REPORTED TO	Palmer Environmental Consulting Group Inc.	**WORK ORDER**	4090397
PROJECT	Coffee Gold	**REPORTED**	Sep-17-14

The following section displays the quality control (QC) data that is associated with your sample data. Groups of samples are prepared in fibatchesfl and analyzed in conjunction with QC samples that ensure your data is of the highest quality. Common QC types includ

- **Method Blank (Blk)**: Laboratory reagent water is carried through sample preparation and analysis steps. Method Blanks indicate that results are free from contamination, i.e. not biased high from sources such as the sample container or the laboratory environment
- **Duplicate (Dup)**: Preparation and analysis of a replicate aliquot of a sample. Duplicates provide a measure of the analytical method's precision, i.e. how reproducible a result is. Duplicates are only reported if they are associated with your sample data.
- **Blank Spike (BS)**: A known amount of standard is carried through sample preparation and analysis steps. Blank Spikes, also known as laboratory control samples (LCS), are prepared from a different source of standard than used for the calibration. They ensure that the calibration is acceptable (i.e. not biased high or low) and also provide a measure of the analytical method's accuracy (i.e. closeness of the result to a target value).
- **Standard Reference Material (SRM)**: A material of similar matrix to the samples, externally certified for the parameter(s) listed. Standard Reference Materials ensure that the preparation steps in the method are adequate to achieve acceptable recoveries of the parameter(s) tested.

Each QC type is analyzed at a 5-10% frequency, i.e. one blank/duplicate/spike for every 10 samples. For all types of QC, the specified recovery (% Rec) and relative percent difference (RPD) limits are derived from long-term method performance averages and/or prescribed by the reference method.

General Comments:

CARO Analytical Services employs methods which are conducted according to procedures accepted by appropriate regulatory agencies, and/or are conducted in accordance with recognized professional standards using accepted testing methodologies and quality control efforts, except where otherwise agreed to by the client.

The results in this report apply to the samples analyzed in accordance with the Chain of Custody or Sample Requisition document. This analytical report must be reproduced in its entirety. CARO is not responsible for any loss or damage resulting directly or indirectly from error or omission in the conduct of testing. Liability is limited to the cost of analysis. Samples will be disposed of 30 days after the test report has been issued unless otherwise agreed to in writing.

Work Order Comments:

Receipt temperature unavailable.

ANALYSIS INFORMATION

REPORTED TO	Palmer Environmental Consulting Group Inc.	**WORK ORDER**	4090376
PROJECT	Coffee Gold	**REPORTED**	Oct-31-14

Analysis Description	Method Reference	Technique	Location
Metals in Tissue	EPA 200.3 / EPA 6020A	HNO3+HCl+H2O2 Hot Block Digestion / Inductively Coupled Plasma-Mass Spectroscopy (ICP-MS)	Richmond
Moisture	ASTM D2974-87 *	Gravimetry (Dried at 105C)	N/A

Note: An asterisk in the Method Reference indicates that the CARO method has been modified from the reference method

Method Reference Descriptions:

ASTM	ASTM International Test Methods
EPA	United States Environmental Protection Agency Test Methods

Glossary of Terms:

MRL	Method Reporting Limit
<	Less than the Reported Detection Limit (RDL) - the RDL may be higher than the MRL due to various factors such as dilutions, limited sample volume, high moisture, or interferences
% wet	Percent (wet weight)
mg/kg wet	Milligrams per kilogram (wet weight)

REPORTED TO	Palmer Environmental Consulting Group Inc.	**WORK ORDER**	4090376
PROJECT	Coffee Gold	**REPORTED**	Oct-31-14

The following section displays the quality control (QC) data that is associated with your sample data. Groups of samples are prepared in fibatchesfl and analyzed in conjunction with QC samples that ensure your data is of the highest quality. Common QC types includ

- **Method Blank (Blk)**: Laboratory reagent water is carried through sample preparation and analysis steps. Method Blanks indicate that results are free from contamination, i.e. not biased high from sources such as the sample container or the laboratory environment
- **Duplicate (Dup)**: Preparation and analysis of a replicate aliquot of a sample. Duplicates provide a measure of the analytical method's precision, i.e. how reproducible a result is. Duplicates are only reported if they are associated with your sample data.
- **Blank Spike (BS)**: A known amount of standard is carried through sample preparation and analysis steps. Blank Spikes, also known as laboratory control samples (LCS), are prepared from a different source of standard than used for the calibration. They ensure that the calibration is acceptable (i.e. not biased high or low) and also provide a measure of the analytical method's accuracy (i.e. closeness of the result to a target value).
- **Standard Reference Material (SRM)**: A material of similar matrix to the samples, externally certified for the parameter(s) listed. Standard Reference Materials ensure that the preparation steps in the method are adequate to achieve acceptable recoveries of the parameter(s) tested.

Each QC type is analyzed at a 5-10% frequency, i.e. one blank/duplicate/spike for every 10 samples. For all types of QC, the specified recovery (% Rec) and relative percent difference (RPD) limits are derived from long-term method performance averages and/or prescribed by the reference method.

General Comments:

CARO Analytical Services employs methods which are conducted according to procedures accepted by appropriate regulatory agencies, and/or are conducted in accordance with recognized professional standards using accepted testing methodologies and quality control efforts, except where otherwise agreed to by the client.

The results in this report apply to the samples analyzed in accordance with the Chain of Custody or Sample Requisition document. This analytical report must be reproduced in its entirety. CARO is not responsible for any loss or damage resulting directly or indirectly from error or omission in the conduct of testing. Liability is limited to the cost of analysis. Samples will be disposed of 30 days after the test report has been issued unless otherwise agreed to in writing.

QUALITY CONTROL DATA

REPORTED TO	Palmer Environmental Consulting Group Inc.	**WORK ORDER**	5061952
PROJECT	Coffee Gold	**REPORTED**	Jul-10-15

The following section displays the quality control (QC) data that is associated with your sample data. Groups of samples are prepared in fibatchesfl and analyzed in conjunction with QC samples that ensure your data is of the highest quality. Common QC types includ

- **Method Blank (Blk)**: Laboratory reagent water is carried through sample preparation and analysis steps. Method Blanks indicate that results are free from contamination, i.e. not biased high from sources such as the sample container or the laboratory environment
- **Duplicate (Dup)**: Preparation and analysis of a replicate aliquot of a sample. Duplicates provide a measure of the analytical method's precision, i.e. how reproducible a result is. Duplicates are only reported if they are associated with your sample data.
- **Blank Spike (BS)**: A known amount of standard is carried through sample preparation and analysis steps. Blank Spikes, also known as laboratory control samples (LCS), are prepared from a different source of standard than used for the calibration. They ensure that the calibration is acceptable (i.e. not biased high or low) and also provide a measure of the analytical method's accuracy (i.e. closeness of the result to a target value).
- **Standard Reference Material (SRM)**: A material of similar matrix to the samples, externally certified for the parameter(s) listed. Standard Reference Materials ensure that the preparation steps in the method are adequate to achieve acceptable recoveries of the parameter(s) tested.

Each QC type is analyzed at a 5-10% frequency, i.e. one blank/duplicate/spike for every 10 samples. For all types of QC, the specified recovery (% Rec) and relative percent difference (RPD) limits are derived from long-term method performance averages and/or prescribed by the reference method.

General Comments:

CARO Analytical Services employs methods which are conducted according to procedures accepted by appropriate regulatory agencies, and/or are conducted in accordance with recognized professional standards using accepted testing methodologies and quality control efforts, except where otherwise agreed to by the client.

The results in this report apply to the samples analyzed in accordance with the Chain of Custody or Sample Requisition document. This analytical report must be reproduced in its entirety. CARO is not responsible for any loss or damage resulting directly or indirectly from error or omission in the conduct of testing. Liability is limited to the cost of analysis. Samples will be disposed of 30 days after the test report has been issued unless otherwise agreed to in writing.

Work Order Comments:

Please note this is an amended report - additional parameters reported 11/30/2015 KF

ANALYSIS INFORMATION

REPORTED TO	Palmer Environmental Consulting Group Inc.	**WORK ORDER**	5080309
PROJECT	Coffee Gold	**REPORTED**	Nov-30-15

Analysis Description	Method Reference	Technique	Location
Available Cations (Ca/Mg/K/Na)	MSSMA 4.51	1N Ammonium Acetate Extraction, Atomic Spectroscopy	Sublet
Available NH4-N and NO3-N in Soil	Carter 4	Nitrate and Exchangeable Ammonium Nitrogen	Sublet
Carbon, Total Organic in Solids	Carter 21.2	Catalytic Combustion and Infrared Detection	Kelowna
Chlorophyll-A	APHA 10200 H	Spectrophotometry	Kelowna
Metals in Tissue	EPA 200.3 / EPA 6020A	HNO3+HCl+H2O2 Hot Block Digestion / Inductively Coupled Plasma-Mass Spectroscopy (ICP-MS)	Richmond
Moisture	ASTM D2974-87*	Gravimetry (Dried at 105C)	N/A
Particle Size - Dry Sieve Fractions	N/A	N/A	Richmond
pH in Soil (1:2 Soil/Water)	Carter 16.2 / APHA 4500-H+ B	1:2 Soil/Water Slurry / Electrometry	Richmond
Phosphorus, Available (Bray)	UBCPLMM 6.1	Bray Extraction, Colorimetric	Sublet
Strong Acid Leachable Metals	BCMOE SALM V.2 / EPA 6020A	HNO3+HCl Hot Block Digestion / Inductively Coupled Plasma-Mass Spectroscopy (ICP-MS)	Richmond
Total Solids	APHA 2540 B	Gravimetric (Dried at 103-105C)	Kelowna
Total Volatile Solids (550C)	APHA 2540 E	Gravimetry (Ignited at 550C)	Kelowna

Note: An asterisk in the Method Reference indicates that the CARO method has been modified from the reference method

Method Reference Descriptions:

APHA	Standard Methods for the Examination of Water and Wastewater, 22nd Edition, American Public Health Association/American Water Works Association/Water Environment Federation
ASTM	ASTM International Test Methods
Carter	Soil Sampling and Methods of Analysis, 2nd Edition (2007), Carter/Gregorich
EPA	United States Environmental Protection Agency Test Methods
MSSMA	Manual on Soil Sampling and Methods of Analysis, J.A. McKeague
UBCPLMM	Methods Manual, Pedology Laboratory, 1977/1981, L.M. Lavkulich, UBC Department of Soil Science

Glossary of Terms:

MRL	Method Reporting Limit
<	Less than the Reported Detection Limit (RDL) - the RDL may be higher than the MRL due to various factors such as dilutions, limited sample volume, high moisture, or interferences
%	Percent
% dry	Percent (dry weight)
% wet	Percent (wet weight)
mg/kg dry	Milligrams per kilogram (dry weight)
mg/kg wet	Milligrams per kilogram (wet weight)
mg/L	Milligrams per litre
pH units	pH < 7 = acidic, ph > 7 = basic
µg/L	Micrograms per litre

REPORTED TO	Palmer Environmental Consulting Group Inc.	**WORK ORDER**	5080309
PROJECT	Coffee Gold	**REPORTED**	Nov-30-15

The following section displays the quality control (QC) data that is associated with your sample data. Groups of samples are prepared in "batches" and analyzed in conjunction with QC samples that ensure your data is of the highest quality. Common QC types include:

- **Method Blank (Blk)**: Laboratory reagent water is carried through sample preparation and analysis steps. Method Blanks indicate that results are free from contamination, i.e. not biased high from sources such as the sample container or the laboratory environment
- **Duplicate (Dup)**: Preparation and analysis of a replicate aliquot of a sample. Duplicates provide a measure of the analytical method's precision, i.e. how reproducible a result is. Duplicates are only reported if they are associated with your sample data.
- **Blank Spike (BS)**: A known amount of standard is carried through sample preparation and analysis steps. Blank Spikes, also known as laboratory control samples (LCS), are prepared from a different source of standard than used for the calibration. They ensure that the calibration is acceptable (i.e. not biased high or low) and also provide a measure of the analytical method's accuracy (i.e. closeness of the result to a target value).
- **Standard Reference Material (SRM)**: A material of similar matrix to the samples, externally certified for the parameter(s) listed. Standard Reference Materials ensure that the preparation steps in the method are adequate to achieve acceptable recoveries of the parameter(s) tested.

Each QC type is analyzed at a 5-10% frequency, i.e. one blank/duplicate/spike for every 10 samples. For all types of QC, the specified recovery (% Rec) and relative percent difference (RPD) limits are derived from long-term method performance averages and/or prescribed by the reference method.

PROJECT	Coffee Gold	**REPORTED**	Nov-20-15
PROJECT INFO		**COC NUMBER**	B31312

General Comments:

CARO Analytical Services employs methods which are conducted according to procedures accepted by appropriate regulatory agencies, and/or are conducted in accordance with recognized professional standards using accepted testing methodologies and quality control efforts, except where otherwise agreed to by the client.

The results in this report apply to the samples analyzed in accordance with the Chain of Custody or Sample Requisition document. This analytical report must be reproduced in its entirety. CARO is not responsible for any loss or damage resulting directly or indirectly from error or omission in the conduct of testing. Liability is limited to the cost of analysis. Samples will be disposed of 30 days after the test report has been issued unless otherwise agreed to in writing.

Work Order Comments:

Please note this is an amended report - updated matrix description 11/18/15 KF
Nov.20/15- This is an amended report, results have been revised.- JLS

ANALYSIS INFORMATION

REPORTED TO	Palmer Environmental Consulting Group Inc.	**WORK ORDER**	5091469
PROJECT	Coffee Gold	**REPORTED**	Nov-20-15

Analysis Description	Method Reference	Technique	Location
Metals in Tissue	EPA 200.3 / EPA 6020A	HNO3+HCl+H2O2 Hot Block Digestion / Inductively Coupled Plasma-Mass Spectroscopy (ICP-MS)	Richmond
Moisture	ASTM D2974-87*	Gravimetry (Dried at 105C)	N/A
Strong Acid Leachable Metals	BCMOE SALM V.2 / EPA 6020A	HNO3+HCl Hot Block Digestion / Inductively Coupled Plasma-Mass Spectroscopy (ICP-MS)	Richmond

Note: An asterisk in the Method Reference indicates that the CARO method has been modified from the reference method

Method Reference Descriptions:

ASTM	ASTM International Test Methods
EPA	United States Environmental Protection Agency Test Methods

Glossary of Terms:

MRL	Method Reporting Limit
<	Less than the Reported Detection Limit (RDL) - the RDL may be higher than the MRL due to various factors such as dilutions, limited sample volume, high moisture, or interferences
% wet	Percent (wet weight)
mg/kg dry	Milligrams per kilogram (dry weight)
mg/kg wet	Milligrams per kilogram (wet weight)

The following section displays the quality control (QC) data that is associated with your sample data. Groups of samples are prepared in fibatchesfl and analyzed in conjunction with QC samples that ensure your data is of the highest quality. Common QC types includ

- **Method Blank (Blk)**: Laboratory reagent water is carried through sample preparation and analysis steps. Method Blanks indicate that results are free from contamination, i.e. not biased high from sources such as the sample container or the laboratory environment
- **Duplicate (Dup)**: Preparation and analysis of a replicate aliquot of a sample. Duplicates provide a measure of the analytical method's precision, i.e. how reproducible a result is. Duplicates are only reported if they are associated with your sample data.
- **Blank Spike (BS)**: A known amount of standard is carried through sample preparation and analysis steps. Blank Spikes, also known as laboratory control samples (LCS), are prepared from a different source of standard than used for the calibration. They ensure that the calibration is acceptable (i.e. not biased high or low) and also provide a measure of the analytical method's accuracy (i.e. closeness of the result to a target value).
- **Standard Reference Material (SRM)**: A material of similar matrix to the samples, externally certified for the parameter(s) listed. Standard Reference Materials ensure that the preparation steps in the method are adequate to achieve acceptable recoveries of the parameter(s) tested.

Each QC type is analyzed at a 5-10% frequency, i.e. one blank/duplicate/spike for every 10 samples. For all types of QC, the specified recovery (% Rec) and relative percent difference (RPD) limits are derived from long-term method performance averages and/or prescribed by the reference method.

EXECUTIVE SUMMARY

Aquatic data was collected in 2017 to add to the baseline and provide pre-project monitoring data for future comparisons. Data was collected on fish, fish habitat, invertebrates, periphyton and sediment. Specifically, fish and environmental DNA (eDNA) sampling was completed to determine fish presence within the Halfway and YT-24 creeks. Habitat was assessed along the length of Halfway Creek as well as the headwater streams within the Mine footprint. Fish density sampling was completed in several locations and fish tissue was collected for metals analysis. Sediment, invertebrates, periphyton and fish were collected and analyzed for metals. Invertebrates were also sampled for community composition (using Canadian Aquatic Biomonitoring Network (CABIN) protocols).

Studies associated with the Northern Access Route included sampling at the Yukon River Barge landings, a spawning survey for chum salmon in the Yukon and Stewart rivers and investigations of a back channel of the Stewart River.

A summary of the results is presented below.

- Fish use of Halfway Creek was limited to the lower 600 m of the stream.
- Habitat investigations documented numerous impediments on Halfway Creek and found that headwater drainages within the mine footprint are either not streams or small streams with poor fish habitat.
- One Arctic grayling was captured near the mouth of YT-24. This was the first fish captured in the stream beyond the back flooded area at the mouth. The stream channel was affected by a recent localized flood event.
- Fish species composition in Latte, Coffee and Independence was consistent with previous sampling and fish densities were low.
- Late winter eDNA sampling in 2017 provided results very similar to 2016 overwintering study results with fish eDNA only detected in Coffee Creek and the Yukon River.
- Summer spawning surveys did not find any evidence of Chinook spawning in Coffee or Independence creeks.
- Fish tissues, including muscle and liver from Arctic grayling and whole-body samples for slimy sculpin, benthic invertebrates and periphyton tissues were collected and analyzed for general chemistry. This data increases the pre-Project dataset for fish and benthic invertebrate tissues and was the first year of periphyton tissue data collection.
- Benthic invertebrate community sampling was conducted following CABIN methodology. Additional reference sites were added in 2017.

- Primary productivity sampling including chlorophyll-a and ash-free dry mass confirmed that streams within the Project area are very nutrient-poor (oligotrophic).
- Juvenile Chinook were the most common species captured at/near the barge landings.
- Very high fall chum returns to the Yukon River were documented by Fisheries and Oceans Canada (DFO). The spawning survey revealed continued use of side channel habitats in the Yukon and Stewart rivers for this species but also identified some spawning in previously undocumented areas.

ACKNOWLEDGEMENTS

Jennie Gjertsen managed this project on behalf of the Goldcorp Inc. and provided project direction needed to successfully complete the project. Jasmin Dobson, Becky Partridge and Ryan Fetterley from Goldcorp provided exceptional logistical support to ensure our field crews could complete the work in an efficient and effective matter.

EDI would like to highlight the exceptional assistance provided by Goldcorp's Environmental Monitors. Evan Warren and Derek Scheffen provided local insight and assistance for components that were based from the mine.

Jared Hobbs (Hemmera), Caren Helbing, Jessica Round (University of Victoria) and Susan Dulc (Aurora Ecological Consulting) provided insight into the eDNA sampling component of the field studies and assisted with interpretation of the laboratory analysis.

AUTHORSHIP

This report was prepared by EDI Environmental Dynamics Inc. Staff who contributed to this project include:

Pat Tobler B.Sc., R.P. Bio., CPESC ..... Author, Senior Review

Lyndsay Doetzel, M.Sc., R.P. Bio ..... Section Author

Petra Szekeres, M.Sc., P. Biol. ..... Section Author

Vicki Smith, B.Sc., R.P. Bio. ..... Section Author

Brodie Smith, B.Sc. ..... Section Author

Emily McDougall, B.Sc ..... Data Entry, Analysis

Hannah Gray, B.Sc ..... GIS Mapping and Database Management

Members of the EDI field crew for the 2017 fieldwork included the following EDI personnel: Petra Szekeres, Lyndsay Doetzel, Brodie Smith, Ben Schonewille, Dawn Hansen, Jake Duncan and Pat Tobler.

1 INTRODUCTION

The Coffee Gold Project (Coffee Project; the Project) is a proposed gold mine in west-central Yukon, located 130 km south of Dawson City. Gold was initially discovered at Coffee Creek in 2010, and exploration activities have been ongoing since then. Baseline environmental studies began in 2010 and were expanded in the following years in anticipation of future regulatory requirements.

The proposed Project will consist of an open pit gold mine and heap leach facility. The projected mine life is ten years with an 18-month construction period. The feasibility study proposes four open pits mined by conventional shovel and truck methods. The mine and associated activities will generally be located on a relatively high elevation ridge top and will not extend into the lower elevations where the larger streams are located. The mine footprint does include the upper part of some headwater watersheds (including Halfway Creek, YT-24 and unnamed tributaries to Latte Creek). Most prominently, the main proposed Waste Rock Storage Facility (WRSF) will be positioned in the upper Halfway Creek watershed.

The Project will be accessed by road from Dawson City via a 214-km single-lane, gravel road with pull outs. The initial part of this route, from the highway to Sulphur Creek utilizes a government-maintained gravel road. Beyond Sulphur Creek, the Northern Access Route (NAR) mainly follows existing placer mine roads which will be upgraded to provide all season access to supply vehicles. Approximately 30 km of new road will be constructed (Figure 1). Electricity will be generated onsite by diesel-powered generators. The majority of mine staff will access the site by air.

The Coffee Project is located on Crown land within the Traditional Territory of the Tr'ondëk Hwëch'in and the asserted traditional territory of the White River First Nation. A portion of Goldcorp's claim block is located in the Traditional Territory of the Selkirk First Nation and the proposed road also overlaps with the Traditional Territory of the First Nation of the Na-Cho Nyak Dun.

The proposed Project will require an Executive Committee Screening from the Yukon Environmental and Socio-economic Assessment Board (YESAB), a Type A Water Licence issued by the Yukon Water Board and a Quartz Mining License issued by the Yukon Government, among other permits and licences.

1.1 STUDY PURPOSE AND SCOPE

Results from the study provide additional fish and aquatic resource baseline and pre-project monitoring information for the Coffee Project. Palmer Environmental Consulting Group collected baseline data around the mine in 2014 and 2015 (PECG 2017) and along the access road in 2015 (PECG 2016). EDI collected additional baseline data in 2016 around the mine and NAR (EDI 2017) and summarized all data collected to date. The study conducted in 2017 is also intended to support the effects assessment for the Project and provide pre-project information that can be used for effects monitoring. A concordance table of all data collected to date is provided in APPENDIX A.

- Project components for the Mine study area (Figure 2) field studies include:
    - winter and summer environmental DNA (eDNA);
    - fish sampling;
    - fish and fish habitat investigations (Halfway Creek);
    - drainage assessments for headwater tributaries in the mine footprint;
    - spawning surveys for Chinook salmon;
    - fish tissue sampling for metals;
    - benthic invertebrate and periphyton tissue sampling for metals;
    - Canadian Aquatic Biomonitoring Network (CABIN) invertebrate sampling;
    - periphyton sampling and analysis for chlorophyll-a and ash free dry mass; and
    - sediment sampling for metals.

- Methods and results for the 2017 NAR study area (Figure 3) field studies include:
    - fish sampling and fish habitat characterization at proposed barge landings (Yukon River);
    - fish habitat investigations in a back channel of Stewart River; and
    - spawning surveys for chum salmon in the Yukon and Stewart rivers.

1.2 BASELINE SAMPLING STATION CONCORDANCE

Aquatic sampling stations established during the 2014/2015 baseline studies (within the Mine study area) were given the form "AQ##", where the hashtags represented a numerical station designation. An alternate set of sample station codes were developed as a component of the Coffee Project water quality baseline data collection program; these were used during recent aquatics sampling programs as sampling was conducted in areas not visited as part of the 2014/2015 program. Going forward, EDI has developed the following station designation codes that allow for easy determination of station location and the addition of new stations, if and where needed:

1. Each station ID designation begins with a two or three letter code for each stream in the Mine study area. Three letter codes are used for unnamed tributaries to named streams; LCC therefore corresponds to Latte Creek Tributary C.

2. Following the stream letter code is a numeric designation that represents the straight-line distance (kilometers) of a sampling station from its major confluence.

3. For stations in the Yukon River, the same naming convention was used although distances were measured in a straight line from the Coffee Creek confluence. A 'U' was used to indicate a station upstream of Coffee Creek and a 'D' for stations downstream. To assist in rectifying previous sampling stations with the new system, a table of concordance is shown below (Table 1).

4. Discrete sampling locations within the same station are designated as sites (e.g., station CF2.3 sediment sampling sites 1, 2 and 3).

Table 1. Concordance table of Coffee Project fisheries and aquatic field sampling station identifiers.

Stream	2014/2015 Aquatic Baseline Station Name (PECG 2017)	Water Quality and Hydrology Station (Lorax 2016)	2016 Station Name (this report)

Los Angeles Creek	AQREF2		LaC4.8

[1] While this site was labeled LC0.5, the actual distance of this site from the mouth of Latte Creek is ~50 m.

2 METHODS

Methods are presented separately for mine and northern access route (NAR) study areas in the below sections.

2.1 MINE STUDY AREA

Aquatic resources sampling included fish sampling, habitat assessment (summer and overwintering), sediment and periphyton sampling, benthic invertebrate community composition via CABIN methods, and fish and benthic invertebrate tissue analysis for total metals. These activities were carried out in several streams in the Mine study area and reference areas:

- Halfway, Latte and YT-24 watersheds directly drain the Mine Site and are those that are predicted to be most affected by project activities. These streams are considered 'near' to project activities.
- Latte Creek flows into Coffee Creek. Therefore, while Coffee Creek is downstream of the Project area, the reaches that are downstream of the Latte confluence are considered 'far' from Project activities due to the limited influence on water quality/quantity predicted from the Project (Lorax 2017).

Independence, Los Angeles, and Coffee Creek upstream of the Latte Creek confluence were studied as part of the baseline program as 'reference' sites. Additionally, there were six sites sampled as potential future benthic invertebrate (CABIN) reference sampling sites; these included two sites on Dan Man Creek, one site on Excelsior Creek, one on a tributary to upper Excelsior, and two on an unnamed creek in a watershed adjacent to Excelsior.

2.1.1 ENVIRONMENTAL DNA SAMPLING

The eDNA sampling conducted during March, August, and October 2017 involved the collection of water samples with the objective of supplementing conventional fish sampling results for Coffee, Latte, Halfway and Independence creek watersheds. Water-based eDNA samples provided an indication of fish presence during the three sample periods (winter, summer, and autumn). Field sampling for eDNA included 10 stations on March 20 and 21, 11 stations from August 2 to 9, and three stations on October 20 (Table 2; Figure 4).

Table 2. Summary of 2017 eDNA sampling stations at the Coffee Gold Project.

GOLDCORP EDI

Path: O:\2018\18-Y0024_Coffee_Aquatic_Monitoring\GIS\Field\Report\2017_20180313\Fig4_eDNASites_20180313.mxd

The eDNA methods involved disinfection, sampling, as well as preparing samples for laboratory analysis. Before leaving for the field, all equipment and sample bottles were cleaned and disinfected with 10% bleach solution and 85% ethanol and left to dry before being packed for transport. All equipment was kept in separate bags in the transport bin (e.g., envelopes, bottle triplicates, etc.) to mitigate contamination of equipment.

Only one watershed was sampled for eDNA each day. During sampling programs, one member was designated the eDNA sampler. This individual was responsible for sample collection, storage and handling to eliminate potential contamination. The eDNA sampler would not carry any other fish sampling equipment for the day and no one else was allowed in the water within 50 m of the sampling location. New nitrile gloves were worn at each site. Triplicate sample bottles for each site were kept together in bags to prevent bottles from different sites coming in contact with one another.

All samples were taken starting at downstream sites, working upstream throughout the day to keep from contaminating samples. Once arriving at the site, the eDNA sampler removed the three bottles for the site from their respective bag. Each of the three sample bottles were rinsed three times downstream of where the actual sample was taken; bottles were rinsed to remove any disinfectant residue. After rinsing bottles, they were replaced back into their bags and sealed while the sampler moved upstream to take the sample being analyzed for eDNA. Cascades were the preferred areas to take samples; otherwise the sampler would try to stay out of the water (i.e., step on rocks), or take the sample from the shoreline. The main consideration for sampling was that it was from the main flow of the stream and not from eddies or still pools (Hobbs 2017). Each sample bottle was filled, capped, and placed back into their bags and sealed; samples were left in a cooler or field pack until being processed later that night. In the winter samples were kept in a cooler with a hot water bottle to prevent freezing.

At the end of the day samples were processed at the Coffee camp. Using a peristaltic pump, each triplicate sample was processed separately. The 1 L sample was filtered through a 45 µL filter; once the water had been filtered, the pump continued for another 2-5 minutes to continue drying out the sample. Using disinfected forceps (10% bleach and 85% ethanol), the filter paper was folded and placed into a small pre-labelled coin envelope and sealed. All three samples from each site received their own envelopes, but they were all kept together in a Ziploc bag with two teaspoons of desiccant (silica) beads. Beads were checked periodically for signs of dampening (i.e., turning clear or pink) and were replaced accordingly.

Samples were shipped priority to the University of Victoria for analysis which was conducted as outlined in Hobbs (2017).

2.1.2 FISH SAMPLING

Fish sampling was conducted by field members at several locations downstream of the Mine site within the Mine study area. Fish sampling took place between August 2nd and August 10th, 2017 (Figure 5). The objectives of fish sampling were to better understand fish distribution and usage in select steams within the Mine study area. Stream specific sampling objectives were dependent upon drainage basin area, fish habitat potential, and proximal location to the mine's downstream effluent environment. Fish sampling methods varied between

sites and were dependent upon physical stream features and characteristics, as well as targeted fish species. Fish sampling methods utilized within the Mine study area included beach seining (BS), electrofishing (EF), and minnow trapping (MT). All fish captured during field sampling events were identified to the species, measured and weighed. Fork length measurements were recorded on fork-tailed fish species (Arctic grayling and Chinook salmon) and total length was recorded on non-forked tails fish species (slimy sculpin). Whole body weights were recorded for fish retained for tissue metal and aging structure analysis.

The beach seine used was 10 m in length, 1.5 m deep and constructed of a 5 mm mesh, with buoyant float lines and submersible lead lines. Beach seine hauls were conducted with field crews of two members within the Mine study area and consisted of varying lengths, widths, and depths dependent on the stream environment. Electrofishing was conducted using a Smith Root 12B-POW electrofisher set at 30 Hz or 60 Hz frequencies with 4 ms or 6 ms pulses (depending on site conditions). Electrofishing voltage settings ranged from 200 to 300 volts, depending on the in-situ specific conductivity at each site (i.e., higher volts were used at stations with lower conductivity). Electrofishing techniques varied between sites including single (open site) and triple pass (closed site) efforts. Minnow traps were deployed at select sites to increase fish sampling efforts at stations where water depths were sufficiently deep and stream velocities were not excessive. At each station, small mesh gee-type minnow traps (0.6 cm mesh size) were baited with Yukon River chum roe and were deployed along stream margins in slow water habitats. Trap set depths were recorded and traps were set overnight. At all fish sampling stations, in-situ water quality parameters including temperature, dissolved oxygen, specific conductivity and pH were collected, in addition to site photos.

The sampling points were measured and named based on the linear distance from the creek mouths. For electrofishing, the fishing effort was enumerated on the device and given in total seconds of active electrofishing. Beach seining efforts were measured by the length and width of a seine haul (i.e., area seined; m^2). Lastly, total minnow trapping efforts were enumerated based on the number of traps multiplied by soak times (HH:MM).

