Seismic Hazard Assessment for Minto, YK

1- Introduction

A limited site-specific seismic hazard analysis has been performed for the site of a tailings facility near Minto, Yukon (62.62N 137.23W), for annual exceedence probabilities in the range from 1/100 to 1/10,000 per annum (p.a.). The rationale and input parameters for the hazard assessment are provided in Sections 2 to 4. Section 5 provides the ground-motion parameters determined in this study for a range of probability levels.

The analysis determines the likelihood of ground motion at the site by considering the magnitudes, rates of occurrence, and locations of earthquakes throughout the region, using the probabilistic Cornell-McGuire method. The method is widely used throughout North America and forms the basis for seismic zoning maps in building codes in Canada (Adams and Halchuk, 2003; Halchuk et al., 2014). This assessment represents an update and refinement of the type of estimate provided in the 2005 and 2010 National Seismic Hazard maps by the Geological Survey of Canada (GSC), both of which were based on the model described by Adams and Halchuk (2003). The results of this study consider the effects of major uncertainties on the hazard at the site, and incorporate up-to-date information on seismicity and ground motion prediction equations (GMPEs), which have evolved considerably over the last 10 years (e.g. see Atkinson and Goda, 2011; Atkinson and Adams, 2013 for discussion). The model employed here makes use of information developed for the new national seismic hazard maps of Canada produced by the GSC, which have been approved for incorporation into the 2015 National Building Code of Canada (NBCC) (Halchuk et al., 2014). Additional factors that are important to the Minto site, but not evaluated in the national-level model, are also considered. We note that this analysis addresses natural seismicity, and does not address the probability of potential induced seismicity sources, if any.

In analyzing the engineering effects of ground motion, both the amplitude and frequency content of the vibrations are important. Therefore the seismic ground motions are expressed using the response spectrum (PSA(f)), which shows the maximum acceleration that a simple structure would experience as a function of its natural frequency. The response spectrum result is a Uniform Hazard Spectrum (UHS), in which the amplitude for each frequency corresponding to a specified exceedence probability is provided. The peak ground acceleration (PGA) for this probability is also estimated, as is the peak ground velocity (PGV). The frequency associated with the PGA varies, but in general the PGA is associated with high-frequency motions (near 10 Hz); the PGV is associated with motions near 2 Hz. The UHS results of this study are presented in the figures and tables provided in Section 5.

We perform hazard calculations at the site for NEHRP B/C conditions (near-surface shear-wave velocity of 760 m/s); this is the reference site condition for the results. These results would apply to facilities at or near the site, provided it is founded on NEHRP B/C or a similar soft-rock condition. The results can be adjusted for site class A to be applicable to very hard rock site conditions (shear-wave velocity >1500 m/s), using conversion factors that represent average site amplifications for such conditions. The conversion factors for correcting results to site class A are given herein.

2 – Seismicity and Tectonic Setting

The Minto site is located in an area of moderate seismicity and complex geology. The active Denali fault system lies >100 km to the south, while the less-active Tintina fault lies to the north. The less-known Teslin fault passes near the site, and could be associated with moderate seismicity. In view of the geological complexity of the site area, a desktop fault study was conducted by SRK (Kramer, 2015). Figure 1 highlights the main findings of that study with regards to faults in the site area that may be associated with seismicity. It is noted that although the Teslin fault is the most prominent, the site area is traversed by a network of faults. The major faults identified by SRK include the northwest-trending Denali, Tintina, Teslin, Coghlan, and Big Creek faults, and the north northwest-trending Braeburn, Towhata, and Big Salmon faults. SRK recommended to treat the Teslin fault as a fault system with distributed seismicity. Specifically, Kramer (2015) recommended the faults be considered as an areal zone, roughly 23 km measured at surface across the Minto mine in a northeast-southwest direction (perpendicular to the strike of the faults), and extending 100 km beyond the Minto mine to the northwest.

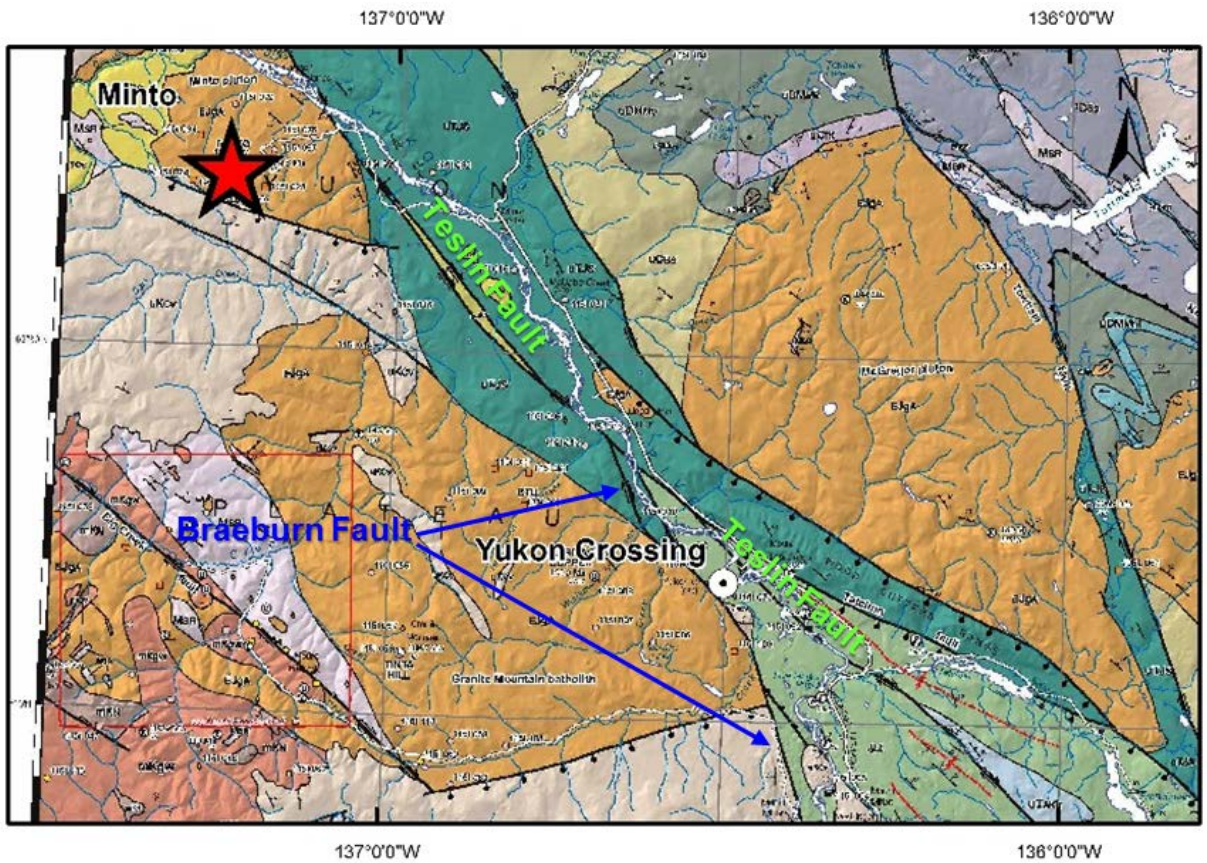

Figure 1 – Faults intersecting near the Minto site, from Kramer (2015) memorandum. Minto site is indicated by the red star.

Figure 2 shows the seismicity in the region around the site in relation to seismotectonic source zones considered in this study. Within the new seismic zoning models developed by the Geological Survey of Canada for the 2015 National Building Code of Canada (Halchuk et al., 2014), the Minto area lies within the YUS areal source zone. This is a very broad areal source zone that apparently contains non-homogeneous seismicity, with events tending to preferentially occur close to the Tintina and Teslin faults, at least in some regions (by inspection of Fig. 2). The GSC model uses fault sources for the active Denali faults to the south, but does not explicitly model the Tintina or Teslin faults, probably because these faults are less active, and there is less available information about them. Site-specific aspects such as the relationship of a site to particular potential seismic sources are not generally considered in the overview-level treatment of seismic sources that is incorporated into the national hazard maps.

We examined the GSC national model to consider the potential impact of defining an areal source zone for the observed seismicity in the region of the Teslin fault and its extension. Because the site lies within this zone, the hazard will be sensitive to how its seismicity is modeled. (By contrast, the Tintina fault is far enough away that hazard is less sensitive to how it is modeled.)

We considered defining a specific source zone to represent the network of faults identified by SRK, as shown by the irregular polygon source on Figure 2 (in which the points of the polygon were provided by Kramer). However, a careful examination of the seismicity at the M>2.7 level reveals that there is no concentration of seismicity in this zone relative to the average rate observed in the YUS zone as a whole. We verified through preliminary hazard calculations that defining this as a separate source, based on the observed rates of M>2.7 events, does not impact the calculated hazard.

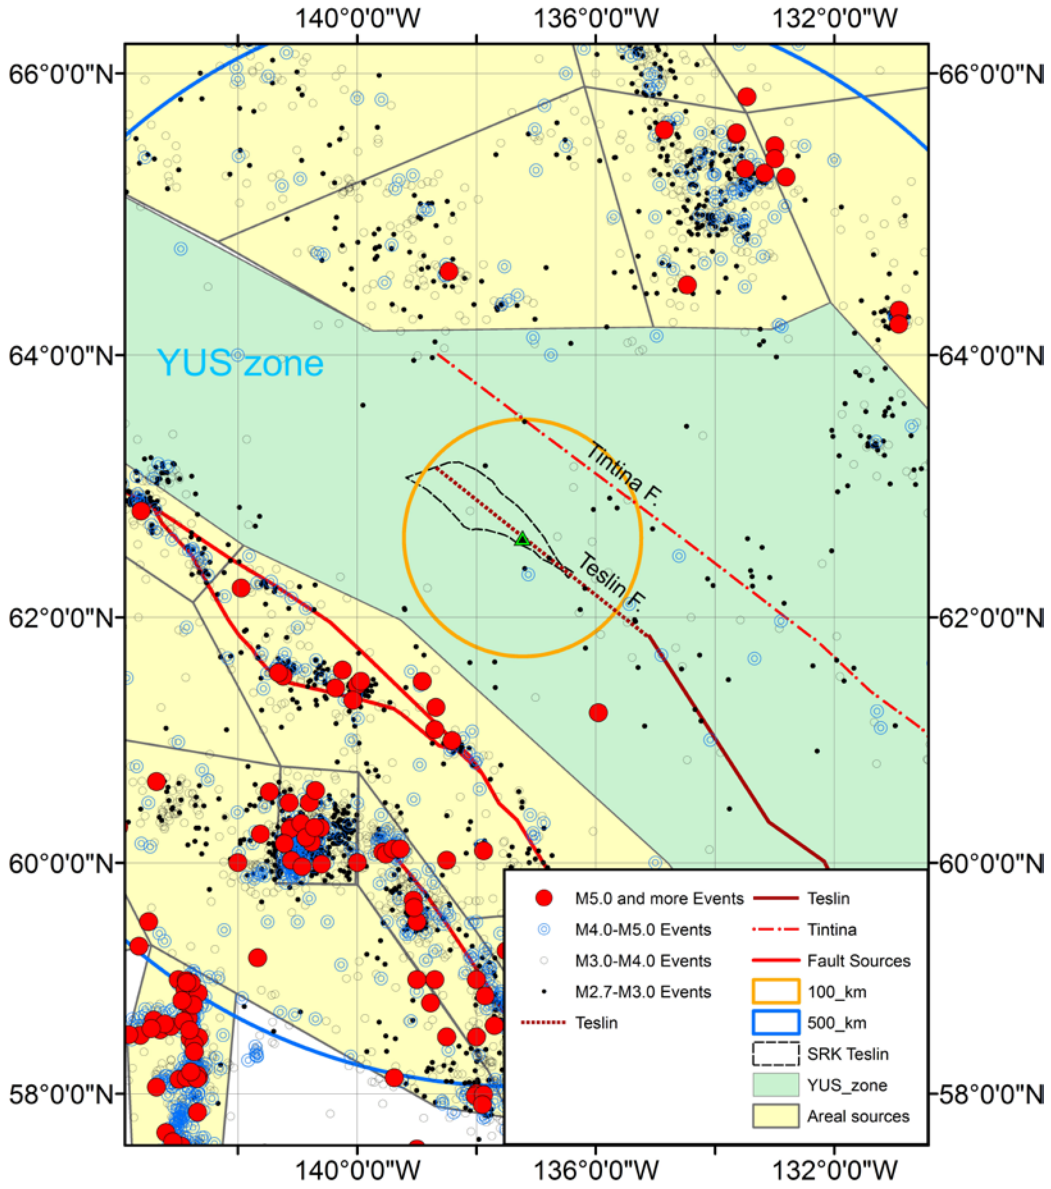

Figure 2 – Historical Seismicity in the Minto area, showing all events of M>2.7 in the catalog within approximately 500 km of the site. Note that the catalog is not complete at lower magnitude levels. We show the regional sources defined in the GSC 2015 model (the solid red lines are the Denali fault sources, the grey lines are areal source zone boundaries, with the YUS zone shown in green). We also show the approximate trace of the Tintina and Teslin Faults as dashed red lines. The dashed black lines outline an alternative source model that contain a group of faults, as suggested by SRK.

While examining the seismicity that might be associated with the network of faults in the site area in detail, we noted that there is an apparent linear trend of low-level (M2 to 2.5) seismicity that passes through the site area, approximately perpendicular to the trace of the Teslin fault. This apparent seismicity trend is shown in Figure 3. Although these events are listed as earthquakes in the Geological Survey of Canada catalogue, a close inspection reveals that they must in fact be blasting events. In addition to the narrow range of magnitudes that they exhibit, we note that if one looks at the time of day of the events, plotted in Figure 4, they occur almost exclusively between 8am and 7pm local time, with most events occurring between 4pm and 6pm – this is characteristic of blasting activity. Therefore we filtered out all events of M<2.7 (thus excluding potential blasts that may have been misidentified as earthquakes) to properly examine the regional seismicity with relation to the faults (Figure 2). Our conclusion is that, in the absence of evidence to suggest geologically-recent activity associated with the faults in the site area, the seismicity environment is best represented by the broad YUS areal source zone. It is recognized that within this broad source zone seismicity occurs at a moderate rate on a diffuse network of faults, which may or may not be recognized in surface expression.

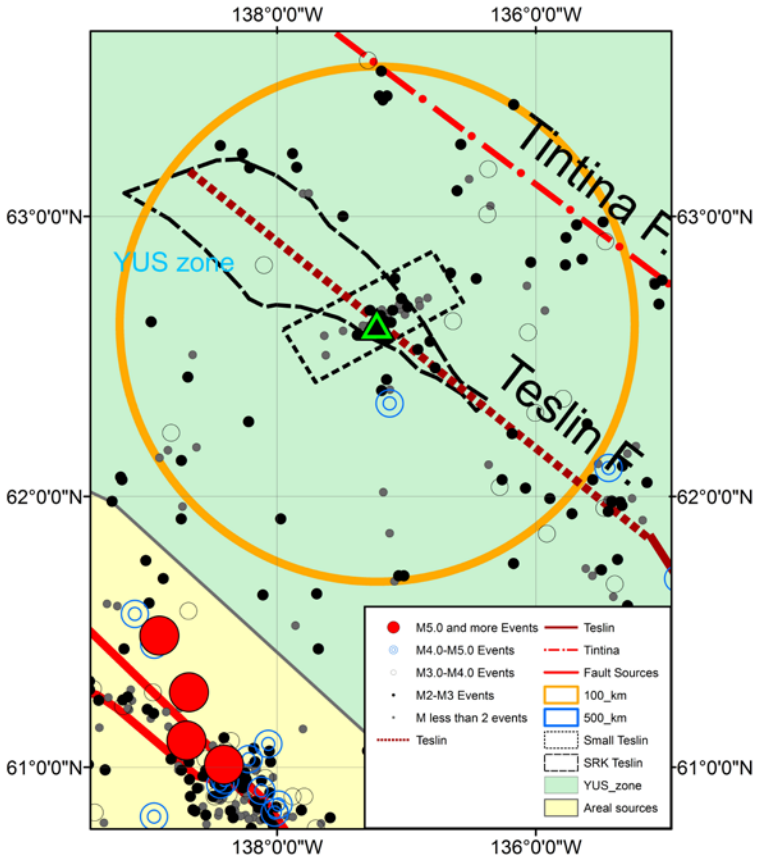

Figure 3 –Enlargement of alternative definitions of the Teslin areal zones. The small dashed black line shows an apparent linear trend of seismicity (see Figure 4). The large dashed black line outlines the fault zone surrounding the Teslin fault as defined by SRK. Dotted red line shows main trend of Teslin fault.

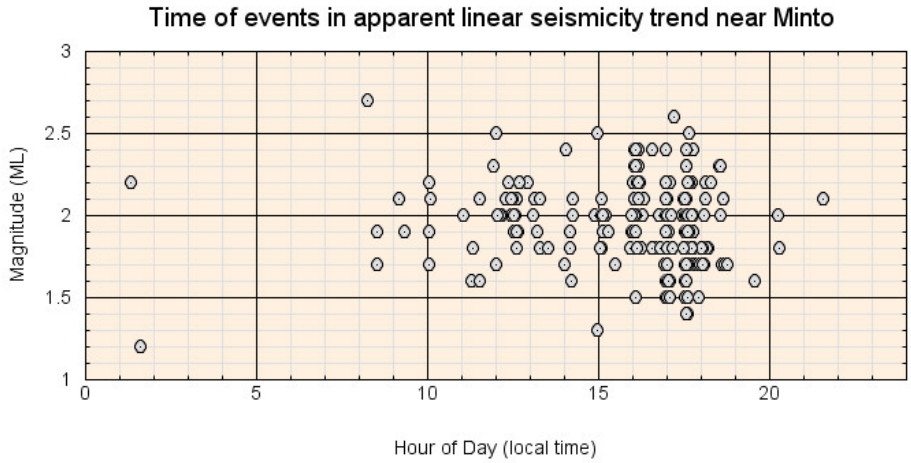

Figure 4 – Plot of time of day in which the events within the apparent linear trend of seismicity noted in Figure 3 occur. Because the events occur almost exclusively between 8am and 7pm, with most being clustered from 4pm to 6pm, we conclude these are actually blasts, not earthquakes.

3 - Seismic Hazard Methodology

We conduct the seismic hazard analysis for Minto using the EqHaz software (Assatourians and Atkinson, 2013). This is an open-source software package that performs probabilistic seismic hazard analysis according to the Cornell-McGuire method, using a Monte Carlo algorithm. It has been validated by checking against the results of FRISK88 as implemented by the Geological Survey of Canada, at selected cities, as described in Assatourians and Atkinson (2013). Furthermore, it was validated for this particular project by checking that the calculated 1/2500 per annum (p.a.) ground motions obtained using EqHaz, for the standard GSC-2015 hazard model, closely match the corresponding results obtained by GSC for the national hazard maps, at a nearby site.

Seismic hazard analyses in Canada are based on probabilistic concepts which allow incorporation of both geologic interpretations of seismic potential and statistical data regarding the locations and sizes of past earthquakes. The Cornell-McGuire method (Cornell, 1968; McGuire, 1976, 1977, 1995; Risk Engineering, 1988) has proven particularly well-suited to calculate expected ground motions for a wide range of seismic hazard environments, offering flexibility in the consideration of spatial and temporal characteristics of regional earthquake occurrence, and the basic physics of the earthquake process.

The spatial distribution of earthquakes is described by defining seismic source zones (areas or faults) on the basis of seismicity and seismotectonic interpretations. The earthquake potential of these zones is often assumed to be spatially uniform; however, an alternative is a “smoothed seismicity” approach, in which the spatial distributions of past event clusters drives the expected seismicity pattern. The GSC uses the uniform seismicity approach exclusively in national

seismic hazard mapping, as the software they are currently using does not have the capability to implement the smoothed-seismicity approach. The U.S. Geological Survey uses a smoothed-seismicity approach (Petersen et al., 2008). In this study, we consider both alternatives.

The frequency of earthquake occurrence within each source zone is described by a magnitude recurrence relationship, truncated at an upper magnitude bound, Mx. Earthquake ground motion prediction equations (GMPEs) provide the link between the occurrence of earthquakes of various magnitudes and the resulting ground motion levels at any site of interest. The probability of exceeding a specified level of ground motion at a site can then be calculated by summing up the hazard contributions over all magnitudes and distances, including all source zones. In most cases, including this study, the hazard is generally dominated by contributions from the source zone within which the site is located – although sometimes active distant sources can be important contributors to long-period hazard. The hazard integral sums up the likelihood of earthquakes at all distances within all source zones, assuming that earthquakes are distributed randomly in space across the source zone (or alternatively by using a spatial smoothing algorithm to consider the historical distribution of seismicity patterns more closely). To obtain ground motion levels or earthquake response spectra for a specified probability, calculations are repeated for a number of ground motion values, for all desired ground motion parameters, and interpolation is used to determine the relationship between ground-motion amplitude and annual probability.

The Cornell-McGuire framework has been well-accepted in all parts of North America. In Canada, it forms the basis for the seismic hazard maps in the National Building Code of Canada (NBCC, 1985 and beyond), and is the usual basis for seismic hazard evaluations of all important engineered structures. The results are generally expressed as a Uniform Hazard Spectrum (UHS), in which the amplitude for each frequency corresponding to a specified target probability is provided. The peak ground acceleration (PGA) and velocity (PGV) for the target probability may also be estimated. When time histories of ground-motion are required for use in engineering analyses, these may be derived to be consistent with the expected ground motion characteristics of the UHS for the target probability (e.g. McGuire, 2004).

The calculations are carried out using the EqHaz program set developed by Assatourians and Atkinson (2013) (www.seismotoolbox.ca/EQHAZ.html). This program performs probabilistic seismic-hazard analysis (PSHA) by the Monte Carlo simulation method (Musson, 1998, 1999, 2000, 2012a; Hong and Goda, 2006; Assatourians and Atkinson, 2013). The program can handle areal and fault sources with magnitude-recurrence statistics as described by Gutenberg–Richter (untruncated, truncated, or tapered), or a user-specified discretized cumulative or incremental magnitude-recurrence distribution. Ground-motion amplitudes are modeled as user-specified functions of magnitude and distance (in a table format). Both epistemic and aleatory uncertainty in the key input parameters can be modeled. The user may treat these uncertainty sources as equivalent (in terms of our ability to predict future ground motions), enabling the treatment of ground motions realized over a long simulated catalog as an extreme-value statistical problem. Alternatively, the user may treat epistemic uncertainty separately using confidence fractiles on

the input parameters, which has been traditional practice (e.g., McGuire, 2004). The mean-hazard results, which are the focus of this study, are not sensitive to this choice.

To utilize the capabilities of EqHaz, we require a description of seismic hazard parameters and their uncertainties. This includes the delineation of the region into alternative source zone models (which may include both areal sources and fault sources), representing alternative tectonic interpretations of the seismicity, with estimates of the likelihood that each zonation model is the 'true' model. Within each source model, alternative geometric configurations (and associated weights) may be specified for each individual source, if desired. For this study, the main focus is on the regional hazard model defined by the GSC for the 2015 national hazard maps, including its alternative seismicity parameters. However, we also examined the implications of faults not modeled in the GSC model, specifically the Tintina and Teslin faults. We evaluated the sensitivity of the hazard calculations to alternative treatments of seismicity that appears to be associated with these faults.

For each source zone of each model, magnitude recurrence parameters and their uncertainty are modeled by alternative No, beta pairs (eg. rate and slope of the Gutenberg - Richter recurrence relation), with associated weights. Three pairs were used for each source zone. Maximum magnitudes for each source zone were also specified by three alternative values. For each ground motion parameter, three alternative GMPEs were defined; parameters included the 5% damped pseudo-acceleration (average horizontal component), for frequencies of 0.2 to 20 Hz, plus peak ground acceleration and velocity. The alternatives for each input parameter and their weightings follow the GSC 2015 national seismic hazard model, with one exception. The exception is that we also consider a smoothed-seismicity representation of the distribution of epicenters, which better models the spatial distribution of seismicity within the zones. This may help to consider the implications of fault zones that lie within areal sources, which may act to concentrate seismicity over the regional background levels.

4 - Input Parameters for Seismic Hazard Analysis at Minto

To explore the main uncertainties in seismic hazard assessment at Minto, while keeping the scope of the study limited, we have used the GSC national hazard model (as summarized in Halchuk et al., 2014, and Atkinson and Adams, 2013) as a starting point, then added in consideration of the uncertainties that are specific to the Minto site, including information from the geological report on faulting in the site area prepared by SRK (Kramer, 2015). In essence, we use the GSC regional model, but examine the implications of alternative definitions for the seismogenic source zone in which Minto is located, in particular considering the potential sensitivity of hazard to major faults that are near the site (the Tintina and Teslin faults). We also consider uncertainty in the distribution of events within zones, by considering a smoothed-seismicity model that better reproduces concentrations of events that have occurred historically within the source zones. For the smoothed seismicity model, and for consideration of fault activity, we use the Canadian Composite Seismicity Catalogue (CCSC), updated to 2013. The Appendix lists the model parameters employed in the analysis by EqHaz, which follow those used by the GSC in the national hazard maps for 2015.

Source Zones

Known seismicity in the Minto region is mapped in Figure 2, along with the source zones used to characterize seismicity in the Minto region region. The seismicity is taken from the Canadian Composite Seismicity Catalogue (CCSC) (see Fereidoni et al., 2012); information downloaded from the GSC website (www.earthquakescanada.nrcan.gc.ca) is also considered in Figures 3 and 4. All catalogue events for Figure 2 were converted from local magnitude scales to moment magnitude as required, as described in Fereidoni et al. (2012). Most of the events in the catalogue are local magnitude (ML), which was converted to moment magnitude (**M**), using **M**= ML-0.18. This relationship was developed using empirical correlations between **M** and ML for events in the region.

The areal source zones follow those defined by the GSC. In addition to using the GSC approach of assuming uniform seismicity within each zone, we also consider the sensitivity of results to use of the smoothed-seismicity approach, in which epicenters tend to cluster in a manner similar to their historical distribution. The GSC includes fault-source zones for the Denali faults (shown in red in Figure 2; parameters as given in Appendix A).

In the GSC model, a very large geographic region is included within the YUS source zone. Based on examination of the seismicity and major regional faults, it appears that the seismicity within YUS is in places concentrated along the trends of the Tintina and Teslin faults. Moreover, the Teslin fault is part of a complex system of faults in the site area, as documented by SRK (Kramer, 2015). The properties of these faults are not well known, probably due in part to the remoteness of the area. As discussed in Section 2, a careful evaluation of the seismicity in the area led us to the conclusion that it is best modeled using the broad YUS source zone. To consider the implications of clustering of seismicity with the YUS zone, along potential fault sources that it may include, we consider both the uniform and smoothed-seismicity spatial distributions.

Our seismic hazard assessment explicitly considers the influence of all source zones within a 300 km radius of Minto. There are additional active zones at greater distance, but these are too far away to contribute significantly to hazard, relative to the nearby sources. A possible exception is that at long periods (>2 s), there may be a significant contribution to hazard from the subduction zone bordering Alaska. We treat this subduction source deterministically, by considering a M9 scenario event at a distance of 530 km (approximate distance for the nearest approach of the subduction zone). Ground motions from this event will be assessed at the median plus sigma level, and compared to the results from the probabilistic hazard assessment. For this exercise, the medium-level subduction GMPE as given in Atkinson and Adams (2013) (at the +sigma level) is used.

Magnitude Recurrence Relations

Recurrence data, expressing the relative frequency of occurrence of earthquakes within a zone as a function of magnitude, can generally be fit to the Gutenberg-Richter relation:

$$\text{Log } N(M) = a - b\,\mathbf{M}$$

where N(M) is the number of events per annum of magnitude **≥M**, **M** is moment magnitude, and *a* and *b* are the rate and slope of the relation. (Note: various types of truncation to a maximum magnitude can be applied to the above expression; in EQHAZ we use an exponential truncation.) In most parts of the world, *b* values are in the range from 0.8 to 1, while *a* values vary widely depending on the activity level of the region.

For this study, as we have adopted the recently-developed source zone models of the GSC, we likewise adopt their magnitude-recurrence relations for all zones (from Halchuk et al., 2014). These recurrence relations were calculated with a maximum likelihood algorithm, using the seismicity data of the SHEEF2011 moment-magnitude catalog of the GSC (Halchuk et al, 2014). The SHEEF2011 catalog (Geological Survey of Canada) is very similar to the Canadian Composite Catalog of Fereidoni et al. (2011). The magnitude recurrence relations for the most critical zone, the YUS zone, is shown in Figure 5, including the best-estimate rates, and upper and lower alternative curves that express uncertainty in the recurrence rates; the uncertainty in the maximum magnitude is also shown.

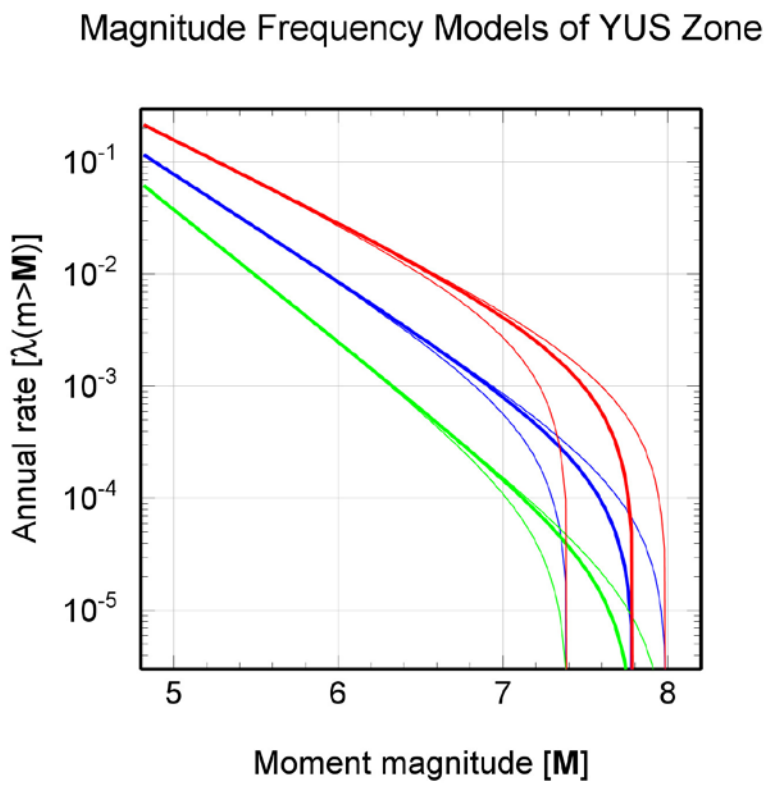

Figure 5 – Recurrence Relations for the YUS (Yukon South) zone. The best-estimate (most-heavily weighted) is the heavy blue line, while red line shows upper-branch recurrence model and green line shows lower-branch recurrence model. Each alternative relation (line) is associated with three alternative Mx (maximum magnitude) values (low, best, high).

The complete set of seismicity parameters for all zones as implemented in this study are given in the Appendix. For all zones outside the YUS the contributions to hazard at Minto will be relatively modest by comparison. For all zones we follow the distributions of the recurrence relations and maximum magnitudes used by the GSC.

The implemented source model incorporates epistemic uncertainty in recurrence parameters and maximum magnitudes. For the minimum magnitude, we used a value of 4.8, consistent with the GSC value. For the maximum magnitude, the range of considered values in the YUS zone is from **M**7.4 to **M**8.0. Larger events, up to **M**8.4, are considered for the Denali fault zone. The relative weights for the alternative models follow those used by GSC, as provided in the Appendix.

An additional modification to the GSC approach that we consider concerns the distribution of seismicity within the zones. In the GSC model, the seismicity within each zone is assumed to be uniformly distributed in space over the entire zone. We consider also an alternative, in which the spatial smoothing algorithm described by Assatourians and Atkinson (2013) is implemented. The spatially-smoothed seismicity more nearly accords with historical clustering of seismicity within each zone (as based on the Canadian Composite Catalog). The spatial smoothing approach is similar to that implemented by the USGS (Petersen et al., 2008). This provides a test of the sensitivity of results to the spatial distribution of events, and its unevenness in some zones.

The completeness intervals used in interpreting the historical seismicity distribution for the spatial-smoothing model are as follows (where it is assumed that the historical catalog is complete for each magnitude level beginning with the years quoted):

Year to begin statistics:

M3.0	**M**3.8	**M**4.3	**M**4.8	**M**5.3	**M**5.8	**M**6.3	**M**7.2
1979	1972	1965	1962	1951	1935	1917	1899

Ground motion prediction equations

Ground motions for the reference ground condition of B/C boundary are given in this analysis by the ground-motion prediction equations (GMPEs) of Atkinson and Adams (2013) for crustal events in western North America (WNA). The equations provide peak ground acceleration (PGA) and velocity (PGV), as well as response spectra (PSA, 5% damped horizontal component) as a function of moment magnitude and distance. The equations were developed considering the alternative GMPEs available from the NGA-West1 project. To consider epistemic uncertainty in the median GMPEs, Atkinson and Adams define a central, lower, and upper suite of GMPEs for input to the hazard analysis. These alternatives were defined by considering alternative proposed GMPEs for WNA, and the data that guided them. The central (preferred) curve follows the Boore and Atkinson (2008) GMPE, as updated by Atkinson and Boore (2011); this is referred to as BA08'. Low and high alternative curves were defined considering uncertainty as indicated by the alternative NGA-West GMPEs (shown in Figure 6), and the constraints on these curves suggested by the data from which they were developed. The epicentral distance version of the

Atkinson and Adams equations is used for areal sources, as the events are treated as point sources in the hazard analysis, with appropriate conversions from finite-source to point-source distance metrics implemented as described by Atkinson and Adams (2013).

We considered these three alternative GMPEs with weights of 0.5 (middle), 0.3 (upper) and 0.2 (lower). The considered suite of ground-motion relations is shown on Figure 6 for NEHRP B/C site conditions (random horizontal component). Conversion of results to other site conditions is discussed in Section 5.

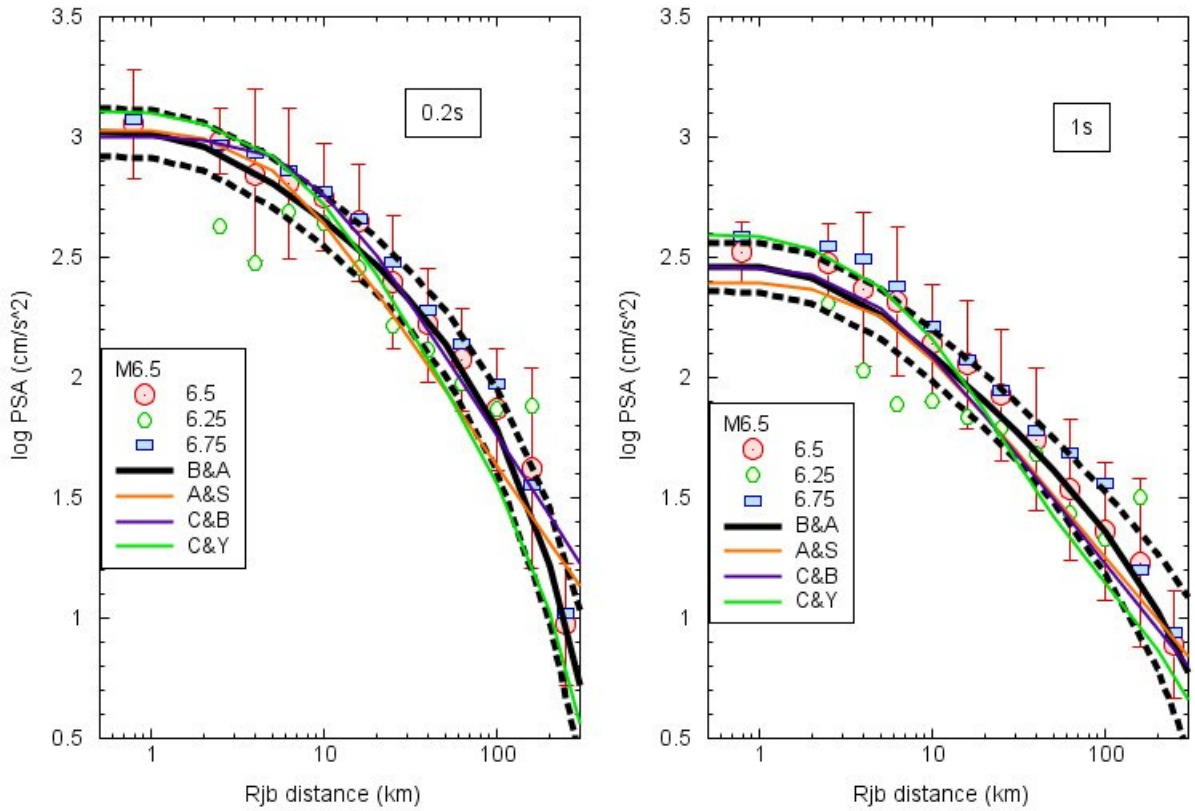

*Figure 6 – Proposed lower, central and upper GMPEs, for **M**6.5 crustal events in WNA. Solid black line is central equation (BA08'); dashed black lines are lower and upper equations, obtained by adding and subtracting delta from the central equation. Solid lines show other PEER-NGA equations. Symbols show means of the log amplitudes for various 0.5 unit magnitude bins; error bars show standard deviation for the M6.5 magnitude bin. (from Atkinson and Adams, 2013)*

Random uncertainty in the GMPEs was modeled by a lognormal distribution of ground motion amplitudes about these median relations, with a standard deviation of 0.23 log (base 10) units for high frequencies, increasing to 0.27 units at low frequencies. This random uncertainty is consistent with recent studies (eg. Atkinson, 2012; Atkinson and Adams, 2013).

Ground-motion prediction equations are also required to consider the deterministic scenario postulated for the subduction zone bordering Alaska. For this event, we use the "weighted-

mean" GMPE of Atkinson and Adams (2013) for a **M**9 subduction event at 530 km, multiplied by a factor of two to provide median plus one sigma motions (approximately).

5 - Seismic Hazard Results for Minto

Figure 7 provides the mean-hazard curves for the Minto site for a selection of frequencies, showing how the amplitude of motion increases as the probability of its exceedence decreases. The calculations are performed for a B/C reference site condition (near-surface shear wave velocity of 760 m/s). We show hazard curves for both the uniform and smoothed-seismicity distribution of seismicity. It is noted that the results are very similar. Our preferred model is that from the uniform-seismicity approach as it is slightly more conservative, yet not so different as to suggest that the uniform-seismicity distribution is unreasonable for the site area.

