professional judgment to such limited data.

The Professional Document is not applicable to any other sites, nor should it be relied upon for types of development other than those to which it refers. Any variation from the site conditions present, or variation in assumed conditions which might form the basis of design or recommendations as outlined in this report, at or on the development proposed as of the date of the Professional Document requires a supplementary investigation and assessment.

TETRA TECH is neither qualified to, nor is it making, any recommendations with respect to the purchase, sale, investment or development of the property, the decisions on which are the sole responsibility of the Client.

1.7 ENVIRONMENTAL AND REGULATORY ISSUES

Unless stipulated in the report, TETRA TECH has not been retained to investigate, address or consider and has not investigated, addressed or considered any environmental or regulatory issues associated with development on the subject site.

1.8 NATURE AND EXACTNESS OF SOIL AND ROCK DESCRIPTIONS

Classification and identification of soils and rocks are based upon commonly accepted systems and methods employed in professional geotechnical practice. This report contains descriptions of the systems and methods used. Where deviations from the system or method prevail, they are specifically mentioned.

Classification and identification of geological units are judgmental in nature as to both type and condition. TETRA TECH does not warrant conditions represented herein as exact, but infers accuracy only to the extent that is common in practice.

Where subsurface conditions encountered during development are different from those described in this report, qualified geotechnical personnel should revisit the site and review recommendations in light of the actual conditions encountered.

1.9 LOGS OF TESTHOLES

The testhole logs are a compilation of conditions and classification of soils and rocks as obtained from field observations and laboratory testing of selected samples. Soil and rock zones have been interpreted. Change from one geological zone to the other, indicated on the logs as a distinct line, can be, in fact, transitional. The extent of transition is interpretive. Any circumstance which requires precise definition of soil or rock zone transition elevations may require further investigation and review.

1.10 STRATIGRAPHIC AND GEOLOGICAL INFORMATION

The stratigraphic and geological information indicated on drawings contained in this report are inferred from logs of test holes and/or soil/rock exposures. Stratigraphy is known only at the locations of the test hole or exposure. Actual geology and stratigraphy between test holes and/or exposures may vary from that shown on these drawings. Natural variations in geological conditions are inherent and are a function of the historic environment. TETRA TECH does not represent the conditions illustrated as exact but recognizes that variations will exist. Where knowledge of more precise locations of geological units is necessary, additional investigation and review may be necessary.

1.11 PROTECTION OF EXPOSED GROUND

Excavation and construction operations expose geological materials to climatic elements (freeze/thaw, wet/dry) and/or mechanical disturbance which can cause severe deterioration. Unless otherwise specifically indicated in this report, the walls and floors of excavations must be protected from the elements, particularly moisture, desiccation, frost action and construction traffic.

1.12 SUPPORT OF ADJACENT GROUND AND STRUCTURES

Unless otherwise specifically advised, support of ground and structures adjacent to the anticipated construction and preservation of adjacent ground and structures from the adverse impact of construction activity is required.

1.13 INFLUENCE OF CONSTRUCTION ACTIVITY

There is a direct correlation between construction activity and structural performance of adjacent buildings and other installations. The influence of all anticipated construction activities should be considered by the contractor, owner, architect and prime engineer in consultation with a geotechnical engineer when the final design and construction techniques are known.

1.14 OBSERVATIONS DURING CONSTRUCTION

Because of the nature of geological deposits, the judgmental nature of geotechnical engineering, as well as the potential of adverse circumstances arising from construction activity, observations during site preparation, excavation and construction should be carried out by a geotechnical engineer. These observations may then serve as the basis for confirmation and/or alteration of geotechnical recommendations or design guidelines presented herein.

1.15 DRAINAGE SYSTEMS

Where temporary or permanent drainage systems are installed within or around a structure, the systems which will be installed must protect the structure from loss of ground due to internal erosion and must be designed so as to assure continued performance of the drains. Specific design detail of such systems should be developed or reviewed by the geotechnical engineer. Unless otherwise specified, it is a condition of this report that effective temporary and permanent drainage systems are required and that they must be considered in relation to project purpose and function.

1.16 BEARING CAPACITY

Design bearing capacities, loads and allowable stresses quoted in this report relate to a specific soil or rock type and condition. Construction activity and environmental circumstances can materially change the condition of soil or rock. The elevation at which a soil or rock type occurs is variable. It is a requirement of this report that structural elements be founded in and/or upon geological materials of the type and in the condition assumed. Sufficient observations should be made by qualified geotechnical personnel during construction to assure that the soil and/or rock conditions assumed in this report in fact exist at the site.

1.17 SAMPLES

TETRA TECH will retain all soil and rock samples for 30 days after this report is issued. Further storage or transfer of samples can be made at the Client's expense upon written request, otherwise samples will be discarded.

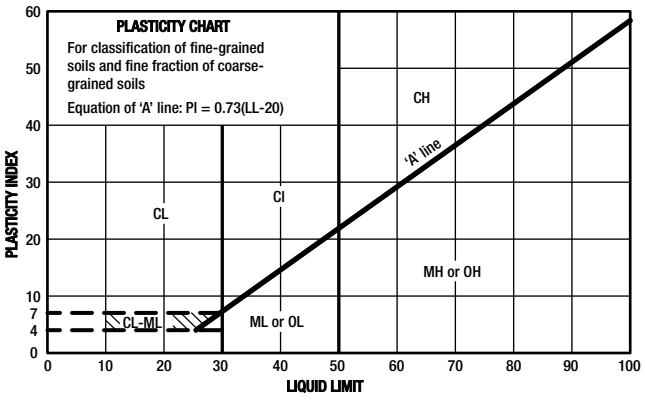
MODIFIED UNIFIED SOIL CLASSIFICATION

MAJOR DIVISION			GROUP SYMBOL	TYPICAL DESCRIPTION	LABORATORY CLASSIFICATION CRITERIA	
COARSE-GRAINED SOILS More than 50% retained on 75 µm sieve*	GRAVELS 50% or more of coarse fraction retained on 4.75 mm sieve	CLEAN GRAVELS	GW	Well-graded gravels and gravel-sand mixtures, little or no fines	Classification on basis of percentage of fines GW, GP, SW, SP GM, GC, SM, SC Borderline Classification requiring use of dual symbols	$C_U = D_{60} / D_{10}$ Greater than 4 $C_c = \frac{(D_{30})2}{D_{10} \times D_{60}}$ Between 1 and 3
			GP	Poorly graded gravels and gravel-sand mixtures, little or no fines		Not meeting both criteria for GW
		GRAVELS WITH FINES	GM	Silty gravels, gravel-sand-silt mixtures		Atterberg limits plot below "A" line or plasticity index less than 4
			GC	Clayey gravels, gravel-sand-clay mixtures		Atterberg limits plot above "A" line or plasticity index greater than 7 Atterberg limits plotting in hatched area are borderline classifications requiring use of dual symbols
	SANDS More than 50% of coarse fraction passes 4.75 mm sieve	CLEAN SANDS	SW	Well-graded sands and gravelly sands, little or no fines	Less than 5% Pass 75 µm sieve More than 12% Pass 75 µm sieve 5% to 12% Pass 75 µm sieve	$C_U = D_{60}/D_{10}$ Greater than 6 $C_c = \frac{(D_{30})2}{D_{10} \times D_{60}}$ Between 1 and 3
			SP	Poorly graded sands and gravelly sands, little or no fines		Not meeting both criteria for SW
		SANDS WITH FINES	SM	Silty sands, sand-silt mixtures		Atterberg limits plot below "A" line or plasticity index less than 4
			SC	Clayey sands, sand-clay mixtures		Atterberg limits plot above "A" line or plasticity index greater than 7 Atterberg limits plotting in hatched area are borderline classifications requiring use of dual symbols
FINE-GRAINED SOILS (by behavior) 50% or more passes 75 µm sieve*	SILTS Liquid limit <50		ML	Inorganic silts, very fine sands, rock flour, silty or clayey fine sands of slight plasticity		
	SILTS Liquid limit >50		MH	Inorganic silts, micaceous or diatomaceous fine sands or silts, elastic silts		
	CLAYS Above "A" line on plasticity chart negligible organic content Liquid limit <30		CL	Inorganic clays of low plasticity, gravelly clays, sandy clays, silty clays, lean clays		
	CLAYS Above "A" line on plasticity chart negligible organic content Liquid limit 30-50		CI	Inorganic clays of medium plasticity, silty clays		
	CLAYS Above "A" line on plasticity chart negligible organic content Liquid limit >50		CH	Inorganic clays of high plasticity, fat clays		
	ORGANIC SILTS AND CLAYS Liquid limit <50		OL	Organic silts and organic silty clays of low plasticity		
	ORGANIC SILTS AND CLAYS Liquid limit >50		OH	Organic clays of medium to high plasticity		
HIGHLY ORGANIC SOILS			PT	Peat and other highly organic soils		



* Based on the material passing the 75 mm sieve

† ASTM Designation D 2487, for identification procedure see D 2488 USC as modified by PFRA

SOIL COMPONENTS

FRACTION	SIEVE SIZE		DEFINING RANGES OF PERCENTAGE BY MASS OF MINOR COMPONENTS	
	PASSING	RETAINED	PERCENTAGE	DESCRIPTOR
GRAVEL				
coarse	75 mm	19 mm	>35 %	"and"
fine	19 mm	4.75 mm	21 to 35 %	"y-adjective"
SAND				
coarse	4.75 mm	2.00 mm	11 to 20 %	"some"
medium	2.00 mm	425 µm		
fine	425 µm	75 µm	>0 to 10 %	"trace"
SILT (non plastic) or CLAY (plastic)	75 µm		as above but by behavior

EXECUTIVE SUMMARY

Tetra Tech Canada Inc. (Tetra Tech) was retained by JDS Energy & Mining Inc. (JDS) to provide geotechnical consulting services for a testpitting program in the Coffee Gold Project (the Project) area in the fall of 2018. The objective of the testpitting program was to investigate the composition, diggability, and thickness of the overburden materials overlying bedrock throughout the Project area.

The Fall 2018 Testpitting Program was carried out from September 5 to September 26, 2018 and consisted of excavation of testpits, logging, and sampling of the exposed surficial materials at the following proposed mine development and construction sites: Java Airstrip alignment, Supremo, Double Double, and South Latte/Supremo Open Pit areas, the Facility Pond area, the Halfway Diversion, the Latte Diversion Channel (Latte Diversion), and the potential borrow source located at km 0.3 of the existing site access road. The fall 2018 program augments a testpitting program completed by Tetra Tech within proposed infrastructure footprints and in the proposed open pit areas in the fall of 2017.

To achieve the objective of the testpitting program, overburden materials were exposed in 69 testpits by either hand-digging or the use of an excavator. Due to the Halfway Diversion being inaccessible by the excavator, testpits in this area were dug by hand. Unfrozen (or thawed) and frozen overburden soil and bedrock exposed in the completed testpits was logged and sampled.

Representative samples of overburden material, including five samples collected by JDS in the potential borrow sources located between 2-3 km and 6-7 km sections of the existing access road, were tested at Tetra Tech's geotechnical laboratories in Whitehorse and Edmonton. The completed testing included particle size distribution, moisture content analyses, and a limited number of hydrometer, Atterberg limit, excess ice content, and bulk density tests. Bulk samples taken from the testpits excavated along the Java Airstrip alignment were combined for California Bearing Ratio (CBR) testing at Tetra Tech's geotechnical laboratory in Edmonton. The five soil samples collected by JDS in the km 2-3 and km 6-7 Borrow Source areas were tested for moisture-density (Proctor) relationship in Whitehorse.

Various types of overburden surficial materials were identified within the testpits. These include loess, weathered bedrock, bedrock fragments in a soil matrix, colluvium, alluvium, and organic material (peat and moss cover). Descriptions of these surficial materials provided in the report augment Tetra Tech's previous characterization of surficial geology units in the Project area. Permafrost was observed in many of the testpits. Frozen soils with non-visible ice and visible ground ice formations were described in the testpit logs, photographed, and sampled for geotechnical laboratory testing.

The suitability of the materials from potential borrow source areas for construction was assessed. At the proposed Java Airstrip site, the suitability of the cut materials is limited in most construction applications where durable materials are required. The unprocessed material can be used as road or airstrip subgrade fill, or as general fill. However, the high silt content of the overburden materials excavated in cut locations along the airstrip will make them very difficult to compact to suitable levels during the winter but would be suitable for placement in the summer. The processed material can be used as a subgrade fill in the airstrip, apron, and taxiway. There has been mention of significant screening being undertaken to generate a suitably graded material for use as airstrip surfacing material. Tetra Tech believes that although the desired gradation might possibly be able to be produced, there is a high possibility that the produced material will not be suitably durable and will break down generating excessive dust. Other sources of material such as the alluvial gravel at km 0.3 or quarried material from durable bedrock are recommended to produce airstrip surfacing gravel.

The excessive content of fines in the overburden materials in the Supremo and the Double Double Open Pit areas indicate that these overburden materials, including uppermost fractured, fragmented, and highly weathered bedrock easily break down making these materials marginal for use in most construction applications. The unprocessed material could be used as road subgrade and as general fill, if placed during the summer. If the material is processed, either by screening or crushing oversize boulder-sized rock fragments, it may be used for general fill or potentially as an embankment fill for dam construction subject to the design specifications. This processed material would not be suitable as a structural fill required below building foundations or slabs on grade.

Overburden materials encountered in the km 0.3 potential borrow source area consist of well-sorted alluvium (sand and sub-rounded gravel) covered by a veneer of silty material and organics. Although this alluvial material is well suited for use in most construction applications, the lack of particle angularity may require crushing of larger aggregates. The processed material can be used for road and airstrip surfacing and concrete aggregate. To achieve better compaction, a selected proportion of the overlying silt may require blending with the alluvium to increase the fines content.

Overburden materials sampled in the km 2-3 and km 6-7 potential borrow sources consist of coarse rock fragments in a well-graded gravelly and sandy matrix with trace to some silt. The particle size distribution analysis done on this material shows the content of fines ranging from 8% to 18%. The durability of the gravel-sized clasts raises concerns about the potential breakdown of these particles into finer material if exposed to either mechanical loading (vehicle traffic) or freeze thaw cycles. The unprocessed material can be used as a general fill and in road and airstrip subgrades. However, the presence of cobble-sized competent rock fragments indicates that if screened and crushed, the processed material could be used in locations where more specific particle size distributions are required (e.g. sand bedding material).

GLOSSARY

Acronyms/Abbreviations	Definition
Active Layer	The top layer of ground subject to annual thawing and freezing in areas underlain by permafrost.
Aggregate Resource	Sand, gravel, or crushed stone used for construction and other industrial purposes.
Alluvium	Materials transported by fluvial action and deposited in river channels and along the floodplains.
Clast	An individual constituent or fragment of a sediment or rock, produced by the physical disintegration (e.g. freeze-thaw cycles) of a larger rock mass. Synonyms include a rock fragment and a stone.
Colluvium	Materials deposited as a result of downslope movements due to gravity, such as rock fall and debris slides.
Cryostructure	The structural characteristics of frozen earth materials determined by the amount and distribution of ground ice (non-visible pore ice and visible excess ice, i.e. ice lenses, inclusions, coatings etc.). Can be described as massive (Nbn and Nbe), layered (Vs), reticulate (Vr) etc.
Cryoturbation	Heaving, churning, and sorting of soil and surficial materials due to repeated freezing and thawing (frost action); results in the development of convoluted structures in the soil, and patterned ground such as stone stripes and sorted polygons.
Debris Slide	A shallow slide consisting of a mass of soil, vegetation, and surficial material; initial displacement is along one or several surfaces of rupture. Composed of comparatively dry and largely unconsolidated earthy material and results in an irregular, hummocky deposit.
Eolian	Well sorted materials, predominantly silt and fine to medium sand, which have been eroded, transported, and deposited by wind.
Excess Ice	The volume of ice in the ground that exceeds the total pore volume that the ground would have under natural unfrozen conditions.
Fibric	The least decomposed state of organic materials – large amounts of weakly decomposed fibres whose botanical origins are readily identifiable are visible. Fibric material has 40% or more by volume of fibre that retains its character upon rubbing.
Frost Jacking	Cumulative upward displacement of objects embedded in the ground, caused by frost action.
Ground Ice	A general term referring to all types of ice (segregated, intrusive, vein etc.) formed in freezing and frozen ground. Occurs in pores, cavities, voids, cracks, fractures, and other openings in frozen soil or rock.
Humic	The greatest decomposed state of organic materials. It has the lowest amount of fiber, the highest bulk density, and the lowest saturated water-holding capacity of the organic materials. It is physically and chemically stable over time, unless drained. Fibres can be easily destroyed by rubbing.

Acronyms/Abbreviations	Definition
Ice Content	The amount of ice contained in frozen or partially frozen soil or rock. Ice content is normally expressed in one of two ways: ▪ On a dry-weight basis (gravimetric), as the ratio of the mass of the ice in a sample to the mass of the dry sample, expressed as a percentage; or ▪ On a volume basis (volumetric), as the ratio of the volume of ice in a sample to the volume of the whole sample, expressed as a percentage.
Loess	A homogeneous massive deposit formed by wind, consisting mainly of silt.
Mesic	Organic material in a stage of decomposition that is intermediate between fibric and humic. Fibre remaining after rubbing constitutes greater than 10% and less than 40% of the volume of the material.
Peat	Unconsolidated compressible material consisting largely of undecomposed, or slightly decomposed, organic matter accumulated under water-saturated conditions. Peat is commonly formed by the slow decay of successive layers of aquatic and semi-aquatic plants in swampy or water-logged areas, where oxygen is absent.
Permafrost	Ground, soil, or rock that remains at or below 0˚C for at least two consecutive years.
Permafrost, Ice-Rich	Permafrost containing excess ice.
Permafrost Table	The upper boundary of permafrost.
Suprapermafrost Water	Water occurring in the active layer above the permafrost table.
Weathered Bedrock	The chemical and physical decomposition and disintegration of bedrock due to exposure to air, moisture, organic matter, and temperature change.

ACRONYMS & ABBREVIATIONS

Acronyms/Abbreviations	Definition
BGS	Below Ground Surface
4WD	Four Wheel Drive
ALT	Active Layer Thickness
CBR	California Bearing Ratio
JDS	JDS Energy & Mining Inc.
Nbe	Well bonded perennially frozen soil with excess ice
Nbn	Well bonded perennially frozen soil with no excess ice
Nf	Poorly bonded or friable perennially frozen soil, no excess ice
Vc	Perennially frozen soil with excess ice visible as ice coating on particles
Vr	Perennially frozen soil with excess ice visible as random or irregularly oriented ice formations
Vs	Perennially frozen soil with excess ice visible as stratified or distinctly oriented ice formations
Vx	Perennially frozen soil with excess ice visible as individual ice inclusions
WRSA	Waste Rock Storage Area

SITE INVESTIGATION WAIVER STATEMENT

To minimize the risk of damage to underground utilities, locating and marking of all underground services will be completed by an independent utility locator service, along with any information provided by the property owner (or their representative) prior to any intrusive field investigation operations. The property owner (or their representative) is responsible for ensuring that any private utilities, such as storm sewers or buried power and gas lines, are identified and located within the investigation areas before the start of any field investigation program. Because Tetra Tech Canada Inc. (Tetra Tech) cannot verify or rely on the accuracy of this information, Tetra Tech will not accept responsibility for damage, or cause for delay, to any party for private or public utilities not properly identified and or located. Any and all costs resulting from the damaged utility, and/or utilities, as a result of our investigation will be the responsibility of JDS Energy & Mining Inc.

LIMITATIONS OF REPORT

This report and its contents are intended for the sole use of JDS Energy & Mining Inc. and their agents. Tetra Tech Canada Inc. (Tetra Tech) does not accept any responsibility for the accuracy of any of the data, the analysis, or the recommendations contained or referenced in the report when the report is used or relied upon by any Party other than JDS Energy & Mining Inc., or for any Project other than the proposed development at the subject site. Any such unauthorized use of this report is at the sole risk of the user. Use of this document is subject to the Limitations on Use of this Document attached in the Appendix or Contractual Terms and Conditions executed by both parties.

1.0 INTRODUCTION

Tetra Tech Canada Inc. (Tetra Tech) was retained by JDS Energy & Mining Inc. (JDS) to provide geotechnical consulting services for a testpitting program in the Coffee Gold Project (the Project) area in the fall of 2018. The site location map is shown in Figure 1. The objective of the testpitting program was to investigate the composition, diggability, and thickness of the overburden materials overlying bedrock throughout the Project area.

Several previous geotechnical site investigation programs were completed in the Project area, including the most recent geotechnical investigations carried out by Tetra Tech (2017a, b) and jointly by Tetra Tech and SRK Consulting (2017c). The Fall 2018 Testpitting Program was designed to augment a testpitting program completed by Tetra Tech within proposed infrastructure footprints and in proposed open pit areas in the fall of 2017 (Tetra Tech 2017a).

The Fall 2018 Testpitting Program took place from September 5 to September 26, 2018. It consisted of excavation of testpits, logging, and sampling of the exposed surficial materials along the proposed Java Airstrip alignment, in the Supremo, Double Double, and South Latte/Supremo Open Pit areas, in the Facility Pond area, along the Halfway Diversion, the Latte Diversion Channel (Latte Diversion), and in the potential borrow source located at km 0.3 along the existing site access road. (Figures 2 and 2a to 2j). Representative samples of overburden material, including five samples collected by JDS in the potential borrow sources located between 2-3 km and 6-7 km sections of the existing access road (Figures 2, 2h, and 2i), were shipped to Tetra Tech's geotechnical laboratory in Whitehorse for index testing. Specialized testing, such as California Bearing Ratio (CBR), for the samples collected along the Java Airstrip alignment, was performed at Tetra Tech's geotechnical laboratory in Edmonton.

This report presents the geotechnical and permafrost data collected during the Fall 2018 Testpitting Program, including testpit logs and geotechnical laboratory test results. The uppermost subsurface conditions in the proposed mine development areas and at mine construction sites are summarized from the new data.

The data acquired is intended to assist in determining the composition and distribution of surficial materials across the Project footprint and can aid in the updating of material inventory and plan for storage and management of excavated materials. The data can also be used to manage surficial materials during the pre-stripping program.

This report incorporates and is subject to Tetra Tech's Limitations on Use of this Document which are included in Appendix A.

2.0 TESTPITTING GEOTECHNICAL INVESTIGATION

2.1 General

The Fall 2018 Testpitting Program was managed by Dr. Vladislav Roujanski, P.Geol., a senior geologist-geocryologist based in Tetra Tech's Edmonton office, who also provided technical support for the field program. Testpit logging and overburden surficial material sampling was performed in the field by Ms. Jasmine Lalli, E.I.T., based in Tetra Tech's Edmonton office.

Ms. Leigh Sawchyn was JDS's representative on site coordinating the testpitting program on behalf of JDS. Excellent support staff was provided by JDS to excavate the testpits both by excavator and by hand.

Access to the mine laydown area was provided by 4WD pickup. A side-by-side all-terrain vehicle was used to access the testpit sites from the mine laydown area and to scout out locations of testpits to determine the least

environmentally damaging path to be taken by the excavator to mobilize to the testpit locations. The hand-dug testpits in the Halfway Diversion area were accessed by helicopter. Accommodation for all was provided at Goldcorp's Coffee Camp.

Daily Field Reports were compiled at the end of each field day and sent to all interested parties at JDS and Tetra Tech. Weather, work undertaken, names and numbers of testpits completed and samples taken, preliminary information acquired from the testpits, safety and environmental information, and any delays/breakdowns were described in the reports.

2.2 Testpit Locations

The Project area is located within Zone 7 of the Universal Transverse Mercator (UTM) Grid. The horizontal datum for this project is the North American Datum 1983 (NAD83).

Survey control for the testpitting program was provided by Tetra Tech field personnel using a handheld GPS unit (Garmin GPSMAP 62) to locate, verify, and take as-built coordinates of the testpit locations. The as-built testpit coordinates are presented on testpit logs in Appendix B and are summarized in Table 1. Testpit locations are also shown on Figures 2 and 2a to 2j.

Table 1: Testpit Information Summary

	TP18-18-74	6974021	594701	-	-	-

2.3 Testpitting Methodology

To achieve the objective of the testpitting program, overburden materials were exposed in 69 testpits by either hand-digging or the use of an excavator. As per their availability, a CAT 320C, CAT 349F, CAT 312C, or, most often, CAT 336E excavator was used. Due to Halfway Diversion being inaccessible by the excavator, testpits in this area were dug by hand.

Unfrozen (or thawed) and frozen overburden soil and bedrock exposed in the completed testpits was logged and sampled immediately following the testpit excavation to ensure that there was minimal thermal disturbance to permafrost exposed in the testpit walls. Representative disturbed soil samples were placed in plastic bags for moisture preservation and transported in plastic pails (unfrozen samples) or in coolers (frozen samples) to the offsite geotechnical laboratory.

Proposed TP18-18-34 and TP18-18-35 locations were found to be originally selected on a very steep slope that was inaccessible to the excavator and, therefore, these two proposed testpits were cancelled. Two additional testpits (TP18-18-03A and TP18-18-04A) were excavated along the proposed Java Airstrip alignment.

Five additional testpits (TP18-18-70 through TP18-18-74) were dug by JDS in the potential borrow sources located between 2-3 km and 6-7 km sections of the existing access road after Tetra Tech personnel left the Project site. No testpit logs are available for these testpits. One sample was collected from each of the five testpits (sample numbers TP70-01 through TP74-01). All five samples were tested at Tetra Tech's geotechnical laboratory in Whitehorse and the test results are included in this report.

All testpits were infilled immediately following logging and sampling. Organic cover was removed first and set aside; it was replaced last to help insulate the disturbed overburden material and prevent permafrost thaw. Photos were taken of the soils and bedrock encountered, as well as of the infilled excavations to record the reclamation efforts. Selected photographs of the overburden and fragmented bedrock, as well as some photos of the testpit sites before and after excavation, are presented in the "Photographs" section of this report.

2.4 Geotechnical Logging

Overburden soils were logged according to the Modified Unified Soil Classification System guidelines (Appendix B), ASTM and Tetra Tech's methodology for logging frozen and unfrozen overburden, which includes soil composition, particle shape, moisture, colour, and consistency of soil (ASTM D2488 and Tetra Tech's WM4400), and frozen soil classification based on whether ice is visible or not (ASTM D4083 and Tetra Tech's WM4102).

Information recorded in the testpit logs included types of surficial materials, depth to bedrock (where applicable), presence of peat/organic soil, grain size and composition of deposits, frozen/unfrozen state, diggability, active layer thickness (ALT), and amount and type of ground ice, if present. The field testpit logs are provided in Appendix B.