2.1.2.1 Coffee Creek

Fish sampling methods used at Coffee Creek included beach seining, open site electrofishing and minnow trapping. Triple pass electrofishing was not completed due to previous experience indicating that this method has limited utility on this stream. Coffee Creek consisted of four different sampling areas in the vicinity of CF3.9, described in greater detail in the results section (Section 3.2.1). Eleven beach seining hauls were conducted at select locations along the stream reach. Open site electrofishing was conducted 700 m downstream from CF3.9 and continued for a straight-line distance of 250 m back upstream towards CF3.9. Twelve minnow traps were set overnight at various locations with ranging distances from the stream mouth. Fish tissue and aging structure samples (otoliths) were retained from Arctic grayling and slimy sculpin captured in Coffee Creek.

2.1.2.2 Halfway Creek

Fish sampling at Halfway Creek was completed to further document fish species distribution and habitat usage within the stream. Fish sampling methods used at Halfway Creek included open site electrofishing and minnow trapping. Given the low densities found in the past, no triple pass electrofishing was completed in this creek. Open site electrofishing was completed between the mouth of the creek (HF0.1) to 4.5 km upstream (HF4.5) in several segments of the creek, with over 2 km of active electrofishing occurring at different sites throughout. Eight minnow traps were set to immerse overnight at various locations with ranging distances from the stream mouth. Sampling was conducted at eight stations throughout Halfway Creek, discussed in greater detail in the results (Section 3.2.2). Fish tissue and aging structure samples (otoliths) were retained from Arctic grayling captured in Halfway Creek.

2.1.2.3 Latte Creek

Fish sampling at Latte Creek was completed to collect pre-project fish density information. Fishing sampling methods used in Latte Creek included three pass electrofishing at the LC2.7 site, with three adjacent replicates. Triple pass electrofishing occurred over an aerial extent of 125 m^2 for the first replicate, 135 m^2 for the second replicate, and 183 m^2 for the final replicate. Fish tissue and aging structure samples (otoliths) were retained from Arctic grayling captured in Latte Creek.

2.1.2.4 Independence Creek

Fish sampling at Independence Creek was completed to collect pre-project fish density information. Fishing sampling methods used in Independence Creek included triple pass electrofishing, with efforts focused on three adjacent replicates at the ID1.9 site. Triple pass electrofishing was attempted within three closed sites. Fish tissue and aging structure samples (otoliths) were retained from Arctic grayling and slimy sculpin captured in Independence Creek.

2.1.2.5 YT-24 Creek

Fish sampling methods used at YT-24 Creek included open site electrofishing. Open site electrofishing was conducted in three segments from the mouth of the creek (YT0.0) to approximately 2 km upstream (YT1.9), with active electrofishing effort covering approximately 1 km. Fish tissue and aging structure samples (otoliths) were retained from Arctic grayling captured in YT-24 Creek.

2.1.2.6 Triple Pass Electrofishing Depletion Model

Triple pass electrofishing was conducted to estimate fish population density within streams by applying a depletion model. Each site included three adjacent replicates which were triple pass electrofished. Each replicate had net barriers installed on the up- and downstream ends of the approximate 100 m^2 electrofishing area. Rebar was pounded into the substrate with fine mesh netting secured and strung across, and large rocks

piled along the bottom to eliminate fish escapement during electrofishing efforts. Each electrofishing pass aimed to have approximately the same amount of effort (i.e., seconds electrofished) for consistency between passes. Fish that were not retained for contaminant sampling were released on the downstream end of the net barrier. Following three passes in one replicate, the downstream barrier was removed and moved up above the upstream location, leaving a buffer area between the two replicates to eliminate the possibility of recapturing the same fish. The next two replicates were installed and electrofished in the same manner.

The program Microfish© was used to calculate population estimates for each species in the replicate of a site (e.g., three replicates to a site); each replicate had its area determined and recorded in the field. The density of each species per replicate was calculated by dividing the population estimate by the replicate area and multiplying by 100 (to arrive at fish/100 m^2). Densities of fish species from the same site were then averaged and the standard error (SE) was determined. When there were fish caught in the first electrofishing pass, but not in the subsequent second or third pass, Microfish© was unable to calculate a population estimate. In these situations, the population estimate was assumed to be what the total catch was in the first pass. In the event that a fish species was not captured in all replicates of a single site, any replicates where none were caught received a fish density of zero and was used in the average for calculating fish densities. Both the current 2017 and previous 2016 data are reported. Data from 2016 was not previously analyzed for density estimations.

Power analysis was used to assess the utility of the depletion method for determining if there are any changes to fish density pre-project compared with post-project. This analysis used the pre-project average fish density and the standard deviation to determine the statistical power of the current sample size, as well as the required sample size of replicates per site to detect a 50% change in fish density. An alpha of 0.05 was used and 0.8 was used as the minimum required level of statistical power.

2.1.3 FISH HABITAT INVESTIGATIONS

Fish habitat investigations included a walk of the entire length of Halfway Creek to assess fish passage and general habitat quality. Impediments to fish passage were documented where present. Habitat information was collected on BC MOE (2008) Site Cards for reaches where information did not exist.

Assessments of the headwater drainages within the proposed mine footprint were walked/assessed to determine which drainages were streams. A stream was defined as having flow on a perennial or seasonal basis, having a continuous channel bed that was scoured by water, and containing deposits of alluvium[2]. Drainages in the Halfway, Latte and YT-24 watersheds were assessed.

2.1.4 CHINOOK SALMON SPAWNING SURVEYS

Chinook spawning surveys were completed in areas where Traditional Knowledge indicated past presence and (Coffee Creek, TH 2012) where habitat appeared to be suitable for Chinook spawning (Coffee and Independence Creek). Aerial surveys were completed by helicopter on Coffee Creek on July 21, August 2 and 9th. Both streams were surveyed from the Yukon River upstream to a point where the stream was thought to be too small for adult Chinook (Independence was surveyed for 16 km and Coffee for 13 km; Figure 6). Observers were located in the front and backseats and the pilot positioned them over the river, flying sideways with the best possible vantage point at approximately 40-45 m above ground level. Observers wore polarized glasses to reduce glare. Weather was sunny and light conditions were considered very good. Tannins in both streams reduced the visibility in very deep pools, but the river could be seen to a depth of ~1 m.

A stream walk was completed on Coffee Creek to look for any sign of spawning activity. On August 8th, a crew of 3 (2 biologists and a local environmental monitor) walked from CF2.8 to CF3.9. On Aug 9th, a crew of 3 walked from CF8.4 (mouth of Latte) to CF3.9. Conditions were very good for observing adult salmon, redds or associated wildlife (i.e., eagles, bears). The crews were able to walk within the channel either in or alongside the wetted portion of the channel.

[2] This definition is consistent with BC Ministry of Forests (1998); no such definition of stream in the Yukon could be found. A key consideration is that fish species found in Yukon would not use habitats that do not meet this definition of stream (unless it is a lake or open water wetland).

2.1.5 TISSUE METALS ANALYSIS; FISH

Fish tissue collection and analysis is described in the below sections.

2.1.5.1 Sample Collection

Fish tissues were collected and submitted for metals analysis in 2017 to add to data collected in preceding years. Fish collection for tissue and aging structures as well as fish habitat assessments took place from August 3-10, 2017. Fish tissue sampling included both tissue (liver and muscle) and whole-body samples from Arctic grayling and slimy sculpin (Table 3). Otolith aging structures were collected from fish retained for tissue metals analysis and were sent to North/South Consultants Inc. in Winnipeg, MB for aging analysis. Fish sampling efforts attempted to capture between 8 and 10 individuals of each species, Arctic grayling and slimy sculpin, from each sampling location within the Mine study area. After retained fish were identified, measured and weighed in the field they were individually labelled, stored in sterile storage bags, then kept on ice in insulated containers until they could be dissected and placed in freezers at the end of each sampling day. Otoliths were removed from all retained fish and sent to North/South Consultants Inc. for age analysis. Liver, muscle (sample weight), gonad weights, sex identification, and diet analysis data were recorded for Arctic grayling. Slimy sculpin were kept whole (minus otoliths) for metal analysis. All samples were sent to the ALS Environmental laboratory in Vancouver, BC for tissue metals analysis.

2.1.5.2 Laboratory Analysis

ALS Environmental conducted analysis on tissue samples for both percent moisture and metals concentrations. For percent moisture, the lab sample analysis was carried out gravimetrically by drying samples at a temperature of < 60 ºC for a minimal three-day period (PSEP 1997). ALS analytics analyzed metal concentrations in fish tissue samples by homogenizing samples and sub-sampling prior to hotblock digestion with nitric acid, hydrochloric acids, and hydrogen peroxide (EPA 1994, 1998, and 2005); depending on the amount of sample available ALS selected standard or micro sample digestion techniques. ALS analysis was conducted by atomic fluorescence spectrophotometry or atomic absorption spectrophotometry. ALS instrumental analysis was conducted by collision cell inductively coupled plasma - mass spectrometry (ICP/MS). There were 34 total metals analyzed with detection limits low enough to allow comparison with applicable guidelines (Table 4).

Table 3. Fish collected for baseline tissue metal analysis in the Coffee Project area in August 2017.

Stream	Sample Site	Species	Sample Type	Samples Collected

2.1.5.3 Data Analysis

Tissue guidelines exist for both selenium and mercury; these metals are known to bioaccumulate, and as such, can pose a danger through human consumption. The 2017 selenium and mercury concentrations in the muscle and liver samples were compared with applicable guidelines including the Health Canada total mercury guideline for commercial sale of fish (0.5 mg/kg; Heath Canada 2007), CCME methylmercury guideline (0.033 mg/kg ww, CCME 2000a) and the Environmental Protection Agency tissue guideline for selenium concentration (11.3 mg/kg for muscle and liver tissue samples, and 8.5 mg/kg dw for whole-body samples, United State Environmental Protection Agency 2016).

The selenium concentrations were converted to dry weight using the percent moisture data to allow comparisons to EPA guidelines. The lab could not complete percent moisture for 16 of the grayling muscle tissue samples, 23 of the grayling liver tissue samples and 20 of the slimy sculpin tissue samples in due to insufficient mass in 2017. Percent moisture data was also not available from some samples from previous years, also due to insufficient mass. An average percent moisture value was calculated from existing data for each sample type (muscle and liver) and species and was used where lab data was not available (Table 5). Methylmercury concentrations were estimated based on total mercury concentrations and known proportions published in literature (Table 6).

Table 5. Average percent moisture values used for samples where lab data was not available.

Sample	Average Percent Moisture
Arctic grayling muscle	68.80 %
Arctic grayling liver	75.35 %
slimy sculpin whole body	76.56 %

Table 6. Methylmercury proportions used to convert mercury concentrations to estimated methylmercury (MeHg) concentration by fish species.

Species	MeHg Proportions	Reference
Arctic grayling	0.94	Jewett et al 2003
slimy sculpin	0.81	EPA 2005

2.1.6 TISSUE METALS ANALYSIS; BENTHIC INVERTEBRATE AND PERIPHYTON

Benthic invertebrate and periphyton sample collection and analysis is described in the below sections.

2.1.6.1 Sample Collection

Benthic invertebrate and periphyton sampling was conducted for tissue metal analysis in the Mine study area and reference sites on August 2-8, 2017 (

Figure 7; Table 7). The sampling objective was to increase the tissue metal data sets for both benthic invertebrate and periphyton.

Benthic invertebrate sampling was conducting using a combination of kick netting and hand-collection; kick netting was conducted using a 400 micron mesh and detachable collection cup. Benthic invertebrates were displaced from their habitat by kicking at the stream substrate and sweeping the net vigorously along the stream bed. After each kick net event, the collection cup was rinsed with stream water into a larger collection basin where the macroscopic invertebrates were separated from sediment and organic debris using tweezers and compiled to form a composite sample. Benthic invertebrate composites were field-stored in sterile storage bags and later preserved by freezing at the end of each sampling day. Kick netting efforts were continued until a sufficient mass of benthic invertebrate tissue had been collected at each site. Dependent upon habitat suitability and benthic invertebrate abundance, up to five replicates were collected at each sampling site.

Periphyton samples scraped from rocks at select sampling sites were combined to form composite samples of sufficient mass for laboratory analysis. Periphyton samples were labelled with site name, date and replicate number and were stored in sterile storage bags. Samples were field stored in cooled insulated containers and transferred to freezers at the end of each sampling day. The number of replicate samples collected for periphyton tissue was dependent upon the availability of periphyton at each site. Additional in-situ water quality data collected at each sample site included water temperature, pH, specific conductivity and dissolved oxygen concentration. Benthic invertebrate and periphyton samples were kept frozen until delivery under chain of custody (COC) documentation to the ALS Environmental laboratory for percent moisture and total metals concentrations in tissues analysis.

Table 7. Summary of 2017 benthic invertebrate and periphyton sampling for tissue metals analysis in the Mine study area.

Station Name/Site Name	Stream	Sampling Date	Sample Type	Number of Replicates
ID1.9	Independence Creek	2-Aug-17	Benthic invertebrate	4

HF6.3	Halfway Creek	6-Aug-17	Benthic invertebrate	5

2.1.6.2 Lab and Data Analysis

Laboratory analysis for percent moisture and total metals followed the same methodology as for fish tissue (Section 2.1.5)

Benthic invertebrates are prey organisms near the bottom of the food chain. Selenium and mercury guidelines have been established as these contaminants can bioaccumulate and work their way up the food chain. The 2017 selenium and mercury concentrations in the benthic invertebrate tissue samples were compared with the CCME tissue residue methylmercury guideline (0.033 mg/kg ww, CCME 2000a). The selenium concentrations were converted to dry weight using percent moisture data to allow to comparisons to EPA guidelines. Percent moisture data was provided by the lab. Methylmercury concentrations were estimated based on total mercury concentrations and known proportions published in literature. The methylmercury proportion for benthic invertebrate tissue samples is 50% as determined by Lucotte and Tremblay (1997).

2.1.7 BENTHIC INVERTEBRATE COMMUNITY SAMPLING

Benthic invertebrates provide insight on water quality, toxicological conditions, food availability, and overall health of the aquatic environment. Benthic invertebrates are exposed to stream water and sediments, along with any anthropogenic contaminants (e.g., metals) within these mediums, throughout their lifecycle. Some taxa are more tolerant to anthropogenic contaminants than others, which can lead to the increased presence of more pollution tolerant taxa relative to pollution sensitive taxa at impacted areas (Maret et al. 2003). Community metrics such as total abundance, community composition, species richness, and diversity provide useful indicators of change within aquatic ecosystems.

The objectives of the benthic invertebrate sampling program were to:

- Document the condition of benthic invertebrate communities in streams associated with the proposed Project footprint; and
- Establish baseline conditions that will facilitate control-impact (i.e., before-after) comparisons throughout the lifespan of the Project and support future monitoring programs.

The fish and aquatic resources baseline program for the Coffee Gold Project (the Project) included sampling at 17 benthic invertebrate sample sites throughout the Project study area in 2017 (Figure 8; Table 8). Eight of these 17 sample sites were previously assessed in 2014 and/or 2015 by Palmer Environmental Consulting Group Inc. (PECG 2017).

2.1.7.1 Benthic Invertebrate Field Sampling

All 2017 field work was completed between August 2 and 10, 2017. Aquatic habitat data and benthic invertebrate data were collected as per Canadian Aquatic Biomonitoring Network (CABIN) field methods (Environment Canada 2012). Benthic invertebrate samples were collected from riffle and glide habitats. Sampling was conducted in an upstream direction within the identified riffle or glide at water depths between 5–30 cm for a period of three minutes with a 400µm mesh, CABIN protocol kick net. Substrate and debris upstream of the kick net were disturbed by kicking and turning rocks over to dislodge benthic invertebrates. After the three-minute kick, the kick net was removed from the stream and all benthic invertebrates and debris in the net and collection cup were carefully rinsed into a clean plastic sample container and preserved in a 10% formalin solution. Water depth and velocity were measured at each kick sample site. General site and location data, reach data, in-situ water quality data, channel data, and substrate data were also recorded at each kick sample site.

Benthic invertebrate samples were sorted and enumerated to the lowest practicable level by Cordillera Consulting in Summerland, BC. Laboratory QA/QC was completed according to Cordillera Consulting protocols.

2.1.7.2 Benthic Invertebrate Data Analyses

Climate data for the Project study area was obtained from the weather station at the Coffee Creek mine site and was provided by Lorax Environmental Services Ltd. Landcover data for the Project study area was obtained from Natural Resources Canada (Wulder and Nelson 2003). All field data, climate data, and landcover data were uploaded to the CABIN database and compared to the Yukon 2013 reference model (Reynoldson and Bailey 2014) as per the Reference Condition Approach. The predictor variables for the Yukon 2013 reference model are identified in Table 9.

Table 9. Predictor variables for the Yukon 2013 reference model.

Landscape Variables	Landcover Variables	Climate Variables	Channel Variables
Altitude (fasl)	Broadleaf open (%)	Precipitation – February (mm)	Average depth (cm)
Longitude (°W)	Bryoids (%)	Precipitation – March (mm)	Average velocity (m/s)
	Mixedwood open (%)	Precipitation – June (mm)	
	Wetland herb (%)	Precipitation – July (mm)	
		Rainfall – June (mm)	
		Temperature – April maximum (°C)	

The CABIN analyses included a Benthic Assessment of Sediment (BEAST) analysis, a River Invertebrate Prediction and Classification System (RIVPACS) analysis, and a Bray-Curtis analysis for each test site and reference site. All CABIN analyses were completed in CABIN using the Data Analysis tools (Environment Canada 2017). The BEAST analysis is a test site assessment that is used to determine whether each test site is in reference condition (Environment Canada 2017). The BEAST analysis determines which group of reference sites in the model are most closely matched to each test site. The benthic community within the

matched group of sites is referred to as the reference condition. Ordination is then used to assess the degree of divergence between the test site and the reference condition (i.e., similar to reference, mildly divergent, divergent, or highly divergent). The RIVPACS analysis determines the probability of a taxonomic group occurring at each test site based on which taxa are expected to occur in the reference condition (Environment Canada 2017). Each test site is assigned a ratio of observed to expected (O:E). A ratio closer to one generally indicates a test site is in good condition whereas a lower ratio generally indicates a test site is in poor condition. The Bray-Curtis analysis determines how similar the benthic invertebrate community structure at each test site is to the benthic invertebrate community structure of the median reference community (Environment Canada 2017). A value of one indicates a test site is entirely different from the median reference community whereas a value of zero indicates a test site is identical to the median reference community. All analysis results from 2017 were compared to analysis results from 2014/2015 (PECG 2017).

The CABIN analyses also included an assessment of community composition metrics for each test site and reference site. All metrics were calculated in CABIN using the Data Analysis tools (Environment Canada 2017). Analysis of the metrics was completed in Microsoft Excel®. Community composition metrics calculated in CABIN included the following:

- Total abundance
- Total Ephemeroptera-Plecoptera-Trichoptera (EPT) abundance
- % Ephemeroptera
- % Plecoptera
- % Trichoptera
- % Diptera + Non-insects
- Total taxonomic richness
- EPT taxonomic richness
- Simpson's diversity
- Simpson's evenness

All metrics from 2017 were compared to metrics from 2014/2015 (PECG 2017).

2.1.8 PERIPHYTON: CHLOROPHYLL–A AND ASH-FREE DRY MASS

Periphyton sample collection for chlorophyll-A and ash free dry mass field methods and laboratory analysis is described in the below sections.

2.1.8.1 Sample Collection

Periphyton sampling within the Mine study area including chlorophyll-a and ash-free dry mass (AFDM), was conducted on August 2-6, 2017 (Table 10). Chlorophyll-a and AFDM samples were collected in late summer when communities were expected to have reached maximum density and diversity. Sampling sites were selected to standardize, where possible, water depth, velocity, gradient, substrate, and sunlight exposure (Table 10).

Sampling for the two parameters was completed using the same methods. Six rocks were randomly selected at each site, and from each rock one sample for each of chlorophyll-a and AFDM was collected. Samples were collected using a 5 cm (2") diameter template and stainless-steel razor blade used to scrape periphyton from the rocks within the sample area, as determined by the template. Each rock represented one replicate, resulting in a total of six replicates collected per site for each parameter. Periphyton scraped from within the template area was placed on 47 mm diameter cellulose nitrate filter paper (0.45 µm). Rocks containing visible periphyton tissue were selected, allowed to dry, then scraped using a 5 cm (2") template. Periphyton scraped from rocks at select sample sites were individually labelled with the site name, date and replicated number and folded into aluminum foil and stored in sterile storage bags. Aluminum foil protected the samples from light exposure and mitigated potential for chlorophyll-a photo-degradation. Samples were field stored in cooled insulated containers and transferred to freezers at the end of each sampling day. Filter and tissue samples were kept frozen and dark until they were transferred to the ALS laboratory under chain of custody (COC) documentation.

2.1.8.2 Laboratory and Data Analysis

Chlorophyll-a samples were sent to ALS Environmental in Vancouver, BC where they were processed using routine acetone extraction followed by fluorometry analysis using the non-acidification procedure. The AFDM samples, also sent to ALS Environmental in Vancouver, BC, were analyzed by determining gravimetrical differences between the sample dry weight and ash weight. Dry weights were calculated by effectively drying samples at a temperature of 105ºC. Subsequently, ash weights were determined by ashing the dried sample at a temperature of 500ºC. AFDM values were computed by dividing ash-free dry weights by the area sampled; resulting in AFDM units of g/m^2. Results were presented as an index of periphyton productivity of mass/area ($\mu g/cm^2$ or mg/m^2) as the lab was provided with the known volume of periphyton sampled per unit area of substrate surface sampled at each site.

Upon receipt of data results from the ALS laboratory, summary statistics for each site including minimum, maximum and mean values were calculated from the six replicates collected at each site. Mean values from each site were used to perform a between site comparison.

2.1.9 SEDIMENT

Sediment sample collection and lab analysis is described in the below sections.

2.1.9.1 Sample Collection

Sediment samples were collected at eleven sites within the Mine study area from August 2 to 7, 2017 (Table 11). The objectives of sediment sampling were to assess texture and to analyze metal concentrations within the soils. At each sampling site three replicates were collected from various depositional areas within the stream using a stainless-steel spoon. The collection device was rinsed with 95% ethanol between sites to avoid sediment cross contamination. Fine textured sediments from depositional areas were targeted for sampling because fine sediments have the highest consumption rate among benthic invertebrates, making fine sediments a useful parameter for determining potential risks to various aquatic organisms. Sample replicates from the different stream areas within each site were combined to form sediment composite samples. Sample composites for each site were contained within a sterile storage container and were labelled by field crew with sample name, date and location. Sediment samples were field stored at room temperature until delivered to the ALS Environmental laboratory under chain of custody (COC) documentation.

2.1.9.2 Laboratory Analysis

Sediment samples were sent to ALS Environmental in Vancouver, BC and Saskatoon, SK for laboratory analysis of metals, total organic carbon, nutrients and particle size. Physical soil tests were conducted using a procedure in which samples were dried (<60ºC), sieved (No. 10/2mm) and mixed with deionized/distilled water at a 1:2 ratio of sediment to water. The pH of the solution was measured using a standard pH probe. Particle size analysis was conducted using dry sieving, wet sieving and pipette sedimentation (Soil Survey Staff

2014). Samples used for soil metals analysis were manually homogenized, dried (60 ºC), sieved (63 µm/230 cm mesh) and the dry material subsample was weighed (US EPA 2005; Martin et al 1994). A hot block digester was employed to digest the sample at 95 ºC for two hours using concentrated nitric and hydrochloric acids. Instrumental analysis for mercury was conducted using either atomic fluorescence spectrophotometry or atomic absorption spectrophotometry. Instrumental analysis for all remaining soil metals was conducted using collision cell inductively coupled plasma – mass spectrometry (ICP/MS).

2.2 NORTHERN ACCESS ROUTE

Methods for the three project components related to the northern access route are described below.

2.2.1 BARGE LANDING INVESTIGATIONS

Proposed barge landings on the Yukon River were visited and sampled for fish during August 2017. Visual observations were made to describe the fish habitat in these areas. Fish sampling was conducted using beach seining. In the case of the north bank, the beach seining sites were located approximately 75 m downstream of the proposed landing sites due to the presence of vertical banks which were not conducive to fish sampling. A total of seven beach seining hauls were completed at proposed barge landing sites and one at an existing barge landing near the Coffee Camp (Figure 9).

The beach seine used was 10 m in length, 2 m deep and constructed of 5 mm mesh. Information collected for each beach seine haul included seine haul dimensions (length, width, depth). All fish captured were identified to species and measured to fork length.

2.2.2 STEWART RIVER BACK CHANNEL INVESTIGATIONS

A back channel on the Stewart River which will be encroached upon by the Northern Access Route was visited on September 3, 2017. Photos and notes were taken on the characteristics of the channel. Fish sampling was not completed as the channel was predominantly dry at the time of the visit.

2.2.3 CHUM SALMON SPAWNING SURVEYS

Aerial surveys were completed by helicopter on the Yukon and Stewart rivers on October 19, 2017. The Yukon River was surveyed from just upstream of Excelsior Creek (7 km upstream of Coffee Creek) downstream to near the confluence of Carlisle Creek, a river distance of approximately 33.5 km (Figure 10). The Stewart River was surveyed from Black Hills Creek, downstream to a point 6 km downstream of Three Kings Creek for a total river distance of approximately 34.6 km (Figure 10).

Observers were located in the front and backseats and the pilot positioned them over the river, flying sideways with the best possible vantage point at approximately 40-45 m above ground level. Surveys were completed in a downstream manner with both observers wearing polarized glasses to reduce glare. Air temperatures during the survey were relatively mild (-3°C), although ice cover was observed in some of the Yukon River side channels. Particularly the Stewart River had many ice pans forming on the river, and side channel ice cover limited the ability to see spawning chum. All open water areas within river channel were surveyed, although an emphasis was placed on side channel habitats where groundwater discharge areas were present (known preferred spawning areas for chum salmon on large Yukon rivers).

3 RESULTS AND DISCUSSION – MINE STUDY AREA

Results and discussion for the mine study area are presented per project component in the below sections.

3.1 ENVIRONMENTAL DNA SAMPLING

3.1.1 MARCH 2017

Few environmental DNA samples filtered from water collected in March 2017 tested positive for Arctic grayling or Chinook salmon DNA markers (Table 12; APPENDIX B). A positive hit for Chinook DNA was found in one of the three sampled sites in Coffee Creek (CF8.1), and a positive hit for Arctic grayling was found in one of the two Yukon River sites. These late winter results were in contrast to the March 2016 data which found positive samples for Chinook DNA at all 4 Coffee Creek sites and positive samples for Arctic grayling at all three Yukon River sites sampled and in one Coffee Creek site. The lower Halfway Creek site (HF0.2) was frozen to the bed, from bank to bank (Photo 1). Coffee Creek and the Yukon River (CF0.1, CF2.7, CF8.1; YRD11.0, YRD20.5) were sampled as positive controls (i.e., where fish detection was anticipated), whereas a deionized water sample (PS2.4) was used as a negative control (i.e., where no detection was expected).

It is suspected that the year to year difference in the results in Coffee Creek is related to the difference in winter conditions. Specifically, 2017 was a colder winter than 2016, reflected by the higher amounts of ice and lesser amount of flowing water observed in Coffee Creek. Such conditions appear to affect the amount and quality of overwintering habitat that is present in the creek.

Table 12. Summary of eDNA detection results in the Mine study area, March 2017.

Station Name	Arctic Grayling eDNA Detected (Yes/No)	Chinook Salmon eDNA Detected (Yes/No)
CF0.1	No	No
CF2.7	No	No
CF8.1	No	**Yes**
LC0.5	No	No
LC9.9	No	No
ID1.9	No	No
HF0.2	Frozen to bed – no sample collected	
YT0.2	Frozen to bed – no sample collected	
HF6.3	No	Inconclusive[1]
YRD11.0	**Yes**	No
YRD20.5	No	No
PS2.4 Control (Deionized Water)	No	No

[1] One of the three samples was positive for Chinook; however, it is believed that this was a false positive as there has never been fish documented in this location and the sample was collected from a hole right next to another sampling station used a few days earlier by another crew (which could have led to contamination).

Photo 1. Looking upstream, HF0.2 frozen to the bed from bank to bank during eDNA sampling efforts, March 2017.

Overwintering conditions did not appear affected in the Yukon River; it is suspected that YRD20.5 was negative for Arctic grayling as it was collected in an area with groundwater inputs (i.e., may not be reflective of the entire river). At other sites, conditions and eDNA results were similar to 2016 which included negative results for Arctic grayling and Chinook salmon in Independence and Latte Creek.

3.1.2 AUGUST 2017

During the 2017 summer eDNA sampling, four different watersheds were assessed for the presence of eDNA (Table 13). Halfway Creek was thoroughly investigated, and only had Arctic grayling detected 0.1 and 0.5 km from the mouth which was consistent with fish sampling results (see Section 3.2.2). These samples did not detect the presence of juvenile Chinook, which were caught at HF0.1 and HF0.2 using electrofishing techniques (see Section 3.2.2). A plausible explanation for this may be that juvenile chinook were present in too low of densities to be detected, particularly as they are small fish and shed less DNA into the surrounding water. In YT-24, samples appeared to be compromised as no DNA of any kind (including algae) was detected in the samples. Coffee Creek (CF8.0) and the Yukon River (YR) were sampled as positive controls and were positive for both grayling and Chinook, whereas a distilled water sample (WD0.6) was used as a negative control and was negative for any DNA.

Table 13. Summary of eDNA detection results in the Mine study area, August 2017.

Station Name	Arctic Grayling eDNA Detected (Yes/No)	Chinook Salmon eDNA Detected (Yes/No)
HF0.1	**Yes**	No
HF0.5	**Yes**	No
HF1.0	No	No
HF2.0	No	No
HF4.0	No	No
HF6.3	No	No
CF8.0	**Yes**	**Yes**
YT0.1	No[1]	No[1]
YT1.0[1]	No[1]	No[1]
YT2.0[1]	No[1]	No[1]
YR	**Yes**	**Yes**
WD0.6 Control (Distilled water)	No	No

[1]Samples appeared to be compromised (no DNA of any kind detected); possible traces of disinfectant or sample not dried for long enough duration.

3.1.3 OCTOBER 2017

In October 2017 Halfway Creek was revisited, and two samples were taken at 0.1 and 0.2 km from the mouth of the creek. The Halfway Creek samples 0.1 km from the mouth of the creek (HF0.1) contained no genetic material of Chinook or Arctic grayling (Table 14). Conversely, 0.2 km from the mouth (HF0.2) contained Chinook genetic material, but no Arctic grayling (Table 14). A sample from the Yukon River (YR) and a distilled water sample (WD0.1) were used as a positive and negative control, respectively. As anticipated, the Yukon River sample contained Arctic grayling genetic material, whereas the distilled water sample did not (Table 14); these findings validate the sampling and filtering techniques.

Table 14. Summary of eDNA detection results in the Mine study area, October 2017.

Station Name	Arctic Grayling eDNA Detected (Yes/No)	Chinook Salmon eDNA Detected (Yes/No)
HF0.1	No	No
HF0.2	No	**Yes**
YR	**Yes**	No
WD0.1	No	No

The positive result of Chinook in Halfway Creek was interesting as previous winter investigations found this part of the creek frozen to bed (Photo 1). It is not clear if these fish would leave before winter conditions set in or had already left given that eDNA can persist in water between seven to 21 days, depending on various environmental factors (Hobbs 2017).

3.2 FISH SAMPLING

Fish sampling results from 2017 are described by stream in the below sections (data provided in APPENDIX C and APPENDIX D). Use of the triple pass depletion model to estimate fish densities is presented and discussed in Section 3.2.6, including data from 2017, as well as 2016, which was not previously analyzed in this manner.