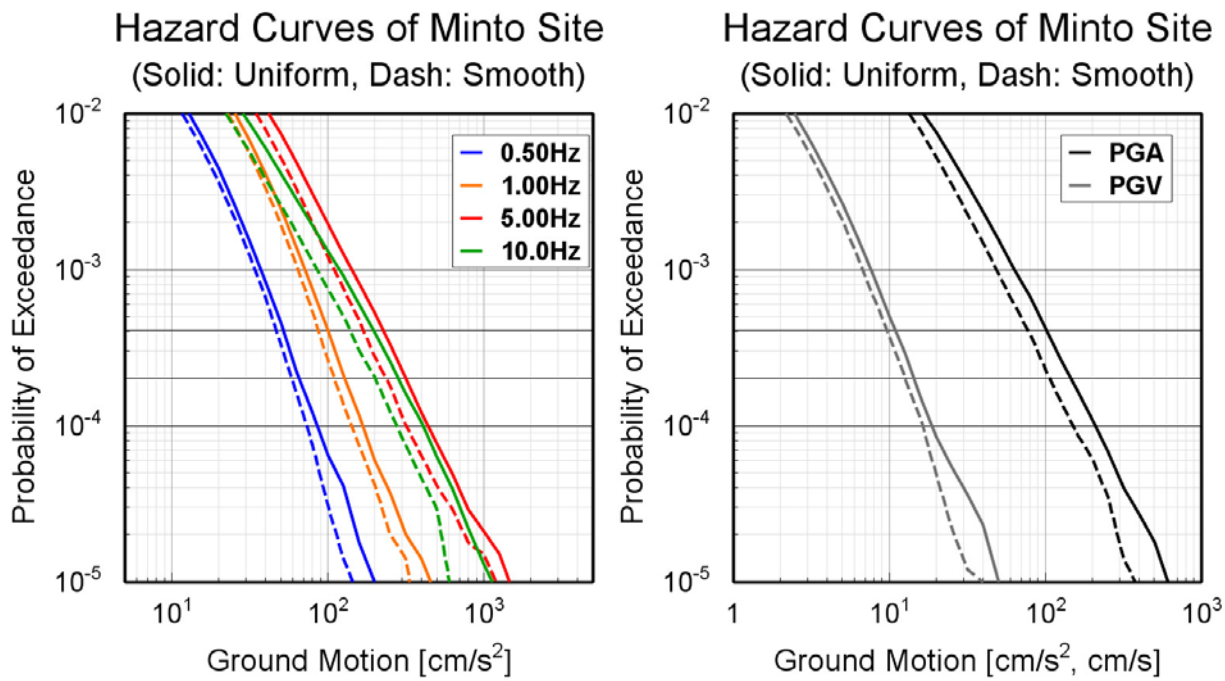

Figure 7 – Mean-hazard curves for Minto for selected frequencies(B/C site conditions). Both the uniform-seismicity and the smoothed-seismicity spatial distribution implementations are shown.

Figure 8 provides an overview of mean-hazard results for a range of probabilities, for B/C conditions (the reference condition, for which all hazard calculations were performed). Probability levels of 0.01 to 0.0001 per annum, corresponding to "return periods" of 100 to 10,000 years, are shown; note that the return period is simply the inverse of the annual probability. The results are given as a Uniform Hazard Spectrum (UHS), in which the mean-hazard motion for each spectral frequency is plotted for a specified probability of exceedence. The peak ground acceleration (PGA) is plotted at 90Hz for reference, even though it does not correspond to a specific frequency.

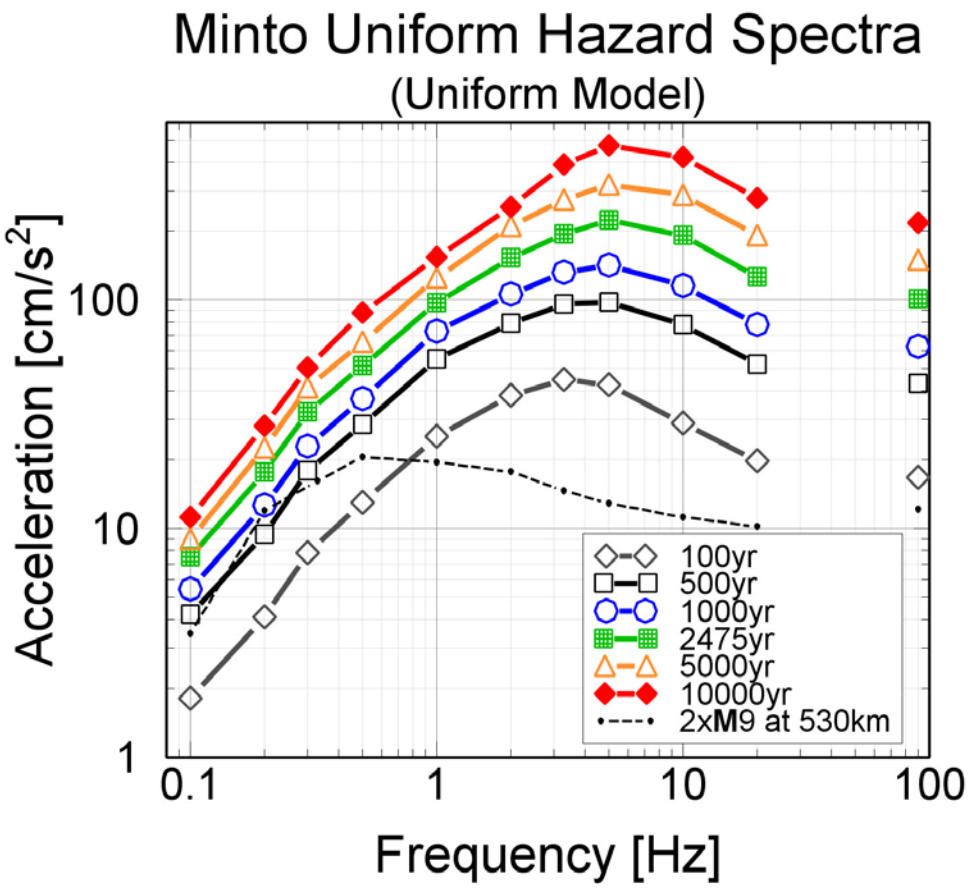

*Figure 8 – Mean-hazard Uniform Hazard Spectrum (UHS) at Minto for a range of return periods (B/C conditions). Deterministic scenario motions for a **M**9 subduction event at 530 km are also shown (the median **M**9 motions are multiplied by a factor of two to represent median + one standard deviation amplitudes). PGA is plotted for reference at a frequency of 90Hz. The uniform seismicity model is assumed.*

Table 1 presents the plotted values in cgs units, while Table 2 presents the equivalent values in units of g (where 1g=980 cm/s^2). (Note: these values use the uniform-seismicity assumption within each source zone.) We also include conversion factors if results are desired for hard-rock site conditions (NEHRP A with near-surface shear wave velocities of >2000 m/s) or NEHRP C (firm ground, with near-surface shear wave velocities of 450 m/s). The conversion to NEHRP A follows that given in Atkinson and Adams (2013), while the conversion to C follows that being recommended for the 2015 NBCC.

The ground-motion spectrum for the **M**9 deterministic scenario subduction median+sigma event at 530 km is also shown on Figure 8 and in Table 1. The motions from this event are much less than the UHS at all frequencies, for return periods of 1000 years and greater. Therefore the **M**9 scenario can be neglected, except for any facilities that may be sensitive to low amplitudes of shaking with very long duration.

On Figure 9, the UHS is compared to the motions in the current (2010) building code. To make the comparisons applicable to the same site condition, the building code results for Class C were first reduced to the equivalent values for B/C, dividing by the B/C to C factors shown in Table 1. The increase in the UHS relative to the 2010 NBCC values largely reflects additional modeled fault sources in the region, as well as updated representations of ground motions and their uncertainty. Moreover, it may be noted that both this study and the 2015 GSC model provide mean-hazard spectra, whereas the 2010 model is closer to median-hazard.

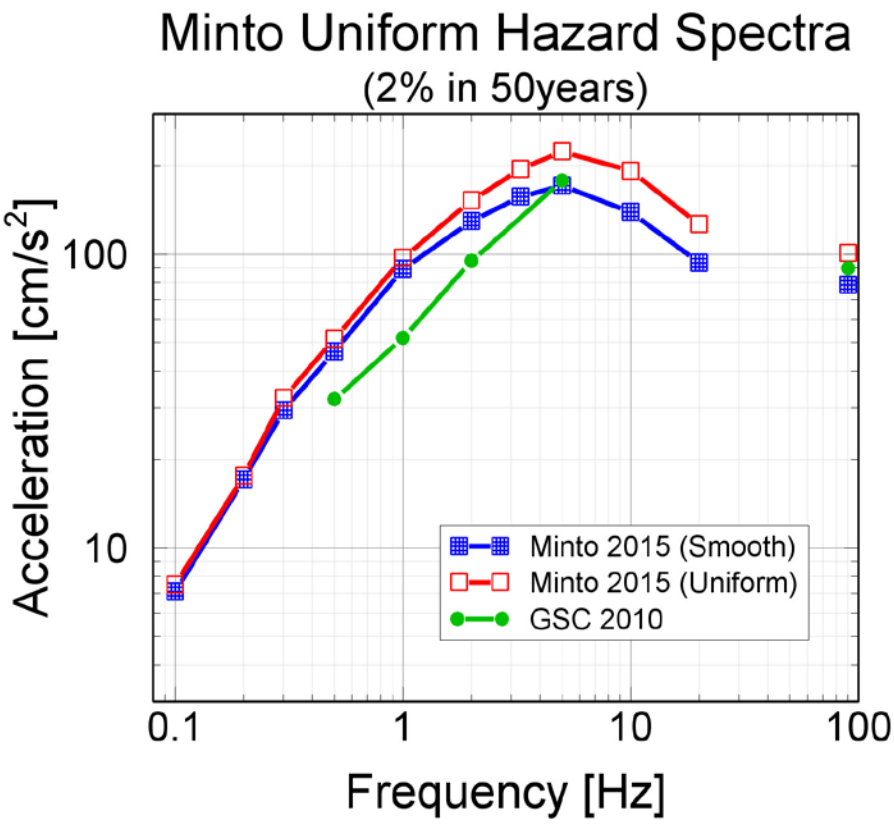

Figure 9 – Comparison of mean-hazard spectrum for Minto at 1/2500 p.a.(2% in 50 years) with results from 2010 building code values, all for B/C site conditions. PGA plotted at 90 Hz for reference. GSC 2010 model is derived from GSC online automatic calculator and converted to B/C site class, while Minto 2015 model is based on implementing 2015 NBCC model in EqHaz.

The seismic hazard can be deaggregated to show the dominant contributions to the hazard at any probability level as a function of magnitude and distance. Figure 10 presents such deaggregations, for selected frequencies, for the 1/10,000 p.a. probability. Note that

deaggregations for the 1/2500 p.a. probability are similar, except that the weights of the distributions shift to slightly closer distances, and slightly lower magnitudes.

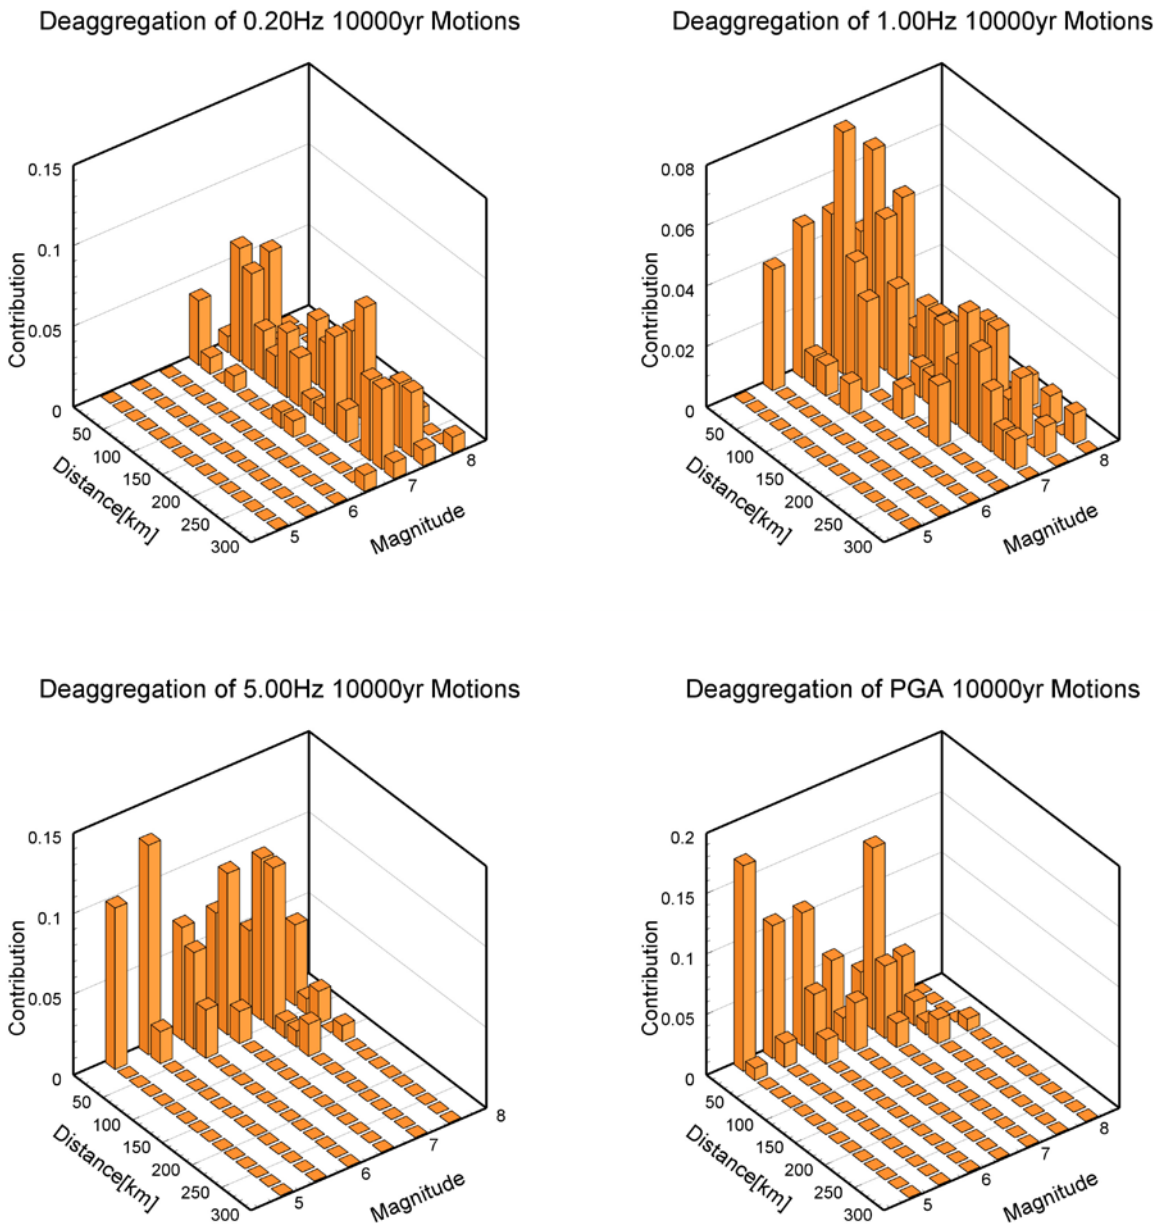

Figure 10 – Deaggregation of Minto hazard for 1/10,000 p.a. motions, for selected frequencies and PGA.

The deaggregation results are useful in the selection of time histories for use in analyses of the dynamic response of structures. Based on the deaggregation results shown, representative time

histories for low-probability events would be events in the M 6.5 to 7.5 range, at distances less than 50 km; at high frequencies the contributions shift to somewhat lower magnitudes. On Figure 11, we compare some typical scenario events in the appropriate magnitude-distance range to the Minto mean-hazard UHS at 1/10,000 p.a. probability.

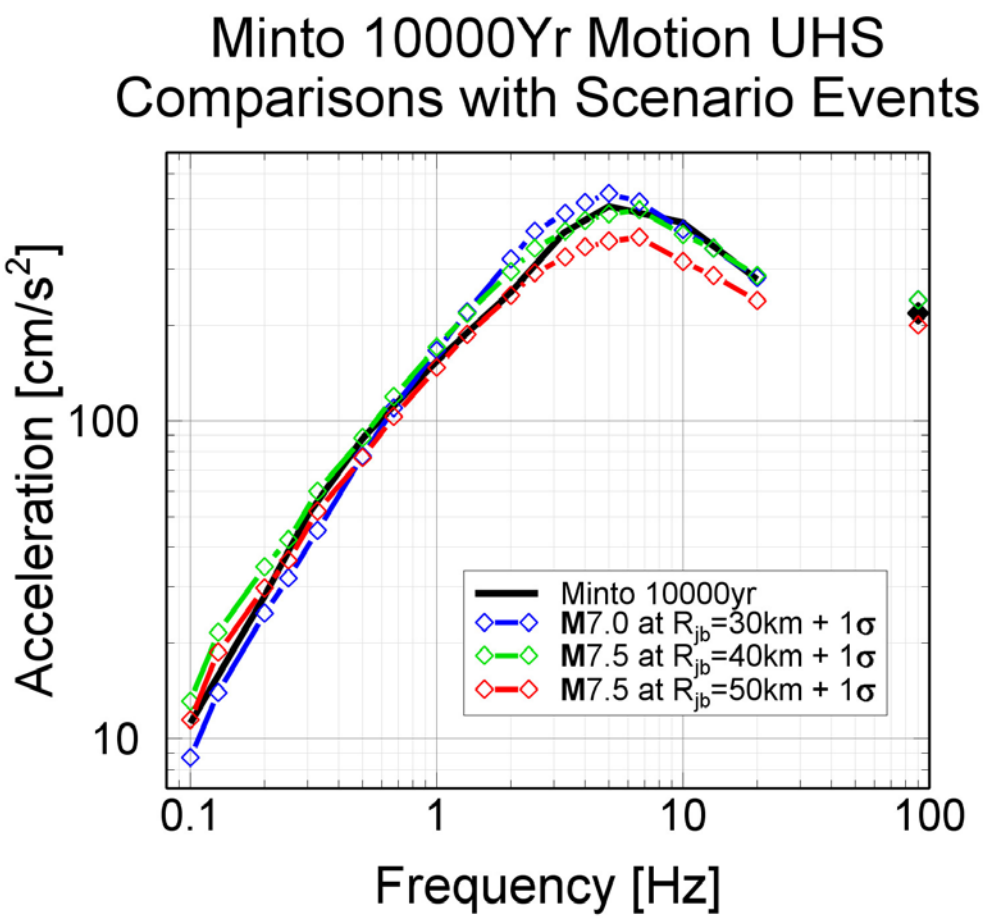

Figure 11 – Comparison of mean-hazard UHS at Minto (B/C site conditions) at 1/10,000 p.a. to selected scenario events. The central GMPE (BA08'), at approximately the +one sigma level, is used to estimate spectra for the scenario events.

6 – Summary and Conclusions

A seismic hazard analysis has been performed for the Minto, Yukon site. Considering the major regional source zones as defined in the GSC national seismic hazard model, for an annual probability of exceedence of 0.0001, corresponding to a 10,000 year return period ground motion, the mean-hazard value of peak ground acceleration (PGA) at Minto is approximately 22%g (220 cm/s^2) for NEHRP B/C soil conditions (average shear-wave velocity of 760 m/s in upper 30 m). The mean-hazard ground motions are provided in Table 1. The motions at 1/10,000 p.a. are similar to those that would be expected for events in the M7 range, at distances

less than 50 km. Such an event could be considered as a deterministic scenario on a fault in the site area.

We note that the calculated hazard is potentially sensitive to the treatment of activity near the site. Under the source-zone geometry defined by SRK, the site lies within a broad network of area faults having seismicity levels that are consistent with those in the broader YUS area as a whole. Thus the local area faults have minimal impact on the computed seismic hazard in this study. However, if any of the faults near the site has indications of geologically-recent activity, this could impact the hazard significantly. In this study, we have assumed that none of the faults in the site area have enhanced activity, relative to that for the region as a whole. This assumption is consistent with the observed seismicity in the site area.

EXECUTIVE SUMMARY

Existing climatological, meteorological and hydrological conditions at and around the Minto Mine site are characterized using regional and local data. Regional data are obtained through Environment Canada, Environment Yukon or Water Survey of Canada and provide a long-term record, while local data are collected via instrumentation deployed at site and manual surveys.

The long-term (>50 years) regional records shows an increasing trend in annual mean, minimum, and maximum temperatures. The average annual minimum temperature has been increasing at a faster rate than the average annual maximum temperature, and similarly, January (winter) mean temperatures have experienced much higher rates of increase than July (summer) mean temperatures. The mean annual temperature at site for the period of record is -1.9°C for the HOBO (2005-2014) station and -0.9°C for the Campbell Scientific station (2010-2016). Extremes ranged from -43.2°C to 30.3°C.

Mean annual precipitation at regional stations range from 279 mm to 345 mm. The proportion of total annual precipitation falling as rain ranges from 61% to 68%. At site, average annual total precipitation is 281.2 mm as measured with the tipping bucket and snowfall adaptor and 248.5 mm as measured with the total precipitation gauge. Both values are less than the estimated total of 303.2 mm based on the HOBO rainfall measurements and regional data. Peak snowpack is generally observed in April at all regional stations with SWE values ranging between 78 and 127 mm. Ten years of snow surveys conducted at site have found that the average water-equivalent snow depth remaining on the first day of March and April is 86.3 mm and 86.7 mm, respectively. Data indicate that the majority of runoff due to snowmelt occurs in April.

Dominant winds at site originate from the South, Southeast and Northwest, with an average speed of 2.8 m/s and gusts up to 26.8 m/s. Relative humidity is typically greater than 80% between October and February. During the summer months, the daily mean is typically in the range of 50% to 60%. Annually, mean RH is 70%. A strong seasonal pattern is evident in incoming solar radiation, with maximum near the summer solstice in late June, and values just slightly above zero around the winter solstice when the site experiences only about 3 hours of direct sunlight per day. Large fluctuations from the general trend during the summer are due to cloud cover. Barometric pressure is slightly higher on average between May and August (above 1009 hPa), and lowest between September and April (below 1008 hPa). Mean annual sea-level equivalent barometric pressure is 1006.5 hPa. Mean annual lake evaporation is estimated to be 460 mm for Pelly Ranch. Potential evapotranspiration is calculated at site using other meteorological parameters and the annual average is 428 mm.

Regional hydrometric stations operated by Water Survey of Canada (WSC) can provide insight on long-term trends. Big Creek near the Mouth station located in the vicinity of the Project area has been monitored since 1975. No clear long-term trend in mean monthly or annual discharge emerges from Big Creek data. Minto Explorations Ltd. maintains a network of hydrometric stations as part of its regular monitoring of surface water hydrological conditions at the Minto Mine in Minto and McGinty Creeks. Minto personnel conduct regular discrete discharge measurements and maintenance at the stations where Solinst Levelogger and Barometric Loggers are utilized to capture continuous stage records. The hydrological data record is relatively short at most sites and does not allows to detect trends. Sites W1 and W3 have a longer record for the open water season and capture more year to year variability, but no long-term trend in flow rates or timing emerges at this point.

LIST OF APPENDICES

APPENDIX A. MINTO METEOROLOGICAL STATIONS DESCRIPTION

APPENDIX B. MINTO AND MCGINTY CREEK HYDROGRAPHS

GLOSSARY

Coefficient of determination (R^2): statistical measure of how well the regression line approximates the real data points.

Evapotranspiration: the process by which water is transferred from the land to the atmosphere by evaporation from the soil and other surfaces and by transpiration from plants.

Hectopascal: a metric measurement unit of pressure commonly used to measure atmospheric pressure.

Penman Combination Equation: approximates net evapotranspiration, requiring input data including daily mean temperature, wind speed, relative humidity and solar radiation.

Quality Assurance: the process or set of processes used to measure and assure the quality of a product.

Quality Control: the process of ensuring products and services meet consumer expectations.

Snow Water Equivalent: the amount of water contained within the snowpack.

Velocity-Area: a method of measuring discharge in a channel cross section by dividing it into imaginary vertical panels of known area and measuring and assigning a mean velocity to each panel which cumulatively can be used to compute total discharge.

1. INTRODUCTION

The existing meteorology of the project area and the climate trends and projections for the region of Yukon Territory around the Minto Mine were first described in detail in EBA's report "Minto Mine—2010 Climate Baseline Report" (EBA, 2010). This report was subsequently updated by Access Consulting Group (ACG) in 2012 (ACG, 2012) with a data cut off date of July 31, 2012, in support of the Minto Phase V/VI Project Proposal submission to Yukon Environmental and Socio-Economic Assessment Board (YESAB).

The baseline surface water hydrology of the Minto Creek watershed prior to mining activity was detailed in Clearwater Consultants Ltd. Memorandum CCL-MC6 "Minto Copper Project—Surface Water Hydrology Conditions" (CCL, 2010). CCL-MC6 also covered conditions during Mine Operations until 2009. A subsequent report was prepared by ACG to update CCL-MC6 by presenting those previous data, and data gathered since then until the end of the 2012 open water season (ACG, 2013). Additionally, this report included data since 2009 gathered in McGinty Creek, a catchment of similar size to Minto Creek, also draining into the Yukon River and located directly north of the Minto Creek catchment (Figure 2-1).

Because of their interconnected nature, meteorology and surface water hydrology are combined in the present report, which constitutes an update to the latest "Minto Climate Baseline Report" and to the "Surface Water Hydrology Baseline Conditions" and includes additional data collected to the end of 2016. This is a component to the more comprehensive Site Characterization Plan for Minto Mine, provided under a condition of Minto's Quartz Mining Licence QML-0001.

1.1 REGIONAL SETTING

The Minto Mine is in the subarctic continental climate zone (Köppen climate classification), which is characterized by long, cold winters and short, cool summers. The area experiences moderate precipitation in the form of rain and snow and a large range of temperatures on a yearly basis with a mean annual temperature below 0°C.

1.2 SITE DESCRIPTION

The Minto Mine is a high grade copper mine located within Selkirk First Nation (SFN) Category A Settlement Land Parcel R-6A approximately 240 km northwest of Whitehorse, Yukon Territory (62° 37' N latitude and 137 °15' W longitude; Figure 1-1). It is owned and operated by the Minto Explorations Ltd. a wholly owned subsidiary of Capstone Mining Corporation. Development of the mine was initiated in 1997, commercial operations started in October 2007, and the currently anticipated operating life is to 2020 with permitted resources to 2022. The Minto Mine is permitted to conduct open pit and underground mining, and to mill the copper/gold/silver ore at a rate of 4,200 tonnes of per day. In 2016 (the most recent year of record), the Minto Mine produced 69.3 million pounds of copper from milling approximately 1.49 million tones or ore.

In addition to open pit mines, underground mines, and the mill, the Minto Mine site includes a number of waste rock dumps, a concentrate storage shed, a dry stack tailings storage facility (DSTSF), a water retention dam with a water storage pond (WSP), a water treatment plant, administrative offices, an airstrip, and a camp (Figure 1-2). Mill tailings are stored in the DSTSF and in mined-out open pits. Mine-impacted seepage from the DSTSF and under the Mill Valley Fill (MVF) is collected at the toe of the MVF in sump W62 and is pumped to the Main Pit (Figure 1-2). Non-impacted water and treated mine-impacted water are collected in the WSP (Figure 1-2). Effluent from the WSP is periodically discharged to Minto Creek under conditions specified in Water Use Licence (WUL) QZ14-031 (August 2015). Minto Creek, in turn, discharges to the Yukon River approximately 7.7 km south-east of the WSP (Figure 1-2).

2. CLIMATE AND METEOROLOGICAL DATA

The following section presents regional and site-specific climatic and meteorological data. Regional data are available through Environment Canada (EC) and Environment Yukon. Meteorological data have been collected on site continuously since a first meteorological station was installed in 2005. A second meteorological station was commissioned in late October 2010 while the first was decommissioned in 2014.

2.1 METHODS

2.1.1 REGIONAL DATA

Long-term trends were evaluated by reviewing long-term records from stations in the region (regional analysis). EC meteorological stations used for this regional analysis were selected based on location/proximity and data availability, and are presented in Table 2-1 below. Figure 2-1 shows the location of these stations.

Stewart Crossing	2101030	1963-2007	63°22'48" N	136°40'48" W	480.1 m	102 km
McQuesten	2100719	1986-2014	63°35'24" N	137°31'12" W	458.2 m	114 km

2.1.2 SITE DATA

To record meteorological parameters on site, a basic meteorological station was established at the Minto Mine site in late September 1993 at an elevation of 884 meters above sea level (masl) and intermittent temperature and precipitation data were collected in September and October 1993 as well as in June, July and August 1994 (HKP 1994).

On September 7, 2005, a HOBO meteorological station on a three-metre tripod was installed by ACG, with instrumentation to record wind speed and direction, air temperature, relative humidity, barometric pressure, solar radiation and rainfall at a location near camp. On April 11, 2006, the station was relocated to the airstrip (N 62°36'17", W 137°13'19", el. 887 masl). The station has recorded, at hourly sampling intervals, the parameters of: average wind speed and direction; highest three-second wind gust; air temperature; relative humidity; on-site barometric pressure; incident solar radiation and total wet precipitation. Specifications of the installed instrumentation and details of the data collection program are contained in Appendix A. This station was decommissioned on June 25, 2014.

On October 15, 2010, a Campbell Scientific (CS) meteorological station was installed adjacent to the existing HOBO meteorological station, whose anemometer was damaged by strong winds in May 2010. The other sensors of the HOBO station remained functional during the summer of 2010; therefore, only wind data are missing for the transition period. The Campbell Scientific meteorological station's anemometer was installed on a 10-meter mast, which is the standard height for collecting wind data used in air dispersion models. The other sensors installed on the Campbell Scientific station include a temperature and relative humidity sensor, a pyranometer, a rain gauge and a barometer. A snowfall conversion adaptor was added in October 2011; a total precipitation gauge was installed in November 2014 and an evaporation pan and outgoing radiation sensor were commissioned in 2016. Specifications of the installed instrumentation and details of the data collection program are presented in Appendix A.

2.1.2.1 QA/QC

The site meteorological station is regularly visited and inspected by Minto Mine staff and all maintenance actions are documented. Suspicious data are identified graphically, investigated and invalidated where needed. Third party review of the data is conducted when suspicious data or inconsistent instrument performance are identified.

2.2 RESULTS

2.2.1 TEMPERATURE

2.2.1.1 Regional Data

Extreme and average minimum and maximum, as well as mean monthly and annual temperatures were calculated for each regional station over the entire period of existing records (Table 2-2), except for Carmacks where the two stations were combined to provide a longer record. The mean annual temperatures ranged from -2.4°C at Stewart Crossing to -3.7°C at Pelly Ranch, and extreme annual temperatures ranged from -60.0°C at Pelly Ranch in February to 35.0°C at Pelly Ranch in June and Carmacks in May and June.

Long-Term Trends

Of the four regional stations presented above, Pelly Ranch and Carmacks have the longest records and were analyzed for historical trends. Figure 2-2 and Figure 2-3 illustrate the annual maximum (plotted in red), mean (green) and minimum (blue) air temperatures along with the respective trendlines and slopes for Pelly Ranch for the available data

set between 1957 and 2014 and for Carmacks between 1964 and 2016 respectively. Annual maximums and minimums are calculated as an average of monthly maximum and minimum temperatures for each year.

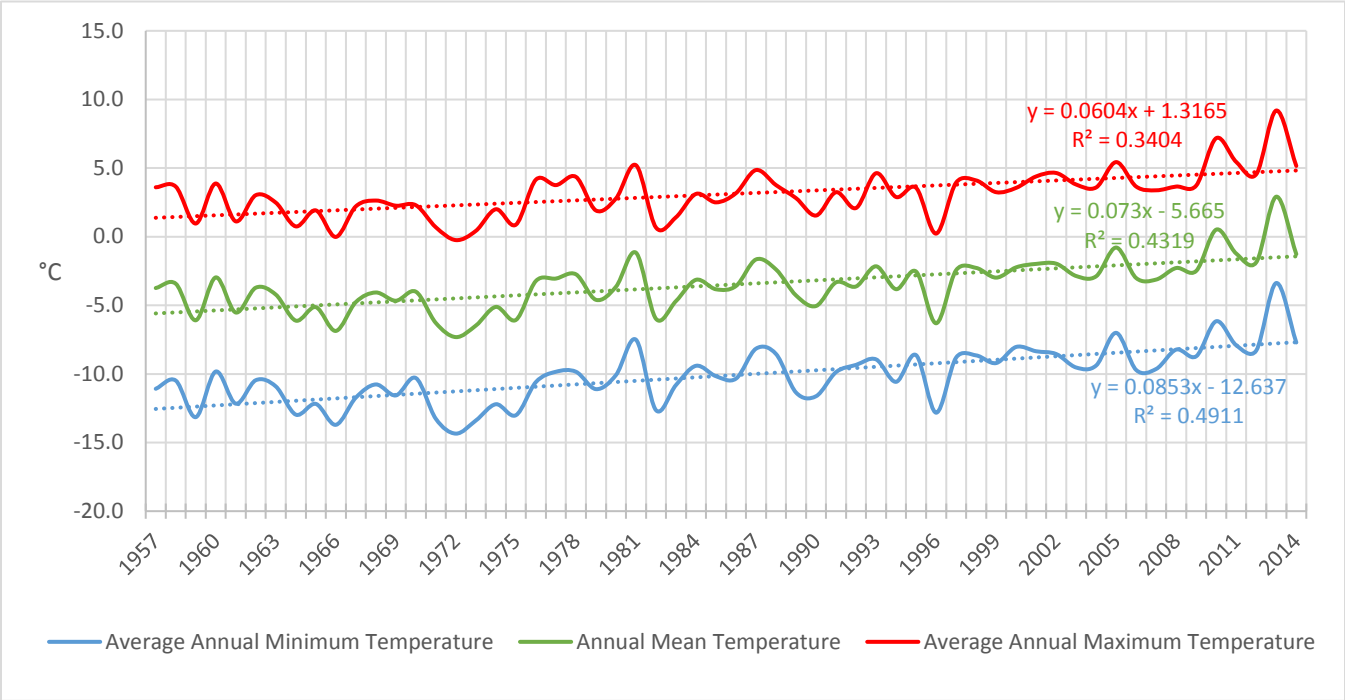

Figure 2-2: Pelly Ranch Average Annual Air Temperature Trends 1957-2014.

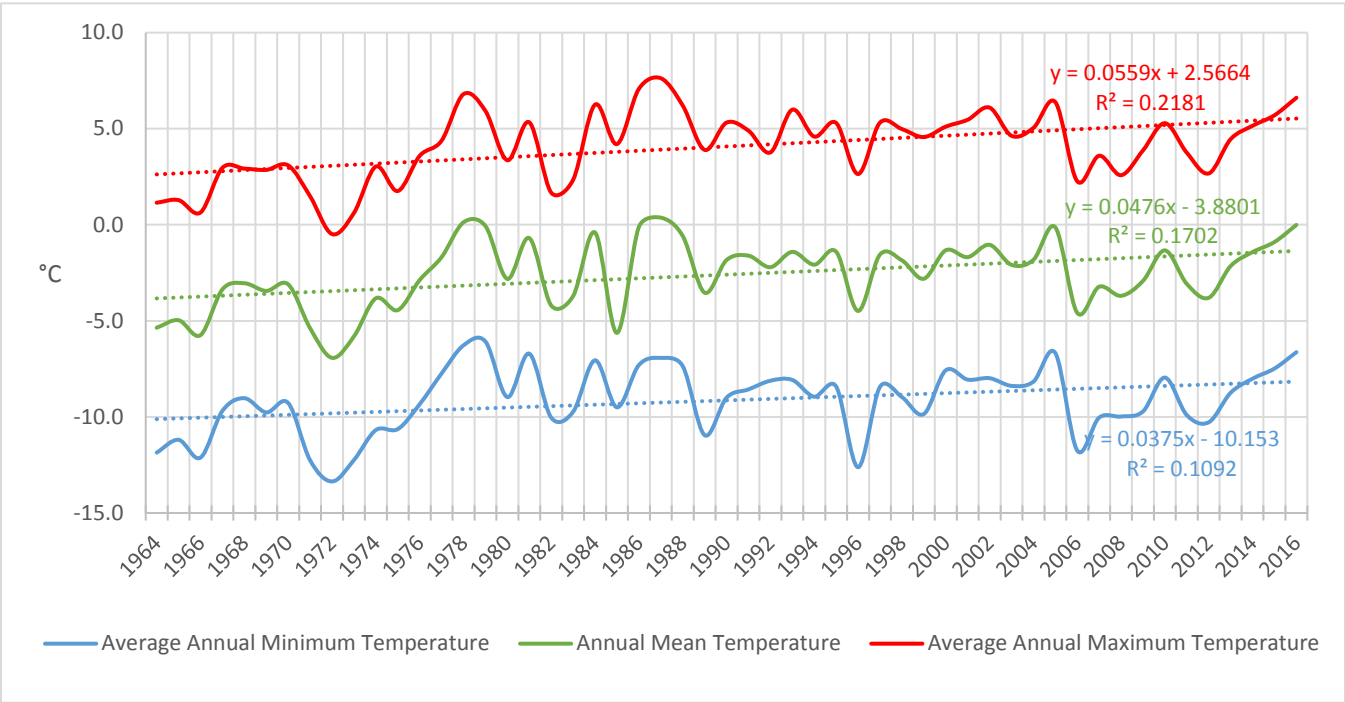

Figure 2-3: Carmacks Average Annual Air Temperature Trends 1964-2016.

The plots show a similar trend for all annual averages. The annual mean temperature has been increasing at Pelly Ranch by 0.07°C per year on average over the 57-year period corresponding to a total average increase of 4.2°C from 1957 to 2014. For Carmacks, the average rate of increase of the annual mean temperature is slightly less at 0.05°C per year, resulting in an average increase of 2.5°C for the 52-year period. It is also important to note that the average annual minimum temperature has been increasing at a faster rate than the average annual maximum temperature at both stations, thus implying that the average diurnal range has also been decreasing.

Figure 2-4 and Figure 2-5 illustrate the mean temperatures for January (blue) and July (orange) at the two regional stations over the same periods as above, in order to better illustrate the trend with respect to seasonality. The graphs show that January (winter) mean temperatures have experienced much higher rates of increase (0.15°C per year at Pelly Ranch and 0.22°C per year at Carmacks) than July (summer) mean temperatures (0.03°C per year at Pelly Ranch and 0.02°C per year at Carmacks).