2.5 Laboratory Testing

2.5.1 General

Laboratory testing of a select number of representative samples of various overburden surficial material types were taken for analysis to Tetra Tech's geotechnical laboratory in Whitehorse. Testing performed included particle size distribution and moisture content analyses, and a limited number of hydrometer, Atterberg limit, excess ice content, and bulk density tests. Bulk samples taken from the testpits excavated along the Java Airstrip alignment (Figures 2 and 2g) were combined for California Bearing Ratio (CBR) testing at Tetra Tech's geotechnical laboratory in Edmonton. The five soil samples collected by JDS in the km 2-3 and km 6-7 Borrow Source areas (Figures 2, 2h, and 2i) were tested for moisture-density (Proctor) relationship.

The geotechnical laboratory soil testing results are summarized in Tables 2 and 3, are shown on the testpit logs in Appendix B, and are presented fully in Appendix C.

2.5.2 Index Testing

Index testing was conducted to characterize and determine physical-mechanical characteristics of the various overburden materials. The testing included particle size distribution and moisture content analysis on most of the samples. Atterberg limit tests were performed, as requested by SRK, on a select number of samples from the Facility Pond Area, Halfway Diversion, Latte Diversion, and South Latte areas. Samples that were able to remain frozen received excess ice content determination and bulk density testing.

2.5.3 California Bearing Ratio

CBR testing was conducted to evaluate the mechanical strength of the overburden material along the proposed Java Airstrip alignment. It was performed on a combined sample of all material collected from the Java Airstrip alignment to aid in the airstrip design. The results of the CBR testing are summarized in Table 3 and shown fully in Appendix C.

Table 3: Summary of California Bearing Ratio Test Results

	Before Soaking			After Soaking		
	10 Blows	**25 Blows**	**56 Blows**	**10 Blows**	**25 Blows**	**56 Blows**
Bearing Ratio (0.1")	25.6%	43.0%	51.4%	19.4%	30.0%	34.1%
Bearing Ratio (0.2")	34.8%	59.9%	61.9%	25.0%	46.6%	48.8%
Moisture Content	11.0%	11.0%	11.0%	12.8%	11.2%	11.1%
Moisture Content at Top 1"	-	-	-	13.4%	12.4%	11.4%

2.5.4 Moisture-Density Relationship (Proctor)

The Proctor compaction test was conducted on the samples obtained from the potential borrow sources located between 2-3 km and 6-7 km sections of the existing access road to determine the optimal moisture content at which the borrow material will reach its maximum dry density. The moisture-density relationship was determined using the Modified Proctor method as per ASTM D1557. The moisture-density relationship was also determined for the samples obtained from the Java Airstrip alignment as part of the CBR testing. These Proctor test results are summarized in Table 2 and shown fully in Appendix C.

3.0 SUBSURFACE CONDITIONS

3.1 General

Sixty-nine testpits were excavated during the Fall 2018 Testpitting Program along the proposed Java Airstrip alignment, in the Supremo, Double Double, and South Latte/Supremo Open Pit areas, in the Facility Pond area, along the Halfway Diversion, the Latte Diversion, and in the km 0.3 potential borrow source area. The testpit locations are shown in Figures 2 and 2a to 2j. Testpit logs containing sample locations and geotechnical laboratory test results are provided in Appendix B.

The overburden materials and subsurface conditions, observed in all 69 testpits are summarized for each of the proposed mine development and construction sites in the following sections. The summary includes ground diggability assessment to describe the influence of ground conditions on excavating equipment performance. The

diggability range of 1 to 10, with 10 being the most difficult to dig and 1 being the easiest, established by Tetra Tech to compare testpit materials in the Project area (Tetra Tech 2017a) was used in this report.

Permafrost was observed in many of the testpits. Frozen soils with non-visible ice and visible ground ice formations were described in the testpit logs (Appendix B), photographed and sampled for geotechnical laboratory testing.

Selected photographs of the overburden and bedrock exposed in the completed testpits are presented in the "Photographs" section of this report.

3.2 Surficial Materials

Various types of overburden surficial materials were identified within the testpits. These include loess, weathered bedrock, bedrock fragments in a soil matrix, colluvium, alluvium, and organic material (peat and moss cover). These surficial materials are briefly described below to augment Tetra Tech's previous characterization of surficial geology units (Tetra Tech 2017a).

3.2.1 Loess

Loess in the Project area is of wind-blown (eolian) origin (Bond and Lipovsky 2011). As opposed to a generally uniform homogeneous silty soil mass found in other regions, the loess in the Project area tends to become mixed with weathered bedrock or infill voids in fragmented bedrock.

Loess mixed with varying amounts of coarser overburden material particles was generally observed in the uppermost portion of the excavated testpits. It commonly forms a matrix for varying amounts of rock fragments of a wide range of sizes – from gravel to boulders.

3.2.2 Weathered Bedrock

The proposed open pit areas (Supremo, Double Double, Latte) are often covered with weathered bedrock ranging from slightly to completely weathered into residual soil varieties. The residual soil consists of rock material converted into soil. The original rock mass structure and material fabric are completely destroyed; however, the resultant soil has not been significantly transported.

The residual soil forms a soft mica sand in schist areas (TP18-18-24) and an easily crumbled sand to pea-sized gravel in granitic areas (TP18-18-59). Testpitting with an excavator commonly had refusal on competent fractured bedrock, whereas fragmented, frost-shattered bedrock was still diggable.

3.2.3 Colluvium

Colluvium was identified in several testpits on slopes (Photo 7 and Photo 135). A textural indicator used to confirm this type of surficial material was the presence of void spaces between angular cobble-sized and boulder-sized rock fragments and a lack of finer material.

3.2.4 Organic Material

Organic material described in the testpit logs includes moss and an underlying peat layer of varying thickness, but generally not exceeding 0.7 m (TP18-18-37).

3.3 Java Airstrip

3.3.1 Subsurface Conditions

Six testpits (TP18-18-01 to TP18-18-04A) were excavated along the proposed Java Airstrip alignment (Figures 2 and 2g). The subsurface conditions of the site are discussed below and are summarized in Table 4.

Table 4: Overburden and Bedrock Condition Summary, Java Airstrip

Testpit ID	Organic Layer Thickness (m)	Approx. Overburden Thickness (m)	Major Overburden Soil Types	Approximate Active Layer Thickness (m)	Permafrost Condition	Diggability (1-10)	Completion Depth (m)
TP18-18-01	0.20	0.50	Rock fragments in a gravel, silty, sandy, trace to some clay matrix	N/A	Unfrozen	-	1.60
TP18-18-02	0.20	0.50	Rock fragments in a gravel, silty, sandy, trace to some clay matrix	N/A	Unfrozen	-	1.70
TP18-18-03	0.20	0.50	Rock fragments in a gravel, silty, sandy, trace to some clay matrix	N/A	Unfrozen	-	1.00
TP18-18-03A	0.10	1.30	Rock fragments in a gravel, silty, sandy, trace to some clay matrix	N/A	Unfrozen	1 (0-1.3 m) 3 (1.3-2.3 m) 10 at 2.3 m	2.30
TP18-18-04	0.35	0.80	Rock fragments in a gravel, silty, sandy, trace to some clay matrix	N/A	Unfrozen	-	1.50
TP18-18-04A	0.10	0.40	Rock fragments in a gravel, silty, sandy, trace to some clay matrix	N/A	Unfrozen	1 (0-0.4 m) 3 (0.4-1.2 m) 10 at 1.2 m	1.20

The organic material layer along the proposed airstrip alignment consists of moss, lichen and peat (fibric to mesic), and rootlets up to 0.35 m thick, dry to damp, light to dark brown.

Cobble-sized and boulder-sized rock fragments approximately 10% to 40% by volume in a gravel, silty, sandy trace to some clay matrix make up the bulk of the residual soil (weathered bedrock) overburden unit. In TP18-18-03A, a layer of cobbly colluvium approximately 0.7 m thick was observed on gentle slope (Photo 7). Thickness of the overburden layer along the airstrip alignment ranged from 0.4 m in TP18-18-04A to 1.3 m in TP18-18-03A.

Permafrost was not encountered in any of the six testpits.

3.3.2 Suitability of Overburden and Upper Bedrock Material for Construction

The proposed Java Airstrip has been designed using a cut and fill approach (Tetra Tech 2018), the suitability of the cut materials for use in the fill sections is discussed here.

Overburden materials along the proposed airstrip alignment (under the thin organic veneer) consist of coarse schist rock fragments (up to 40% by volume) in a well-graded silty, gravelly, sandy matrix. The overburden material has an excessive fines content of up to 34% and is predominantly silt. Furthermore, the likelihood that the uppermost fractured, fragmented, and highly weathered bedrock may easily break down limits the use of this material in most construction applications where durable materials are required.

The unprocessed material can be used as road or airstrip subgrade fill, or as general fill; however, the high silt content will make it difficult to attain suitable compaction during winter construction. It is most suitable for placement during summer months, when it can be placed in an unfrozen condition. Winter placement of the overburden material may cause potential settlement of the runway surface during the following thaw season. If settlement is tolerable in the first summer, then the materials could be considered for use in the airstrip subgrade.

Materials excavated along the airstrip alignment can be improved using appropriate treatment to meet the recommended material specifications and allow for placement with sufficient densification during the winter. The excessive silt in the overburden material requires removal through sieving or blending (McGregor et al. 2010). The presence of boulder-sized rock fragments will need screening and possibly crushing of the oversized fraction. The processed material can be used as a subgrade fill in the airstrip, apron, and taxiway.

In an attempt to achieve suitably graded material for use as airstrip surfacing material, significant screening of the material excavated from the airstrip would have to be undertaken. Tetra Tech believes that although the desired gradation might be produced, there is a high possibility that the produced material will not be suitably durable and will break down generating excessive dust. Other sources of material such as the alluvial gravel material at km 0.3 or quarried material from durable bedrock are recommended to produce airstrip surfacing gravel.

The difficulty of testpit diggability increased with depth ranging from 1 to 3 in the upper soil units to 10 at the bottom of the excavation at depths ranging between 1.2 m to 2.3 m. Testpit excavation refusal occurred on fractured bedrock.

3.4 Supremo Open Pit

3.4.1 Subsurface Conditions

Fifteen testpits (TP18-18-10 to TP18-18-24) were excavated in the Supremo Open Pit area (Figures 2 and 2c). The subsurface conditions of the site are discussed below and are summarized in Table 5.

Table 5: Overburden and Bedrock Condition Summary, Supremo Open Pit

Testpit ID	Organic Layer Thickness (m)	Approximate Overburden Thickness (m)	Major Overburden Soil Types	Approximate Active Layer Thickness (m)	Permafrost Condition	Diggability (1-10)	Completion Depth (m)
TP18-18-10	0.30	Undetermined	Rock fragments, gravel, sand	N/A	Unfrozen	8-9	1.70
TP18-18-11	0.30	0.60	Silt, rock fragments, sand, gravel	N/A	Unfrozen	6-8	1.50
TP18-18-12	0.20	Undetermined	Silt, gravel	1.2	Nbe	-	1.20
TP18-18-13	0.10	0.30	Silt, rock fragments, sand	N/A	Unfrozen	5; 10 at 1.3 m	1.30
TP18-18-14	0.25	0.70	Silt, gravel, rock fragments	0.70	Vs, Vc, Vx, 10-15%	1-2 (0-0.7 m) 9-10 at 1.4 m	1.40
TP18-18-15	0.30	0.60	Silt, rock fragments, gravel	N/A	Unfrozen	-	1.60
TP18-18-16	0.30	1.00	Rock fragments, silt, gravel	N/A	Unfrozen	1-2; 10 at 1.3 m	1.30
TP18-18-17	-	0.50	Rock fragments, gravel, sand, silt	N/A	Unfrozen	1; 10 at 1.8 m	1.80
TP18-18-18	-	1.20	Sand, gravel, cobbles	N/A	Unfrozen	1; 10 at 1.6 m	1.60
TP18-18-19	0.30	0.70	Cobbles, silt, gravel, sand	N/A	Unfrozen	1-2; 10 at 1.5 m	1.50
TP18-18-20	0.30	0.80	Gravel, rock fragments	0.5	Vx, 30% Nbe underneath	1-2; 9-10 at 1.7 m	1.70
TP18-18-21	0.30	2.00	Rock fragments, gravel, sand	N/A	Unfrozen	1-2 (0-2 m) 6-7 at 3.5 m	3.50
TP18-18-22	0.30	2.50	Sand and gravel	N/A	Unfrozen	1-2; 10 at 4.0 m	4.00
TP18-18-23	0.40	Undetermined	Silt, gravel, rock fragments	0.7	Vx, (% unknown) Nbe underneath	1-2; 10 at 1.3 m	1.30
TP18-18-24	0.40	2.00	Sand and gravel, silt, sand	N/A	Unfrozen	1-2 (0-2 m) 5-6 to 4.0 m	4.00

The organic material layer within the Supremo Pit footprint consists of moss and peat (fibric to mesic) up to 0.4 m thick, and rootlets, damp to moist, light to dark brown. The organic material is underlain by rock fragments in a finer soil matrix, weathered bedrock (residual soil) or silt (loess).

Silt (loess) in the testpits is mixed with varying amounts of coarser particles. It is also present in the underlying surficial materials, forming a matrix to coarser soil particles. Silt was also observed in the fragmented bedrock. Thickness of the loess layer varies from 0.2 m in TP18-18-13 to more than 0.8 m in TP18-18-12.

Rock fragment units consist of cobble-sized and boulder-sized angular to sub-angular clasts in a finer soil matrix.

Permafrost conditions with both non-visible ice (Nbe) and visible ice (Vx, Vc, Vs) were observed in four testpits (TP18-18-12, -14, -20, and -23; Photos 32, 44, and 50). The volumetric ice content was estimated to be as high as 30% (TP18-18-20). The ALT ranged from 0.5 m (TP18-18-20) to 1.2 m (TP18-18-12).

3.4.2 Suitability of Overburden Material for Construction

Overburden materials encountered below a veneer of organics in the Supremo Open Pit area consists of coarse schist and granite rock fragments of up to 70% by volume. Overburden materials range from a poorly-graded silt (loess) to well-graded silty, gravelly, sandy matrix. The fines content in the overburden material is up to 59% and is predominantly silt. The likelihood that the uppermost fractured, fragmented, and highly weathered bedrock may easily break down, makes this material marginal for use in most construction applications. The unprocessed material could be used as road subgrade and as a general fill if placed during the summer.

Marginal materials can be improved using appropriate treatment to meet the recommended material specifications. Excessive content of silt in the material requires its removal through sieving or blending (McGregor et al. 2010). The presence of boulder-sized rock fragments will need screening and possibly crushing of the oversized fraction. The processed material can be used as a general fill across the site and potentially as an embankment fill for dam construction subject to the design specifications. This processed material would not be suitable as a structural fill required below building foundations or slabs on grade.

Shallow ice-rich permafrost (up to 30% by volume) encountered in some locations will require additional special measures, such as drainage control and air drying of the excavated stockpiled material.

Refusal in the testpits occurred either on frozen ground or fractured bedrock. Diggability ranged from 1 to 2 in the upper soil units and 9 to 10 in the lower units.

3.5 Double Double Open Pit

3.5.1 Subsurface Conditions

Seven testpits (TP18-18-25 to TP18-18-31) were excavated in the Double Double Pit area (Figures 2 and 2f). The subsurface conditions of the site are discussed below and are summarized in Table 6.

Table 6: Overburden and Bedrock Condition Summary, Double Double Open Pit

Testpit ID	Organic Layer Thickness (m)	Approximate Overburden Thickness (m)	Major Overburden Soil Types	Approximate Active Layer Thickness (m)	Permafrost Condition	Diggability (1-10)	Completion Depth (m)
TP18-18-25	0.20	0.50	Gravel and sand	N/A	Unfrozen	1-4; 10 at 1.4 m	1.40
TP18-18-26	0.20	1.30	Silt, rock fragments, gravel	N/A	Unfrozen	1-2 (0-0.5 m); 7 (0.5-1.8 m); 9 at 1.8 m	1.80
TP18-18-27	0.30	1.50	Sand and gravel	N/A	Unfrozen	1-2; 8 at 4 m	4.00
TP18-18-28	0.20	1.20	Gravel and sand	N/A	Unfrozen	1-2; 8-9 at 2.2 m	2.20
TP18-18-29	0.20	0.50	Silt, rock fragments	N/A	Unfrozen	1-2; 10 at 1.5 m	1.50
TP18-18-30	0.30	0.70	Gravel and sand, rock fragments, silt	N/A	Unfrozen	1-2; 8-9 at 1.7 m	1.70
TP18-18-31	0.30	0.90	Silt, rock fragments	N/A	Unfrozen	1-2; 9 at 1.9 m	1.90

The organic material layer within the Double Double Pit footprint consists of moss and peat (fibric to mesic) up to 0.3 m thick, and rootlets, damp to moist, light to dark brown. The organic material was found to be underlain by weathered bedrock (residual soil) in TP18-18-25, - 27, -28, and -30 and silt (loess) in TP18-18-26, -29, and -31.

Well graded gravel and sand with varying amounts of silt, clay and cobbles in the testpits make up the bulk of the residual soil (weathered bedrock) overburden unit.

Silt (loess) was found to be mixed with gravel in TP18-18-26 and TP18-18-31, and gravel and cobbles in TP18-18-29. Thickness of the loess layer varies from 0.3 m in TP18-18-26 and TP18-18-29 to 0.6 m in TT18-18-31.

Rock fragment units consist of cobble and boulder-sized angular to sub-angular clasts in a finer soil matrix.

Permafrost was not encountered in any of the seven testpits.

3.5.2 Suitability of Overburden Material for Construction

Overburden materials encountered below a veneer of organics in the Double Double Open Pit area consists of coarse schist rock fragments of up to 80% by volume, in a poorly-graded (silt, loess) to well-graded silty, gravelly, sandy matrix. The fines content in the overburden material is up to 25%, and the fines are predominantly made up of silt. The likelihood that the uppermost fractured, fragmented, and highly weathered bedrock may easily break down make this material marginal for use in most construction applications. The unprocessed material can potentially be used as road subgrade and as a general fill, if placed during the summer.

Marginal materials can be improved using appropriate treatment to meet the recommended material specifications. Excessive content of silt in the material requires its removal through sieving or blending (McGregor et al. 2010).

The presence of boulder-sized rock fragments will need screening and possibly crushing of the oversized fraction. The processed material can be used as a general fill across the site and potentially, as an embankment fill for dam construction subject to the design specifications. This processed material would not be suitable as a structural fill such as might be required below building foundations or slabs on grade.

Refusal in the testpits occurred on fractured bedrock. Diggability ranged from 1 to 2 in the upper soil units to 9 to 10 in the deeper overburden.

3.6 Latte Diversion

Fourteen testpits (TP18-18-50 to TP18-18-63) were excavated along the proposed Latte Diversion (Figures 2, 2d, and 2e). The subsurface conditions of the site are discussed below and are summarized in Table 7.

Table 7: Overburden and Bedrock Condition Summary, Latte Diversion

Testpit ID	Organic Layer Thickness (m)	Overburden Thickness (m)	Major Overburden Soil Types	Approximate Active Layer Thickness (m)	Permafrost Condition	Diggability (1-10)	Completion Depth (m)
TP18-18-50	0.50	Undetermined	Rock fragments, silt	N/A	Vx, 10-15%	1-2 (0-1.3 m); 10 at 1.3 m	1.30
TP18-18-51	0.50	Undetermined	Sand, silt, rock fragments	0.5	Vx, 5-10%	1 (0-2.1 m); 10 at 2.1 m	2.10
TP18-18-52	0.50	1.00 (?)	Sand, gravel	N/A	Unfrozen	10 at 2.3 m	2.30
TP18-18-53	0.35	1.25	Silt, sand, gravel, cobbles	N/A	Unfrozen	1-2 (0-2.6 m); 10 at 2.6 m	2.60
TP18-18-54	0.30	2.00	Silt, sand, gravel, rock fragments	N/A	Unfrozen	1-2 (0-2.5 m); 10 at 2.5 m	2.50
TP18-18-55	0.30	1.50	Silt, sand, rock fragments	N/A	Unfrozen	1-2 (0-2.5 m); 10 at 2.5 m	2.50
TP18-18-56	0.30	0.70 (?)	Silt, sand, rock fragments	N/A	Unfrozen	1-2 (0-1.7 m); 10 at 1.7 m	1.70
TP18-18-57	0.30	1.20 (?)	Silt, sand, rock fragments	N/A	Unfrozen	1-2 (0-1.2 m); 7 (1.2-2.3 m) 10 at 2.3 m	2.30
TP18-18-58	0.40	Undetermined	Silt, sand, cobbles, boulders	1.3	Vx, Vs, 20%	1-2 (0-1.3 m); 10 at 1.3 m	1.30
TP18-18-59	0.35	Undetermined	Sand, gravel, boulders	N/A	Unfrozen	10 at 2.3 m	2.30
TP18-18-60	0.20	Undetermined	Silt, sand, gravel, boulders	N/A	Unfrozen	3-4 (0-2.3 m); 10 at 2.3 m	2.30

Table 7: Overburden and Bedrock Condition Summary, Latte Diversion

Testpit ID	Organic Layer Thickness (m)	Overburden Thickness (m)	Major Overburden Soil Types	Approximate Active Layer Thickness (m)	Permafrost Condition	Diggability (1-10)	Completion Depth (m)
TP18-18-61	0.40	Undetermined	Silt, boulders	N/A	Unfrozen	8-9	1.90
TP18-18-62	0.45	Undetermined	Gravel, sand, rock fragments	N/A	Unfrozen	5-6 (0-1.5 m); 10 at 1.5 m	1.50
TP18-18-63	0.25	Undetermined	Silt, rock fragments	N/A	Unfrozen	6 (0-2.1 m); 9 at 2.1 m	2.10

The organic material layer along the proposed Latte Diversion channel consists of moss and peat (fibric to humic) up to 0.5 m thick, and rootlets, damp to wet, medium to dark brown. The organic material was found to be underlain by rock fragments in a finer soil matrix, weathered bedrock (residual soil) or silt (loess).

Silt (loess) in the testpits is mixed with varying amounts of coarser particles – cobble and boulder-sized rock fragments, gravel and sand. It is also present in the underlying surficial materials, often forming a matrix to coarser soil particles, and in the fragmented bedrock. Thickness of the loess layer varies from 0.4 m in TP18-18-56 to 1.7 m in TP18-18-54.

Rock fragment units consist of cobble-sized and boulder-sized angular to sub-angular clasts in a finer soil matrix, including loess.

Permafrost conditions with visible ice (Vx, Vs) were observed in three testpits (TP18-18-50, -51, and; -58; Photos 100, 102, and 116). The volumetric ice content was estimated to be as high as 20% (TP18-18-58). The ALT ranged from 0.5 m (TP18-18-51) to 1.3 m (TP18-18-58).

Refusal in the testpits occurred either on frozen ground or fractured bedrock. Diggability ranged from 1 to 2 in the upper soil units and 9 to 10 in the lower units.

3.7 South Latte / Supremo Open Pit Area

Six testpits (TP18-18-32, TP18-18-33, and TP18-18-36 to TP18-18-39) were excavated in the South Latte/Supremo area (Figures 2 and 2e). The subsurface conditions of the site are discussed below and summarized in Table 8.

Table 8: Overburden and Bedrock Condition Summary, South Latte / Supremo Open Pit Area

Testpit ID	Organic Layer Thickness (m)	Overburden Thickness (m)	Major Overburden Soil Types	Approximate Active Layer Thickness (m)	Permafrost Condition	Diggability (1-10)	Completion Depth (m)
TP18-18-32	0.15	1.20	Gravel and sand	N/A	Unfrozen	1	4.00
TP18-18-33	0.20	1.20	Gravel, sand	N/A	Unfrozen	1 (0-1.2 m); 3 (1.2-1.7 m); 10 at 1.7 m	1.70
TP18-18-36	0.50	Undetermined	Gravel, rock fragments, sand	1.0	Vx, 5-10%	1-2 (0-1 m); 10 at 1.7 m	1.70
TP18-18-37	0.70	Undetermined	Silt, gravel, cobbles	1.0	Vx, Vc, 15-20%	1-2 (0-1 m); 10 at 1.0 m	1.00
TP18-18-38	0.40	Undetermined	Silt, gravel, rock fragments	1.2	Vx, Vc, 25-30%	1 (0-1.2 m); 10 at 1.2 m	1.20
TP18-18-39	0.20	0.20 (?)	Rock fragments, silt	N/A	Unfrozen	10 at 1.2 m	1.20

The organic material layer consists of moss and peat (fibric to mesic) up to 0.7 m thick (TP18-18-37), damp to wet, medium to dark brown. The organic material was found to be underlain either by rock fragments in a finer soil matrix, mostly weathered bedrock (residual soil) or silt (loess) in TP18-18-38.

The units of rock fragments consist of cobble-sized angular to sub-angular clasts in a finer soil matrix.

Permafrost conditions with visible ice (Vx, Vc,) were observed in three testpits (TP18-18-36, -37, and -38; Photos 72, 74, and 76). The volumetric ice content was estimated to be as high as 30% (TP18-18-38). The ALT ranged from 1.0 m to 1.2 m.

Refusal in the testpits occurred either on frozen ground or fractured bedrock. Diggability ranged from 1 to 2 throughout the testpits (3 in the middle of TP18-18-33), until refusal, where diggability was rated 10.

3.8 Facility Pond Area

Ten testpits (TP18-18-40 to TP18-18-49) were excavated in the Facility Pond area (Figures 2 and 2e). The subsurface conditions of the site are discussed below and are summarized in Table 9.

Table 9: Overburden and Bedrock Condition Summary, Facility Pond Area

Testpit ID	Organic Layer Thickness (m)	Approximate Overburden Thickness (m)	Major Overburden Soil Types	Approximate Active Layer Thickness (m)	Permafrost Condition	Diggability (1-10)	Completion Depth (m)
TP18-18-40	0.30	1.00	Gravel and sand	N/A	Unfrozen	1 (0-3 m); 10 at 3 m	3.00
TP18-18-41	0.45	0.90	Gravel and sand	N/A	Unfrozen	1-2 (0-2.3 m); 10 at 2.3 m	2.30
TP18-18-42	0.40	1.00	Sand, gravel, rock fragments	1.90	Vx, 5-10%	1-2 (0-2.5 m); 10 at 2.5 m	1.90
TP18-18-43	0.20	0.80	Gravel, sand	N/A	Unfrozen	1-2 (0-2 m); 10 at 2 m	2.00
TP18-18-44	0.30	1.90	Silt, sand, rock fragments	N/A	Unfrozen	1-2 (0-2 m); 5 (2-2.8 m) 10 at 2.8 m	2.80
TP18-18-45	0.40	0.80	Silt, rock fragments	2.0	Vx, 20%	1-2 (0-2 m); 10 at 2 m	2.00
TP18-18-46	0.40	Undetermined	Silt, cobbles	1.2	Vx, 10-15%	1 (0-1.2 m); 10 at 1.2 m	1.20
TP18-18-47	0.30	Undetermined	Silt, rock fragments	N/A	Unfrozen	1-2 (0-2 m); 3-4 (2-2.7 m); 10 at 2.7 m	2.70
TP18-18-48	0.30	1.00	Gravel and sand	N/A	Unfrozen	1-2 (0-2.7 m); 10 at 2.7 m	2.70
TP18-18-49	0.40	1.30	Sand, cobbles	N/A	Unfrozen	1-2 (0-2.1 m); 10 at 2.1 m	2.10

The organic material layer within the Facility Pond Area consists of moss and peat (fibric to humic) up to 0.4 m thick, and rootlets, damp to wet, medium to dark brown. The organic material was found to be underlain mainly by rock fragments in a finer soil matrix, weathered bedrock (residual soil) or silt (loess).