3.2.1 COFFEE CREEK

Juvenile Chinook salmon, Arctic grayling, and slimy sculpin were captured in Coffee Creek during the 2017 field program; these findings are supported by previous years' sampling efforts (e.g., 2014-2016). During all combined sampling efforts in 2017, there were 30 juvenile Chinook captured, with minnow trapping being the most effective method (n = 18), followed by electrofishing (n = 7) and beach seining (n = 6; Table 15). Arctic grayling were primarily captured using beach seining (n = 21), and electrofishing to a lesser extent (n = 3; Table 15). Electrofishing captured the most slimy sculpin (n = 39), with minnow trapping (n = 3) and beach seining (n = 2) contributing substantially fewer captures (Table 15). These results highlight the importance of employing various capture methods to ensure representation of various fish species during sampling efforts. The 2017 field program was the first year that beach seining was used in Coffee Creek; this was also the first year that young of the year (YOY) Arctic grayling were captured. There was a total of three YOY Arctic grayling visually observed, and one captured in the first seine haul (Table 15; Photo 2). The capture of YOY Arctic grayling suggests that spawning occurs in this region of Coffee Creek.

Table 15. Summary of fish sampling and capture data in Coffee Creek, site CF3.9, during the August 2017 field investigation

Sample Date	Sampling Method	Total Sampling Effort	Number of Fish Captured	Comments
8-Aug-17	Electrofishing	2,049 seconds	39 CCG 7 Juvenile CH 3 GR	EF began at 700 m downstream of site, continued 250 m upstream.
8-Aug-17	Beach seining	36 m²	1 Juvenile GR	BS haul #1 –located 150 m downstream of site
8-Aug-17	Beach seining	70 m²	1 GR	BS haul #2 –located 150 m downstream of site
8-Aug-17	Beach seining	25 m²	1 CCG	BS haul #3 –located 150 m downstream of site
8-Aug-17	Beach seining	32 m²	3 GR	BS haul #4 –located 50 m downstream of site
8-Aug-17	Beach seining	40 m²	8 GR	BS haul #5 –located 50 m downstream of site
8-Aug-17	Beach seining	24.5 m²	3 GR	BS haul #6 –located 50 m downstream of site
8-Aug-17	Beach seining	32 m²	1 GR	BS haul #7 –located 50 m downstream of site
8-Aug-17	Beach seining	60 m²	NFC	BS haul #8 –located 100 m upstream of site
8-Aug-17	Beach seining	40 m²	1 CCG	BS haul #9 –located 100 m upstream of site
8-Aug-17	Beach seining	36 m²	1 Juvenile CH 1 GR	BS haul #10- located 150 m downstream of site
8-Aug-17	Beach seining	60 m²	3 GR 3 Juvenile CH	BS haul #11 located 150 m downstream of site
8, 9-Aug-17	Minnow trapping	278 hr	18 Juvenile CH 3 CCG	12 MT set

NFC = no fish caught; CCG = slimy sculpin; CH = Chinook salmon; GR = Arctic grayling; EF = electrofishing; BS = beach seining; MT = minnow trapping.

Photo 2. Young of the year Arctic grayling captured during beach seining efforts at CF3.5

3.2.2 HALFWAY CREEK

Halfway Creek was extensively sampled using electrofishing and minnow trapping during the 2017 field program. Minnow trapping did not result in any fish captures in Halfway Creek (Table 16). Conversely, electrofishing caught Arctic grayling up to 0.6 km from the creek mouth, and juvenile Chinook salmon up to 0.2 km upstream of the creek mouth (Table 16). Between 0.6 km and 4.5 km upstream from the creek mouth, a total of 2,290 seconds and approximately 1.4 km distance was electrofished, with no fish being captured or observed. These findings are consistent with past fish and 2017 eDNA sampling in this creek, with fish use limited to the lower portions of the drainage.

Table 16. Summary of fish sampling and capture data in Halfway Creek during the August 2017 field investigation

Sampling Site	Sample Date	Sampling Method	Total Sampling Effort	Number of Fish Captured	Comments
HF0.1	2-Aug-17	Minnow trapping	34hr 12m	NFC	2 MT set
	3-Aug-17	Electrofishing	960 seconds	3 Juvenile CH	EF began ~30 m upstream of stream mouth and for continued 100 m upstream
HF0.2	2-Aug-17	Minnow trapping	22hr 50min	NFC	2 MT set
	3-Aug-17	Electrofishing	1,260 seconds	6 GR 2 Juvenile CH	EF began just upstream of HF0.1 and continued for 150 m upstream
HF0.3	3-Aug-17	Electrofishing	858 seconds	1 GR	EF began at HF0.3, continued 250 m upstream

Sampling Site	Sample Date	Sampling Method	Total Sampling Effort	Number of Fish Captured	Comments
HF0.5	2-Aug-17	Minnow trapping	44hr	NFC	2 MT set
HF0.6	3-Aug-17	Electrofishing	638 seconds	1 GR	EF began at HF0.6, continued 220 m upstream
HF0.9	2-Aug-17	Minnow trapping	51hr	NFC	2 MT set
HF1.0	3-Aug-17	Electrofishing	223 seconds	NFC	EF began at HF1.0, continued 100 m upstream
HF1.1	3-Aug-17	Electrofishing	277 seconds	NFC	EF began at HF1.1, continued 140 m upstream
HF1.5	3-Aug-17	Electrofishing	109 seconds	NFC	EF began at HF1.5, continued 60 m upstream
HF2.1	4-Aug-17	Electrofishing	1,155 seconds	NFC	EF began at HF2.1 then continued 585 m upstream
HF4.5	4-Aug-17	Electrofishing	526 seconds	NFC	EF began at HF4.5, continued 530 m upstream

NFC = no fish captured; CH = Chinook salmon; GR = Arctic grayling

3.2.3 LATTE CREEK

On Latte Creek, triple pass electrofishing was employed in an attempt to estimate fish population density using a depletion model (Section 3.2.6). The raw data from the triple pass electrofishing served to provide species presence (Table 17). The capture of exclusively adult and sub-adult grayling is consistent with previous sampling results at this site.

Table 17. Summary of fish sampling and capture data in Latte Creek during the August 2017 field investigation

Sampling Site - Replicate	Sample Date	Sampling Method	Total Sampling Effort	Number of Fish Captured	Pass Number
LC2.7-1	6-Aug-17	Triple Pass EF	402 seconds	4 GR	EF Pass 1
			382 seconds	NFC	EF Pass 2
			364 seconds	NFC	EF Pass 3
LC2.7-2	6-Aug-17	Triple Pass EF	702 seconds	3 GR	EF Pass 1
			530 seconds	1 GR	EF Pass 2
			572 seconds	NFC	EF Pass 3
LC2.7-3	6-Aug-17	Triple Pass EF	673 seconds	6 GR	EF Pass 1
			455 seconds	4 GR	EF Pass 2
			573 seconds	3 GR	EF Pass 3

NFC = no fish caught; GR = Arctic grayling

3.2.4 INDEPENDENCE CREEK

Similar to Latte Creek, Independence Creek was triple pass electrofished with results used in a depletion model (Section 3.2.6). The raw data from electrofishing on Independence Creek served to inform on species presence in the areas sampled. Juvenile Chinook salmon, Arctic grayling, and slimy sculpin were caught in the first and third replicate; the second replicate only captured juvenile Chinook salmon and Arctic grayling. Independence

Creek appears to contain small populations of juvenile Chinook salmon, as well as Arctic grayling and slimy sculpin. The relatively large number of slimy sculpin captured indicates that this reach of Independence Creek contains suitable overwintering habitat; however, eDNA sampling in 2016 and 2017 has not detected the presence of Arctic grayling or Chinook salmon in the late winter.

Table 18. Summary of fish sampling and capture data in Independence Creek during the August 2017 field investigation

Sample Site - Replicate	Sample Date	Fish Sampling Type	Total Sampling Effort	Number of Fish Captured	Pass Number
ID1.9-1	7-Aug-17	Triple Pass EF [a]	1,850 seconds	23 CCG 2 Juvenile CH 2 GR	EF Pass 1
			125 seconds	1 Juvenile CH 1 GR	EF Pass 2
ID1.9-2	7-Aug-17	Triple Pass EF	780 seconds	3 CCG 3 GR	EF Pass 1
			659 seconds	1 GR	EF Pass 2
			589 seconds	1 CCG	EF Pass 3
ID1.9-3	7-Aug-17	Triple Pass EF[b]	845 seconds	6 CCG 2 Juvenile CH 4 GR	EF Pass 1
			695 seconds	1 CCG	EF Pass 2

EF = electrofishing; CCG = slimy sculpin; CH = Chinook salmon; GR = Arctic grayling

[a] The second and third pass were aborted as net became compromised.

[b] The third pass was aborted as due to dead battery, but the failure to capture GR and CH in the second pass would prevent predicting densities for these species.

3.2.5 YT-24

Electrofishing was completed on YT-24. Near the mouth of the creek (50 m upstream) one Arctic grayling was captured (Table 19). Farther upstream, no fish were captured (Table 19). The Arctic grayling was the first fish that has been captured in YT-24 (beyond the back flooded portion of the mouth) since the sampling program began in 2014 (EDI 2017). Investigation of the creek showed that there had been a severe flooding event in the spring which resulted in a significant amount of bedload movement with the stream channel, restructuring much of the creek (Photo 3). This was due to a peak flow event that was associated with a high magnitude rainfall event on July 15, 2017 (Jackson Pers. Comm. 2017). Sections of the stream had moved and were flowing through vegetation (Photo 4). As in previous years, several impediments to fish passage were observed in the lower 2 km of the stream (Photo 5, Photo 6).

Table 19. Summary of fish sampling and capture data in YT-24 during the August 2017 field investigation

Sampling Site	Sample Date	Sampling Method	Total Sampling Effort	Number of Fish Captured	Comments
YT0.1	5-Aug-17	Electrofishing	396 seconds	1 GR	EF began 27 m upstream from mouth and continued for 100 m
YT0.2	5-Aug-17	Electrofishing	1,313 seconds	NFC	EF began at YT0.2, continued 540 m upstream
YT1.9	5-Aug-17	Electrofishing	740 seconds	NFC	EF began at YT1.9, continued 370 m upstream

NFC = no fish caught; GR = Arctic grayling

Photo 3. Mouth of YT-24 showing recently deposited bed material into the Yukon River channel.

Photo 4. A washed-out area of YT-24 where the creek now flows through vegetation.

Photo 5. Cascade on YT-24 located ~1.2 km upstream from the mouth.

Photo 6. Falls (1.05 m high) over debris jam ~1.3 km upstream from the mouth (YT-24).

3.2.6 TRIPLE PASS ELECTROFISHING DEPLETION MODEL

The objective of the 2016 and 2017 triple pass electrofishing programs was to use a depletion model to ascertain fish density in each respective creek. The 2016 field program assessed Latte, Independence, and Coffee Creek, whereas in 2017 Latte and Independence creeks were sampled using this method. These creeks are considered cold, low-productivity creeks, and do not contain large populations of fish. As such, in both years the catches of Arctic grayling and juvenile Chinook salmon were quite low; where present, and slimy sculpin were captured in higher densities (Table 20).

Table 20. 2016 field program fish density results from triple pass electrofishing depletion model.

Creek	Species	Average fish density (fish/100m2 ± SE)
Latte	Arctic grayling	3.47 ± 2.22
Independence	Slimy sculpin	4.37 ± 2.15
Coffee (lower site, CF3.9)	Arctic grayling	3.00 ± 2.08
	Slimy sculpin	12.67 ± 4.06
Coffee (upper site, CF10.0)	Juvenile Chinook salmon	0.40 ± 0.40
	Slimy sculpin	27.41 ± 4.01

Table 21. 2017 field program fish density results from triple pass electrofishing depletion model.

Creek	Species	Average fish density (fish/100m2 ± SE)
Latte	Arctic grayling	4.97 ± 1.89
Independence	Arctic grayling	1.74 ± 0.36
	Juvenile Chinook salmon	0.35 ± 0.35
	Slimy sculpin	2.26 ± 0.16

The depletion results for 2016 had relatively high standard errors, suggesting variable catch data during sampling. These relatively large standard errors are likely due to the high-water levels experienced, resulting in inconsistent 'knock-down' of fish catches between passes. Fish occur in low numbers in these creeks, consequently leading to small sample sizes, which also contributes to large standard errors.

In 2016, slimy sculpin were caught in higher numbers with proportionately lower standard errors than juvenile Chinook salmon or Arctic grayling (Table 20). In 2017, water levels were lower than the 2016 field program and overall conditions appeared to be more conducive for using the depletion model on results. While still not altogether ideal, the 2017 results did more closely satisfy the objective. In Latte Creek the field crew captured more Arctic grayling, leading to a higher population estimate and slightly higher average fish density, but with substantially smaller standard errors than in 2016 (i.e., more precision in average density; Table 21). This suggests that there was little variation between replicates, and each one was a more accurate estimate of Arctic grayling population than in 2016. This is due to the higher catch numbers in 2017, but also because there was a more representative 'knock-down' between passes (i.e., capturing fewer fish each pass). In 2017 there were juvenile Chinook salmon, Arctic grayling, and slimy sculpin captured in Independence, compared with only slimy sculpin caught in 2016 (Table 20, Table 21). None of the species caught were present in particularly high densities, although the 'knock-downs' were generally consistent, resulting in lower standard errors. An exception in both 2016 and 2017 was the capture of juvenile Chinook salmon; they were captured in very low densities and were caught inconsistently in the adjacent replicates that made up a site. Often the juvenile Chinook were only captured in one replicate of a site, leading to many zeros used in the calculation of the mean and standard error (Table 20, Table 21).

Without having more replicates per site, the depletion method of analysis has very low statistical power, and therefore lacks in its utility to accurately inform on changes to fish densities (Table 22, Table 23). With fish occurring at such low numbers, there would need to be an excessive amount of time and electrofishing effort devoted to three pass electrofishing for the depletion method to pass the rigors of statistical testing and analysis post-project. This is primarily a result of the substantial variation in fish population estimates and densities between replicates and sites, reducing statistical power. As an example, the 2016 depletion results and subsequent power analysis on Arctic grayling in Coffee Creek suggested there would need to be 46 replicates to detect a 50% change in the fish population post-project (a requirement of power analysis; Table 22). When the average effort of a replicate is considered (approximately 1,500 seconds of electrofishing for the three passes; Table 15) and the density at which Arctic grayling exist in Coffee Creek, it would take nearly 70,000 seconds (~19.5 hr) of electrofishing for a site before a 50% change can be detected. Even the more modest example of the 2017 Latte Creek Arctic grayling results requires 14 replicates (average 1,500 seconds of electrofishing per replicate; Table 17), resulting in approximately 21,000 seconds of sampling effort before

a 50% change can be detected at the site. In addition to the time spent electrofishing, there is also a substantial amount of time devoted to setting up each replicate site. The depletion method results followed by the power analysis collectively indicate that three-pass electrofishing is not an appropriate metric for measuring changes in fish density post-project.

Table 22. Power analysis results for the 2016 depletion model.

Creek	Site Name	Species	Average density (fish/100m^2)	Power at current density	Post-project replicates per site needed for a power of 0.8
Latte	LC2.7	Arctic grayling	3.47	0.12	30
Independence	ID1.9	Slimy sculpin	4.37	0.17	23
Coffee	CF3.9	Slimy sculpin	27.41	0.93	3
Coffee	CF10.0	Arctic grayling	3.00	0.11	46
Coffee	CF10.0	Slimy sculpin	12.67	0.35	10

Table 23. Power analysis results for the 2017 depletion model.

Creek	Site Name	Species	Average density (fish/100m^2)	Power at current density	Post-project replicates per site needed for a power of 0.8
Latte	LC2.7	Arctic grayling	4.97	0.26	14
Independence	ID1.9	Arctic grayling	1.74	0.06	110
Independence	ID1.9	Slimy sculpin	2.26	1.00	2

3.2.7 FISH TISSUE SAMPLING DATA

Data on retained fish is summarized in the below sections (see APPENDIX D for raw data).

3.2.7.1 Age Data

Several watersheds in the Mine Study Area had Arctic grayling and slimy sculpin aged, with the objective of collecting ten specimens per watershed; this objective was not possible in all creeks due to low densities of fish. Arctic grayling ranged in age from one to 11 years, whereas slimy sculpin ranged in age from one to five years old (Table 24). There was a similar age distribution of Arctic grayling and slimy sculpin present in all the creeks assessed.

Table 24. Arctic grayling and slimy sculpin age data from watersheds within the Mine study area.

Creek	Species	*n*	Age Range (years)	Mean Age (years)
Coffee Creek	Arctic grayling	8	1-8	4.0
Coffee Creek	Slimy sculpin	10	1-3	2.3
Halfway Creek	Arctic grayling	7	3-9	5.4
Latte Creek	Arctic grayling	10	3-9	5.8
Independence Creek	Arctic grayling	7	1-11	5.1
Independence Creek	Slimy sculpin	11	1-5	2.5
YT-24 Creek	Arctic grayling	1	3	3.0

3.2.7.2 Gonads

Gonad weight was sampled from Arctic grayling in various watersheds to provide baseline data on the reproductive potential of individuals rearing in the creeks within the Mine Study Area (Table 25). Individuals in Halfway and Independence Creek had the highest mean gonad weights.

Table 25. Arctic grayling gonad weight from watersheds within the Mine study area.

Creek	Species	*n*	Gonad weight range (g)	Mean gonad weight (g)[a]
Coffee Creek	Arctic grayling	9	<0.1 – 2.7	0.8
Halfway Creek	Arctic grayling	7	<0.1 – 4.4	1.2
Latte Creek	Arctic grayling	10	<0.1 – 1.9	0.6
Independence Creek	Arctic grayling	7	<0.1 – 4.4	2.2
YT-24 Creek	Arctic grayling	1	<0.1	<0.1

[a] For determining mean gonad weight, in the case of a <0.1 reading, 0.1 was used to average.

3.2.7.3 Arctic grayling diets

Arctic grayling within the study area were found to be opportunistic in their diet composition and consumed a variety of items (Table 26; APPENDIX D). Primarily Arctic grayling consumed insects (e.g., chironomids, mayfly and stonefly larvae, adult flies, ants), although in several fish there was a significant amount of organic debris in their stomach content (e.g., coniferous needles, twigs, woody debris).

Table 26. Diet composition of Arctic grayling from watersheds within the Mine study area.

Creek	Species	*n*	Diet composition (primary; secondary)
Coffee Creek	Arctic grayling	8	Insects
Halfway Creek	Arctic grayling	2	Insects; Organic debris
Latte Creek	Arctic grayling	10	Insects
Independence Creek	Arctic grayling	7	Insects; Organic debris
YT-24 Creek	Arctic grayling	1	Insects

3.3 FISH HABITAT INVESTIGATIONS

Habitat investigations were completed on Halfway Creek and headwater drainages within the proposed mine footprint. Site card and stream attribute data can be found in APPENDIX C.

3.3.1 HALFWAY CREEK

The Halfway Creek watershed is narrow with few significant tributaries to the lower and middle section of the creek. Based on habitat characteristics Halfway Creek was split into four stream reaches, with the main difference between the reaches being gradient, which became progressively steeper moving in an upstream direction (Table 27).

Table 27. Summary of biophysical characteristics of the four reaches of Halfway Creek.

Reach Number	Site Card Location	Channel Width (m)	Gradient (%)	Bed Material (dominant/subdominant)	Total Cover	Dominant Cover Type
1	HF0.2	4.80	2.25	Cobble/gravel	Moderate	Undercut bank
2	HF2.7	2.66	4.25	Boulder/cobble	Moderate	Boulder
3	HF8.8	2.60	10.5	Boulder/cobble	Trace	Undercut bank, boulders
4	HF9.5	0.94	14	Boulder/cobble	Trace	Boulder

Reach 1 extends from the mouth to 1.1 km upstream (straight line distance; Figure 11). This reach is characterized by low gradients (~2 %), with cobble/gravel dominated bed material, a several deep pools and a moderate amount of cover for fish (Photo 7). Previous to 2017, fish had only been documented in the lower 350 m; however, in 2017 a grayling was captured 600 m upstream of the mouth. There is a logjam barrier, with a 0.8 m falls, at HF0.9 which currently would pose a barrier to upstream fish passage. While this barrier is not permanent, no fish have been captured in the area immediately (300 m) downstream of the falls.

Reach 2 extends from 1.1 km to 6.5 km upstream from the mouth. This reach has a moderate gradient (~4.5 %) and is dominated by boulder and cobble bed material (Photo 8). Cover for fish is dominated by boulders with pools and small woody debris providing areas of cover. There are notable areas of shallow fast flow with limited fish habitat. There are numerous (24) impediments to fish passage throughout this reach; while none represent a permanent barrier to fish they are an indication of the difficulty associated in accessing this seasonal habitat (Figure 11). A 15% cascade over 10 m was documented at the upper end of this reach (Photo 9). Temperatures were very low in this reach despite warm summer conditions during the survey (3.3°C at HF2.7 at 10:30 hrs, August 4).

Reach 3 extends from the 15% cascade 7.8 km upstream of the mouth to the junction of the 2nd order streams in the upper watershed (9.4 km from mouth). This reach is characterized by a narrower channel, steeper gradients and faster flow (Photo 10). Cover is provided by undercut banks and boulders. Snow/ice was found

during the August survey in a side channel ~8.1 km from the mouth, temperatures in the main channel above this snow/ice was 2.6 °C at 11:30 hrs on August 9.

Reach 4 extends from the junction of two 2nd order streams upstream to near the top of the watershed. The stream is small (<1 m channel width), has a higher average gradient than the rest of the stream (~14%) and has generally poor fish habitat (Photo 11).

3.3.2 FOOTPRINT DRAINAGES

All drainages within the mine footprint were walked and assessed for stream characteristics. A summary of the findings are presented below (Figure 12).

Latte Tributary B

This tributary was assessed in 2016 (EDI 2017) and was determined to be a seepage area.

Latte Tributary C

The lower portion of this tributary to Latte Creek was surveyed in 2016 and found to be not suitable for fish beyond the 15 m from the mouth (EDI 2017). Within the project footprint, the lower 400 m is a small stream (0.6 m channel width) with a high gradient (20%) and due to its location in the watershed, steep gradient, small size and lack of pools does not provide any fish habitat (Photo 12). Further upstream, the drainage goes subsurface with occasional flow over organics and through terrestrial vegetation (Photo 13).

Photo 12. Upstream view of Latte Tributary C at the project footprint boundary.

Photo 13. Upstream view of Tributary C flowing over vegetation ~200 m upstream of the footprint boundary.

Latte Tributary A

This drainage flows into Latte Tributary C near the border of the project footprint (Figure 12). This drainage had areas of spread out seepage flow (Photo 14) and areas of subsurface flow. Small isolated patches of alluvial bed material were found; however, the drainage was dominated by flow over moss and through vegetation. This drainage is not a stream.

Photo 14. Upstream view of Latte Tributary A showing spread out seepage flow through vegetation.

Latte Tributary D

Crews walked 100 m on each side of mapped drainage at and downstream of the project footprint boundary; no signs of surface or subsurface flow were found within this area. This area is a forested hillside with no drainage present (Photo 15).

Photo 15. View of the forested area in the location of this mapped drainage (Tributary D). No evidence of flow.

Latte Tributary E

The extent within the project footprint was found to be a depression with areas of intermittent flow. Flow was often subsurface and alluvial material was not present (Photo 16). This drainage is not a stream.

Photo 16. Upstream view of Latte Tributary E.

YT-24

The uppermost portion of YT-24 within the project footprint had minimal evidence of surface flow, no channel and no alluvial bed material (Photo 17). This portion of the drainage is not a stream.

Photo 17. Upstream view of YT-24 at the project footprint boundary.

Halfway Tributary F

This was a small drainage with minimal flow and no streambanks or alluvial bed material (Photo 18). Flow is over organics and vegetation; this drainage was considered a seepage area.

Photo 18. Upstream view of Halfway Tributary F near the confluence with Halfway Creek.

Halfway Tributary G

This drainage had notable flow in the lower 100 m; however, much was subsurface or over moss or organics with a few isolated pockets of alluvial bed materials and no continues streambanks (Photo 19). Further upstream, 200 m from the mouth, there was no detectable flow with signs of seasonal flow over moss. This was not a stream.

Photo 19. Upstream view of Halfway Tributary G near the confluence with Halfway Creek showing discontinuous ponded water.

Halfway Tributary J

This drainage had a stream channel for its entire mapped extent. In fact, it extended even further upstream for approximately 150 m before losing channel characteristics. Near the mouth, the stream was small (0.35 m) with poor habitat (shallow with a gradient of 15%) within a thick alder riparian (Photo 20). Water temperature was 1.6 °C measured in the late afternoon of a warm day (Aug 9th, 2017).

Photo 20. Upstream view of Halfway Tributary J in a rare open patch of riparian.

Halfway Tributary H

The upper portion this tributary had flow over moss and vegetation with discontinuous channels running in multiple directions (Photo 21). Approximately 200 m downstream of the origin of the mapped drainage a groundwater spring enters the watercourse and increases flow significantly. Below this point the drainage tuned into a stream and had relatively consistent alluvial materials within a poorly defined channel (Photo 22). The stream is very shallow and flowed underground in places. The stream was larger downstream near the mouth (0.6 m wide); however, had sections with a gradient of over 20% and poor fish habitat (EDI 2017).

Photo 21. Upstream view of the upper portion of Halfway Tributary H, with discontinues channel and flow over moss.

Photo 22. Upstream view of middle portion of Halfway Tributary H with alluvial materials in a poorly defined channel.

Halfway Tributary I

The upper 200 m of this drainage had signs of flow over/through vegetation with no scouring or channel formation (Photo 23a). Below this point the drainage had relatively consistent alluvial materials within a poorly developed inconsistent channel (Photo 23b). The lower portion of the drainage was determined to be a stream based on the presence of alluvial materials; however, there was no habitat for fish due to gradient, water depth and inconsistent channel formation (area with underground and flow over/through vegetation).

Photo 23. (a) denotes the upper portion of the Tributary I (not a stream), while (b) illustrates the lower part of drainage with alluvial materials (stream).

3.4 CHINOOK SPAWNING SURVEYS

Despite good viewing conditions during all surveys, no adult Chinook salmon, carcasses or salmon redds were observed during any of the Chinook spawning surveys. Also, there were no observations of wildlife such as bears or eagles which typically feed on salmon during the spawning season.

3.5 METAL CONCENTRATIONS IN TISSUES

Metal concentrations in fish and benthic invertebrates are described in the following sections. Laboratory data is presented in APPENDIX E.

3.5.1 METAL CONCENTRATIONS IN FISH TISSUE

In 2017, Arctic grayling and slimy sculpin samples were collected from Latte, Independence, Halfway, Coffee and YT-24 creeks; muscle and liver tissues were collected from Arctic grayling, and full body samples (minus heads) were collected from sculpin.

Currently, there is a Health Canada human consumption guideline for total mercury, and a CCME tissue residue guideline for wildlife consumers of aquatic biota for methylmercury (Environment Canada 2002). These guidelines are for muscle or whole-body samples and were not designed for liver samples. There are no federal guidelines for tissue concentrations of selenium. There is a BC MOE tissue guideline for selenium (BC MOE 2014), however this guideline was developed for use in British Columbia, and not for broader application in other regions with different aquatic biota populations, and different baseline concentrations of selenium in the aquatic environment (fish throughout Yukon commonly exceed this level). Further, the BC MOE guideline incorporates an unnecessarily high built-in safety factor, given the steep nature of the dose-response curve. The US Environmental Protection Agency (EPA) has developed more broadly applicable guidelines for both muscle tissue and whole-body samples (8.5 mg/kg dw for whole body and 11.3 mg/kg dw for fish tissue, US EPA 2016). There are no guidelines for uranium concentrations in tissues, however, uranium concentrations in fish tissues were analysed as uranium is naturally elevated in some streams in the Mine study area (especially during low flows).

3.5.1.1 Arctic Grayling

In 2017, liver and muscle tissue samples were collected from 10 Arctic grayling in Latte Creek (site LC2.7), one grayling captured at the mouth of YT-24, seven grayling in Independence Creek (site ID1.9), seven grayling in Halfway Creek (site HF0.2), and nine fish in Coffee Creek (CF3.9). Metal concentrations were higher in liver tissue samples than muscle tissue samples for mercury, selenium and uranium.

The lowest estimated methylmercury (MeHg) concentrations found in muscle tissue and liver tissue samples were from YT-24, at 0.0275 mg/kg and 0.057 mg/kg respectively (Figure 13). Coffee Creek had the highest mean estimated MeHg concentration in a liver tissue sample, with a concentration of 0.170 mg/kg ww, and

Latte Creek had the highest mean estimated MeHg concentration in a muscle tissue sample at 0.061 mg/kg (Figure 13). Many of the muscle tissue samples also exceeded the CCME tissue residue guidelines, except for three muscle samples from Coffee Creek, three samples from Halfway Creek, two samples from Independence Creek, one sample from Latte Creek, and the one sample from YT-24.

The lowest mean selenium concentrations found in a muscle tissue sample was from Latte Creek, at 2.54 mg/kg dw, and the highest mean selenium concentration found in a muscle tissue sample was from YT-24, with a concentration of 4.65 mg/kg dw (Figure 14). All muscle tissue samples were below the US EPA guideline for selenium (11.3 mg/kg dw). The lowest mean selenium concentration, 14.09 mg/kg dw, was in a liver tissue sample was from Halfway Creek (HF0.2); the highest mean selenium concentration, 24.52 mg/kg dw, was in a liver tissue sample from Independence Creek (Figure 14).

The lowest mean uranium concentration found in a muscle tissue sample was from Latte Creek, at 0.0015 mg/kg, and the lowest mean uranium concentration found in a liver tissue sample was from YT-24, at 0.0021 mg/kg (Figure 15). The highest mean uranium concentration found in muscle and liver tissue samples was from Coffee Creek, at 0.0040 mg/kg and 0.0073 mg/kg respectively (Figure 15).