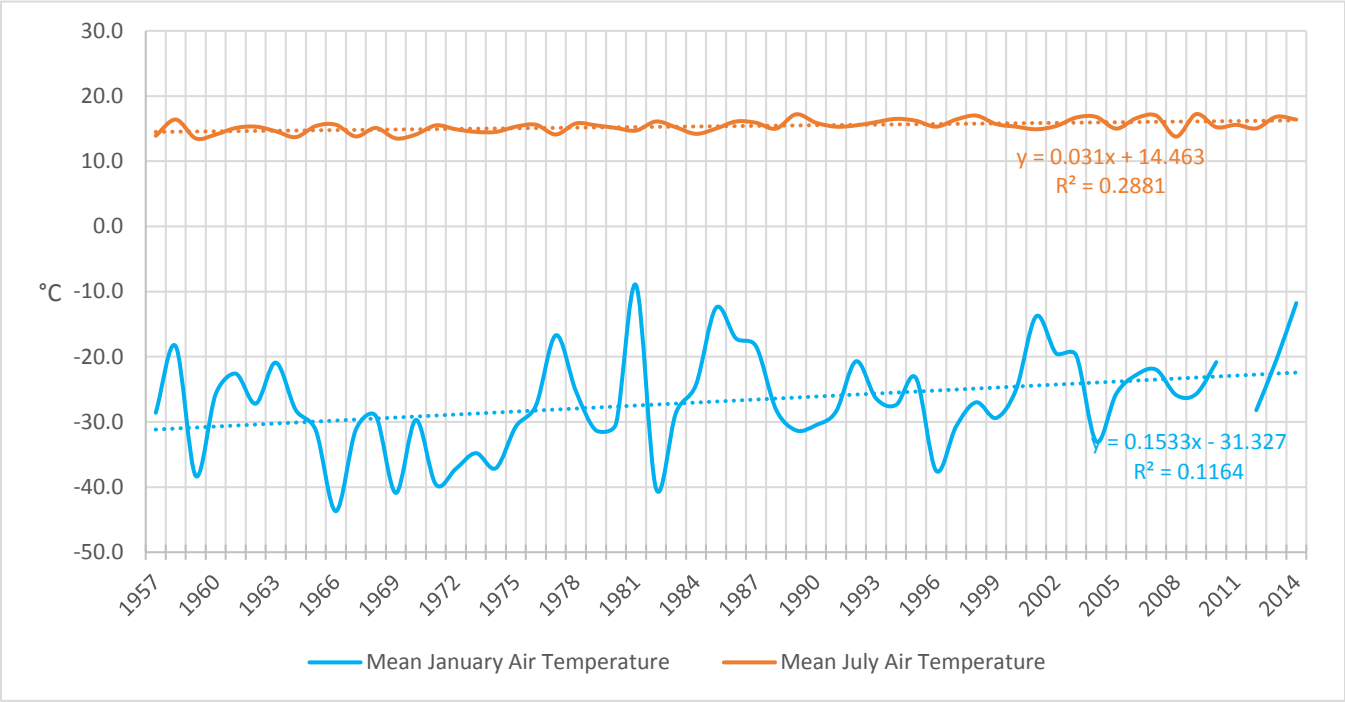

Figure 2-4: Pelly Ranch Seasonal Air Temperature Trends 1957-2014.

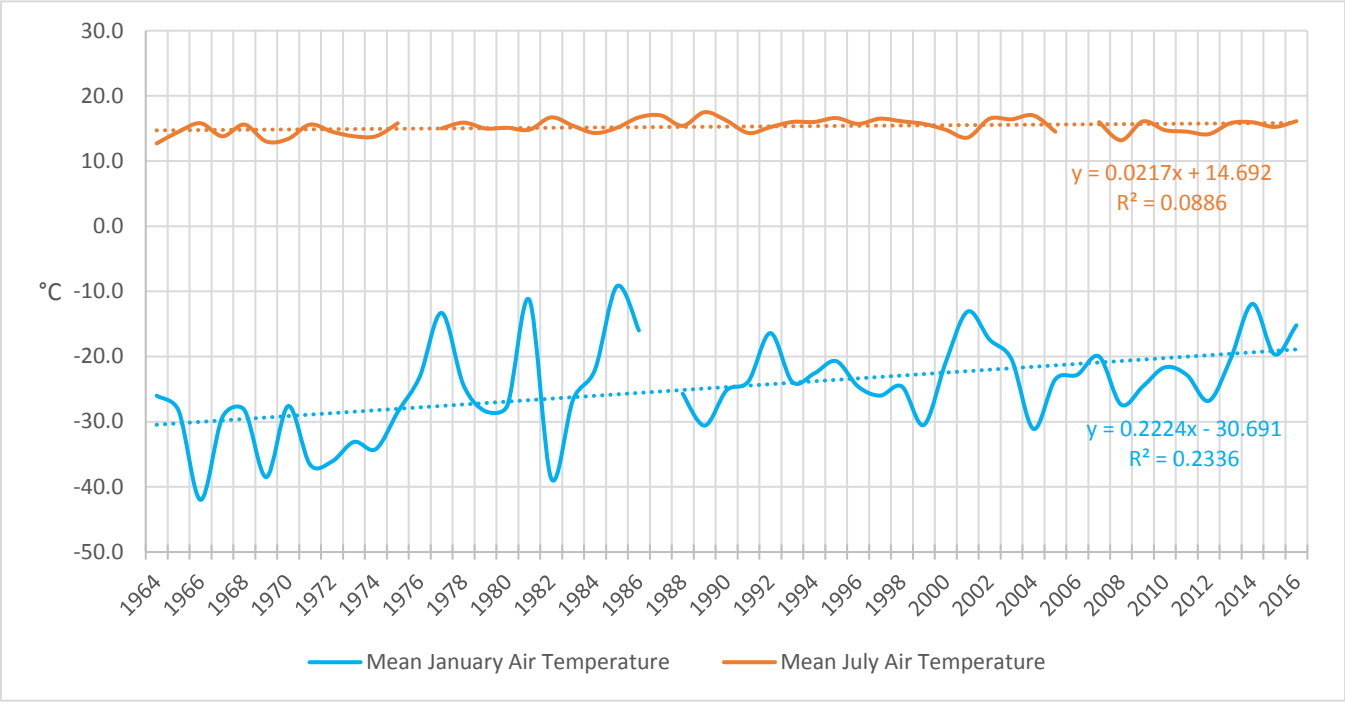

Figure 2-5: Carmacks Seasonal Air Temperature Trends 1964-2016.

2.2.1.2 Site Data

Hourly air temperatures have been plotted for the entire period of record for both stations in Figure 2-6. The plot shows a strong sinusoidal seasonal pattern. The summer period, between late-May and early-September, is characterized by temperatures in the range of 10 to 20°C. The winter period, between October and March, is characterized by a much larger day-to-day variation in air temperatures, typically between –10 and –30°C, although winter temperatures in the range of 0 and –40°C are not uncommon. The transitions between these seasons are characterized by a quick rise or fall in air temperatures during March/April and mid-September/early-October, respectively.

Monthly average minimum, maximum, mean and extreme temperatures were compiled from the hourly data collected at the Project's two meteorological stations for the period of record and are shown in Table 2-3. The mean annual temperature for the period of record is -1.9°C for the HOBO station and -0.9°C for the Campbell Scientific station. Extremes ranged from -43.2°C to 30.3°C.

Based on the data record, air temperatures would be expected to remain above zero throughout the day between June and September, while between October and March, air temperatures would typically remain below zero. The maximum air temperature ever recorded was 30.3°C on July 29, 2009. The minimum air temperature ever recorded was –43.2°C on November 27, 2006 and again on January 8, 2009. Air temperatures higher than 5°C have been observed in every winter month. Sub-zero temperatures have been recorded every month except in July.

Table 2-3: Minto Mine Monthly Extreme and Average Air Temperature (°C).

2.2.2 PRECIPITATION

2.2.2.1 Regional Data

Mean monthly rain, snow and total precipitations were calculated for the entire period of record for each station listed in Table 2-1 (with the two Carmacks stations combined). Mean annual precipitation ranges from 279 mm at Carmacks to 345 mm at McQuesten. The proportion of total annual precipitation falling as rain ranges from 61% at McQuesten to 68% at Carmacks (Table 2-4). Figure 2-7 presents the average monthly distribution of rain and snow across all regional stations. The greatest amount of precipitation generally falls between June and September for all stations.

Source: EC, 2017

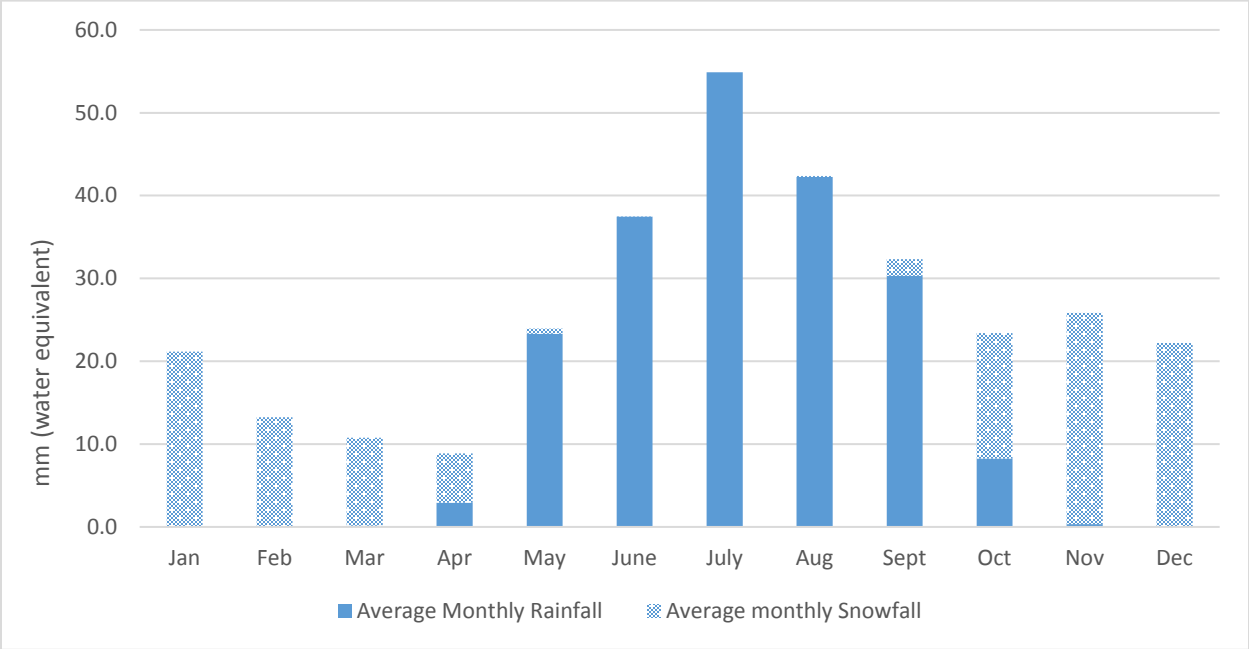

Figure 2-7: Monthly Distribution of Rain and Snow across Four Regional Stations for the Period of Record.

Long-Term Trends

Of the four regional stations presented above, Pelly Ranch and Carmacks have the longest records and were analyzed for historical trends. Figure 2-8 illustrates total annual precipitation along with the respective trendlines and slopes for Pelly Ranch between 1957 and 2014 and for Carmacks between 1964 and 2016 respectively. Although an increasing trend is observed at both stations, the correlation is weak (R^2 of 0.04 and 0.03 for Pelly Ranch and Carmacks respectively). Figure 2-9 shows that the proportion of total precipitation falling as rain also displays an increasing trend of the period of record, but again, the correlation is weak (R^2 of 0.13 and 0.02 for Pelly Ranch and Carmacks respectively).

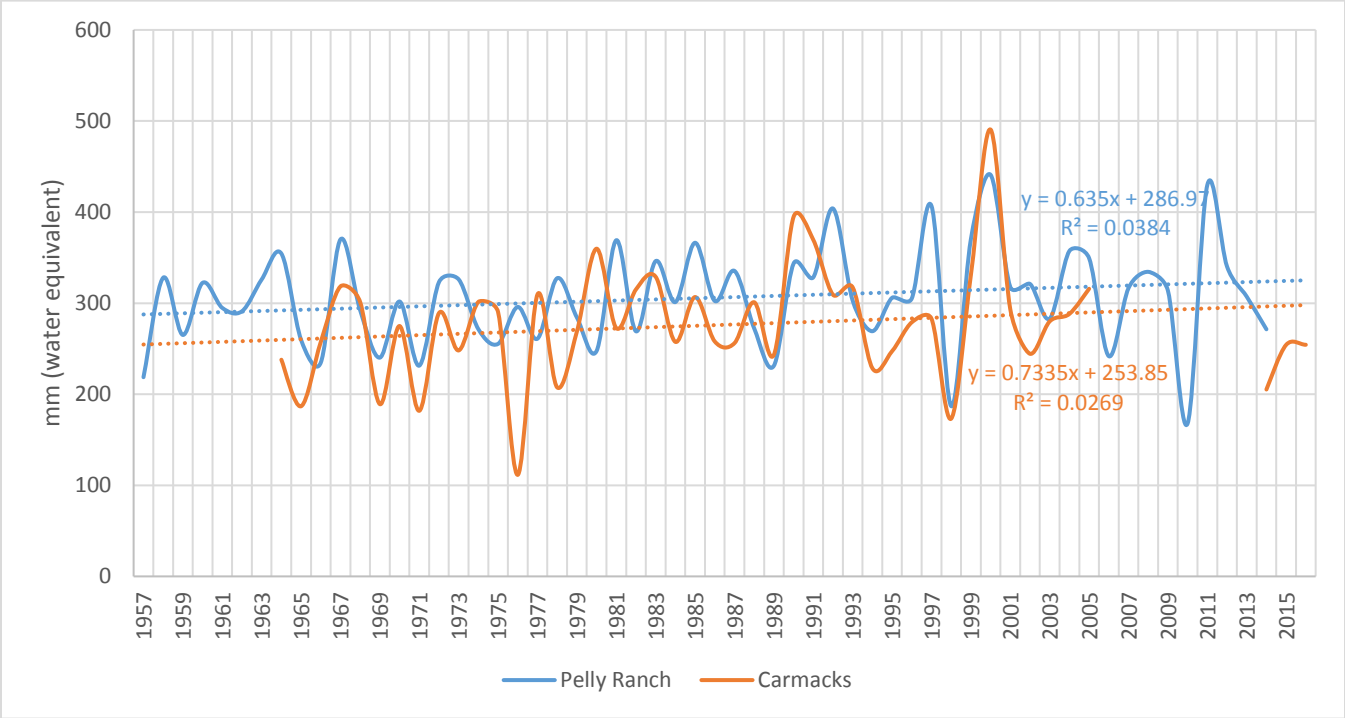

Figure 2-8: Long-Term Trends in Total Annual Precipitation at Regional Stations.

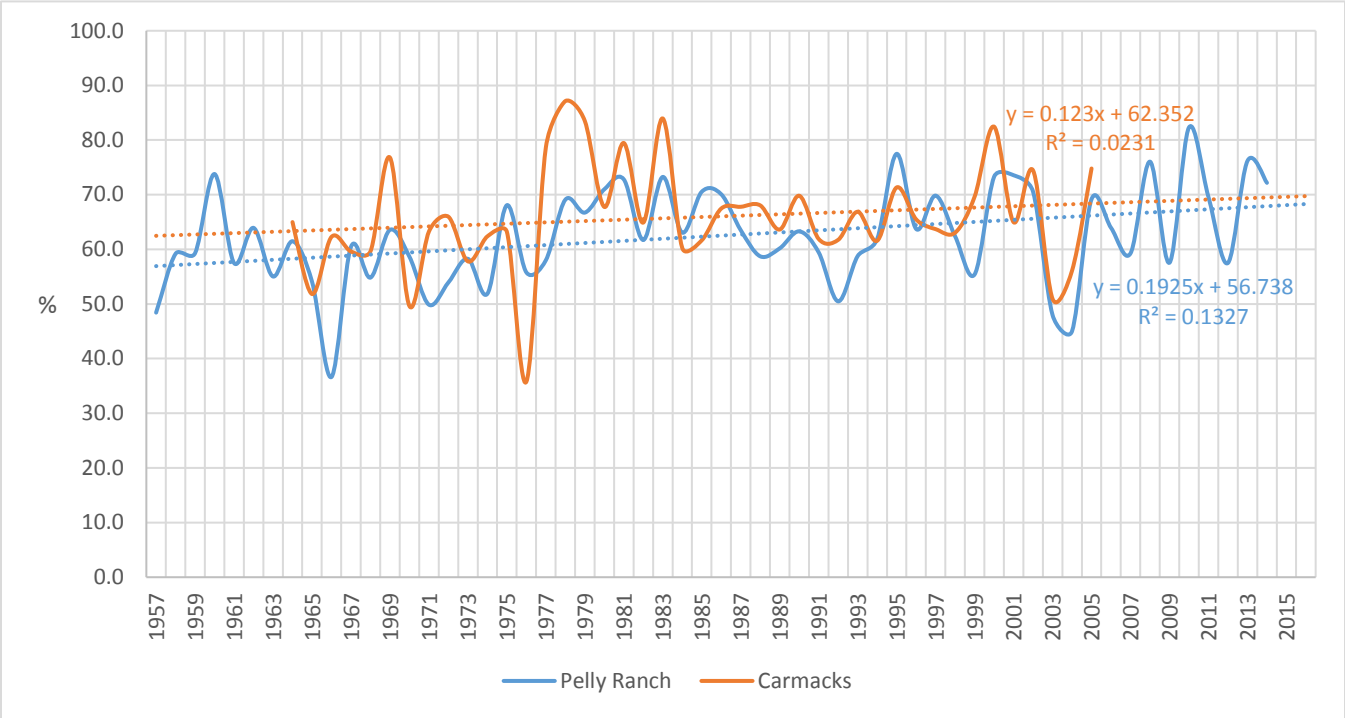

Figure 2-9: Long-Term Trends in Percent of Total Annual Precipitation Falling as Rain at Regional Stations.

2.2.2.2 Site Data

Rainfall

The Minto Mine HOBO meteorological station has been recording rainfall on site since its installation in September 2005 until decommissioning in June 2014. Table 2-5 below presents monthly and annual total for the period of record. Note that only complete months/years were used for computing average values.

Table 2-5: Monthly and Annual Rainfall (mm) - Minto HOBO Station.

	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual
2005									*21.6*	23	11.6	4.6	
2006	0	*0.4*	*2.8*	0	22.8	35.8	28.6	29.2	12.2	12.2	0	0	144
2007	0.2	0	0.4	5.8	4.6	36	47.8	21	33.8	11.8	0	0	161.4
2008	1.2	2	0.8	1.8	9.6	26.2	*25.8*	100.6	21.8	6.4	0	0	196.2
2009	5.2	0	0.8	3.2	*9.2*		*6.1*	*50.8*	7.2	16.6	0	0	*99.1*
2010	0	0	0	0	7.6	48.8	75.6	46.4	18	10.2	0	0	206.6
2011	0	6	0	0.2	8.9	*43.8*	95.2	58	15	6.4	0	4.6	238.1
2012	0	0.6	0.6	0.4	8.8	33.4	44	36.6	36	13.8	0	0.6	174.8
2013	0.2	0.2	1.4	3.6	18.4	36.2	77.6	31.4	36.8	15.4	0	7.2	228.4
2014	3.4	0	0	2.4	14	*7.6*							
Avg	**1.1**	**1.1**	**0.5**	**1.9**	**11.8**	**36.1**	**61.5**	**46.2**	**22.6**	**12.9**	**1.3**	**1.9**	**192.8**

Note: Values in grey italics indicate a partial total

Based on regional data presented above, about 64% of total annual precipitation falls as rain (average proportion over the period of record for four regional stations). Applying this ratio to the average annual rainfall of 192.8 mm measured at the Minto Mine HOBO station would result in a total annual precipitation value of 303.2 mm.

Total Precipitation

The Campbell Scientific station was recording rainfall only from time of commissioning until October 14, 2011, when a snowfall conversion adaptor was installed on the tipping bucket to allow for measurement of total precipitation. It consists of an antifreeze reservoir, over-flow tube, and catch tube. Snow captured in the catch tube dissolves into the antifreeze and the melted snow raises the level of the antifreeze and water solution. The mixture then flows through the over-flow tube into the tipping bucket where it is measured by the tipping bucket mechanism. On November 18, 2014, a Geonor T-200B vibrating wire all weather precipitation gauge was installed in addition to the existing tipping bucket and rainfall adaptor to improve accuracy and validate total precipitation measurements. Tables 2-6 and 2-7 present monthly and annual snow-water equivalent (SWE) totals with the tipping bucket and snowfall adaptor and total precipitation gauge respectively, while Figure 2-10 shows a graphical comparison of results with the two different instruments.

Table 2-6: Monthly and Annual Total Precipitation (mm SWE) - Minto Mine Campbell Scientific Tipping Bucket and Snowfall Adaptor.

	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual
2010											1.2	0.0	
2011	0.0	6.4	0.4	0.6	15.4	56.0	101.8	64.8	15.6	10.8	0.1	3.9	275.9

Note: Shaded cells indicate rainfall only (prior to installation of snowfall adaptor) and were not used in calculating averages

Table 2-7: Monthly and Annual Total Precipitation (mm SWE) - Minto Mine Campbell Scientific Total Precipitation Gauge.

	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual
2014											9.5	21.0	
2015	12.3	0.0	11.8	8.5	4.8	20.5	37.7	80.3	16.7	27.7	7.1	11.3	238.0
2016	11.7	7.8	3.3	14.7	31.5	22.2	68.2	35.8	17.8	9.8	22.0	14.1	258.9
Avg	**12.0**	**3.5**	**7.5**	**11.6**	**18.2**	**21.4**	**52.9**	**58.0**	**17.2**	**18.8**	**12.9**	**15.5**	**248.5**

Average annual total precipitation is 277.6 mm with the tipping bucket and snowfall adaptor and 248.5 mm with the total precipitation gauge. Both values are less than the estimated total of 303.2 mm based on the HOBO rainfall measurements and regional data. This could indicate potential undercatch of both the snowfall adaptor and total precipitation gauge, however, other factors such as wind or snow pillow formation can also play a role. More years of total precipitation data will allow a more meaningful comparison.

Figure 2-10 shows a relatively good agreement in total precipitation measured with both instruments, with no systematic bias one way or the other. The difference in annual totals measured with the two instruments for the years 2015 and 2016 is less than 10%.

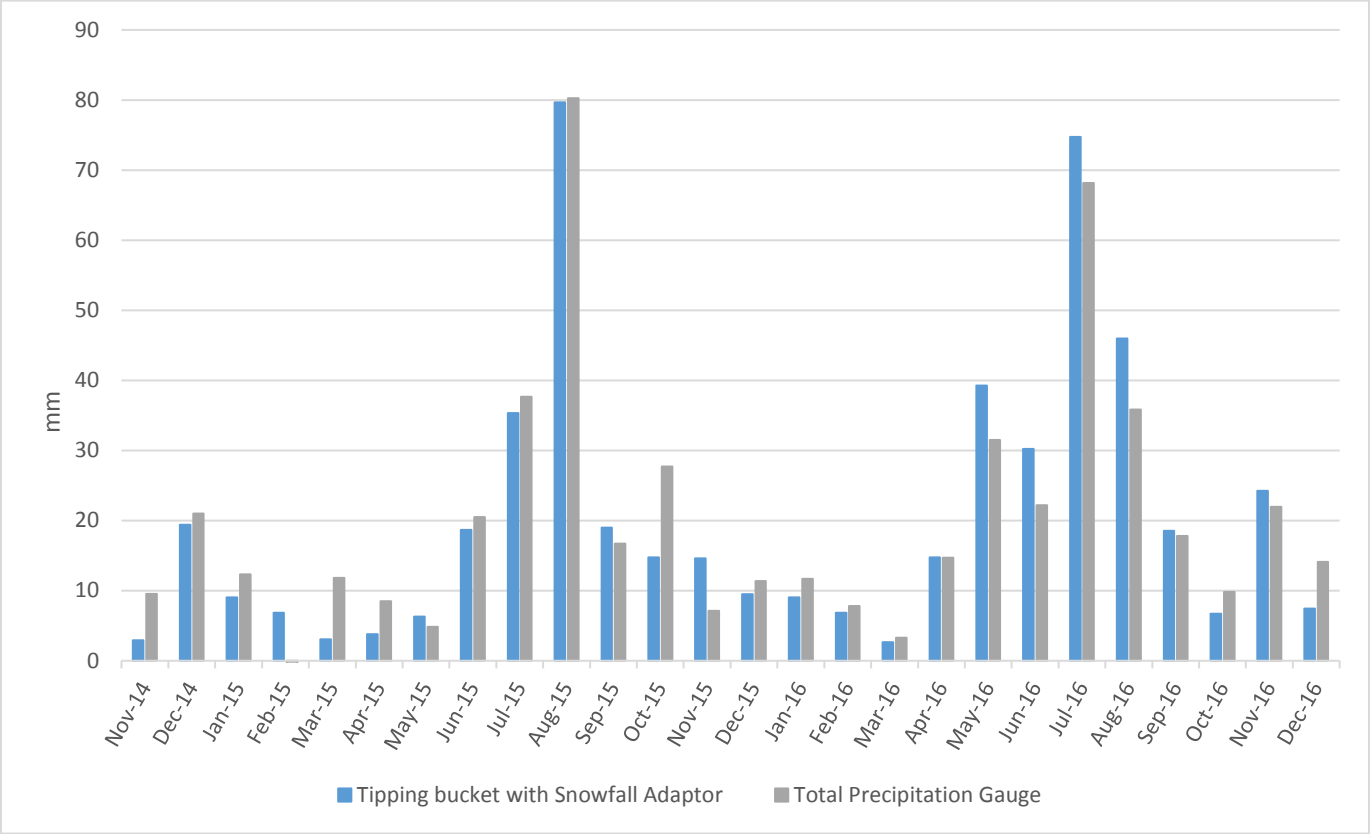

Figure 2-10: Monthly Total Precipitation (SWE) - Minto Mine Campbell Scientific Meteorological Station.

2.2.3 SNOWPACK

2.2.3.1 Regional Data

Environment Yukon conducts regular snow surveys across the territory, on or around March 1, April 1, and May 1 of each year. Average SWE values for the stations located in the Project region are summarized in Table 2-8 (see Figure 2-1 for station locations). Peak snowpack is generally observed in April at all stations.

Table 2-8: Regional Average Snow Water Equivalent (mm).

Station Name	Pelly Farm	Williams Creek	Mount Nansen	Casino Creek	Mount Berdoe

2.2.3.2 Site Data

Annual snow surveys have been conducted by J. Gibson & Associates in 1994, 1995, 1998, and annually from 2006 to 2013, at three locations in the Minto Creek catchment area. Minto#1 is located south of the airstrip with a north-facing aspect. Minto#2 is located near the explosives storage area with an east-facing aspect. Minto#3 is located north of the mill with a south-facing aspect. From 2013 to date, Minto environmental staff have conducted the annual snow surveys at the same stations described above. Due to site operations, the snow survey sites were relocated to their present positions in 2007 at the approximate aspects and elevations of the previous sites. A fourth station located at the dry stack storage facility was added in 2016. Snow sampling locations are shown on Figure 2-11.

Snow surveys have been conducted on the first day of March, April and May, or within 2 days before or after these dates, as conditions allowed. Due to the lack of snow remaining on site by May 1, February snow surveys were initiated in 2009 to ensure a consistent annual 3-month record. May snow surveys have subsequently been discontinued for the same reason. Snow collection procedures are in accordance with the Snow Survey Sampling Guide (SS13-81) published by the British Columbia Ministry of Environment (Water Management Branch, Surface Water Section).

Table 2-9 shows, as an average of data recorded at all snow survey stations, the mean snowpack depth (cm), snow density (%) and water-equivalency (mm) on the first day of each month of the survey. Possible errors in the record identified in quality checking of the field data (where the recorded water-equivalency does not equal the product of the recorded snow density and snow depth) have been shaded grey, and retained in the analysis.

All snow surveys from 1994 - 2013 performed by J. Gibson & Associates

= possible measurement error

** zero snow recorded at #2 and #3 - density is based on #1 only, average depth and water-equivalent is average of all sites*
*** zero snow at #3, density is an average of snowpack at #1 and #2, average depth and water-equivalent is average of all sites*
**** omitted snow survey site #3 - error in snow depth reading*
***** includes potential measurement error from site 3*

Based on the ten years of snow surveys, the average water-equivalent snow depth remaining on the first day of March and April is 86.3 mm and 86.7 mm, respectively.

In four of the seven May surveys, the snowpack had melted entirely by May 1. In the three years where snow remained on the ground on May 1 (1995, 2006, & 2008), the mean snowpack had reduced 10%, 27%, and 20%, respectively, of the peak measured snowpack in that year. The data indicate that the majority of runoff due to snowmelt occurs in April.

Figure 2-12 below shows the average snow water equivalent trend over the period of record.

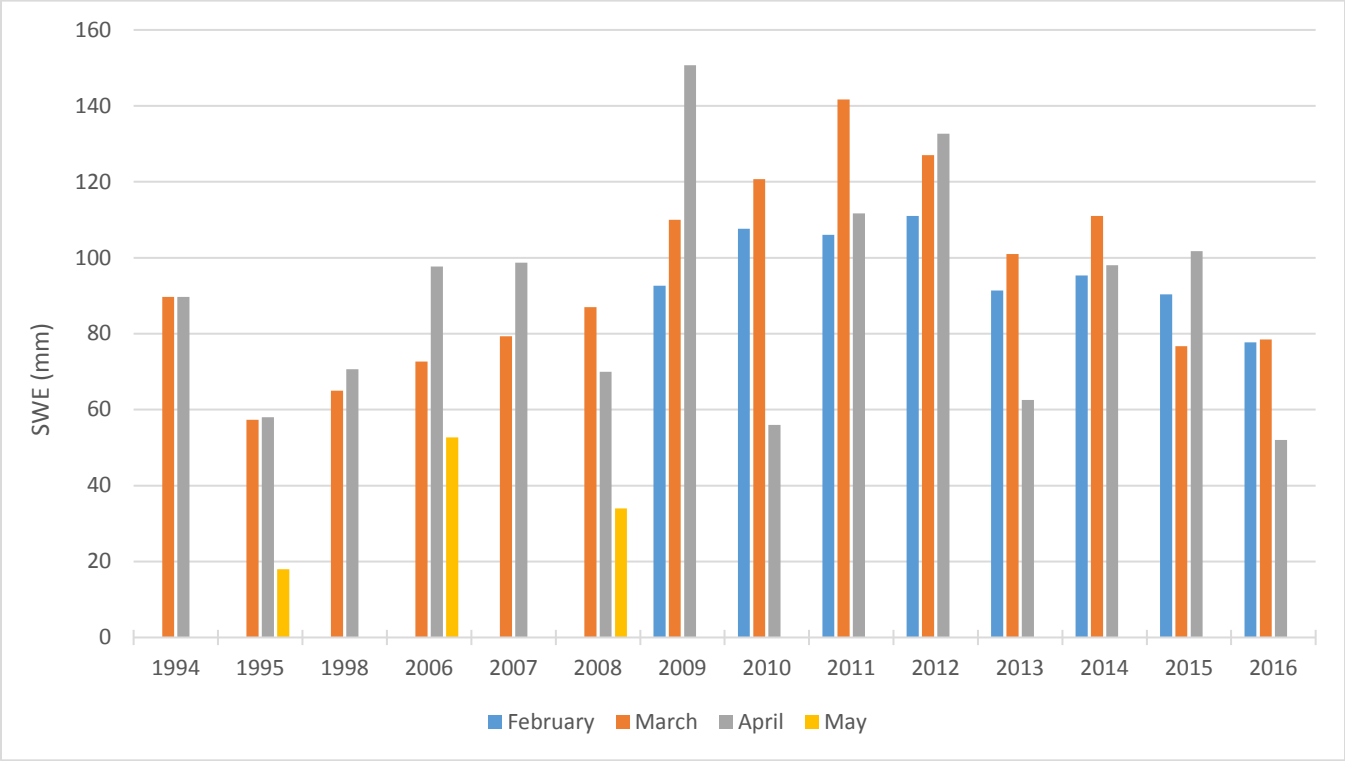

Figure 2-12: Snow Water Equivalent (SWE) Data from Minto Mine Snow Surveys, 1994 – 2016.

2.2.4 WIND SPEED AND DIRECTION

The average wind speed and direction and the maximum wind gust averaged over a three second period for each hour were recorded by the Minto Mine HOBO meteorological station, at a height of 3 meters above the ground. The anemometer was damaged by strong winds in May 2010, so that month marks the extent of the HOBO wind record. Since the HOBO wind sensor was strongly affected by rime icing (see Figure 2-13), much of the record is ice-affected at temperatures below zero.

Figure 2-13: Rime Icing Affecting the Minto Mine HOBO Anemometer *(Source*: *EBA 2010*).

Periods when the anemometer cups are not rotating due to ice build-up are recorded as 0 m/s and are easily identified in the record and flagged (for both the HOBO and the Campbell Scientific anemometers). However, ice build-up on the anemometer can result in extended periods of non-zero but diminished wind speeds of varying degree and duration which are difficult to arbitrarily omit from the record. In EBA's *2010 Climate Baseline Report*, all wind speeds and directions recorded below 0°C were flagged and omitted from analysis to reduce uncertainty in the data. For consistency, that same approach was kept in the present report for the HOBO wind data. Note that this introduces a bias in the winter wind data, as almost exclusively strong southerly winds (associated with warmer temperatures) end up being kept in the winter wind record.

The new Campbell Scientific anemometer is at a height of 10 meters above the ground and was programmed to record wind speed and direction. This anemometer seems to have been much less affected by ice so far, so most of the winter wind data were retained in the record, to provide a general idea of winter wind patterns. It is however important to keep in mind that if some icing occurred on the Campbell Scientific anemometer, winter wind speeds may be underestimated in the record. Summary statistics for both weather stations are presented in Table 2-10.

The wind roses in Figure 2-14 and Figure 2-15 are graphical representations of wind observations recorded by the two Minto Mine meteorological stations over the period of record. Because the anemometer height is different on the two stations (3 meters for the HOBO stations and 10 meters for the CS station), the wind data collected by each station were treated separately. Table 2-11 contains information on the data used for each wind rose, and Figure 2-16 shows statistics on the wind data used to produce the HOBO wind rose with regards to seasonal availability as discussed above.

Table 2-10: Monthly and Annual Average and Maximum Wind Speed, Minto Mine.

	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual
HOBO (2005-2010)													
Average Wind Speed (m/s)	3.9	6.0	3.8	2.6	3.0	2.6	2.5	2.0	2.5	3.2	5.3	4.0	2.7

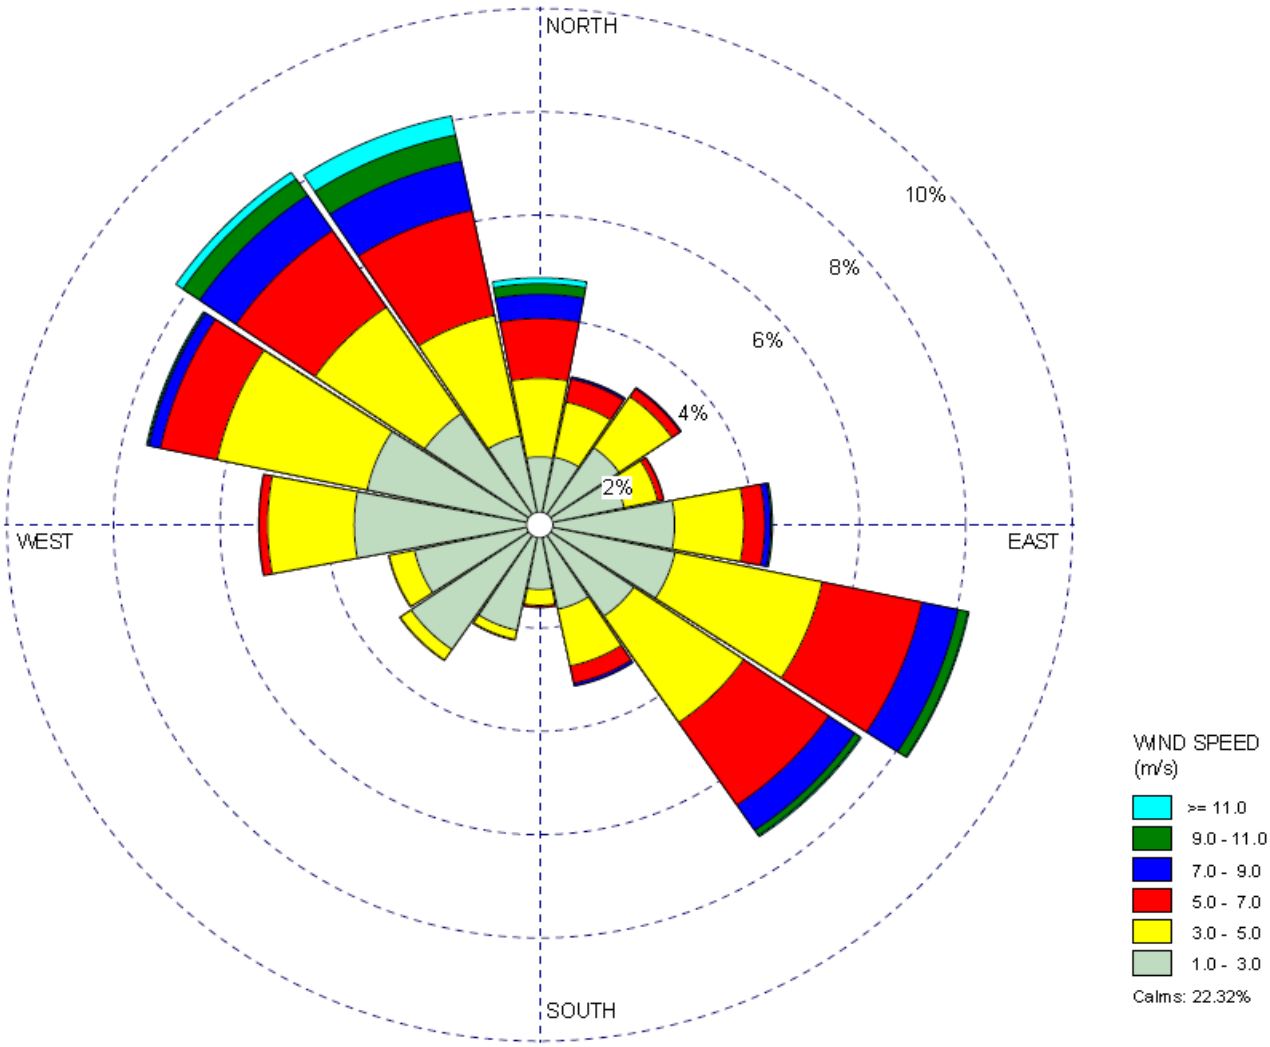

Figure 2-15: Minto Mine Campbell Scientific Meteorological Station Wind Plot, October 2010 – December 2016.