Silt (loess) in the testpits is mixed with varying amounts of coarser particles – cobble and boulder-sized rock fragments, gravel and sand. It is also present in the underlying surficial materials, often forming a matrix to coarser soil particles, and in the fragmented bedrock. Thickness of the loess layer varies from 0.4 m in TP18-18-45 to 1.7 m in TP18-18-47.

Permafrost conditions with visible ice (Vx) were observed in three testpits (TP18-18-42, -45, and -46; Photos 84, 90, and 92). The volumetric ice content was estimated to be as high as 20% (TP18-18-45). The ALT ranged from 1.2 m (TP18-18-46) to 2.0 m (TP18-18-45).

Refusal in the testpits occurred either on frozen ground or fractured bedrock. Diggability ranged from 1 to 2 throughout most of the testpits, 3 to 5 in some of the intermediate units, and 10 in the lower units.

3.9 Halfway Diversion

Six testpits (TP18-18-64 to TP18-18-69) were excavated along the proposed Halfway Diversion alignment (Figures 2, 2a, and 2b). The subsurface conditions of the site are discussed below and summarized in Table 10.

Table 10: Overburden and Bedrock Condition Summary, Halfway Diversion

Testpit ID	Organic Layer Thickness (m)	Approximate Overburden Thickness (m)	Major Overburden Soil Types	Approximate Active Layer Thickness (m)	Permafrost Condition	Diggability (1-10)	Completion Depth (m)
TP18-18-64	0.30	Undetermined	Silt and sand	0.3	Vc, Vx, Vs, 15-35%	10	1.00
TP18-18-65	0.20	Undetermined	Gravel and sand	N/A	Unfrozen	-	1.40
TP18-18-66	0.50	Undetermined	Silt and sand, gravel, rock fragments	0.70	Vx, Vs, 30%	10 at 1.1 m	1.10
TP18-18-67	0.30	0.80	Gravel and cobbles, silt, sand	N/A	Unfrozen	-	1.40
TP18-18-68	0.10	Undetermined	Cobbles and gravel, gravel and sand	N/A	Unfrozen	-	1.20
TP18-18-69	0.40	Undetermined	Silt	0.4	Vx, Vc, Vs, 30-45%	-	1.20

The organic material layer along the proposed Halfway Diversion consists of moss and peat (fibric to humic) up to 0.5 m thick, and rootlets, damp to wet, medium to dark brown. The organic material was found to be underlain by silt (loess) in TP18-18-64, -66, and -69, weathered bedrock (residual soil) in TP18-18-65 and gravel- and cobble-sized colluvium in TP18-18-67 and TP18-18-68.

Silt (loess) in the testpits is mixed with varying amounts of coarser particles as well as trace amounts of clay. Silt (loess) is also present in the underlying surficial materials, forming a matrix to coarser soil particles, and in the fragmented bedrock. Thickness of the loess layer along the proposed Halfway Diversion alignment varies between 0.2 m in TP18-18-66 and 0.8 m in TP18-18-69.

Well graded gravel and sand with varying amounts of silt, clay, and cobbles make up the bulk of the residual soil (weathered bedrock) overburden unit.

The units of rock fragments consist of cobble-sized and boulder-sized angular to sub-angular clasts in a finer soil matrix, including loess.

Refusal in the testpits occurred either on frozen ground or fractured bedrock.

Permafrost conditions with visible ice (Vx, Vs, Vc) were observed in three testpits (TP18-18-64, -66, and -69; Photos 127, 132, and 139). The volumetric ice content was estimated to be as high as 45% (TP18-18-69). An excess ice content (Beaker) test performed on a frozen soil sample collected at a depth of 0.9 m in TP18-18-69 showed volumetric ice content of 42%. The ALT ranged from 0.3 m in TP18-18-64 to 0.7 m in TP18-18-66.

3.10 Km 0.3 Borrow Source

3.10.1 Subsurface Conditions

Five testpits (TP18-18-05 to TP18-18-09) were excavated in the potential borrow source located at km 0.3 of the existing site access road (Figures 2 and 2j). The subsurface conditions of the site are discussed below and are summarized in Table 11.

Table 11: Overburden and Bedrock Condition Summary, km 0.3 Borrow Source Area

Testpit ID	Organic Layer Thickness (m)	Approximate Overburden Thickness (m)	Major Overburden Soil Types	Approximate Active Layer Thickness (m)	Permafrost Condition	Diggability (1-10)	Completion Depth (m)
TP18-18-05	0.15	-	Silt and sand, sand	3.0	Vx, 15-20%	1; 10 at 3.0	3.00
TP18-18-06	0.15	-	Sand and silt, sand	4.0	Vx, 10-15%	1; 10 at 4.0	4.00
TP18-18-07	0.15	-	Silt, sand	0.8 m one one end of pit; 1.5 m for the rest of pit	Nbn; Vx, 15-20%	1; 10 at 1.7 m	1.70
TP18-18-08	0.15	-	Silt, sand and gravel, sand	3.7	Vx, 25-30% Nbe underneath	1; 10 at 3.7 m	3.70
TP18-18-09	0.10	-	Sand	N/A	Unfrozen	1	4.50

The organic material layer within the km 0.3 Borrow Source area consists of moss and peat (fibric to mesic) up to 0.15 m thick, damp, medium to dark brown. The organic material was found to be underlain by alluvium (silt, sand, and gravel).

Silt in the testpits was found almost entirely in the uppermost layers only (ranging from 0.5 m to 1.25 m), with little to no silt found in the layers below. Clean sand with varying amounts of gravel ranging from 1% to 42%, was generally found in the lower layers until refusal on permafrost was reached. The only exception to this was in TP18-18-06, where some silt was found below 1.5 m depth; however, no silt was found in an intermediate layer from 1.0 m to 1.5 m.

Permafrost conditions with both non-visible ice (Nbe, Nbn) and visible ice (Vx) were observed in four testpits (TP18-18-05 to TP18-18-08). The volumetric ice content was estimated to be as high as 30% (TP18-18-08). The ALT in these pits ranged from 0.75 m in TP18-18-07 to 4.0 m in TP18-18-06. No permafrost was encountered in TP18-18-09.

3.10.2 Suitability of Overburden Material for Construction

Overburden materials encountered in the km 0.3 Borrow Source area consist of well-sorted alluvium (sand and sub-rounded gravel) covered by a veneer of silty material and organics. Although this material is well suited for use in most construction applications, the lack of particle angularity may require crushing of larger aggregates found at

this location. The processed material can be used for road and airstrip surfacing, or even as concrete aggregate. To achieve better compaction, alluvium material may require blending and mixing in with the overlying silt.

Ice-rich permafrost (up to 30% by volume) encountered in some locations within the km 0.3 Borrow Source area will require additional special measures, such as drainage control and air drying of the excavated stockpiled material.

Diggability was consistently at a rating of 1 throughout all the testpits in the km 0.3 Borrow Area until refusal. Refusal in all testpits, except for TP18-18-09, occurred on frozen ground. No frozen ground was encountered in TP18-18-09 to a depth of 4.5 m, at which the testpit excavation was terminated.

3.11 Km 2-3/Km 6-7 Borrow Source Areas

Five samples collected from five additional testpits excavated by JDS in the potential borrow sources located between 2-3 km and 6-7 km sections of the existing access road were examined and tested at Tetra Tech's geotechnical laboratories. The test results are summarized in Table 2 and included in Appendix C.

Overburden materials sampled in these potential borrow areas consist of coarse rock fragments in a well-graded gravelly and sandy, trace to some silt matrix (Photos 140 and 141). The gravelly matrix breaks down primarily into sand, as the particle size distribution analysis done on this material shows the content of fines ranging from 8% to 18% (Table 2). The durability of the gravel-sized clasts raises concerns about the potential breakdown of these particles into finer material, if exposed to either mechanical loading (vehicle traffic) or freeze thaw cycles.

The unprocessed material can be used as a general fill and in road and airstrip subgrades. However, the presence of cobble-sized competent rock fragments (Photos 140 and 141) indicates that if screened and crushed, the processed material could be potentially used in locations requiring more stringent particle size distributions (e.g. bedding material).

4.0 CLOSURE

We trust this document meets your present requirements. If you have any questions or comments, please contact the undersigned.

APPENDIX A

TETRA TECH'S LIMITATIONS ON USE OF THIS DOCUMENT

LIMITATIONS ON USE OF THIS DOCUMENT

GEOTECHNICAL

1.1 USE OF DOCUMENT AND OWNERSHIP

This document pertains to a specific site, a specific development, and a specific scope of work. The document may include plans, drawings, profiles and other supporting documents that collectively constitute the document (the "Professional Document").

The Professional Document is intended for the sole use of TETRA TECH's Client (the "Client") as specifically identified in the TETRA TECH Services Agreement or other Contractual Agreement entered into with the Client (either of which is termed the "Contract" herein). TETRA TECH does not accept any responsibility for the accuracy of any of the data, analyses, recommendations or other contents of the Professional Document when it is used or relied upon by any party other than the Client, unless authorized in writing by TETRA TECH.

Any unauthorized use of the Professional Document is at the sole risk of the user. TETRA TECH accepts no responsibility whatsoever for any loss or damage where such loss or damage is alleged to be or, is in fact, caused by the unauthorized use of the Professional Document.

Where TETRA TECH has expressly authorized the use of the Professional Document by a third party (an "Authorized Party"), consideration for such authorization is the Authorized Party's acceptance of these Limitations on Use of this Document as well as any limitations on liability contained in the Contract with the Client (all of which is collectively termed the "Limitations on Liability"). The Authorized Party should carefully review both these Limitations on Use of this Document and the Contract prior to making any use of the Professional Document. Any use made of the Professional Document by an Authorized Party constitutes the Authorized Party's express acceptance of, and agreement to, the Limitations on Liability.

The Professional Document and any other form or type of data or documents generated by TETRA TECH during the performance of the work are TETRA TECH's professional work product and shall remain the copyright property of TETRA TECH.

The Professional Document is subject to copyright and shall not be reproduced either wholly or in part without the prior, written permission of TETRA TECH. Additional copies of the Document, if required, may be obtained upon request.

1.2 ALTERNATIVE DOCUMENT FORMAT

Where TETRA TECH submits electronic file and/or hard copy versions of the Professional Document or any drawings or other project-related documents and deliverables (collectively termed TETRA TECH's "Instruments of Professional Service"), only the signed and/or sealed versions shall be considered final. The original signed and/or sealed electronic file and/or hard copy version archived by TETRA TECH shall be deemed to be the original. TETRA TECH will archive a protected digital copy of the original signed and/or sealed version for a period of 10 years.

Both electronic file and/or hard copy versions of TETRA TECH's Instruments of Professional Service shall not, under any circumstances, be altered by any party except TETRA TECH. TETRA TECH's Instruments of Professional Service will be used only and exactly as submitted by TETRA TECH.

Electronic files submitted by TETRA TECH have been prepared and submitted using specific software and hardware systems. TETRA TECH makes no representation about the compatibility of these files with the Client's current or future software and hardware systems.

1.3 STANDARD OF CARE

Services performed by TETRA TECH for the Professional Document have been conducted in accordance with the Contract, in a manner consistent with the level of skill ordinarily exercised by members of the profession currently practicing under similar conditions in the jurisdiction in which the services are provided. Professional judgment has been applied in developing the conclusions and/or recommendations provided in this Professional Document. No warranty or guarantee, express or implied, is made concerning the test results, comments, recommendations, or any other portion of the Professional Document.

If any error or omission is detected by the Client or an Authorized Party, the error or omission must be immediately brought to the attention of TETRA TECH.

1.4 DISCLOSURE OF INFORMATION BY CLIENT

The Client acknowledges that it has fully cooperated with TETRA TECH with respect to the provision of all available information on the past, present, and proposed conditions on the site, including historical information respecting the use of the site. The Client further acknowledges that in order for TETRA TECH to properly provide the services contracted for in the Contract, TETRA TECH has relied upon the Client with respect to both the full disclosure and accuracy of any such information.

1.5 INFORMATION PROVIDED TO TETRA TECH BY OTHERS

During the performance of the work and the preparation of this Professional Document, TETRA TECH may have relied on information provided by persons other than the Client.

While TETRA TECH endeavours to verify the accuracy of such information, TETRA TECH accepts no responsibility for the accuracy or the reliability of such information even where inaccurate or unreliable information impacts any recommendations, design or other deliverables and causes the Client or an Authorized Party loss or damage.

1.6 GENERAL LIMITATIONS OF DOCUMENT

This Professional Document is based solely on the conditions presented and the data available to TETRA TECH at the time the data were collected in the field or gathered from available databases.

The Client, and any Authorized Party, acknowledges that the Professional Document is based on limited data and that the conclusions, opinions, and recommendations contained in the Professional Document are the result of the application of professional judgment to such limited data.

The Professional Document is not applicable to any other sites, nor should it be relied upon for types of development other than those to which it refers. Any variation from the site conditions present, or variation in assumed conditions which might form the basis of design or recommendations as outlined in this report, at or on the development proposed as of the date of the Professional Document requires a supplementary investigation and assessment.

TETRA TECH is neither qualified to, nor is it making, any recommendations with respect to the purchase, sale, investment or development of the property, the decisions on which are the sole responsibility of the Client.

1.7 ENVIRONMENTAL AND REGULATORY ISSUES

Unless stipulated in the report, TETRA TECH has not been retained to investigate, address or consider and has not investigated, addressed or considered any environmental or regulatory issues associated with development on the subject site.

1.8 NATURE AND EXACTNESS OF SOIL AND ROCK DESCRIPTIONS

Classification and identification of soils and rocks are based upon commonly accepted systems and methods employed in professional geotechnical practice. This report contains descriptions of the systems and methods used. Where deviations from the system or method prevail, they are specifically mentioned.

Classification and identification of geological units are judgmental in nature as to both type and condition. TETRA TECH does not warrant conditions represented herein as exact, but infers accuracy only to the extent that is common in practice.

Where subsurface conditions encountered during development are different from those described in this report, qualified geotechnical personnel should revisit the site and review recommendations in light of the actual conditions encountered.

1.9 LOGS OF TESTHOLES

The testhole logs are a compilation of conditions and classification of soils and rocks as obtained from field observations and laboratory testing of selected samples. Soil and rock zones have been interpreted. Change from one geological zone to the other, indicated on the logs as a distinct line, can be, in fact, transitional. The extent of transition is interpretive. Any circumstance which requires precise definition of soil or rock zone transition elevations may require further investigation and review.

1.10 STRATIGRAPHIC AND GEOLOGICAL INFORMATION

The stratigraphic and geological information indicated on drawings contained in this report are inferred from logs of test holes and/or soil/rock exposures. Stratigraphy is known only at the locations of the test hole or exposure. Actual geology and stratigraphy between test holes and/or exposures may vary from that shown on these drawings. Natural variations in geological conditions are inherent and are a function of the historic environment. TETRA TECH does not represent the conditions illustrated as exact but recognizes that variations will exist. Where knowledge of more precise locations of geological units is necessary, additional investigation and review may be necessary.

1.11 PROTECTION OF EXPOSED GROUND

Excavation and construction operations expose geological materials to climatic elements (freeze/thaw, wet/dry) and/or mechanical disturbance which can cause severe deterioration. Unless otherwise specifically indicated in this report, the walls and floors of excavations must be protected from the elements, particularly moisture, desiccation, frost action and construction traffic.

1.12 SUPPORT OF ADJACENT GROUND AND STRUCTURES

Unless otherwise specifically advised, support of ground and structures adjacent to the anticipated construction and preservation of adjacent ground and structures from the adverse impact of construction activity is required.

1.13 INFLUENCE OF CONSTRUCTION ACTIVITY

There is a direct correlation between construction activity and structural performance of adjacent buildings and other installations. The influence of all anticipated construction activities should be considered by the contractor, owner, architect and prime engineer in consultation with a geotechnical engineer when the final design and construction techniques are known.

1.14 OBSERVATIONS DURING CONSTRUCTION

Because of the nature of geological deposits, the judgmental nature of geotechnical engineering, as well as the potential of adverse circumstances arising from construction activity, observations during site preparation, excavation and construction should be carried out by a geotechnical engineer. These observations may then serve as the basis for confirmation and/or alteration of geotechnical recommendations or design guidelines presented herein.

1.15 DRAINAGE SYSTEMS

Where temporary or permanent drainage systems are installed within or around a structure, the systems which will be installed must protect the structure from loss of ground due to internal erosion and must be designed so as to assure continued performance of the drains. Specific design detail of such systems should be developed or reviewed by the geotechnical engineer. Unless otherwise specified, it is a condition of this report that effective temporary and permanent drainage systems are required and that they must be considered in relation to project purpose and function.

1.16 BEARING CAPACITY

Design bearing capacities, loads and allowable stresses quoted in this report relate to a specific soil or rock type and condition. Construction activity and environmental circumstances can materially change the condition of soil or rock. The elevation at which a soil or rock type occurs is variable. It is a requirement of this report that structural elements be founded in and/or upon geological materials of the type and in the condition assumed. Sufficient observations should be made by qualified geotechnical personnel during construction to assure that the soil and/or rock conditions assumed in this report in fact exist at the site.

1.17 SAMPLES

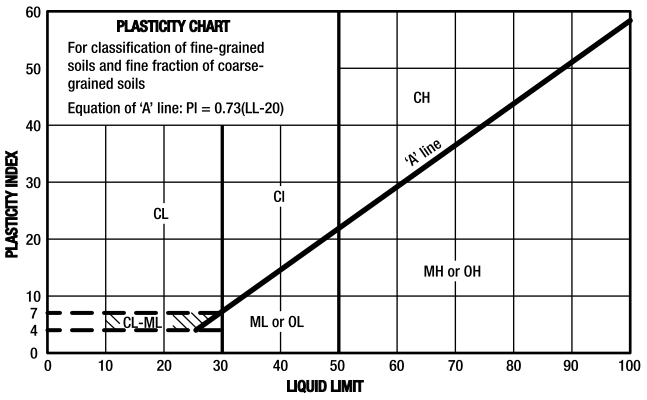
TETRA TECH will retain all soil and rock samples for 30 days after this report is issued. Further storage or transfer of samples can be made at the Client's expense upon written request, otherwise samples will be discarded.

APPENDIX B

TESTPIT LOGS

MODIFIED UNIFIED SOIL CLASSIFICATION

MAJOR DIVISION			GROUP SYMBOL	TYPICAL DESCRIPTION	LABORATORY CLASSIFICATION CRITERIA	
COARSE-GRAINED SOILS More than 50% retained on 75 µm sieve*	GRAVELS 50% or more of coarse fraction retained on 4.75 mm sieve	CLEAN GRAVELS	GW	Well-graded gravels and gravel-sand mixtures, little or no fines	Classification on basis of percentage of fines GW, GP, SW, SP GM, GC, SM, SC Borderline Classification requiring use of dual symbols $C_U = D_{60} / D_{10}$ Greater than 4 $C_C = \frac{(D_{30})2}{D_{10} \times D_{60}}$ Between 1 and 3	
			GP	Poorly graded gravels and gravel-sand mixtures, little or no fines	Not meeting both criteria for GW	
		GRAVELS WITH FINES	GM	Silty gravels, gravel-sand-silt mixtures	Atterberg limits plot below "A" line or plasticity index less than 4	Atterberg limits plotting in hatched area are borderline classifications requiring use of dual symbols
			GC	Clayey gravels, gravel-sand-clay mixtures	Atterberg limits plot above "A" line or plasticity index greater than 7	
	SANDS More than 50% of coarse fraction passes 4.75 mm sieve	CLEAN SANDS	SW	Well-graded sands and gravelly sands, little or no fines	Less than 5% Pass 75 µm sieve More than 12% Pass 75 µm sieve 5% to 12% Pass 75 µm sieve $C_U = D_{60}/D_{10}$ Greater than 6 $C_C = \frac{(D_{30})2}{D_{10} \times D_{60}}$ Between 1 and 3	
			SP	Poorly graded sands and gravelly sands, little or no fines	Not meeting both criteria for SW	
		SANDS WITH FINES	SM	Silty sands, sand-silt mixtures	Atterberg limits plot below "A" line or plasticity index less than 4	Atterberg limits plotting in hatched area are borderline classifications requiring use of dual symbols
			SC	Clayey sands, sand-clay mixtures	Atterberg limits plot above "A" line or plasticity index greater than 7	
FINE-GRAINED SOILS (by behavior) 50% or more passes 75 µm sieve*	SILTS Liquid limit <50		ML	Inorganic silts, very fine sands, rock flour, silty or clayey fine sands of slight plasticity		
	SILTS Liquid limit >50		MH	Inorganic silts, micaceous or diatomaceous fine sands or silts, elastic silts		
	CLAYS Above "A" line on plasticity chart negligible organic content Liquid limit <30		CL	Inorganic clays of low plasticity, gravelly clays, sandy clays, silty clays, lean clays		
	CLAYS Above "A" line on plasticity chart negligible organic content Liquid limit 30-50		CI	Inorganic clays of medium plasticity, silty clays		
	CLAYS Above "A" line on plasticity chart negligible organic content Liquid limit >50		CH	Inorganic clays of high plasticity, fat clays		
	ORGANIC SILTS AND CLAYS Liquid limit <50		OL	Organic silts and organic silty clays of low plasticity		
	ORGANIC SILTS AND CLAYS Liquid limit >50		OH	Organic clays of medium to high plasticity		
HIGHLY ORGANIC SOILS			PT	Peat and other highly organic soils		



* Based on the material passing the 75 mm sieve

† ASTM Designation D 2487, for identification procedure see D 2488 USC as modified by PFRA

SOIL COMPONENTS

FRACTION	SIEVE SIZE		DEFINING RANGES OF PERCENTAGE BY MASS OF MINOR COMPONENTS	
	PASSING	RETAINED	PERCENTAGE	DESCRIPTOR
GRAVEL coarse fine	75 mm 19 mm	19 mm 4.75 mm	>35 % 21 to 35 % 11 to 20 % >0 to 10 %	"and" "y-adjective" "some" "trace"
SAND coarse medium fine	4.75 mm 2.00 mm 425 µm	2.00 mm 425 µm 75 µm		
SILT (non plastic) or CLAY (plastic)	75 µm		as above but by behavior	

OVERSIZE MATERIAL

Rounded or subrounded

COBBLES	75 mm to 300 mm
BOULDERS	> 300 mm

Not rounded

ROCK FRAGMENTS	>75 mm
ROCKS	> 0.76 cubic metre in volume

TETRA TECH

GROUND ICE DESCRIPTION

VISIBLE ICE LESS THAN 50% BY VOLUME

GROUP SYMBOL	SYMBOL	SUBGROUP DESCRIPTION	SKETCH	PHOTOGRAPH
V	Vx	Individual ice crystals or inclusions		
	Vc	Ice coatings on particles		
	Vr	Random or irregularly oriented ice formations		
	Vs	Stratified or distinctly oriented ice formations		
	Vu	Ice formations uniformly distributed throughout frozen soil		

ICE NOT VISIBLE

GROUP SYMBOL	SYMBOL	SUBGROUP DESCRIPTION	SKETCH	PHOTOGRAPH
N	Nf	Poorly-bonded or friable		
	Nbn	No excess ice, well-bonded		
	Nbe	Excess ice, well-bonded		

LEGEND: Soil ☐ Ice ■

NOTES:

1. Dual symbols are used to indicate borderline or mixed ice classifications.
2. Visual estimates of ice contents indicated on borehole logs ± 5%
3. This system of ground ice description has been modified from NRC Technical Memo 79, Guide to the Field Description of Permafrost for Engineering Purposes.

VISIBLE ICE GREATER THAN 50% BY VOLUME

GROUP SYMBOL	SYMBOL	SUBGROUP DESCRIPTION	SKETCH	PHOTOGRAPH
ICE	ICE + Soil Type	Ice with soil inclusions (greater than 25 mm thick)		
	ICE	Ice without soil inclusions (greater than 25 mm thick)

GEOTECHNICAL LABORATORY SOIL TEST RESULTS

CALIFORNIA BEARING RATIO (CBR) TEST REPORT

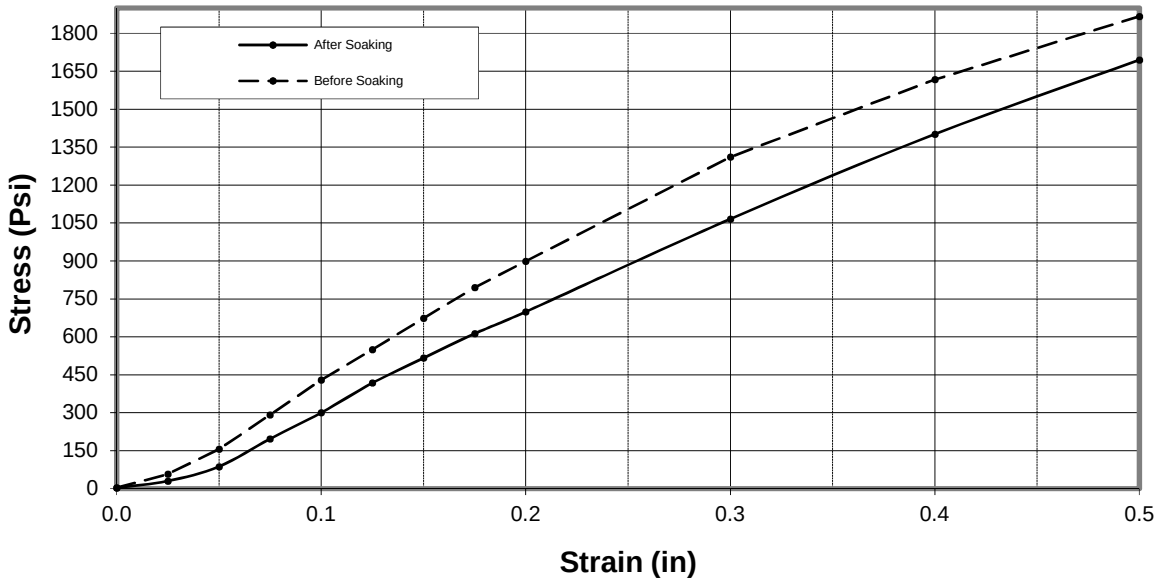
ASTM D1883

Project:	Fall 2018 Testpitting Program	Sample No.:	TP01-01 to TP-04A-01 Combined
Client:	JDS Energy & Mining	CBR Specimen Density:	2003 kg/m³
Project No.:	ENG.EARC03094-06.003	CBR Specimen Compaction	98.2 %
Test Date:	October 12, 2018	Total Swell:	0.30 %
Soaking:	96.0 Hours	Surcharge Mass:	4.54 kg
Description:	GRAVEL, silty, sandy, brown.	Optimum Moisture Content:	10.9 %
Material Retained 19-mm:	16.0%	Max. Dry Density:	2040 kg/m³
		by (ASTM D698) Standard Proctor	

	Before Soaking	After Soaking	Corrected for Zero *
Bearing Ratio (0.1") =	**43.0 %**	**30.0 %**	Yes
Bearing Ratio (0.2") =	**59.9 %**	**46.6 %**	
Moisture Content =	**11.0 %**	**11.2 %**	
Moisture Content @ top 1" =	**-**	**12.4 %**	

* CBR corrected for zero point adjustment as per ASTM D1883, Fig. 2

Load-Penetration



Remarks: 25 Blows

Laboratory: Edmonton **Reviewed By:** _____ P.Eng.