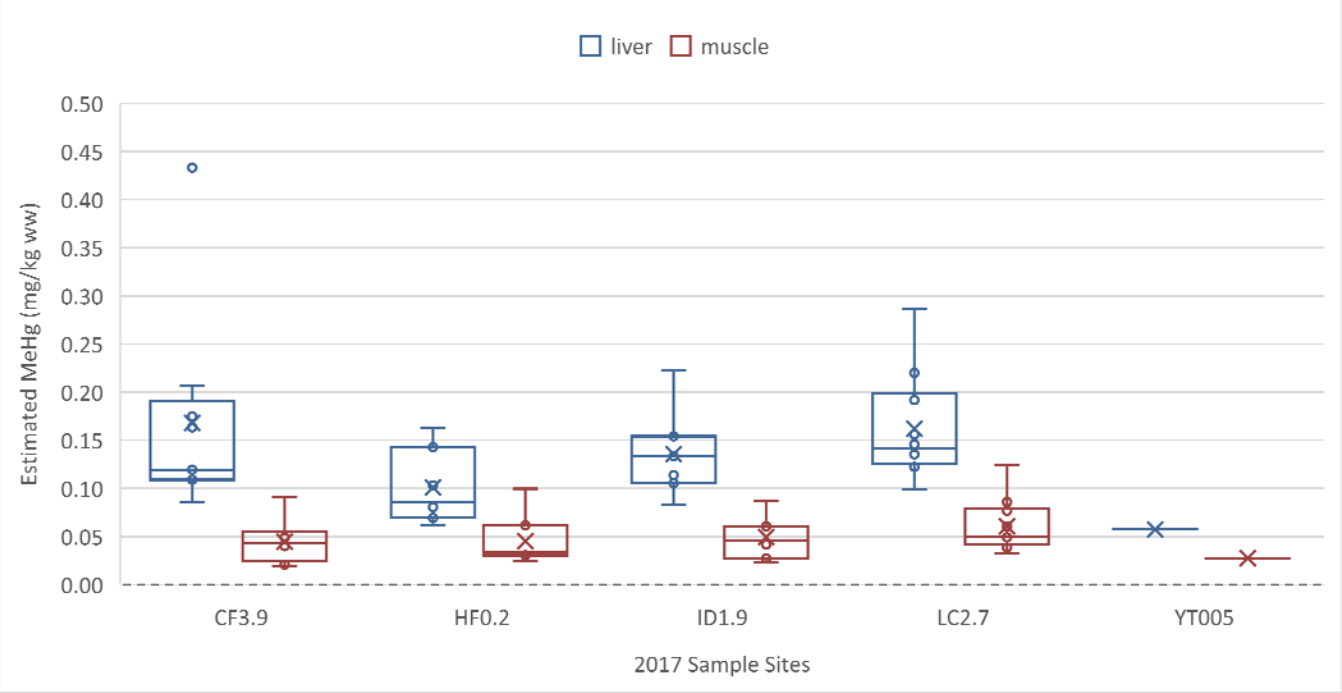

Figure 13. Estimated methylmercury concentrations in Arctic grayling liver and muscle tissue samples from 2017. Box plots were used to display the results in the context of the catch variability per set. The mean value is displayed by an x, the box showing the interquartile range. The vertical lines ('whiskers') show values within 1.5 times the interquartile range. The dots outside the vertical lines represent the outliers, which are more than 1.5 times the interquartile range. The dashed grey line is the CCME methylmercury guideline for the protection of wildlife consumers of aquatic biota (CCME 2000a) and is not applicable to liver tissues.

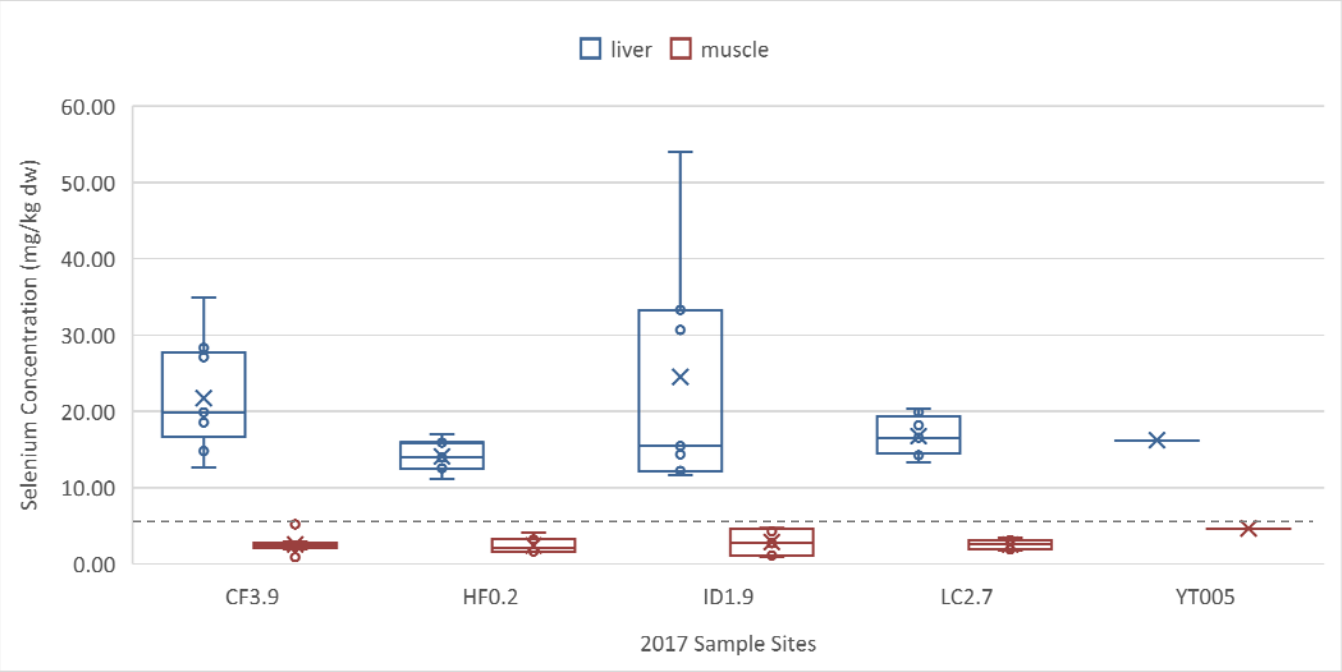

Figure 14. Selenium concentrations in Arctic grayling liver and muscle tissue samples from 2017. The dashed grey line is the US EPA selenium guideline for freshwater aquatic life for tissue samples (US EPA 2016) and is not applicable to liver tissues.

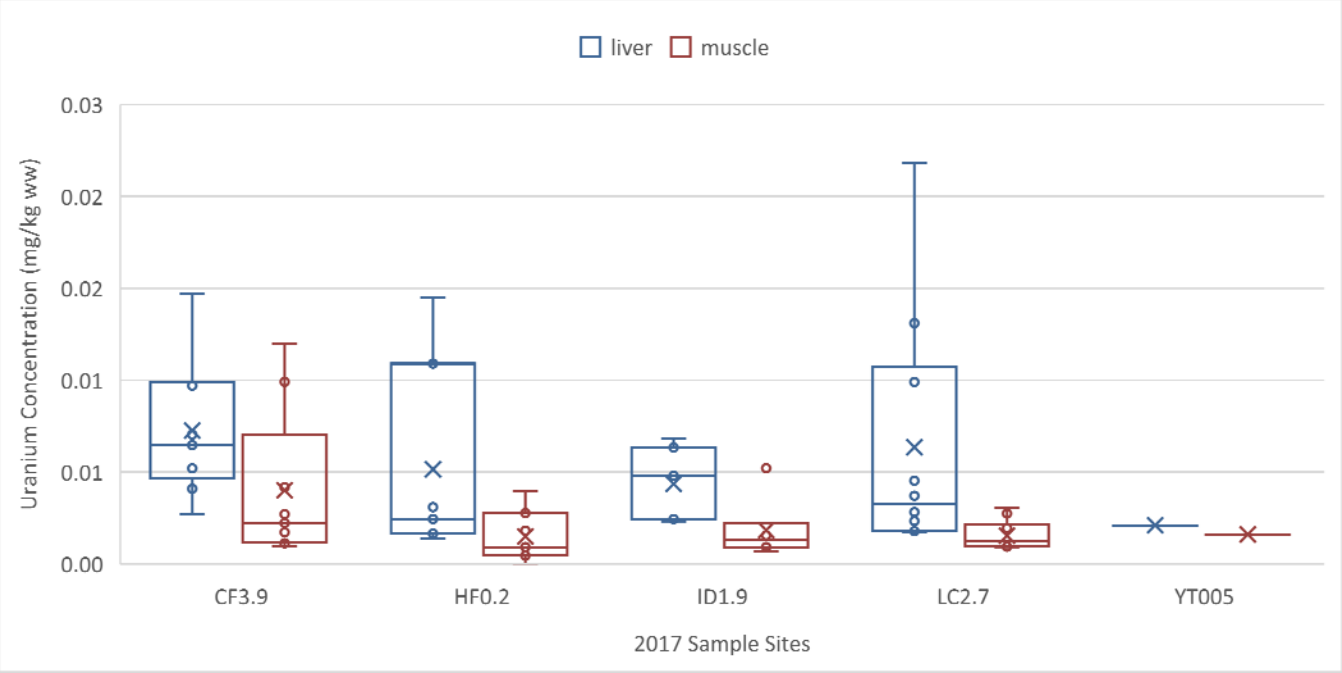

Figure 15. Uranium concentrations in Arctic grayling liver and muscle tissue samples from 2017. The dots outside the vertical lines represent the outliers, which are more than 1.5 times the interquartile range.

Baseline total mercury concentrations in all Arctic grayling muscle tissues did not exceed the Health Canada guideline for human consumption (0.5 mg/kg ww; Health Canada 2007; Table 28; APPENDIX E). In

contrast, estimated methylmercury concentrations (95% of total mercury concentrations, Jewett et. al. 2003) in most of the Arctic grayling muscle tissue samples from all the creeks sampled in 2017 were above the CCME tissue residue guideline for the protection of piscivorous wildlife (0.033 mg/kg ww; CCME 2000a). Selenium concentrations in Arctic grayling muscle tissue did not exceed the EPA's interim guideline for selenium (11.3 mg/kg dw; EPA 2016).

Table 28. Number of Arctic grayling muscle tissue samples that exceed mercury, methylmercury and selenium guidelines, in 2017.

Creek	Sample Type	No. of samples above mercury guideline (0.5 mg/kg ww)	No. of samples above MeHg guideline (0.033 mg/kg ww)	No. of samples above selenium guideline (11.3 mg/kg dw)
Coffee	muscle (N=9)	0	6	0
Halfway	muscle (N=7)	0	4	0
Independence	muscle (N=7)	0	5	0
Latte	muscle (N=10)	0	9	0
YT-24	muscle (N=1)	0	0	0

3.5.1.2 Slimy Sculpin

Twenty-one slimy sculpin tissue samples were collected in 2017, including 11 samples from Independence Creek (site ID1.9) and 10 samples from Coffee Creek (site CF3.9).

The mean estimated MeHg, selenium, and uranium concentrations from the slimy sculpin tissue samples were higher in Coffee Creek than in Independence Creek. The mean estimated MeHg from Coffee Creek (CF3.9) was 0.070 mg/kg ww, and 0.051 mg/kg ww at Independence Creek (ID1.9); all the samples from both creeks exceeded the CCME methylmercury guideline (Figure 16). The mean selenium concentration was 6.668 mg/kg dw at Coffee Creek (CF3.9) and 4.531 mg/kg dw at Independence Creek (ID1.9); all samples from both creeks had selenium concentrations less than the US EPA selenium guideline (Figure 17). The mean uranium concentration was 0.082 mg/kg in Coffee Creek (CF3.9), and 0.051 mg/kg at Independence Creek (ID1.9; Figure 18).

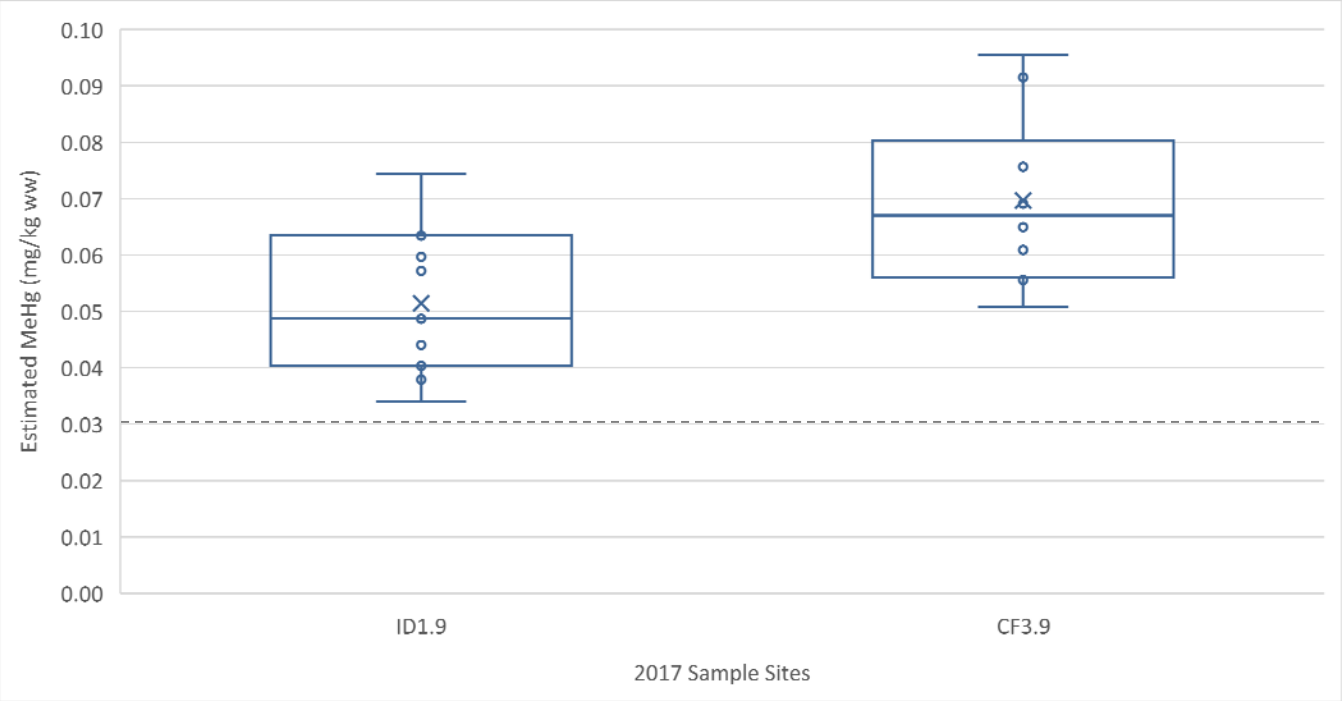

Figure 16. Estimated methylmercury concentrations in slimy sculpin whole-body tissue samples from 2017. The mean value is displayed by an x, the box showing the interquartile range. The vertical lines ('whiskers') show values within 1.5 times the interquartile range. The dots outside the vertical lines represent the outliers, which are more than 1.5 times the interquartile range. The dashed grey line is the CCME methylmercury tissue residue guideline for the protection of wildlife consumers of aquatic biota (Environment Canada 2002).

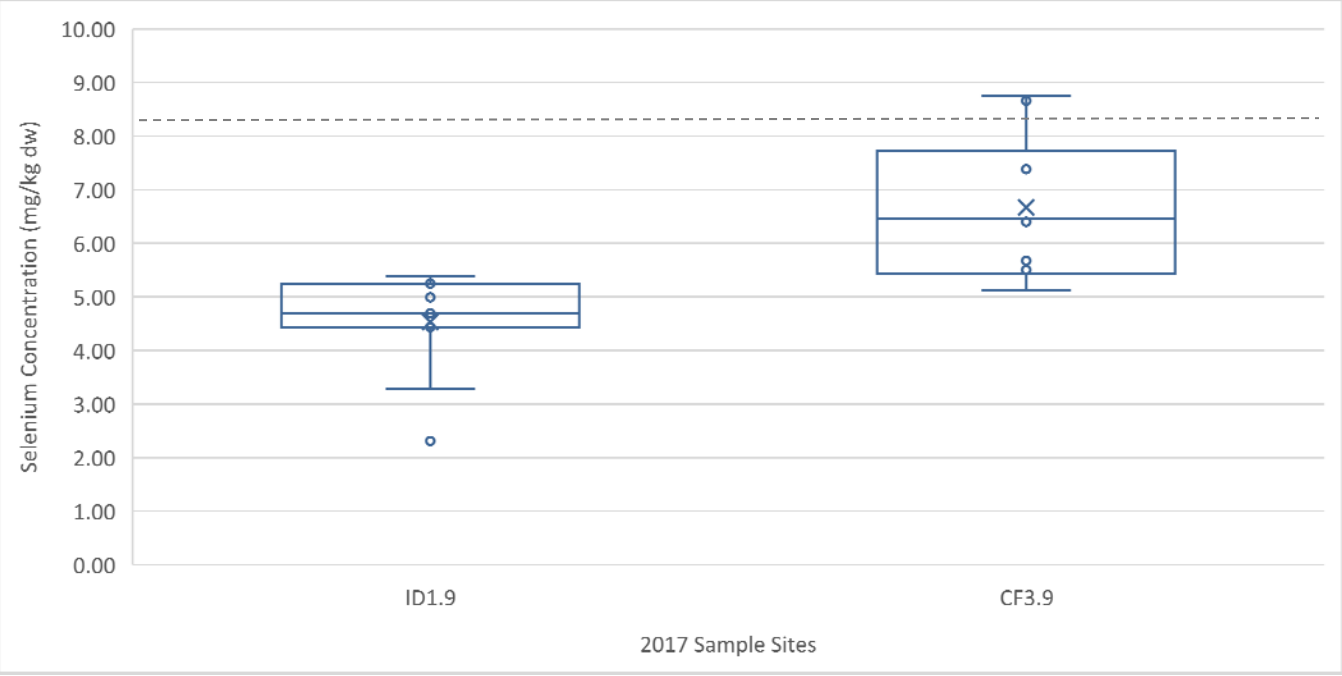

Figure 17. Selenium concentrations in slimy sculpin whole-body tissue samples from 2017. The dashed grey line is the US EPA selenium guideline for freshwater aquatic life for whole body tissue samples (US EPA 2016).

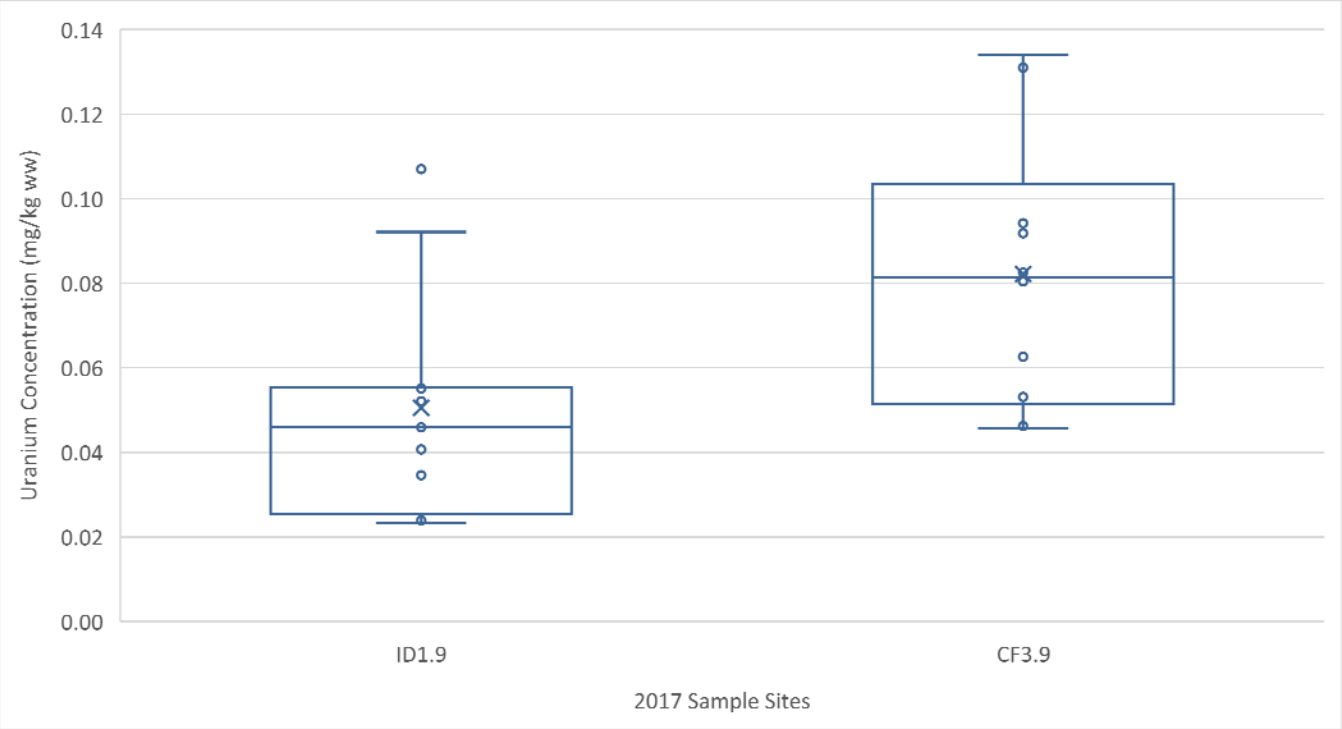

Figure 18. Uranium concentrations in slimy sculpin whole-body tissue samples from 2017. The mean value is displayed by an x, the box showing the interquartile range.

The Health Canada guideline for total mercury does not apply to slimy sculpin because they are not a human food source (Health Canada 2007). The estimated methylmercury concentrations (81% of total mercury concentrations, Raymond et al. 2005) exceeded the CCME tissue guideline (0.033 mg/kg ww; CCME 2000a) in all the slimy sculpin samples from Coffee Creek and Independence Creek in 2017 (Table 29). Selenium concentrations were below the EPA's guideline (8.5 mg/kg dw; EPA 2016) in all the whole-body slimy sculpin samples from Independence Creek. All but two sampled from Coffee Creek were below the EPA selenium guideline in 2017.

Table 29. Number of slimy sculpin whole-body samples compared to mercury, methylmercury, and selenium guidelines in 2017.

Creek	Sample Type	No. above mercury guideline (0.5 mg/kg ww)	No. above MeHg guideline (0.033 mg/kg ww)	No. above selenium guideline (8.5 mg/kg dw)
Coffee	whole-body (N=10)	0	10	2
Independence	whole-body (N=11)	0	11	0

3.5.2 METAL CONCENTRATIONS IN BENTHIC INVERTEBRATES AND PERIPHYTON

Benthic invertebrate samples were collected in August 2017. Benthic invertebrate tissue metal concentration guidelines exist for methylmercury (0.033 mg/kg ww, CCME 2000a). No guidelines exist for uranium; however, uranium concentrations were analysed as uranium can be naturally elevated in some streams in the Project Area.

The highest mean estimated MeHg concentration, 0.0319 mg/kg ww, was from samples collected at upper Latte Creek (LC9.9; Figure 19). The lowest mean estimated MeHg concentration, 0.0051 mg/kg ww, was from samples collected at lower YT-24 (YT0.2). In Coffee Creek, the mean estimated MeHg concentrations decreased moving upstream; the highest mean MeHg concentration, 0.0181 mg/kg ww, was from CF3.9, and the lowest, 0.0089 mg/kg ww, was from CF10.0 (Figure 19). Estimated methylmercury concentrations in all benthic invertebrate tissue samples (54% of total mercury, Lucotte and Tremblay 1997) did not exceed the CCME guideline set for the protection of piscivorous wildlife (0.033 µg/g ww; CCME 2000a), except for one sample from Latte Creek (Figure 19).

The highest mean selenium concentration was from lower Coffee Creek (CF3.9), at 10.41 mg/kg dw; the lowest mean selenium concentration, (0.051 mg/kg dw) was from upper YT-24 (YT5.0; Figure 20). In Coffee and Latte creeks, the mean selenium concentration increased moving downstream. However, in Halfway Creek and YT-24, the mean selenium concentrations were higher at the upstream site compared to the downstream site.

The highest mean uranium concentration, 3.092 mg/kg ww, was from benthic invertebrates collected at upper Halfway Creek (HF6.3; Figure 21). The lowest mean uranium concentration, 0.0908 mg/kg ww, was from upper YT-24 (YT5.0; Figure 21). In Coffee Creek, the highest mean uranium concentration was from the mid-creek site, CF8.0, and the lowest mean uranium concentration was at the downstream site CF3.9. In Latte and Halfway creeks, the mean uranium concentration was higher at the upstream sites compared to the downstream. Mean uranium concentrations in YT-24 were higher at the downstream site.

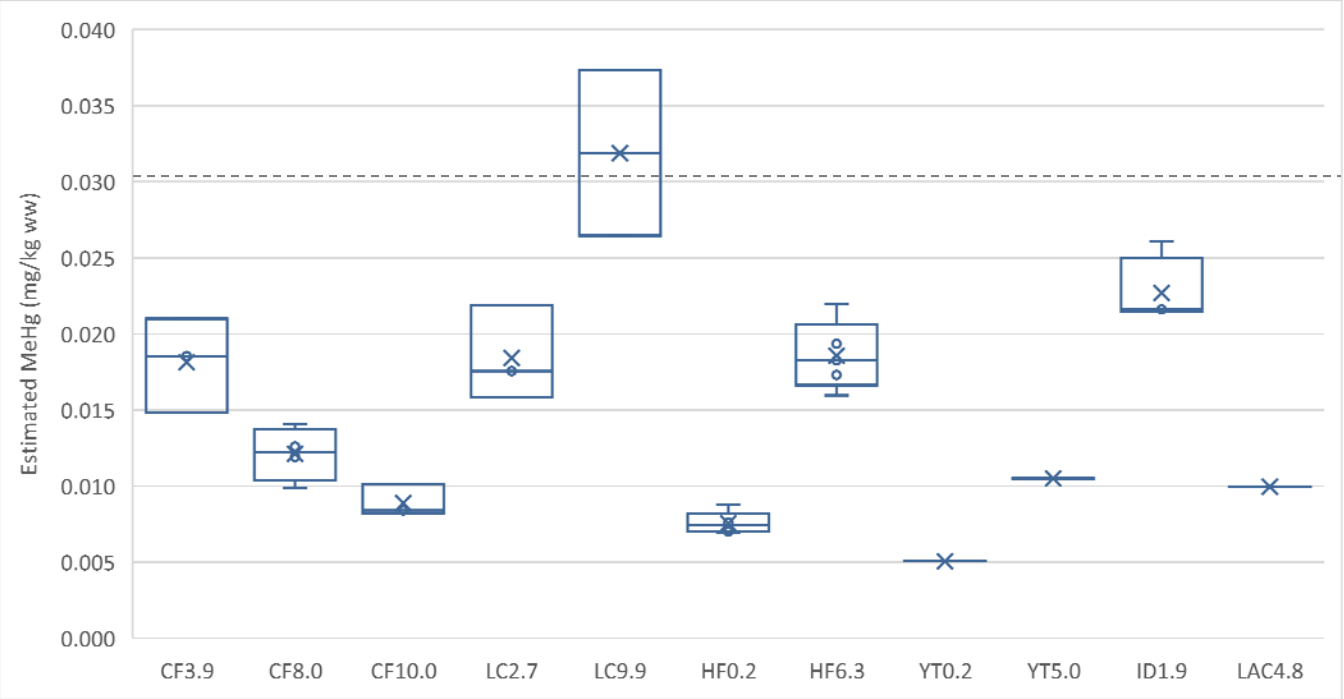

Figure 19. Estimated methylmercury concentrations in benthic invertebrate tissue samples from 2017. The mean value is displayed by an x, the box showing the interquartile range. The vertical lines ('whiskers') show values within 1.5 times the interquartile range. The dots outside the vertical lines represent the outliers, which are more than 1.5 times the interquartile range. The dashed grey line is the CCME methylmercury guideline for the protection of wildlife consumers of aquatic biota (CCME 2000a).

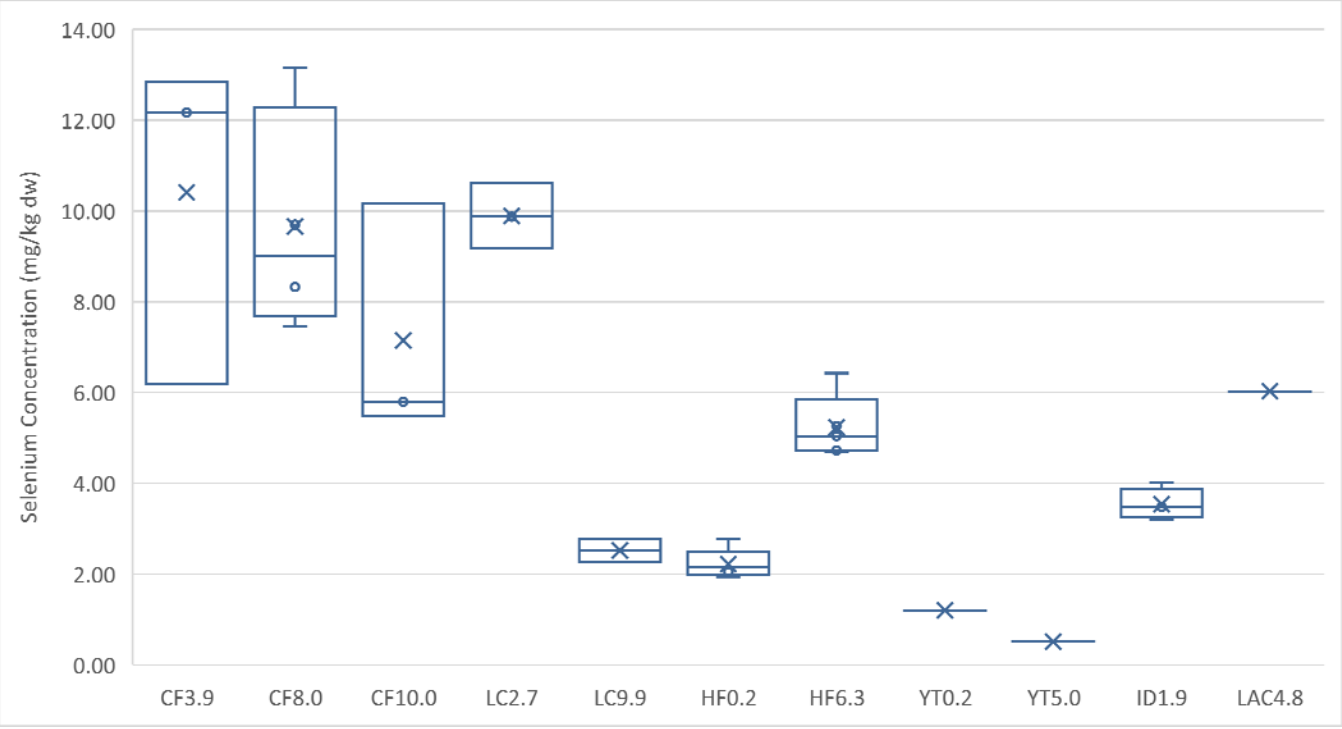

Figure 20. Selenium concentrations in benthic invertebrate tissue samples from 2017.

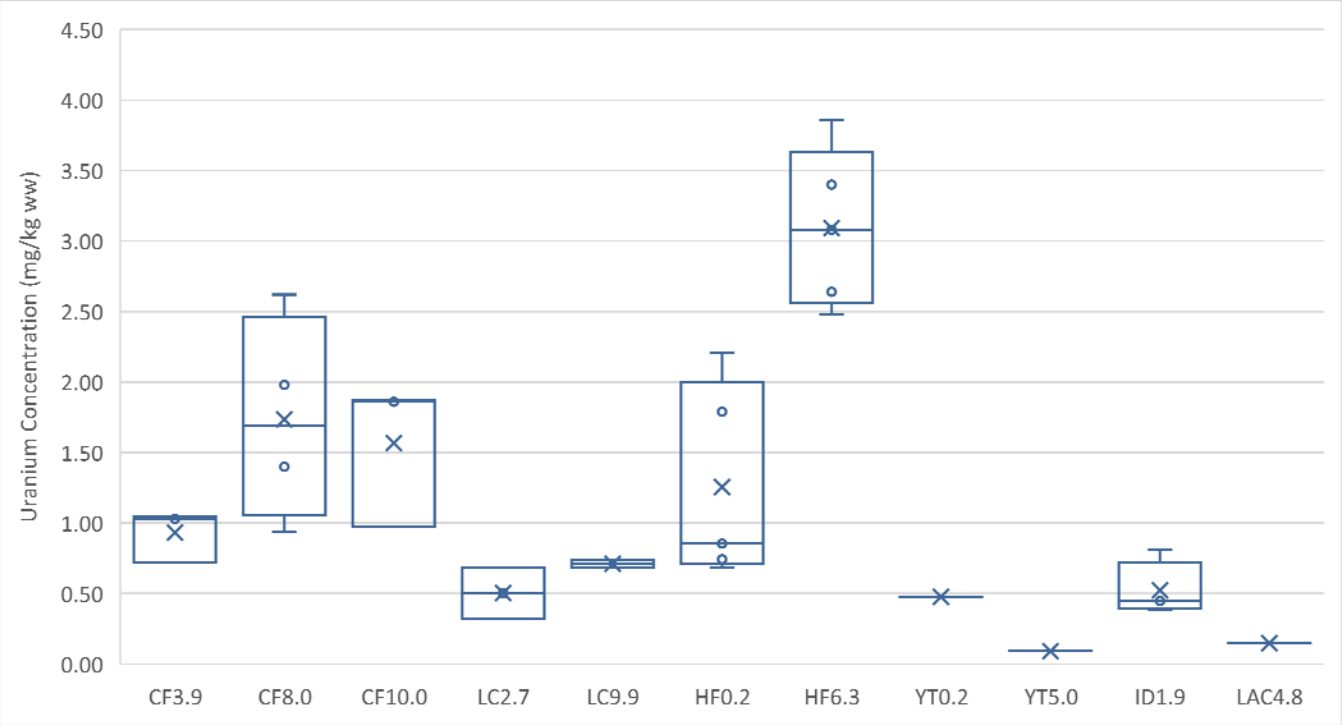

Figure 21. Uranium concentrations in benthic invertebrate tissue samples from 2017.