Table 2-11: Wind Data Summary Table.

	HOBO	Campbell Scientific
Dates	September 2005 – April 2010	October 2010 – December 2016
Number of hours of data	39,531	54,366
Average wind speed	2.65 m/s	2.75 m/s
Calm winds count	3,227	12,135
Calm winds frequency	8.16%	22.32%
Data Available	42.17%	90.74%
Incomplete or missing data count	22,862	5,032
Total data used	16669	49,334

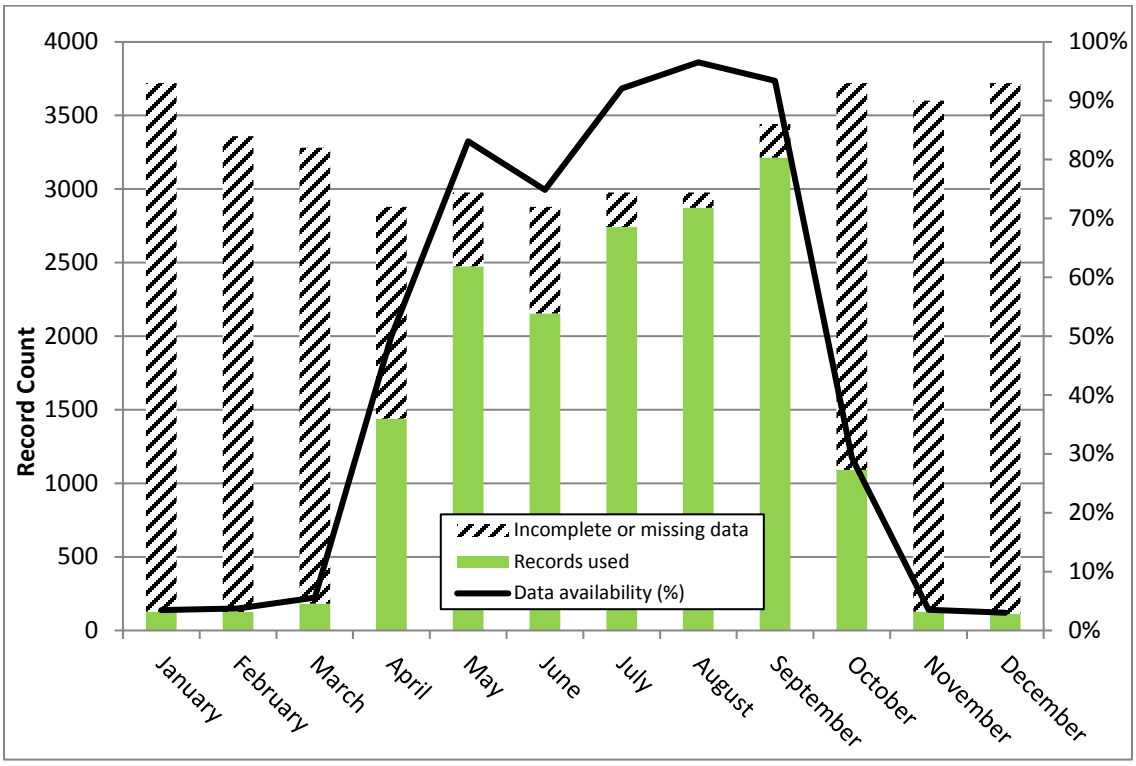

Figure 2-16: HOBO Wind Data Availability Statistics 2005–2010.

It is interesting to note that the record from the two stations is relatively consistent in terms of wind speed and direction, although the Campbell Scientific station generally recorded higher wind speeds and a more southeasterly direction while the HOBO displays a more southerly direction. This can be explained by the fact that the CS anemometer is higher above the ground (where there is less friction and less turbulence) and that the CS record is missing less data (90.74% data available for CS anemometer versus 42.16% for the HOBO).

2.2.5 RELATIVE HUMIDITY

Hourly relative humidity (RH) recorded at the site is plotted for the entire period of record in Figure 2-17 and illustrates a seasonal pattern. RH is highest during the winter months (typically in the range of 75% to 95%) and lowest during the spring and early summer, typically in the range of 40% to 60%; although levels exceeding 90% in summer are not uncommon.

RH has a much larger day-to-day variability during the summer months. The lowest recorded hourly RH was 10.25% (June 20, 2007). The highest was 100%, on several occasions. Table 2-12 shows the average monthly mean %RH.

Table 2-12: Monthly and Annual Average Relative Humidity (%), Minto Mine.

	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual
HOBO (2005-2014)	83	79	68	57	52	57	61	69	71	84	85	83	71
Campbell Scientific (2010-2016)	83	78	61	55	49	54	62	65	68	81	85	83	69

RH is typically greater than 80% between October and February. During the summer months, the daily mean is typically in the range of 50% to 60%, although part of the reason for the lower average is a higher variance. Annually, mean RH is 70% (average over the two meteorological stations).

Figure 2-17 shows the hourly RH record for both stations.

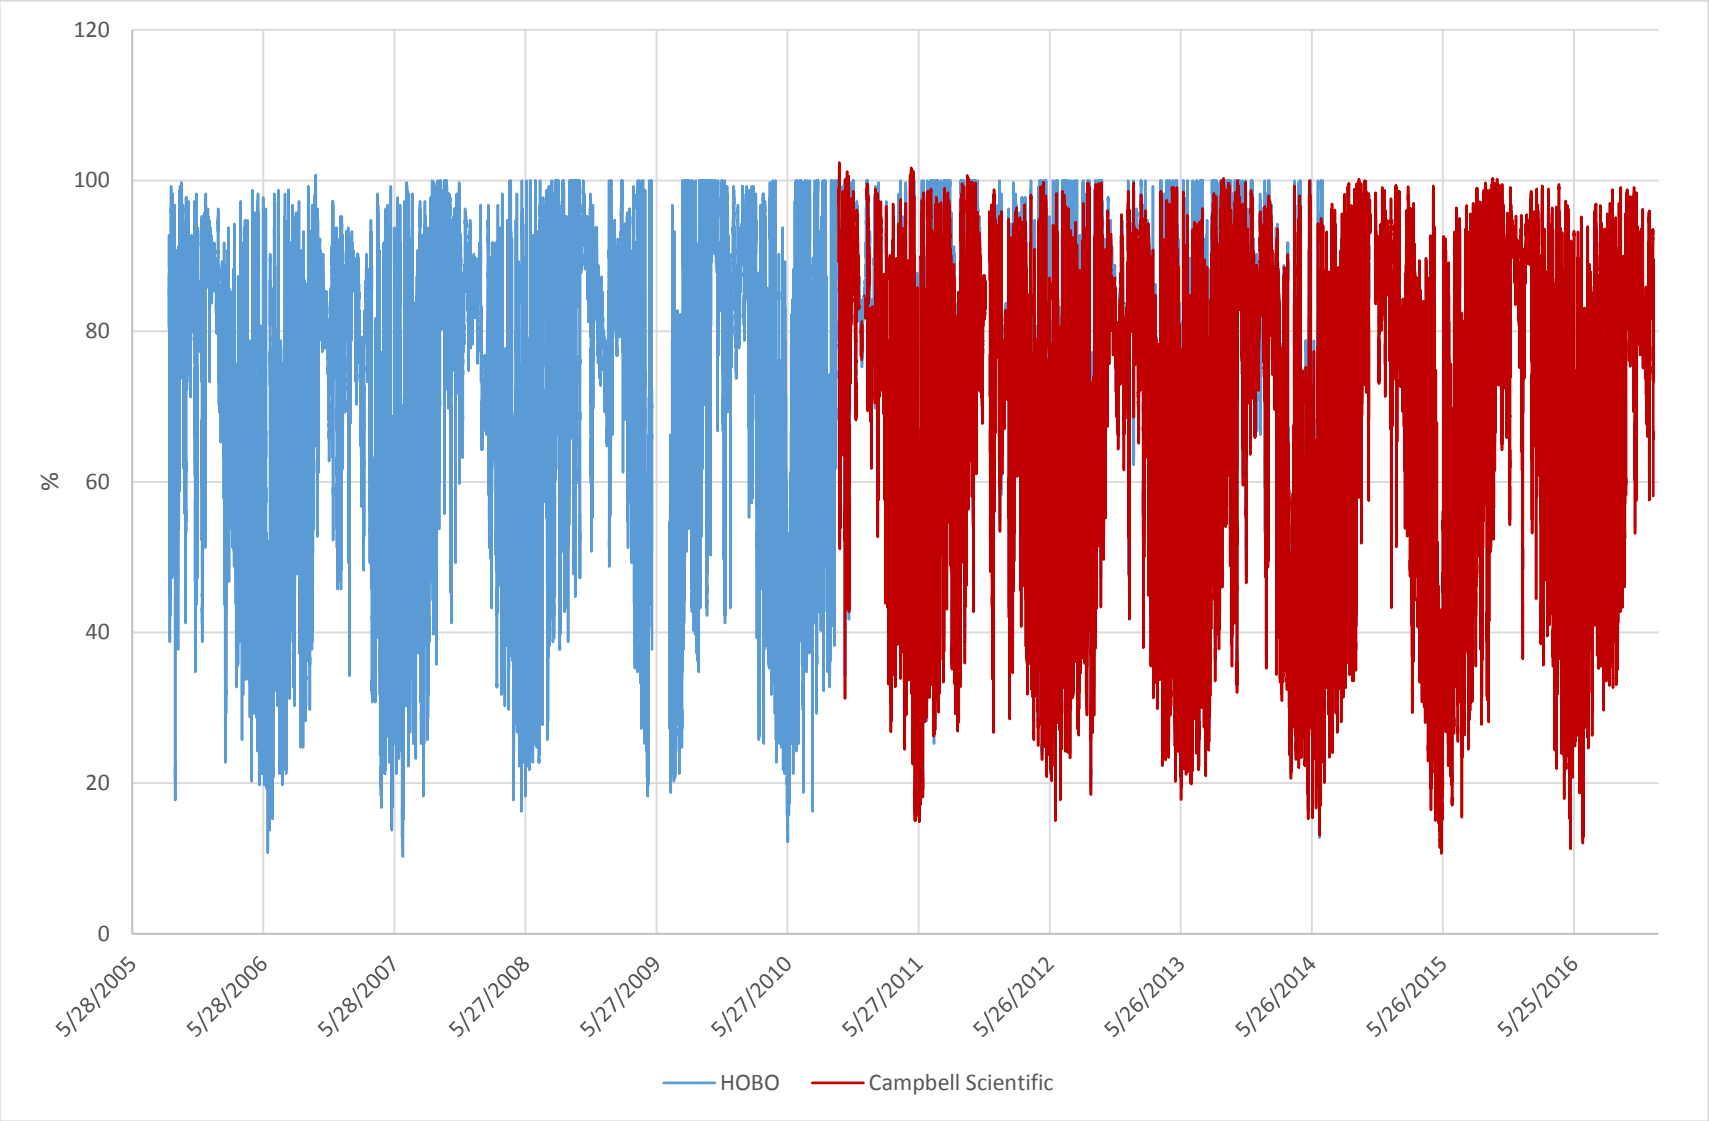

Figure 2-17: Minto Mine Hourly Relative Humidity (%), 2005–2016.

2.2.6 SOLAR RADIATION

Table 2-13 shows the average amount of solar radiation received each day at the site by month. The highest amount is received on average in June and the lowest is in December. Mean annual solar radiation is 108 W/m^2 (averaged over the two meteorological stations).

Table 2-13: Monthly and Annual Average Incoming Solar Radiation (W/m^2), Minto Mine.

	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual
HOBO (2005-2014)	10	41	109	175	221	237	215	168	104	47	14	5	112
Campbell Scientific (2010-2016)	9	31	98	167	216	225	197	154	95	42	10	4	104

Hourly solar radiation is plotted for the entire period of record in Figure 2-18. As would be expected at a latitude of 62.6 °N, a strong seasonal pattern is evident, with maximum solar radiation observed near the summer solstice in late June, and values just slightly above zero around the winter solstice when the site experiences only about 3 hours of direct sunlight per day. Large fluctuations from the general trend during the summer are due to cloud cover.

On July 20, 2016, a second pyranometer was installed at the Campbell Scientific station to measure outgoing radiation. Monthly averages for July (partial) to December are shown in Table 2-14.

Table 2-14: Monthly Average Outgoing Radiation (W/m^2), Minto Mine.

	Jul-16	Aug-16	Sep-16	Oct-16	Nov-16	Dec-16
Campbell Scientific	*32*	34	22	24	12	6

Note: grey italics indicate an average based on partial data

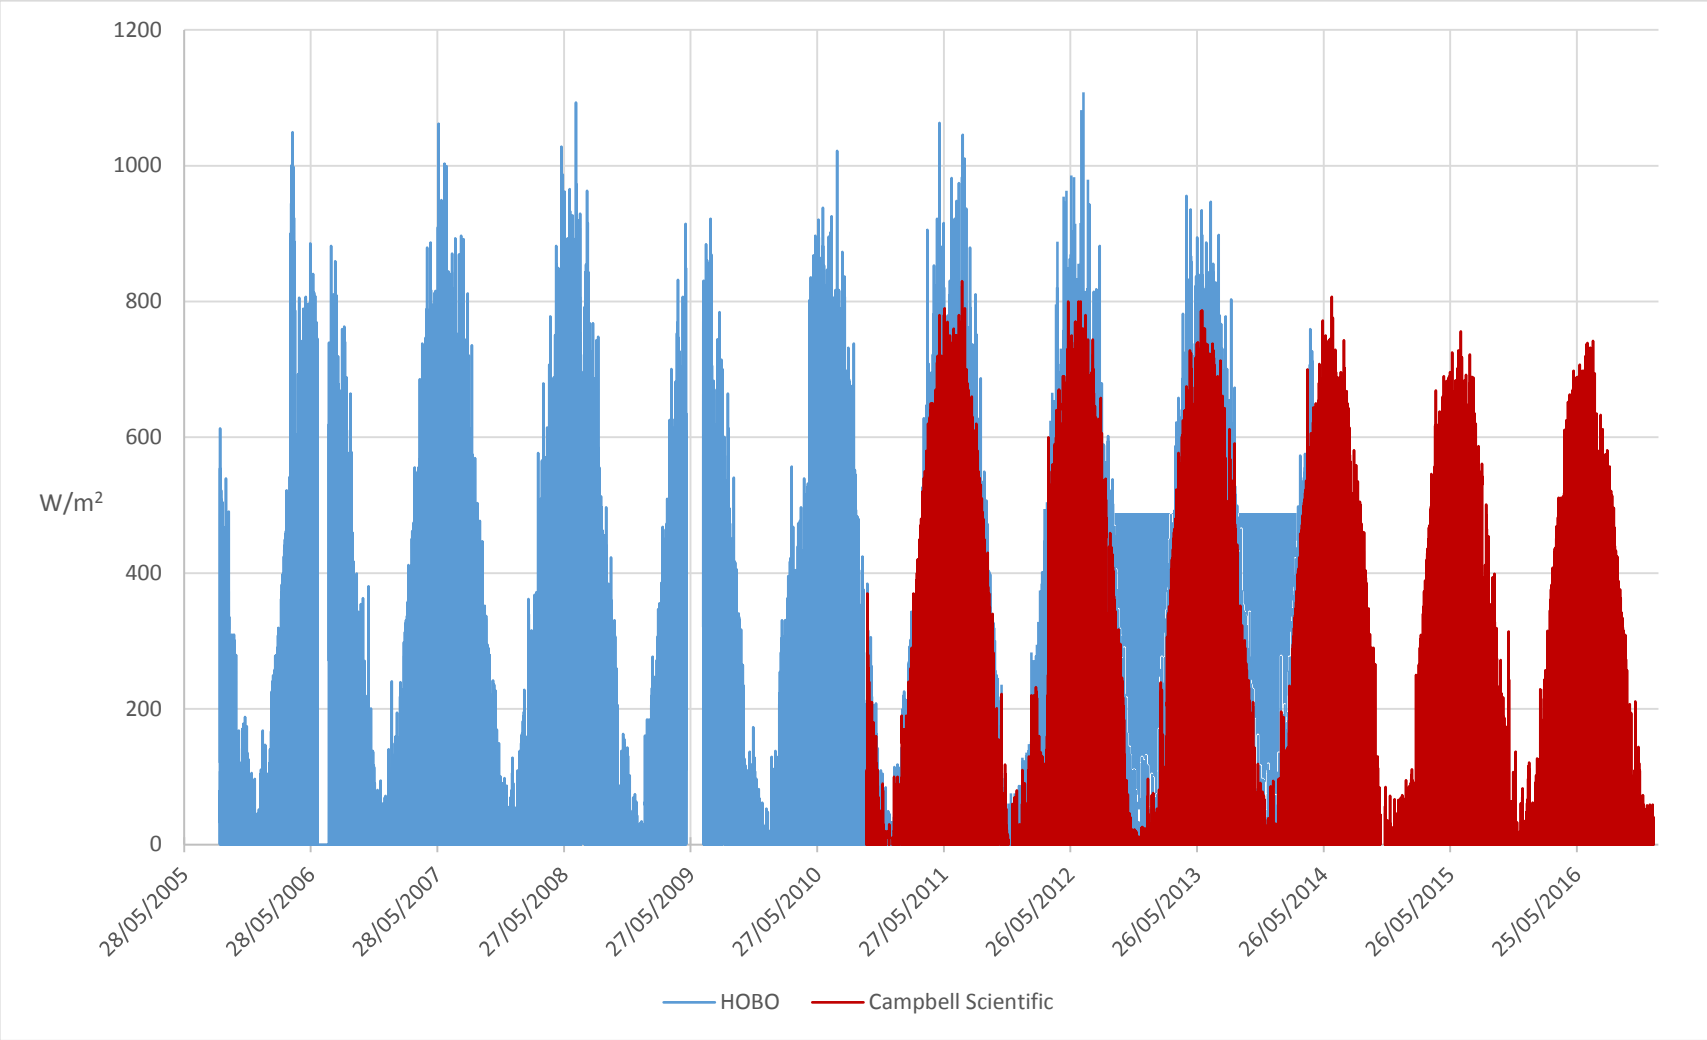

Figure 2-18: Minto Mine Hourly Incoming Solar Radiation (W/m²), 2005–2016.

2.2.7 BAROMETRIC PRESSURE

Barometric pressure recorded on-site at 885 m elevation has been converted into a meteorological standard sea-level equivalent using the formula:

$$BP_{sl} = BP_{el} + 1013.25\left[1 - \left(1 - \frac{h}{44307.69231}\right)^{5.253283}\right]$$

where: BP_{sl} = sea-level equivalent barometric pressure
BP_{el} = barometric pressure recorded at elevation
h = height above sea level (in m)

Table 2-15 shows average sea-level equivalent barometric pressure by month at the site. Barometric pressure is slightly higher on average between May and August (above 1009 hPa), and lowest between September and April (below 1008 hPa). Mean annual sea-level equivalent barometric pressure is 1006.5 hPa (average of both meteorological stations).

Table 2-15: Monthly and Annual Average Sea-Level Equivalent Barometric Pressure (hPa), Minto Mine.

	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual
HOBO (2005-2014)	1006	1007	1003	1007	1011	1010	1011	1009	1008	1006	1005	1006	1006
Campbell Scientific (2010-2016)	1005	1006	1005	1006	1011	1010	1011	1010	1005	1007	1004	1006	1007

Hourly sea-level equivalent barometric pressure recorded at the site is plotted for the entire period of record in Figure 2-19. A slight seasonal pattern can be observed with higher values during summer than during fall and early winter. Winter is also characterized by a much higher day-to-day variability. Note that the barometric pressure sensor on the Campbell Scientific weather station malfunctioned (possibly as a consequence of low battery voltage) and had to be sent back for repair; hence the data gap between November 12, 2010 and March 4, 2012.

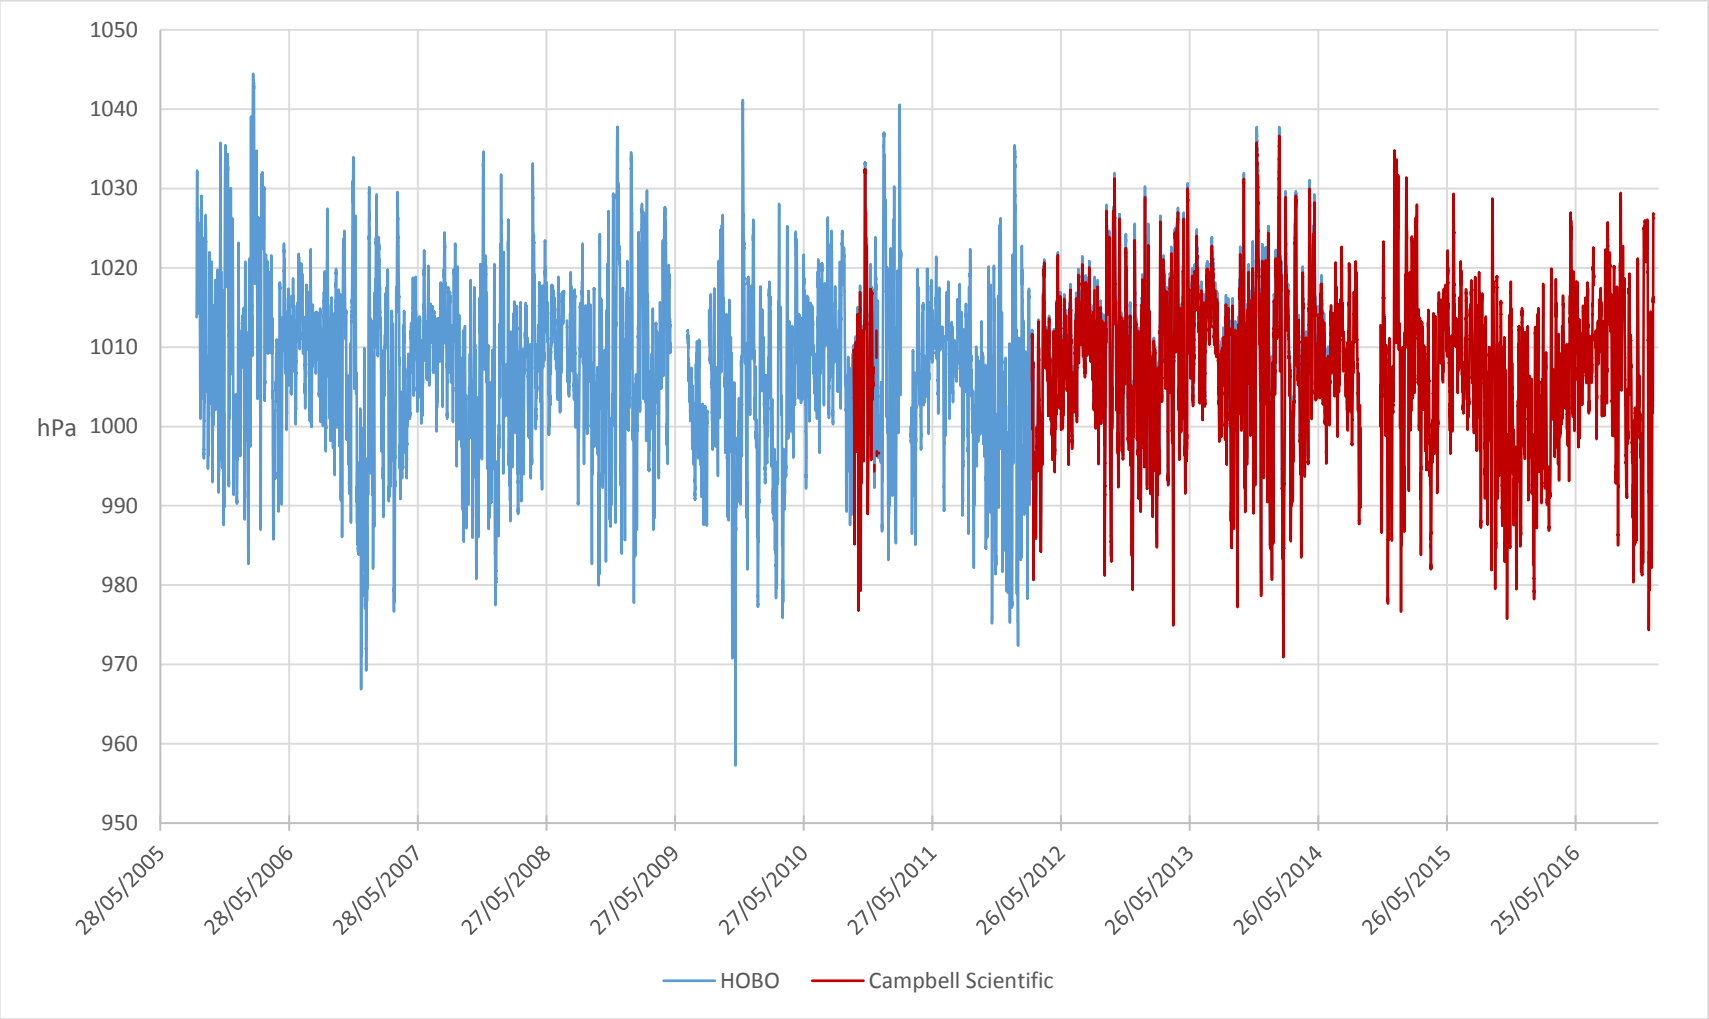

Figure 2-19: Minto Mine Hourly Sea-Level Equivalent Barometric Pressure (hPa), 2005–2016.

2.2.8 EVAPORATION AND EVAPOTRANSPIRATION

2.2.8.1 Regional Data

Monthly lake evaporation was reported by Environment Canada for Pelly Ranch over the period of 1971–1999 as a mean daily evaporation. Data show measurable evaporation occurring only between May and September. An estimate of mean annual lake evaporation is determined to be 460 mm for Pelly Ranch by multiplying each month's daily mean by the number of days in the month. The Ministry of Environment's Manual of Operational Hydrology in B.C. suggests a reduction in evaporation with elevation equal to 10% per 350 m elevation rise (HPK 1994). With an elevation difference of slightly over 400 m, the extrapolation would suggest an annual evaporation at site on the order of 400 mm/year.

2.2.8.2 Site Data

No evaporation records are available for the Minto Mine site. An evaporation pan was deployed on site during the summer of 2016, however, due to a system error, data are invalid.

Starting in August 2012, the Campbell Scientific datalogger program incorporated an instruction for the calculation of potential evapotranspiration (PET) using the American Society of Civil Engineers (ASCE) standardized reference evapotranspiration equation (Penman-Monteith). The PET instruction uses temperature, relative humidity, wind speed, solar radiation, latitude, longitude and altitude to calculate an evaporation rate for a short grass crop. This provides an approximation of actual evaporation, which varies locally depending on surface type and micro topography. Table 2-16 presents the average monthly calculated PET.

Table 2-16: Monthly and Annual Average Potential Evapotranspiration (mm), Minto Mine.

Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual
-5.7	-0.5	19.9	47.4	95.6	106.5	81.7	64.5	31.1	0.9	-3.2	-5.3	427.8

The average total annual PET is 428 mm which is similar to the estimated mean evaporation value of 400 mm/year based on regional data. Figure 2-20 shows the hourly calculated PET, which displays a strong seasonal pattern. Maximum PET occurs in June while winter months (November to February) often display negative values, which can be interpreted as an increase in soil moisture.

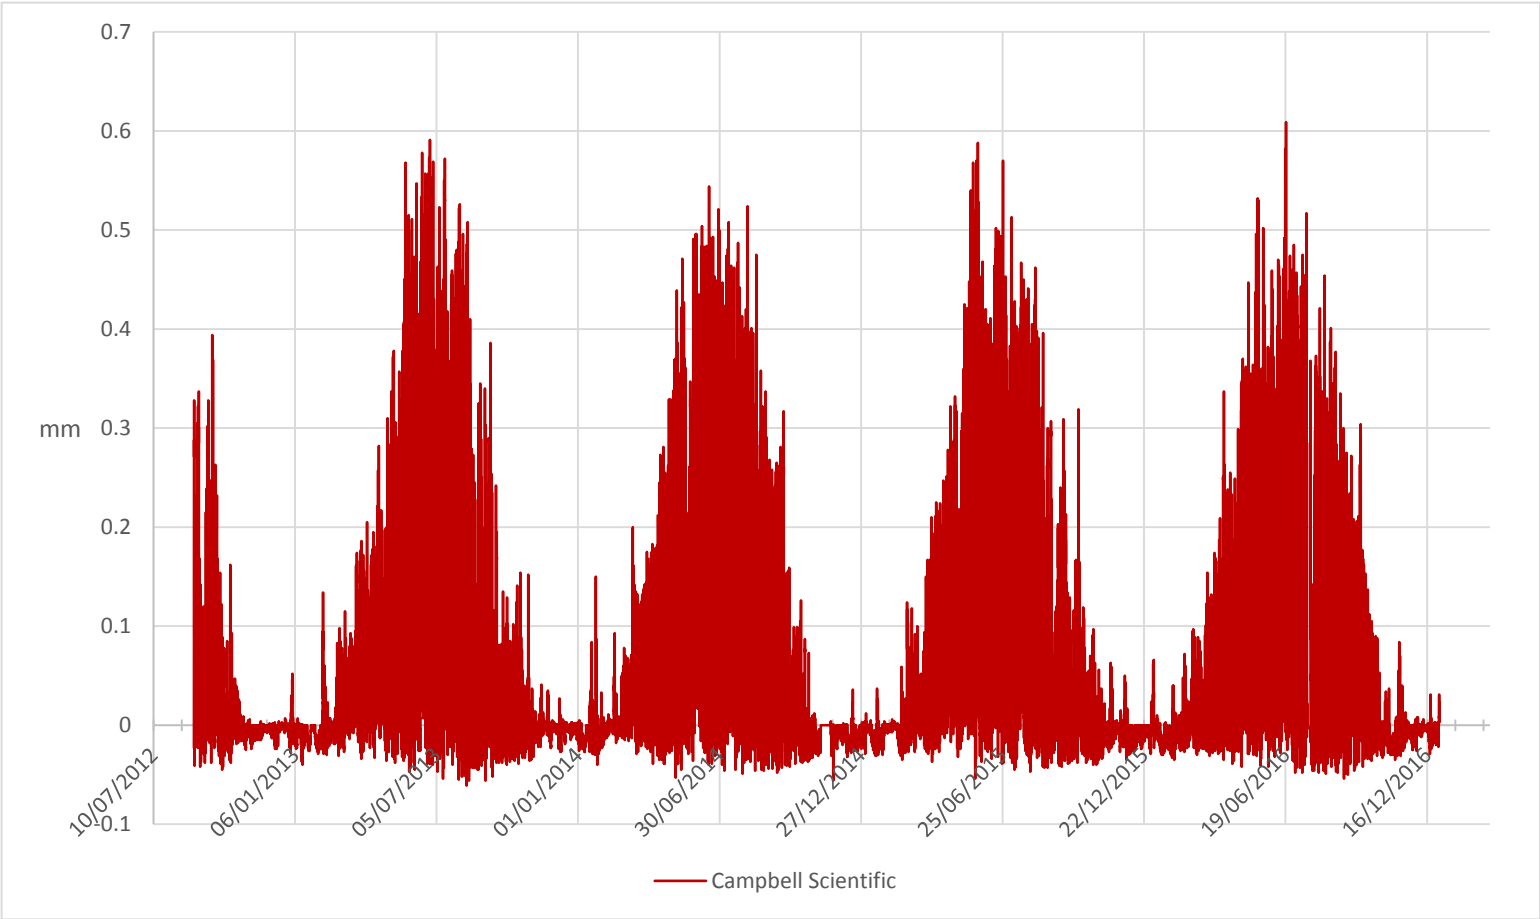

Figure 2-20: Minto Mine Hourly Potential Evapotranspiration (mm), 2012–2016.

3. SURFACE WATER HYDROLOGY

3.1 METHODS

3.1.1 REGIONAL DATA

Regional hydrometric stations operated by Water Survey of Canada (WSC) can provide insight on long-term trends. Big Creek near the Mouth station (09AH003) is located in the vicinity of the Project area (see Figure 3-1) and has been monitored since 1975. Although the drainage area of Big Creek is much larger than that of Minto Creek or McGinty Creek (1800 km^2 compared to 42.2 km^2 and 33.8 km^2 for Minto creek and McGinty creek catchments respectively), the long-term record at Big Creek can be used as a proxy for the site.

3.1.2 SITE DATA

Minto Explorations Ltd. (Minto) maintains a network of hydrometric stations as part of its regular monitoring of surface water hydrological conditions at the Minto Mine in Minto and McGinty Creeks (Figure 3-1). Minto Mine personnel conduct regular discrete discharge measurements and maintenance at the stations where Solinst Levelogger and Barometric Loggers are utilized to capture continuous stage records.

Data coverage from year to year varies, depending on when in situ dataloggers were installed and removed, and when instantaneous discharge measurements were taken. Instantaneous discharge is measured using the velocity-area method using a current meter. Solinst Water Leveloggers are used to collect continuous stage readings which are then corrected based on physical staff gauge measurements. The records are processed into a continuous discharge record based on the stage-discharge relationship. This relationship (stage and discharge) is established each season through rating measurements obtained during regular field visits to the sites. Hydrographs for stations and seasons where enough data are available to produce rating curves are presented in Appendix B.

Paired Solinst Leveloggers and Barologgers are utilized to collect the continuous stage record. All measurements are entered into a master spreadsheet and .CSV files are created which include date, time, staff gauge height and discharge measured. These rating measurements are then imported into a data management software package (Aquatic Informatics' Aquarius Time-Series was used from 2012 to 2015) and a rating curve is built. Rating curve development considers which measurements should be included and when and where shifts to the rating are appropriate. All measurements within the continuous period are included in the hydrographs (Appendix B). Rating curve shifts are used at some Minto sites when and where appropriate.

3.1.2.1 QA/QC

Hydrometric data are collected and managed throughout the open water season by Minto staff on both Minto and McGinty Creeks. Minto utilizes the Velocity-Area method of discharge calculation and measures velocity using a Hach FH950 handheld electromagnetic flow meter. Measurements are conducted manually and paired with staff gauge observations and site photographs. In general, multiple visits per month occur on Minto Creek and monthly visits occur on McGinty Creek during the open water season.

These data are checked for entry and calculation errors and suspect measurements by Minto after field personnel have entered measurements into a calculation spreadsheet. Suspect measurements are verified against photos and field notes (e.g. if they differ greatly from the stage-discharge relationship). This can be due to ice effects or other changing control conditions such as scour, aggradation and vegetation control.

Barometrically compensated Solinst water level data are imported into Aquarius software from .CSV files which are exported from Solinst software following compensation. Aquarius allows for adjustment of the Solinst record to match the staff gauge observations, for development of rating curves with the field data, and for automatic processing of continuous discharge records. This preserves the raw data in an easy to reference format and changes can be made to the data at any time which then cascade through the various time series. For example, at new sites, rating curves may improve after several seasons and alter a previous year's continuous record as the high or low end of the rating curve becomes better defined. Stage time series are adjusted for drift, offset and erroneous data are deleted or omitted from discharge computation if they are deemed ice affected. The rating curve is automatically applied to the continuous stage record for a specified time period to create the continuous discharge time series.

3.2 RESULTS

3.2.1 REGIONAL DATA

Table 3-1 presents the mean monthly discharge for the period of record at WSC station Big Creek near the Mouth, and Figure 3-2 displays the annual mean discharge. No clear long-term trend in mean monthly or annual discharge emerges from Big Creek data. Peak flows typically occur in May.

Table 3-1: Mean monthly discharge (m^3/s), Big Creek near the Mouth (WSC station).

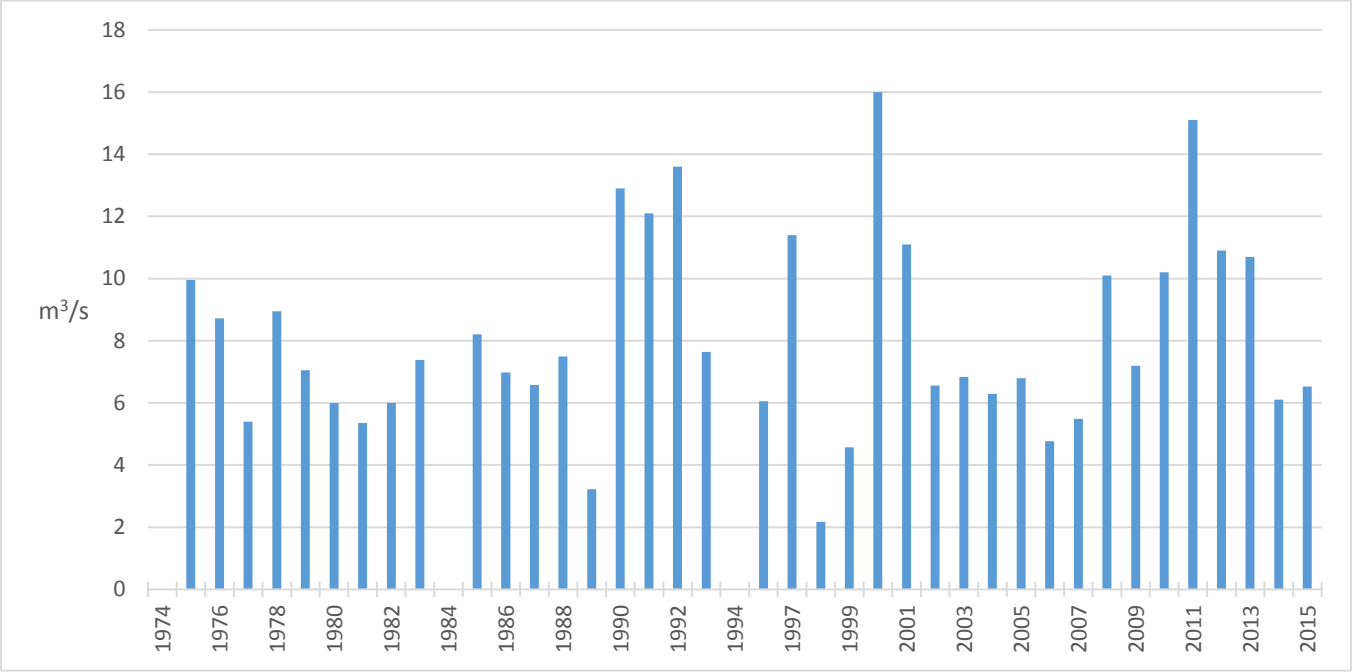

Figure 3-2: Mean annual discharge (m^3/s), Big Creek near the Mouth (WSC station).