APPENDIX 2-J

Initial Ecohydrological Modelling in support of Coffee Gold Reclamation

IEG
Integral Ecology Group
iegconsulting.com

MEMORANDUM

January 16, 2019

TO:	Jennie Gjertsen, Goldcorp Inc.
FROM:	Justin Straker
RE:	Initial ecohydrological modelling in support of Coffee Gold reclamation, 2019
COPY:	Ryan Herbert, Goldcorp; Pamela O'Hara, EcoWest

Per our approved scope of work of November-December 2018, please find below results of our initial ecohydrological modelling for the Coffee Gold project. These results address:

- target ecosystems;
- expected outcomes and potential revisions to the current reclamation-cover plan; and
- ecohydrological implications.

We also discuss potential next steps in this work and data gaps.

Target ecosystems

We analyzed ecosystem mapping provided by EDI Environmental Dynamics Inc. (2017) to understand pre-development conditions and potential post-closure reclamation targets. To do so, we focussed on mapping that includes the current planned project footprint and what is described by EDI as a minimum 1000-m buffer around this footprint. Mapping around access and infrastructure features was not included in our analysis. This approach yielded a study area of approximately 8100 ha, which is divided roughly 60% in the Boreal High bioclimate zone and 40% into the Subalpine bioclimate zone (Environment Yukon, 2016).

Ecosystems in the Boreal High bioclimate zone can be depicted on a two-dimensional edatopic grid, where the vertical axis represents soil moisture regime (SMR) and the horizontal axis represents soil nutrient regime (SNR) – a simplified version of the edatopic grid used by EDI in their mapping is shown in Figure 1. Our analysis of EDI's data indicates that over 90% of the assessed study area is composed of ecosystems with mesic or wetter SMRs[1], with only about 7% of the assessed area occupied by ecosystems with SMRs of submesic or drier. This analysis should be refined in future based on actual boundaries of currently planned mine facilities, rather than on this analysis of a

[1] The 01 and 30 ecosites occur in a range of submesic-mesic, but have a mean SMR in the mesic class, and are counted here as mesic ecosystems.

1% FOR THE PLANET

buffered local study area, but suggests that the initial targets for reclamation are predominantly mesic or wetter. This information is summarized in Table 1, below.

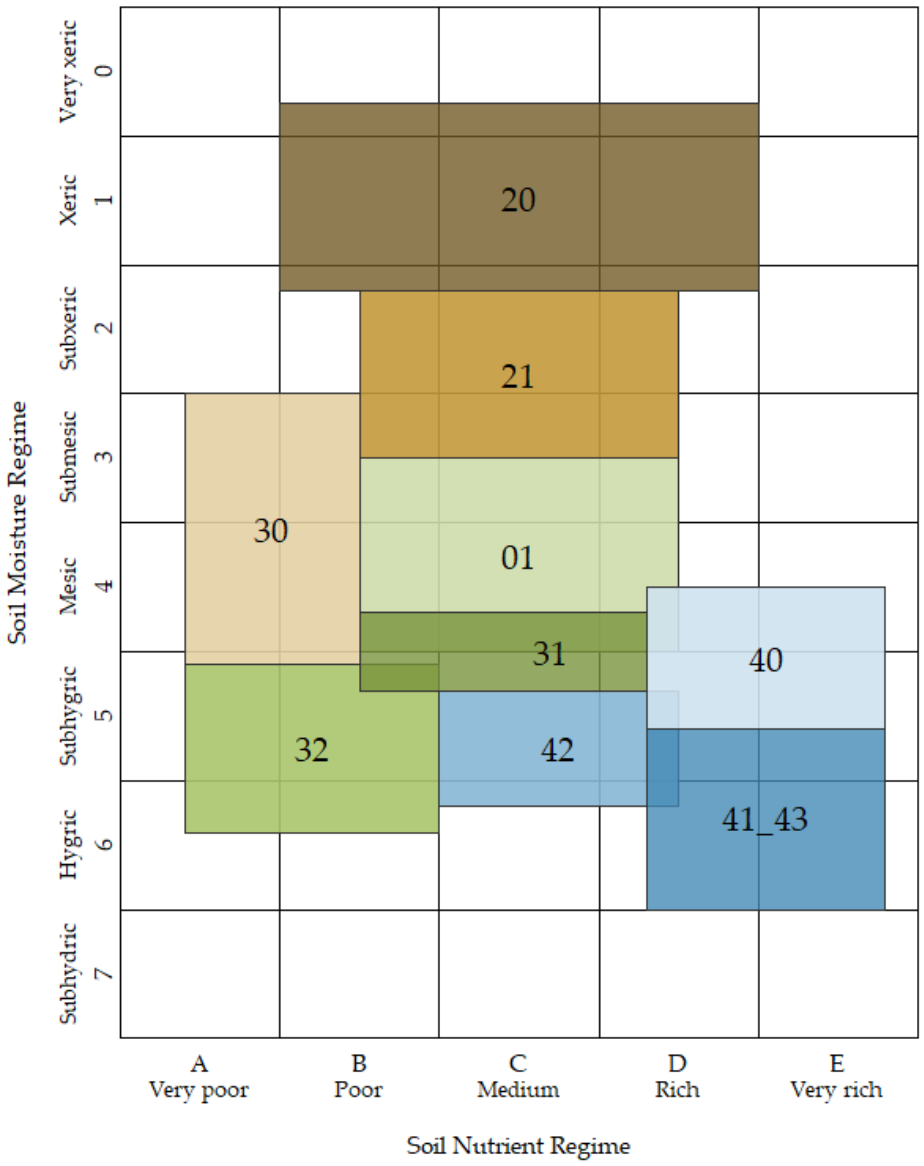

Figure 1. Edatopic grid for the Yukon Boreal High bioclimate zone. Different ecosystems, called ecosites, are labelled with two-digit numbers, and occupy the conditions delineated by coloured boxes associated with the labels.

Table 1. Proportions of ecosystems by soil moisture class in the mine local study area. Associated ecosites for the Boreal High bioclimate zone, corresponding to Figures 1-4, are shown in parentheses. Values in the table are derived from data for both the Boreal High and Subalpine bioclimate zones.

SMR	%
Xeric (20)	1
Subxeric (21)	3
Submesic (Subalpine only)	3
Mesic (01, 30)	55
Subhygric and wetter (31, 40, etc.)	39

Current reclamation-cover plan

Our understanding of the current reclamation-cover plan and its core assumptions is based largely on the Oct. 25, 2018 JDS memo on surface material for reclamation. Key assumptions from this work include the following:

- the reclamation salvage program will involve recovery within footprints of selected facilities such that organics and upper silt layers are overstripped 20 cm into lower gravels – this material is defined as "topsoil";
- the area-weighted average depth of topsoil salvage is ~100 cm, resulting in an assumed over-stripped mix that is approximately 80% organics + upper silt and 20% lower gravels;
- JDS assumes a potential recovery of 3.35M m^3 of topsoil;
- the topsoil mix will be replaced at a depth of 30 cm on the following features:
    - Haul Roads
    - Mine Service Roads
    - Java Airstrip
    - Coffee Airstrip
    - ROM Stockpile Pad
    - Crusher Pad
    - Bulk Explosive Storage Area
    - Laydowns and Storage Areas
    - Heap Leach Facility
    - Alpha Waste Rock Storage Facility
    - Plant Site, Truck Shop, Fuel Storage Pads

resulting in a demand-side balance of 2.09M m^3, and thus a projected surplus in the reclamation materials balance.

In addition, we derived information on particle-size distributions (PSDs) for upper silts and lower gravels from Tetra Tech's 2017 test-pitting report; information on waste-rock PSDs and "topsoil" organic-matter contents were provided by David Flather and John Dockrey of Lorax Environmental Services Ltd.

We modelled these assumptions. Based on our work, we make the following observations:

1. Given current PSD data, all waste-rock types (gneiss, schist, and granite) hold negligible water over a range of plant-available tensions, due to the lack of particles less than 1 mm in diameter – this information represents a critical data gap in our work, and we need better information on the anticipated full particle-size distributions of waste-rock types at Coffee. At this time, perhaps in part due to a lack of information, our work is not sensitive to assumptions on waste-rock types.
2. Our current analysis suggests that replacement of the dominant target ecosystems (e.g., those with SMRs of mesic or wetter) will require more than the currently planned 30 cm of cover.[2] Projected ecosystem outcomes for 30 cm of cover (with mean PSDs) overlying waste rock are shown for flat, north-facing, and south-facing slopes in Figure 2. For the bulk of the ecosystems that we need to try to replace through reclamation at Coffee (i.e., 01, 30[3]), 30 cm of cover is insufficient to provide the required soil-water conditions. Even on a north slope, where the projected SMR edges into edaphic conditions associated with the 01 ecosite, the projection is right on the boundary of the ecosite delineation, and we would generally use more cover to try to reconstruct this ecosite. Thirty-centimetre covers will support re-establishment of subxeric ecosystems, but our current analysis indicates that these ecosystems form a very small proportion of the pre-development landscape.
3. Based on our current understanding of likely waste-rock characteristics, direct revegetation of these materials – i.e., without a reclamation cover – is very likely to be highly ineffective.

[2] Our modelling includes effects of textural discontinuities that retard water drainage through the reclamation-cover system.

[3] Most of the submesic-mesic ecosystems are 01s, with 30s a much smaller component.

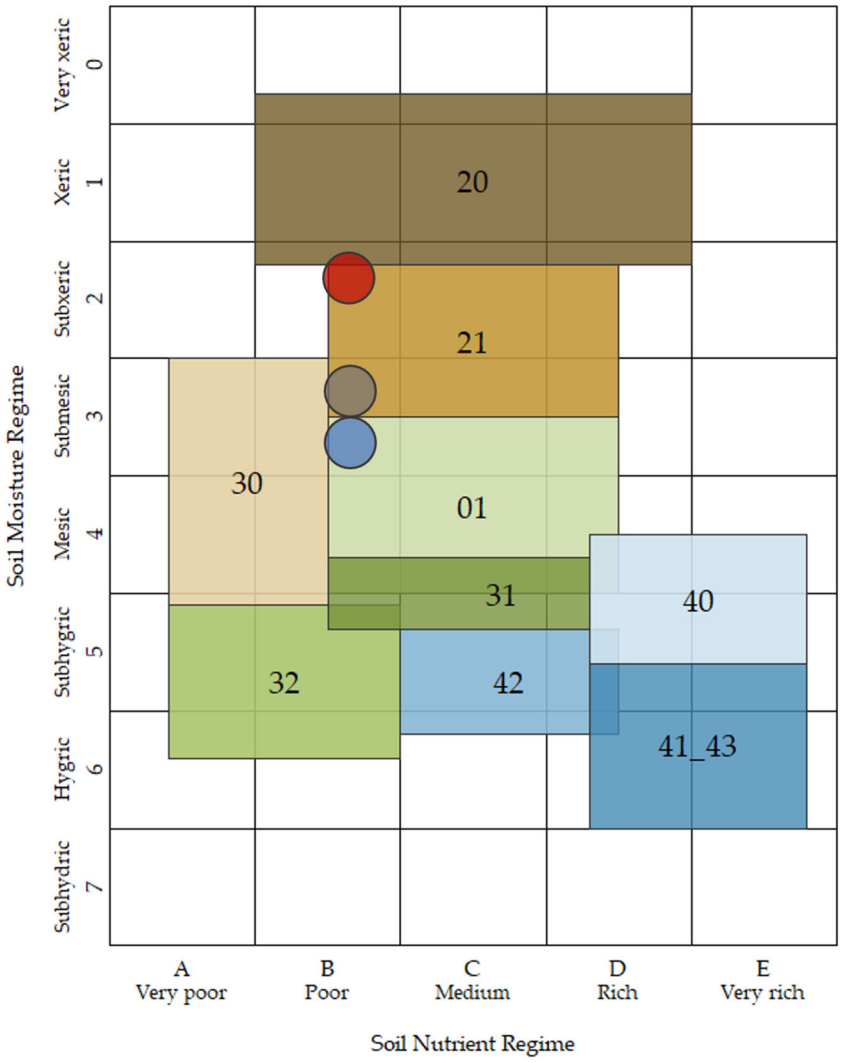

Figure 2. Projections for reclamation outcomes modelled with 30 cm of topsoil cover over waste rock. The grey dot represents the projected outcome for mean PSDs for cover and waste-rock materials, while the blue dot represents the projected outcome for a 27-degree north-facing slope, and the red dot represents the projected outcome for a 27-degree south-facing slope.

In order to meet soil-water requirements for replacement of mesic ecosystems, we estimate that a cover depth of 50 cm will be required, on all slopes (possibly more on south-facing slopes), which is shown in Figure 3. These are the dominant ecosystems in the pre-development landscape. Even this relatively small increase of cover depth

from 30 to 50 cm has substantial implications for the demand side of the reclamation balance – if this increased cover depth were applied ubiquitously across the reclaimed landscape, cover demand (~3.48M m^3) would exceed currently projected supply (3.35M m^3).

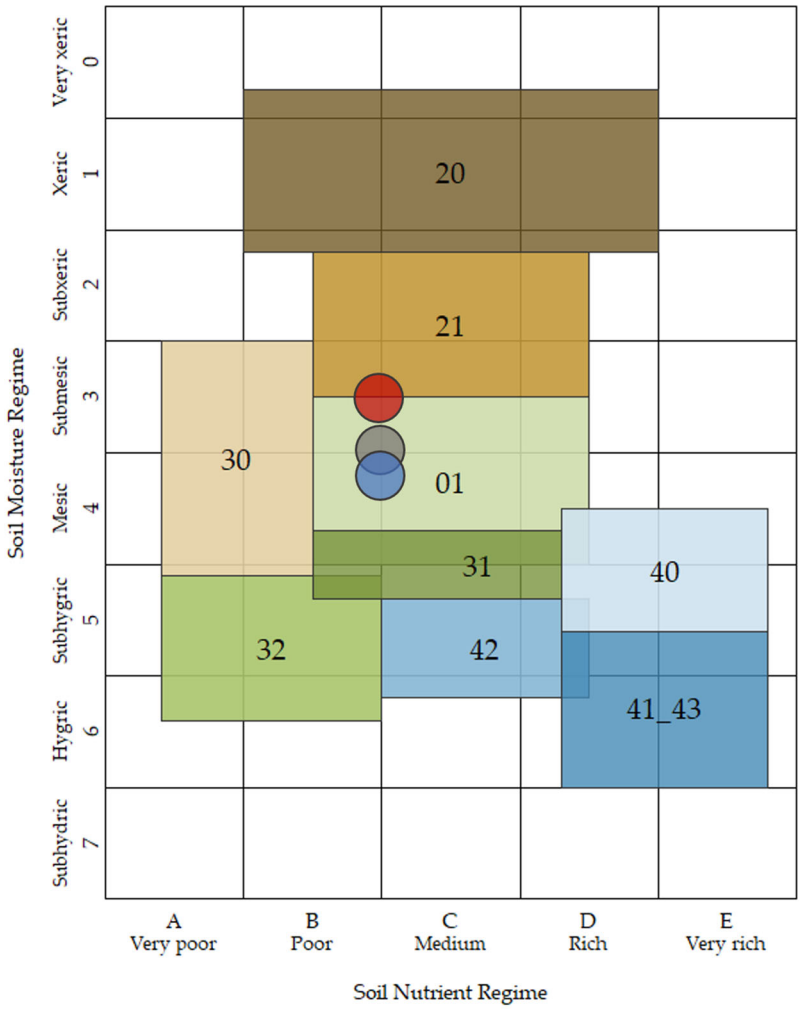

Figure 3. Projections for reclamation outcomes modelled with 50 cm of topsoil cover over waste rock. The grey dot represents the projected outcome for mean PSDs for cover and waste-rock materials, while the blue dot represents the projected outcome for a 27-degree north-facing slope, and the red dot represents the projected outcome for a 27-degree south-facing slope.

Subhygric and wetter ecosystems require inputs of groundwater, which are uncommon on waste-rock landforms, and/or very high soil-water storage capacity.

Relying solely on soil-water storage as the mechanism for supporting these ecosystems, assuming a lack of input groundwater, replacement of these ecosystems would require a cover depth in excess of 80 cm (Figure 4).

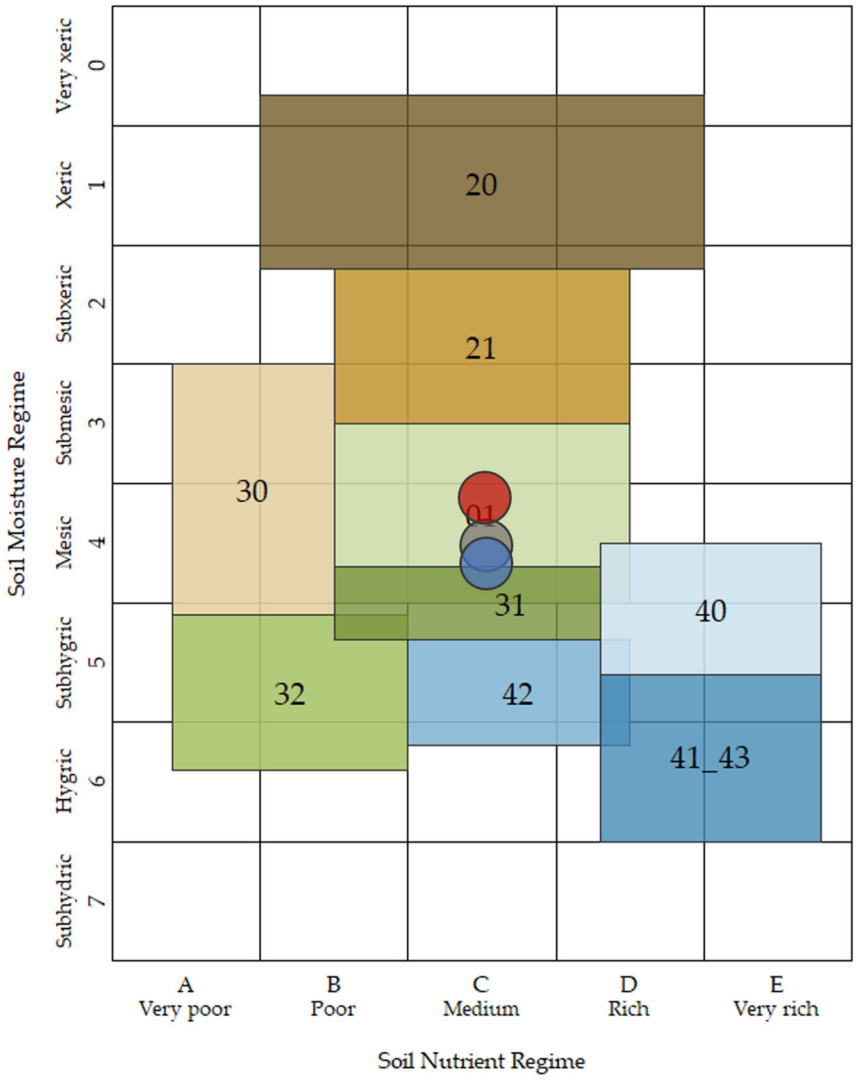

Figure 4. Projections for reclamation outcomes modelled with 50 cm of topsoil cover over waste rock. The grey dot represents the projected outcome for mean PSDs for cover and waste-rock materials, while the blue dot represents the projected outcome for a 27-degree north-facing slope, and the red dot represents the projected outcome for a 27-degree south-facing slope.

Ecohydrological implications of reclamation

Lorax states in their water-balance report (2017) that they assume, for the purpose of their work, that evapotranspiration on site is 182 mm/yr. Our work[4] suggests that this value can be raised on fully revegetated reclamation sites, perhaps as high as 260-290 mm/yr (Figure 5 and Figure 6 show modelled surface-water-balance terms, including evapotranspiration, for a 30-cm and 50-cm cover, respectively). Our estimates are likely to overestimate evapotranspiration, as our simple model assumes capture and use of all growing-season precipitation, but they still suggest that generation of "excess water" – i.e., the difference of $P - E$ (where P is precipitation and E is evaporation, including evapotranspiration) – will be lower on fully vegetated reclamation sites than the value used in the Lorax water-balance model. This suggestion is supported by data from direct measurement of evapotranspiration by eddy-covariance techniques at a research site near Whitehorse. This subalpine site shows annual evapotranspiration values of approximately 250 mm[5], and while it is located at lower latitude, it is also located at higher altitude than the Coffee site, and is thus likely to be substantially comparable. A comparison of projected results for the 30-cm and 50-cm cover suggests that evapotranspiration can be increased by approximately 10% through addition of 20 cm of cover to the 30-cm base case.

[4] For this work we used climate information from ClimateWNA (http://www.climatewna.com/). This dataset is similar to both Lorax's measured and reconstructed data, but generally shows lower temperature, precipitation, and potential evapotranspiration than the Lorax datasets. Use of the Lorax datasets in our model results in higher evapotranspiration numbers, so for now we have retained the ClimateWNA data in order to be more conservative in our evapotranspiration estimates.

[5] Sean Carey, McMaster University, personal communication.

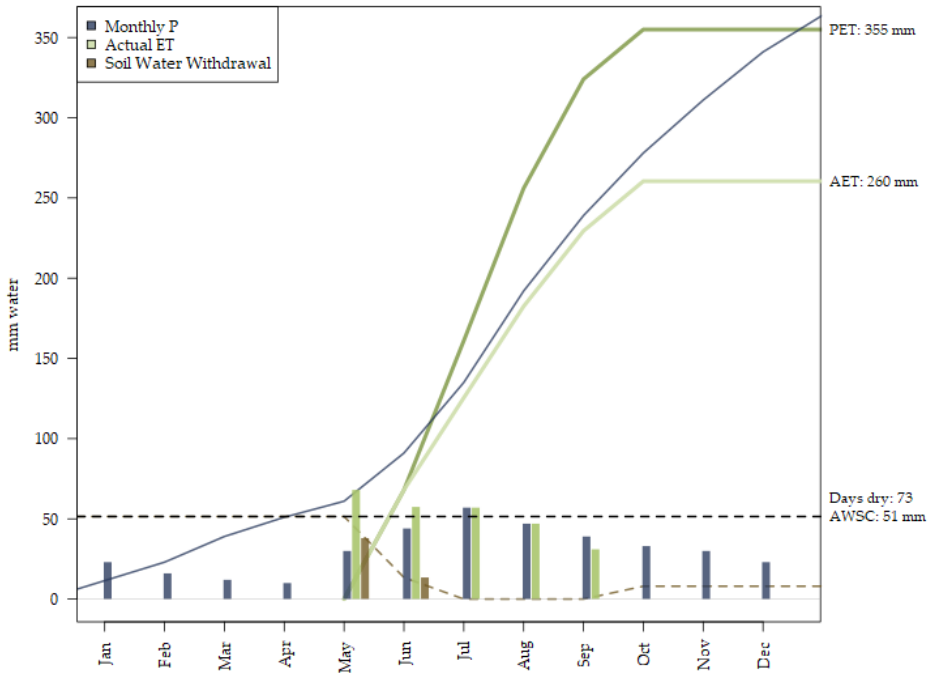

Figure 5. Modelled surface-water-balance terms over a mean climate year for a flat reclamation site with 30 cm of topsoil cover at 1100 m elevation. Modelled evapotranspiration is shown as a light green line with an annual value of 260 mm. Stored soil water is shown as a dashed brown line, and shows that stored soil water is substantially depleted by the end of June, limiting evapotranspiration for the remainder of the growing season. These projections assume full vegetation coverage.

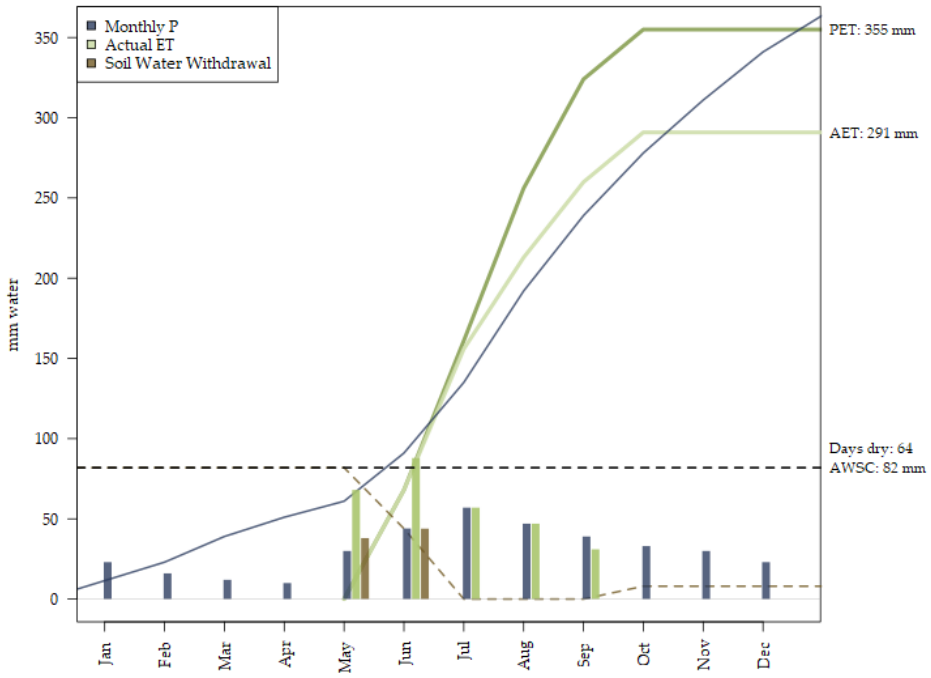

Figure 6. Modelled surface-water-balance terms over a mean climate year for a flat reclamation site with 50 cm of topsoil cover at 1100 m elevation. Modelled evapotranspiration is shown as a light green line with an annual value of ~290 mm. Stored soil water is shown as a dashed brown line, and shows that stored soil water is depleted in July, limiting evapotranspiration for the remainder of the growing season. These projections assume full vegetation coverage.