3.5.3 METAL CONCENTRATIONS IN PERIPHYTON TISSUES

Concentrations of metals in periphyton tissues were collected for the first time in 2017 (APPENDIX E). In general, periphyton is present in streams in the Project Area in very small amounts, limiting the sites that samples could be collected from, as well as the number of replicates that were collected at each site.

Total mercury concentrations were highest in periphyton collected from Independence Creek (ID1.9), where the mean concentration was 0.056 mg/kg ww, followed by Latte Creek (LC2.7) with a concentration of 0.044 mg/kg ww (Figure 22). Concentrations in Coffee Creek were similar across all sites with mean total mercury concentrations of 0.027 mg/kg ww, 0.029 mg/kg ww and 0.031 mg/kg ww, respectively at CF10.0, CF8.0 and CF3.9 (Figure 22). Total mercury concentrations were low in periphyton collected from lower Halfway Creek (HF0.2), with a concentration of 0.026 mg/kg ww (Figure 22).

Detection limits for selenium in periphyton tissues varied due to the small sample sizes, making review of the data difficult. Measurable tissue concentrations were similar across the project area, ranging from 0.104 mg/kg ww in samples from ID1.9 to 0.175 mg/kg ww in periphyton tissues collected from LC2.7 (APPENDIX E).

Uranium concentrations were highest in periphyton tissues collected from Halfway Creek, with a mean concentration of 5.335 mg/kg ww (Figure 23). As with mercury, uranium concentrations in periphyton collected from Coffee Creek were similar across all sampling locations, with mean concentrations of 2.442 mg/kg ww, 2.804 mg/kg ww, and 2.890 mg/kg ww, respectively at CF10.0, CF8.0 and CF3.9 (Figure

23). The lowest uranium concentration in periphyton tissues was in samples from Independence Creek (ID1.9), with a concentration of 0.767 mg/kg ww (Figure 23).

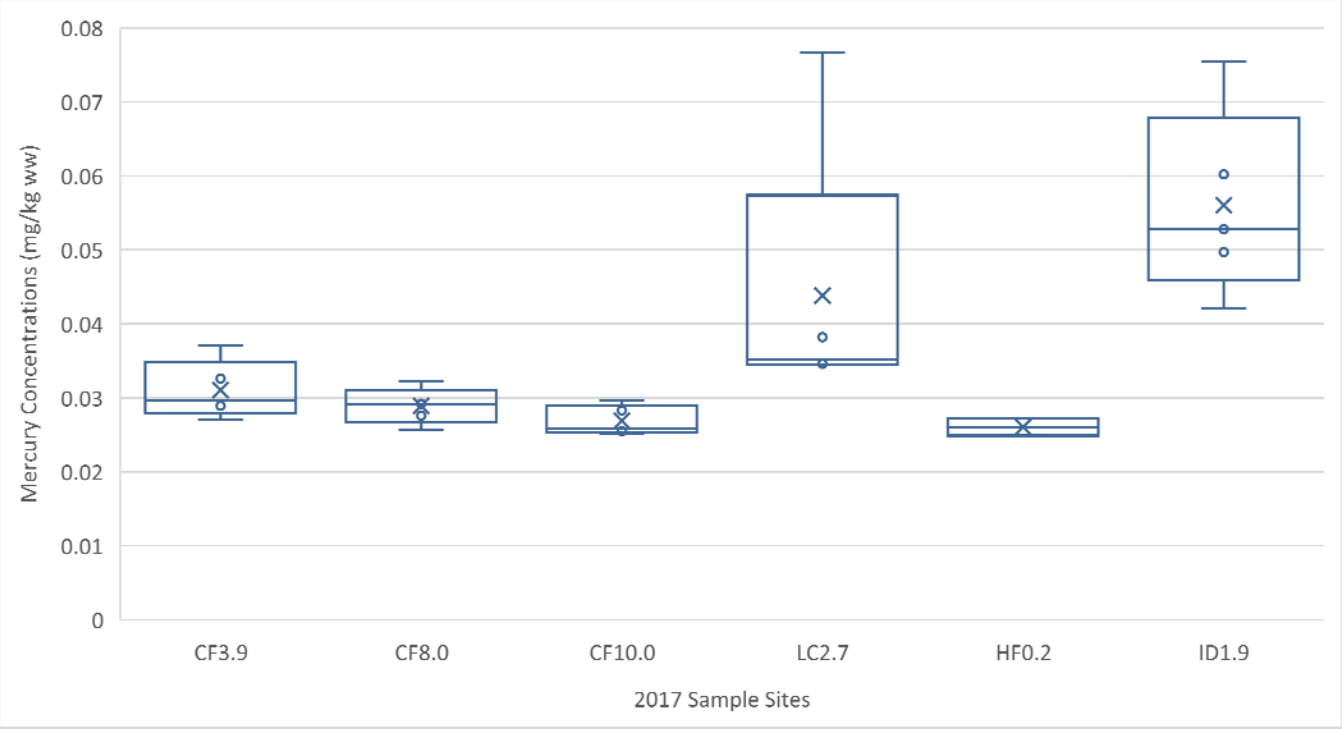

Figure 22. Mercury concentrations in periphyton tissue samples from 2017.

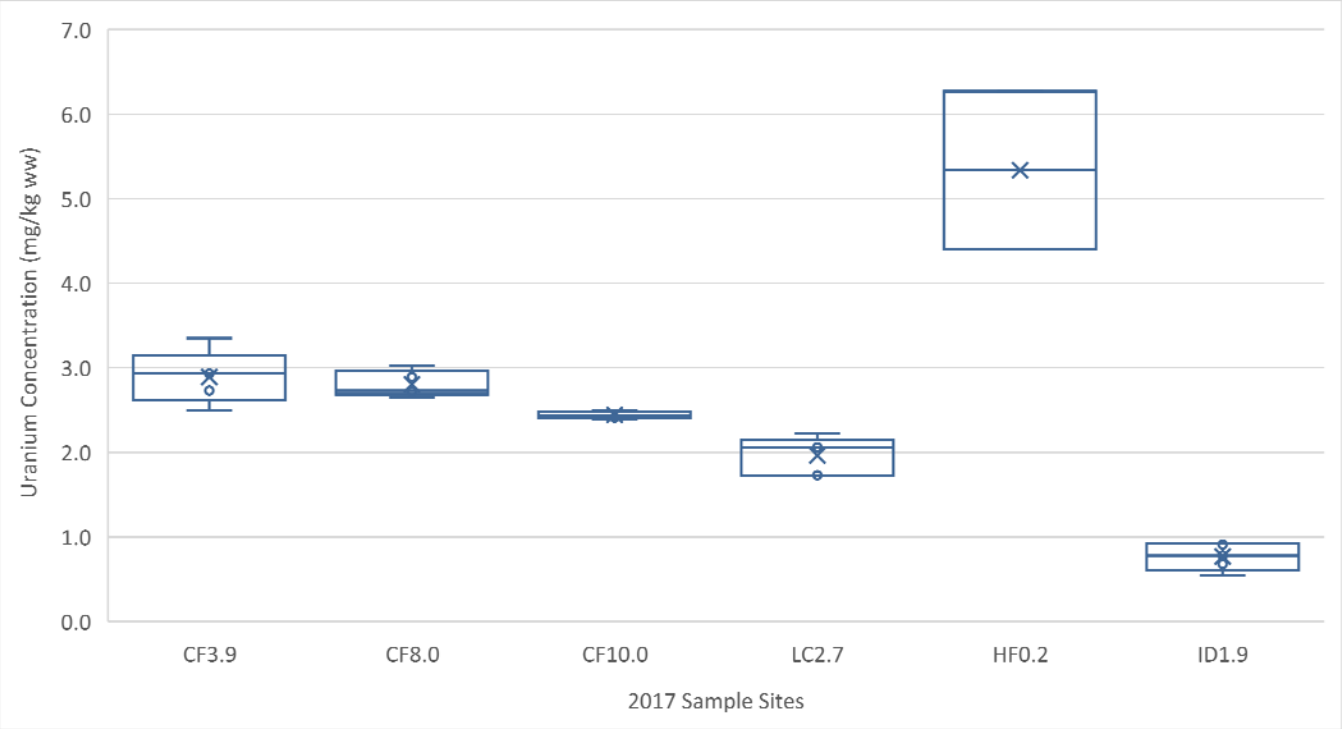

Figure 23. Uranium concentrations in periphyton tissue samples from 2017.

3.6 BENTHIC INVERTEBRATE COMMUNITY

The BEAST analysis indicated that all test sites and reference sites in 2017 belonged to Group 2 with membership probabilities ranging from 84.4% to 97.6%. As such, all test site data and reference site data were compared to Group 2 reference sites in the Yukon 2013 reference model. In 2014/2015, almost all test sites and reference sites belonged to Group 1 with membership probabilities ranging from 50.6% to 95.3%. Site LC2.7 was the exception, which belonged to Group 2 with a membership probability of 47.8%. All CABIN-generated site reports are available in APPENDIX F.

The results of the 2017 BEAST assessment indicated that 13 of the 17 sites were either similar to reference condition or mildly divergent from reference condition (Table 30). Sites ID1.9 and SYT0.6 were assessed as divergent from reference condition in 2017. Site ID1.9 was previously assessed in 2014 and 2015 as divergent and highly divergent, respectively. Site SYT0.6 was not previously assessed. Sites LaC4.8 and DM4.6 were assessed as highly divergent from reference condition in 2017. Site LaC4.8 was previously assessed in 2015 as highly divergent. Site DM4.6 was not previously assessed. All other sites assessed in 2017 that were also previously assessed in 2014 and/or 2015 generally had similar divergence classifications. Exceptions occurred at sites CF8.0 and YT0.2, which were both previously assessed in 2014 and 2015 as mildly divergent and highly divergent, respectively, before being assessed as mildly divergent in 2017. Similarly, site HF0.2 was previously assessed as mildly divergent in both 2014 and 2015 before being assessed as similar to reference in 2017.

Sites that were assessed as mildly divergent, divergent, or highly divergent from reference condition in 2014, 2015, and/or 2017 may suggest some level of natural or anthropogenic impairment. Reference sites that were determined to have some level of divergence are likely not good candidates for reference sites in the Project study area, especially those assessed as divergent or highly divergent from reference condition.

The RIVPACS analysis indicated that all test sites and reference sites in 2017 were in good condition with more taxa than expected generally observed. The O:E ratios at most of the sites ranged from 1.19 and 1.24 with lower values at sites CF3.9 and SYT3.5 (0.90 and 0.91, respectively). Values less than one indicate fewer taxa than expected were observed; however, 0.90 and 0.91 are close to one, which indicates these sites are in good condition. The O:E ratios for sites previously assessed in 2014 and/or 2015 were also greater than one; however, the O:E ratios in 2017 were generally higher indicating more taxa were observed than expected in 2017 compared to previous sample years. The exception occurred at site CF3.9, which had a lower O:E ratio in 2017 (0.90) compared to 2014 and 2015 (1.06 and 1.05, respectively).

The Bray-Curtis analysis indicated that the benthic invertebrate community structure at each test site and reference site in 2017 was dissimilar from the median reference community. The Bray-Curtis values ranged from 0.48 to 0.96. Sites YT5.0 and HF0.2 (0.48 and 0.65, respectively) were the most similar in community structure to the median reference community. Sites LaC4.8 and DM4.6 (0.96 and 0.94, respectively) were the least similar in community structure to the median reference community. The Bray-Curtis values for sites previously assessed in 2014 and/or 2015 were generally higher (ranged from 0.81-1.00) than the results in 2017 indicating the sites were more dissimilar in previous years. The exception occurred at site LC2.7, which had the same Bray-Curtis value between 2014 and 2017. Like the other CABIN analyses, the results of the Bray-Curtis analysis can be used to establish baseline conditions to compare both test and control sites to the reference condition in future monitoring years.

Table 30. CABIN results for BEAST analysis, RIVPACS analysis, and Bray-Curtis Analysis for the Coffee Gold Project in 2017.

Site	BEAST Analysis			RIVPACS Analysis			Bray-Curtis Analysis
	Group	Probability	Assessment	Expected Taxa P>0.70	Observed Taxa P>0.70	O:E (p > 0.7)	
HF0.2	2	89.6%	Similar to Reference	3.23	4.00	1.24	0.65
HF6.3	2	94.9%	Mildly Divergent	3.30	4.00	1.21	0.82
LC2.7	2	97.6%	Mildly Divergent	3.35	4.00	1.19	0.81
LC9.9	2	93.7%	Mildly Divergent	3.35	4.00	1.19	0.83
YT0.2	2	88.9%	Mildly Divergent	3.22	4.00	1.24	0.75
YT5.0	2	94.4%	Similar to Reference	3.30	4.00	1.21	0.48
CF3.9	2	95.5%	Mildly Divergent	3.32	3.00	0.90	0.83

Site	BEAST Analysis			RIVPACS Analysis			Bray-Curtis Analysis
	Group	Probability	Assessment	Expected Taxa P>0.70	Observed Taxa P>0.70	O:E (p > 0.7)	
CF8.0	2	95.3%	Mildly Divergent	3.33	4.00	1.20	0.80
CF10.0*	2	93.3%	Mildly Divergent	3.28	4.00	1.22	0.79

Sites are grouped by watershed. An asterisk (*) indicates a reference site.

3.6.1 BENTHIC INVERTEBRATE ABUNDANCE

Total abundance of benthic invertebrates ranged from 221 to 5,967 individuals per kick sample in 2017 (Figure 24) and from approximately 200 to 4,000 individuals per kick sample for comparable sites in 2014/2015. Total abundance at most sites was less than 2,000 individuals per kick sample in 2017 and less than 1,700 individuals per kick sample for comparable sites in 2014/2015. In 2017 there was notably high total abundance at sites LaC4.8 and DM4.6 (5,967 and 3,733 individuals per kick sample, respectively). In 2014/2015 there was notably high total abundance at sites ID1.9 and LaC4.8 (approximately 4,000 and 3,300 individuals per kick sample, respectively).

For watersheds with multiple sites in 2017, total abundance increased in an upstream direction on Dan Man Creek and Halfway Creek, and decreased in an upstream direction on Coffee Creek, Latte Creek, YT-24 Creek, and the stream south of YT-24 Creek. Coffee Creek and Latte Creek were the only watersheds with multiple sites that were assessed previously. Patterns of total abundance in 2014/2015 were similar to those observed in 2017 on Latte Creek and the opposite of those observed in 2017 on Coffee Creek.

EPT abundance ranged from 136 to 4,283 individuals per kick sample in 2017 (Figure 24) and from approximately 100 to 1,900 individuals per kick sample for comparable sites in 2014/2015. Similar to total abundance, EPT abundance at most sites was less than 1,200 individuals per kick sample in 2017, with notably high EPT abundance at sites LaC4.8 and DM4.6 (4,283 and 3,311 individuals per kick sample, respectively).

EPT abundance at most comparable sites in 2014/2015 was less than approximately 800 individuals, with notably high EPT abundance at site LaC4.8 (approximately 1,900 individuals per kick sample).

For watersheds with multiple sites in 2017, EPT abundance increased in an upstream direction on Dan Man Creek, Halfway Creek, and Latte Creek, and decreased in an upstream direction on Coffee Creek, YT-24 Creek, and the stream south of YT-24 Creek. Coffee Creek and Latte Creek were the only watersheds with multiple sites that were assessed previously. Patterns of EPT abundance in 2014/2015 were the opposite of those observed in 2017 in Coffee Creek and Latte Creek.

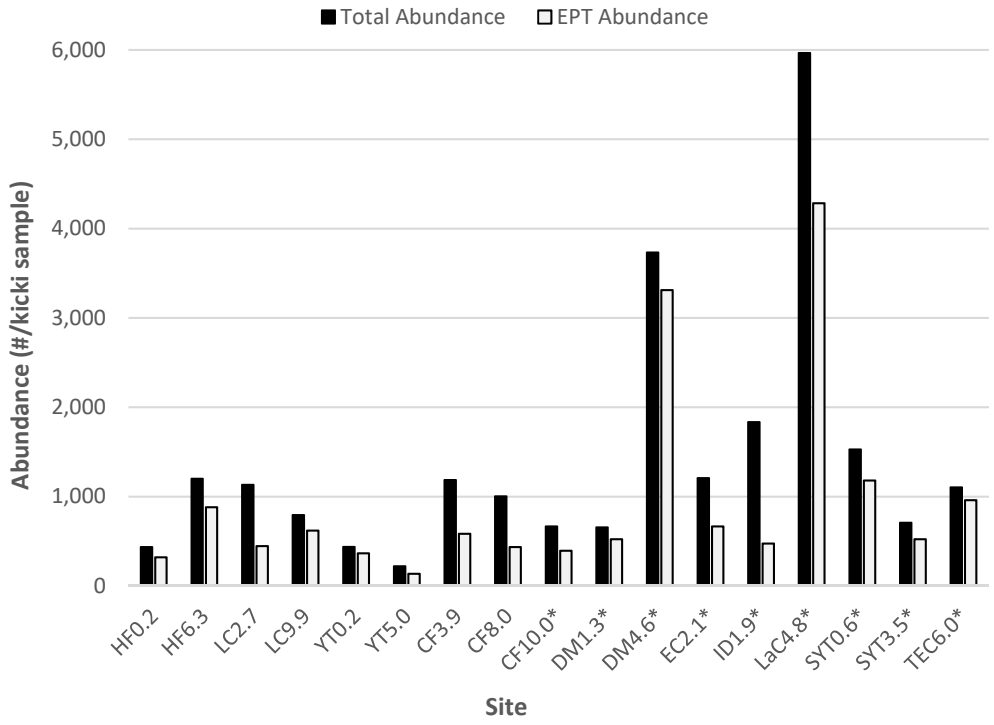

Figure 24. Benthic invertebrate total abundance and Ephemeroptera-Plecoptera-Trichoptera (EPT) abundance by site for the Coffee Gold Project in 2017. Sites are grouped by watershed. An asterisk (*) indicates a reference site.

3.6.2 BENTHIC INVERTEBRATE COMMUNITY COMPOSITION

The benthic invertebrate community at each site in 2017 was composed of primarily mayflies (Ephemeroptera), stoneflies (Plecoptera), and true flies (Diptera) + non-insects, with small amounts of caddisflies (Trichoptera) at approximately half of the sites (Figure 25). Mayflies were not documented at site SYT3.5. Caddisflies were not documented at sites DM4.6 or HF0.2, or at any sites on Los Angeles Creek, YT-24 Creek, the stream south of YT-24 Creek, or the tributary to Excelsior Creek.

Mayflies, true flies + non-insects were the most dominant groups in 2017 with each group contributing approximately 34% to overall community composition (Figure 25). Stoneflies contributed approximately 31% to overall community composition and caddisflies contributed less than 1% to overall community

composition (Figure 25). In 2014/2015, true flies were the most dominant group (approximately 50%) followed by mayflies (26%), stoneflies (21%), and small percentages of ringed worms (Annelids) and caddisflies. At sites comparable between 2014 to 2017, the percent density of EPT organisms generally increased in 2017 with the only decreases occurring at site CF3.9 (approximately 62% down to 49%) and site LC2.7 (approximately 48% down to 40%).

The majority of taxa in the EPT orders are generally considered more sensitive to pollution compared to taxa in the Diptera order; as water quality decreases, EPT abundance and richness generally decreases (Rosenberg and Resh 1993; Sylvestre et al. 2005; Environment Canada 2013). In 2017, site ID1.9 had the highest percentage of true flies and non-insects, and the lowest relative percentage of EPT organisms. Similar results were observed in 2014/2015.

For watersheds with multiple sites in 2017, the percentage of EPT organisms increased in an upstream direction on Coffee Creek, Dan Man Creek, and Latte Creek, and decreased in an upstream direction on YT-24 Creek and the stream south of YT-24 Creek. The percentage of EPT organisms fluctuated minimally between the two sites on Halfway Creek. Coffee Creek and Latte Creek were the only watersheds with multiple sites that were assessed previously. General patterns of EPT percent density in 2014/2015 were similar to those observed in 2017.

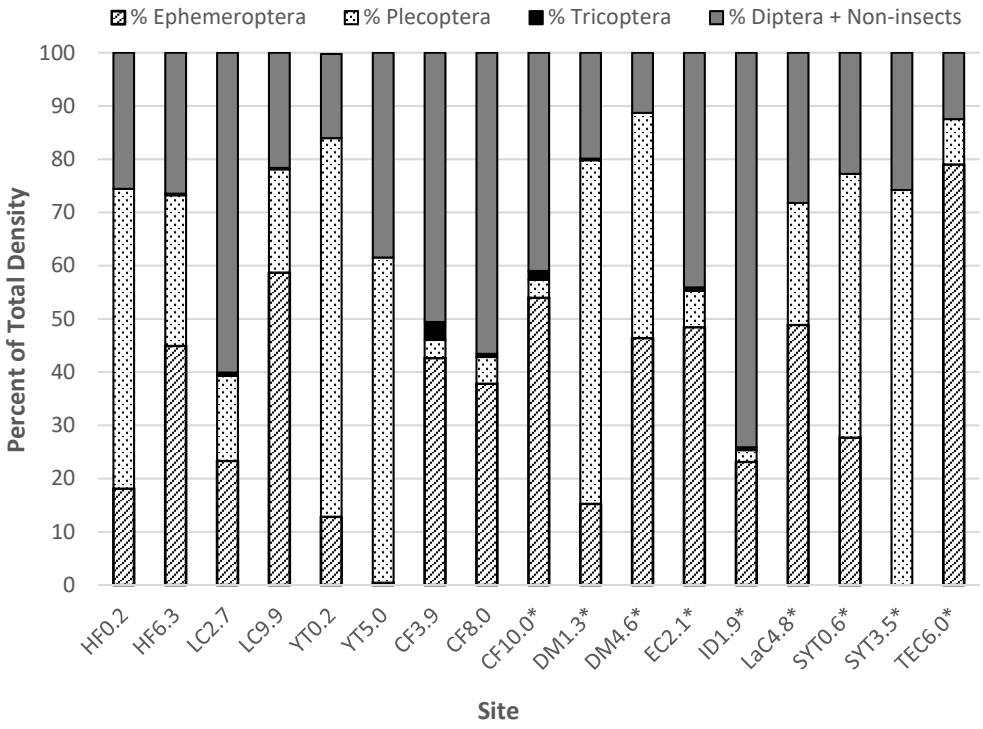

Figure 25. Relative percent densities of benthic invertebrate communities by site for the Coffee Gold Project in 2017. Sites are grouped by watershed. An asterisk (*) indicates a reference site.

3.6.3 BENTHIC INVERTEBRATE TAXONOMIC RICHNESS

Total benthic invertebrate taxonomic richness ranged from six to 17 taxa in 2017 (Figure 26). At sites comparable between 2014 to 2017, total taxonomic richness was lower in 2017 with approximately 20 to 35 taxa in 2014/2015 compared to 10 to 15 taxa in 2017. The highest total taxonomic richness in 2017 was documented at site CF10.0 (17 taxa) followed by sites CF3.9 and CF8.0 (15 and 14 taxa, respectively). The lowest total taxonomic richness in 2017 was documented at sites DM4.6 and SYT3.5 (six taxa at each site). In 2014/2015, sites on Coffee Creek and Latte Creek has the highest taxonomic richness (greater than 23 taxa per site).

For watersheds with multiple sites in 2017, total taxonomic richness increased in an upstream direction on Coffee, Creek, Halfway Creek, and Latte Creek, and decreased in an upstream direction on Dan Man Creek, YT-24 Creek, and the stream south of YT-24 Creek (SYT0.6 and SYT3.5). Coffee Creek and Latte Creek were the only watersheds with multiple sites that were assessed previously. General patterns of total taxonomic richness in 2014/2015 were the same as those observed in 2017 on Coffee Creek and stayed similar between sites on Latte Creek.

EPT richness ranged from two to nine taxa per site in 2017 (Figure 26). Similar to total taxonomic richness, the highest EPT richness was documented at sites CF10.0 and CF3.9 (nine taxa at each site) followed by site CF8.0 (eight taxa). The lowest EPT richness was documented at site SYT3.5 (two taxa). EPT richness for 2014/2015 was not presented in PECG (2017).

Within-watershed patterns for EPT richness in 2017 were similar to within-watershed patterns for total taxonomic richness in 2017, with the exception that EPT richness stayed the same between sites on Latte Creek and YT-24 Creek. The highest site in the watershed on Coffee Creek also had the same EPT richness as the lowest site.

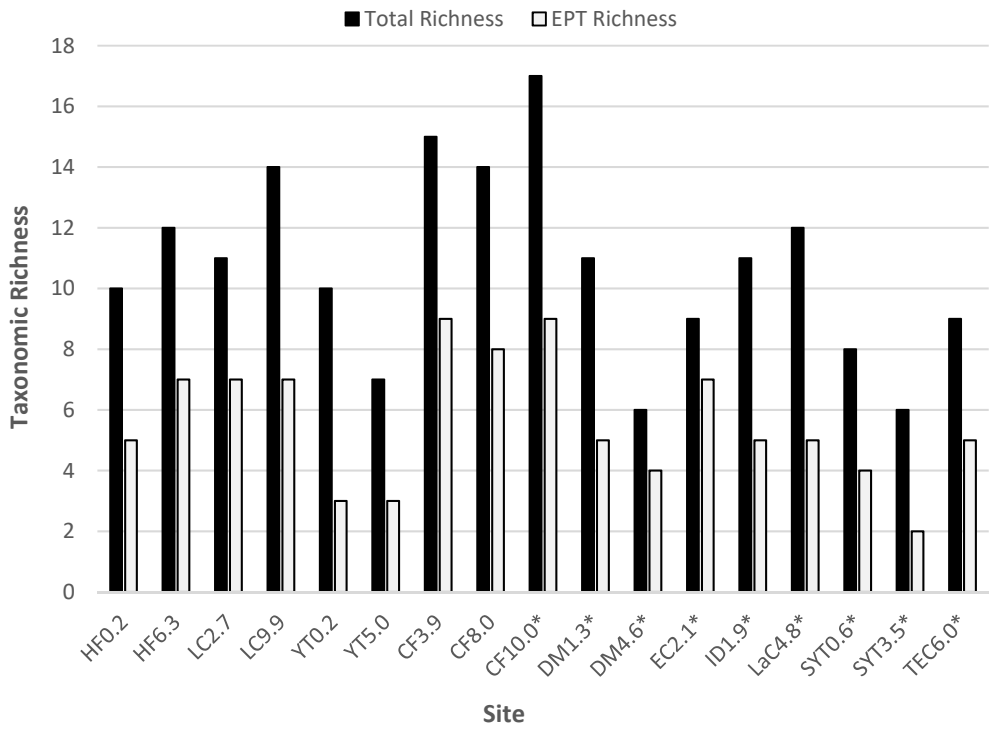

Figure 26. Total taxonomic richness and Ephemeroptera-Plecoptera-Trichoptera (EPT) richness of benthic invertebrate communities by site for the Coffee Gold Project in 2017. Sites are grouped by watershed. An asterisk (*) indicates a reference site.

3.6.4 BENTHIC INVERTEBRATE DIVERSITY AND EVENNESS

Simpson's diversity values ranged from 0.39 to 0.82 in 2017 (Figure 27). At sites comparable between 2014 to 2017, Simpson's diversity was 0.72 to 0.92 in 2014/2015 versus 0.50 to 0.79 in 2017. Site CF10.0 had the highest diversity value (0.82) in 2017 and site TEC6.0 had the lowest diversity value (0.39) in 2017. At the watershed level in 2017, the three sites on Coffee Creek had the highest diversity values (0.78-0.82) and the three sites on YT-24 Creek and the tributary to Excelsior Creek had the lowest diversity values (0.39-0.53). The remaining sites in 2017 had intermediate diversity values (0.61 to 0.77). In 2014/2015, sites on Coffee Creek, Latte Creek, and Los Angeles Creek had the highest diversity values (greater than approximately 0.83).

For watersheds with multiple sites in 2017, Simpson's diversity increased in an upstream direction on Coffee Creek, Dan Man Creek, Halfway Creek, and YT-24 Creek, and decreased in an upstream direction on Latte Creek and the stream south of YT-24 Creek. Coffee Creek and Latte Creek were the only watersheds with multiple sites that were assessed previously. General patterns of diversity in 2014/2015 were similar to those observed in 2017 on Coffee Creek and the opposite of those observed in 2017 on Latte Creek.

Simpson's evenness values ranged from 0.18 to 0.53 in 2017 (Figure 27). At sites comparable between 2014 to 2017, Simpson's evenness ranged from approximately 0.20 to 0.43 in 2014/2015 versus 0.18 to 0.39 in

2017. Site SYT0.6 had the highest evenness value (0.53) in 2017 and site LC9.9 had the lowest evenness value (0.18) in 2017. In 2014/2015, site LC9.9 had the highest evenness value (approximately 0.43).

Within-watershed patterns for Simpson's evenness in 2017 were similar to within-watershed patterns for Simpson's diversity in 2017. Coffee Creek and Latte Creek were the only watersheds with multiple sites that were assessed previously. General patterns of evenness in 2014/2015 were similar to those observed in 2017 on Coffee Creek and the opposite of those observed in 2017 on Latte Creek.

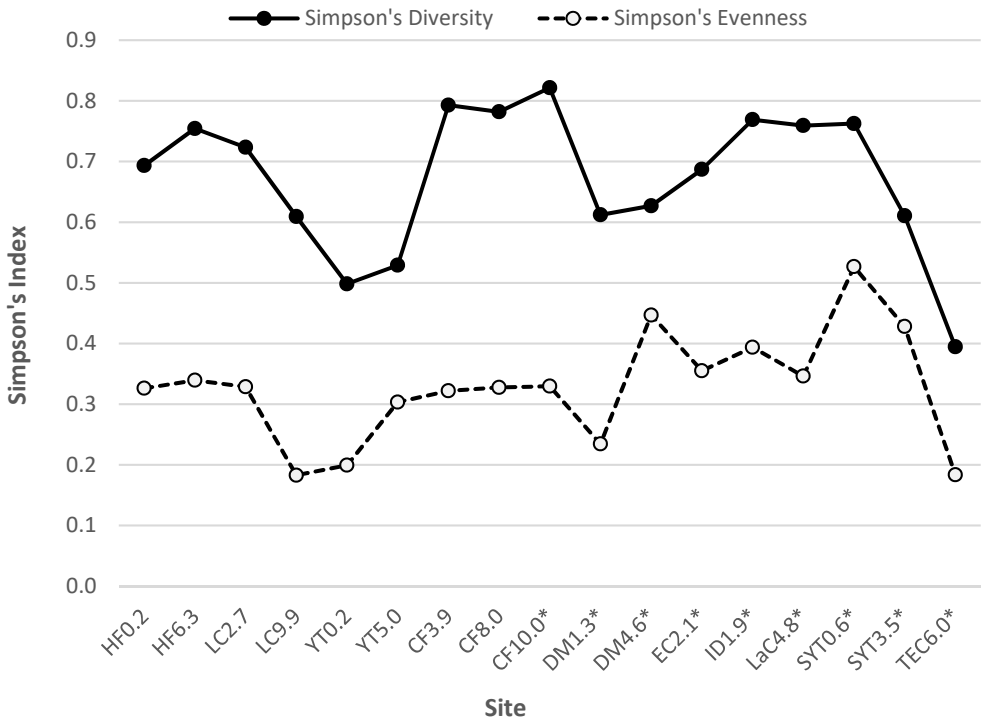

Figure 27. Simpson's diversity and evenness indices of benthic invertebrate communities by site for the Coffee Gold Project in 2017. Sites are grouped by watershed. An asterisk (*) indicates a reference site.