3.2.2 MINTO CREEK

Monitoring of hydrological parameters on Minto Creek began in 1993 and has continued intermittently to date at sites W1 and W3 (Figure 3-1). Monitoring has been more intensive since mine commissioning in 2007. The locations for which the greatest amount of data have been collected are stations W1, "Minto Creek near the mouth" (catchment area of 42 km^2); and W3, "Minto Creek downstream of water storage pond dam" (catchment area of 10.4 km^2 area). In 2010, another continuously monitored hydrometric site called MC-1 was added, approximately 2 km upstream of W1. W3 is now an in-stream trapezoidal flume with a manufacturer-specified stage-discharge relationship. Both discharge and stage are read on an integrated gauge in the throat of the flume. A Solinst Levelogger record is calibrated with these field observations to process a continuous discharge record at this site. Sites MC-1 and W1 are natural stream channels where manual velocity measurements are taken across the channel and discharge is calculated using the velocity area method. Continuous water levels from Solinst Leveloggers are processed into continuous discharge using these rating measurements.

3.2.2.1 Station W3 – Flume below Water Storage Pond Dam

Water level is continuously monitored in the flume which is approximately 500m from the toe of the Minto Water Storage Pond dam via a Solinst Levelogger in combination with a barometric logger. Frequent observations by Minto staff (minimum weekly) allow for correction of the level logger to the actual height of water in the flume and confirmation of the manufacturer's specified stage-discharge relationship. This provides a record with a high degree of accuracy. Table 3-2 summarizes the continuous data as mean monthly flows, hydrographs are presented in Appendix B. The winter stage record was interpolated using the discrete stage observations. In general, the flume typically flows at 3-4 L/s, but it should be noted that flows at W3 are impacted by storage within, and discharge from the Water Storage Pond.

Table 3-2: Mean monthly discharge (m^3/s), Minto Creek at W3.

[3]Insufficient data for calculation.

3.2.2.2 Station MC-1 – Minto Creek Mid-Catchment

Hydrometric station MC-1 is located between the flume at W3 and is just upstream of the canyon on lower Minto Creek. This site is characterized by shallow channel slope and slower moving water above the control of the canyon. Table 3-3 summarizes these data as mean monthly flows and Appendix B presents the hydrographs.

MC-1 experiences a later summer shift which is likely due to aggradation in the channel. This seasonal shift from the base rating curve appears consistently, but is not exactly the same from year to year. Minto staff report that MC-1 freezes to the stream bed in winter. Discharge is again observed to be greater at this site than at W1 which supports the theory that Minto creek loses significant water to groundwater networks as it flows towards the Yukon River.

Table 3-3: Mean monthly discharge (m^3/s), Minto Creek at MC-1.

3.2.2.3 Station W7 – Tributary of Minto Creek

This site is located on the first tributary of Minto Creek below W3 (Figure 3-1). A staff gauge was installed at this station during the summer of 2013. Historically, this station was a regularly monitored surface water station prior to the installation of the staff gauge. In 2014, the staff gauge was damaged by ice and repaired for the hydrometric program in 2015. In 2016, several discrete discharge measurements were recorded without a corresponding stage. Table 3-4 provides a summary of historically measured flows at W7. These flows are based on discrete measurements only. Although pressure transducers were deployed at this site in 2013, 2014, and 2015, a rating curve was not established given the limited amount of flow and stage data available. There currently is no pressure transducer and datalogging unit at this site. The low discharge combined with the dynamic nature of channel morphology at this site do not contribute to the consistent development of a continuous record, and instead contribute low confidence in the existing continuous record. To obtain good quality data with a pressure transducer, an artificial control such as a v-notch weir is recommended. Appendix B presents hydrographs for seasons where a pressure transducer was deployed at this site.

Notes: [1] Based on discrete measurements only

3.2.2.4 Station W1 – Lower Minto Creek above Road Crossing

W1 station is located on the lower reach of Minto Creek before flowing into the Yukon River. W1 is located downstream of MC-1 and it is expected that flows would be larger because it has a much larger catchment area than MC-1. W1 flows are typically lower than MC-1 from mid-spring through fall suggesting that the section of stream from the bottom of the Minto Creek canyon (upstream of W1) to near the mouth is a 'losing' reach. A portion of the surface water downstream

of MC-1 and the canyon recharges the groundwater system and by-passes the surface water hydrometric measurements at station W1. Table 3-5 summarizes these W1 data as mean monthly flows and hydrographs can be found in Appendix B.

Table 3-5: Mean monthly discharge (m^3/s), Minto Creek at W1.

3.2.3 McGINTY CREEK

McGinty Creek has two main sub-catchments that each have two water quality monitoring stations, one just above the confluence and one near the headwaters. MN-4.5 is located on the main stem below the confluence of the tributaries near the mouth; just above the Yukon River (Figure 3-1). MN-0.5 and MN-0.2 are the lower and upper stations on the west tributary, respectively. MN-2.5 and MN-1.5 are the lower and upper stations on the east tributary, respectively. Stations MN-0.2 and MN-1.5 are not set up with continuous loggers and generally exhibit very low flows. As such they are not included in the discussion below.

3.2.3.1 Station MN-4.5 – McGinty Creek near the Mouth

Station MN-4.5, situated near the mouth of McGinty Creek, is similar in catchment area to Minto Creek, but exhibits consistently higher flows than W1 (located at a similar location Minto Creek). Table 3-6 summarizes the monthly mean values from the continuous record with earlier years' values included for comparison. Hydrographs are presented in Appendix B.

Table 3-6: Mean monthly discharge (m^3/s), McGinty Creek at MN-4.5.

Notes: [1] Based on incomplete or derived data

4. CONCLUSIONS

Regional and local hydrometeorological data are used to characterize existing conditions at the Project site, which are being refined and updated as more years of data become available. Ten years of meteorological data collected at site allow a reasonably good characterization of year to year variability, but may not capture extremes. No clear trend emerges from site meteorological data over the period of record. The hydrological data record is relatively short at most sites and does not allows for the detection of meaningful trends. Sites W1 and W3 have a longer record for the open water season and capture more year to year variability, but no long-term trend in flow rates or timing emerges at this point.

APPENDIX A.

Minto Meteorological Stations Description

MINTO HOBO METEOROLOGICAL STATION

Site Identification: Minto HOBO Station

Installation Date: September 18, 2005
Decommissioning Date: June 25, 2014

Station Coordinates: North 62° 36' 17"
West 137° 13' 19"

Tower Height: 3 m
Site Elevation above Sea Level: 887 m

STATION DESCRIPTION

The weather station consists of a three-meter tripod with instrumentation to measure wind speed and direction, air temperature, relative humidity, barometric pressure, incident solar radiation, and rainfall (wet-precipitation). The station is powered by four AA batteries. Data are recorded to a HOBO data logger. Data are averaged over the one-hour archiving period and saved to the logger memory. The station has an internal flash memory capacity of 512 Kb.

SITE LOCATION

The meteorological station is located approximately 70 meters northeast of the north end of the airstrip. The station sits on the southern ridge of the main river valley and has good exposure in all directions. Surrounding the station are sparse conifers under 2 meters.

INSTALLATION NOTES

The tower base supports are fixed to a square wooden frame. Sandbags are used at the base of the tripod legs to help stabilize the station.

The wind anemometer is installed at the top of the tower with the pyranometer and tipping bucket rain gauge fastened on the center pole slightly below. The air temperature/RH sensor is installed inside a radiation shield near the middle of the tower. The barometric pressure sensor is located inside the logger box.

RECORDED DATA NOTES

Winds

Cup revolutions are accumulated every three seconds for the duration of the logging interval (one hour). Wind speed is the average speed for the entire logging interval. Gust speed is the highest three-second wind in the logging interval.

Vector components of wind direction are accumulated every three seconds for the duration of the logging interval. Average direction is calculated from the sum of the vector components over the logging interval, and represents the direction from which the wind is blowing.

MINTO CAMPBELL SCIENTIFIC METEOROLOGICAL STATION

Site Identification:	**Minto Campbell Scientific Station**	Installation Date:	October 15, 2010
Station Coordinates:	North 62° 36' 17"	Tower Height:	10 m
	West 137° 13' 19"	Site Elevation above Sea Level:	887 m

STATION DESCRIPTION

The weather station consists of a ten-meter tower with instrumentation to measure wind speed and direction, air temperature, relative humidity, barometric pressure and incident solar radiation. Rainfall (wet-precipitation) is measured with a tipping bucket installed on a separate mounting post, located about 2m away from the main tower. The station is powered by a 12V battery which is recharged by a 20W solar panel. Data are averaged over one-hour and 24-hour archiving periods, and saved to the data logger memory. The logger has an internal flash memory capacity of 2 Mb.

SITE LOCATION

The meteorological station is located approximately 70 meters northeast of the north end of the airstrip. The station sits on the southern ridge of the main river valley and has good exposure in all directions. Surrounding the station is sparse growth of conifers under 2 meters. A radius of 30m around the tower is clear of trees.

INSTALLATION NOTES

The tower base is anchored into a 91 X 91 X 122 cm concrete block and three guy wires are attached to the tower at a height of about 8 meters. The guy wires are tied to dead man anchors located five meters away from the tower that consist of 3-foot long 6” X 6” timber buried 2–4 feet underground.

The wind anemometer is installed on a cross arm at the top of the tower. The pyranometer is on a mounting arm at a height of about 2 m and is facing southeast. The solar panel faces south and has a tilt angle of 78°. For latitudes between 46° and 65°, the tilt angle is obtained by adding 15° to the latitude. The air temperature/RH sensor is installed inside a radiation shield at a height of about 1.75 m above the ground and faces west. The barometric pressure sensor is located inside the logger box, which is at a height of 1.5 m, on the north-facing side of the tower. To ensure moisture doesn’t affect the instruments in the enclosure, desiccant was placed inside (it should be replaced periodically, when its indicator turns pink). The tipping bucket rain gauge is fastened onto a 1 m-high mounting pole located about 2 m east of the tower.

RECORDED DATA NOTES

Time

All data are recorded in standard time and is not adjusted for daylight saving time.

Barometric Pressure

The barometric pressure sensor is powered for one minute before the top of each hour, at which time the sensor is polled for a measurement.

The datalogger program includes a correction for elevation and pressure is reported as sea-level-equivalent. The correction formula is as follows:

$$BP_{sl} = BP_{el} + 1013.25\left[1 - \left(1 - \frac{h}{44307.69231}\right)^{5.253283}\right]$$

where: BP_{sl} = sea-level-equivalent barometric pressure
BP_{el} = barometric pressure recorded at elevation
h = height above sea level (in m)

Winds

Wind data are recorded as wind vector. Output data include mean horizontal wind speed (S), unit vector mean wind direction (θ1), and standard deviation of wind direction (σ(θ1)). Note that in this case of a wind vector, the wind direction is the direction **towards** which the wind is blowing.

CAMPBELL SCIENTIFIC STATION INSTRUMENTATION

Instrument	Model	Measuring Range	Sensitivity/Accuracy
Wind Speed and Direction	RM Young 05103AP-10	Speed: 0–60 m/s Gust survival 100 m/s	Accuracy: ± 0.3 m/s Threshold sensitivity = 1.1 m/s
		Direction: 0–355° (5° deadband)	n/a

		Temp: -50°C–+50°C	Accuracy: ± 0.1°C (at 0°C), ± 0.35°C (at ±50°C) Resolution: 0.1°C
Barometric Pressure	RM Young 61302V	500–1100 hPa	Accuracy (at 25°C): ± 0.2 hPa Resolution: 0.01 hPa
Pyranometer	Kipp & Zonen SP Lite 2	Spectral Range: 400–1100 m	Sensitivity: <±2% shift per year
Tipping Bucket Rain Gauge	Texas Electronics TE525M	Infinite in increments of tip (least count) of rainfall	Accuracy: ±1.0% up to 10 mm/hr +0, -3% (10–20 mm/hr) +0, -5% (20–30 mm/hr) Resolution : 0.1 mm
Snowfall Conversion Adaptor	CS705	Depends on tipping bucket	Depends on tipping bucket
Total Precipitation Gauge	Geonor T-200B (one sensor)	600 mm capacity	Better than 0.1 mm

MINTO MINE SITE CHARACTERIZATION – SURFACE WATER QUALITY

MINTO AND MCGINTY CREEKS WATER QUALITY CHARACTERIZATION

JANUARY 2005 – DECEMBER 2016

MIN-17-01-500_005_Minto Site Characterization Water Quality_RevA_180125

January 2018

Prepared for:

MINTO EXPLORATIONS LTD.

ALEXCO ENVIRONMENTAL GROUP INC. SIGNATURES

Report prepared by:	Matthew Corriveau, M.Sc. Environmental Geoscientist	1/25/2018
Report reviewed by:	Andrew Gault, Ph.D. Environmental Chemist	1/25/2018
Report reviewed by:	T. Scott Keesey, B.Sc. EP Sr. Environmental Manager	1/25/2018

TABLE OF CONTENTS

1 INTRODUCTION 2

1.1 WATER MANAGEMENT HISTORY 2
1.2 PREVIOUS WATER QUALITY CHARACTERIZATION REPORTING 3
1.2.1 Minto Creek 3
1.2.2 McGinty Creek 4

2 METHODS 7

2.1 MONITORING STATION ORGANIZATION 7
2.1.1 Minto Mine Site 7
2.1.1.1 Upper Mine Site 8
2.1.1.2 Lower Mine Site 8
2.1.2 Minto North Pit 10
2.1.3 Minto Creek 10
2.1.4 McGinty Creek 13
2.2 DATA COLLECTION, HANDLING AND QUALITY ASSESSMENT 15
2.3 WATER QUALITY STANDARDS AND OBJECTIVES 17
2.4 INTERPRETATION OF WATER QUALITY DATA 21

3 RESULTS AND DISCUSSION 22

3.1 MINTO MINE SITE 22
3.1.1 Upper Minto Mine Site 22
3.1.1.1 Physical Parameters, Anions and Nutrients 22
3.1.1.2 Metals 30
3.1.2 Lower Minto Mine Site 41
3.1.2.1 Physical Parameters, Anions and Nutrients 41
3.1.2.2 Metals 47
3.2 MINTO NORTH PIT 57
3.2.1 Physical Parameters, Anions and Nutrients 57
3.2.2 Metals 57
3.3 MINTO CREEK 68
3.3.1 Operational Phase without Mine Discharge 68
3.3.1.1 Physical Parameters, Anions and Nutrients 68
3.3.1.2 Metals 72
3.3.2 Operational Phase with Mine Discharge 76
3.3.2.1 Physical Parameters, Anions and Nutrients 76
3.3.2.2 Metals 79
3.4 MCGINTY CREEK 109
3.4.1 McGinty Creek East Arm 109
3.4.1.1 Physical Parameters, Anions and Nutrients 109
3.4.1.2 Metals 114
3.4.2 McGinty Creek West Arm Reference 124
3.4.2.1 Physical Parameters, Anions and Nutrients 124
3.4.2.2 Metals 128

4 SUMMARY 137

4.1 MINTO MINE SITE 137
4.2 MINTO NORTH PIT 138
4.3 MINTO CREEK 138
4.4 MCGINTY CREEK 139

LIST OF APPENDICES

APPENDIX A BACKGROUND WATER QUALITY OF LOWER MINTO CREEK FOR APPLICATION IN THE DERIVATION OF POST-CLOSURE WATER QUALITY OBJECTIVES

APPENDIX B METHODS FOR COMPUTING SUMMARY STATISTICS FOR CENSORED DATA

APPENDIX C MINTO CREEK, MCGINTY CREEK AND MINTO MINE WATER QUALITY DATA (JANUARY 2005 – DECEMBER 2016)

EXECUTIVE SUMMARY

Surface water quality in and around the Minto Mine has been the subject of numerous characterization efforts since 1994. In this report, surface water quality at the Minto Mine site and downstream water courses was characterized using data collected from January 2005 to December 2016. The water quality characterization was organized by grouping data into areas including critical water management monitoring locations in the Minto Mine site operational area, the mainstem of Minto Creek during the operational phase of the Minto Mine, the Minto North Pit, and McGinty Creek. Minto Creek receiving environment data were further divided into periods of active effluent discharge and no discharge from the mine site. Where applicable, comparison of water quality was made to the effluent quality standards (EQS) and water quality objectives (WQO) stipulated within water use licence (WUL) QZ14-031. Summary statistics are presented with graphical plots of concentrations over time at key water quality monitoring stations.

The pH of the Mine Site, Minto North Pit, Minto Creek, and McGinty Creek waters was predominantly circumneutral to slightly alkaline. Nitrogen species concentrations were generally highest in the pit lake and DSTSF drainage sites reflecting leaching of nitrogen residue from blasting activity. Nitrate-N levels showed marked seasonality in Minto Creek sites within the site and downstream of the site and in McGinty Creek with higher concentrations in the winter and lower concentrations in the spring and summer, responding to nitrogen uptake demand by primary producers and dilution from spring meltwater. Nitrate-N levels were typically higher in Minto Creek during and following mine discharge periods. Dissolved organic carbon (DOC) concentrations were often highest during spring snowmelt likely due to flushing of labile organic carbon from soils. Higher DOC levels were also observed in late summer in sampling locations farther downstream in Minto Creek and McGinty Creek.

At all flowing sites, dissolved hardness concentrations were typically lowest during spring snowmelt and increased through the year, peaking in winter, suggestive of a marked groundwater component to hardness levels. Dissolved iron, and to a lesser extent aluminum, were often observed at concentrations higher than expected from equilibrium with their oxyhydroxide minerals under the prevalent oxidizing, circumneutral pH conditions. Reasonable correlations between dissolved iron and DOC at several sites on the mine site and in McGinty and Minto Creek suggest complexation with dissolved organic matter likely maintains these elevated dissolved iron (and often arsenic) and aluminum levels.

On the Mine Site, dissolved copper concentrations were highest in the DSTSF drainage and tended to peak with freshet, suggestive of some association with DOC. Dissolved copper concentrations in Minto Creek were higher during and following mine discharge periods, particularly during the emergency site discharge period of June 26 to August 6, 2009. Dissolved copper concentrations in McGinty Creek also tended to be higher during spring snowmelt, correlating reasonably well with DOC concentrations.

Dissolved concentrations of both selenium and molybdenum increased approximately four-fold in the pit lake sites over the past two to three years, alongside sulphate. In Minto Creek and downstream of the mine site and in McGinty Creek, selenium exhibited seasonal cycling with concentrations lowest at freshet, then rising through the year, peaking in winter, suggestive of a strong groundwater contribution. The opposite pattern was observed in the drainage from the DSTSF where selenium levels oscillated on an annual basis between summer peaks and winter troughs. Dissolved selenium concentrations in Minto Creek downstream of the mine site were higher during and following mine effluent discharge periods, while in McGinty Creek higher selenium concentrations were observed in the west arm (reference tributary) of McGinty Creek than the east arm.

1 INTRODUCTION

The Minto Mine is a high-grade copper mine located within Selkirk First Nation (SFN) Category A Settlement Land Parcel R-6A approximately 240 km northwest of Whitehorse, Yukon Territory (62°37'N latitude and 137°15'W longitude; Figure 1-1). It is owned and operated by the Capstone Mining Corporation. Development of the mine was initiated in 1997, commercial operations started in October 2007, and the currently anticipated operating life is to 2020. The Minto Mine is permitted to conduct open pit and underground mining, and to mill the copper/gold/silver ore at a rate of 4,200 tonnes of per day. In 2016 (the most recent year of record), the Minto Mine produced 69.3 million pounds of copper from the milling of 1.49 million tonnes of ore. Mill tailings are deposited into both the Main Pit Tailings Management Facility and the Area 2 Pit Tailings Management Facility (Figure 1-2). Mine-impacted seepage from the Dry Stack Tailings Storage Facility (DSTSF) and under the Mill Valley Fill Expansion (MVFE) is collected at the toe of the MVFE and pumped to the Main Pit (Figure 1-2). Non-impacted water and treated mine-impacted water are collected in a Water Storage Pond (WSP; Figure 1-2). Effluent from the WSP is periodically discharged to Minto Creek under conditions specified in Water Use Licence (WUL) QZ14-031 (August 2015). Minto Creek, in turn, discharges to the Yukon River approximately 7.7 km south-east of the WSP (Figure 1-2).

Minto Creek and McGinty Creek are receiving environments for Minto Mine and both have been previously characterized in numerous reports. These previous reporting initiatives are summarized in Section 1.2. This report provides updates to the water quality characterizations of both Minto and McGinty Creek stations and for key mine site water management and monitoring stations, and includes monitoring results to December 2016. Methods used in the evaluation of water quality data are summarized in Section 2 and results which form the basis of the characterization of water quality for Minto Creek and McGinty Creek are provided in Section 3.

1.1 WATER MANAGEMENT HISTORY

Minto constructed, commissioned and operated the Minto Mine under the water management plan and restrictions in the initial project Water Use Licence, QZ96-006. Extremely low effluent quality standards (EQS) – for copper in particular – and low precipitation in 2006 and 2007 led to no effluent discharge from the site. Minto had begun test work and planning to support a licence amendment application to revise the water management strategy – including discharge standards – in 2008, when exceptional summer precipitation led to an inevitable discharge of inventory water that did not meet current EQS. Minto applied for and received an Emergency WUL amendment to release water in August and September of 2008. Minto did so, releasing 350,000m^3 of water from the Pit and Water Storage Pond over 35 days.

The Yukon Territory's unusually high precipitation of the 2008 summer continued throughout the 2008/2009 winter and snow pack measurements taken in February 2009 at the Minto Mine were at least 50% above average (70% in some locations). As a result of this and unusually high spring temperatures, the Minto Mine experienced a more voluminous freshet than normal in early May 2009 and diverted all run-off into the WSP and Pit in order to avoid non-compliant discharge. Following 2009 freshet the WSP contained 300,000 m^3 of water and the Pit contained 700,000 m^3. On application from Minto, the Water Board determined the existence of an emergency and granted an amendment to the WUL on June 26, 2009 authorizing Minto to discharge up to 300,000 m^3 of water from the WSP and the Pit, provided such water met, at a minimum, MMER standards. Minto discharged this water between June 26 and August 6, 2009. In August 2009, Minto received an Inspector's direction from Yukon Government to reduce the inventory of water in the Main Pit for geotechnical reasons. Again, Minto

applied for and received an emergency amendment to the WUL and discharged water to Minto Creek between August 13 and October 30, 2009.

Following this event, Minto commissioned a study to evaluate options for implementing a permanent water treatment plant at the mine. Shortly after the completion of the water treatment evaluation, Minto commissioned detailed design, procurement, and construction of a water treatment plant. The water treatment plant installed at Minto in 2010 was designed to remove suspended solids and dissolved metals; in particular, copper and cadmium. The design was based on meeting effluent quality limits in effect at the time (Water Use Licence QZ96-006 Amendment 6). The total copper concentration limit of 0.01 mg/L was the primary water treatment challenge.

In June 2010, Minto applied for amended effluent quality standards. When Amendment 7 of the Water Use Licence came into effect in March 2011, Minto completed an evaluation of water treatment technologies that would be suitable for producing effluent that would meet the new effluent quality limits. The water treatment evaluation concluded that the main water treatment challenges would be to meet the selenium, nitrate and (to a lesser extent) nitrite limits specified in Amendment 7 (0.003 mg/L, 7.65 mg/L and 0.15 mg/L, respectively). Minto's existing plant would not be effective at removing these parameters.

In 2012, two reverse osmosis (RO) trains capable of handling 2,500 m^3/day per train were added to the treatment process downstream of the existing clarification and filtration units, for treating nitrate and selenium, based on water quality limits received in the Water Use Licence Amendment 7. Treated effluent from the RO units may also be amended, when necessary, with sodium bicarbonate to adjust the pH and add salinity and alkalinity. The RO process removes 95–99% of all constituents in the feed water. The feed water for the RO unit is the effluent from clarification and filtration unit, which is operated as a pre-treatment step.

In 2014, Minto submitted an amendment application for the Phase V/VI Expansion Project, which included operational downstream water quality objectives (WQO) and revised EQS. These WQO and EQS were included in Amendment 8 (August 2015) and are the regulatory benchmarks currently in place for the project.

These water management and effluent discharge milestones are important in understanding the Minto site and receiving environment water quality, as presented and interpreted in this report.

1.2 PREVIOUS WATER QUALITY CHARACTERIZATION REPORTING

1.2.1 Minto Creek

Minnow Environmental Inc. (Minnow) first characterized background water quality of Minto Creek to the end of 2008 within the report entitled *Evaluation of the Background Water Quality of Minto Creek and Options for the Derivation of Site Specific Water Quality Objectives* (Minnow 2009). In 2010, Minnow prepared the *Characterization of Baseline and Operational Water Quality of Minto Creek* including water quality results to the end of 2009 (Minnow 2010). The Minnow 2009 evaluation report focused on defining background concentrations of key metals to represent Minto Creek as a whole and for potential application as site-specific water quality objectives in lower Minto Creek (Minnow 2009). The Minnow 2010 report characterized water quality for discrete time intervals of relevance to the mine (Minnow 2010). In 2014, Access Consulting Group (ACG) and Minnow worked in conjunction to update the water quality characterization for Minto Creek (including data

collected between 2005 and 2012). The most recent report provided an update to the 2014 characterization of Minto Creek water quality and included January 2005 to December 2015 monitoring data. This update also included a dedicated evaluation of background water quality data, which was commissioned to support the development of post-closure water quality objectives, an initiative that was undertaken as a collaboration with Selkirk First Nation representatives in the Bilateral Technical Working Group. The report *Background Water Quality of Lower Minto Creek for Application in the Derivation of Post-Closure Water Quality Objectives* was issued in 2016 (Minnow, 2016). The pre-operational water quality characterization for Minto Creek has not been updated from that which was provided in Minnow's 2016 report (Appendix A). This characterization report focuses on updates to the operational period (with and without mine discharge).

1.2.2 McGinty Creek

Access Consulting Group (ACG) and Minnow Environmental Inc. prepared an initial baseline water quality characterization report for McGinty Creek in 2013, which included water quality data collected between May 2009 and July 2012 (ACG, 2013). In 2016, ACG prepared an update to the initial characterization report with the inclusion of additional water quality data collected between July 2012 and December 2015.

Activity within the upper McGinty watershed consisted of surface exploration between 2008 and 2009. Road construction and pit stripping started on August 5th, 2015, when water use license QZ14-031 was issued, allowing mining of the Minto North open pit, which was completed on October 1, 2016. During this pit development period, Minto North pit water was collected and trucked to the Main Pit Tailings Management Facility (MPTMF) within the Minto Creek catchment area and managed with the mine water management systems. Water quality monitoring in the McGinty Creek catchment is ongoing as required under WUL QZ14-031. Where relevant, McGinty Creek data are analyzed for the pre-operations period (May 2009 to July 2015) and operations period (August 2015 to December 2016).

2 METHODS

Section 2 presents water quality sampling locations, steps followed for water quality data collection and handling, and methodology for data interpretation.

2.1 MONITORING STATION ORGANIZATION

Minto monitors water quality at several locations on the mine site and in the receiving environment downstream of mining operations. Key monitoring stations were selected for inclusion in this characterization of water quality, and were organized into four distinct groupings:

- Minto Mine Site (Section 2.1.1);
- Minto North Pit (Section 2.1.2);
- Minto Creek (Section 2.1.3); and
- McGinty Creek (Section 2.1.4).

2.1.1 Minto Mine Site

This report summarizes the water quality for ten monitoring stations around the Minto Mine Site including W8, W8A, W12, W15, W16, W35, W35A, W35B, W45, and W62. For ease of discussion and presentation of results, these stations are further divided into two groupings: the "upper mine site" and "lower mine site". The Minto Mine Site stations and groupings are described in Table 2-1 and shown in Figure 2-1. Water quality is monitored at many more locations on the Minto site, but these ten stations are the most critical with respect to decisions regarding the conveyance, storage, and treatment of site water.

Table 2-1: Minto Mine Monitoring Station Locations.

Station	Description / Location
Upper Mine Site	
W12	Main Pit
W15	Minto Creek, d/s of Southwest Waste Rock Dump
W35	South Diversion Ditch
W35A	North End of South Diversion Ditch
W35B	South End of South Diversion Ditch
W45	Area 2 Pit
Lower Mine Site	
W8	Dry Stack Tailings Storage Facility drainage, west
W8A	Dry Stack Tailings Storage Facility drainage, east
W16	Water Storage Pond
W62	Sump at toe of Mill Valley Fill Extension

2.1.1.1 Upper Mine Site

The upper mine site grouping consists of the W12, W15, W35, W35A, W35B, and W45 stations described in detail below.

The Main Pit (W12) has been used as the reservoir for any site water that could not be directly discharged. Given the water management constraints at the site (effluent and water quality standards), the Main Pit has received a significant influx of site water each year and has carried an inventory of runoff and impacted water each year since 2007. The W12 monitoring water quality data determine ongoing site water treatment.

Station W15 is a key water collection point downstream of the Southwest Waste Dump (SWD). Runoff and seepage water currently collects at W15 in a sump and then is conveyed to the Main Pit for treatment (if required) or off site for discharge if appropriate. Monitoring of the water quality at this location determines the fate of this runoff and provides an indication of altered seepage quality from the SWD.

W35 is the current monitoring station at the south end of the South Diversion Ditch. It receives runoff from the Ridgetop exploration areas, the exploration camp and the airstrip, but the majority of the W35 catchment is undisturbed. The quality of this water determines its ultimate storage facility, and as such monitoring at this location is of importance to site water managers. W35A and W35B – at the south end/inlet and north end/outlet of the diversion ditch, respectively – are historic sites which have not been monitored since December 2012.

W45 is a monitoring station in the Area 2 Pit. Water in this pit is a collection of local surface runoff, underground mine water, groundwater, Main Pit water, and tailings supernatant.

2.1.1.2 Lower Mine Site

The lower mine site grouping consists of the W8, W8A, W62, and W16 stations described in detail below.

Stations W8 and W8A are monitoring locations for seepage from the Dry Stack Tailings Storage Facility (DSTSF). These two sites are monitored weekly (although W8 has been dry since 2014) and the combined flows are represented by flow at W62.

W62 is a collection sump at the toe of the MFVE and replaced W37 which was buried by the expansion of the MVFE. Contributors to this collection point include subsurface drainage from the DSTSF, the Mill Valley Fill and extension, and other local groundwater contributions.

Station W16 is the Water Storage Pond (WSP). This important site water management feature accepts water from all site diversions and drainage, except for Water Treatment Plant effluent or other directly discharged runoff (although each of these is often combined with WSP water prior to discharge.) Results from monitoring at Station W16 determine the WSP's fitness for discharge, or alternatively any requirements to withhold or further treat the WSP water.

2.1.2 Minto North Pit

The Minto North Pit is located at the northernmost tip of the mine site (Figure 2-1). Station MN was established with the initiation of the mining activities in the Minto North Pit (August 2015), and the monitoring results presented in the report for this station are all 'operational' results. Water quality data from the Minto North Pit are considered in isolation since the pit does not discharge at present and is not anticipated to discharge during the operational period.

2.1.3 Minto Creek

Several water quality stations are monitored on Minto Creek during the operational period. Data from four of these monitoring stations are provided in this report: W50, W3, MC1, and W2. These stations are described in Table 2-2 and their location shown in Figure 2-2. These stations are all on the 'mainstem' of Minto Creek.

Table 2-2: Minto Creek Monitoring Station Locations

Station	Description / Location
W50	Minto Creek, approximately 50m downstream of toe of WSP dam
W3	Downstream of Water Storage Pond dam, MMER Final Discharge Point (Flume) – Effluent
MC1	Receiving Environment station upstream of the canyon fish barrier on Minto Creek.
W2	Lower Minto-Creek at Road Crossing – Receiving Environment station in reach with documented fisheries usage.

W50 is located downstream of the inflow of the treated water and is a point of compliance for EQS as outlined in WUL QZ14-031 (August 5th, 2015). EQS are presented and discussed in further detail in Section 2.3. Station W3 – located downstream of the Water Storage Pond dam – is the mine effluent monitoring and compliance point per the Metal Mining Effluent Regulations (MMER). Station W2 is the lowermost Minto Creek receiving environment monitoring location before the confluence with the Yukon River, and is the "WQO Station" designated in the Water Use Licence QZ94-031 during the period when flow is encountered at stations W15 and W35 (see Section 2.3). Both W2 and W3 have been monitored regularly since 2005. Station MC1 in Minto Canyon serves as a comparison monitoring point between W3 and W2 and began regular monitoring in 2010.

Four additional stations (W6, W7, C4 and C10) situated on tributaries to Minto Creek are monitored regularly or semi-regularly. The data for these stations are not included in this reporting update as they were a component of the Minto Creek background water quality evaluation in 2016, and are included in Minnow Environmental Inc. (2016) (Appendix A).

For the most part, sampling occurs during the open water season between April and October. Minto Creek, like most small creek systems in the region, freezes entirely during the winter months with only periodic and localized flow persisting in some locations due to groundwater discharge (e.g. station W3). Minto Creek can also be dry at W2 in summer months during prolonged periods without precipitation.

The Minto Creek water quality characterization is divided into pre-mining (January 2005 to March 31, 2006) and operational (April 1, 2006 to December 31, 2016) periods. Monitoring results from the pre-mining period were compiled and included in the Minto Creek background water quality evaluation in 2016, and are reported in *Background Water Quality of Lower Minto Creek for Application in the Derivation of Post-Closure Water Quality Objectives* report by Minnow Environmental Inc. (2016) (Appendix A). This data evaluation was developed in collaboration with technical representatives from Selkirk First Nation through Minto and SFN's Bilateral Technical Working Group as the basis for representing background (non-degraded) water quality, so this data set, including the pre-mining results, has not been updated or re-evaluated.

The Minto Creek operational phase data are further differentiated by grouping data from periods when the mine was discharging effluent, and periods when there was no mine discharge. Operational phase periods with mine discharge to Minto Creek included:

- August 26 to September 30, 2008;*
- June 26 to August 6, 2009;*
- August 13 to October 30, 2009;*
- July 14 to October 27, 2010;
- April 16 to May 11, 2012;
- April 20 to May 22, 2013;
- April 3 to May 26, 2014;
- December 8 to December 16, 2014;
- April 3 to June 1, 2015;
- April 8 to May 6, 2016;
- May 15 to Jun 11, 2016;
- June 13 to June 26, 2016; and
- July 7 to Oct 25, 2016.

**Note that discharge during the first three effluent discharge periods was through emergency amendments to the WUL, as described in Section 1.1.*

These periods are illustrated for reference on the data plots in Section 3.3.

2.1.4 McGinty Creek

McGinty Creek water quality was monitored monthly by ACG from May 2009 until July 2012 and has since been monitored monthly by Minto Mine Environment Department staff.

Water quality is monitored at five stations in the McGinty Creek watershed, described in Table 2-3 and shown in Figure 2-3. Water quality results for McGinty Creek stations are presented and discussed in two groups:

1. East arm of McGinty Creek (MN-1.5 and MN-2.5) and MN-4.5; and
2. West arm of McGinty Creek (MN-0.2 and MN-0.5).

The east arm of McGinty Creek is considered the 'exposure tributary' as it originates downgradient of the Minto North deposit where the Minto North pit is located, while the west arm of McGinty Creek is considered the 'reference tributary'. It is important to note that no discharge from the Minto North Pit to McGinty Creek (or elsewhere) has occurred as of the time of writing (January 2018) and no future discharge is anticipated during the operational period.

Table 2-3: McGinty Creek Monitoring Station Locations

Station	Description / Location
East Arm of McGinty Creek	
MN-1.5	Upper east arm of McGinty Creek downstream of the Minto North deposit
MN-2.5	East arm of McGinty Creek just upstream of confluence with the west arm
MN-4.5	Lower mainstem McGinty Creek near confluence with Yukon River
West Arm of McGinty Creek (Reference Stations)	
MN-0.2	Upper west arm of McGinty Creek
MN-0.5	West arm of McGinty Creek just upstream of the confluence with the east arm

Monitoring at the upper reference station MN-0.2 was suspended between June 2009 and April 2011, which explains in part the lower total number of samples collected at this station. Similar to Minto Creek, McGinty Creek typically freezes in the winter months with little to no flow observed at all monitoring stations during this time.

2.2 DATA COLLECTION, HANDLING AND QUALITY ASSESSMENT

Water quality data were obtained from Minto Mine with the understanding that results have been subject to appropriate quality assurance and quality control procedures so that they may be used in the characterization of Minto and McGinty Creeks.

All water quality data are imported and managed in an EQWin database. This continually growing database allows for the assessment of temporal water quality trends for specific parameters of interest, although it is noted that higher detection limits for some parameters limit the value of some of the older data.

An assessment of data outliers has been carried out for water quality data from monitoring stations from May 2005 to December 2016. The purpose of the outlier assessment was to identify potentially erroneous results (e.g., incorrectly transcribed from field notes or laboratory certificates of analysis [COA]) or results that were not representative of the water quality present at a particular site at a particular time (e.g., substrate disturbed in sample collection). The methodology for identifying outliers was adopted from Minnow (2016), as those methods were developed in collaboration with SFN through the Bilateral Technical Working Group. The methodology is summarized below.

The following parameters were examined in the outlier screening process. These are the parameters which have either an associated EQS and/or WQO or are important for the interpretation of other water quality conditions (e.g., toxicity modification):

- pH, conductivity, temperature, turbidity;
- Total suspended solids (TSS), TDS, hardness, alkalinity, chloride, fluoride, sulphate, dissolved organic carbon (DOC);
- Nitrate, nitrite, and ammonia;
- Total and dissolved aluminum, arsenic, cadmium, chromium, copper, iron, lead, molybdenum, nickel, selenium, silver and zinc;
- Radium-226; and
- Total and weak acid dissociable (WAD) cyanide.

First any sample entries in the database that were a replicate of another entry (i.e., erroneously entered twice or duplicated) were identified and removed to avoid biasing any entries. The data were then screened for results that returned very high detection limits. For some analytes, older analyses would have detection limits that were elevated relative to detection limits from more recent analyses, such that the detection limit of older analyses were higher than more recent measured results. These high detection limit results would then bias the dataset containing lower concentration measured data. Therefore, detection limits that exceeded the upper quartile of measured data (i.e., >75%) were removed. The remaining detection limit data were converted to half the detection limit. The lower and upper quartile and the interquartile range (IQR; the difference between the upper and lower quartile of the dataset) were then calculated for each analyte. Outliers for an analyte dataset were

considered to be results that were either less than the lower outlier boundary or above the high outlier boundary such that:

Low Outlier Boundary = Lower Quartile – 3*IQR; and

High Outlier Boundary = Upper Quartile + 3*IQR;

As the water quality data exhibit a log-normal distribution, the outlier screening was performed on the regular dataset and a log10-transformed dataset (note that since pH is a log function, the pH data were anti-log transformed). A result was only deemed an outlier if both the untransformed and log10-transformed value met the outlier criteria.