We are not claiming that our evapotranspiration numbers are correct and that Lorax's are not, but simply highlighting that a very different way of examining this issue yields a different estimate, and that is in our opinion worth some discussion between the technical teams working on this project. We should also emphasize that our evapotranspiration projections assume full vegetation coverage, which may take many years to achieve on reclamation sites at the Coffee project, given the site's high latitude and altitude.

Discussion

Our analysis indicates that the majority of the pre-development landscape, and thus the initial targets for reclamation, is composed of ecosystems with mesic and wetter soil moisture regimes, and that conditions supportive of these ecosystems cannot be replaced using the currently assumed 30-cm cover depth, at least not directly over waste-rock substrates. Replacement of these ecosystems generally requires minimum

cover depths of 50 cm, and the current supply side of the reclamation materials balance would constrain the ubiquitous use of this cover depth. Cover depths of 30 cm can be used to support local ecosystems, but with a frequency distribution that does not approximate the pre-development landscape, as it skewed towards drier ecosystems than previously existed.

Although replacement through reclamation of similar proportions of ecosystems as those present prior to development is an initial target for closure planning, it is a target that is generally not possible to meet, for all projects, due to changes that mining imposes on local landforms. An approach to coming as close as possible to meeting this target for the Coffee project would involve increasing cover use and depths across the project, which would involve use of all the currently identified reclamation material, and even exploration of sourcing additional reclamation materials. It is possible that the materials balances could be adjusted to supply greater cover quantities by stripping deeper into the lower gravel layers, but this would need to be confirmed through additional evaluation of information on local surficial materials. However, even this approach "maximum-cover" approach would result in disparity between pre-development and post-closure ecosystems, and Goldcorp is not obliged to take this approach. Goldcorp could maintain the current cover plan, or some modification of it, and show greater disparity between pre-development and post-closure conditions. Some discussion of this topic is likely required at Goldcorp, and perhaps between Goldcorp and its external stakeholders, to examine the costs and benefits of uses of thicker covers to maximize replacement of pre-development ecosystems.

Our work also suggests that evapotranspiration may be higher on fully vegetated covers than the value of 182 mm/yr used in the Lorax report. We believe that this suggestion warrants further discussion between disciplines working on the closure plan, and may have implications for cover design and performance. In general, increasing cover depths over the range of depths discussed in this report will increase evapotranspiration and decrease generation of excess water that would be expressed as runoff, interflow (over a heap-leach liner), and/or infiltration into mine waste materials underlying cover layers.

Suggested next steps

Our current work is meant as an initial exploration of conditions on the Coffee Gold project area, and has associated limitations. In order to address these limitations and make this work stronger, we suggest the following:

1. The analysis of pre-development ecosystem occurrence should be based on ecological mapping clipped to the current projected mine footprint, rather than on a buffered local study area. This analysis is straightforward and not time consuming, but would require provision of shapefiles for the current mine plan.

2. In this work we applied an aspatial analysis of cover-system requirements for ecosystem replacement. The next iteration should employ a spatial analysis complete with delineation of reclamation polygons based on a full-build-out mine footprint and associated digital elevation model for mine facilities.
3. Our work is based on limited information on cover-material characteristics and very little information on waste-material characteristics. More in-depth work should be supported with increased information for these materials. Data gaps are discussed further below.
4. Our ecohydrological work on surface water balances could be augmented to include analysis of climate-change projections.

Data gaps

Key data gaps that affect our initial work include the following:

1. We require additional information on cover-material properties and volumes – ideally we would have information from more samples across areas that will potentially be stripped for mine development. As part of this, we need better information on the ratio of organics to silt in the upper layers of potentially salvaged material, and on the characteristics of those organic materials.
2. We need to try to generate additional information on the probable post-placement characteristics of waste rock generated by the Coffee project. Current information indicates a material with very low ability to store water over a range of plant-available tensions, and we are likely currently underestimating waste-rock contributions to soil moisture regime. It is possible that this underestimation is not substantial, but it would be good to confirm or reject this possibility.
3. Current ecological classification for the Coffee project is not consistent with more recent development of the Yukon Ecological Landscape Classification system – ideally we would have an analysis of plot data conducted to update the classification scheme.

Closure

We thank Goldcorp for the opportunity to be involved in reclamation and closure planning for the Coffee Gold project. Please feel free to be in touch any time via jstraker@iegconsulting.com, or at 250 701 0600, to discuss any aspect of this work.

1.0 ALTERNATIVES ASSESSMENT OVERVIEW

The proposed Coffee Gold Mine (the Project) is an open-pit gold mine owned by Goldcorp Kaminak Ltd, a subsidiary of Newmont, located in the White Gold District of west-central Yukon, approximately 130 km south of the City of Dawson, 140 km west of Pelly Crossing, 95 km south-west of Beaver Creek, and 330 km northwest of Whitehorse. Throughout the closure planning process, Newmont has identified alternative options for closing and reclaiming the major mine components to achieve the Project-specific closure objectives as well as the closure vision for the site. As the End Land Use Plan for the Project is advanced, the final closure measures may be re-evaluated to ultimately result in a final landform that reflects the interests of all stakeholders, First Nations, and the local community. As such, this alternatives assessment process may be advanced based on the End Land Use Plan that is developed for the site.

Alternative means are the various technically and economically feasible ways under consideration by Newmont that would allow the Project to be reclaimed and closed. This report presents the assessment process that was carried out to evaluate the alternative means for closing the major mine components, and to identify the options that meet expectations for consideration as the 'base case' for the Project. The Project mine plan is designed to integrate closure considerations into the planning and operational processes; therefore, this assessment includes both the location of facilities and infrastructure as well as the measures to close them. Specifically, the following aspects have been assessed, as relevant to the major mine components:

- Component location for supporting mine development and Coffee Gold Mine closure objectives.
- Means of reclaiming and closing or decommissioning components to meet Coffee Gold Mine closure objectives.
- Timing of closure, involving the reclaiming and closing components either progressively or post-mining.

In the absence of specific Yukon guidance on the assessment of alternatives, this alternatives assessment has been conducted based on the guidance provided in the *Canadian Environmental Assessment Act, 2012* (*CEAA;* Government of Canada 2012) and the Operational Policy Statement: Addressing "Purpose of" and "Alternative Means" under CEAA 2012 (OPS; Government of Canada 2015). The four steps outlined in OPS to determine the preferred means are as follows:

- Step 1: Identify technically and economically feasible alternative means
- Step 2: List their potential effects on valued component
- Step 3: Select the approach for the analysis of alternative means
- Step 4: Assess the environmental effects of alternative means.

These steps were modified in this assessment to evaluate relevant aspects of each component (i.e., both component location and closure measures), optimize and integrate workshop discussions, and to identify base case closure options. Step 2 of this assessment was carried out through a collaborative discussion to identify the potential effects of the alterative means on the Project-specific closure values. Step 3 of the assessment advanced various evaluations to identify the preferred alternative means. The options were then advanced for further evaluation in a workshop through the failure modes and effects analysis (FMEA) process under Step 4 of the assessment.

The following alternatives were considered in this assessment:

- Backfilling of open pits
- Location of waste rock storage facilities
- Cover for water rock storage facilities
- Location of heap leach facility
- Cover for heap leach facility
- Decommissioning of water management infrastructure including the Alpha dam/pond and west diversion
- Decommissioning of the Northern Access Route (NAR).

Alternatives to the location and/or closure of other Project components such as mine site roads, haul roads, and buildings have not been evaluated further than what was described in the Yukon Environmental and Socioeconomic Act (YESAA) Project Proposal, as this type of infrastructure is currently planned to be decommissioned and reclaimed as per Yukon Government requirements or guidelines (YG 2006, EMR and YWB 2013).

2.0 STEP 1: IDENTIFY FEASIBLE ALTERNATIVE MEANS

Technical feasibility relates to the appropriateness of an alternative from an engineering or operational perspective and incorporates aspects of known performance, reliability, and implementation for the Project. Economic feasibility of an alternative relates to the overall costs including capital, operating, and maintenance, as relevant to the closure aspect. The following steps were taken to identify and describe technically and economically feasible alternative means of closing the Project:

- Select potential alternative means
- Develop criteria to measure the technical and economic feasibility of the alternative mean
- Identify the alternative means that are technically and economically feasible based on qualitative evidence and professional judgment
- Document the rationale for the alternative means retained for further consideration in the assessment.

In general, alternatives were selected and assessed based on a review of available reports, consultation with qualified professionals, as well as input from various levels of government and First Nations in support of the Yukon Environmental and Socioeconomic Board (YESAB) Executive Committee Project Proposal. Through this process, Newmont has received comments and recommendations that relate to reclamation and closure alternatives. For example, First Nations have requested that Newmont develop a closure scenario that does not include long-term pit lakes. These comments and recommendations have been integrated into this assessment process, as well as feedback received from Newmont consultants and regulatory agencies during various assessments conducted for and during Project review under *YESAA*, including:

- The YESAB Project Proposal which included the alternative means of developing the Project.
- The Preliminary Project FMEA completed in March 2018 on a conceptual level of design for the Project for key site facilities (Appendix 2-K of the RCP). The objective of this analysis was to identify and prioritize key Project risks in order to incorporate risks and failure modes into detailed design and maximize risk control resources. The analysis focused on key site facilities and infrastructure, including open pits, waste storage facilities and material stockpiles, heap leach facility components, and water management facilities. All Project components were assessed as being low or moderate risk, except for a potential slope failure around the Alpha Pond, which was identified as a moderately high risk based on an almost certain likelihood of occurrence and a minor consequence.
- A heap leach facility (HLF) Alternatives Assessments was completed in August 2018, based on recommendations documented in the Preliminary Project FMEA and feedback during Project consultation, to refine and optimize the closure configuration with respect to maintaining long-term stability of the heap slopes and function of diversion ditches. The assessment included a Multiple Accounts Analysis (MAA) in accordance with Environment and Climate Change Canada guidance to determine the preferred closure alternative for the HLF; the report is provided in the RCP (Appendix 2-L).

2.1 Technical Feasibility Criteria

The evaluation that was carried out to determine the technical feasibility of the closure alternatives included comparison of the alternatives against a series of general technical criteria that are defined below. The evaluation also considered whether the potential alternatives (either individually or collectively) would be

able to meet the Coffee Gold Mine closure objectives outlined in Section 4.1.2 of the RCP. The following criteria were used where relevant to evaluate the technical feasibility of each alternative:

- Long-term chemical and/or geochemical stability
- Long-term physical stability of infrastructure or facilities
- Physical stability of cover material
- Quantity of natural cover material available
- Ability to meet technical design criteria
- Ability to be progressively reclaimed
- Supports the mine development plan with respect to mining stages
- Location or design provides required capacity/storage
- Does not impound water.

The technical feasibility assessment identified the relevant technical criteria for each evaluated component and determined the ability of each alternative to meet the criteria. If an alternative was considered to not meet one or more technical criteria, it was considered not technically feasible, did not proceed to the economic feasibility screening, and was eliminated from further consideration.

2.2 Economic Feasibility Criteria

The economic feasibility assessment for closure alternatives qualitatively considered the acceptability of conceptual-level costs. Alternatives were considered unfeasible if the cost was unreasonably excessive when evaluated within the context of the following economic criteria:

- Cost to implement is acceptable
- Will not result in resource sterilization
- Maintenance liability is finite.

Where technical and economic feasibility screening identified only one feasible closure option, this option was advanced as the base case, and no further evaluation was conducted. Where more than one feasible closure option was identified, the options were advanced to Step 2 for further evaluation. If an alternative did not meet the economic criteria listed above, it was no longer considered a viable option and was not advanced to Step 2.

2.3 Feasibility Screening

A summary of the feasibility screening results is provided in

Table 2-1, and the rationale for the feasibility determinations is described in detail in the following sections.

Table 2-1 Feasibility Screening of Alternative Means Relevant to Project Closure

Alternative Means Considered			Feasibility Screening
Open Pit Backfilling	Latte Pit	No backfill	Not technically feasible
		Partial backfill- backfill used as haul roads	Feasible
		Partial backfill- backfill for other purpose	Feasible
		Complete backfill – progressively	Feasible
		Complete backfill – end of mine life	Feasible
	Double Double	No backfill	Feasible
		Partial backfill	Feasible
		Complete backfill	Feasible
	Kona	No backfill	Feasible
		Partial backfill	Feasible
		Complete backfill	Feasible
	Supremo	No backfill	Not technically feasible
		Partial backfill- backfill used to optimize mine development	Feasible
		Partial backfill- backfill for other purpose	Not economically feasible
		Complete backfill	Not economically feasible
Waste Rock Storage Location(s)	Location(s) for non-Kona waste	3 WRSFs – West, South & North (as per FS)	Not technically feasible
		2 WRSFs - West & South	Feasible
		2 WRSFs – North & South	Not technically feasible
		2 WRSFs - West & North	Not technically feasible
		1 WRSF - Alpha	Feasible
		1 WRSF - North	Not technically feasible
		1 WRSF - South	Not technically feasible
		1 WRSF – West & maximized in-pit backfill	Not economically feasible
		1 WRSF – North & maximized in-pit backfill	Not technically feasible
		1 WRSF – South & maximized in-pit backfill	Not economically feasible
		No WRSF (no permanent ex-pit storage)	Not economically feasible
	Waste storage duration for Kona waste	Temporary Beta WRSF Location	Feasible – linked to Kona pit backfilling alternatives assessment
		Permanent Beta WRSF Location	Feasible – linked to Kona pit backfilling alternatives assessment
		All Kona waste rock to primary WRSF	Feasible

Alternative Means Considered			Feasibility Screening
Waste Rock Cover	Overall slope steeper than 3:1 but flatter than angle of repose	No cover	Feasible
		Partial cover on flats	Feasible
		Complete cover	Not technically feasible
	Overall slope 3:1*	No cover	Feasible
		Partial cover on flats	Feasible
		Complete cover	Feasible
	Overall slope flatter than 3:1**	No cover	Feasible
		Complete cover	Feasible
HLF Location	Ridgetop A & B leach pads		Not technically feasible
	2016 Feasibility Study leach pad		Feasible, linked to HLF cover alternatives assessment
	Valley C leach pad		Feasible, linked to HLF cover alternatives assessment
	KP Valley leach pad		Not technically feasible
HLF Cover	No cover required as heap used to backfill open pits (temporary facility)		Not economically feasible
	2016 Feasibility Study leach pad	No cover	Not technically feasible
		Partial cover:	Feasible
		• (1) 2.5:1 construction and closure slopes; GCL installed on flat surfaces progressively	
		• (5b) 2.5:1 construction and 3:1 closure slopes by regrading during closure (wings); GCL installed on flat surfaces progressively and on wings at closure	
		• (8, 8a) 2.5:1 construction and 3:1 closure slopes by buttressing slopes with waste rock progressively; GCL installed on flat surfaces progressively	
		Complete cover:	Feasible
		• (5a) 2.5:1 construction and 3:1 closure slopes; all surfaces covered with GCL progressively	
		• (4) 3:1 construction and closure slopes; all surfaces covered with GCL progressively	
		• (7) 2.5:1 construction and closure slopes; all surfaces covered with GCL by keying into slopes	
		• (8b) 2.5:1 construction and 3:1 closure slopes by buttressing slopes with waste rock progressively; GCL installed on all surfaces	
	Valley C leach pad	No cover	Not technically feasible
		Partial cover	Feasible
		Complete cover	Feasible

Alternative Means Considered			Feasibility Screening
Decommissioning of Water Management Infrastructure	Alpha Dam/Pond	Remove dam completely	Feasible
		Create channel without completely removing dam materials	Feasible
		Do nothing, allow excess water to overflow via spillway designed and installed for closure	Not technically feasible
	West Diversion	Leave in place	Not technically feasible
		Partial decommissioning at natural depression drainages	Feasible
		Complete decommissioning (re-grade to slope)	Feasible
Decommissioning of NAR	Decommission Project-associated NAR sections (37 km)		Feasible
	Leave Project-associated NAR sections (37 km) in place		Feasible
	Close additional road sections beyond those that are Project-specific		Feasible

Notes: * Internal slopes are <3:1, but overall slope is 3:1; ** Assumes re-grading of slopes and no benches

2.3.1 Backfill Alternatives for Open Pits

The alternatives considered for backfilling of each pit were chosen to evaluate the potential to achieve the post-mine vision for the Project, including returning the site to conditions as close as possible to pre-mining (i.e., no pit lakes). The Project includes four open pits: Latte, Double Double, Supremo, and Kona (RCP; Figure 1-2). To maximize economic returns and achieve the target throughput of approximately 9.0 Mt per year during the 10-year Operation Phase, the open pit mining sequence is planned to begin with the Latte pit, Double Double pit, and Supremo pit. Smaller Supremo pit sections, Kona, and Latte Phase 2 and 3 will be mined toward the end of mine life. Although Latte and Supremo have multiple phases and pushbacks due to their size, Double Double and Kona are both planned to be mined in a single phase. Additional information on pit sizes and waste material volumes is provided in Section 5 of the RCP.

A portion of the waste rock is planned to be backfilled into mined out pits at Latte, Supremo and Double Double in order to create causeways and facilitate shorter ore haulage routes to the crusher. Table 2-2 summarizes the feasibility screening for backfilling options based on technical and economic criteria, which were selected to allow for a comparative analysis, as well as the rationale.

Table 2-2 Open Pit Backfilling Alternatives - Technical and Economic Feasibility Evaluation

Open Pit	Alternatives	Feasibility Evaluation						Alternative feasible?
		Technical Criteria				Economic Criteria		
		Long-term chemical stability	Long-term physical stability	Progressively reclaimed	Supports mine development plan	Implementation costs	Resource sterilization	
Latte	No Backfill	Yes	Yes	N/A	No - waste rock/ backfill required to build haul roads to connect Supremo to the plant site	N/A, not technically feasible		No, based on technical criteria
	Partial Backfill - backfill used as haul roads	Yes	Yes	Yes	Yes	Yes	Yes	Yes
	Partial backfill - backfill for haul roads and other purpose (based on closure objectives)	Yes	Yes	Yes	Yes	Yes	Yes	Yes
	Complete Backfill - progressive reclamation	Yes	Yes	Yes	Maybe - May need water storage in Latte for HLF rinse water	Yes	Maybe	Yes
	Complete Backfill - end of mine life	Yes	Yes	N/A	N/A	Yes	N/A - Mining complete	Yes
Double Double	No Backfill	Yes	Yes	Yes	Yes	Yes	Yes	Yes
	Partial Backfill	Yes	Yes	Yes	Yes	Yes	Yes	Yes
	Complete Backfill	Yes	Yes	Yes	Yes	Yes	Yes	Yes

Open Pit	Alternatives	Feasibility Evaluation						Alternative feasible?
		Technical Criteria				Economic Criteria		
		Long-term chemical stability	Long-term physical stability	Progressively reclaimed	Supports mine development plan	Implementation costs	Resource sterilization	
Kona	No Backfill	Maybe - 20% of pit wall is PAG.	Yes	Yes - would be flooded with water to prevent ARD.	Yes	Yes	Yes	Yes
	Partial Backfill	Maybe - 20% of pit wall is PAG. Partial backfill would cover the PAG portion. Backfill would be non-ML/ARD leaching in sub-aqueous conditions.	Yes	Yes	Maybe	Maybe - cost to transport gneiss waste rock may be cost prohibitive	Yes	Yes
	Complete Backfill	Maybe - Backfill cannot be granite waste rock	Yes	Yes	Yes	Maybe - cost to transport gneiss waste rock may be cost prohibitive	Yes	Yes
Supremo	No Backfill	Yes	Yes	N/A	No, need backfill for haul routes.	N/A, not technically feasible		No, based on technical criteria
	Partial Backfill - backfill used to optimize mine development	Yes	Yes	Yes	Yes	Yes	Maybe - but could be economically acceptable	Yes
	Partial backfill - backfill for other purpose (based on closure objectives)	Yes	Yes	Yes	Yes	Yes	No - resource is open at depth (not feasible based on current understanding of the resource).	No, based on economic criteria

Open Pit	Alternatives	Feasibility Evaluation						Alternative feasible?
		Technical Criteria				Economic Criteria		
		Long-term chemical stability	Long-term physical stability	Progressively reclaimed	Supports mine development plan	Implementation costs	Resource sterilization	
	Complete Backfill	Yes	Yes	Yes - partially, through to Stage 5. Filling of Stage 5 would require re-handling waste	Yes	No - Stage 5 filling re-handle would be cost prohibitive	No	No, based on economic criteria

2.3.2 Waste Rock Storage Facilities Location Alternatives

Over the life of mine, a total of approximately 300 – 330 Mt of waste rock will be excavated from the open pits. An evaluation of Waste Rock Storage Facility (WRSF) location alternatives for waste from Latte, Double Double, and Supremo was conducted as part of the YESAB Project Proposal and included three sites: Alpha (referred to as West), South, and North. One large and multiple smaller facilities were evaluated. Figure 2-1 illustrates the general location of the WRSF locations that were evaluated, noting that the size of the facilities would change depending on the number of storage sites ultimately used and the volume of rock backfilled into pits. Figure 2-1 displays the proposed mine layout at the time of the feasibility assessment; the layout has since been updated and is presented in Figure 1-2 of the RCP.

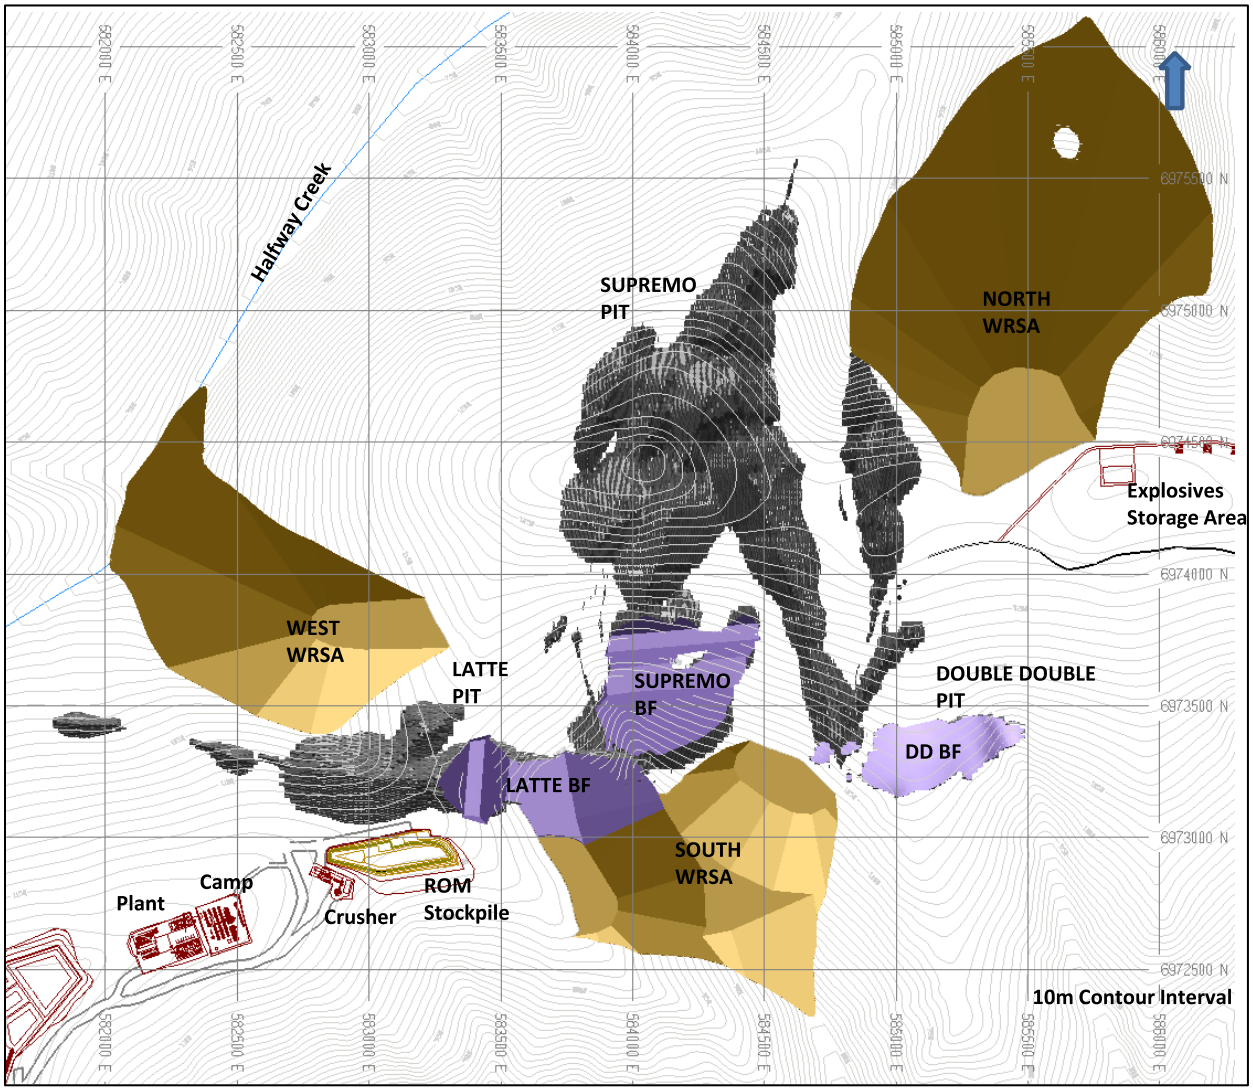

Figure 2-1 Evaluated WRSF General Locations - West (Alpha), South, and North

Geotechnical investigations and subsequent analyses indicate that the foundation conditions are considered conducive to construction of the Alpha (labeled as West in Figure 2-1), South, and North WRSFs. Permafrost is deep beneath the Alpha and North WRSFs and non-existent to shallow beneath the South WRSF. Depending on the configuration, the WRSFs may be constructed on permafrost soils, which are expected to provide suitable foundation conditions for WRSFs, provided the foundation soils remain frozen.

The Alpha WRSF would be built from the bottom up (i.e., hauling to the base of the dump and constructing the dump upwards in lifts) by placing material at its natural angle of repose in 40-m lifts. The toe of each subsequent lift would be set back 60 m from the crest of the previous lift, resulting in an overall angle of 3.0:1 (H:V). Flow-through rock drains would be required beneath the WRSF.

The South WRSF would be constructed from the top (ultimate crest) downward as bottom-up construction is not considered practical due to the large elevation difference and steep terrain between the pits and the ultimate toe of the WRSFs. Individual lifts of waste rock should not exceed 50 m in height except for the first lifts of the South WRSF where thicker bottom lifts will be required due to the steep terrain and valley inverts. Approximately 56-m-wide berms would be left between each lift resulting in an overall slope angle of 2.5:1 (H:V). Flow-through rock drains would be required beneath the WRSF.