3.7 PERIPHYTON: CHLOROPHYLL–A AND ASH-FREE DRY MASS

Chlorophyll-a and ash-free dry mass (AFDM) were again measured in 2017. Prior to 2017 chlorophyll-a and AFDM were both measured in 2014 and 2015, and chlorophyll-a was measured in 2016 to address exceeded laboratory holding times associated with 2014 and 2015 sampling.

Chlorophyll-a concentrations in 2017 were similar to 2014 and 2015 data (Figure 28); higher concentrations in 2016 may have been associated with a warmer winter season in 2015/2016, followed by an earlier, warmer spring in 2016. In 2017, Chlorophyll-a was highest in Coffee Creek (CF 3.9 and CF10.0), with concentrations of 2.95 and 2.44 mg/m^2, respectively. The lowest concentrations were found in upper Latte Creek (LC9.9),

and lower YT-24 (YT0.2) with concentrations of 0.09 and 0.10 mg/m², respectively. Both Coffee Creek locations are located in a wide valley, with large amounts of available sunlight in the summer season, while upper Latte Creek and lower Halfway Creek sampling sites are located in headwater V shaped valleys with less exposure; it has been previously reported that differences in chlorophyll-a content may have been due to varying light conditions, nutrient availability, and periphyton taxonomy, which results in different proportions of photosynthetic:non-photosynthetic organisms that comprise periphyton (Barbour et al. 1999).

Ash-free dry mass was also low in 2017. As with chlorophyll-a results, the highest AFDM was from Coffee Creek (CF 3.9 and CF10.0), with concentrations of 6.35 and 11.04 g/m², respectively (Figure 29). Again, the lowest AFDM was found at upper Latte Creek (LC9.9) and lower YT-24 (YT0.2) with concentrations of 0.42 and 0.42 g/m², respectively. Concentrations of AFDM vary widely and there is little between year or between site correlations over the sampling years. Concentrations are low enough that small variations in temperature, weather and water quality may result in changing AFDM amounts.

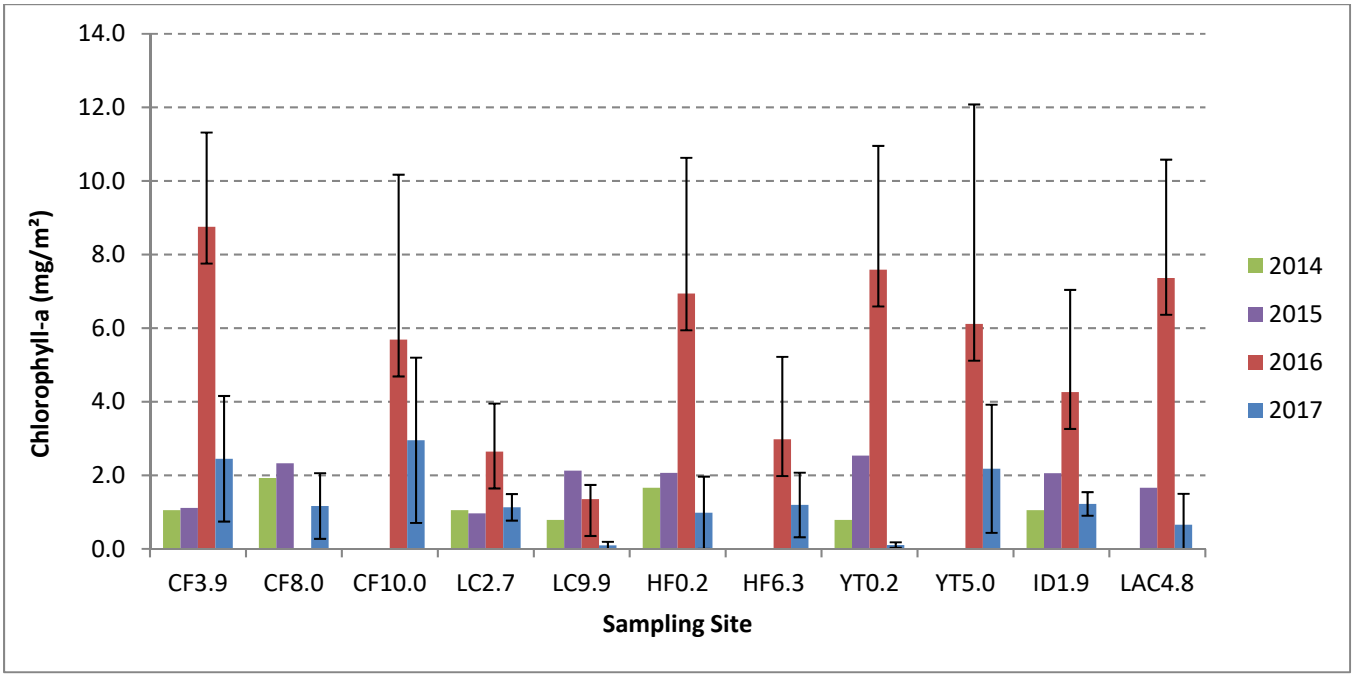

Figure 28. Mean and standard deviation for chlorophyll-a concentrations throughout the Coffee Creek mine site from 2014 through 2017. Data from 2014 and 2015 reflects composite samples for which no error bars can be calculated, mean data and standard deviation for 2016 and 2017 was calculated from five to six samples per site collected and analysed from each sample location.

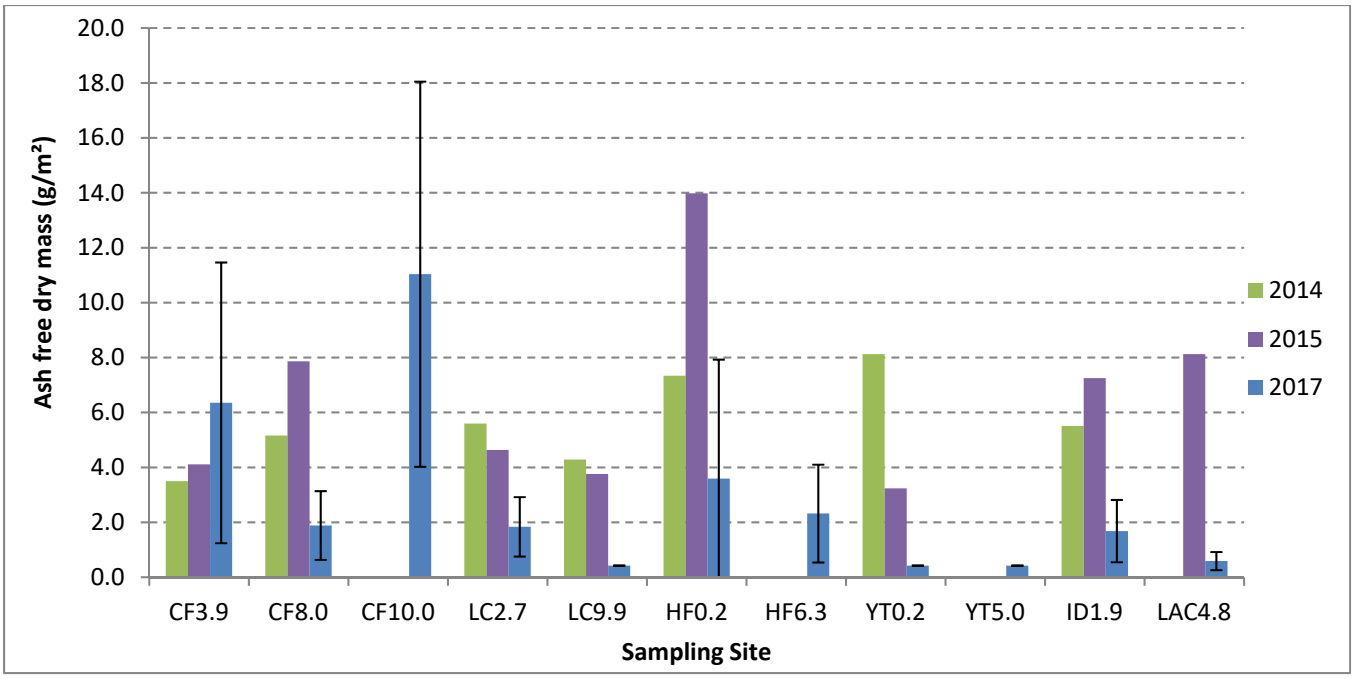

Figure 29. **Mean and standard deviation for ash free dry mass (AFDM) concentrations throughout the Coffee Creek mine site from 2014 through 2017. Data from 2014 and 2015 reflects composite samples for which no error bars can be calculated, mean data and standard deviation for 2017 was calculated from six samples per site collected and analysed from each sample location. LC9.9, YT0.2, and YT5.0 sample analysis indicated that AFDM was below detection in all samples. Figure was created using the detection limit for those sites.**

3.8 SEDIMENT

3.8.1 PARTICLE SIZE DISTRIBUTION

Sediment samples were collected from depositional areas along the margins and in pools. Samples collected from Coffee Creek (CF3.9, CF8.0 and CF10.0) were mostly composed of sand sized particles (2.0 - 0.063 mm), with percentages of 67, 77 and 91%, respectively. There were lesser amounts of silt (0.063 mm - 4 µm), and small amounts of clay (<4µm) and gravel (>2 mm; Figure 30). The sample from lower Latte Creek (LC2.7) has 76% sand, 15% silt, 7.5 % gravel and small amounts of clay. Upper Latte Creek had 50% sand, 38% silt, and smaller amounts of gravel and clay. Lower Halfway Creek had 51% sand, 38% silt and smaller amounts of gravel and clay. Upper Halfway Creek (HF6.3) was 84% sand, with smaller amount of silt, gravel and clay. Samples from upper and lower YT-24 had larger amounts of silt (67% and 47%, respectively, and 26 and 46% respectively of sand, and smaller amounts of gravel and clay. Independence and Los Angeles Creeks had large amount of sand (75 and 61%, respectively) and smaller amounts of silt and gravel. Independence Creek had a small amount of gravel, while the sample from Los Angeles Creek had undetectable amounts of gravel.

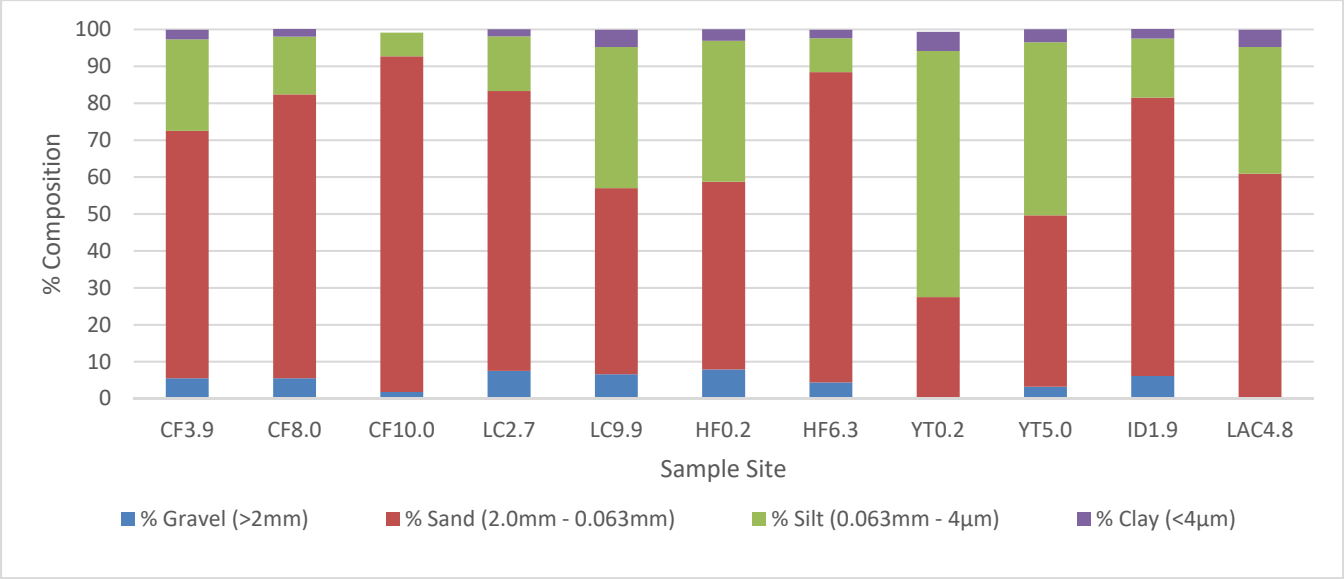

Figure 30. Sediment particle size distribution by site.

3.8.2 METAL CONCENTRATIONS IN SEDIMENT

Sediment samples were collected in 2017 for metals analysis. Previously, analyses of baseline metals concentrations in stream sediments collected in the study area in 2014 and 2015 (PECG 2017) indicated that arsenic and chromium were consistently present at concentrations that exceeded the CCME Interim Freshwater Sediment Quality Guidelines (ISQG; CCME 2000b). Data from 2017 also indicated that concentrations of arsenic and chromium were elevated across the Mine Site area (Table 31; Figure 31). Concentrations of arsenic exceeded the ISQG in samples collected from all sites, while samples from Latte Creek (LC2.7), Halfway Creek (HF0.2 and HF6.3) and YT-24 (YT5.0) also exceeded the Probable Effects Level (PEL; CCME 2000b).

Chromium concentrations in sediment exceeded the ISQG in all sample locations except Coffee Creek at (Table 31; Figure 32). Also, chromium concentrations in sediment from Latte Creek (LC2.7) exceeded the PEL.

Sediment quality guidelines (ISQGs and PELs) also exist for cadmium, copper, lead, mercury, and zinc. Concentrations of these metals in sediment from all sample sites were below these guidelines (Figure 32, Figure 33, Figure 34, Figure 35, Figure 36, Figure 37).

Table 31. Sediment quality parameters exceeding applicable CCME guidelines including the Interim Freshwater Sediment Quality Guideline (ISQG) and the Probable Effects Level (PEL); 2017.

Creek	Sample Site	Interim Freshwater Sediment Quality Guideline (ISQG)	Probable Effects Level (PEL)
Coffee	CF3.9	arsenic chromium	
	CF8.0	arsenic	
	CF10.0	arsenic chromium	
Latte	LC2.7	arsenic chromium	arsenic chromium
	LC9.9	arsenic chromium	
Halfway	HF0.2	arsenic chromium	arsenic
	HF6.3	arsenic chromium	arsenic
YT-24	YT0.2	arsenic	
	YT5.0	arsenic chromium	arsenic
Independence	ID1.9	arsenic chromium	
Los Angeles	LaC4.8	arsenic chromium

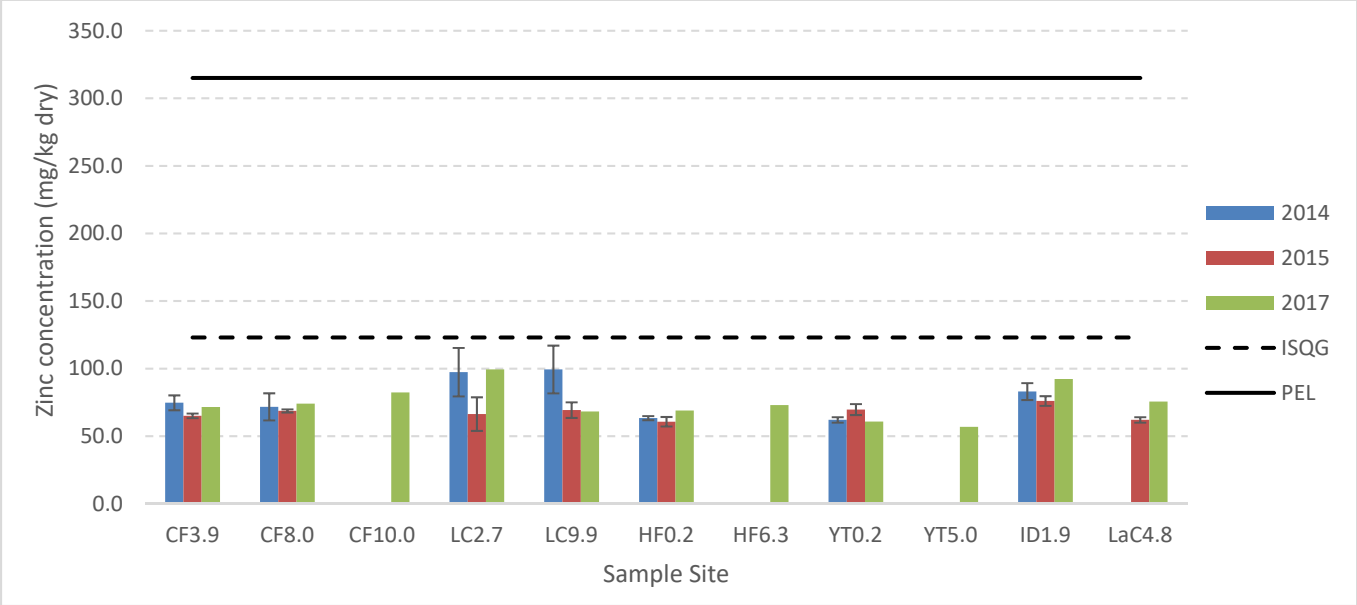

Figure 37. Zinc concentrations in sediment. The 2014 and 2015 data present mean and standard deviation, while 2017 results present concentration in a composite sample. The solid black line is CCME Interim Sediment Quality Guideline (ISQG) and dashed black line is CCME Probable Effects Level (PEL) guideline.

4 RESULTS AND DISCUSSION – NORTHERN ACCESS ROUTE STUDY AREA

Results and discussion for the Northern Access Route Study area are described in the below sections.

4.1 BARGE LANDINGS – YUKON

Past work at the barge landings on the Yukon River indicates that the sites are located in areas that have typical streambank habitat associated with these large rivers. The right bank landing site is in a location where the river banks are vertical, and the river is deep and not conducive to beach seining (Photo 24); similar habitat upstream of this site was minnow trapped in 2016 (EDI 2017). On the left bank, the landing site is in an area with sloping banks/riverbed (Photo 25). Sampling was conducted in the Yukon River to provide additional information on fish species presence within the vicinity of the proposed barge landings and an existing landing site near the current mine camp. Due to the vertical banks at the right bank, beach seining was completed approximately 70 m downstream of the proposed barge landing.

Photo 24. View of proposed barge landing site on the right bank of Yukon River, showing vertical banks.

Photo 25. View of proposed barge landing on the left bank of Yukon River showing sloping lower banks.

A total of four species were captured during the 2017 Yukon River sampling at/near the proposed barge landings (n = 61; Table 32). Similar to the results of 2016, juvenile Chinook were the most frequently captured species in the Yukon River, comprising almost 80% of the catch (n = 48), and were captured in all seven seine hauls at the proposed barge landings (Table 32). Arctic grayling were the next most common species caught (n = 7), then longnose sucker (n = 4), and lastly slimy sculpin (n = 2). An additional seine haul was conducted at an existing barge landing at Coffee camp and captured eight juvenile Chinook salmon (Table 32).

Table 32. Summary of 2017 beach seine sampling methods for current and proposed barge landing locations along the Yukon River.

Location	Sample Site	Sampling Effort			Number of Fish Captured
		Length (m)	Width (m)	Area (m²)	
Right Bank – Downstream of Proposed Barge Landing	YRU1.9	8	6	48	1 Juvenile CH
Right Bank - Downstream of Proposed Barge Landing	YRU1.9	10	7	70	3 Juvenile CH
					2 LSU
Right Bank - Downstream of Proposed Barge Landing	YRU1.9	10	7	70	1 Juvenile CH
Right Bank - Downstream of Proposed Barge Landing	YRU1.9	10	7	70	1 CCG
					2 Juvenile CH
					1 LSU
Left Bank – Proposed Barge Landing	YRU1.6	10	6	60	12 Juvenile CH
					2 GR
Left Bank – Proposed Barge Landing	YRU1.6	10	5	50	1 CCG
					19 Juvenile CH
					5 GR
					1 LSU
Left Bank – Proposed Barge Landing	YRU1.6	10	6	60	10 Juvenile CH
Left Bank – Existing Barge Landing	YRD2.1	10	7	70	8 Juvenile CH

Notes: CH – Chinook salmon; CCG - slimy sculpin, GR, Arctic grayling, LSU – longnose sucker

4.2 STEWART RIVER BACK CHANNEL

Previous investigations indicated this channel had limited fish habitat during low flows in the Stewart River (PECG 2016 and EDI 2017). During the September 3rd site visit the channel was mainly dry with only a few isolated puddles of water present. In the vicinity of the encroachment areas, this channel appears to be only wetted during high flows in the Stewart River and is most likely used as refuge habitat by species utilizing the area downstream (i.e., lake chub, northern pike and perhaps whitefish). The channel bottom consists of fines and organics. No critical habitats will be affected by the encroachment on the edge of this channel.

Photo 26. Downstream view of Stewart River back channel in the vicinity of an encroachment area (right side of photo).

Photo 27. Upstream view of Stewart River back channel in the vicinity of an encroachment area (left side of photo).

4.3 CHUM SPAWNING SURVEYS

In October 2017, the Yukon River was ice-free in the main channel, with a few side channels partially ice covered. The Stewart River had ice pans forming and a significant number of side channels were entirely ice covered, making it more difficult to detect spawning chum. There were approximately 907 spawning chum salmon and 482 carcasses observed in the Yukon River; conversely, there were 102 spawning chum salmon and 25 carcasses observed in the Stewart River (Figure 39, Figure 40, Figure 41). There were 38 redds observed in the Yukon River and nine in the Stewart River (Figure 40).

For perspective, at the Eagle SONAR station in 2017, the Yukon River chum salmon run was quantified at 419,099; this is substantially higher than during 2016 (161,027), or the five-year (2012-2016) average of chum returns on the Yukon River (165,810; Figure 38; Alaska Department of Fish and Game 2017).

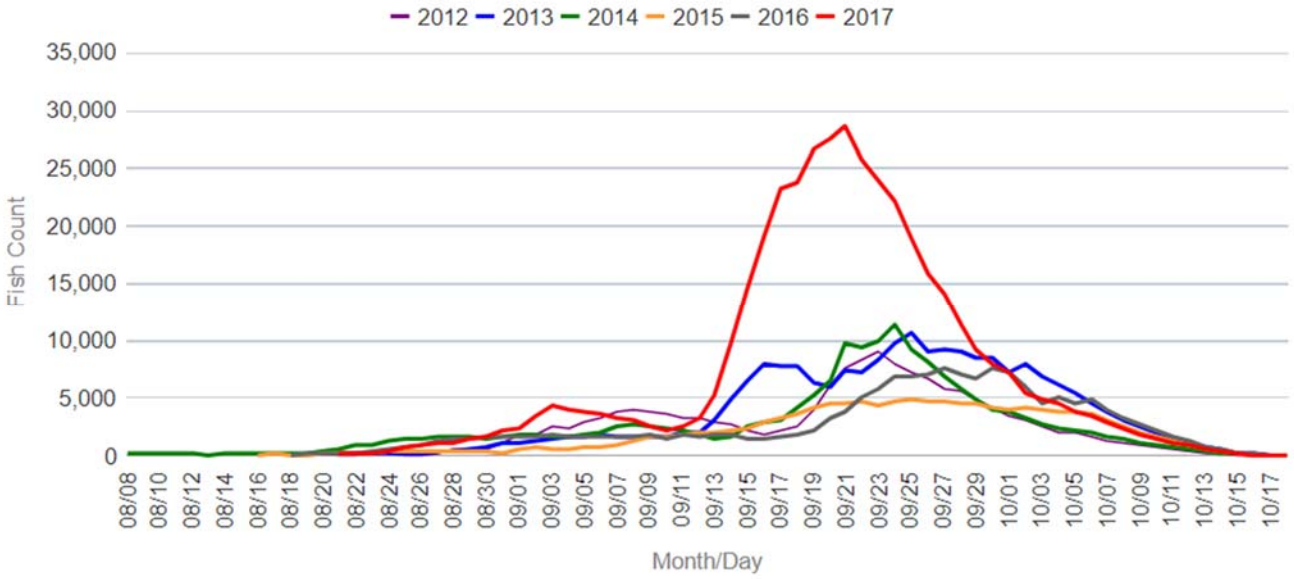

Figure 38. Eagle Sonar (Yukon/Canadian Border) historical daily passage of chum salmon (Alaska Department of Fish and Game, 2017)

In the Yukon River in 2017, there were substantially more chum salmon observed than in previous surveys; including in areas where chum salmon activity was not previously documented. Many of the locations where redds were found in the 2013 and 2016 surveys (Figure 40) had notable ice cover in 2017 and thus limited redds were observed in these locations. However, notable numbers of live chum were observed in these locations (Figure 39) and it is presumed that considerable spawning did occur in these areas. These side channels are fed by groundwater, which are typical of chum spawning locations (refer to EDI 2017). Geist et. al. (2002) report that chum salmon spawn in upwelling water that is typically warmer than the surrounding river. However, 2017 surveys also found an expansion of spawning activity in the Yukon River to include a

few main channel areas primarily near the mouth of Coffee Creek and near some mid-channel islands. Such expansion of activity is thought to be related to the high returns to the system in 2017. No activity was observed at the barge or winter road landings, the closest redd was located approximately 200 m upstream of the south winter road crossing in a side channel (Figure 40).

In the Stewart River fewer live fish, redds and carcasses were observed than the Yukon River; however, observed activity was higher than in 2016. The activity that was observed was typically associated with side channels downstream of the NAR. No spawning activity was documented near the barge landings.

Notes:

Fish species codes as follows: GR = Arctic grayling, CH = Chinook salmon (juvenile), CCG = Slimy sculpin, LSU = Longnose sucker.

APPENDIX E. 2017 TISSUE METALS DATA; FISH AND BENTHIC INVERTEBRATE AND PERIPHYTON

This page is intentionally blank.

Table E- 1 Tissue metals data collected from fish tissues, benthic invertebrates and periphyton in 2017, aluminum through manganese.

Notes:
GR – Arctic grayling
CCG – slimy sculpin
P = periphyton
BI – benthic invertebrate
WB – whole body

Table E- 2 Tissue metals data collected from fish tissues, benthic invertebrates and periphyton in 2017, mercury through zirconium.

Qualifiers for Individual Parameters Listed:

Qualifier	Description
DLA	Detection Limit adjusted for required dilution
DLIS	Detection Limit Adjusted: Insufficient Sample
DUP-H	Duplicate results outside ALS DQO, due to sample heterogeneity.
MB-LOR	Method Blank exceeds ALS DQO. Limits of Reporting have been adjusted for samples with positive hits below 5x blank level.
RRR	Refer to Report Remarks for issues regarding this analysis

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
HG-WET-CVAFS-N-VA	Tissue	Mercury in Tissue by CVAFS (WET)	EPA 200.3, EPA 245.7

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Analysis is by atomic fluorescence spectrophotometry or atomic absorption spectrophotometry, adapted from US EPA Method 245.7.

HG-WET-MICR-CVAF-VA	Tissue	Mercury in Tissue by CVAFS Micro (WET)	EPA 200.3, EPA 245.7

This method is adapted from US EPA Method 200.3 "Sample Procedures for Spectrochemical Determination of Total Recoverable Elements in Biological Tissues" (1996). Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with repeated additions of hydrogen peroxide. Analysis is by atomic fluorescence spectrophotometry or atomic absorption spectrophotometry, adapted from US EPA Method 245.7.

MET-WET-CCMS-MID-VA	Tissue	Metals in Tissue by CRC ICPMS (WET)	EPA 200.3/6020A

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen

Reference Information

peroxide. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.

MET-WET-CCMS-N-VA Tissue Metals in Tissue by CRC ICPMS (WET) EPA 200.3/6020A

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.

MET-WET-MICR-HRMS-VA Tissue Metals in Tissue by HR-ICPMS Micro (WET) EPA 200.3/200.8

Trace metals in tissue are analyzed by high resolution inductively coupled plasma mass spectrometry (HR-ICPMS) modified from US EPA Method 200.8, (Revision 5.5). The sample preparation procedure is modified from US EPA 200.3. Analytical results are reported on wet weight basis.

Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.

MOISTURE-BIOPSY-VA Tissue Moisture Content (low weight) in tissue Puget Sound WQ Authority, Apr 1997

This analysis is carried out gravimetrically by drying the sample at <60 deg. C for a minimum of three days.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.
mg/kg - milligrams per kilogram based on dry weight of sample.
mg/kg wwt - milligrams per kilogram based on wet weight of sample.
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.
mg/L - milligrams per litre.
< - Less than.
D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Reference Information

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
AREA SAMPLED-VA	Biota	Area Sampled (cm2)	Not Applicable
ASHFREE-DRYWT-VA	Biota	Ashfree Dry Weight in Biota	APHA 10300 C

This analysis is done using procedures modified from APHA 10300 Peryphyton Sample Analysis. Ash Free Dry Weight is determined by the difference between 'Dry Weight' and 'Ash Weight' which are both determined gravimetrically. Dry Weight is determined by drying the sample at 105 "C and the Ash Weight is subsequently determined by ashing the dried sample at 500 "C. Note: Biota samples are typically submitted as scrapings on a filter.

CHLOROA-F-VA	Biota	Chlorophyll a in Biota by Fluorometer	EPA 445.0

This analysis is done using procedures adapted from EPA Method 445.0. Chlorophyll-a is determined by a routine acetone extraction followed with analysis by fluorometry using the non-acidification procedure. This method is not subject to interferences from chlorophyll b. Note: Biota samples are typically submitted as scrapings on a filter.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.
mg/kg - milligrams per kilogram based on dry weight of sample.
mg/kg wwt - milligrams per kilogram based on wet weight of sample.
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.
mg/L - milligrams per litre.
< - Less than.
D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Reference Information

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
C-TIC-PCT-SK	Soil	Total Inorganic Carbon in Soil	CSSS (2008) P216-217

A known quantity of acetic acid is consumed by reaction with carbonates in the soil. The pH of the resulting solution is measured and compared against a standard curve relating pH to weight of carbonate.

C-TOC-CALC-SK	Soil	Total Organic Carbon Calculation	CSSS (2008) 21.2

Total Organic Carbon (TOC) is calculated by the difference between total carbon (TC) and total inorganic carbon. (TIC)

C-TOT-LECO-SK	Soil	Total Carbon by combustion method	CSSS (2008) 21.2

The sample is ignited in a combustion analyzer where carbon in the reduced CO2 gas is determined using a thermal conductivity detector.