Outliers were identified and reviewed by AEG and returned to Minto for comparison of outlier result with original COA and/or field notes. Where obvious errors were identified (i.e., transcription, incorrect units reported, etc.), erroneous results were replaced with the correct values. Where review of field notes indicated problematic sampling conditions or instruments, or professional judgement indicated an erroneous result (e.g., dissolved element concentration significantly greater than the corresponding total, unfiltered concentration), the outlier result was removed from the dataset. Most "outliers" were kept in the datasets as either the result was confirmed as "real", a typo correction was made, or there was insufficient evidence to justify their removal. The removed outliers for parameters focussed on this report are summarized in Table 2-4.

Table 2-4: Summary of removed outlier water quality data.

Station	Date	Parameter	Concentration (mg/L)	Rationale for Removal
W8	27-May-08	Dissolved Aluminum	0.99	Significantly higher than total concentration
W8	19-Oct-09	Dissolved Arsenic	0.0085	Significantly higher than total concentration
W8	30-Jun-11	Dissolved Arsenic	0.0028	Significantly higher than total concentration
W8A	19-Oct-09	Dissolved Arsenic	0.0066	Significantly higher than total concentration
W16	19-Oct-12	Dissolved Zinc	0.083	Significantly higher than total concentration
W16	24-Nov-12	Dissolved Zinc	0.066	Significantly higher than total concentration
W35A	10-Apr-12	TSS	1460	Poor sampling conditions
W35A	10-Apr-12	Hardness	355	Poor sampling conditions
W35B	8-Jul-09	Field Conductivity	11358	Typo Assumed
W50	19-Oct-09	Dissolved Arsenic	0.0031	Significantly higher than total concentration
W50	13-Apr-12	Dissolved Arsenic	0.0017	Significantly higher than total concentration
W3	28-Oct-06	Dissolved Chromium	0.0098	Significantly higher than total concentration
W3	30-Oct-07	Nitrite-N	4.04	Likely incorrect data entered, original COA unavailable
W3	30-Oct-07	Nitrate-N	<0.02	Likely incorrect data entered, original COA unavailable
W3	27-May-09	Dissolved Cadmium	0.0437	Significantly higher than total concentration
W3	5-Jan-10	Dissolved Cadmium	0.0037	Significantly higher than total concentration
W3	10-Mar-10	Dissolved Cadmium	0.0058	Significantly higher than total concentration
W3	24-Apr-10	Dissolved Oxygen	404.5 (%)	Typo Assumed
W3	30-Dec-10	Dissolved Oxygen	192 (%)	Typo Assumed
W3	2-Apr-12	Dissolved Oxygen	105.7	Typo Assumed
W2	20-May-08	Dissolved Arsenic	0.0018	Significantly higher than total concentration
W2	30-Apr-09	Dissolved Cadmium	0.001	Significantly higher than total concentration
W2	6-Dec-10	Dissolved Cadmium	0.00049	Significantly higher than total concentration

The outlier-screened data were supplied to Minnow to generate summary statistics for each water quality sampling station. A robust method of handling below detection level values was employed by Minnow to avoid

biasing summary statistics that can occur with data sets that contain significant portions of below detection level data. Further details of the statistical processing employed by Minnow are provided in Appendix B.

2.3 WATER QUALITY STANDARDS AND OBJECTIVES

Water quality performance (effluent and receiving environment) for Minto Mine is governed by both the Type A Water Use Licence QZ14-031 and the federal Metal Mining Effluent Regulations (MMER). The Water Use Licence is typically more restrictive in terms of effluent parameter concentrations and sets EQS for compliance comparison at "Effluent Points". Effluent points include: W16a, W17, W50 and WTP. The focus of comparison for effluent water quality and compliance standards in this report is Station W50 vs. the current WUL QZ14-031 EQS (Table 2-5) and Station W3 vs. the MMER guidelines (Table 2-6).

Table 2-5: Effluent Quality Standards for Site W50

Parameter	Effluent Standards
Total Suspended Solids, excluding March, April and May, mg/L	15
Total Suspended Solids, March, April and May Only, mg/L	30
pH, pH Units	6.0 – 9.0
Ammonia - N, mg/L	0.75
Nitrite - N, mg/L	0.18
Nitrate - N, mg/L	27.3
Aluminum (dissolved), mg/L	0.3
Arsenic (dissolved), mg/L	0.015
Cadmium[1] (dissolved), µg/L	$3*e^{(0.736(\ln(hardness)-4.943)}$
Chromium (dissolved), mg/L	0.003
Copper (dissolved), mg/L (when [DOC] @ W2 >10 mg/L)	0.06
Copper (dissolved), mg/L (when [DOC] @ W2 ≤10 mg/L)	0.039
Iron (dissolved), mg/L	3.3
Lead (dissolved), mg/L	0.012
Molybdenum (dissolved), mg/L	0.219
Nickel (dissolved), mg/L	0.33
Silver (dissolved), mg/L	0.0003
Selenium (dissolved), mg/L	0.006
Zinc (dissolved), mg/L	0.09

Table 2-6: MMER Authorized Limits of Deleterious Substances for Site W3

Parameter	Maximum Authorized Monthly Mean Concentration	Maximum Authorized Concentration in a Composite Sample	Maximum Authorized Concentration in a Grab Sample
Total Suspended Solids, mg/L	15	22.5	30
Arsenic (total), mg/L	0.5	0.75	1.0
Copper (total), mg/L	0.3	0.45	0.6
Cyanide, (total), mg/L	1.0	1.5	2.0
Lead (total), mg/L	0.2	0.3	0.4
Nickel (total), mg/L	0.5	0.75	1.0
Zinc (total), mg/L	0.5	0.75	1.0
Radium 226 (total), Bq/L	0.37	0.74	1.11

The Operations Adaptive Management Plan (AMP; Minto 2017) includes performance thresholds for surface water quality in both Minto Creek and McGinty Creek based on the parameters that comprise the EQS and WQO lists in WUL QZ14-031. The AMP thresholds – based primarily on WQO – are evaluated at WQO Stations upstream of the confluence with the Yukon River. For Minto Creek, the WQO Station is defined as:

- Station W2 during the period when flow is encountered at stations W15 and W35; or
- Station W50 during the period when flow is not encountered at stations W35 and W15.

The Minto Creek WQO are presented in Table 2-7 below. Since the issuance of QZ14-031 in August of 2015, there has predominantly been no discharge of effluent when flow is not encountered at stations W35 and W15 (winter). Between October 11th and 26th 2016, W50 was used as the WQO station as there was no flow at W15/W35 due to frozen conditions and discharge occurred. Aside from this date range, there was no discharge of effluent when flow was not encountered at W35 and W15. As such, this report uses Station W2 as the WQO Station for evaluation purposes.

Table 2-7: Water Quality Objectives for Minto Creek Site W2

Parameter	Water Quality Objectives
pH, pH Units	6.0 - 9.0
Ammonia - N, mg/L	0.25
Nitrite - N, mg/L	0.06
Nitrate - N, mg/L	9.1
Aluminum (dissolved), mg/L	0.1
Arsenic (dissolved), mg/L	0.005
Cadmium[1] (dissolved), µg/L	$e^{(0.736(\ln(hardness)-4.943)}$
Chromium (dissolved), mg/L	0.001
Copper (dissolved), mg/L (when [DOC] @ W2 >10 mg/L)	0.02
Copper (dissolved), mg/L (when [DOC] @ W2 ≤10 mg/L)	0.013
Iron (dissolved), mg/L	1.1
Lead (dissolved), mg/L	0.004
Molybdenum (dissolved), mg/L	0.073
Nickel (dissolved), mg/L	0.11
Silver (dissolved), mg/L	0.0001
Selenium (dissolved), mg/L	0.002
Zinc (dissolved), mg/L	0.03

Site MN-4.5 is the WQO station on McGinty Creek as part of the AMP (Minto, 2017). The WQO for individual data points at MN-4.5 are presented in Table 2-8 and used for discussion of water quality data in McGinty Creek at MN-4.5.

Table 2-8: Water Quality Objectives for McGinty Creek Site MN-4.5, AMP Individual Data Point Evaluator

Parameter	Water Quality Objectives
TSS, mg/L	269
Ammonia - N, mg/L	0.12
Nitrite - N, mg/L	0.05
Nitrate - N, mg/L	0.232
Aluminum (dissolved), mg/L	0.135
Arsenic (dissolved), mg/L	0.00061
Cadmium (dissolved), mg/L	0.000041
Chromium (dissolved), mg/L	0.001
Copper (dissolved), mg/L	0.0035
Iron (dissolved), mg/L	0.403
Lead (dissolved), mg/L	0.00020
Molybdenum (dissolved), mg/L	0.001
Nickel (dissolved), mg/L	0.0018
Silver (dissolved), mg/L	0.000020
Selenium (dissolved), mg/L	0.00020
Zinc (dissolved), mg/L	0.0052

2.4 INTERPRETATION OF WATER QUALITY DATA

Interpretation of water quality data incorporated summary statistics generated from complete water quality data sets and a discussion of parameters over time (i.e., identification of trends, seasonality, etc.) at each station. The parameters discussed included those stipulated in the EQS and WQO lists as well as additional physical parameters that aid in interpretation of results or derivation of an EQS/WQO (i.e., hardness, DOC). The statistical summaries for each parameter at each station include the following:

- Maximum detection limit (DL);
- Average;
- Count (total number of entries for a parameter);
- Minimum;
- Maximum;
- Percent below DL;
- Standard deviation;
- First quartile;
- Median; and
- Third quartile.

For stations W50, W2, and MN-4.5 for which EQS or WQO apply, the following statistics are also provided when applicable:

- Count above EQS/WQO; and
- Percent above EQS/WQO.

Plots were generated for each parameter for temporal discussions. Concentrations that were reported as less than DL were plotted as half the DL. For each group of locations, physical parameters, anions and nutrients are first discussed, followed by dissolved metal concentrations.

3 RESULTS AND DISCUSSION

For the discussion of water quality data, results are presented from monitoring locations in four groupings:

1. Minto Mine Site (Section 3.1);
2. Minto North Pit (Section 3.2);
3. Minto Creek (Section3.3); and
4. McGinty Creek (Section 3.4).

For the sites in each grouping, in situ and EQS/WQO-regulated anion (nitrate, nitrite) and nutrient (ammonia) parameters are discussed. Hardness and DOC that act as modifiers of metal toxicity are also discussed, along with metals that are regulated within Water License QZ14-031 (dissolved aluminum, arsenic, cadmium, chromium, copper, iron, lead, molybdenum, nickel, silver, selenium, and zinc). All summary statistic tables were based on the water quality dataset supplied to AEG by Minto and were calculated by Minnow (2017) as per the methodology described in Appendix B. For graphical presentation purposes only, results that were below laboratory detection levels are presented as one half the detection limit. The full water quality dataset (excluding outliers) is presented in Appendix C.

3.1 MINTO MINE SITE

Discussion of water quality data on the Minto Mine property comprises results for sample stations in the upper mine site group (W12, W15, W35, W35A, W35B, W45) and lower mine site group (W8, W8A, W16, W62) as described in Section 2.1.1. Examined parameters included those with designated EQS in Water License QZ14-031.

3.1.1 Upper Minto Mine Site

Upper Minto Mine Site station water quality is presented in discussed with respect to physical parameters and anion and nutrient concentrations in Section 3.1.1.1 and dissolved metals concentrations in Section 3.1.1.2.

3.1.1.1 Physical Parameters, Anions and Nutrients

Statistical summaries of physical parameters and anion and nutrient concentrations at sites W12, W15, W35, W35A, W35B and W45 are presented in Table 3-1 through Table 3-6. TSS, field pH, nitrate, nitrite, ammonia, and sulphate data at each of the lower Minto Mine Site stations are presented in Figure 3-1 through Figure 3-6.

The pH of the upper mine site sampling locations has largely remained circumneutral to mildly alkaline over the period of record (Figure 3-2), with median pH ranging between 7.5 (site W35A) to 8.0 (site W12). Temperature varied seasonally from -0.3 to 23 °C. Aside from the Main Pit (W12) and the Area 2 Pit (W45), the surface waters in the upper mine site were typically well oxygenated, with median oxygen content of 81% to 92% saturation. The flooded pits exhibited lower dissolved oxygen levels (median 59% and 61% respectively), which tended to vary seasonally such that dissolved oxygen was lowest over winter as ice cover restricted replenishment of oxygen to the underlying lake water that was consumed by indigenous microorganisms, whereas higher dissolved oxygen measurements were recorded during the ice-free months. Field conductivity was highest at the

flooded pit sites (median 652 and 869 µS/cm for sites W12 and W45, respectively), with the highest measurements typically occurring during winter. The South Diversion ditch sites (W35, W35A and W35B) had the lowest median conductivity (120 to 144 µS/cm), with the lowest conductivity typically observed in April/May when spring meltwaters provided dilution. The Minto Creek W15 site exhibited similarly seasonality, with conductivity lowest in April/May before generally rising through the spring before stabilizing in summer/fall.

Flowing water sites on Minto Creek (W15) and the South Diversion Ditch (W35, W35A and W35B) typically returned higher TSS values in April or May (Figure 3-1), likely caused by erosional mobilization of particulate material with higher flow rates caused by snowmelt; much lower TSS values were often observed throughout the rest of the year (median range of 1 to 6.5 mg/L). TSS concentrations in the pit lake sites did not show this same seasonality and had higher median concentrations than flowing water sites (9 and 17 mg/L for W12 and W45, respectively).

The pit lake sites (W12 and W45) had the highest median nitrogen species concentrations for the Upper Mine Site area, with median nitrite-N, nitrate-N, and ammonia N for W12 of 0.24, 15.2, and 1.5 mg/L, respectively, and 1.0, 17.7, and 3.2 mg/L for W45, respectively (Table 3-1 and Table 3-6; Figure 3-3 to Figure 3-5. These elevated nitrogen species concentrations likely reflect nitrogen residues from blasting activity. Nitrite-N and nitrate-N showed marked seasonality in Minto Creek at site W15 (Figure 3-3 and Figure 3-4), with concentrations highest in winter and lowest over summer/fall due to uptake by primary producers that are most active over summer/fall.

Median DOC concentrations ranged from 12.4 mg/L in the Main Pit (W12; Table 3-1) to 24.8 mg/L at W35B in the South Diversion Ditch. Concentrations were generally highest in April/May when runoff from spring snowmelt likely flushed surface soils, leaching labile organic carbon that had accumulated over the previous summer/fall.

Sulphate concentrations were highest in the pit lakes (median 419 mg/L and 182 mg/L at W45 and W12, respectively), with an increasing trend noted in the Main Pit, where sulphate concentrations have gradually risen from approximately 120 mg/L in summer 2013 to 650 mg/L by December 2016 (Figure 3-6). Sulphate levels in Minto Creek (W15) displayed distinct seasonality, with the lowest concentrations observed during freshet in April/May followed by an increase over the year peaking in winter before declining again during spring due to snowmelt dilution. The South Diversion Ditch sites (W35, W35A, W35B) generally had low sulphate concentrations (median 5 mg/L), with sporadic spikes up to 200 mg/L noted for W35A and W35B (Figure 3-6).

Table 3-1: Summary Statistics for Physical Parameters, Anions and Nutrients at Site W12

3.1.1.2 Metals

Statistical summaries of dissolved metals concentrations at sites W12, W15, W35, W35A, W35B and W45 are presented in Table 3-7 through Table 3-12. Dissolved metal concentrations at each of the upper Minto Mine Site stations are plotted in Figure 3-7 through Figure 3-18.

Dissolved hardness concentrations, which has a toxicity modifying effect on a number of metals (e.g., copper, cadmium, lead, nickel, zinc), were highest in the pit waterbodies (median 274 mg/L and 562 mg/L at W12 and W45, respectively; Table 3-7 and Table 3-12). Although no seasonal variation was noted in the pit lakes, hardness levels displayed strong seasonal changes in Minto Creek (W15) and the South Diversion Ditch sites (W35, W35A, W35B), where hardness concentrations were lowest in April/May due to dilution from snow meltwater, and increased over the remainder of the year, peaking in winter. This is consistent with the ephemeral nature of the South Diversion Ditch with groundwater from various up-gradient spring sources providing flow to the ditch outside of precipitation events and freshet-related flows.

Dissolved chromium, lead, and silver concentrations showed little variation since they were typically close to or below their respective detection limits (Table 3-7 to Table 3-12). Dissolved aluminum and iron concentrations were lowest in the pit lake sites (median 0.018 mg/L aluminum and 0.013 mg/L iron at W12; median 0.01 mg/L aluminum and 0.02 mg/L iron at W45), reflecting the low solubility of these elements at circumneutral pH and residence time for iron oxidation and precipitation. Median dissolved aluminum and iron concentrations were highest at W35A (0.042 mg/L) and W15 (0.28 mg/L), respectively. Indeed, elevated dissolved aluminum and iron concentrations were observed in both the Minto Creek (W15) and South Diversion Ditch (W35, W35A, W35B) sites, perhaps maintained as soluble species via complexation with dissolved organic matter given the high DOC concentrations recorded at these sites.

Dissolved arsenic, cadmium, nickel, and zinc concentrations exhibited sporadic spikes in concentrations at most sites, but generally showed no seasonality and were often close to or below detection (Figure 3-8, Figure 3-9, Figure 3-15, and Figure 3-18). Between April 2013 and March 2015, dissolved cadmium (0.0001 to 0.0005 mg/L) and zinc (0.006 to 0.07 mg/L) concentrations were elevated relative to their baselines at site W45 (Figure 3-9 and Figure 3-18). Molybdenum and copper concentrations were also relatively elevated at W45 during this period (Figure 3-11 and Figure 3-14), as was sulphate. Indeed, molybdenum concentrations increased markedly in the Area 2 Pit (W45), from a range of 0.01 to 0.05 mg/L between April 2013 and March 2015 to 0.09 to 0.12 mg/L between September 2015 and October 2016. Dissolved molybdenum levels also showed an increasing trend in the Main Pit (W12), rising from 0.02 mg/L in November 2012 to 0.1 in August 2015, before stabilizing around 0.08 mg/L (Figure 3-14).

Selenium exhibited similar behaviour to molybdenum in the pit lakes, rising from 0.004 mg/L in early 2013 in the Main Pit (W12) to 0.021 mg/L in August 2015, before stabilizing at approximately 0.015 mg/L (Figure 3-17). Dissolved selenium concentrations in the Area 2 Pit (W45) also rose sharply in September 2015 to 0.024 mg/L, then stabilized close to 0.02 mg/L (Figure 3-17). Minto Creek (W15) selenium levels ranged between 0.00015 and 0.05 mg/L (median 0.0014 mg/L). Here, dissolved selenium displayed some seasonality, with concentrations lowest during spring freshet and highest over winter, suggestive of a significant groundwater component to Minto Creek selenium levels. The South Diversion Ditch sites typically had the lowest selenium concentrations (generally <0.001 mg/L).

Dissolved copper showed sporadic peaks of between 0.28 and 0.48 mg/L for sites W12, W15, W35B, and W45, typically during the winter (Figure 3-11). Otherwise, dissolved copper concentrations were generally below 0.1 mg/L. One exception was the Area 2 Pit (W45), which varied markedly between 2012 and 2015 (0.01 to 0.28 mg/L) before declining to lower concentrations between 0.001 and 0.02 mg/L in 2016 (Figure 3-11).

3.1.2 Lower Minto Mine Site

Lower Minto Mine Site station water quality is presented and discussed with respect to physical parameters and anion and nutrient concentrations in Section 3.1.2.1 and dissolved metals concentrations in Section 3.1.2.2.

3.1.2.1 Physical Parameters, Anions and Nutrients

Statistical summaries of physical parameters and anion and nutrient concentrations at sites W8, W8A, W16 and W62 are presented in Table 3-13 through Table 3-16. TSS, field pH, sulphate, nitrate, nitrite, and ammonia data at each of the lower Minto Mine Site stations are presented in Figure 3-19 through Figure 3-24.

The pH at all of the Lower Mine Sites was typically circumneutral to mildly alkaline, with the median pH ranging from 7.4 (W8A) to 7.9 (W16). Temperature varied seasonally from -1 to 24 °C. Median dissolved oxygen levels ranged from 53% (W8A) to 83% (W8) saturation, with lower levels typically recorded during the winter months, likely due to ice cover and associated limitations on oxygen replenishment of the under-ice waters. The highest field conductivity was typically measured in drainage from the DSTSF (median 1194 and 647 µS/cm at W8 and W8A, respectively).

In 2009 through 2011 at W8, TSS was typically highest in spring months – likely due to erosional inputs from spring meltwater – and lower throughout the rest of the year (median 13 mg/L), whereas higher TSS concentrations at W8A were observed later in the summer (median 12 mg/L; Figure 3-19). Relatively higher spring TSS concentrations were also observed at W62 in certain years (e.g. 2012). TSS was more variable and showed less seasonality at all lower mine site since 2013, likely related to day-to-day activities at the mine site.

Nitrate-N concentrations were highest in drainage from the DSTSF (median 22.1 mg/L and 9.4 mg/L for W8 and W8A, respectively) and demonstrated some seasonality, typically recorded low concentrations during freshet with its associated dilution, followed by a rise over spring and summer, then declining in winter (Figure 3-22). Nitrite-N and ammonia-N concentrations did not display any distinct seasonal changes. The east drainage from the DSTSF (W8) generally returned the highest concentrations (median 0.17 mg/L nitrite-N and 0.14 mg/L ammonia-N). Similar nitrite-N levels were observed for sites W8A (median 0.023 mg/L), W16 (median 0.029 mg/L), and W62 (median 0.021 mg/L). Ammonia-N concentrations at sites W8A and W16 were also comparable (median 0.06 mg/L; Figure 3-24), with the lowest concentrations typically observed in the MVF sump (W62; <0.005 to 0.23 mg/L, median 0.008 mg/L).

Excluding W62 (for which only two DOC analyses are available), DOC concentrations generally ranged between 1 and 30 mg/L for all sites (median 12 mg/L). DOC concentrations were typically highest during spring freshet as organic matter was flushed from surrounding soils by snowmelt.

The highest sulphate concentrations in the Lower Mine Site were observed at the MVF Sump (W62; median 154 mg/L) and DSTSF drainages (median 120 mg/L for both W8 and W8A). The longer period of record for the east DSTSF drainage (W8A) exhibits an increasing trend, with annual maxima increasing from approximately 180 mg/L in 2012 to 350 mg/L in 2016 (Figure 3-21). This increasing trend shows a seasonal wave-like overprint, with concentrations peaks and troughs typically observed in November/December and April/May, respectively (Figure 3-21). Sulphate concentrations displayed a similar trend in the Water Storage Pond (W16), but the pattern was more subdued than that of W8A (Figure 3-21).

3.1.2.2 Metals

Statistical summaries of dissolved metals concentrations at sites W8, W8A, W16 and W62 are presented in Table 3-17 through Table 3-20. Dissolved metal concentrations at each of the lower Minto Mine Site stations are plotted in Figure 3-25 through Figure 3-36.

It should be noted that the final few samples collected in October and November 2013 at site W8 are likely influenced by the installation of galvanized vertical culverts, as evidenced by the elevated hardness, iron, and particularly zinc concentrations present in these samples (Figure 3-30 and Figure 3-36). As such, the discussion of the dissolved metals data does not consider these final few samples from W8, although they are included in the figures and summary statistics.

For the Lower Mine Sites, dissolved hardness was highest in drainage from the DSTSF (median 551 mg/L at W8 and 475 at W8A). Aside from the limited dataset for site W62, hardness levels displayed marked seasonal patterns: dilution from snowmelt results in the lowest hardness levels in April/May, followed by a steady increase over the year peaking in winter immediately before the next snowmelt cycle. This is suggestive of a prominent groundwater component to the hardness content of the DSTSF drainage (W8 and W8A) and water storage pond (W16) since the groundwater contribution will be highest during the low flow winter period and lowest during the high surface flows of freshet.

Dissolved concentrations of chromium, lead, and silver were generally close to or below detection (Figure 3-28, Figure 3-31, and Figure 3-35). Dissolved nickel concentrations were also generally close to or below detection, with sporadic spikes throughout the period of record (Figure 3-33). Similarly, cadmium and zinc concentrations were close to or below detection for all sites except for the east drainage from the DSTSF (W8A). At W8A, dissolved cadmium showed an increasing trend from approximately 0.00011 mg/L in early 2013 rising to 0.00067 in February 2015, before declining and stabilizing at 0.0003 mg/L in fall 2016 (Figure 3-27). Dissolved zinc concentrations at W8A showed more striking changes, increasing by approximately two orders of magnitude from ≤0.025 mg/L prior to May 2011 to 0.07 to 5.2 mg/L since September 2012 (Figure 3-36). This change is an artefact of the installation of galvanized vertical culverts at this site which leach zinc.

Dissolved aluminium and arsenic concentrations were comparable across all four Lower Mine Sites with medians ranging between 0.004 and 0.009 mg/L for aluminium and 0.0004 and 0.0005 for arsenic (Table 3-17 to Table 3-20). Little seasonal variation was evident for either constituent. Dissolved iron concentrations also displayed no clear patterns over the period of record at any of the Lower Mine Sites. Iron concentrations were slightly higher in the DSTSF drainage (median 0.09 and 0.1 mg/L for W8 and W8A, respectively) than the Water Storage Pond (W16; median 0.06 mg/L) or the MVF Sump (W62; median 0.05 mg/L). That dissolved iron concentrations were often higher than may be expected for well oxygenated, circumneutral pH waters, where equilibrium with ferric oxyhydroxides would be expected to maintain dissolved iron levels at <0.01 mg/L, may be due to complexation by dissolved organic matter given the relatively high DOC concentrations in these waters.

Copper concentrations were highest in the DSTSF drainage (median 0.09 and 0.11 mg/L for W8 and W8A, respectively) and lowest in the Water Storage Pond (W16; median 0.02 mg/L). Dissolved copper levels tended to peak during spring freshet (Figure 3-29), consistent with peaks in DOC concentrations. Dissolved molybdenum levels were also highest in the DSTSF drainages (median 0.008 and 0.01 mg/L at W8 and W8A, respectively), with sporadic spikes in concentration observed for W8 (Figure 3-32). No seasonal trend was discernible in the molybdenum dataset.

Finally, dissolved selenium concentrations were also highest in the DSTSF drainages (median 0.004 and 0.005 mg/L for W8 and W8A, respectively), with the lowest concentrations generally observed in the Water Storage Pond (W16; median 0.001 mg/L). Selenium levels in the DSTSF east drainage (W8) displayed distinct seasonality (Figure 3-34). Here, the lowest selenium concentrations were observed over winter, followed by a sharp rise over spring and summer, peaking in late summer/fall before declining sharply in early winter. Such behaviour mirrored the seasonality observed for sulphate concentrations.

3.2 MINTO NORTH PIT

The Minto North Pit (sampling site MN) has not discharged any water and is not expected to discharge water during the operational period. As such, its water quality is considered separately here.

3.2.1 Physical Parameters, Anions and Nutrients

Statistical summaries of physical parameters and anion and nutrient concentrations at site MN are presented in Table 3-21. TSS, field pH, nitrate, nitrite, ammonia, and sulphate data are presented in Figure 3-37 through Figure 3-42.

The waters in the Mino North pit were circumneutral to mildly alkaline, ranging from pH 7.0 to 8.6 (median 7.7). Temperature varied seasonally from 0.2 to 18°C. Unlike the other flooded pits at the mine site, the Minto North Pit water appeared relatively well oxygenated (median 85% oxygen saturation) and did not exhibit any oxygen diminution over winter; however, only one set of winter data has been collected to date. Field measured conductivity was relatively high (median 1132 µS/cm) and showed no clear seasonal trends. TSS ranged from <3 mg/L to 142 mg/L (median 29 mg/L) and also showed no seasonal trends.

Sulphate concentrations ranged from 27 to 193 mg/L (median 77 mg/L) with the highest concentrations observed over summer/fall 2016. Elevated concentrations of nitrogen species were observed in the Minto North Pit with median concentrations of nitrite-N, nitrate-N and ammonia-N of 3.8, 122, and 8.7 mg/L, respectively. These elevated nitrogen species concentrations are likely related to nitrogen resides from blasting activity in the pit.

3.2.2 Metals

Statistical summaries of dissolved metals concentrations at site MN are presented in Table 3-22. Dissolved metal concentrations are plotted in Figure 3-43 through Figure 3-54.

Minto North Pit water has high hardness (median 567 mg/L) and did not display any seasonal variation during the monitored period. Indeed, no obvious seasonal trends were observed in the Minto North Pit trace element data, perhaps due to its relatively limited dataset.

Dissolved chromium and lead concentrations were below detection for all the MN samples collected to date. The majority of silver (73%) and zinc (55%) measurements were also below detection, with the measurable data indicating generally low concentrations of both elements in the Minto North Pit.

Concentrations of dissolved aluminum, arsenic, cadmium, molybdenum, and nickel were also unremarkable, with median values of 0.004, 0.0005, 0.00003, 0.02, and 0.0006 mg/L, respectively. Dissolved iron levels were also generally low (median 0.03 mg/L), with sporadic spikes in concentration approximately an order of magnitude higher than the median (Figure 3-48). Dissolved selenium concentrations were also relatively stable throughout the period of record (median 0.01 mg/L). MN waters generally contained elevated dissolved copper concentrations (0.012 to 0.56 mg/L; median 0.1 mg/L).

3.3 MINTO CREEK

Discussion of water quality data in Minto Creek comprises results for sample stations W50, W3, MC1 and W2 as outlined in Section 2.1.3. Examined parameters included those included in the list of EQS and WQO in Water License QZ14-031. Interpretation of water quality results was performed in terms of operations without mine discharge (Section 3.3.1) and operations with mine discharge (Section 3.3.2). Water quality in the pre-operations phase was presented and discussed previously in Minnow, 2016 which is found as Appendix A. Plots depicting examined parameters (physical parameters, anions, nutrients and dissolved metals concentrations) temporally at Minto Creek stations are shown in Figure 3-55 through Figure 3-105.

EQS, WQO, and MMER standards are shown on plots for W50, W2, and W3, respectively, for reference. In the case of the hardness-dependent cadmium EQS/WQO, the line depicting the EQS/WQO was calculated based on lower quartile hardness at W2 without mine discharge (121 mg/L). In the case of the DOC-dependent EQS/WQO for copper, the lower EQS/WQO is depicted on the plots for reference. Actual exceedances of these varying EQS/WQO were determined on a sample to sample basis and are reflected in the count of exceedances listed in the summary statistics tables.

To delineate the effects of mine site discharge on downstream water quality in Minto Creek, Sections 3.3.1 and 3.3.2 review the chemistry of Minto Creek for periods with and without mine site discharge, respectively. In general, higher concentrations of constituents related to the mine site (e.g., nitrogen species, copper, molybdenum, and selenium) were observed in downstream Minto Creek waters during periods of mine discharge.

3.3.1 Operational Phase without Mine Discharge

Water quality data collected at Minto Creek stations during the operational phase without mine discharge are presented and discussed for physical parameters and anion and nutrient concentrations in Section 3.3.1.1 and for dissolved metals in Section 3.1.1.2.

3.3.1.1 Physical Parameters, Anions and Nutrients

Statistical summaries for physical parameters and anion and nutrient concentrations at Minto Creek stations during periods without mine discharge are presented in Table 3-23 through Table 3-26.

The pH in Minto Creek without mine discharge has been circumneutral with medians ranging from pH 7.7 at W3 to pH 8.0 at MC1 and W2. Temperature varied seasonally from -1.5 to 13.7 ^{o}C. The waters of Minto Creek were well oxygenated with occasional lower oxygen content measurements (<40% saturation) generally made in winter months when ice cover could inhibit oxygen ingress to the creek. Median field conductivity decreased going downstream from W50 (280 µS/cm) and W3 (297 µS/cm) to MC1 (200 µS/cm) and W2 (215 µS/cm). Lower conductivity values at W2 were typically measured during high flow periods where dilution would have been provided by spring meltwater while higher measurements were typically made in late summer, fall and winter. This seasonal trend was less apparent at W3 closer to the site where higher conductivity measurements appeared to follow periods of mine discharge.

At all sites, TSS concentrations typically peak in April/May during freshet when the resulting higher flow regime washes particulates into Minto Creek and promotes erosive mobilization of particulates within the wetted width of the creek. TSS levels were generally lower at the upstream sites W3 and W50 (median 1 and 2 mg/L, respectively) than further downstream (median 5 and 8 mg/L at sites W2 and MC1, respectively). TSS concentrations exceed the EQS at W50 in two samples (5% of dataset) when there was no discharge from the mine site; however, both sampling events occurred before this TSS EQS came into effect with the issuance of WUL QZ14-031 (August 2015). Exceedances of the MMER grab sample TSS guideline (30 mg/L) occurred in 20 samples (3% of dataset) at site W3 when there was no discharge from the mine site.

Nitrate-N concentrations at W3 and W50 appeared to be influenced by site discharge with higher concentrations often following periods of site discharge. Concentrations decreased following the end of a discharge period and typically reached minima in late summer/early fall due to uptake by primary producers that are most active during those times. Aside from mine discharge – and more apparent farther downstream at MC1 and W2 – nitrate-N concentrations typically increased during winter when uptake by primary producers was likely lowest. During periods without discharge from the mine site, ammonia-N concentrations were similar throughout Minto Creek stations with median concentrations ranging from 0.018 mg/L at W50 to 0.025 mg/L at MC1. No seasonal trends are apparent and higher concentrations often followed periods of mine discharge. Nitrite-N concentrations were often close to or below detection level at W3 and were higher downstream at W2 after periods of mine discharge. No exceedances of the nitrogen species EQS were observed at W50 during periods when the mine was not discharging. Four exceedances of the ammonia-N WQO were observed at W2; however, these occurred prior to August 2015 when this WQO was established with water licence QZ14-031.

DOC concentrations were higher in downstream stations MC1 (median 10.5 mg/L) and W2 (median 10.4 mg/L) than upstream station W3 (median 5.7 mg/L); however, DOC concentrations at W50 were similar to downstream stations (9.3 mg/L), albeit in relatively fewer samples. At W3, higher DOC concentrations typically were recorded after a period of discharge or in April/May when high flows from snowmelt likely mobilized organic carbon that had accumulated in soils from the previous year. At MC1 and W2, DOC concentrations were generally higher in later summer (August/September) and were lowest in the winter.

3.3.1.2 Metals

Statistical summaries for dissolved metal concentrations of interest at Minto Creek stations during periods without mine discharge are presented in Table 3-27 through Table 3-30.

Dissolved hardness was consistently highest at station W3 in Minto Creek without mine discharge with a median hardness of 243 mg/L and decreased going downstream to stations MC1 (median 150 mg/L) and W2 (median 145 mg/L). Seasonal variations in hardness were apparent, particularly in W50 and downstream stations MC1 and W2, as the lowest concentrations were observed in April/May when dilution was likely provided by snowmelt and concentrations increased through the summer, fall and winter as baseflow – the portion of flow that seeps from the ground and is not from runoff or direct precipitation – likely comprised an increasing proportion of Minto Creek flow. The seasonal trend is less obvious in W3 perhaps due to a more consistent, year-round contribution of groundwater to Minto Creek between W50 and W3.

Dissolved aluminium concentrations were generally higher in downstream Minto Creek stations MC1 and W2 (both median 0.012 mg/L) than in upstream stations W50 (median 0.007 mg/L) and W3 (median 0.006 mg/L). Concentrations were typically higher in April/May when higher flows caused by snowmelt likely mobilized more aluminium and decreased through the remainder of the year. Dissolved arsenic and iron were also higher in downstream stations MC1 (median 0.00057 mg/L arsenic and 0.17 mg/L iron) and W2 (0.0005 mg/L arsenic and 0.10 mg/L iron) than upstream stations W50 (median 0.00039 mg/L arsenic and 0.016 mg/L iron) and W3 (median 0.0003 mg/L arsenic and 0.026 mg/L iron). Concentrations of arsenic and iron followed a seasonal trend with higher concentrations typically observed in August/September and lower concentrations in winter and early spring. A moderate correlation between dissolved iron and DOC concentrations at W2 suggests that DOC may be responsible for higher concentrations of iron in solution in Minto Creek throughout the summer months.

Concentrations of dissolved cadmium and nickel were often below detection in Minto Creek at all four monitoring stations. Above detection level concentrations typically followed periods of mine discharge and appear to have decreased during 2009 to 2012. Aside from some scatter in pre-2011, dissolved chromium, lead, and zinc concentrations were also predominantly below or close to detection.

During periods without discharge from the mine site, dissolved copper concentrations were generally higher at W50 and W3 with medians of 0.007 mg/L and 0.003 mg/L, respectively, than at downstream sites MC1 and W2 (median of 0.002 mg/L at both). Higher concentrations typically occurred following a mine discharge period or during April/May when higher DOC concentrations (associated with higher freshet flows) could likely mobilize more copper. Dissolved molybdenum was also higher at upstream stations W50 and W3 with median concentrations of 0.0059 and 0.004 mg/L, respectively. While dissolved molybdenum concentrations were fairly stable, more of a seasonal trend was apparent at MC1 and W2 where higher concentrations were typically observed in May and lower concentrations in the winter, suggesting that the higher spring flows caused by meltwater could be responsible for mobilizing more molybdenum.

During periods without discharge from the mine site, dissolved selenium was consistently higher at W50 (median 0.00060 mg/L) and W3 (median 0.00039 mg/L) than at downstream stations MC1 and W2 with median concentrations of 0.00013 and 0.00012 mg/L, respectively. Higher concentrations appeared to follow mine discharge periods – particularly the discharge period ending October 27, 2010. Aside from discharge periods, a marked seasonality was evident with higher concentrations observed in the winter and lower concentrations

observed in the summer, suggesting that baseflow likely contributes a significant portion of selenium to Minto Creek.

During periods when the mine site was not discharging, one exceedance of the dissolved copper EQS at site W50 and the dissolved copper WQO at site W2 were recorded; however, these occurred before these EQS and WQO came into effect with the issuance of WUL QZ14-031 (August 2015). Similarly, one dissolved silver, four dissolved selenium, and ten dissolved chromium concentrations exceeded their respective WQO at W2; however, this occurred before the WQO at this site came into effect with the issuance of WUL QZ14-031 (August 2015). No MMER grab sample exceedances were observed for dissolved metals at site W3.

3.3.2 Operational Phase with Mine Discharge

3.3.2.1 Physical Parameters, Anions and Nutrients

Statistical summaries for physical parameters and anion and nutrient concentrations at Minto Creek stations during mine discharge periods are presented in Table 3-31 and Table 3-34.