The North WRSF would be constructed from the bottom up and may pose technically challenging conditions. It would be necessary to ensure the foundation remains frozen by placing the first lift (approximately 5 m) during the winter season. Access would be required to the toe of the facility and long-term facility stability may be difficult to achieve.

Table 2-3 summarizes the feasibility evaluation of WRSF location alternatives (both as individual sites and in combination to achieve the required storage volume) based on differentiating technical and economic criteria.

Table 2-3 Waste Rock Storage Facility Location Alternatives – Technical and Economic Feasibility Evaluation

Alternatives		Feasibility Evaluation				Alternative feasible?
		Technical Criteria		Economic Criteria		
		Long-term physical stability	Sufficient Storage	Implementation costs	Resource sterilization	
Location(s) for non-Kona Pit waste	3 WRSFs - West, South & North (as per FS)	No - North WRSF not physically stable	Yes	N/A, not technically feasible		No, based on technical criteria
	2 WRSFs - West & South	Yes	Yes	Yes	Yes	Yes
	2 WRSFs - North & South	No - North WRSF not physically stable	Maybe	N/A, not technically feasible		No, based on technical criteria
	2 WRSFs - West & North	No - North WRSF not physically stable	Yes	N/A, not technically feasible		No, based on technical criteria
	1 WRSF - Alpha	Yes	Yes	Maybe - highest cost configuration based on preliminary assessment	Yes	Yes
	1 WRSF - North	No - North WRSF not physically stable	No	N/A, not technically feasible		No, based on technical criteria
	1 WRSF - South	Yes	No - insufficient storage with a single facility	N/A, not technically feasible		No, based on technical criteria
	1 WRSF: West & maximized in-pit backfill	Yes	Yes	Maybe	No - because backfill will sterilize resources	No, based on economic criteria
	1 WRSF: North & maximized in-pit backfill	No - North WRSF not physically stable	Yes	N/A, not technically feasible		No, based on technical criteria
	1 WRSF: South & maximized in-pit backfill	Yes	Yes	Maybe	No - because backfill will sterilize resources	No, based on economic criteria

Alternatives		Feasibility Evaluation				Alternative feasible?
		Technical Criteria		Economic Criteria		
		Long-term physical stability	Sufficient Storage	Implementation costs	Resource sterilization	
	No WRSF - no permanent ex-pit storage	Yes	Yes - if stored above grade	Maybe - might have unacceptable re-handling costs	No	No, based on economic criteria
	Double Double Waste Rock Storage	Yes	Yes, but not for all waste generated	Yes	Yes, backfilling would be done post mining	Yes, linked to Double Double pit backfilling alternatives assessment
Waste storage duration for Kona Pit waste	Temporary Beta WRSF	Yes	Yes	Yes	Yes	Yes, linked to Kona pit backfilling alternatives assessment
	Permanent Beta WRSF	Yes	Yes	Yes	Yes	Yes, linked to Kona pit backfilling alternatives assessment
	All Kona Pit waste rock to primary WRSF*	Yes	Yes	Yes	Yes	Yes, further evaluation required.

***** Alternative was added during Step 2 of the assessment.

2.3.3 Waste Rock Storage Facilities Cover Alternatives

The cover system for the WRSF will ultimately depend upon the WRSF location as well as component-specific closure objectives. Cover system planning for the WRSF includes material balance evaluations that would inform the quantity of material that is available, as well as the suitability of material, to cover the WRSF. Current material balance estimates indicate sufficient quantity of reclamation material for a WRSF cover; however, these estimates will require field confirmation during mining operations and the WRSF cover options will be re-evaluated at that time.

Three alternatives were selected for WRSF configuration, which would then inform an assessment of the WRSF cover design. The configurations include:

- Overall slope steeper than 3:1 but flatter than angle of repose
- Overall slope 3:1
- Overall slope flatter than 3:1.

Each configuration was then evaluated for the application of either no cover, partial cover on flats, or complete cover, with the exception of the overall slope flatter than 3:1, which was did not include an evaluation for partial cover on flats. Table 2-4 summarizes the feasibility evaluation of WRSF cover alternatives.

Table 2-4 Waste Rock Storage Facility Cover Alternatives – Technical and Economic Feasibility Evaluation

Alternatives		Feasibility Evaluation						Alternative feasible?
		Technical Criteria					Economic Criteria	
		Long-term physical stability	Long-term chemical stability	Physical stability/erosion potential of the cover	Sufficient cover material available	Progressively reclaimed	Implementation costs	
Overall slope steeper than 3:1 but flatter than angle of repose	No cover	Yes	Yes	N/A	N/A	Yes	Yes	Yes
	Partial cover on flats	Yes	Yes	Yes	Maybe	Yes	Maybe	Yes
	Complete cover	Yes	Yes	No	Maybe	Yes	N/A, not technically feasible	No, based on technical criteria
Overall slope 3:1	No cover	Yes	Yes	N/A	N/A	Yes	Yes	Yes
	Partial cover on flats	Yes	Yes	Yes	Maybe	Yes	Maybe	Yes
	Complete cover	Yes	Yes	Maybe	Maybe	Yes	Maybe	Yes
Overall slope flatter than 3:1	No cover	Yes	Yes	N/A	N/A	Yes	Yes	Yes
	Complete cover	Yes	Yes	Yes	Maybe	Yes	Maybe	Yes

2.3.4 Heap Leach Facility Location Alternatives

An assessment of alternative locations for the HLF was conducted as part of the YESAA Project Proposal. The location of the HLF is relevant to this closure alternatives assessment, as the HLF location is an important consideration for achieving the overall vision for the Project post-mining and site-specific closure objectives.

Two leach pad technologies were previously evaluated for the Project: including conventional free-draining pads and valley fills. Investigations of the two technologies led to four HLF location options, as shown in Figure 2-2, including:

- Ridgetop A and B Leach Pads (Option 1) – Two conventional, multi-lift (nominally 10 m), free-draining ridge-top leach pads, with the shortest haul distance from the crushing plant compared to other options. The combined capacity would be 60 Mt, with the Ridgetop A pad having a starter capacity of 5 Mt and a total capacity of 25 Mt. Construction would involve cut and fill and the maximum pad slope would be 5%. Ridgetop B would commence operations in about Year 5.
- 2016 FS Leach Pad (Option 2) - One ridgetop leach pad consisting of a conventional, multi-lift free-draining heap over a gently sloping heap leach pad, which would extend along the axis of the ridge to the west of the process plant. The leach pad would be constructed on a graded area in stages, with each stage providing capacity for 1.5 to 3 years of operation. The nominal capacity of the HLF is 61.4 Mt with capacity to expand to approximately 67 Mt.
- Valley C Leach Pad (Option 3) - A free draining configuration was selected at this location as there is room for conventional external ponds. This option would involve management of steep slopes primarily on the southern abutment side, as well as permafrost removal. The ultimate capacity would be 61 Mt.
- KP Valley Leach Pad (Option 4) - An impounding (in-heap pond) valley leach pad that would require at least two full summer seasons for starter pad construction, primarily due to site preparation activities on steep slopes. The starter capacity would be an estimated 12 Mt, with an ultimate capacity of 60 Mt. Approximately 3 Mt of pre-production waste would be used to construct the impoundment dam and platform, and permafrost removal would be required.

In the original evaluation, Options 3 and 4 were evaluated as being unfeasible as, among other reasons, the facilities were not amendable to progressive reclamation, which would increase the overall closure risk. Option 1 was also deemed unfeasible, as using two heap leach pads rather than one would increase the complexity of construction, operation, and reclamation and closure activities. Option 2 was subsequently incorporated into the mine design.

These location alternatives have been re-evaluated with respect to technical and economic feasibility, the results of which are provided in Table 2-5. The feasibility evaluation of HLF cover alternatives is provided in Table 2-6.

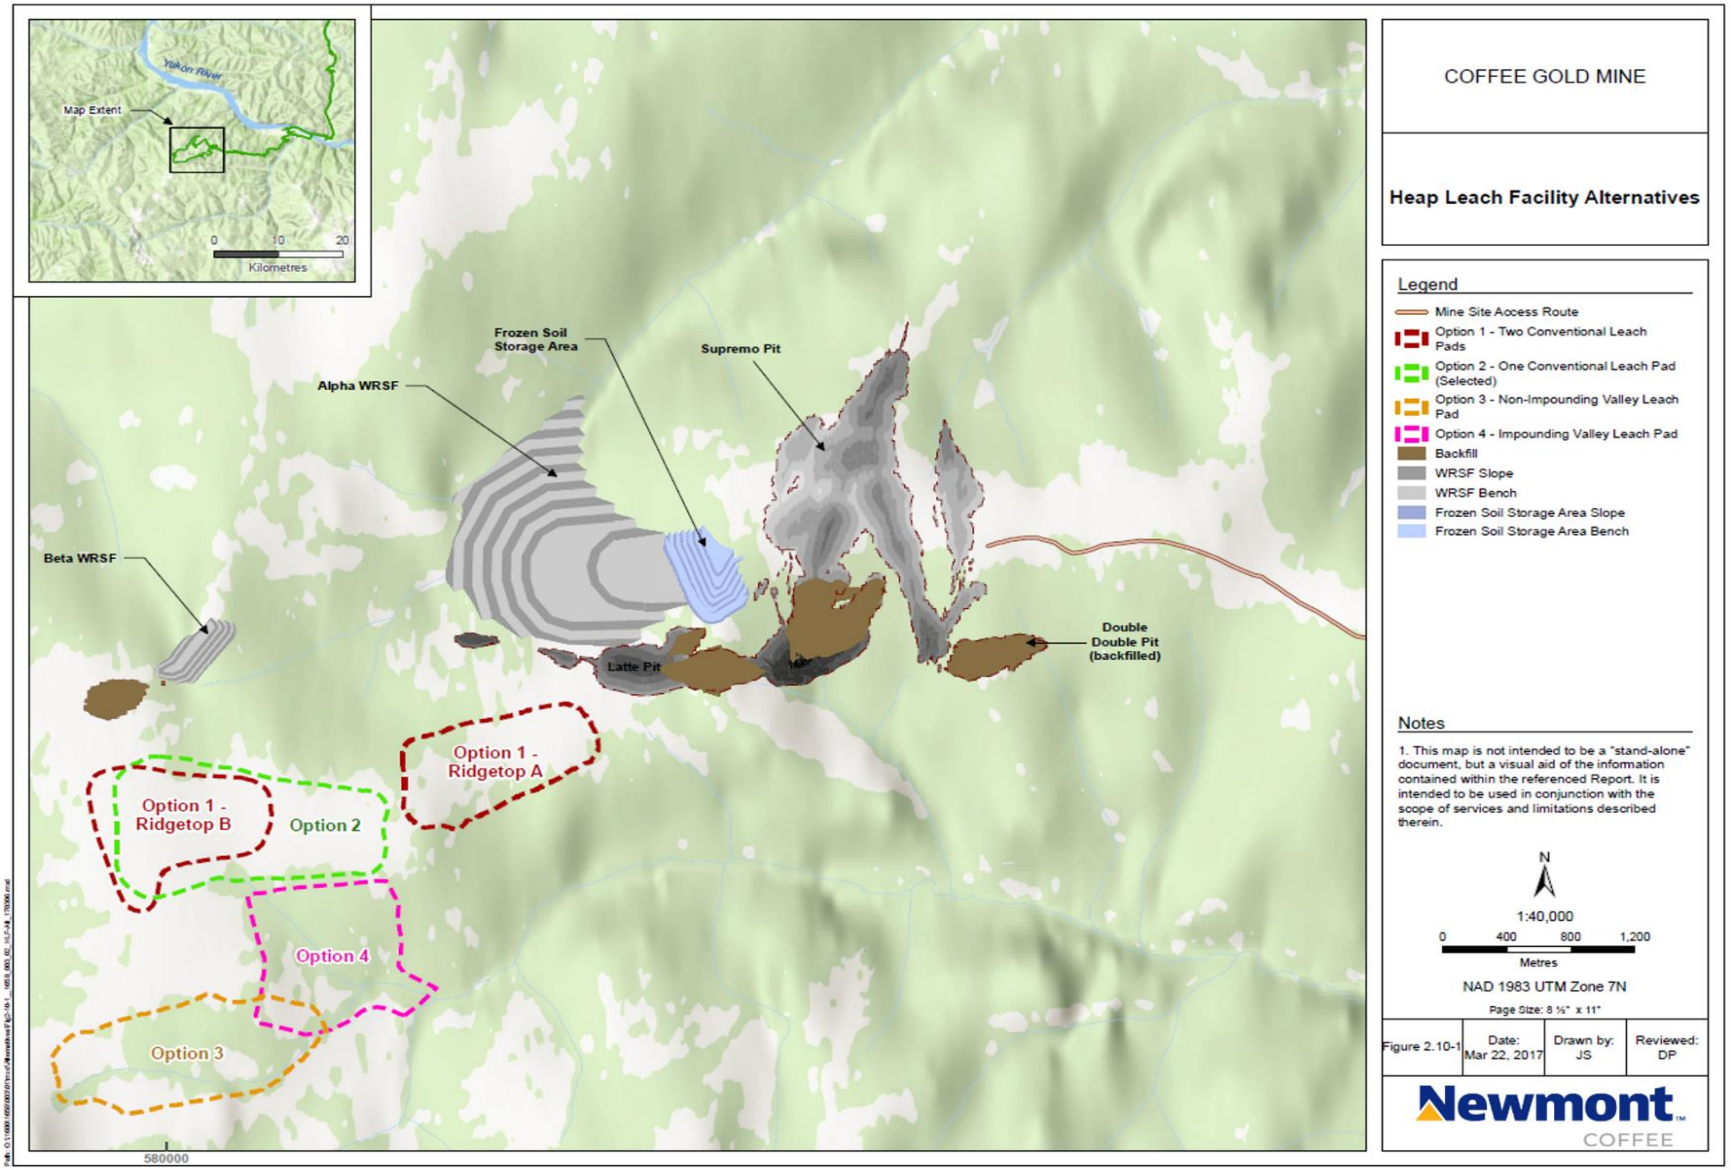

Figure 2-2 Heap Leach Facility Location Alternatives

Table 2-5 Heap Leach Facility Location Alternatives – Technical and Economic Feasibility Evaluation

Alternatives	Feasibility Evaluation					Alternative feasible?
	Technical Criteria			Economic Criteria		
	Long-term physical stability	Meets technical design criteria	Sufficient storage	Implementation costs	Resource sterilization	
Ridgetop A and B Leach Pads	Yes	No	Yes	N/A, not technically feasible		No, based on technical criteria
2016 FS Leach Pad	Yes	Yes	Yes	Yes	Maybe	Yes, linked to HLF cover alternatives assessment
Valley C Leach Pad	Yes	Yes	Yes	Yes	Yes	Yes, linked to HLF cover alternatives assessment
KP Valley Leach Pad	Maybe	No	Maybe	N/A, not technically feasible		No, based on technical criteria

2.3.5 Heap Leach Facility Cover Alternatives

An assessment of cover alternatives for the HLF was previously conducted through a 2018 HLF Alternatives Assessment and was advanced to determine the base case design that would best reflect the interests of stakeholders, Project partners, and First Nations. The cover system for the HLF was evaluated based on the base case HLF location that would ultimately be identified through the alternatives assessment process, and also included an evaluation of a temporary HLF facility (i.e., spent material would be moved to backfill the open pits) that would not require a cover.

The HLF cover alternatives assessment evaluated the options of no cover, partial cover, and complete cover at both the 2016 FS Leach Pad and the Valley C Leach Pad locations. The alternatives for partial cover and complete cover at the 2016 FS Leach Pad location were advanced further by identifying specific cover configurations for these scenarios at this location. The specific configurations for partial cover and complete cover at the 2016 FS Leach Pad location include:

- Partial cover:
  - (1) 2.5:1 construction and closure slopes; GCL installed on flat surfaces progressively.
  - (5b) 2.5:1 construction and 3:1 closure slopes by regrading during closure (wings); GCL installed on flat surfaces progressively and on wings at closure.
  - (8, 8a) 2.5:1 construction and 3:1 closure slopes by buttressing slopes with waste rock progressively; GCL installed on flat surfaces progressively.
- Complete cover:
  - (5a) 2.5:1 construction and 3:1 closure slopes; all surfaces covered with GCL progressively.
  - (4) 3:1 construction and closure slopes; all surfaces covered with GCL progressively.
  - (7) 2.5:1 construction and closure slopes; all surfaces covered with GCL by keying into slopes.
  - (8b) 2.5:1 construction and 3:1 closure slopes by buttressing slopes with waste rock progressively; GCL installed on all surfaces.

The feasibility screening for the HLF cover alternatives presented in Table 2-6 was carried out at the level of cover scenario (i.e., no cover, partial cover, complete cover), and was therefore not carried out on the specific cover configurations.

Table 2-6 Heap Leach Facility Cover Alternatives - Technical and Economic Feasibility Evaluation

Alternatives		Feasibility Evaluation			Alternative feasible?
		Technical Criteria		Economic Criteria	
		Long-term geochemical stability	Sufficient cover material available	Implementation costs	
No cover required as heap used to backfill open pits (temporary facility)		Maybe	N/A	No	No, based on economic criteria
2016 FS Leach Pad	No cover	No	N/A	N/A, not technically feasible	No, based on technical criteria
	Partial cover:	Yes	Yes	Yes	Yes
	• (1) 2.5:1 construction and closure slopes; GCL installed on flat surfaces progressively				
	• (5b) 2.5:1 construction and 3:1 closure slopes by regrading during closure (wings); GCL installed on flat surfaces progressively and on wings at closure				
	• (8, 8a) 2.5:1 construction and 3:1 closure slopes by buttressing slopes with waste rock progressively; GCL installed on flat surfaces progressively				
	Complete cover:	Yes	Yes	Maybe	Yes
	• (5a) 2.5:1 construction and 3:1 closure slopes; all surfaces covered with GCL progressively				
	• (4) 3:1 construction and closure slopes; all surfaces covered with GCL progressively				
	• (7) 2.5:1 construction and closure slopes; all surfaces covered with GCL by keying into slopes				
	• (8b) 2.5:1 construction and 3:1 closure slopes by buttressing slopes with waste rock progressively; GCL installed on all surfaces				
Valley C Leach Pad	No cover	No	N/A	N/A, not technically feasible	No, based on technical criteria
	Partial cover	Yes	Yes	Yes	Yes
	Complete cover	Yes	Yes	Maybe	Yes

Note: Feasibility evaluations were conducted at a high level for the partial/complete cover alternatives. The specific options were not individually assessed for feasibility.

2.3.6 Water Management Infrastructure Decommissioning Alternatives

Table 2-7 summarizes the feasibility evaluation of water management infrastructure decommissioning alternatives, including the Alpha dam/pond and the West Diversion, based on differentiating technical and economic criteria.

Table 2-7 Water Management Infrastructure Decommissioning Alternatives - Technical and Economic Feasibility Evaluation

Water Management Infrastructure	Alternatives	Feasibility Evaluation			Alternative feasible?
		Technical Criteria		Economic Criteria	
		Long-term physical stability	Does not impound water	Implementation costs	
Alpha Dam/Pond	Remove dam completely	Yes	Yes	Yes	Yes
	Create channel without completely removing dam materials	Yes	Yes	Yes	Yes
	Do nothing, allow excess water to overflow via spillway designed and installed for closure	Yes	No	N/A, not technically feasible	No, based on technical criteria
West Diversion	Leave in place	No	N/A	N/A, not technically feasible	No, based on technical criteria
	Partial decommissioning at natural depression drainages	Maybe	N/A	Yes	Yes
	Complete decommissioning (re-grade to slope)	Yes	N/A	Yes	Yes

2.3.7 Northern Access Route Decommissioning Alternatives

Table 2-8 summarizes the feasibility evaluation of NAR decommissioning alternatives, based solely on differentiating economic criteria (i.e., from a technical standpoint, criteria were not differentiating).

Table 2-8 NAR Decommissioning Alternatives - Technical and Economic Feasibility Evaluation

Alternatives	Feasibility Evaluation			Alternative Feasible
	Technical Criteria	Economic Criteria		
	N/A	Implementation costs	Finite liability	
Decommission the Project-associated NAR sections (37 km) and barge landings	Yes	Yes	Yes	Yes
Leave Project-associated NAR sections (37 km) and barge landings in place	Yes	Yes	Maybe	Yes
Close additional road sections beyond those that are Project-specific*	Yes	Yes	Yes	Yes, limited by regulatory regime

***** Alternative was added during Step 2 of the assessment.

3.0 STEP 2: IDENTIFY POTENTIAL EFFECTS OF ALTERNATIVE MEANS ON COFFEE GOLD MINE CLOSURE VALUES

Alternative closure measures that were identified as feasible during Step 1 were advanced for further consideration in Step 2 to compare the merits of each alternative in relation to valued components that may be adversely (or beneficially) affected by them, in accordance with the OPS (Government of Canada 2015). Rather than valued components, the Coffee Gold Mine closure values were applied for comparison in this step of the assessment based on input from TH as well as a close linkage of closure values to both intermediate components (ICs) and valued components (VCs), as described below. The assessment was carried out at a level sufficient to distinguish the relative merits of the different options based on the consideration of the advantages and disadvantages of each. The following steps were taken in Step 2 to advance the evaluation of feasible alternatives that were identified in Step 1.

- Identify the key closure values potentially affected by the alternative means; and
- Examine the relative potential effects each alternative may have on the closure values (with the intent of relating the potential effect of the alternative under consideration on ICs and VCs).

The following closure values were selected to represent Project ICs and VCs in the Step 2 analysis:

- Physical and chemical stability
- Health and safety
- Ecological processes and functions
- Land use
- Socio-economics
- Aesthetics.

It is important to recognize that Project alternatives are inter-connected, and that decisions with respect to component location or closure measure may be linked. There is also a decision-making chronology to Project development that influences the ultimate identification and selection of Project alternatives relevant to closure. This context was brought into the assessment where appropriate.

Table 3-1 summarizes the Project ICs and VCs that are assumed to be associated with each of the Coffee Gold Mine closure values. The green cells indicate the closure values selected for the Step 2 analysis. The rationale for omission of the other closure values from this evaluation process is also provided in Table 3-1. Notes: Green cells indicate the closure values that were selected for the potential effects evaluation (Step 2**)**

Table 3-2 provides the IC/VC and alternative matrix to illustrate how Project ICs and VCs are represented in the analyses that follows.

Table 3-1 Coffee Mine Reclamation and Closure Values and Associated Project ICs and VCs

Closure Value	Closure Objectives	Associated Project ICs and VCs	Rationale for Omission of Closure Value from Evaluation
Physical and Chemical Stability	All mine-related infrastructure is physically and chemically stable and performing in accordance with designs, which take into consideration longer term risks such as for severe climatic and seismic events. Protect and maintain the land, air, and water in a condition that provides for sustainable use. Ensure water remains substantially unaltered from pre-mining conditions to the extent practicable with respect to quantity, quality, and rate of flow, including seasonal rate of flow.	Surficial Geology, Terrain and Soils Surface Water Quality Surface Hydrology Groundwater Quality Air Quality and Greenhouse Gases Vegetation Fish and Fish Habitat Aquatic Organisms Wildlife and Wildlife Habitat Birds and Bird Habitat	Not applicable as closure value considered
Health and Safety	Protect the health and safety of people and area wildlife using and accessing the site by emulating pre-mining conditions to the extent practicable.	Surface Water Quality Noise Fish and Fish Habitat Aquatic Organisms Wildlife and Wildlife Habitat Birds and Bird Habitat Land and Resource Use Social Economy Community Health and Well-being	Not applicable as closure value considered
Ecological Processes and Functions	Protect or enhance ecological processes and functions in order to maintain ecosystem condition and support diverse, productive, and self-sustaining biological communities, with assemblages and abundances of species that are typical for the geographic area and are consistent with site capabilities that emulate pre-mining conditions.	Surficial Geology, Terrain and Soils Surface Water Quality Surface Hydrology Groundwater Quality Air Quality and Greenhouse Gases Vegetation Fish and Fish Habitat Aquatic Organisms Wildlife and Wildlife Habitat Birds and Bird Habitat	Not applicable as closure value considered
Land Use	Protect and maintain environmental quality (a combination physical and chemical stability as well as ecological processes and functions) consistent with the principle of Sustainable Development. Restore lands affected by mine-related activities to allow for future land use similar to surrounding areas to the extent practicable. Ensure the site and specific assets are available for use post-closure.	Land and Resource Use Social Economy Community Infrastructure and Services (NAR)	Not applicable as closure value considered
Economics	Avoid or minimize adverse economic effects on the potentially-affected community and First Nations, while supporting economic sustainability during and beyond the life of mine.	Education Services Economic Conditions	Note: This value is included but may not be not differentiating enough for the alternatives. (number of jobs, supply and procurement benefits)
Aesthetics	Restore views at the site to pre-mining conditions to the extent practicable to facilitate learning and teaching on the land.	Land and Resource Use Social Economy (learning, teaching on the land; traditional economy)	Not applicable as value considered
Country Food and Traditional Economy	To protect the long-term optimal productivity, quality, and diversity of the traditional economy, including the health and viability of country foods and other harvestable resources.	Community Health and Well-being Land and Resource Use Social Economy	If the land is healthy and safe, the ecological processes and functions as well as aesthetics are maintained (both of these values are considered), this value will be achieved.
Participation and Positive Relationship	Maintain ongoing positive relationships or partnerships between Newmont and Yukon First Nations through closure and post-closure Ensure participation of Yukon First Nations in project planning and incorporate First Nations knowledge and experience in closure planning and implementation.	N/A	Not applicable as this value is not differentiating between the alternatives
Culture and Heritage	Recognize, protect and foster the culture and tangible and intangible heritage of Yukon First Nations for the benefit of future generations.	Heritage Resources (tangible only) Community Health and Well-being Education and Training Land and Resource Use Social Economy	This value will be achieved with respect to the site if land use, aesthetics, ecological processes and functions are maintained (these values are considered). Non-site based aspects of heritage are not differentiating for the alternatives.

Closure Value	Closure Objectives	Associated Project ICs and VCs	Rationale for Omission of Closure Value from Evaluation
Community Health and Well-Being	Protect and promote the well-being of affected First Nations, their communities, governments, and internal capacities and structures. Protect and promote the well-being of other Yukon residents and the interests of the public.	Demographics Community Health and Well-being Community Infrastructure and Services	This value is not site based and therefore is not differentiating for the alternatives.
Long-term Certainty	Increase certainty and decrease risk regarding Post-closure conditions and outcomes (through, as examples, contingency planning, revised closure planning based on improved understanding from operations and reclamation research, and adaptive management). Minimize the need for long-term operations, maintenance, and monitoring after reclamation activities are complete by reducing outstanding liabilities and risks.	N/A	N/A – all preferred means of closure will be economically feasible.