HG-63UM-CVAF-VA	Soil	Hg in Soil by CVAFS	EPA 200.2/245.7

This analysis is carried out using procedures from CSR Analytical Method: "Strong Acid Leachable Metals (SALM) in Soil", BC Ministry of Environment, 26 June 2009, and procedures adapted from EPA Method 200.2. The sample is manually homogenized, dried at 60 degrees Celsius, sieved through a 63 um (230 mesh) sieve, and a representative subsample of the dry material is weighed. The sample is then digested at 95 degrees Celsius for 2 hours by block digester using concentrated nitric and hydrochloric acids. Instrumental analysis is by atomic fluorescence spectrophotometry or atomic absorption spectrophotometry (EPA Method 245.7).

Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may be environmentally available. By design, elements bound in silicate structures are not normally dissolved by this procedure as they are not usually mobile in the environment.

Deviation from Reference Method: This procedure deviates from the BC CSR SALM method, which specifies sieving to 2 mm (10 mesh).

IC-CACO3-CALC-SK	Soil	Inorganic Carbon as CaCO3 Equivalent	Calculation
MET-63UM-CCMS-VA	Soil	Metals in Soil by CRC ICPMS	EPA 200.2/6020A

This analysis is carried out using procedures from CSR Analytical Method: "Strong Acid Leachable Metals (SALM) in Soil", BC Ministry of Environment, 26 June 2009, and procedures adapted from EPA Method 200.2. The sample is manually homogenized, dried at 60 degrees Celsius, sieved through a 63 um (230 mesh) sieve, and a representative subsample of the dry material is weighed. The sample is then digested at 95 degrees Celsius for 2 hours by block digester using concentrated nitric and hydrochloric acids. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modifed from EPA Method 6020A).

Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may be environmentally available. By design, elements bound in silicate structures are not normally dissolved by this procedure as they are not usually mobile in the environment.

PH-1:2-VA	Soil	pH in Soil (1:2 Soil:Water Extraction)	BC WLAP METHOD: PH, ELECTROMETRIC, SOIL

This analysis is carried out in accordance with procedures described in the pH, Electrometric in Soil and Sediment method - Section B Physical/Inorganic and Misc. Constituents, BC Environmental Laboratory Manual 2007. The procedure involves mixing the dried (at <60°C) and sieved (No. 10 / 2mm) sample with deionized/distilled water at a 1:2 ratio of sediment to water. The pH of the solution is then measured using a standard pH probe.

PSA-PIPET+GRAVEL-SK	Soil	Particle size - Sieve and Pipette	SSIR-51 METHOD 3.2.1

Particle size distribution is determined by a combination of techniques. Dry sieving is performed for coarse particles, wet sieving for sand particles and the pipette sedimentation method for clay particles.

Burt, R. (2009). Soil Survey Field and Laboratory Methods Manual. Soil Survey Investigations Report No. 5. Method 3.2.1.2.2. United States Department of Agriculture Natural Resources Conservation Service.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
SK	ALS ENVIRONMENTAL - SASKATOON, SASKATCHEWAN, CANADA
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

Reference Information

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.
mg/kg - milligrams per kilogram based on dry weight of sample.
mg/kg wwt - milligrams per kilogram based on wet weight of sample.
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.
mg/L - milligrams per litre.
< - Less than.
D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

EXECUTIVE SUMMARY

Aquatic data has been collected for several years at the Coffee Gold Project (herein referred to as the Project), with Environmental Dynamics Inc. (EDI) collecting baseline and monitoring data annually since 2016. Fieldwork in 2018 was intended to supplement existing pre-project data and provide additional monitoring data to allow for future comparisons following mine operation. The 2018 field season occurred over the months of July and August, with a focus on environmental DNA (eDNA), fish sampling, fish habitat assessments, barge wake investigations, and aerial surveys on salmon spawning.

Specifically, eDNA sampling was conducted on creeks with existing information on fish presence (e.g., Halfway and YT-24 creeks) as well as creeks where eDNA has not been conducted (e.g., Dan Man, Kona Tributary, Independence Creek Tributary A and B). Minnow trapping was completed on Coffee Creek, and electrofishing was performed on Halfway and YT-24 creeks, as well as upper Independence Creek (IC), and IC Tributary A and B (new to 2018). Beach seining was conducted in the Halfway and YT-24 Creek mixing zones within the Yukon River, and the Stewart River back channel that extends along the proposed Northern Access Route (NAR). Proposed barge landing sites were also beach seined on the Yukon and Stewart rivers. The Fish Habitat Assessment Protocol (FHAP) was followed for assessing fish habitat on Latte, Halfway, and YT-24 creeks. Opportunistic barge wake investigations were completed on the Yukon River with a focus on wake extent on shore. Similar to previous years, Coffee and Independence creeks had aerial Chinook salmon spawning surveys completed in July and August, and the Yukon and Stewart rivers were surveyed for spawning chum salmon in October.

Pertinent results from the 2018 field season include:

- High rainfall event leading up to the August sampling period may have impacted fish sampling results (e.g., DNA dilution from an influx of freshwater, juvenile fish being flushed from smaller watersheds, etc.).
- Arctic grayling were detected using eDNA sampling at five of thirteen sites sampled. Juvenile Chinook were only detected in Independence Creek (the positive control).
- No juvenile Chinook captured in Halfway or YT-24 Creek while electrofishing; single Arctic grayling were captured in lower 250 m of Halfway Creek, and lower 50 m of YT-24 Creek.
- Juvenile Chinook salmon caught electrofishing up IC Tributary B, approximately 16 km from confluence with the Yukon River.
- IC Tributary A is unlikely to contain fish above ~500 m from the confluence with Independence Creek due to a potential barrier to fish and increased grade (17-20%).
- Both the Halfway and YT-24 mixing zones contained higher species diversity and higher abundance of juvenile Chinook than elsewhere sampled on the Yukon River.

- No evidence of spawning activity during Chinook salmon spawning surveys in Coffee and Independence creeks.
- Juvenile Chinook were most abundant species captured at/near proposed barge landings, except for the Stewart River proposed north barge landing where no juvenile Chinook were captured.
- Little wake or lasting impact detected during barge wake investigations; largest lapping wave came up 50 cm on shore. Wake extent proved very dependent on shore slope.
- The Stewart River back channel located along the NAR appeared to provide nursery habitat for juvenile whitefish, northern pike, and burbot during July sampling.
- No chum salmon observed on the Stewart River and fewer were observed on the Yukon River than in 2017 (albeit 2017 was an anomalously high spawning year). Water levels were very low on both rivers, resulting in dewatered side channels where past spawning has been previously observed.

ACKNOWLEDGEMENTS

Jennie Gjertsen managed this project on behalf of Goldcorp Inc. and provided project direction needed to successfully complete the project. Jasmin Dobson, Becky Partridge, and Ryan Fetterley from Goldcorp provided exceptional logistical support to ensure our field crews could complete the work in an efficient and effective matter.

EDI would like to highlight the exceptional assistance provided by Goldcorp's Environmental Monitors. Derek Scheffen and Andrew Taylor provided local insight and assistance for components that were based from the mine. The Environmental Monitor Managers Alex Charron and Chris LeGoff assisted with field logistics and also field work.

Jared Hobbs (J Hobbs Ecological Consulting Ltd), Dr. Caren Helbing (University of Victoria), and Susan Dulc (Aurora Ecological Consulting) provided insight into the eDNA sampling component of the field studies and assisted with interpretation of the laboratory analysis.

1. INTRODUCTION

The Coffee Gold Project (Coffee Project; the Project) is a proposed gold mine in west-central Yukon, located 130 km south of Dawson City. Gold was initially discovered at Coffee Creek in 2010, and exploration activities have been ongoing since then. Baseline environmental studies began in 2010 and were expanded in the following years in anticipation of future regulatory requirements.

The proposed Project will consist of an open pit gold mine and heap leach facility. The projected mine life is ten years with an 18-month construction period. The feasibility study proposes four open pits mined by conventional shovel and truck methods. The mine and associated activities will generally be located on a relatively high elevation ridge top and will not extend into the lower elevations where the larger streams are located. The mine footprint does include the upper part of some headwater watersheds (including Halfway Creek, YT-24 and unnamed tributaries to Latte Creek). Most prominently, the main proposed Waste Rock Storage Facility (WRSF) will be positioned in the upper Halfway Creek watershed.

The Project will be accessed by road from Dawson City via a 214-km single-lane, gravel road with pull outs. The initial part of this route, from the highway to Sulphur Creek utilizes a government-maintained gravel road. Beyond Sulphur Creek, the Northern Access Route (NAR) mainly follows existing placer mine roads which will be upgraded to provide all-season access to supply vehicles. Approximately 30 km of new road will be constructed (Figure 1). Electricity will be generated onsite by diesel-powered generators. The majority of mine staff will access the site by air.

The Coffee Project is located on Crown land within the Traditional Territory of the Tr'ondëk Hwëch'in and the asserted traditional territory of the White River First Nation. A portion of Goldcorp's claim block is located in the Traditional Territory of the Selkirk First Nation and the proposed road also overlaps with the Traditional Territory of the First Nation of the Na-Cho Nyak Dun.

The proposed Project will require an Executive Committee Screening from the Yukon Environmental and Socio-economic Assessment Board (YESAB), a Type A Water Licence issued by the Yukon Water Board and a Quartz Mining License issued by the Yukon Government, among other permits and licences.

1.1. STUDY PURPOSE AND SCOPE

Results from the 2018 field season provide some additional fish and aquatic resource baseline and pre-project monitoring information, in addition to preliminary investigations at previously unstudied areas within Goldcorp's claim area. Palmer Environmental Consulting Group collected baseline data around the mine in 2014 and 2015 (PECG 2017) and along the access road in 2015 (PECG. EDI collected additional baseline data in 2016 and 2017 around the mine and Northern Access Route (NAR; EDI 2017, 2018) and summarized all data collected to date. The study conducted in 2018 was intended to expand the baseline (both spatially and quantitatively), support the effects assessment for the Project and provide pre-project information that can be used for effects monitoring.

- Project components for the Mine Study Area (Figure 2) 2018 field studies include:
    - environmental DNA (eDNA);
    - fish sampling;
    - fish and fish habitat investigations;
    - spawning surveys for Chinook salmon; and,
    - sampling Halfway and YT-24 creek mixing zones at the confluence with the Yukon River.
- Project components for the NAR Study Area (Figure 3) 2018 field studies include:
    - fish sampling and general fish habitat characterization at proposed barge landings (Yukon River, Stewart River);
    - barge wake investigations;
    - fish habitat investigations in a back channel of Stewart River; and,
    - spawning surveys for chum salmon in the Yukon and Stewart rivers.

1.2. BASELINE SAMPLING STATION CONCORDANCE

In an effort for consistency between all groups working on aquatic and fisheries work within the Project area, a new station naming system has been developed for 2018. To assist in rectifying previous sampling stations with the new system, a table of concordance is shown below (Table 1). The new naming system will allow for easy determination of station location and the addition of new stations, if and where needed:

1. Each station ID designation begins with a two or three letter code for each creek in the Mine Study Area. Three letter codes are used for unnamed tributaries to named creeks; therefore, LCC corresponds to Latte Creek, Tributary C.

2. Following the creek letter code is a numeric designation that represents the stream distance (kilometers) of a sampling station from its major confluence (i.e., following the meandering of the creek).

3. For stations in the Yukon River, the naming convention follows the number of kilometers from the confluence with the White River.

Table 1. Concordance table of Coffee Project fisheries and aquatic field sampling station identifiers.

Waterbody	Water quality and hydrology station (Lorax 2016)	2016 station name	2017 station name	2018 station name

2. METHODS

Methods are presented separately for the mine and Northern Access Route (NAR) study areas in the below sections.

2.1. MINE STUDY AREA

Aquatic resource sampling included environmental DNA (eDNA), fish sampling (beach seining, electrofishing, minnow trapping), Fish Habitat Assessment Procedures (FHAP; Johnston and Slaney 1996), Chinook salmon spawning surveys (aerial and on foot). In-situ water quality was taken at all sampled sites (APPENDIX A). These activities were carried out in several streams in the Mine Study Area and reference areas, in addition to some creeks that may become affected if there is future expansion of the Coffee mine:

- Halfway, Latte and YT-24 watersheds directly drain the Mine Site and are those that are predicted to be most affected by project activities. These streams are considered 'near' to project activities.

- Latte Creek flows into Coffee Creek. Therefore, while Coffee Creek is downstream of the Project area, the reaches that are downstream of the Latte confluence are considered 'far' from Project activities due to the limited influence on water quality/quantity predicted from the Project.

- Dan Man, Kona, Independence Creek (IC) Tributary A and IC Tributary B are all within regions of potential future exploration and had baseline fisheries information collected on them (eDNA and fish sampling on IC Tributary A and B). Currently, only Dan Man and Kona are considered to be in areas of current mining operations.

2.1.1. ENVIRONMENTAL DNA SAMPLING

The environmental DNA (eDNA) sampling conducted during August 2018 involved collecting one liter water samples from several creeks, with the objective of both supplementing existing information on previously studied creeks (Halfway, YT-24, and Independence creeks), and also to provide a baseline for creeks that have not been studied in past years by EDI (Dan Man, Kona Tributary, IC Tributary A and B). The water-based eDNA samples provide information on Chinook salmon and Arctic grayling presence and absence. August was chosen as it is the month when fish densities are highest and small creeks are more likely to be inhabited than during other periods in the year. Field sampling included thirteen sites that were sampled August 10-13, 2018 (Table 2; Figure 4).

Table 2. Summary of 2018 eDNA sampling stations in the Mine Study Area, August 2018.

The eDNA methods involved disinfection, sampling, as well as preparing samples for laboratory analysis. Before leaving for the field, all equipment and sample bottles were cleaned and disinfected with 10% bleach solution and 85% ethanol and left to dry before being packed for transport. All equipment was kept in separate bags in the transport bin (e.g., envelopes, bottle triplicates, etc.) to mitigate contamination of equipment.

During sampling programs, one field member was designated the eDNA sampler. This individual was responsible for sample collection, storage and handling to eliminate potential contamination. The eDNA sampler would not carry any other fish sampling equipment for the day and no one else was allowed in the water within 50 m of the sampling location. New nitrile gloves were worn at each site. Triplicate sample bottles for each site were kept together in bags to prevent bottles from different sites coming into contact with one another.

All samples were taken starting at downstream sites, working upstream throughout the day to keep from contaminating samples. Once arriving at the site, the eDNA sampler removed the three bottles for the site from their respective bag. Each of the three sample bottles were rinsed three times downstream of where the actual sample was taken; bottles were rinsed to remove any disinfectant residue. After rinsing bottles, they were replaced back into their bags and sealed while the sampler moved upstream to take the samples being analyzed for eDNA. Cascades were the preferred areas to take samples; otherwise, the sampler would try to stay out of the water (i.e., step on rocks), or take the sample from the shoreline. The main consideration for sampling was that it was from the main flow of the stream and not from eddies or still pools (Hobbs 2017). Each sample bottle was filled, capped, and placed back into their bags and sealed; samples were left in a cooler or field pack until being processed later that afternoon.

At the end of the day samples were processed at the Coffee Gold Camp. Using a peristaltic pump, each triplicate sample was processed separately. The 1 L sample was filtered through a 45 µL filter; once the water had been filtered, the pump continued for another 4-7 minutes to continue drying out the sample. Using disinfected forceps (10% bleach, distilled water, 85% ethanol, distilled water), the filter paper was folded and placed into a small pre-labelled coin envelope and sealed. All three samples from each site received their own envelopes, but they were all kept together in a Ziploc bag with two teaspoons of desiccant (silica) beads. Beads were checked periodically for signs of dampening (i.e., turning clear or pink) and were replaced accordingly. Samples were shipped priority to the University of Victoria for analysis which was conducted as outlined in Hobbs (2017).

2.1.2. FISH SAMPLING AND HABITAT INVESTIGATIONS

Fish sampling was conducted at numerous sites within the Mine Study Area. Fish sampling took place over two field events, spanning July 11-14 and August 8-18, 2018 (Figure 5). The objectives of fish sampling were to better understand fish distribution, assemblages, and usage in several select steams within the Mine Study Area, and in streams that may be within the footprint of future exploration. The fish sampling method used at each site was dependent on physical stream features and suitability of the method for the targeted species. The sampling methods used included electrofishing (EF), beach seining (BS), and minnow trapping (MT). All captured fish were identified to species (unless larval stage, then were identified to genus), with the

remaining fish enumerated before all fish were released back at their site of capture. There were two new creeks investigated during the 2018 field season, which were both tributaries high in the Independence Creek watershed. These two creeks are referred to as IC Tributary A and IC Tributary B; IC Tributary A is lower in the watershed, approximately 14.2 km from the confluence with the Yukon River, while IC Tributary B is approximately 15.7 km upstream from the confluence.

Two different electrofishers were used during the two separate field events. During the July field event a Smith Root LR-24 was used, while a Smith Root 12-B POW electrofisher was used during August. All electrofishing effort was conducted using open-site single-pass methods. The beach seine used was 10 m in length, 1.5 m deep and constructed of a 5 mm mesh, with a buoyant float line and sinking lead line. Beach seine hauls were conducted with field crews of two members and consisted of varying lengths, widths, and depths dependent on the stream environment. Minnow traps were placed in areas of good cover and suitable depth and stream velocity. Each site had three small mesh gee type minnow traps (0.6 cm mesh size) baited with Yukon River chum roe in a perforated bag and were deployed along stream margins in slow water habitats. Water depth, site characteristics, and photos were recorded for each trap and traps were left to soak overnight. During the July field event, a YSI ProPlus was used to collect in-situ water quality parameters (temperature, dissolved oxygen, specific conductivity, and pH) at all fish sampling sites, while the August field event used a pH and specific conductivity pen and thermometer; dissolved oxygen was not recorded in August. Digital photos and GPS coordinates were taken of all sites sampled for fish.

Previously, site naming used the linear distance from creek mouths. In 2018 this was changed for all creeks and will continue for sampling in the future. Each sampling location was named based on the shortened watershed name, followed by the stream-distance from each respective creek mouth (e.g., HC0.7 – Halfway Creek 0.7 km from the mouth, accounting for meandering of stream). For electrofishing, the fishing effort was enumerated on the device and given in total seconds of active electrofishing as well as the approximate distance from the electrofishing starting GPS point. Beach seining efforts were measured by the length and width of a seine haul (i.e., area seined; m^2). Lastly, total minnow trapping effort were enumerated based on the number of traps multiplied by soak times (HH:MM). Ten of each species was weighed (g) and measured to fork length (e.g., Chinook, whitefish) or total length (e.g., slimy sculpin; mm) at every site for each sampling method. In some instances, weight couldn't be recorded because fish were either too big or too small. The mean fork length and weight (± standard error; SE) was calculated for each group of fish per species, per sampling event. In cases where no weight was taken, fish length was still used in calculations.

2.1.2.1. Coffee Creek

Chinook salmon spawning surveys were completed in both July and August (refer to Section 2.1.5). Minnow trapping was completed on Coffee Creek (CC5.6) on August 15-16, 2018 consisting of three sites (three traps per site; Figure 5). Minnow trapping was used in favour of electrofishing or beach seining due to high-water levels and strong currents at the time of sampling. There were several attempts to beach seine; however, all efforts were aborted partway through due to strong currents and safety concerns.

2.1.2.2. Halfway Creek

Fish sampling on Halfway Creek was completed during both field events from July 12-14, as well as August 10-15, 2018. Halfway Creek was sampled for fish with the objective of supplementing and supporting previous years' findings. Halfway Creek fish sampling involved open site electrofishing during both the July and August field events (Figure 5; Table 3); the mixing zone of the Halfway Creek outlet and the Yukon River was also assessed for fish presence using beach seining (refer to Section 2.1.3).

Table 3. Electrofishing methods summary on Halfway Creek during July and August sampling, 2018.

Sampling site	Date	Distance (m)	Fishing effort (seconds)	Electrofisher settings	Duty cycle (%)
HC0.1	August 15, 2018	150	1,178	400 V, 60 Hz, 4 ms	24
HC0.2	July 13, 2018	150	958	340 V, 45 watts, 0.1 amps	n/a[1]
HC0.2[2]	August 12, 2018	160	993	300 V, 60 Hz, 0.5 ms	3
HC0.7	August 12, 2018	150	698	400 V, 60 Hz, 4 ms	24
HC1.1	August 12, 2018	160	774	400 V, 60 Hz, 4 ms	24
HC2.2	August 10, 2018	150	745	300 V, 60 Hz, 6 ms	36
HC6.7	August 10, 2018	300	634	300 V, 60 Hz, 6 ms	36

[1]Not recorded.
[2] Settings on device changed while manoeuvring through creek to a lower setting.

2.1.2.3. YT-24 Creek

Fish sampling on YT-24 Creek followed much the same methodology as on Halfway Creek. Open site electrofishing was completed on July 13 and August 12, 2018. During the July field visit YT0.05 and YT0.6 were sampled, and YT1.0 was sampled in August (Table 4; Figure 5). The mixing zone of YT-24 Creek outlet and the Yukon River was also sampled using beach seining in both July and August (refer to Section 2.1.3).

Table 4. Electrofishing methods summary on YT-24 Creek during July and August sampling, 2018.

Sampling site	Date	Distance (m)	Fishing effort (seconds)	Electrofisher settings	Duty cycle (%)
YT0.05	July 13, 2018	150	768	340 V, 45 watts, 0.1 amps	n/a[1]
YT0.6	July 13, 2018	160	626	340 V, 45 watts, 0.1 amps	n/a[1]
YT1.0	August 12, 2018	150	671	400 V, 60 Hz, 4 ms	24

[1]Not recorded.

2.1.2.4. Independence Creek

A Chinook salmon spawning survey was completed in August on Independence Creek (refer to Section 2.1.5). Independence Creek was sampled for fish on August 17, 2018 (Figure 5). Independence Creek was electrofished 15.6 km from the creek mouth (IC15.6) for 60 m and 588 seconds to determine fish presence directly downstream of the confluence with IC Tributary B.

2.1.2.5. Independence Creek, Tributary A

This was the first year that IC Tributary A was investigated and sampled, as it is within the footprint of potential future exploration at the Project; it is a tributary to Independence Creek, approximately 14.2 km upstream from the confluence of Independence Creek and the Yukon River. Independence Creek Tributary A was flown on August 10 to get a better understanding of the creek characteristics and possible barriers to fish; electrofishing was also completed on August 16 and 17 at ICA0.4 and ICA0.9 (Table 5; Figure 5). The creek was then walked on foot from the mouth of the creek to a point approximately 500 m up, where there was a perceived barrier to fish. Locations below and above the perceived barrier were spot-electrofished to get an idea of fish presence. Due to time constraints there were limitations on the amount of electrofishing that could be completed; instead, the focus was to confirm the presence of fish below and above the perceived barrier and take measurements, notes, and photos of the perceived barrier.

Table 5. Electrofishing methods summary on IC Tributary A during August sampling, 2018.

Sampling site	Date	Distance (m)	Fishing effort (seconds)	Electrofisher settings	Duty cycle (%)
ICA0.4	August 17, 2018	150	256	600 V, 60 Hz, 4 ms	24
ICA0.9	August 16, 2018	150	626	400 V, 60 Hz, 4 ms	24

2.1.2.6. Independence Creek, Tributary B

Similar to IC Tributary A, this was the first year that IC Tributary B was observed; as such, the methodology on both creeks was fairly similar for the 2018 field season. Independence Creek Tributary B also flows into Independence Creek, approximately 1.5 km upstream from where IC Tributary A enters (approximately 15.7 km from the Yukon River confluence). The creek was flown on August 10 and had electrofishing completed on August 17 at ICB0.2 and ICB0.6 (Table 6; Figure 5). Water quality parameters were recorded, in addition to gradient from a number of locations in both IC Tributary A and B.

Table 6. Electrofishing methods summary on IC Tributary B during August sampling, 2018.

Sampling site	Date	Distance (m)	Fishing effort (seconds)	Electrofisher settings	Duty cycle (%)
ICB0.2	August 17, 2018	150	754	400 V, 60 Hz, 4 ms	24
ICB0.6	August 17, 2018	120	531	400 V, 60 Hz, 4 ms	24

2.1.3. YUKON RIVER MIXING ZONES

As suggested by the Selkirk First Nation, fish sampling was completed at the confluences (mixing zones) of both Halfway and YT-24 creeks with the Yukon River. The mixing zone of Halfway Creek and nearby Yukon River sites were sampled July 12 and August 8, while YT-24 Creek was sampled July 13 and August 9, 2018. The mixing zones for each creek (i.e., where the creek flows into the Yukon River) were sampled using beach seining (Figure 6). During each sampling event three to four seine hauls were completed, beginning at the mouth of the creek and going progressively downstream on the Yukon River. There was only a fourth seine completed if one of the three seine hauls was considered poor but not fully aborted. Additionally, an area 130 m downstream of the Halfway Creek mouth was also sampled in August to determine the extent of the mixing zone, and if species composition and abundance was more comparable to the mixing zone or other Yukon River sites.

Three additional seine hauls were conducted upstream of Halfway and YT-24 creeks on the Yukon River, intended to act as controls to the mixing zone results. These sites were used as controls based on proximity to the mixing zone sites; however, the upstream habitats immediately above the mixing zones on the Yukon River were substantially different from those in the mixing zones (e.g., characterized by very steep banks and deep, fast moving water). These sites also proved very difficult to beach seine. Therefore, while they satisfied the need for a control based on proximity, they were not the same habitat type as the mixing zones. As a result, other seine hauls from the Yukon River future north barge landing (YUK51.2) were used as a reference site to compare catch-per-unit-effort (CPUE) results to, in an effort to compare similar habitat types. On YT-24 Creek in August, due to the difficulty of beach seining directly upstream of the mixing zone, a new site was chosen as a control based on proximity; this site was located approximately 40 m across from the YT-24 Creek mouth on the sandbar of an island (Figure 6). Beach seine hauls were conducted with field crews of two members for a length of approximately 15 m. Fish captured were enumerated, and a subset of ten fish per species had their length and weight taken from each seine haul. Fish measurement metrics were summarized (fork length and weight, ± SE) for all species captured. Due to the difference in habitat characteristics and difficulty seining directly upstream of the mixing zones, CPUE of juvenile Chinook salmon and Arctic grayling were only compared between mixing zones and the Yukon River reference site (north barge landing).

2.1.4. FISH HABITAT ASSESSMENTS

Fish habitat surveys were conducted on three streams during August 2018 following the Fish Habitat Assessment Procedures (FHAP) survey methodology (Table 7). The FHAP survey documents the characteristics and frequency of different fish habitats by enumerating different habitat units (e.g., pool, riffle, glide), and measuring various parameters (e.g., average depth, width, length, etc.). A detailed methodology is outlined in the FHAP guide (Johnston and Slaney 1996). The length of habitat units was measured using a laser range finder, whereas wetted widths, bankfull widths, and depths were measured with a measuring tape and/or meter stick.

Table 7. Summary of fish habitat assessments in August 2018.

Creek	Date	Distance (m)	Latitude	Longitude
Halfway Creek	August 14, 2018	591	62.943954	-139.249186
YT-24 Creek	August 13, 2018	535	62.931105	-139.233907
Latte Creek	August 10, 2018	656	62.861508	-139.297579

2.1.5. CHINOOK SALMON SPAWNING SURVEYS

Chinook spawning surveys were completed in areas where Traditional Knowledge (TK) indicated past presence, such as Coffee Creek (Tr'ondëk Hwëch'in 2012) and in watersheds that appear to have habitat to support spawning Chinook; as such, Coffee Creek and Independence Creek have been investigated and surveyed for spawning Chinook salmon annually since 2014. During the 2018 field season, Coffee Creek had three surveys while Independence Creek had two aerial surveys completed. Coffee Creek also had a stream walk to record any evidence of Chinook salmon spawning (Figure 7).

During the survey, observers were located on the right of the helicopter, with one observer in the front and the other directly behind them. The pilot positioned the helicopter over the river at an angle approximately 40-45 m above the creek. Surveys were generally completed from the mouth of the creek upstream and conducted early in the day to keep the sun at the observer's back. The last survey in August was completed slightly later in the day; therefore, in order to reduce glare, the creeks were flown in the opposite direction, starting upstream and continuing downstream towards the Yukon River. Observers also wore polarized glasses to reduce glare. Weather was moderate for the first two surveys and overcast for the final survey.

The first aerial survey on Coffee Creek was conducted on July 14, 2018 with a flight of approximately 50 minutes and good visibility; this survey was not completed on Independence Creek due to helicopter availability. The second survey was on July 25, 2018 lasting 40 minutes on Coffee Creek, and 37 minutes on Independence Creek, with good visibility. The final survey occurred on August 11, 2018 and consisted of approximately 25 minutes on Coffee Creek, and 37 minutes on Independence Creek; water levels during this survey were fairly high, resulting in difficulty seeing into deep pools.

On August 16, 2018 a stream walk was completed on Coffee Creek to look for any sign of spawning activity. A field crew of two walked Coffee Creek from the confluence with Latte Creek downstream to approximately 4.0 km from the Yukon River. Conditions were very good for observing adult salmon, redds

or associated wildlife (i.e., eagles, bears). The crew was able to walk the channel either in or alongside the wetted portion of the creek.

2.2. NORTHERN ACCESS ROUTE

During the 2018 field season, there were three investigations completed similar to previous years' sampling (barge landings, Stewart River back channel, and chum spawning surveys). In addition, opportunistic barge wake investigations were completed. The Stewart River back channel was visited earlier in the year than previously, which allowed for more thorough investigations to be completed in 2018.

2.2.1. BARGE LANDING INVESTIGATIONS

Proposed barge landings on the Yukon and Stewart rivers were visited and sampled for fish during July 2018, and the Yukon River proposed barge landings were revisited in August 2018. Fish sampling was conducted using beach seining along the banks of the proposed barge landings. A total of eleven beach seining hauls were completed at/near the proposed barge landing sites on the Yukon River including three beach seining hauls at the proposed South winter road crossing, and an additional three hauls at the existing barge landing near the Coffee Camp during 2018 sampling (Figure 8). A total of six beach seining hauls were completed near the proposed barge landing sites on the Stewart River. Information collected for each beach seine haul included seine haul dimensions (length, width, depth), and fish were identified and enumerated; a random ten individuals from each species was weighed and had fork length measured for each seine haul.. All seine hauls were conducted at the site of the proposed barge landings, with the exception of the Yukon River north bank proposed barge. The Yukon River north bank barge landing has steep eroding banks and deep water; as such, the seine hauls were completed 75 m downstream. Fish measurement metrics were summarized (fork length and weight, ± SE) for all species captured.

2.2.2. BARGE WAKE INVESTIGATIONS

EDI field crews conducted four river barge wake investigations from shore (Figure 9). These investigations were opportunistically completed when a crew was working along the Yukon River and a barge was approaching. Photos and videos were taken before, during, and after the barge passing. Approximate distance of the barge was recorded, in addition to what the load appeared to be visually, as well as any other observations. After the barge had passed, the wave runout (slope distance waves travelled up the previously dry shoreline) extent was recorded.

2.2.3. STEWART RIVER BACK CHANNEL INVESTIGATIONS

A back channel on the Stewart River that is adjacent to the NAR was visited and assessed by field crews on July 11 and 12, 2018 (Figure 10). The length of the channel was walked and 10 beach seine hauls were completed (Table 8). The wetted channel was investigated and had photos and notes recorded of the channel characteristics. Information collected for each beach seine haul included seine haul dimensions (length, width, depth) and water quality parameters (temperature, dissolved oxygen % and mg/L, pH, and SPC). Fish were identified and enumerated; a random ten individuals from each species was weighed and had fork length measured for each seine haul. Fish measurement metrics were summarized (fork length and weight, ± SE) for all species captured, as well as determining CPUE across all seine hauls.