During mine discharge, the pH of the waters of Minto Creek was circumneutral to slightly alkaline with medians ranging from pH 7.7 at W50 to pH 8.2 at W2. Temperatures varied seasonally with the highest generally minimum and maximum temperatures recorded at W50 -1.2°C and 15.3°C, respectively. The waters of Minto Creek were generally well oxygenated with median oxygen content increasing moving downstream from 88.4% at W50 to 99.4% at W2. Field conductivity was generally higher at upstream stations W50 and W3 than downstream stations MC1 and W2. Increasing trends in field conductivity were visible, particularly during longer duration discharge periods (e.g. August 13, 2009 to October 30, 2009 and July 14, 2010 to Oct 27, 2010). However, many of the discharge periods that displayed these trends were in the months following early spring when meltwater would likely have diluted the waters of Minto Creek and therefore the increase in conductivity could also be partially due to less dilution from meltwater in summer and fall.

The highest TSS concentrations throughout Minto Creek were typically encountered during April/May due to mobilization of particulates under the high flow freshet conditions typical of this time of year. TSS concentrations were typically lower in upper Minto Creek (median 1 and 3.8 mg/L at W3 and W50, respectively) than farther downstream (median 6 and 15 mg/L at W2 and MC1, respectively). Two TSS measurements exceeded the EQS at site W50; however, both of these events occurred before the current TSS EQS came into effect with the issuance of WUL QZ14-031 (August 2015). Exceedances of the MMER grab sample TSS guideline (30 mg/L) occurred in 11 samples (4% of dataset) at site W3 when there was discharge from the mine site.

Nitrogen species were higher at W50 and W3 during mine discharge phases than at MC1 and W2. At W50, the median concentrations of ammonia-N and nitrite-N during mine discharge were 0.062 and 0.016 mg/L, respectively, and 0.019 and 0.0080 mg/L at W2, respectively. While median nitrate-N concentrations were similar at W50 and W2, visual inspection shows a marked decrease in nitrate-N from upstream to downstream stations on Minto Creek. Generally, nitrogen species were higher during discharge periods than non-discharge periods.

DOC concentrations were fairly similar at all sites in Minto Creek during mine discharge with medians ranging from 9.3 mg/L at W3 to 12.0 mg/L at W2. While it appears higher DOC concentrations were observed during mine discharge, discharge periods commonly occurred during April/May when higher flows caused by snowmelt would likely mobilize organic carbon from soils and these increased flows likely played an important role in these elevated DOC concentrations.

3.3.2.2 Metals

Statistical summaries for dissolved metal concentrations of interest at Minto Creek stations during mine discharge periods are presented in Table 3-35 through Table 3-38.

Dissolved hardness was generally higher in the upstream Minto Creek stations W50 and W3 than downstream stations MC1 and W2 during mine discharge. As was the case with field conductivity, dissolved hardness appeared to increase through several of the longer duration discharge periods. It is likely that high flows related to April/May snowmelt that commonly coincide with the beginning portion of discharge periods and dilute the hardness to decreasing extent moving into the summer and fall months.

Dissolved aluminum concentrations ranged from medians 0.0095 mg/L at W50 to 0.057 mg/L at W3; however, the relatively high median aluminum concentration for W3 is buoyed by numerous, high concentrations observed during the July 14 to October 27, 2010 discharge period. Aside from this discharge period, dissolved aluminum concentrations were often similar in all Minto Creek stations and appear elevated relative to during non-discharge periods likely due to mine discharge often occurring in April/May when high flows caused by meltwater could mobilize aluminum.

Dissolved arsenic was commonly below detection in Minto Creek before 2011. Dissolved arsenic concentrations were generally lower in upstream sites W50 and W3 with median concentrations of 0.00036 and 0.00030 mg/L, respectively compared to downstream sites MC1 and W2, which both had a median concentration of 0.00050 mg/L. Dissolved arsenic concentrations at W50 and W3 were generally slightly higher or similar with or without mine discharge, whereas arsenic concentrations at MC1 and W2 were generally dependent on the seasonality discussed in Section 3.3.1.2 than on mine discharge.

Dissolved cadmium was often elevated in Minto Creek stations during periods when the mine site was discharging water relative to without mine discharge, with slightly higher concentrations observed at upstream stations W50 and W3 than downstream stations. Nevertheless, many dissolved cadmium concentrations were close to or below detection limits, particularly in older samples (pre-2012) when detection levels were higher than in more recent years. Generally, above detection level concentrations appear to have decreased in since 2009.

Aside from some above detection level concentrations observed in the discharge period between August 13, 2009 to October 30, 2009, dissolved chromium, lead and zinc were predominantly below detection levels during mine discharge periods from 2010 to 2015. In 2016 with lower detection levels, above detection level concentrations were observed but concentrations were fairly similar to previous detection limits. In the case of dissolved lead, concentrations were higher at W50 during 2016 discharge periods, but were below detection at downstream stations. Dissolved silver was consistently below detection levels during mine discharge periods.

Dissolved nickel concentrations were often below detection levels during mine discharge and were generally higher in downstream stations MC1 and W2 than upstream stations W50 and W3.

Dissolved copper, molybdenum and selenium were higher in upstream stations W50 and W3 than downstream stations MC1 and W2 during mine discharge periods. Median dissolved copper concentrations were highest at W50 (0.017 mg/L) and decreased moving downstream with medians of 0.0047, 0.0029, and 0.0022 mg/L at sites

W3, MC1, and W2, respectively. The dissolved copper concentrations were higher during the August 13 to October 30, 2009 discharge period - an emergency discharge period, as discussed in Section 1.1. Dissolved copper concentrations exceeded its WQO at W50 in four samples collected during this period, but it is important to note that the WQO had not yet been established, and DOC – a toxicity modifier used in the determination of the WQO for dissolved copper - was not analyzed in three of these four samples. Similarly, dissolved selenium and molybdenum concentrations were highest at W50 and W3 and decreased moving downstream to MC1 and W2. This downstream decrease in dissolved selenium concentrations was evident graphically on discharge period to discharge period bases, but was not as well represented in statistical summaries. Higher concentrations of dissolved selenium were observed in all Minto Creek stations during the mine discharge phase of July 14, 2010 to October 27, 2010 and to a lesser extent August 13, 2009 to October 30, 2009 – an emergency discharge period – which skewed the statistics for the discharge periods.

Dissolved iron concentrations were often higher in downstream stations MC1 and W2 with medians of 0.11 and 0.079 mg/L, respectively, than upstream stations W50 (median 0.043 mg/L) and W3 (median 0.016 mg/L). Higher concentrations downstream were likely related to seasonal factors and correlated with DOC concentrations as opposed to influences from mine discharge, as discussed in Section 3.3.1.2.

During periods when the mine site was discharging, one exceedance of the dissolved copper EQS at site W50 was recorded; however, this occurred before this EQS came into effect with the issuance of WUL QZ14-031 (August 2015). Similarly, one dissolved aluminium, two dissolved chromium, four dissolved copper, and 46 dissolved selenium concentrations exceeded their respective WQO at W2; however, this occurred before the WQO at this site came into effect with the issuance of WUL QZ14-031 (August 2015). No MMER grab sample exceedances were observed for dissolved metals at site W3.

3.4 MCGINTY CREEK

Discussion of water quality data in Minto Creek comprises results for sample stations MN-1.5, MN-2.5, MN-0.2, MN-0.5 and MN-4.5 as outlined in Section 2.1.4. Examined parameters included those in the list of EQS and WQO in Water License QZ14-031.

3.4.1 McGinty Creek East Arm

The water quality results for the McGinty Creek east arm (MN-1.5, MN-2.5 and MN-4.5) are presented for physical parameters and anion and nutrient concentrations in Section 3.4.1.1 and for dissolved metals in Section 3.4.1.2.

3.4.1.1 Physical Parameters, Anions and Nutrients

Statistical summaries of physical parameters, anions and nutrients in the east arm of McGinty Creek stations are presented in Table 3-39 through Table 3-41. Plots that depict TSS, field pH and nitrogen species temporally at the McGinty Creek east arm stations are presented in Figure 3-106 through Figure 3-110.

The pH in the east arm of McGinty Creek has generally been circumneutral and increases moving downstream from MN-1.5 (median pH 7.3) to MN-4.5 (median pH 7.8) (Figure 3-107). Temperature varied seasonally in McGinty Creek (median 0.5 to 2.4 ^{o}C) and its waters were often well oxygenated; however, relatively lower dissolved oxygen measurements were recorded at MN-1.5 and MN-2.5 during winter months when ice cover likely restricted oxygen ingress to the creek. McGinty Creek typically demonstrated seasonal variability in field conductivity as the lowest annual measurements were predominantly observed in April due to dilution from snowmelt.

Unlike the mine site and Minto Creek locations, the highest TSS concentrations were typically observed during the summer. TSS concentrations were highest at the most upstream station (median 25 mg/L at MN-1.5), where concentrations as high as 8,200 mg/L were recorded (Table 3-39). Much lower TSS concentrations were observed downstream with sites MC-2.5 and MC-4.5 sharing similar median TSS levels (4 and 6 mg/L, respectively). Four sampling events at site MN-4.5 exceeded the AMP WQO (269 mg/L); however, these sampling events occurred before this WQO came into effect (March 2016).

Nitrite-N concentrations were typically below detection levels in McGinty Creek with occasional greater than detection data in later summer measurements. Nitrate-N concentrations in McGinty Creek showed some seasonality with low or below detection level values in April/May due to dilution meltwater, and higher concentrations generally later in the year. Median ammonia-N was highest in the upstream station MN-1.5 (0.04 mg/L), with lower concentrations observed moving downstream to MN-2.5 (median 0.017 mg/L) and MN-4.5 (median 0.013 mg/L). Two ammonia-N results exceeded AMP WQO at MN-4.5, but both these samples were collected before this WQO came into effect (March 2016).

DOC concentrations were highest at the upstream station MN-1.5 (median 17.2 mg/L) compared to MN-2.5 (median 12.1 mg/L) and MN-4.5 (median 12.6 mg/L). In general, DOC levels were highest in April/May when high flows and runoff likely flushed organic carbon that had accumulated in soils during the past year.

3.4.1.2 Metals

Statistical summaries of metal concentrations from the McGinty Creek east arm stations are presented in Table 3-42 through Table 3-44. Plots that depict metal concentrations temporally at the McGinty Creek east arm stations are presented in Figure 3-111 through Figure 3-122.

Dissolved hardness typically increased moving downstream in McGinty Creek from MN-1.5 (median 36 mg/L) to MN-2.5 (median 81 mg/L) and MN-4.5 (median 87 mg/L). Hardness levels generally varied seasonally with lower concentrations in April/May due to dilution from meltwater, followed by increasing concentrations through the rest of the year.

In the east arm of McGinty Creek, dissolved aluminum, arsenic, chromium, copper and iron concentrations were generally higher at the most upstream station MN-1.5 and decreased downstream to MN-2.5 and MN-4.5. Concentrations of dissolved aluminum and copper in McGinty Creek at MN-1.5 were typically higher in late spring, likely due mobilization by the higher DOC concentrations observed at this time of year, and decreased throughout the summer although several spikes in dissolved aluminum were observed in August and September. Dissolved aluminum and copper decreased going downstream from MN-1.5 (median 0.1 mg/L aluminum and 0.0062 mg/L copper) to MN-2.5 (median 0.028 mg/L aluminum and 0.0019 mg/L copper) and MN-4.5 (median 0.017 mg/L and 0.0019 mg/L copper).

Dissolved arsenic and iron concentrations were typically highest in July through September at MN-1.5 and lowest in the spring and winter months. A negative correlation between dissolved iron and oxidation reduction

potential (ORP) suggests the presence of reducing waters (e.g., groundwater seep) perhaps contributing elevated concentrations of dissolved iron to McGinty Creek upstream of MN-1.5. It is possible that the contribution of dissolved arsenic and iron from a reducing groundwater source was muted in spring due to dilution from meltwater, and in fall and winter due to very low flow rates or ice blockage. Dissolved arsenic and iron concentrations decrease moving downstream from MN-1.5 (median 0.00047 mg/L arsenic and 0.54 mg/L iron) to MN-2.5 (median 0.00039 mg/L arsenic and 0.16 mg/L iron) and MN-4.5 (median 0.00038 mg/L and 0.11 mg/L iron), likely due to precipitation of iron minerals and/or dilution.

Dissolved cadmium, lead and zinc have generally decreased in the east arm of McGinty Creek stations from 2009 to 2012 and have often been close to or below their respective detection limits from 2013 through 2016.

Dissolved molybdenum and selenium concentrations were higher at the downstream McGinty Creek station of MN-4.5 (median 0.00085 mg/L molybdenum and 0.00014 mg/L selenium) relative to the east arm of McGinty Creek stations MN-1.5 (median 0.00030 mg/L molybdenum and 0.000078 mg/L selenium) and MN-2.5 (0.00063 mg/L molybdenum and 0.000080 mg/L selenium). MN-4.5 is downstream of the confluence with the west arm of McGinty Creek and relatively elevated concentrations of molybdenum and selenium in the west arm of McGinty Creek likely contributed to the higher concentrations in MN-4.5 compared to MN-1.5 and MN-2.5.

Dissolved nickel concentrations were similar throughout the McGinty Creek east arm stations with median concentrations at MN-1.5, MN-2.5 and MN-4.5 of 0.0012, 0.0012 and 0.0011 mg/L, respectively. Dissolved nickel levels were generally lower in April/May and increased throughout the remainder of the year suggesting dilution by meltwater in the spring and an increasing proportion of dissolved nickel from baseflow in the summer through to the winter.

Exceedances of the AMP WQO for individual indicators evaluated at MN-4.5 were generally limited to samples collected before the WQO came into effect at this station (March 2016); however, one dissolved selenium exceedance of its AMP WQO has occurred since March 2016. Since no discharge from the mine site has occurred during this period, such exceedances are part of the natural variability observed in the water quality of McGinty Creek and are addressed as part of the AMP (Minto, 2017).

3.4.2 McGinty Creek West Arm Reference

Water quality results for the McGinty Creek west arm stations (MN-0.2 and MN-0.5) are presented and discussed for physical parameters, anions and nutrients in Section 3.4.2.1 and for dissolved metals of interest in Section 3.4.2.2.

3.4.2.1 Physical Parameters, Anions and Nutrients

Statistical summaries of physical parameters and anion and nutrient concentrations in MN-0.2 and MN-0.5 are presented in Table 3-45 and Table 3-46, respectively. TSS, field pH and nitrogen species in the McGinty Creek west arm stations over time are presented graphically in Figure 3-123 to Figure 3-127.

The pH in the west arm of McGinty Creek has generally been circumneutral and increases moving downstream from MN-0.2 (median pH 7.2) to MN-0.5 (median pH 7.8). Temperature varied seasonally from -1.4 to 7.9 ^{o}C. Field conductivity was consistently higher in the downstream station of MN-0.5 (median 109 µS/cm) than MN-0.2 (median 48 µS/cm) with no obvious seasonal trend. TSS concentrations were generally higher at site MN-0.5 (median 13 mg/L) than farther upstream at site MN-0.2 (median 3 mg/L), and typically peaked during summer sampling events for both sites.

Nitrate-N concentrations were higher at the downstream MN-0.5 station than at MN-0.2 where nitrate-N was most often below detection levels. Generally, nitrate-N concentrations at MN-0.5 were highest in winter when uptake by primary producers was lowest. Nitrite-N concentrations were typically below detection at both MN-0.2 and MN-0.5. Ammonia-N concentrations were similar at MN-0.2 and MN-0.5 with median concentrations of 0.019 and 0.014 mg/L, respectively.

DOC concentrations decreased slightly moving downstream from MN-0.2 (17.1 mg/L) to MN-0.5 (12.1 mg/L). Concentrations typically varied seasonally with the highest concentrations observed in April/May when spring runoff likely flushed surface soils and leached organic carbon that had accumulated over the previous year.

3.4.2.2 Metals

Statistical summaries of dissolved metals concentrations in MN-0.2 and MN-0.5 are presented in Table 3-47 and Table 3-48, respectively. Dissolved metals of interest in the McGinty Creek west arm stations over time are presented graphically in Figure 3-128 through Figure 3-139.

Dissolved hardness in the west arm of McGinty Creek typically followed a seasonal trend with lower concentrations in April/May due to dilution from meltwater and increasing concentrations through the rest of the year, likely related to an increasing proportion of baseflow in the creek. Hardness levels increased moving downstream from MN-0.2 to MN-0.5 with median concentrations of 30 and 89 mg/L, respectively.

Dissolved aluminium, copper and nickel concentrations were generally higher upstream at MN-0.2 (median 0.065 mg/L aluminium, 0.0025 mg/L and 0.0016 mg/L nickel) than downstream at MN-0.5 (0.019 mg/L aluminium, 0.0017 mg/L copper and 0.001 mg/L). No trends were apparent for aluminium and nickel concentrations, but copper appeared to vary seasonally with higher concentrations in April/May, likely due to mobilization by the elevated DOC levels observed at this time of year, followed by decreasing concentrations through the remainder of the year.

Dissolved arsenic concentrations were similar at MN-0.2 and MN-0.5 except for in 2016 when concentrations were greater at MN-0.2. Similarly, dissolved iron concentrations were greater at MN-0.2 than MN-0.5 in 2015 and 2016 after being fairly similar to the downstream station from 2009 to 2014. Concentrations of dissolved

arsenic and iron were fairly erratic, but higher concentrations were often found in late summer (August) and lower concentrations in April, although this was not observed in every year.

A wide range of dissolved cadmium, lead and zinc concentrations were observed at MN-0.2 and MN-0.5 with no apparent seasonal trends from 2009 through 2013. Since 2013, concentrations appear to have decreased and were often close to or below their respective detection levels. Similarly, dissolved chromium concentrations varied pre-2013 and were close to or below a relatively higher detection level through 2015. In 2016, dissolved chromium concentrations at MN-0.2 appeared to be greater than earlier data however concentrations were still fairly close to previous detection levels. Dissolved silver was often below detection level at both stations on the west arm of McGinty Creek.

Dissolved molybdenum and selenium were higher at the downstream station MN-0.5 (median 0.00093 mg/L molybdenum and 0.00018 mg/L selenium) than upstream at MN-0.2 (median 0.00016 mg/L molybdenum and 0.000069 mg/L selenium). Generally, concentrations varied seasonally with lower concentrations in April with dilution from spring meltwater and increasing concentrations throughout the year as baseflow contributes a greater proportion of flow in McGinty Creek.

4 SUMMARY

The characteristics, trends and patterns associated with the geochemistry of surface waters at the Minto Mine Site, Minto North Pit, Minto Creek, and McGinty Creek is summarized in this section.

4.1 MINTO MINE SITE

- The pH of the waters was predominantly circumneutral to slightly alkaline;
- Although typically well oxygenated, lower levels of dissolved oxygen were often observed during winter, particularly for the pit lake locations, where ice cover limited the the oxygenation of underlying waters;
- Nitrogen species concentrations were generally highest in the pit lake and DSTSF drainage sites, reflecting leaching of nitrogen residue from blasting activity. Nitrate-N levels showed marked seasonality at both the Minto Creek mine site location (W15) and the DSTSF drainage (W8 and W8A), but with different patterns. In Minto Creek, nitrate-N levels were highest in winter and lowest over summer, responding to nitrogen uptake demand by primary producers, whereas the opposite trend was noted in the DSTSF drainage;
- DOC concentrations were highest during spring snowmelt, likely due to snowmelt flushing the surrounding soils of labile organic matter that had accumulated through the previous summer and fall;
- Dissolved hardness concentrations were typically lowest in spring at the flowing water sites due to snowmelt dilution, and increased through the year, peaking in winter, suggestive of a marked groundwater component to hardness levels;
- Concentrations of dissolved iron, and to a lesser extent dissolved aluminum, often appeared higher than may be expected from equilibrium with their oxyhydroxide minerals under the prevalent oxidizing, circumneutral pH conditions. Complexation with dissolved organic matter likely maintains these elevated dissolved iron and aluminum levels;
- Dissolved copper concentrations were highest in the DSTSF drainage and tended to peak with freshet, suggestive of some association with DOC; and
- Dissolved concentrations of both selenium and molybdenum increased approximately four-fold in the pit lake sites over the past two to three years, alongside sulphate. Dissolved selenium exhibited strong seasonal cycling in both Minto Creek (W15) and the DSTSF drainage (W8A), but with offset patterns. In Minto Creek, selenium concentrations were lowest at freshet, then rose through the year, peaking in winter, suggestive of a strong groundwater contribution. The opposite pattern was observed at site W8A, where selenium levels oscillated on an annual basis between summer peaks and winter troughs.

4.2 MINTO NORTH PIT

- Minto North Pit waters were circumneutral to mildly alkaline and well oxygenated over the one year of data collected to date;
- Field-measured conductivity and hardness were relatively high and showed no seasonal trends;
- Nitrogen species were very high in the Minto North Pit, likely due to nitrogen residue from blasting activities;
- Minto North Pit waters generally contained elevated dissolved copper, molybdenum, and selenium concentrations;
- The majority of dissolved silver and zinc measurements were below detection; and
- Dissolved aluminum, arsenic, cadmium, nickel, and iron concentrations were unremarkable although some sporadic spikes in iron levels were an order of magnitude higher than the median dissolved iron concentration.

4.3 MINTO CREEK

- The Minto Creek waters were typically circumneutral to slightly alkaline pH and well-oxygenated;
- Nitrogen species concentrations were generally higher during and following periods of mine discharge, likely due to blasting activity within the mine site. Aside from discharge periods, seasonal trends were observed, particularly for nitrate-N, with lower nitrate-N concentrations typically observed in summer months when primary producers that uptake nitrogen species would be most active;
- Concentrations of DOC at W3 were typically higher during April/May likely due to high flows caused by spring meltwater mobilizing organic carbon that had accumulated over the previous year. DOC concentrations also appeared to be higher during mine discharge periods, but as many of these periods occurred in early spring it is difficult to discern the effects of mine discharge on DOC. At downstream stations MC1 and W2, DOC concentrations were higher in mid to late summer and were generally lower in spring and winter;
- Hardness was often lowest in April and May and increased through the summer and fall suggesting dilution in spring, followed by a higher proportional contribution of groundwater to Minto Creek flow through summer, fall, and winter. This trend was more marked at W50 and downstream stations MC1 and W2, whereas W3 returned higher hardness concentrations with less seasonality;
- Dissolved aluminum concentrations were higher in the spring and decreased through the year, likely due to mobilization by high flows from spring meltwater and possibly complexation by DOC, which also peaked in spring;

- Dissolved arsenic and iron concentrations were typically higher at downstream stations MC1 and W2 than upstream stations and were highest in mid to late summer. A reasonable correlation with DOC concentrations suggests DOC likely enhances iron solubility at MC1 and W2;

- Since 2010, dissolved chromium, lead, silver and zinc has generally been closer to or below detection levels with and without mine discharge;

- Dissolved copper, molybdenum and selenium concentrations were higher during and following periods of mine discharge. Dissolved copper concentrations also appeared to vary seasonally with higher concentrations observed in the spring with higher flows from meltwater and were correlated with DOC concentrations. Dissolved molybdenum concentrations were consistently higher at W3 than W2 in pre-operations and during non-discharge periods.

4.4 MCGINTY CREEK

- Field pH was generally circumneutral to slightly alkaline and increased farther downstream in both arms of McGinty Creek;

- The waters were fairly well-oxygenated with occasional troughs of dissolved oxygen measured in winter months when ice cover likely inhibited ingress of oxygen to McGinty Creek;

- Nitrate-N concentrations were typically lower in April/May due likely to dilution from meltwater and higher values were typically observed in the winter when uptake by primary producers would have been lowest. Nitrite-N was predominantly below detection level in McGinty Creek;

- Concentrations of DOC were typically higher during April/May likely due to mobilization by high flows caused by spring meltwater. Higher concentrations were also commonly observed in mid to late summer;

- Dissolved hardness concentrations increased farther downstream and varied seasonally with lowest concentrations in the spring and increasing concentrations through to the winter, suggesting a significant proportion of hardness from baseflow that is diluted by spring meltwater;

- Dissolved aluminum concentrations were higher in the upstream stations of the east and west arms of McGinty Creek and were erratic, perhaps varying with precipitation events as concentrations were typically higher in April and May when higher flows caused by spring meltwater could mobilize aluminum. Complexation by DOC, which was highest during spring, may also have maintained elevated dissolved aluminum concentrations at this time;

- Dissolved arsenic and iron concentrations were higher in upstream stations of the east and west arm of McGinty Creek and often peaked in August or September. A negative correlation between iron and ORP suggests the presence of a groundwater seep with reducing conditions that could have provided elevated concentrations of iron to McGinty Creek. DOC could also be a factor in maintaining higher iron concentrations in solution;

- Dissolved cadmium and zinc concentrations appeared to decrease from 2010 to 2013 and have been fairly low throughout all McGinty Creek stations post-2013;

- Dissolved chromium concentrations were higher in upstream stations of the east and west arms of McGinty Creek;

- The upstream-most stations – MN-1.5 (east arm) and MN-0.2 (west arm reference tributary) – consistently returned higher dissolved copper concentrations in McGinty Creek. Generally, concentrations were higher in April/May likely due to mobilization by the elevated DOC levels observed at this time of the year;

- Dissolved molybdenum concentrations typically increased moving downstream in McGinty Creek and varied seasonally such that lower concentrations were observed in the spring and higher concentrations were observed in the winter, suggestive of dilution of baseflow providing the bulk of molybdenum to McGinty Creek in the spring;

- Dissolved lead and silver concentrations have generally been close to or below their respective detection levels in McGinty Creek;

- Dissolved selenium concentrations in McGinty Creek were generally highest in the west arm (reference tributary) at MN-0.5, suggesting a significant proportion of loading occurs from the west arm to McGinty Creek downstream of MN-2.5 and upstream of MN-4.5.

5 LIMITATIONS OF REPORT

Alexco Environmental Group (AEG) of Whitehorse, Yukon has prepared this Water Quality Characterization for Minto Creek for the Minto Project for the exclusive use of Minto Explorations Ltd., and is based on data and information managed by Minto Mine. AEG has followed standard professional procedures in conducting the investigations and in preparing the contents of this report. The material in this report reflects AEG's best judgment in light of the information available at the time of the preparation of this report. Any use that a third party makes of this report, or any reliance on decisions to be made based on it, is the responsibility of the third parties. AEG accepts no responsibility for damages, if any, suffered by any third party as a result of decisions made or actions based on this report. AEG believes that the contents of this report are substantively correct.

The information and data contained in this report, including without limitation, the results of any sampling and analyses conducted by AEG, are based solely on the conditions observed at the time of the field assessment and have been developed or obtained through the exercise of AEG's professional judgment and are set to the best of AEG's knowledge, information, and belief. Although every effort has been made to confirm that all such information and data is factual, complete and accurate, AEG offers no guarantees or warranties, either expressed or implied, with respect to such information or data.

AEG shall not by the act of issuing this report be deemed to have represented that any sampling and analyses conducted by it have been exhaustive or will identify all pertinent conditions at the site, and persons relying on the results thereof do so at their own risk.

1.0 INTRODUCTION

1.1 Site Description

The Minto Mine is a high-grade copper mine located within Selkirk First Nation (SFN) Category A Settlement Land Parcel R-6A approximately 240 km northwest of Whitehorse, Yukon Territory (62°37'N latitude and 137°15'W longitude; Figure 1.1). It is owned and operated by Minto Explorations Ltd., a wholly owned subsidiary of Capstone Mining Corporation. Development of the mine was initiated in 1997, commercial operations started in October 2007 and the currently anticipated operating life is to 2018. The facility is permitted to conduct open pit and underground mining, and includes a mill with a capacity of 4,200 tonnes of ore per day. The Minto Mine produced 16,500 kilo-tonnes of copper in 2015 (average copper grade 1.38%). Mineral reserves as of January 1st 2016 were approximately 5,500 kilo-tonnes at an average copper grade of 1.87%.

In addition to open pit mines, underground mines and the mill, the Minto Mine site includes a number of waste rock dumps, a concentrate storage shed, tailings storage facilities, a water retention dam with a water storage pond, a water treatment plant, administrative offices, an airstrip and a camp (Figure 1.2). Mill tailings are stored in dry stack tailings storage facilities and in mined-out open pits. Mine-impacted seepage from the tailings storage facilities and under the Mill Valley Fill Extension (MVFE) is collected at the Mill Valley Fill Extension Stage 2 Collection Sump and is pumped to the main pit (Figure 1.2). Non-impacted water and treated mine-impacted water are collected in a Water Storage Pond (WSP; Figure 1.2). Effluent from the WSP is periodically discharged to Minto Creek under conditions specified in the Minto Mine's Water Use Licence (WUL) QZ14-031 (August 2015; YWB 2015). Minto Creek, in turn, discharges to the Yukon River approximately 7.7 km south-east of the WSP (Figure 1.2).

The Minto Mine is actively planning for closure, which could potentially occur as soon as late 2018. Conceptually, closure will include three stages: 1) an active closure period; 2) post-closure 1; and 3) post-closure 2. All major reclamation work will be completed during the active closure period. This will include re-contouring, cover placement, re-vegetation, construction of closure water conveyance channels, construction of wetland water treatment systems, and building demolition. Water will be actively managed during the active closure period. Post-closure 1 follows the completion of all major reclamation work and represents the period when the closure measures completed during the active closure period become fully established (e.g., vegetation is established, cover material self-armors, constructed wetlands are established, water flow through closure conveyances is established). Water treatment during post-closure 1 will be both active and passive. Post-closure 2 follows post-closure 1 and final

decommissioning (e.g., of the water treatment plant and potentially the camp). It represents the period when all closure measures are fully established, including final water conveyances. Water treatment during post-closure 2 will be by passive treatment only.

1.2 Background

The Minto Mine's WUL includes Water Quality Objectives (WQOs) for lower Minto Creek at water quality monitoring station W2 (Figure 1.3). These WQOs apply during the operational period and are anticipated to also apply during the active closure period and in post-closure 1. A separate set of WQOs will be developed for the post-closure 2 period. The Minto Mine's WUL requires a Reclamation and Closure Plan (RCP) that includes WQOs for post-closure that meet the criteria for non-degradation of background concentrations. Two approaches have been provided in the WUL as guidance to developing closure WQOs (YWB 2015; Clause 112):

1) Establish closure WQOs that meet the criteria for non-degradation of background concentrations in Minto and McGinty creeks; and

2) If non-degradation of water quality is not achievable, the closure WQOs shall be set at no more than 50% of the assimilative capacity of Minto Creek using the following formula:

$$Closure\ WQO = BKGD + (0.5*[WQO_{Operations} - BKGD])$$

where: BKGD = background concentration.

Both approaches for the development of closure WQOs require a clearly-defined background water quality condition.

1.3 Objective

The objective of this report is to define the background water quality data set to be used to develop background water quality for lower Minto Creek and to determine background summary statistics for key analytes to be used in calculating the post-closure WQOs. This document outlines the approach used in considering what data points should be included to define background water quality. This document incorporates the outcomes of discussions among the Minto Mine, SFN, and technical consultants (Appendix A). These discussions covered a number of factors critical to the definition of background water quality, including representative sampling stations, contaminants of potential concern (COPCs), dealing with less than method detection limit (MDL) results, dealing with replicate results, identifying outliers, evaluation of possible data groupings, and designation of summary statistics. The

background water quality data set is then used to calculate summary statistics for the COPCs for application as WQOs for the post-closure 2 period.

1.4 Report Organization

Section 2.0 provides a detailed overview of data organization and step-wise work-through the process of defining background water quality for the development of post-closure WQOs. Section 3.0 provides the proposed background water quality statistics. All references cited in the report are provided in Section 4.0.

2.0 DATA ORGANIZATION

Raw data from the Minto Mine's water quality database were received on May 31st, 2016. The database contained concentrations of water quality analytes measured throughout the open water season from 2005 to 2013. The database was sorted and organized as described below, to obtain a final water quality data set to be used to calculate the background concentrations of COPCs. For a few sampling dates, it was noted that water quality analyses were incomplete (e.g., incomplete dissolved metals in a multi-element scan). Minto Mine and Access Consulting Group were contacted to inquire about any missing data but older data sets were unavailable as they were collected by The North Air Group (Vancouver, BC).

2.1 Sampling Stations

The database included six sampling stations (W1, W2, W3, W8, W9 and W10) that were sampled during baseline studies in 2005 and were subsequently influenced by the mine (Figure 1.3; Appendix B). The database also included four reference sampling stations, W6 (2005 – 2013), W7 (2005 – 2013), C4 (2012, 2013) and C10 (2012, 2013; Figure 1.3; Appendix B).

Data collected at sampling station W8 were removed from the final background data set because water quality at station W8 was determined to poorly represent water quality at station W2 (lower Minto Creek; the point of WQO application). Data collected at W6 from 2009 to 2011 were not included, as these water quality samples were accidently collected at the Minto Creek main stem and not at the W6 tributary. These data would not represent background concentrations because the mine was operational from 2009 to 2011.

2.2 Contaminants of Potential Concern

The COPCs considered herein are those identified in the Water Use Licence (WUL; QZ14-031; YWB 2015). These COPCs are ammonia, pH (laboratory and field), nitrite, nitrate and the following dissolved metals; aluminum, arsenic, cadmium, chromium, copper, iron, lead, molybdenum, nickel, selenium, silver and zinc. In addition to the COPCs, several additional analytes are considered herein due to their importance as supporting parameters (e.g., parameters that may affect other WQOs). These include dissolved organic carbon (DOC), total and dissolved hardness, total suspended solids (TSS) and total dissolved solids (TDS).

2.3 Method Detection Limits

Concentrations that were reported as less than MDL and where the associated MDL exceeded the maximum detected concentration were removed from the data set. Such cases (and consequent removals) were observed for dissolved chromium (11% of samples) and dissolved

silver (24% of samples; Table 2.1). The remaining analytes reported as less than method detection limits (MDL) were substituted with half the MDL for calculations of summary statistics.

2.4 Replicate Samples

Some water samples were collected multiple times in one day at a given sampling station. To account for this, the average concentration of the analyte at a given station on the same day was used to represent the concentration for that day. The relative percent difference (RPD) of the minimum and maximum daily concentrations were calculated prior to calculating a daily mean concentration (Table 2.2). If the RPD was greater than 25% they were investigated further (Table 2.2).

Many analytes that had RPD greater than 25% were dissolved metals or TSS. Although there were instances where the RPD was greater than 25%, this is expected in multi-element scans. The investigation indicated no systemic problems (e.g., instances where all analytes had RPD greater than 25%), therefore all data were retained in the estimate of the daily mean. Regardless of RPDs between the minimum and maximum concentrations, the mean of concentrations measured on the same day were considered to best represent the concentration on that day.

2.5 Outliers

Outliers were evaluated based on data distributions for each analyte. The term “outlier” in the context of this report is used to refer to an observation that is unusually small or large relative to the distribution of observations. Outliers were investigated further to determine whether the value was naturally possible or whether the value could have resulted from an analytical error. The background data distributions for all analytes were non-normally distributed. Outliers were therefore identified using a non-parametric rule (the lower outer fence and upper outer fence) that is frequently used to identify outliers on boxplots (Dawson 2011).

Lower outer fence = Q1 – 3 (IQR)
Upper outer fence = Q3 + 3 (IQR)
where: Q1 = 1st Quartile
Q3 = 3rd Quartile
IQR = Interquartile Range (Q3 – Q1)

Observations less than the lower outer fence or greater than the upper outer fence were considered outliers. Although the rule is non-parametric, the calculation of the IQR is influenced by data transformations. The outlier evaluation was therefore conducted using untransformed and $\log_{10}$-transformed concentrations because many distributions of water

quality analytes are approximately log-normal. Since pH is reported on the logarithmic scale, the outlier rule was applied to the pH data that were untransformed and anti-logged. Any observations that were identified as potential outliers based on both the untransformed and log_{10}-transformed scale (Appendix C) were investigated further. When Q3 could not be estimated because it was below the MDL, the upper outer fence was estimated using the following formula:

$$MDL_{Q3} + 3 * MDL_{Q3}$$

where: MDL_{Q3} *= the MDL corresponding to the observation at the third quartile*

One observation - dissolved arsenic at station C4 on November 17th 2013 (0.0056 mg/L) - was identified as an outlier based on the above rules (Table 2.3). Further investigation of this potential outlier included consideration of potential elevations of other analytes and consideration of analyte ratios (i.e., chemical signature). Hardness, dissolved iron and dissolved manganese were also elevated in this sample. Because the potential outlying value appeared to be naturally possible, was consistent with observations of elevation of other analytes, and there was no unequivocal evidence of unusual ratios of arsenic relative to other analytes (Appendix Table D.1), the concentration of dissolved arsenic at station C4 was retained in the background data set.

2.6 Baseline Investigation

Water samples collected in 2005 before mine operations were considered baseline data. Concentrations of COPCs were plotted using an individual value plot for all sampling stations to determine if concentrations for each station were similar to station W2 and could be used as baseline data to represent station W2 (Figure 2.1). The median and 95th percentile of the background data sets for each analyte were calculated separately for W2 and all sampling stations (including W2) in 2005 (Table 2.4). There appears to be close agreement between the median and 95th percentiles for the two data sets (i.e., W2 and all sampling stations in 2005; Table 2.4). Total hardness differed most among data sets (was greater at station W2), but summary statistics for many analytes did not differ between W2 and all sampling stations (Table 2.4). In general, the distribution of concentrations of COPCs at station W2 was similar to the distribution of concentrations of COPCs from the other sampling stations in 2005, supporting the use of the designated reference water quality data set as representative of station W2.

Table 2.3: Outliers identified and rationale for removing or keeping the data point.

Station	Date	Identified Outlier			
		Analyte	Value	Decision	Rationale
C4	11/17/2013	Dissolved Arsenic (mg/L)	0.0056	Retained	High Hardness, dissolved iron and dissolved manganese in sample.

Dissolved Zinc (mg/L)	6	0.0020	0.0025	42	0.0025	0.011

2.7 Data Grouping

Water quality sampling was typically conducted in batches or “sampling campaigns” such that water quality samples were collected from multiple sampling stations on the same day or within a one week period. Samples collected on the same day may not be fully independent of each other, and therefore different methods of grouping the data were explored. Three options were evaluated: Option 1 did not involve any grouping (i.e., all data were used), Option 2 grouped samples by week, and Option 3 grouped samples by month (Table 2.5; Figure 2.2; Appendix Table D.1). Data were combined for Option 2 by calculating the mean from all sampling stations that were collected within a one week period (Table D.2). Data were combined for Option 3 in two steps: 1) by calculating the mean for each individual sampling station by month; and 2) then calculating the mean of the monthly sampling station means (Table D.3).

2.8 Summary Statistics

The designated reference water quality data set, developed as outlined above, was used to calculate summary statistics for each of the three options. For each analyte, the sample size, mean, median and 95th percentile were calculated for all stations combined over time for all three Options (Table 2.6). In addition, annual medians were calculated for each of the three options, and the 95th percentile of those annual medians was calculated (Table 2.7).