Notes: Green cells indicate the closure values that were selected for the potential effects evaluation (Step 2)

Table 3-2 Alternative Means and Project IC and VC Interaction Matrix

Project Intermediate and Valued Components	Alternative Means						
	Open Pit Backfilling	WRSF Location	WRSF Cover	HLF Location	HLF Cover	Water Management	NAR
Groundwater	□	□	□	□	□	□	□
Hydrology	□	□	□	□	□	□	□

Heritage	x	x	x	x	x	x	x

Note: □ = likely interaction with alternative means and IC/VC; x = no interaction with alternative means and IC/VC

3.1 Relative Effects Evaluation of Alternatives

The Step 2 evaluations were carried out through workshops held with Tro'ndëk Hwëch'in and Selkirk First Nation in August 2018. The evaluations used a six-point scale (with 1 being least preferred and 6 meaning closest to or achieving pre-mining conditions, or achievement towards highest economic/skills benefits) to indicate the relative effects on each closure value between alternatives (i.e., a comparative analysis of potential effects). A weight score on a scale of 0 to 2 was assigned to each closure objective during the Step 2 workshop with Tro'ndëk Hwëch'in, and 0 to 6 during the workshop with Selkirk First Nation to provide a relative scoring matrix for analysis of the feasible alternatives against potentially affected closure objectives. Closure objectives that represent significant perceived importance to the alternative being evaluated were be weighted higher (i.e., 2) than objectives that represent minimal perceived importance (i.e., 0).

Table 3-3 to Table 3-15 provide the results of the Step 2 potential effects evaluation, with separate tables for Tro'ndëk Hwëch'in and Selkirk First Nations for each component evaluated. The relative effects evaluation of feasible open pit backfilling alternatives is summarized in Table 3-3 and Table 3-4. The relative effects evaluations of WRSF location and cover alternatives are summarized in Table 3-5 to Table 3-8. The relative effects evaluations of HLF location and cover alternatives are summarized in Table 3-9 to Table 3-12. The relative effects evaluations of decommissioning of water management infrastructure including the Alpha dam/pond and west diversion are summarized in Table 3-13 and Table 3-14. The relative effects evaluation of decommissioning of the NAR is summarized in Table 3-15 and Table 3-16.

Based on the descriptors of the advantages and disadvantages of each alternative, the preferred alternative(s) was identified and further evaluated in Step 3 of the assessment.

Table 3-3 Evaluation of Feasible Open Pit Backfilling Alternatives - Tro'ndëk Hwëch'in

Alternatives		Relative Closure Values Evaluation - Tro'ndëk Hwëch'in											Relative Total Score
		Physical and Chemical Stability	Health and Safety	Ecological Processes and Functions	Land Use	Country Food and Traditional Economy	Participation and Positive Relationship	Culture and Heritage	Community Health and Well-being	Economics*	Aesthetics	Long-term Certainty	
		Weight											
		2	2	1	2	0	1	0	0	0	1	1	
Latte	Partial Backfill - backfill used as haul roads	3	2	1	1	-	4	-	-	-	2	2	21
	Partial backfill - backfill with other purpose (based on end mine use objectives)	3	3	2	1	-	4	-	-	-	2	2	24
	Complete Backfill - progressive reclamation	5	6	5	5	-	6	-	-	-	4	3	50
	Complete Backfill - end of mine life	4	6	4	4	-	6	-	-	-	4	3	45
Double Double	No Backfill	3	1	1	1	-	4	-	-	-	2	2	19
	Partial Backfill	4	3	3	3	-	4	-	-	-	2	2	31
	Complete Backfill	5	6	5	5	-	6	-	-	-	4	3	50
Kona	No Backfill	1	1	1	1	-	4	-	-	-	2	6	19
	Partial Backfill	3	3	3	3	-	4	-	-	-	2	2	29
	Complete Backfill	5	6	5	5	-	6	-	-	-	4	4	51

Scoring: 1 = least preferred to 6 = closest to or achieves pre-mining conditions (or *achievement towards highest economic/skills benefits).
Weighting: Ranked on 0 to 2 scale relative to other values based on perceived importance to evaluation.
Notes: Physical and chemical stability both included as part of technical criteria in feasibility evaluation; also included in this evaluation due to importance.
For Latte pit backfill, Supremo material would be used; assume partial backfill does have a pit lake (elevation difference between spill point and pit elevation is ~100m).
Country food and traditional economy value not relevant for pit backfilling as pit areas are relatively small compared to area used and relative effects captured under land use.
Culture and heritage, community health and well-being, economic closure values considered to be non-differentiating at this scale (weighting set to zero).

Table 3-4 Evaluation of Feasible Open Pit Backfilling Alternatives - Selkirk First Nation

Alternatives		Relative Closure Values Evaluation - Selkirk First Nation												Relative Total Score
		Physical Stability	Chemical Stability	Health and Safety	Ecological Processes and Functions	Land Use	Country Food and Traditional Economy	Participation and Positive Relationship	Culture and Heritage	Community Health and Well-being	Economics*	Aesthetics	Long-term Certainty	
		Weight												
		3	6	2	3	2	1	3	1	0	0	2	4	
Latte	Partial Backfill - backfill used as haul roads	4	6	4	3	4	4	5	4	-	-	4	5	124
	Partial backfill - backfill with other purpose (based on end mine use objectives)	5	5	4	3	4	4	5	4	-	-	4	5	121
	Complete Backfill - progressive reclamation	6	4	6	6	5	5	6	6	-	-	5	4	137
	Complete Backfill - end of mine life	6	4	6	6	5	5	6	6	-	-	5	4	137
	Weight	3	6	2	3	2	1	3	1	0	0	2	4	
Double Double	No Backfill	4	6	4	1	3	4	6	4	-	-	4	6	111
	Partial Backfill	5	4	4	3	3	4	4	4	-	-	4	5	95
	Complete Backfill	6	3	6	6	5	5	3	6	-	-	5	4	104
	Weight	2	3	2	2	2	1	3	1	0	0	2	5	
Kona	No Backfill	4	5	4	1	3	4	5	4	-	-	4	3	92
	Partial Backfill	5	2	4	3	3	4	4	4	-	-	4	3	75
	Complete Backfill – non granite	6	6	6	6	5	5	6	6	-	-	5	6	139
	Complete Backfill – granite	6	1	6	6	5	5	1	6	-	-	5	2	74

Scoring: 1 = least preferred to 6 = closest to or achieves pre-mining conditions (or *achievement towards highest economic/skills benefits).
Weighting: Ranked on 0 to 6 scale relative to other values based on perceived importance to evaluation.

Table 3-5 Evaluation of Feasible WRSF Location Alternatives - Tro'ndëk Hwëch'in

Alternatives	Relative Closure Values Evaluation - Tro'ndëk Hwëch'in											Relative Total Score
	Physical and Chemical Stability	Health and Safety	Ecological Processes and Functions	Land Use	Country Food and Traditional Economy	Participation and Positive Relationship	Culture and Heritage	Community Health and Well-being	Economics*	Aesthetics	Long-term Certainty	
	Weight											
	2	1	1	1	0	0	0	0	0	2	1	
2 WRSFs - West & South	2	2	2	2	-	-	-	-	-	2	2	16
1 WRSF - Alpha	3	3	4	4	-	-	-	-	-	3	4	27
Temporary Beta WRSF (Kona waste only)	3	4	5	5	-	-	-	-	-	5	5	35
Permanent Beta WRSF (Kona waste only)	3	3	1	3	-	-	-	-	-	2	3	20
No Beta WRSF - Kona waste to primary facility	4	6	6	6	-	-	-	-	-	6	6	44
Double Double Waste Rock Storage (Portion of waste only)	See Pit Backfilling Alternative											

Scoring: 1 = least preferred to 6 = closest to or achieves pre-mining conditions (or *achievement towards highest economic/skills benefits).

Weighting: Ranked on 0 to 2 scale relative to other values based on perceived importance to evaluation.

Notes: For comparison of 2 WRSFs to 1 WRSF locations, protection of Latte and Coffee Creeks favored over protection of Halfway Creek in relative scoring.

Beta WRSF alternatives linked to Kona pit backfilling alternatives assessment.

Double Double Waste Rock Storage linked to Double Double pit backfilling alternatives assessment.

Country food and traditional economy, Participation and positive relationships, Culture and heritage, Community health and well-being, and Economic closure values considered to be non-differentiating amongst alternatives (weighting set to zero).

For Community health and well-being, arsenic not above threshold level based on human health risk assessment (HHRA), and community access to facilities will be deterred/restricted

Table 3-6 Evaluation of Feasible WRSF Location Alternatives - Selkirk First Nation

Alternatives	Relative Closure Values Evaluation - Selkirk First Nation												Relative Total Score
	Physical Stability	Chemical Stability	Health and Safety	Ecological Processes and Functions	Land Use	Country Food and Traditional Economy	Participation and Positive Relationship	Culture and Heritage	Community Health and Well-being	Economics*	Aesthetics	Long-term Certainty	
	Weight												
	6	6	3	3	3	3	6	3	3	0	4	6	
2 WRSFs - West & South	3	2	3	2	3	3	2	3	3	-	3	3	123
1 WRSF - Alpha	5	5	4	4	4	5	5	5	5	-	5	4	215
Weight	4	6	2	2	1	1	3	0	0	0	2	4	
Temporary Beta WRSF (Kona waste only)	6	3	5	4	4	5	3	-	-	-	5	3	100
Permanent Beta WRSF (Kona waste only)	5	4	4	3	3	4	3	-	-	-	2	5	98
No Beta WRSF - Kona waste to primary facility	5	5	4	4	4	4	5	-	-	-	4	5	117
Double Double Waste Rock Storage (Portion of waste only)	See Pit Backfilling Alternative												

Scoring: 1 = least preferred to 6 = closest to or achieves pre-mining conditions (or *achievement towards highest economic/skills benefits).
Weighting: Ranked on 0 to 6 scale relative to other values based on perceived importance to evaluation.

Table 3-7 Evaluation of Feasible WRSF Cover Alternatives- Tro'ndëk Hwëch'in

Alternatives[a]		Relative Closure Values Evaluation[f] - Tro'ndëk Hwëch'in											Relative Total Score
		Physical and Chemical Stability[d,e]	Health and Safety	Ecological Processes and Functions	Land Use	Country Food and Traditional Economy	Participation and Positive Relationship	Culture and Heritage	Community Health and Well-being	Economics*	Aesthetics	Long-term Certainty	
		Weight											
		1	1	1	1	0	0	0	0	0	2	1	
Overall slope steeper than 3:1 but flatter than angle of repose	No cover	3	2	2	2	1	-	-	-	-	1	1	12
	Partial cover on flats	4	2	3	3	2	-	-	-	-	2	1	17
Overall slope 3:1[b]	No cover	2	3	2	2	1	-	-	-	-	1	2	13
	Partial cover on flats	3	3	3	3	2	-	-	-	-	2	1	17
	Complete cover	4	3	4	4	3	-	-	-	-	3	1	22
Overall slope flatter than 3:1[c]	No cover	1	4	3	3	2	-	-	-	-	4	3	22
	Complete cover	3	4	5	5	4	-	-	-	-	5	2	29

Scoring: 1 = least preferred to 6 = closest to or achieves pre-mining conditions (or *achievement towards highest economic/skills benefits).
Weighting: Ranked on 0 to 2 scale relative to other values based on perceived importance to evaluation.
Notes: a. For partial or complete cover alternatives, assume 30 cm cover for purposes of revegetation and minor reduction in infiltration until further investigations are complete.
b. Internal slopes <3:1, but overall slope 3:1.
c. Assumes re-grading and no benches
d. Physical and chemical stability both included as part of technical criteria in feasibility evaluation; also included in this evaluation due to importance.
e. For Physical and chemical stability closure value, assume chemical stability more important than physical stability; longer slope means greater area and more contact water therefore lower relative score; long-term physical stability concerns (e.g., erosion) captured under Long-term Certainty closure value.
f. Participation and positive relationship, Culture and heritage, Community health and well-being, and Economic closure values considered to be non-differentiating for these alternatives (weighting set to zero)

Table 3-8 Evaluation of Feasible WRSF Cover Alternatives - Selkirk First Nation

Alternatives		Relative Closure Values Evaluation - Selkirk First Nation												Relative Total Score
		Physical Stability	Chemical Stability	Health and Safety	Ecological Processes and Functions	Land Use	Country Food and Traditional Economy	Participation and Positive Relationship	Culture and Heritage	Community Health and Well-being	Economics*	Aesthetics	Long-term Certainty	
		Weight												
		6	6	2	4	3	3	4	0	0	0	3	4	
Overall slope steeper than 3:1 but shallower/flatter than angle of repose	No cover	4	3	2	2	2	3	3	-	-	-	3	4	106
	Partial cover on flats	4	4	4	3	3	4	4	-	-	-	4	3	129
Overall slope 3:1	No cover	5	3	3	3	3	3	3	-	-	-	3	5	125
	Partial cover on flats	5	4	5	4	4	4	4	-	-	-	4	3	144
	Complete cover	4	6	5	6	6	5	5	-	-	-	5	4	178
Overall slope flatter than 3:1	No cover	6	2	4	3	3	3	3	-	-	-	3	5	127
	Complete cover	5	5	6	6	6	5	5	-	-	-	5	5	184

Scoring: 1 = least preferred to 6 = closest to or achieves pre-mining conditions (or *achievement towards highest economic/skills benefits).
Weighting: Ranked on 0 to 6 scale relative to other values based on perceived importance to evaluation.
Notes: assume vegetative cover that slightly reduces infiltration

Table 3-9 Evaluation of Feasible HLF Location Alternatives - Tro'ndëk Hwëch'in

Scoring: 1 = least preferred to 6 = closest to or achieves pre-mining conditions (or *achievement towards highest economic/skills benefits).
Weighting: Ranked on 0 to 2 scale relative to other values based on perceived importance to evaluation.

Notes: Alternative #4 included at TH request

a. For 2016 FS Leach Pad closure details, refer to JDS August 2018 HLF Alternatives Assessment Report
b. For Chemical and physical stability value, assume that additional buttress rock runoff draining towards Latte Creek meets use protection of Latte Creek and non-degradation of Coffee Creek
c. For Participation and positive relationship value, relative scoring based on perception of water quality
d. Closure values with weighting of 0 considered to be non-differentiating for these alternatives.

Table 3-12 Evaluation of Feasible HLF Cover Alternatives - Selkirk First Nation

Alternatives			Relative Closure Values Evaluation - Selkirk First Nation											Relative Total Score
			Physical Stability	Chemical Stability	Ecological Processes and Functions	Country Food and Traditional Economy	Participation and Positive Relationship	Culture and Heritage	Community Health and Well-being	Land Use	Economics*	Aesthetics	Long-term Certainty

Alpha Dam/Pond	Remove dam completely	6	-	-	5	-	-	-	-	-	5	5	37
	Create channel without completely removing dam materials	5	-	-	4	-	-	-	-	-	3	4	28
Weight		2	0	1	1	0	0	0	0	0	2	2	
West Diversion	Partial decommissioning at natural depression drainages	3	-	3	3	-	-	-	-	-	3	3	24
	Complete decommissioning (re-grade to slope)	5	-	5	5	-	-	-	-	-	4	5	38

Scoring: 1 = least preferred to 6 = closest to or achieves pre-mining conditions (or *achievement towards highest economic/skills benefits).
Weighting: Ranked on 0 to 2 scale relative to other values based on perceived importance to evaluation.
Notes: for Alpha Dam/Pond assume material is totally gone or channel is removed that everything flows through; for future - potentially evaluate very small dam to act as a sedimentation pond

Table 3-15 Evaluation of Feasible NAR Decommissioning Alternatives - Tro'ndëk Hwëch'in

Alternatives[a]	Relative Closure Values Evaluation[b,c,d] - Tro'ndëk Hwëch'in											Relative Total Score
	Physical and Chemical Stability	Health and Safety	Ecological Processes and Functions	Land Use	Country Food and Traditional Economy	Participation and Positive Relationship	Culture and Heritage	Community Health and Well-being	Economics*	Aesthetics	Long-term Certainty	
	Weight											
	2	2	2	2	1	0	1	0	1	1	0	
Decommission the Project-associated NAR sections (37 km) and barge landings	5	5	5	4	5	-	4	-	2	4	-	53
Leave Project-associated NAR sections (37 km) and barge landings in place	2	2	1	3	1	-	3	-	1	3	-	24
Close additional road sections beyond those that are Project-specific	6	6	6	4	6	-	4	-	3	4	-	61

Scoring: 1 = least preferred to 6 = closest to or achieves pre-mining conditions (or *achievement towards highest economic/skills benefits).

Weighting: Ranked on 0 to 2 scale relative to other values based on perceived importance to evaluation.

Notes: a. Existing road sections will remain in place. Assume no maintenance requirements for sections not reclaimed.

b. Assume that ability to access is captured under Land Use value and quality of resources is captured under Country food and traditional economy values.

c. Community health and well-being value not included in evaluation as duplicative to Land use/Country foods and traditional economy values; Participation and positive relationship not included as not relevant for this evaluation.

d. Long-term certainty closure value considered to be non-differentiating for these alternatives (weighting set to zero).

Table 3-16 Evaluation of Feasible NAR Decommissioning Alternatives - Selkirk First Nation

Alternatives	Relative Closure Values Evaluation - Selkirk First Nation											Relative Total Score
	Physical and Chemical Stability	Health and Safety	Ecological Processes and Functions	Land Use	Country Food and Traditional Economy	Participation and Positive Relationship	Culture and Heritage	Community Health and Well-being	Economics*	Aesthetics	Long-term Certainty	
	Weight											
	0	1	2	1	2	1	1	0	0	0	0	
Decommission the Project-associated NAR sections (37 km) and barge landings	-	5	5	5	5	6	5	-	-	-	-	41
Leave Project-associated NAR sections (37 km) and barge landings in place	-	4	4	2	1	2	1	-	-	-	-	19
Close additional road sections beyond those that are Project-specific	-	6	6	6	6	6	6	-	-	-	-	48

Scoring: 1 = least preferred to 6 = closest to or achieves pre-mining conditions (or *achievement towards highest economic/skills benefits).
Weighting: Ranked on 0 to 2 scale relative to other values based on perceived importance to evaluation.

Notes: If don't decommission road - would likely revert to government agency control and maintenance; assumption that road will be decommissioned properly.

4.0 STEP 3: EVALUATION AND IDENTIFICATION OF BASE CASE DESIGN

Following the Step 1 feasibility screening and the Step 2 relative consideration of effects, technical and economic evaluations were advanced for select alternatives that were identified as requiring additional evaluation. The intent of Step 3 of the assessment was to inform the selection of alternatives that would be identified as the base case closure approach. A process to identify and conduct the evaluations for the alternative means was developed through consultation with qualified professionals and First Nations. These evaluations were carried out to advance the alternatives assessment process for the closure plan based on the current mine plan and Project-specific closure objectives. Advancement of the mine plan and/or development of the End Land Use Plan may require further evaluation and consideration of alternatives that were not identified as the base case for closure during this Step 3 evaluation.

The evaluations that were carried out under Step 3 of the assessment are described below along with the resulting preferred means of closure for each major mine component. The evaluations that were conducted for the assessment were carried out in a priority sequence to allow for the development of required model inputs. The technical evaluations focused on the development of a water quality/balance model, material balance assessment, cover material performance, and water management infrastructure evaluations. In addition, a ranking exercise of disturbed areas within the Mine Site footprint identified the priority areas for reclamation material, which is included in the Heap Leach Facility Cover Design Report (Appendix 7-A of the RCP). The material balance evaluations will be advanced throughout operations to confirm the outcomes of the current material balance projections. The alternatives identified as requiring further evaluation as well as the evaluations that were carried out are listed in Table 4-1. The resulting preferred closure means for major mine components are summarized in Table 4-2.

Additional assessments will be conducted as part of the reclamation research program throughout operations in existing site conditions to optimize the performance of reclamation material. The reclamation research program will include evaluations of cover thickness/type, as well as cover system revegetation capacity and infiltration. Results will be integrated into the closure plan to optimize site reclamation activities. Further details of the reclamation research program are provided in Section 2.3.1 of the RCP.

Table 4-1 Step 3 Evaluations

Alternative Identified as Requiring Further Evaluation			Evaluation
Open Pit Backfilling	Latte Pit	Complete backfill – progressively	• Economic evaluation • Water Management Evaluation
		Complete backfill – end of mine life	
	Double Double	No backfill	• Economic evaluation
	Kona	Complete backfill	• Water quality/geochemical evaluation
Waste Rock Cover	Overall slope 3:1	Partial cover on flats	• Material balance evaluation • Cover material performance • Cover material prioritization • Cover slope/sediment and erosion stability • Revegetation assessment (reclamation research program)
		Complete cover	
	Overall slope flatter than 3:1	Complete cover	
HLF Cover	2016 Feasibility Study Leach Pad	(8,8a) 2.5:1 construction and 3:1 closure slopes by buttressing slopes with waste rock progressively; GCL installed on flat surfaces progressively	• Material balance evaluation • Water quality/balance model • Heap seepage rate • Infiltration/draindown model • Cover slope stability evaluation • Sediment and erosion stability • Trade-off Study
		(5a) 2.5:1 construction and 3:1 closure slopes; all surfaces covered with GCL progressively	
		(4) 3:1 construction and closure slopes; all surfaces covered with GCL progressively	
		*(7) 2.5:1 construction and closure slopes; all surfaces covered with GCL by keying into slopes	
		(8b) 2.5:1 construction and 3:1 closure slopes by buttressing slopes with waste rock progressively; GCL installed on all surfaces	
Water Management Infrastructure Decommissioning	Alpha Dam/Pond	Remove dam completely	• Economic evaluation • Stability Analysis of Partial removal
	West Diversion	Partial decommissioning at natural depression drainages	• Long-term maintenance evaluation

*Option 7 for HLF Cover not flagged for evaluation; however, it was included with other alternatives being evaluated

Table 4-2 Preferred Means for Project Closure

Preferred Closure Means		
Open Pit Backfilling	Latte Pit	Partial backfill - backfill used as haul roads
	Double Double	Complete backfill
	Kona	Complete backfill
	Supremo	Partial backfill- backfill used to optimize mine development
Waste Rock Storage Location(s)	Location(s) for non-Kona waste	One WRSF - Alpha
	Waste storage duration for Kona waste	All Kona waste rock to primary WRSF
Waste Rock Cover	Overall slope 3:1[1]	No cover
HLF Location	2016 Feasibility Study leach pad	
HLF Cover	Partial Cover	2.5:1 construction and closure slopes; geosynthetic clay liner (GCL) installed on flat surfaces progressively
Decommissioning of Water Management Infrastructure	Alpha Dam/Pond	Create channel without completely removing dam materials
	West Diversion	Complete decommissioning (re-grade to slope)
Decommissioning of NAR	Decommission Project-associated NAR sections (37 km)	

[1] Internal slopes are <3:1, but overall slope is 3:1

4.1 Open Pit Backfilling

4.1.1 Latte Pit

The feasible alternatives for the Latte Pit backfill that were identified for additional evaluation include:

- Complete backfill – progressively
- Complete backfill – end of mine life.

An economic evaluation was carried out to assess the option of complete backfill at the end of mine life. The results of this evaluation determined that this alternative would be uneconomical based on the volume of material and rehandling costs that would be required to fill the pit at the end of mine life. A water management evaluation was also carried out through the advancement of the Water Management Plan which determined that the Latte pit will be required for contingency water storage during operations; therefore, progressive complete pit backfill for the Latte Pit is unlikely to be feasible. Additionally, the partially backfilled Latte pit will be utilized for road access to the Supremo pit via a waste rock bridge within the pit. Supremo material would be used for pit backfill, and it is assumed that the partially backfilled pit does have a pit lake (elevation difference between spill point and pit elevation is ~100m). The current preferred closure option for the Latte pit that was advanced as the base case is therefore partial backfill, with the backfill used as haul roads.

4.1.2 Double Double

The feasible alternatives for the Double Double Pit backfill that were identified for additional evaluation include:

- No backfill.

Evaluations carried out to assess closure options for the Double Double pit included the development of a water quality model to verify that acceptable impacts to water quality would occur from backfilled material. The evaluation determined that water quality would not be significantly impacted by complete backfill; therefore, this option was advanced as the base case for the Double Double pit.

4.1.3 Kona

The feasible alternatives for Kona Pit backfill that were identified for additional evaluation include:

- Complete backfill

Evaluations carried out to assess closure options for the Kona pit were identified during the Step 2 potential effects evaluation ranking exercise. The ranking for this alternative was dependent on a geochemical evaluation of the backfill material and development of a water quality model. Should the geochemical evaluation determine the backfill material to be granite, then complete backfill would receive the lowest ranking. If it was determined to be non-granite, this alternative would receive the highest ranking. The evaluation determined that the material that would be utilized for backfill of Kona pit (i.e., Supremo pit material) is non-granite; therefore, complete backfill was determined it to be the preferred closure option and was selected as the base case for closure of the Kona Pit.

4.1.4 Supremo

Step 1 of the assessment identified 'partial backfilling, with the backfill being utilized for mine development optimization' as the only feasible option for the Supremo Pit. This alternative was therefore the option selected as the base case for closure of the Supremo Pit.

4.2 Waste Rock Storage Location

During the Step 2 potential effects evaluation, the option of one WRSF location (Alpha WRSF) was determined to be the preferred option among all parties and was therefore selected as the base case location of non-Kona pit waste rock. Updates to the general mine plan eliminated the Beta WRSF location; therefore, Kona waste options involving the Beta WRSF were eliminated from further consideration. All Kona waste rock reporting to primary WRSF was determined to be the preferred option among all parties and is therefore the selected base case option for Kona generated waste rock.

4.3 Waste Rock Cover

The feasible alternatives for the Waste Rock cover that were identified for additional evaluation include:

- Overall slope 3:1
  - Partial cover on flats
  - Complete cover
- Overall slope flatter than 3:1
  - Complete cover

A material balance evaluation was carried out to determine the quantity of cover material that would be available for use in reclamation and closure, as well as a priority sequence for placement of the cover material at various mine components in closure. The priority sequence exercise identified the Alpha WRSF as a high priority item for reclamation material placement following the HLF.

The current proposed closure option for the waste rock cover is 'no-cover' with an overall slope of 3:1, which was selected based on uncertainties related to available cover material and the prioritization of the HLF for cover. Revegetation assessments, including metals uptake on bare waste rock, will be carried out through the reclamation research program to inform revegetation strategies on the WRSF. The material balance evaluation will be updated during operations to confirm available cover material quantities, and a WRSF cover may be re-evaluated during operations. Development of the End Land Use Plan will ultimately inform the final landform design, which may also lead to the re-evaluation of the WRSF cover as the mine plan advances.

4.4 HLF Location

During Step 2 potential effects evaluation of the HLF location, the 2016 Feasibility Study leach pad location was determined to be the preferred option and is therefore the selected as the base case for the location of the HLF.