3.0 BACKGROUND WATER QUALITY SUMMARY STATISTICS

Based primarily on consideration of potential water quality monitoring frequencies at the post-closure 2 stage (proposed spring, summer, fall), Option 3 is put forward as the proposed basis for defining background water quality. Two key sets of background water quality statistics are appropriate for defining background water quality:

1. the 95th percentile of the background data; and
2. the 95th percentile of the annual medians of the background data.

The intended use of the former (Table 3.1; Appendix Table D.4) is as an “individual data point evaluator” and the intended use of the latter (Table 3.1; Appendix Tables D.5 and D.6) is as a “central tendency evaluator”.

Although application of the WQOs in defining attainment is the subject of ongoing discussion between the Minto Mine and Selkirk First Nation, a fundamental guiding principle is that, because the summary statistics are 95th percentiles, they will be exceeded at an average rate of 5% in the absence of any mine influence on water quality. Thus, definition of attainment must consider natural exceedance rate, and initial response to any observed exceedance must be focussed on distinguishing a mine related influence from natural variability.

Table 3.1: Background water quality summary statistics representing lower Minto Creek (Minnow 2016) [1]

Analytes	**Background Concentration Summary Statistics**	
	Individual Data Point Evaluator (95th percentile)	Central Tendency Evaluator (95th percentile of annual medians)
Ammonia (mg/L)	0.12	0.063
Nitrite (mg/L)	0.040	0.028
Nitrate (mg/L)	0.22	0.15
Dissolved Aluminum (mg/L)	0.053	0.032
Dissolved Arsenic (mg/L)	0.0011	0.00086
Dissolved Cadmium (mg/L)	0.000050	0.000044
Dissolved Chromium (mg/L)	0.0011	0.0010
Dissolved Copper (mg/L)	0.0054	0.0029
Dissolved Iron (mg/L)	0.91	0.57
Dissolved Lead (mg/L)	0.00025	0.00014
Dissolved Molybdenum (mg/L)	0.0015	0.0011
Dissolved Nickel (mg/L)	0.0020	0.0016
Dissolved Selenium (mg/L)	0.00050	0.00046
Dissolved Silver (mg/L)	0.000010	0.000010
Dissolved Zinc (mg/L)	0.0084	0.0046

[1] for contaminants of potential concern (COPCs)

APPENDIX A

JUNE 2ND, 2016 MEETING MINUTES

Minto Mine Bilateral Technical Working Group Meeting
Characterizing Background Water Quality for Use as Water Quality Objectives
SRK Consulting – Vancouver, June 2, 2016
Meeting Notes

Attendees: Bill Slater, Don MacDonald, Jesse Sinclair, Ryan Herbert, Pierre Stecko, Dylan MacGregor

Agenda (developed jointly)

- Background Dataset
- Dealing with Duplicates
- Multiple locations per sampling date
- Dealing with Outliers
- Method Detection Limits
- Conditions / Binning
- Summary Statistics
- Attainment
- Confirmation of COPC list
- Water Quality Predictions Use

Key

Black text = items discussed
Blue text = agreed path forward
Red text = action item

1. Background Dataset

- Rationalize stations
- Test differences? Necessary?
- NOTE → W6 samples were taken at the wrong location in 2009-2011 (see extreme copper concentration from April 09) … exclude W6 for this timeframe
- Exclude W8
- "Background Dataset" was agreed upon … see PHOTOGRAPH of whiteboard matrix
- As with Access 2014, removed W6 data from 2009 to 2011 due to uncertainty about sampling location (may have been sampled in Minto Creek mainstem at some times)
- Prepare the dataset per spreadsheet
- Check against Access 2014. The only difference should be the exclusion of W8

2. Dealing with Duplicates

- There are duplicates in the database, some instances of greater replication
- Approach to consolidate to one data point per site per sampling

- Average discussed. Simple decision when they agree well. What if they do not?
- Average by site and date
- Identify the replicates and compare
- If good agreement, use average

3. **Multiple locations per sampling date**
   - This was an MESL addition to the agenda
   - Objective is to best represent water quality at Station W2
   - Is there pseudo-replication by including numerous reference sites to represent W2 on a given date when an alternative (better?) approach might be to use the reference dataset to identify an surrogate W2 value for that date (or campaign if within a few days)
   - Option 1 → use all data as independent
   - Option 2 → consolidate by sampling date (or campaign) to get one estimate of "W2 background" for that date and then use those data for summary statistics
   - Jesse Sinclair ran scenarios on the spot (using R?)
     - D Copper Option 1 → N 184 95th 6.52 median 1.70
     - D Copper Option 2 → N 124 95th 4.94 median 1.46
     - Not much difference for TDS or NO3
   - Tim Barrett to apply this approach and indicate implications overall (e.g., lower BG for copper [but perhaps better representative of W2])
   - Alternative from Don MacDonald = only consider W2 in 2005?
   - Group … no, now that we have agreed on background dataset, stick with it
   - Check → in baseline ONLY (2005), how would Option 1 versus Option 2 compare to actual W2 (admittedly small dataset!)

4. **Dealing with Outliers**
   - Box plot approach suggested by Tim is appropriate.
   - MESL agrees with boxplot approach, indicates that there is more than one way, but that the 3IQR method is appropriate
   - Go ahead and complete the identification of potential outliers
   - Evaluate concurrent conditions
   - Provide list of outliers to Ryan Herbert at Minto Mine
   - Ryan can help decide what is feasible to investigate. If we can't investigate may have to make a (or practical to just toss)
   - Prepare a final list of proposed outliers to be eliminated
   - Provide list to SFN / MESL

5. **Method Detection Limits**
   - Significant issue for a number of COPCs
   - Pierre Stecko → issue could potentially be avoided by using non-parametric statistics
   - How does ½ substitution affect results if MDLs decrease in the future?
   - Pierre → acknowledge ABOVE in the document and propose a defensible way to deal with them. Part of our responsibility is to make sure that this set up in a way that can be easily

picked up in future reviews. Implications of method changes need to be identified and, to the extent possible, guidance provided on how they should be dealt with (e.g., Tim suggests the Kaplan-Meier method).

6. **Conditions / Binning**
   - Desirable not to bin
   - Evidence of seasonal patterns that indicate a need to "bin"
   - Investigated "under ice" versus "ice free"
   - Ice April to October = ice free; "under ice" = Nov 1 to Apr 1
   - Is under ice necessary? Frozen solid, no source?
   - AGREE … no need to apply under ice (background characterization of "under ice" period is not required
   - Ascending versus descending hydrograph (divisions from MESL 2013)
   - Box plots appear comparable for the analytes that we looked at (copper, nitrate, TDS)
   - Compare these two "bins" for each of the COPCs
   - Statistical contrast of the two groups
   - Discuss with SFN / MESL and make final decisions
   - It is possible that some analytes require binning whereas others do not

7. **Summary Statistics**
   - Two types – "Individual" (applies to grab sample) and "Central Tendency" (applies to average over a specified time frame [year?])
   - Individual
     - 95th percentiles are appropriate
     - See attainment
     - Calculate following agreement on final dataset and approach (all previous items) with SFN / MESL

   - Central Tendency
     - Fairly brief discussion on this
     - PS indicated preference for non-parametric if feasible and defensible (e.g., 95th percentile of medians), but key questions is whether data supports this in a defensible way
     - Calculate the 95th percentile on medians; is this defensible with the given data
     - Calculate other measures of central tendency (UCL of the mean)
     - Compare the methods
     - Select more appropriate

8. **Attainment**
   - Individual (95th percentiles)
     - Exceedances on 2 consecutive samples. If independent, 5% * 5% probability = 0.25%
     - Sufficient time between sample to have reasonable assurance
     - This approach allows a more rapid response than waiting to evaluate exceedance rates

    - Incorporate the final concept(s) into background report
- Central Tendency
    - Evaluate compliance annually. Does the annual median or mean fall within the range of background medians or means.
    - As above, must still recognize small chance of exceedance in the absence of any change.
    - Functionally, this could be an annual review item. Presumably, if the "central tendency" WQO has been exceeded, some "individual" exceedance has also occurred. The annual review should include investigation.
        - One analyte or many?
        - Frequency of exceedance of the "individual WQO"
        - Trending
        - Other?
    - Incorporate the final concept(s) into background report
- Bill Slater → these concepts work well when we are just considering future water quality relative to background, but become more complicated when considering a WQO that is a composite of background and the operation WQO.
- Don MacDonald – SFN would like to see WQO set somewhere between background and 50% of current operational WQO (WUL definition of assimilative capacity).

COPC List

- Don MacDonald – Would like to include TDS as a COPC with reasoning around making it easier to apply it is a communication piece with SFN. Don discussed having TDS as a major ion to follow and show the community that there are no problems with the WQ in Minto Creek.
- The group generally agrees that TDS is not expected to be an issue in closure as it relates to effects on aquatic life.
- No agreement on the inclusion of TDS in the COPC list was confirmed.
- Minto's team to discuss internally the merits of including TDS as a COPC.
- Don MacDonald – asked if we need to develop a framework to evaluating COPC's.
- Dylan MacGregor – Given the time remaining (until August 5th) it was probably not the best use of resources. The group as whole generally agreed.

Water Quality Prediction Appropriate Use

- Dylan MacGregor –Will have updated water quality predictions including CWTS performance expectations near end of month. Dylan has concerns regarding how water quality predictions will be used.
- Don MacDonald – we have to use predictions to determine where WQO should be set.
- Dylan MacGregor – we could use the current predictions as we have said we expect to have the CWTS performance to range from 0 to some upper percentage of removal therefore CWTS performance may not have an impact.
- Further discussions need to be had to agree on how best to use WQ predictions.

TIMING

- Items 1 to 6 by week of June 13th …
- Discuss week of June 20th ??

APPENDIX B

RAW WATER QUALITY DATA

Table B.1: Raw water quality data from Minto Mine, 2005 - 2013.

Station Name	Sample Date	Total Coliforms	Fecal Coliforms	E.Coli	COD (mg/L)	Specific Conductivity in Field (µS/cm)	Radium - 226 (Bq/L)	CBOD (mg/L)	LC50 (%)	LT50 (h)	BOD5 (mg/L)	DO (mg/L)	Cond-F (µS/cm)	DO (%)	ORP (mV)

APPENDIX C

BOXPLOT OUTLIER EXAMINATION

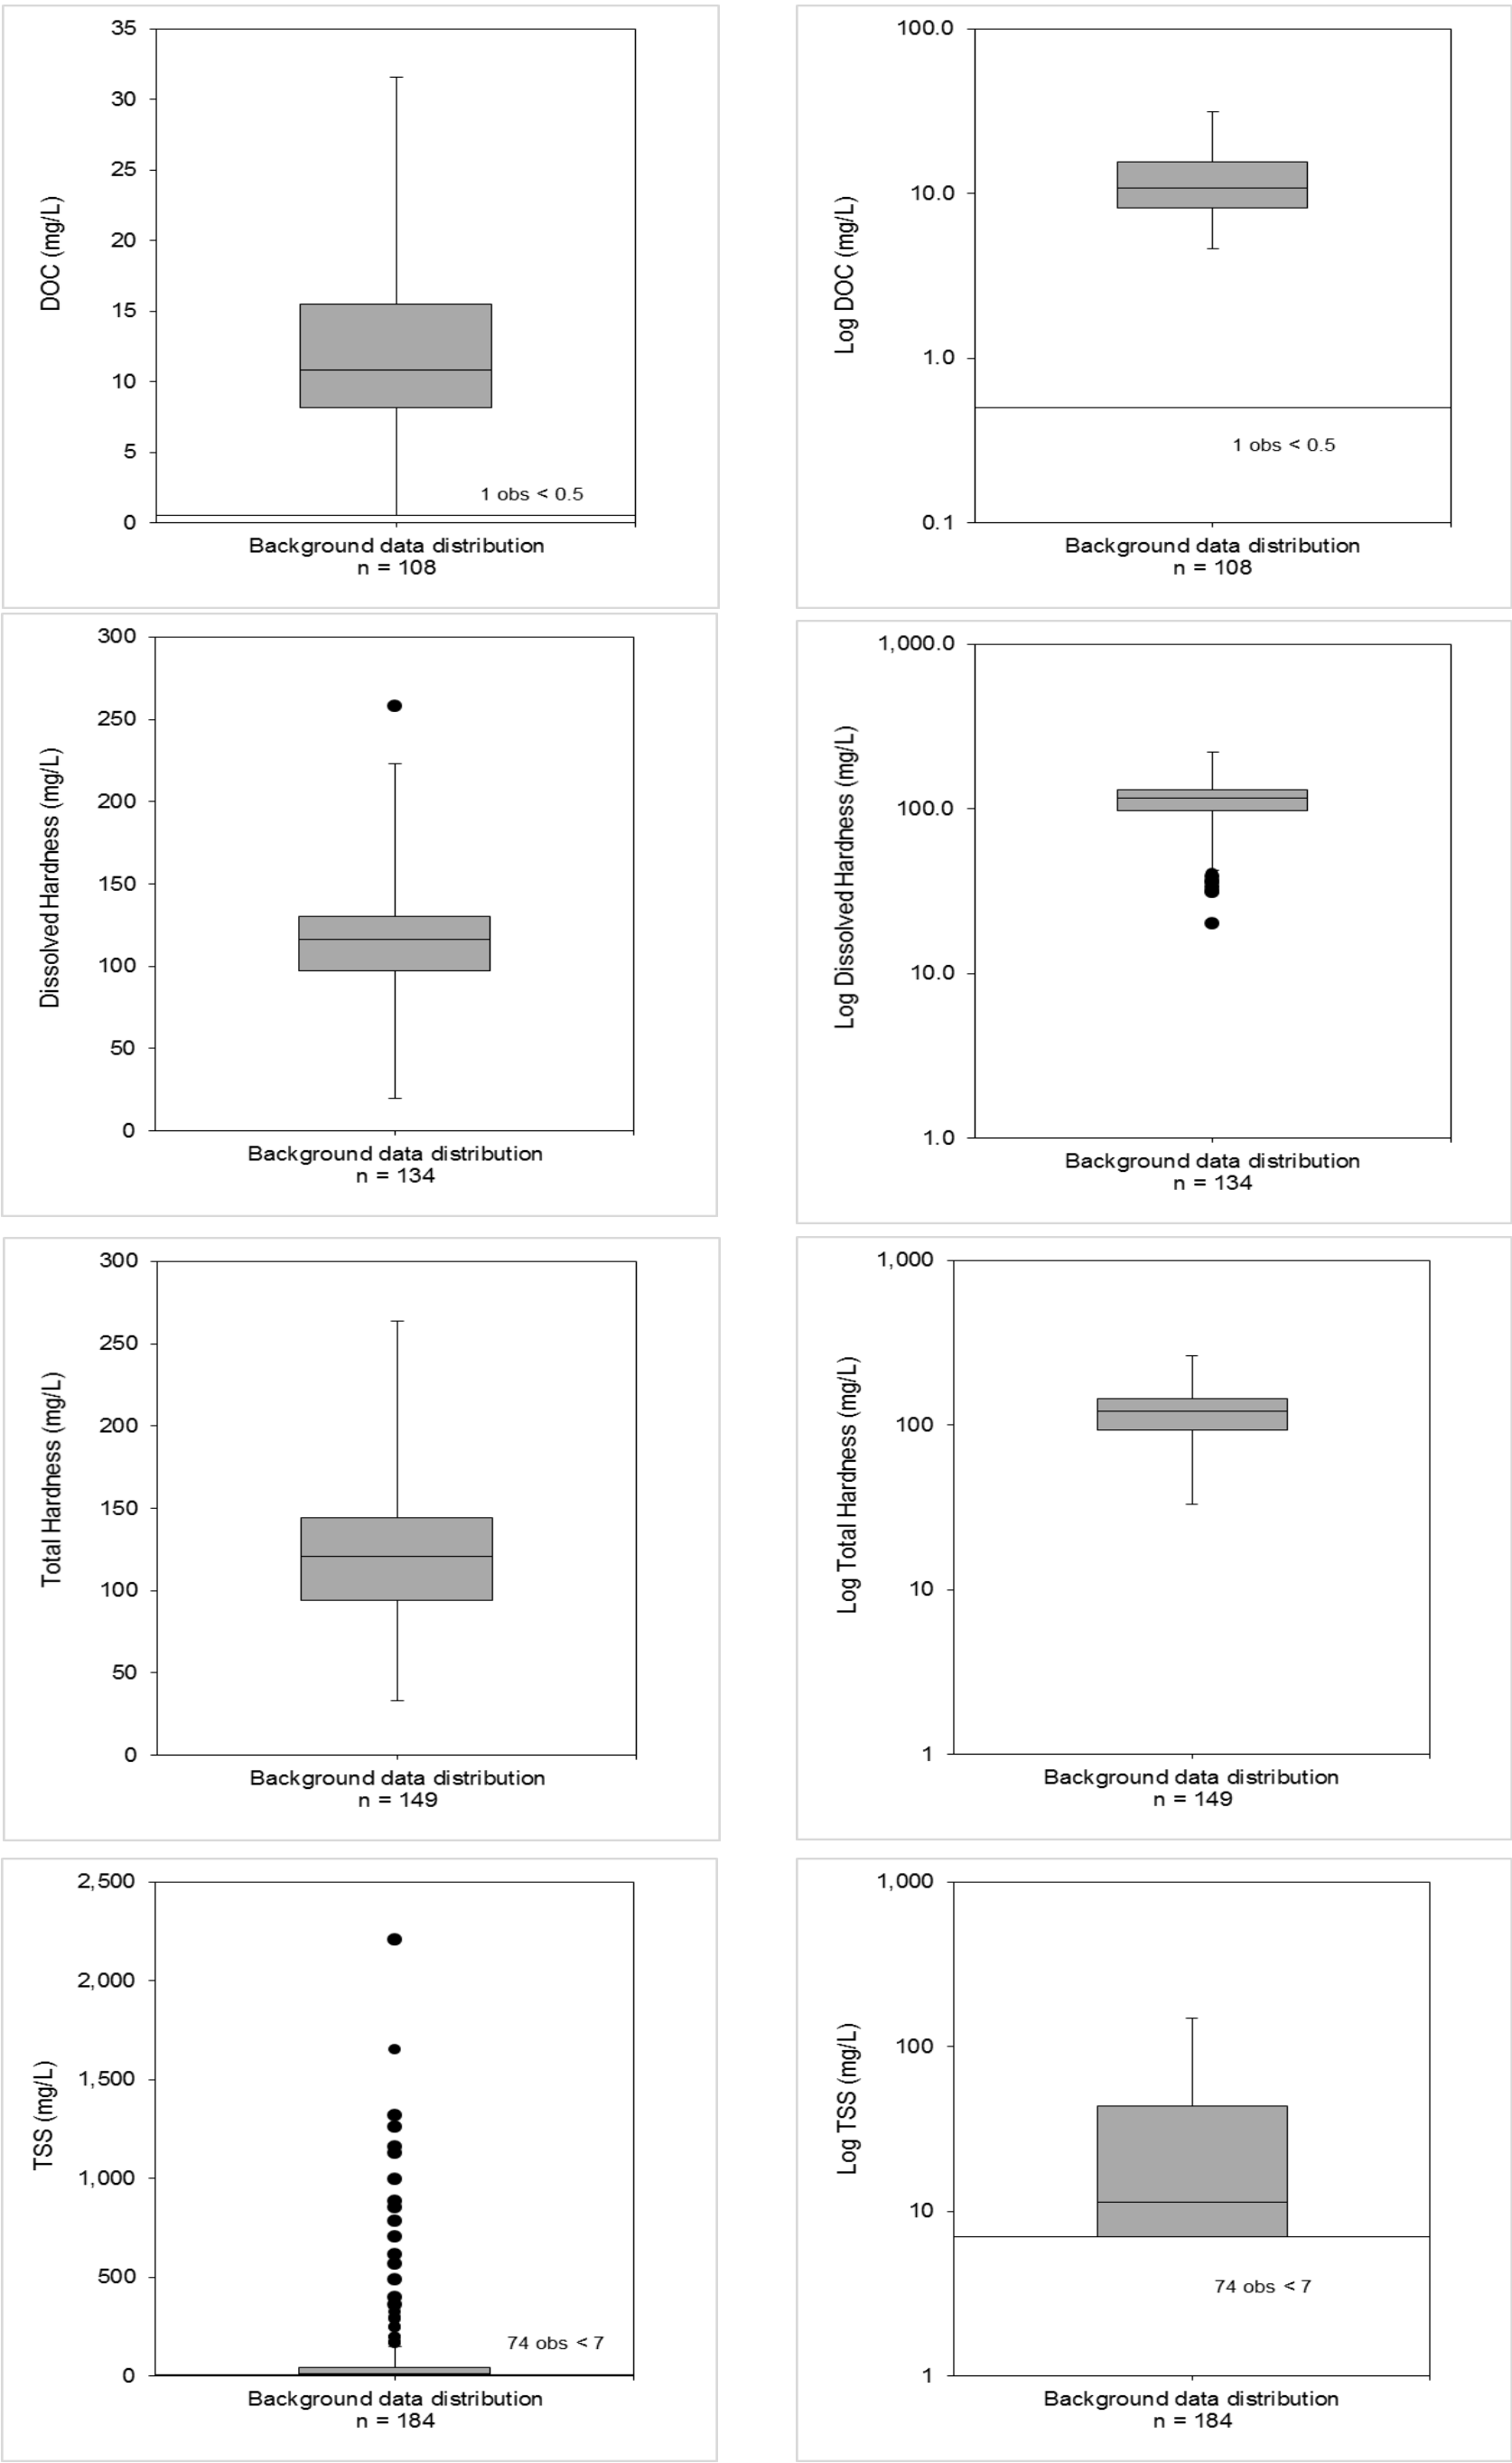

Figure C.1: Boxplots of analytes on non-transformed and log transformed scales. Black dots represent possible outliers. Line represents highest < MDL and any < MDL below this are represented as number of observations below this line.

NOTE: Possible outliers were only considered if they were detected on both non-transformed and log transformed scales

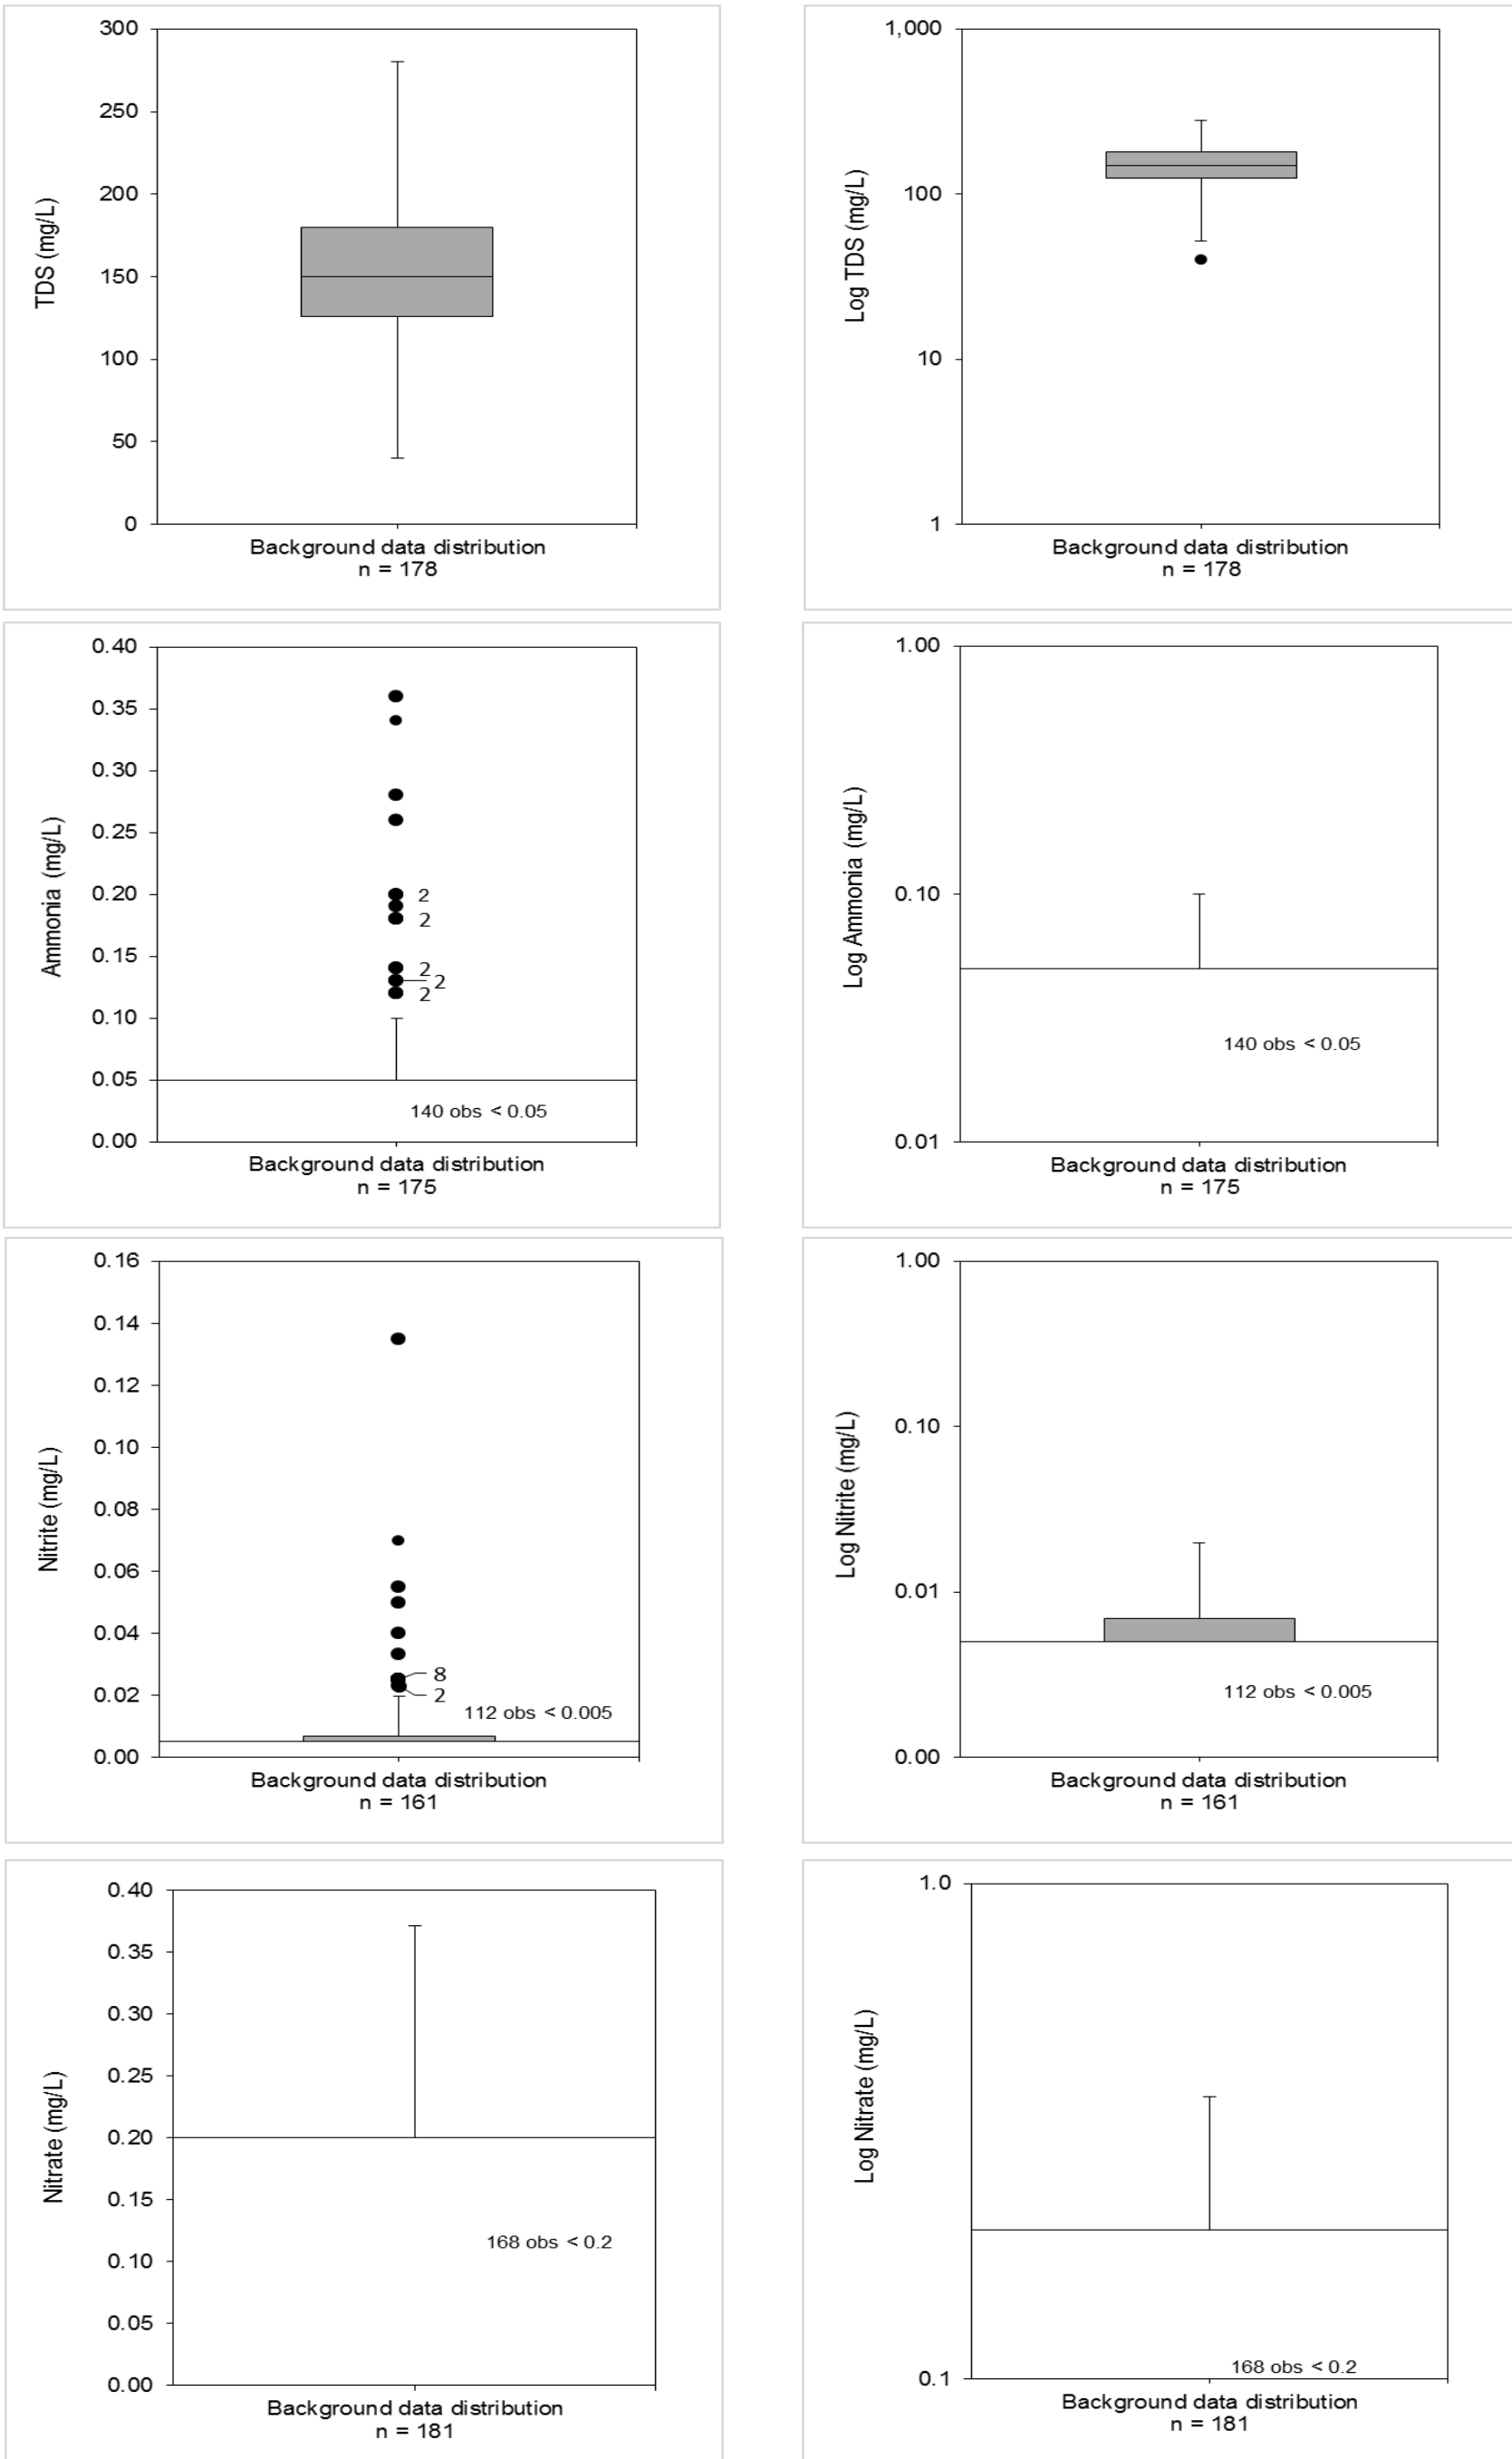

Figure C.1: Boxplots of analytes on non-transformed and log transformed scales. Black dots represent possible outliers. Line represents highest < MDL and any < MDL below this are represented as number of observations below this line.

NOTE: Possible outliers were only considered if they were detected on both non-transformed and log transformed scales

RE: Methods for Computing Summary Statistics for Censored Data

---

Introduction

This technical memorandum describes the statistical methods that Minnow Environmental Inc. (Minnow) has used to calculate summary statistics for water quality data sets for the Minto Mine. These data sets were sent to Minnow in Microsoft Excel spreadsheets via email for analysis in October and November, 2017. The summary statistics were computed for individual samples by sampling station or for monthly means by sampling station. The objective of computing summary statistics for the monthly means is to remove the bias of inconsistent sampling frequencies among months or years. For example, if four samples were collected in January of one year and 15 samples were collected in June of one year, summary statistics on monthly means would be computed with equal weight on the values observed in January and those observed in June.

Commonly employed substitution methods (e.g., substituting censored data with the full or half detection limit) for censored data introduces bias in summary statistics (Helsel 2012), and so more robust methods that do not rely on substitution were employed. In general, the methods follow those described in Helsel (2012), and those used in the R package NADA: Nondetects and Data Analysis for Environmental Data (Lee 2017). All calculations were conducted using R software (R Core Team 2016) using custom scripts written by Minnow. The NADA package was not used in the Minnow R scripts due to an error that Minnow identified in June, 2017 in the cenfit() function in NADA that is used to estimate the mean and standard deviation. Helsel and Lee have been informed of the error and will be updating the NADA package to correct the error (Helsel, personal communication: June 15, 2017 and November 30, 2017) but this has not been completed as of December 2017. Specific details of the statistical methods are described below.

Treatment of Data

Prior to calculating summary statistics, poor detection limits (DLs) were removed from the data set. A poor DL was defined as a value below a DL that exceeds the maximum detected value for that parameter at the given station. Poor DLs were removed from the data set when they consisted of fewer than 80% of the data values. For example, if 49 values were <1 and a single value was detected as 0.7, then the 49 values were not removed as they provide useful information (we would not want to assume that the 0.7 is representative of all 49 values below 1). The removal of the poor DLs does not influence the estimation of the mean or standard deviation, but does influence the overall sample size.

Calculation of Monthly Means

Monthly means were calculated using the Kaplan-Meier (K-M) method. This method involves transforming the left censored (i.e., < value) dataset to a right censored (i.e., > value) dataset, and then using the K-M estimator (used to estimate the mean survival time in survival analysis) to estimate the mean. The calculation was conducted using the survfit() function in the *survival* package (Therneau 2017) in R and involves calculating the area under the K-M survival curve.

The K-M method is non-parametric and can accommodate multiple DLs. The method of estimating the mean is equivalent to using the distribution of detectable values below the DL to represent values that are < DL. For example, the mean of the data set {1, 2, <4, 5} is estimated as the mean of 1, 2, [½×1 + ½×2], and 5 which is 2.375. The value <4 is replaced by the distribution of values below 4 (i.e. 1 and 2 with equal weight of ½). Similarly, the mean of the data set {1, 1.6, 2, 2.1, <4, 5} is estimated as the mean of 1, 1.6, 2, 2.1, [¼×1 + ¼×1.6 + ¼×2 + ¼×2.1], and 5 which is 2.229. Again, the value <4 is replaced by the distribution of values below 4 (i.e. 1, 1.6, 2, and 2.1 with equal weight of ¼). If the minimum value in the data set is below the DL then it is replaced with the DL. Therefore, if there is only one DL and no detected values below the DL, then the K-M estimate of the mean is equivalent to replacing the value below the DL with the DL (i.e., the best estimate for the values < DL is the DL).

Calculation of Summary Statistics

Sample size

The reported sample size is the number of samples (or number of monthly means when the statistics were calculated on monthly means) after the removal of poor DLs.

Maximum DL and % censored values

The maximum detection limit and the percentage of censored values is reported after the removal of the poor DLs

Measures of Position

The measures of position (i.e. percentiles), were estimated using two different methods. First, estimates were calculated using K-M estimator (based on survival analyses as described above for the estimate of monthly means). The percentiles were calculated using the quantile() function for a survival model generated in the *survival* package in R. Estimates of percentiles cannot be generated for highly censored data using the K-M method, and so a second method was used to provide practical estimates of the percentiles. For example, for the data set {<2, <2, <2, <2, 5}, the K-M method will not produce an estimate of the median. However, it is clear that we can state that the median value of this data set is <2. The second method of estimating percentiles was used whenever the K-M method could not generate an estimate. This method involved calculating the percentile after substitution with the DL, then identifying the value in the dataset equal to this value (or the next detected value in the dataset that is below this value). The two methods of estimating percentiles can result in different values (e.g. values for the same statistic can be different, and it is possible to obtain an estimate of the 25th percentile using the second method that is greater than the median using the K-M method). Therefore, a final check was conducted for each dataset to ensure that the estimated percentiles were logical. If an estimated value of a percentile exceeded the value for a higher order percentile (e.g., 25th percentile > median), then the lower percentile was replaced with the estimate of the higher order percentile, under the assumption that the K-M method provides a better estimate of the percentile than the second method.

Mean and standard deviation

The mean and standard deviation were calculated using the K-M method as described above using the using the survfit() function in the *survival* package. When a standard deviation could not be estimated, it was reported as NA (not available). This can occur with a sample with a high proportion of censored values.