4.5 HLF Cover

The feasible alternatives for the HLF cover that were identified for additional evaluation include:

- Partial cover:
  - (Option 8a) 2.5:1 construction and 3:1 closure slopes by buttressing slopes with waste rock progressively; geosynthetic clay liner (GCL) installed on flat surfaces progressively.
- Complete cover:
  - (Option 5a) 2.5:1 construction and 3:1 closure slopes; all surfaces covered with GCL progressively.
  - (Option 4) 3:1 construction and closure slopes; all surfaces covered with GCL progressively.
  - (Option 7) 2.5:1 construction and closure slopes; all surfaces covered with GCL by keying into slopes.
  - (Option 8b) 2.5:1 construction and 3:1 closure slopes by buttressing slopes with waste rock progressively; GCL installed on all surfaces.

Step 2 of the assessment assigned a low rank to Option 8b (complete cover; 2.5:1 construction and 3:1 closure slopes by buttressing slopes with waste rock progressively; GCL installed on all surfaces); therefore, this alternative was not evaluated further. Option 4 (complete cover; 3:1 construction and closure slopes; all surfaces covered with GCL progressively) was initially eliminated during the Step 1 feasibility screening; however, this option was reopened for consideration following consultation with First Nations.

Several interdependent evaluations were carried out to assess the HLF cover alternatives, including an analytical water balance, numerical water balance, water quality model, slope stability evaluations of the cover material, sediment and erosion stability evaluations, and a trade-off study. The analytical water balance determined that a GCL cover on the slopes would reduce net percolation (NP) to very low compared to a store-and-release cover system. Lateral drainage above the GCL however would require surface water management features in order to meet stability requirements. The erosion stability evaluation indicated reduced potential long-term annual erosion for flatter slopes compared to steeper slopes. Details for the evaluations are provided in the Heap Leach Facility Cover Design Report (Appendix 7-A of the RCP) and the Heap Leach Facility Closure Trade-off Study (Appendix 2-M of the RCP).

Through these evaluations as well as through collaborative discussion, Option 1 (partial cover: 2.5:1 construction and closure slopes; GCL progressively installed on flat surfaces) was selected as the base case option for the HLF cover. The Heap Leach Facility Cover Design Report further evaluated the base case HLF cover option, confirmed feasibility, and finalized and advanced the design to subsequent project planning stages. This report is provided in Appendix 7-A of the RCP.

4.6 Water Management Infrastructure Decommissioning

The feasible alternatives for water management infrastructure decommissioning identified for additional evaluation include:

- Alpha Dam/Pond:
  - Remove dam completely.
- West Diversion:
  - Partial decommissioning at natural depression drainages.

An economic evaluation of the complete removal of Alpha Dam was carried out and determined that full removal of the Dam would result in a 64% higher cost compared to partial removal. Engineering of partial decommissioning of the Alpha Dam/Pond has been completed, and in some instances has indicated partial decommissioning as beneficial to buttress/insulate permafrost slopes. Creating a channel without completely removing dam materials was therefore selected as the base case for closure of the Alpha Dam/Pond.

Based on a long-term maintenance evaluation on the partial decommissioning option for closure of the West Diversion, complete decommissioning was selected as the base case closure option for this infrastructure.

4.7 NAR Decommissioning

Public roads that are not intrinsically associated with the Project are not governed by Newmont, and decisions regarding the closure of additional road sections are outside of Newmont's scope. It was therefore determined unlikely to be feasible to close additional road sections beyond new road sections that are constructed for the Project. Decommissioning of the new road sections was identified as the preferred option during the Step 2 potential effects evaluation and is therefore the selected closure option for the NAR.

5.0 STEP 4: FAILURE MODES AND EFFECTS ANALYSIS OF BASE CASE ALTERNATIVE MEANS

The objective of the FMEA was to identify and prioritize key Project risks of the base case design in order to outline strategies for risk mitigation and maximize risk control resources. The analysis applied Project-specific metrics, including timeframes, likelihood definitions, and consequence definitions, for assessing the risks associated with the preferred alternative means for closing the Project components within the near-, short-, and long-term. A workshop was held in February 2022 to collaboratively rank the failure modes that were identified with respect to the overall objectives for the Project.

The FMEA workshop identified ten failure modes that were evaluated as severe or high-risk. No identified failure modes were evaluated as a fatal flaw that would require modification of the base case design. A residual risk assessment determined that all unacceptable risks can be mitigated, with the exception of three high-risk rankings related to major life of project cost consequences. These cost consequences were identified as acceptable given the current Project definition, and as they will not have effects on the environment, Stakeholder consultation and permitting (SCP), or legal consequence categories. The outcomes of the FMEA verified confidence in the base case design for the Project, and the failure modes and effects pathways will continue to be monitored as the project advances. The FMEA Summary Report is provided in Appendix 7-A of the RCP (Heap Leach Facility Cover Design Report).

1.0 Introduction

As part of the planning stages for the Coffee Gold Project, the Coffee Project team has conducted a Failure Modes and Effects Analysis (FMEA) to identify and prioritize key Project risks. This will allow the Project to incorporate risks and Failure Modes into detailed design and to maximize risk control resources. At the present stage, a qualitative FMEA has been conducted at a conceptual level so that the outcomes can guide decision making in the detailed planning stages and provide information to support sound decision making for construction, operations and closure. The results of the FMEA will also inform future similar evaluations or other analyses that will continue as the project advances towards licensing and into mine operations.

2.0 Scope

The scope of the FMEA sessions covered key site facilities, focusing on infrastructure covered in a draft document provided by Yukon Government *Mine licensing Improvement Initiative – Guidelines for Mine Waste Management Facilities*[1]. The preliminary designs for the identified facilities were reviewed, risks were identified, and each risk was evaluated for risk attributes including: relevant Project phases, description, and consequence category.

The early stage FMEA is intended to identify potential Failure Modes and risks, focusing on downstream impacts, in the early stages of planning for incorporation into detail design. More detailed Hazard and Operability Studies (HAZOP) sessions will be performed for all critical facilities after the designs have been progressed in more detail.

Key Facilities selected for the FMEA include:

- Open Pits:
  - Double Double;
  - Latte;
  - Supremo; and
  - Kona.
- Waste Storage Facilities & Material Stockpiles:
  - Alpha Waste Rock Storage Facility;
  - Beta Waste Rock Storage Facility;
  - Frozen Material Stockpile;
  - Overburden Stockpile; and
  - ROM Stockpile.
- Heap Leach Facilities:

[1] Energy Mines and Resources. 2017. *Guidelines for Mine Waste Management Facilities*. Draft for Discussion Purposes, April 2017.

- Heap Leach Pad; and
- Events Ponds.

- Water Management Facilities:
  - Alpha Pond;
  - Facility Pond;
  - Diversions; and
  - Rock Drain.

3.0 Methods

Several multi-party FMEA session were held over the course of two weeks. The first session was held the week of February 12, 2018, and consisted of a risk identification and screening exercise. At this session, the format of the subsequent FMEA sessions and risk rating tools were developed.

The Consequence Categories, Consequence-Severity Matrix, Likelihood Chart and Risk Matrix were developed to align with the Goldcorp risk profile. Project-specific adjustments were made so that the register output would be relevant to external Project stakeholders.

The multidisciplinary FMEA sessions allowed for a holistic review of all the identified facilities; generating a comprehensive list of risks. An outcome of this multidisciplinary approach was that the interconnectivity of various facilities were scrutinized in detail, allowing for the identification of cascading failures and a better understanding of the correlated nature of many failure provoking events. Though Failure Modes for each facility were broken down into three categories: “Water Management”, “Physical Stability” and “Chemical Stability”[2], it was clear that there was a high level of interdependency between various categories. Risks stemming from this interdependency were either duplicated, or referenced as appropriate, as described in the “Session Structures” Section above.

Each session began with a review of the Consequence-Severity Matrix, the Likelihood Chart and the Risk Matrix (see Section 4.0). This was followed by a high-level summary of prior sessions so that all attendees were clear on the format.

The Risk Register that was developed as an outcome of these sessions is included in Appendix A.

The workshops conducted for this study are documented below.

Risk Identification and Screening Session – February 14

Attendees:

- James Scott – Goldcorp
- Jennie Gjertsen – Goldcorp

[2] Risks stemming from ML/ARD, along with other geochemical impacts, were frequently identified over the course of the FMEA sessions. ML/ARD has been used in the risk register as an all-encompassing term that may include other geochemical impacts that are not strictly ML/ARD related.

- Jeet Basi – Goldcorp
- Kelly Bateman – JDS Energy & Mining
- Trevor Herd – JDS Energy & Mining
- Lisa DeSandoli – JDS Energy & Mining
- Carly Church – JDS Energy & Mining

After the structure was developed, a copy of the risk register was distributed to participating individuals for review prior to the individual Facility-specific FMEA sessions. Four Facility-specific sessions were held the week of February 12 and February 19, 2018 with participants attending in person or via remote conference. The details of the individual sessions are outlined below.

Open Pit Waste Storage Facilities & Material Stockpiles - February 15

Attendees:

- Dino Pilotto – JDS Energy & Mining
- Trevor Herd – JDS Energy & Mining
- Kelly Bateman – JDS Energy & Mining
- Carly Church – JDS Energy & Mining
- Mike Levy – JDS Energy & Mining

This session reviewed the Failure Modes of the open pits, the waste storage facilities and material stockpiles.

Water Management Facilities – February 19

Attendees:

- Carly Church – JDS Energy & Mining
- Lisa DeSandoli – JDS Energy & Mining
- Trevor Herd – JDS Energy & Mining
- Kim Doerksen – JDS Energy & Mining
- David Flather – Lorax Environmental Services
- Scott Jackson – Lorax Environmental Services
- John Dockery – Lorax Environmental Services
- Tom Sharp – SRK
- John Kurylo – SRK
- Sarah Portelance - SRK

This session reviewed the Failure Modes of the Water Management Infrastructure.

Heap Leach Facility – February 19

Attendees:

- Mark Smith – RRD International
- Doug Bright – Hemmera
- David Flather – Lorax Environmental Services
- Scott Jackson – Lorax Environmental Services
- John Dockery – Lorax Environmental Services
- Carly Church – JDS Energy & Mining
- Lisa DeSandoli – JDS Energy & Mining
- Trevor Herd – JDS Energy & Mining

This session reviewed the Failure Modes of the Heap Leach Facility, including the Heap Leach Pad and Events Ponds.

Water Quality and Human Health Effects Analysis – February 21

Attendees:

- Doug Bright – Hemmera
- David Flather – Lorax Environmental Services
- Scott Jackson – Lorax Environmental Services
- John Dockery – Lorax Environmental Services
- Carly Church – JDS Energy & Mining
- Lisa DeSandoli – JDS Energy & Mining
- Trevor Herd – JDS Energy & Mining

This session was scheduled to focus on the Water Quality and Human Health Effects and impacts across all facilities. Though the Human Health Effects were reviewed in the individual sessions, a separate session was held with a subject matter expert in this area (Doug Bright), in order to prioritize these impacts and ensure they were adequately captured.

Goldcorp acknowledges that by not having invited participation from external parties (First Nations, 3rd party reviewers or other stakeholders)that there are limitations to the findings of the FMEA, particularly the consequence severities related to Traditional Use and Community/ Media/ Reputation categories. These limitations will be considered in future FMEAs or other similar or complementary decision-making/risk analyses. Goldcorp expects to extend an invite to external parties where it deems appropriate when conducting these analyses.

4.0 FMEA Process

4.1 Session Structures

The Consequence-Severity breakdown, Likelihood Descriptions and Risk Matrix that were developed in the Risks Identification and Screening sessions are shown in Table 1 to Table 3 below. The Consequence Categories and Severity Descriptors as described in Table 1 are generally consistent with Goldcorp's internal risk assessment and management approach.

Table 1. Consequence – Severity Matrix

	Severity Descriptors				
Consequence Categories	**Insignificant**	**Minor**	**Moderate**	**Major**	**Severe**
Environmental Impact (EA)	• On-site environmental damage; and • Does not require containment and clean-up.	• On-site environmental damage; and • Containment or clean-up efforts completed within 1 shift.	• Off-site environmental damage with quick clean-up; or • On-site environmental damage requiring greater than 1 shift to complete containment or clean-up.	• Off-site environmental damage; and • Requires prolonged containment or clean-up, or prolonged public health monitoring and intervention.	• Off-site environmental damage; and • Requires long-term containment or clean-up, or long-term public health monitoring or intervention.
Traditional Use (TU)	• Some disturbance but no impact to traditional land use.	• Minor or perceived impact to traditional land use.	• Some mitigable impact to traditional land use.	• Significant temporary impact to traditional land use.	• Significant permanent impact on traditional land use.
Regulatory and Legal (RL)	• Informal advice from a regulatory agency.	• Technical / Administrative non-compliance with permit, approval or regulatory requirement. Warning letter issued.	• Breach of regulations, permits, or approvals (e.g. 1 day violation of discharge limits). • Order or direction issued.	• Substantive breach of regulations, permits or approvals (e.g. multi-day violation of discharge limits). • Prosecution.	• Major breach of regulation – wilful violation. • Court order issued.
Consequence Costs (CC)	• < $10M	• $10M to $30M	• $30M to $60M	• $60M to $120M	• > $120M
Community/ Media/ Reputation (CMR)	• Local concerns, but no local complaints or adverse press coverage.	• Public concern restricted to local complaints or local adverse press coverage.	• Heightened concern by local community, criticism by NGOs or adverse local / regional media attention.	• Significant adverse national public, NGO or media attention.	• Serious public outcry / demonstrations or adverse International NGO attention or media coverage.

Human Health and Safety (HSS)	• Low-level short-term subjective symptoms. No measurable physical effect. No medical treatment.	• Objective but reversible disability / impairment and/or medical treatment injuries requiring hospitalization.	• Moderate irreversible disability or impairment to one or more people.	• Severe irreversible disability or impairment to one or more people.	• Single fatality or multiple fatalities.

Table 2. Likelihood Ratings

Likelihood	Probability (Life of Project)	Frequency Descriptor
Almost Certain	> 98%	High frequency (more than once every 5 years)
Likely	84 – 89%	Event does occur, has a history, once every 15 years
Possible	16 – 84%	Occurs once every 40 years
Unlikely	2 – 16%	Occurs once every 200 years
Rarely	< 2%	Occurs once every 1000 years

Table 3. FMEA Coffee Project Risk Matrix

Risk Matrix						
Likelihood		Consequence Severity				
		Insignificant	Minor	Moderate	Major	Severe
		1	2	3	4	5
Almost Certain	5	**Moderate**	**Moderately High**	**High**	**Very High**	**Very High**
Likely	4	**Moderate**	**Moderate**	**Moderately High**	**High**	**Very High**
Possible	3	**Low**	**Moderate**	**Moderate**	**Moderately High**	**High**
Unlikely	2	**Low**	**Low**	**Moderate**	**Moderate**	**Moderately High**
Rarely	1	**Low**	**Low**	**Low**	**Moderate**	**Moderate**

Each facility was broken out into several different risk categories to ensure completeness: Water Management, Chemical Stability, and Physical Stability. The group then worked through each risk category to identify potential Failure Modes and the resulting consequences. Each Failure Mode was categorized with a Project Phase (Construction, Operations, Reclamation and Closure) and a Consequence Category. If the Failure Mode was relevant across multiple phases, then all relevant phases were selected. If the consequence impact or likelihood for a Failure Mode was meaningfully different in different phases, then they were itemized as separate Failure Modes.

For any individual Failure Mode, it is possible that there could be multiple independent, contributing factors. All identified contributing factors are listed in the "Leading Factors" column in the Risk Register. All contributing factors were considered when determining the Consequence Rating and Likelihood, with the scored likelihood derived from the most likely leading factor. For example, overtopping and embankment failure of the Alpha Dam from a rain event higher than 1 in 200 year event is more likely than embankment failure due to an earthquake, so the 1 in 200 year event was considered for determining likelihood. Failure Modes with multiple leading factors were only combined on the risk register in the manner described above when the Failure Mode and maximum credible consequences were meaningfully similar. Otherwise they were listed as separate Failures and the consequences and likelihoods were evaluated separately.

Due to the correlative nature of many of the facilities within the Project, Failure Modes of any individual facility may have resulting consequences, inducing cascading impacts on other facilities. As a result, certain Failure Modes may be listed as Leading Factors for other Failure Modes within the register. Additionally, for completeness, several Failure Modes are duplicated across multiple facilities in order to identify, track and emphasize the association among facilities.

4.2 Risk Rating Process

The Maximum Credible Consequence was identified for each Failure Mode, to assist in identifying the appropriate Consequence-Severity ranking. Where a Failure Mode had a meaningful consequence across multiple consequence categories, the Failure Mode was listed separately for each Consequence Category so that each consequence could be evaluated individually. Consistent with the guidance in *Appendix E: Risk Assessment Approach of the Draft Guidelines for Mine Waste Management Facilities*[3]; all risks were evaluated on the basis that planned controls were in place (i.e. a slope stability monitoring program is in place to monitor pit wall stability), so that the resulting risk scores identified the residual risk of each Failure Mode. This provides a more meaningful risk ranking, upon which future risk treatment planning can be prioritized. Planned Controls that were considered are indicated in the "Risk Management Controls in Place" column in the Risk Register (Appendix A).

When identifying the Consequence-Severity rating for a listed Failure Mode, the classification was based on the incremental consequence of the identified failure. This is consistent with hazard classification procedure as outline in the *Canadian Dam Safety Guidelines*[4] and provides the indicative assessment of the overall impact specifically stemming from the identified Failure Mode. In general, the incremental consequence of failure is defined as the total damage from an event with the facility failure incorporated, less the damage that would have resulted from the same event (i.e. large flood event) had the facility not experienced the identified failure.

The Consequence-Severity and likelihood rankings were recorded on the Risk Register spreadsheet, and the overall residual risk ranking was generated based on the Risk Matrix and identified on the spreadsheet. The Risk Register is included in Appendix A.

5.0 Results

The FMEA identified 159 Failure Modes; 75 of these were evaluated as Low risk, 83 were evaluated as Moderate risk, and 1 was identified as Moderately High risk. No identified Failure Modes were evaluated as High or Very High risk. The key Failure Modes are discussed below by Project component.

5.1 Open Pits

Nineteen Failure Modes were identified for the Open Pits (Table 4). 10 Failure Modes were evaluated as being Moderate risk, and 9 were evaluated as being Low risk. Five Failure Modes were identified for Water Management (W), seven were identified for Physical Stability (P), and 8 were identified for Chemical Stability (C).

Table 4. Results of FMEA - Risk Ratings for Open Pits

Likelihood

		Consequence				

Notes: Open Pits (1.1)

The most significant risks identified (with a risk rating of 6) at this phase of Project development are **1.1P2**, **1.1P3**, and **1.1P5**. These risks are further summarized below:

- **1.1P2**. Pit wall failure – mass. Operations phase.
  - *Identified leading factors*: unanticipated rainfall volume, earthquake, geotechnical characteristics (different than anticipated)
  - *Consequence*: loss of life (multiple fatalities)
  - *Consequence Category*: Human Health and Safety
  - *Likelihood*: Rarely. Consequence Severity: Severe. Risk Rating: Moderate.
  - *Risk management controls*: Factor of safety in Open Pit Design, slope stability monitoring, Operations Management Plan
- **1.1P3**. Pit wall failure – mass. Reclamation and Closure phase.

- *Identified leading factors*: unanticipated rainfall volume, earthquake, geotechnical characteristics (different than anticipated)
- *Consequence*: loss of life (multiple fatalities)
- *Consequence Category*: Human Health and Safety
- *Likelihood*: Rarely. Consequence Severity: Severe. Risk Rating: Moderate
- *Risk management controls:* Factor of safety in Open Pit Design

- **1.1P5**. Pit wall failure – localized. Operations phase.
  - *Identified leading factors*: unanticipated rainfall volume, earthquake, geotechnical characteristics (different than anticipated)
  - *Consequence*: loss of life (multiple fatalities)
  - *Consequence Category*: Human Health and Safety
  - *Likelihood*: Rarely. Consequence Severity: Severe. Risk Rating: Moderate
  - *Risk management controls*: Factor of safety in Open Pit Design, Operations Management Plan

5.2 Waste Storage Facilities & Material Stockpiles

Forty three individual Failure Modes were identified for the WRSFs and material stockpiles (Table 5): 16 Failure Modes were evaluated as being Moderate risk, and 27 were evaluated as being Low risk. For all facilities, no Water Management (W) Failure Modes were identified.

For the Alpha WRSF, six Failure Modes were identified for Physical Stability (P), and 8 were identified for Chemical Stability (C). For the Beta WRSF, seven Failure Modes were identified for Physical Stability (P), and six were identified for Chemical Stability (C). For the Run of Mine (ROM) Stockpile, five Failure Modes were identified for Physical Stability (P), and one for Chemical Stability (C). For the Frozen Material Stockpile, two Failure Modes were identified for Physical Stability (P), and three for Chemical Stability (C). For the Overburden Stockpile, one Failure Mode was identified for Physical Stability (P), and four for Chemical Stability (C).

Table 5. Results of FMEA - Risk Ratings for Waste Storage Facilities & Material Stockpiles

		Consequence				

Notes: Alpha Waste Rock Storage Facility (2.1) and Beta Waste Rock Storage Facility (2.2); Run of Mine (ROM) Stockpile (2.3); Frozen Material Stockpile (2.4); Overburden Stockpile (2.5)

The most significant risks identified (with a risk rating of 6) at this phase of project development are **2.1P2**, **2.1P3**, and **2.2P3**. These risks are further summarized below:

- **2.1P2.** Mass slope failure – Alpha WRSF. Operations phase.
    - *Identified leading factors*: unanticipated rainfall volume, earthquake, geotechnical characteristics that are different than anticipated, unanticipated changes to permafrost, blockage of rock drain causing increased pore pressures in the WRSF
    - *Consequence*: failure of the facility resulting in no location to place waste rock
    - *Consequence Category*: Consequence Cost
    - *Likelihood*: Rarely. Consequence Severity: Severe. Risk Rating: Moderate
    - *Risk management controls*: Factor of safety in Alpha WRSF design, slope stability monitoring, Operations Management Plan
- **2.1P3.** Mass slope failure – Alpha WRSF. Operations phase.
    - *Identified leading factors*: unanticipated rainfall volume, earthquake, geotechnical characteristics (different than anticipated), unanticipated changes to permafrost, or blockage of rock drain increasing pore pressures in the WRSF
    - *Consequence*: failure of the facility resulting in fatalities to workers below
    - *Consequence Category*: Human Health and Safety
    - *Likelihood*: Rarely. Consequence Severity: Severe. Risk Rating: Moderate
    - *Risk management controls*: Factor of safety in Alpha WRSF design, slope stability monitoring, and Operations Management Plan
- **2.2P3.** Mass slope failure – Beta WRSF. Operations phase.
    - *Identified leading factors*: mass slope failure caused by unanticipated rainfall volume, earthquake, or geotechnical characteristics (different than anticipated) in the WRSF

- *Consequence*: failure of the facility resulting in fatalities to workers below
- *Consequence Category*: Human Health and Safety
- *Likelihood*: Rarely. Consequence Severity: Severe. Risk Rating: Moderate
- *Risk management controls*: Factor of safety in Beta WRSF design, slope stability monitoring, Operations Management Plan

5.3 Heap Leach Facilities

Forty seven individual Failure Modes were identified for the Heap Leach Facility and Event Ponds (Table 6): forty two Failure Modes were evaluated as being moderate risks, and five were evaluated as being low risk.

For the Heap Leach Facility, five Failure Modes were identified related water management, sixteen Failure Modes related to Physical Stability (P), and nine related Chemical Stability (C). For the Event Ponds, twelve Failure Modes were identified related Physical Stability (P), and five related to Chemical Stability (C). No Water Management (W) Failure Modes were identified for the Event Ponds.

Table 6. Results of FMEA - Risk Ratings for Heap Leach Facilities

Likelihood						
	5					
	4		3.2P12			
	3		3.1W2,3.1W4, 3.1P14, 3.1C1,3.2P9, 3.2C3	3.1W3 3.1W5 3.1P13 3.1P15		
	2		3.2P10 – 11 3.2C4 – 5	3.1P4 – 5, 3.1P9 – 12 3.1C6 – 9 3.2P7 – 8 3.2C1 – 2	3.1W1 3.1P1 – 3 3.1P6 – 7 3.1P16 3.1C3 – 4	
	1	3.1C2			3.2P2 – 6	3.1P8 3.1C5 3.2P1
		1	2	3	4	5
		Consequence				

Notes: Heap Leach Facility (3.1); Event Ponds (3.2)

The most significant risks identified (with a risk rating of 6) at this phase of project development are 3.1W1, 3.1W3, 3.1W5, 3.1P1, 3.1P2, 3.1P3, 3.1P6, 3.1P7, 3.1P8, 3.1P13, 3.1P15, 3.1P16, 3.1C3, 3.1C4, 3.1C5, 3.2P1, 3.2P12. These risks are further summarized below:

- **3.1W1.** Too much water in HLF (impact of raincoats), impacting the Event Pond's ability to hold PMP event. Operations phase.

- *Identified leading factors*: increased precipitation compared to the Water Balance Model (i.e., experienced rainfall higher than current climate model suggests).
- *Consequence*: mine operations would cease until the PMP capacity of the HLF is restored.
- *Consequence Category*: Regulatory and Legal.
- *Likelihood*: Unlikely. Consequence Severity: Major. Risk Rating: Moderate.
- *Risk management controls*: Water Balance Model to be updated dynamically, and Operations Management Plan.

- **3.1W3.** Insufficient water in HLF. Operations phase.
  - *Identified leading factors*: drought, insufficient water quantities not being captured at freshet, or not optimizing planning.
  - *Consequence*: delay in the start of leaching ore.
  - *Consequence Category*: Human Health and Safety.
  - *Likelihood*: Moderate. Consequence Severity: Possible. Risk Rating: Moderate.
  - *Risk management controls*: Operations Management Plan.
- **3.1W5.** Freezing of heap. Operations phase.
  - *Identified leading factors*: experiencing temperatures consistently below anticipated temperatures.
  - *Consequence*: limit ability to stack ore on the HLF to six months per year.
  - *Consequence Category*: Consequence Cost.
  - *Likelihood*: Possible. Consequence Severity: Moderate. Risk Rating: Moderate.
  - *Risk management controls*: Robust thermal modelling and appropriate equipment sizing.
- **3.1P1 – 3.1P3.** Slope Failure of HLF. Operations, Reclamation and Closure phase, slope destabilization due to ground characterization, changing ground conditions (i.e. permafrost), high rain events, earthquake, or loss of permeability of heap causes a significant slope failure significant so that ore leaves containment and contaminates Latte or Halfway Creek.
  - *Identified leading factors*: slope destabilization due to ground characterization, changing ground conditions (i.e. permafrost), high rain events, earthquake, loss of permeability of heap.