2.2.4. CHUM SALMON SPAWNING SURVEYS

Chum salmon spawning surveys were completed by helicopter on the Yukon and Stewart rivers on October 13, 2018. Similar to previous years, the Yukon River was surveyed from just upstream of Excelsior Creek (7 km upstream of Coffee Creek) downstream to near the confluence of Carlisle Creek, a river distance of approximately 33.5 km (Figure 11). The Stewart River was surveyed from Black Hills Creek, downstream to a point 7 km downstream of Three Kings Creek for a total river distance of approximately 34.6 km (Figure 11).

The crew consisted of two observers who were positioned in the front and back seat, with the pilot positioning the aircraft over the river, flying sideways with the best vantage point approximately 40-45 m over the river. The surveys were completed in a downstream manner and polarized glasses were also worn to further reduce glare. Air temperatures were fairly mild (1°C) and there had been little snowfall, which resulted in good visibility for surveying ice-covered areas of the river. Water levels were significantly lower in both the Yukon and Stewart rivers than in previous years of sampling, resulting in many dewatered side channels in areas where chum were previously observed. Where possible, emphasis was placed on areas of known chum spawning, and side channel habitats where groundwater discharge areas were present (known preferred spawning areas for chum salmon on large Yukon rivers).

3. RESULTS AND DISCUSSION – MINE STUDY AREA

Results and discussion for the Mine Study Area are presented per project component in the below sections.

3.1. ENVIRONMENTAL DNA SAMPLING

3.1.1. AUGUST 2018

Few eDNA samples produced positive results for Chinook salmon and Arctic grayling, with only six of 13 sites indicating fish presence whatsoever (Table 9; APPENDIX B). Independence Creek (IC2.6) was considered the positive control, while the distilled water samples were the negative controls. Independence Creek was the only site where both species of fish were detected. Juvenile Chinook were only detected at the Independence Creek site; Arctic grayling were detected in six out of thirteen sites.

Table 9. Summary of eDNA detection results in the Mine Study Area, August 2018.

Station Name	Creek	Chinook salmon eDNA detected (Yes/No)	Arctic Grayling eDNA detected (Yes/No)
DM0.2	Dan Man	No	**Yes**
DM2.2	Dan Man	No	No
DW1.0	Distilled water	No	No
DW2.0	Distilled water	No	No
HC0.2	Halfway Creek	No	No[1]
HC2.2	Halfway Creek	No	No
IC2.6	Independence Creek	**Yes**	**Yes**
ICA0.4	IC Tributary A	No	**Yes**
ICA4.0	IC Tributary A	No	No
ICB0.2	IC Tributary B	No	**Yes**
ICB4.7	IC Tributary B	No	**Yes**
KT0.2	Kona Tributary	No	**Yes**
KT3.4	Kona Tributary	No	No
YT0.1[2]	YT-24 Creek	No	No
YT1.0[2]	YT-24 Creek	No	No

[1] No eDNA detection despite a single Arctic grayling observed at ~230 m.
[2] Similar to 2017 results, samples indicated no algae or fish eDNA present.

The results from the lower 200 m of Dan Man and Kona Tributary indicate Arctic grayling presence; this is a relatively anticipated result due to the proximity to known Arctic grayling rearing habitat (Yukon River). In August, a single Arctic grayling was observed approximately 230 m up Halfway Creek but was not detected by eDNA sampling at 200 m; this is likely due to low density of Arctic grayling, as no fish were successfully electrofished (in August). Arctic grayling presence was validated using electrofishing methods in Independence Creek, IC Tributary A (at ICA0.4), and IC Tributary B (at ICB0.2; see section 3.2). The result from YT-24 sites was consistent with previous years, indicating no eDNA in the sample whatsoever, including algae (EDI 2018). YT-24 Creek is known to be a low productivity creek, requiring high effort in past years of invertebrate sampling (EDI 2018). Supported by the last two years of data, it is likely that YT-24 Creek has too low of productivity to detect algae in the samples.

3.2. FISH SAMPLING AND HABITAT INVESTIGATIONS

Fish sampling results from the 2018 field season are described per stream in the below sections (data provided in APPENDIX C). It is important to note that the week leading up to August fisheries work was characterized by high rainfall, resulting in considerably higher water levels in all the studied watersheds. Fish sampling field work was delayed several days until water levels resumed a safe level which also allowed for more effective sampling. Sampling occurred at moderate flow levels and creeks had resumed relatively high clarity.

3.2.1.1. Coffee Creek

Juvenile Chinook salmon and slimy sculpin were captured using minnow trapping at CC5.6 during the 2018 field program, while Arctic grayling were visually observed; these findings are supported by previous years' findings (PECG 2016, 2017, EDI 2017, 2018). All combined minnow traps (three sites, nine minnow traps total) captured 162 juvenile Chinook salmon and five slimy sculpin in 200.75 trap hours (Table 10).

Table 10. Coffee Creek minnow trapping and fish metrics summary, August 2018.

Sampling site	Minnow trapping site	Sampling effort	Total fish captured	Fish measured	Average fork length (mm ± SE)	Average weight (g ± SE)
CC5.6	1	66.9 hours	CH – 60	CH – 10	CH – 84.9 ± 1.4	CH – 5.9 ± 0.3
	2	66.9 hours	CH – 52 CCG – 2	CH – 17 CCG – 2	CH – 78.1 ± 1.3 CCG – 83.0 ± 8	CH – 4.8 ± 0.2 CCG – 5.8 ± 0.8
	3	66.9 hours	CH – 50 CCG – 3	CH – 20 CCG – 3	CH – 77.5 ± 1.7 CCG – 80.0 ± 1.5	CH – 4.9 ± 0.3 CCG – 5.0 ± 0.9

CH = Chinook salmon; CCG = slimy sculpin

3.2.1.2. Halfway Creek

Halfway Creek was extensively electrofished during both July and August field visits. The only fish successfully captured while electrofishing was a single adult Arctic grayling at HC0.2 in July (FL = 342 mm, weight = 108.0 g; Table 11). There was another Arctic grayling that was visually observed on three occasions in a large, deep pool 230 m upstream from the mouth of the creek; it was visually assessed to be approximately 200 mm in length.

There were no juvenile Chinook salmon captured during the 2018 sampling, contrasted to the five that were captured in the bottom 200 m in 2017 (EDI 2018). Similarly, there were fewer Arctic grayling captured during the 2018 season than in the 2017 season (n = 1 and n = 8, respectively). Overall, both juvenile Chinook and Arctic grayling continue to be captured in low densities in Halfway Creek, with there being inconsistency in the capture of juvenile Chinook salmon from year to year. To date, no fish have been captured beyond 600 m from the mouth of the Yukon River despite multiple years of sampling.

Table 11. Halfway Creek electrofishing and fish captured summary, July and August 2018.

Sampling site	Sampling event	Sampling effort and distance	Total fish captured
HC0.1	August	1,178 seconds; 150 m	NFC
HC0.2	July	958 seconds; 150 m	GR – 1
HC0.2	August	993 seconds; 160 m	NFC[1]
HC0.7	August	698 seconds; 150 m	NFC
HC1.1	August	774 seconds; 160 m	NFC
HC2.2	August	745 seconds; 150 m	NFC
HC6.7	August	634 seconds; 300 m	NFC

[1]One GR was visually observed in a large pool on several occasions but was not successfully captured.
GR = Arctic grayling; NFC = no fish caught

3.2.1.3. YT-24 Creek

YT-24 Creek was electrofished in both July and August 2018. During the July field event, YT0.05 and YT0.6 were both electrofished, with YT0.05 yielding a single Arctic grayling (FL = 176.0, weight = 57.3 g; Table 12). The 2018 results were very similar to those found in 2017, with a single Arctic grayling being captured in the lower 100 m of the creek. These two grayling are the only fish captured in the stream despite multiple years of sampling throughout the steam.

Table 12. YT-24 Creek electrofishing and fish captured summary, July and August 2018.

Sampling site	Sampling event	Sampling effort and distance	Total fish captured
YT0.05	July	768 seconds; 150 m	GR – 1
YT0.6	July	626 seconds; 160 m	NFC
YT1.0	August	671 seconds; 150 m	NFC

GR = Arctic grayling; NFC = no fish caught

3.2.1.4. Independence Creek

A short section of Independence Creek was electrofished in August, just downstream of where IC Tributary B flowed in (approximately 15.6 km from the Yukon River). The cover primarily consisted of large boulders, with several glides in the section sampled (Photo 1). There were eight Arctic grayling captured, as well as a single round whitefish (Table 13; Photo 2). This was the highest point in Independence Creek that has been sampled to date.

Table 13. Independence Creek electrofishing and fish metrics summary, August 2018.

Sampling site	Sampling effort and distance	Total fish captured	Fish measured	Average fork length (mm ± SE)	Average weight (g ± SE)
IC15.6	588 seconds; 60 m	GR – 8 RW – 1	GR – 8 RW – 1	GR – 171.6 ± 15.6 RW – 182.0 ± 0.0	GR – 62.1 ± 17.9 RW – 65.0 ± 0.0

GR = Arctic grayling; RW = round whitefish

Photo 1. A downstream view of the area electrofished on Independence Creek on August 17, 2018.

Photo 2. A round whitefish caught 15.6 km up Independence Creek on August 17, 2018.

3.2.1.5. Independence Creek, Tributary A

The 2018 field season was the first time that IC Tributary A was assessed and sampled for fish using electrofishing techniques (and eDNA; see Section 3.1). The objective was to get a general idea of stream characteristics and fish presence, with the intention of building on this information in future years of study. Due to the rainfall event before the August field trip the water levels of IC Tributary A were fairly high. An aerial investigation determined the lower section (~200 m) of the creek was wide and the bed material consisted primarily of fines (Photo 3). From approximately 200-500 m from the mouth the creek narrowed to about one metre width and was characterized by abundant large woody debris and fines. At 500 m there was a perceived barrier to fish, with the gradient slightly picking up following the perceived barrier. Moving up the drainage beyond the barrier, the creek became characterized by larger boulders and an increasingly steep gradient (Photo 4). The gradient lessened once reaching a plateau approximately 2.5 km up the drainage (Photo 5, Photo 6). Once on top of the plateau, the creek was approximately half the width, although appeared to be substantially deeper, with the bed material consisting of fines and the creek flowing through vegetation in some off-channels. There was evidence of a mining/exploration site on the top of the plateau at ICA4.0, although not in operation during the 2018 season (Photo 5, Photo 7). The flight continued up the drainage, with the creek becoming increasingly braided and flowing through vegetation and diminishing to nothing at the top of the watershed (Photo 8).

Photo 3. **The bottom of IC Tributary A (image right) on August 10, 2018 before flowing into Independence Creek (left).**

Photo 4. A steep section of IC Tributary A at high water on August 10, 2018.

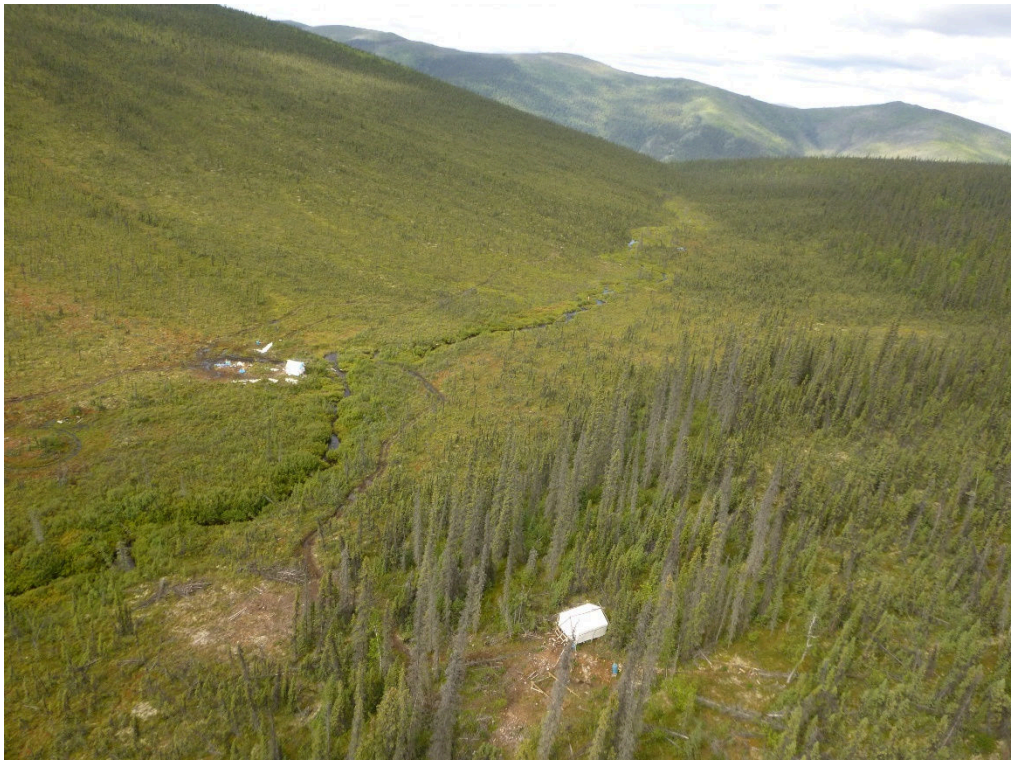

Photo 5. Downstream view of IC Tributary A from on top of the plateau August 10, 2018. The steep change in gradient can be seen at the top of the image.

Photo 6. Upstream view of IC Tributary A cresting over the plateau, approximately 2.7 km from the confluence with Independence Creek on August 10, 2018.

Photo 7. Mining operation next to IC Tributary A, approximately 4.0 km from the confluence with Independence Creek on August 10, 2018.

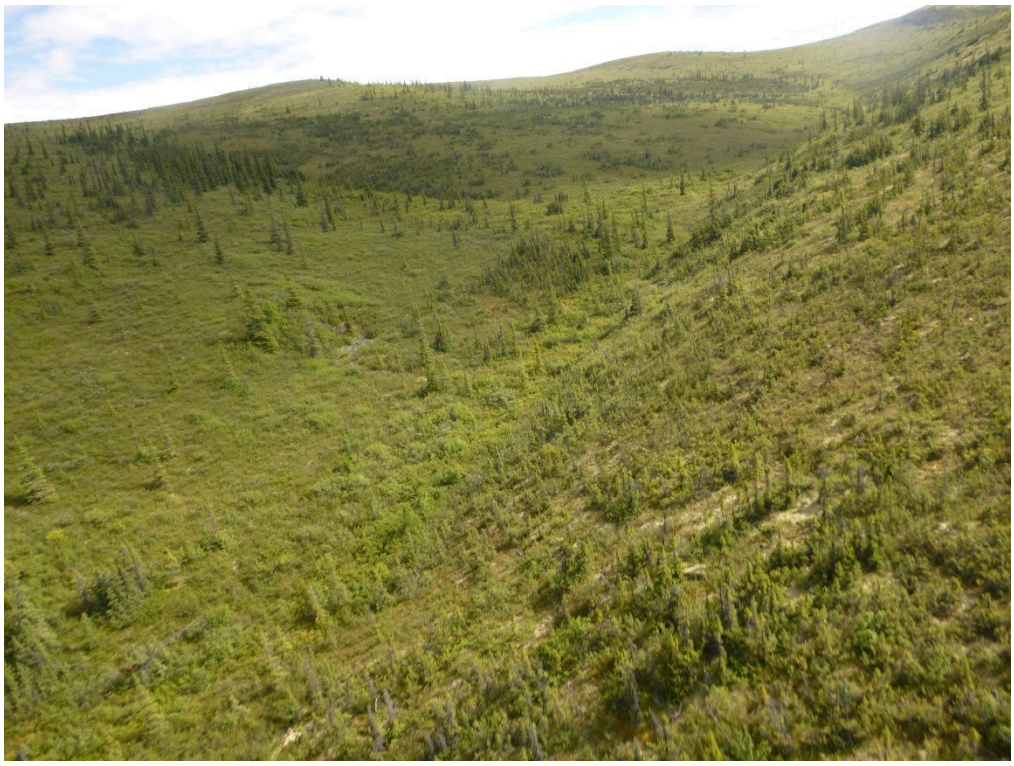

Photo 8. IC Tributary A facing upstream towards the top of the drainage on August 10, 2018.

On August 10 and 16-17, 2018 IC Tributary A was walked by foot during eDNA and electrofishing sampling (up to 1.1 km from the mouth), allowing for more fine-scale observations on stream characteristics. In the lower 500 m the gradient varied between 1-2%, characterized by woody debris, undercut banks and was deeply channeled with glides and fines for bed material (Photo 9). Shortly thereafter, the gradient of the creek increased substantially to approximately 10% between 495 and 510 m. At 525 m there was a significant cascade with a 12% grade and was approximately 4 m high with the cascade spanning a horizontal distance of 6 m from the top of the cascade to the pool (Photo 10). There appeared to be limited resting areas for fish within the cascade and the downstream pool had a max measured[2] pool depth of 1.15 m. The slope increased significantly between 500 m and 1.1 km. Between 885 m and 1.1 km from the mouth of the creek, the gradient varied from 13-20% (Photo 11).

[2] There may have been deeper parts of the pool, but due to excessively slippery substrate the whole pool was not able to be thoroughly investigated.

Photo 9. A representative upstream view of the lower 500 m of IC Tributary A on August 10, 2018.

Photo 10. Upstream view of IC Tributary A at the cascade 525 m upstream of the confluence with Independence Creek on August 17, 2018.

Photo 11. Downstream view of IC Tributary A, approximately 1.0 km from the creek mouth with a gradient of 17% on August 16, 2018.

Electrofishing was conducted on August 16 and 17, 2018 in IC Tributary A, at sites ICA0.4 and ICA0.9. Due to the knowledge of the large cascade at 525 m, the focus with the allotted time was to confirm the presence of fish below the cascade and determine whether there were any fish above the cascade. Minimal electrofishing was conducted below the cascade as many Arctic grayling were readily observed in the lower 500 m. When sampling the pool below the cascade Arctic grayling were so numerous they began jumping and swimming at the surface; efforts were aborted shortly thereafter in favour of sampling the creek above the cascade. The creek was electrofished for 121 seconds up to the pool and had covered approximately 130 m (Table 14). Electrofishing occurred above the cascade with the remaining time, with priority sampling occurring in areas with potential fish habitat (i.e., pools, eddies). Above the cascade was electrofished for 135 seconds and covered a distance of approximately 50 m (Table 14). There were no fish observed or captured above the cascade, despite there being areas with appropriate habitat (Photo 12).

Table 14. IC Tributary A electrofishing and fish metrics summary, August 2018.

Sampling site	Sampling effort and distance	Total fish captured	Average fork length (mm ± SE)	Average weight (g ± SE)
ICA0.4	256 seconds[1]; 150 m	GR – 4	GR – 197.3 ± 25.1	GR – 128.8 ± 35.6
ICA0.9	626 seconds; 150 m	NFC	-	-

[1]Cumulative time below and above cascade.
GR = Arctic grayling; NFC = no fish caught

Given these sampling results (albeit limited), it appears that the cascade at 525 m from the mouth represents a barrier to fish passage. In addition to the extensive cascades further upstream with 15-20% grades and a

lack of overwintering habitat, it is unlikely fish are using the upper watershed. In Alaskan watersheds, the number of Arctic grayling observed above 15% grade is greatly diminished compared to their abundance below 15% (Hershey et al. 2006). Additionally, the BC Fish-stream Crossing Guidebook indicates that any stream with a gradient of 20% or above is unlikely to be considered suitable fish rearing habitat (BC Ministry of Environment 2012).

Recommendations for future investigations include sampling upstream of the lower and upper cascades would also be required to confirm that these are barriers to fish. The high rainfall event leading up to August sampling may give the impression that IC Tributary A provides better fish habitat than may be the case at regular water levels.

Photo 12. Downstream view of IC Tributary A above the cascade on August 17, 2018.

3.2.1.6. Independence Creek, Tributary B

Similar to IC Tributary A, the 2018 field season was the first time that Unnamed Tributary B was investigated and sampled for fish using electrofishing techniques. The objective was to get a general idea of stream characteristics and fish presence, with the intention of building on this information in future years of study. Independence Creek Tributary B was flown up to approximately 5.0 km from the creek mouth; stream characteristics (gradient, size, bed material) appeared relatively consistent throughout (Photo 13), with a few short areas where the creek split into two channels. The gradient appeared to be gradual, with no severe increases in gradient or potential barriers to fish observed. On the ground investigation determined the grade near the mouth of the creek was between 3-4%, while the grade increased to approximately 6% at

410 m. The gradient stayed fairly consistent up to the end of the electrofishing and was 5% at approximately 795 m from the creek mouth.

Photo 13. Upstream view of IC Tributary B at 4.7 km upstream from the confluence with Independence Creek on August 10, 2018.

Independence Creek Tributary B was electrofished at ICB0.2 and ICB0.6 during the August field event (Table 15). The creek split into two channels at ICB0.2; the channel on river right was chosen to electrofish as it appeared to be more representative and had less debris obstructing the creek (Photo 14). Electrofishing captured 16 Arctic grayling at ICB0.2 and eight at ICB0.6, with a number of others observed but not captured (Table 15). Three juvenile Chinook salmon were captured approximately 755 m from the confluence with Independence Creek, in one of the few pools with an eddy observed up to that point (Table 15; Photo 15). Finding juvenile Chinook this far up the watershed was an interesting finding (over 16 km upstream from the Yukon River), particularly as several years of aerial surveys have not found any spawning activity. These findings indicate that these juvenile Chinook are non-natal and travelled up to IC Tributary B in the spring/summer to rear there.

Photo 14. Upstream view of IC Tributary B, approximately 225 m from confluence with Independence Creek on August 17, 2018.

Photo 15. Juvenile Chinook captured during electrofishing at ICB0.6 on August 17, 2018.

Another interesting finding from fish sampling in IC Tributary B was that no slimy sculpin were observed or captured during electrofishing. Slimy sculpin are often considered to have high site fidelity and small home ranges, and do not move very far throughout their lifetime (Gray et al. 2004); these life history characteristics indicate that where slimy sculpin are found there is likely suitable overwintering habitat.

Table 15. IC Tributary B electrofishing and fish metrics summary, August 2018.

Sampling site	Sampling effort and distance	Total fish captured	Fish measured	Average fork length (mm ± SE)	Average weight (g ± SE)
ICB0.2	754 seconds; 150 m	GR – 16	GR – 10	GR – 192.7 ± 19.6	GR – 95.8 ± 25.9
ICB0.6	531 seconds; 120 m	GR – 8 CH – 3	GR – 8 CH – 3	GR – 151.1 ± 15.0 CH – 74.0 ± 1.5	GR – 74.3 ± 20.5 CH – 4.3 ± 0.2

CH = Chinook salmon; GR = Arctic grayling

Given the limited extent of sampling, it is not clear how much of the watershed Arctic grayling and juvenile Chinook use. Future sampling efforts on this stream should focus on determining fish distribution in the upper watershed.

3.3. YUKON RIVER MIXING ZONES

Mixing zone results from the 2018 field season are described for Halfway and YT-24 creeks. Results are compared with nearby Yukon River sites directly upstream of creek mouths, as well as a Yukon River reference site (north barge site).

3.3.1. HALFWAY CREEK

The Halfway Creek mixing zone and an area of the Yukon River directly upstream from the mouth of Halfway Creek were both sampled for fish in July and August; in August, an area 130 downstream of the creek mouth was also sampled.

The Halfway Creek mixing zone had similar species captured during both sampling events (six and seven species, respectively; Table 16, Table 17). Juvenile Chinook, Arctic grayling, slimy sculpin, round whitefish, and an Arctic lamprey were captured in both sampling events; juvenile lake whitefish were captured only in July, and an inconnu and longnose sucker were captured in August (Table 16, Table 17). There were similar numbers of juvenile Chinook (n = 44 and n = 43) and Arctic grayling (n = 5 and n = 6) captured during both sampling periods (Table 16, Table 17).

Table 16. Halfway Creek mixing zone fish metrics (fork length and weight, ± SE) from July sampling, 2018.

Species captured	Total fish captured	Fish measured	Average fork length (mm ± SE)	Average weight (g ± SE)
CH	44	30	61.3 ± 0.8	2.5 ± 0.1
GR	5	5	161.2 ± 19.6	51.7 ± 20.2
CCG	3	3	57.3 ± 10.4	2.4 ± 1.2
RW	4	4	40.8 ± 3.5	0.5 ± 0.1
LW	2	2	29.0 ± 5.0	0.4 ± 0.0[1]
AL	1	1	57.0 ± 0.00	0.3 ± 0.00

[1]Only one LW was measured for weight; the other was larval stage and undetected by scale.
CH = Chinook salmon; GR = Arctic grayling; CCG = slimy sculpin; RW = round whitefish; LW = lake whitefish; AL = Arctic lamprey

Table 17. Halfway Creek mixing zone fish metrics (fork length and weight, ± SE) from August sampling, 2018.

Species captured	Total fish captured	Fish measured	Average fork length (mm ± SE)	Average weight (g ± SE)
CH	43	27	75.4 ± 1.1	4.6 ± 0.3
GR	6	6	108.8 ± 16.1	15.4 ± 5.2
CCG	14	8	57.8 ± 6.2	3.3 ± 0.8
RW	22	20	59.0 ± 2.2	1.9 ± 0.1
AL	1	1	90.0 ± 0.0	n/a
IN	1	1	570.0 ± 0.0	n/a
LSU	1	1	180.0 ± 0.0	59.5 ± 0.0

CH = Chinook salmon; GR = Arctic grayling; CCG = slimy sculpin; RW = round whitefish; LW = lake whitefish; AL = Arctic lamprey; IN = inconnu; LSU = longnose sucker

Sampling the Yukon River upstream of the Halfway Creek mixing zone captured five species and fewer individuals compared to the mixing zone in both July and August (Table 18, Table 19). Juvenile Chinook were captured in the upstream Yukon River site during both the July and August sampling, although substantially fewer than in the mixing zone. The August results from 130 m downstream of the mixing zone were more inline with findings upstream than in the mixing zone, with five species captured and in relatively low numbers (Table 17, Table 19, Table 20), despite there being some Halfway Creek water visible at the rivers edge. The most juvenile Chinook captured in a single seine haul was 27, occurring in the mixing zone during August sampling. An inconnu was also captured in the Halfway Creek mixing zone in August, a finding that has not occurred elsewhere along the Yukon River during other beach seining events (EDI 2017, 2018). It is likely that inconnu use areas like the Halfway Creek mixing zone for opportunistic feeding opportunities.

Table 18. Yukon River (upstream from Halfway Creek) fish metrics (fork length and weight, ± SE) from July sampling, 2018.

Species captured	Total fish captured	Fish measured	Average fork length (mm ± SE)	Average weight (g ± SE)

Catch-per-unit-effort results were only compared between the mixing zone and the Yukon River reference site (north barge landing; YUK51.2) due to different habitat characteristics and difficulty encountered seining directly upstream of mixing zones. During both July and August sampling events, juvenile Chinook CPUE was higher in the Halfway Creek mixing zone than the Yukon River reference site (Table 21; Figure 12).

The distribution of Arctic grayling was much patchier for most sites, with many areas having no individuals. There were Arctic grayling caught in the mixing zone during both sampling events, but only in Augest at the Yukon River reference site (Table 21).

Table 21. Average CPUE (± SE) of juvenile Chinook salmon and Arctic grayling in the Halfway Creek mixing zone, upstream Yukon River control site, and reference Yukon River site during the summer of 2018.

Site name	Location	Sampling event	No. of hauls	Juvenile Chinook salmon		Arctic grayling	
				Average CPUE (fish/100m^2 ± SE)	Range	Average CPUE (fish/100m^2 ± SE)	Range
HC_MZ	Halfway Creek mixing zone	July	3	11.3 ± 1.5	8.3 – 13.5	1.7 ± 1.7	0.0 – 5.2

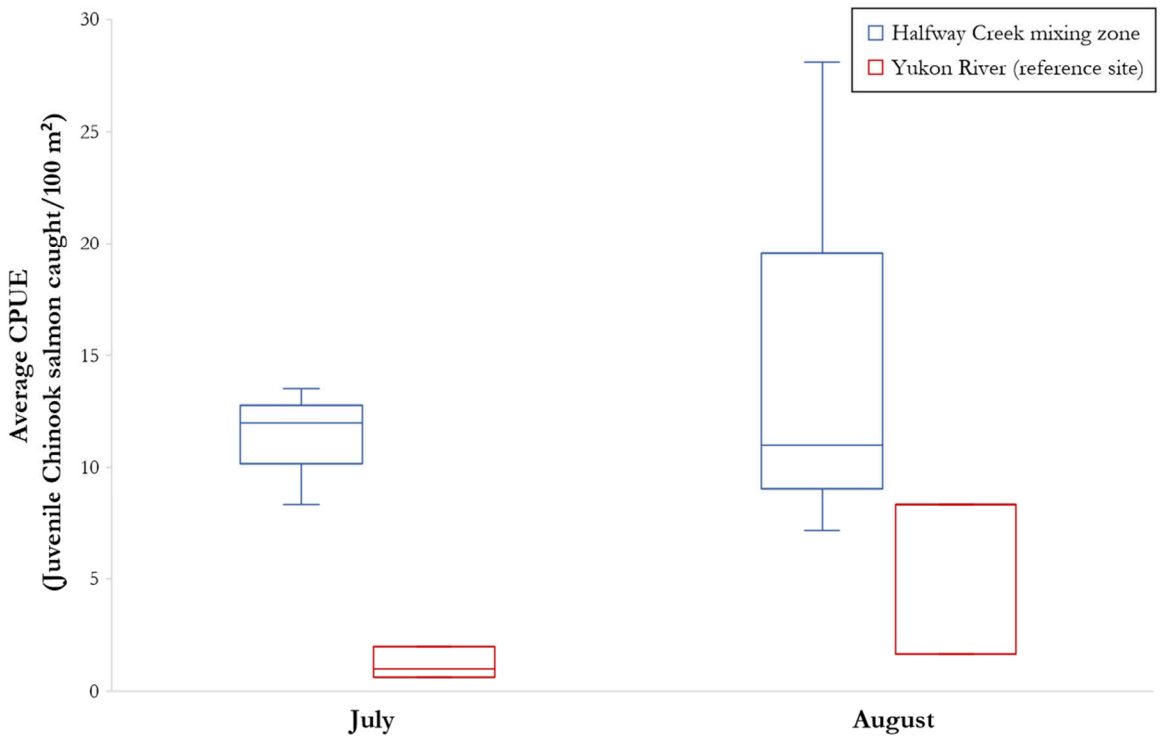

Figure 12. Average CPUE of juvenile Chinook caught in the Halfway Creek mixing zone and the Yukon River reference site in July and August 2018.

3.3.2. YT-24 CREEK

Similar sampling occurred near the mouth of YT-24 Creek during both July and August, with results differing slightly from Halfway Creek. During the July sampling period there were eight species of fish captured, while only two were captured in August (Table 22, Table 23). The species captured in the YT-24 mixing zone in July were similar to those captured in the Halfway Creek mixing zone, suggesting they both provide similar benefits to nearby fish communities. Similar to Halfway Creek, the July sampling event in YT-24 Creek also produced an adult inconnu, likely engaging in opportunistic feeding opportunities.

Table 22. YT-24 Creek mixing zone fish metrics (fork length and weight, ± SE) from July sampling, 2018.

Species captured	Total fish captured	Fish measured	Average fork length (mm ± SE)	Average weight (g ± SE)
CH	139	32	63.6 ± 1.1	2.7 ± 0.2
GR	1	1	200.0 ± 0.0	92.0 ± 0.0
CCG	1	1	39.0 ± 0.0	0.4 ± 0.0
RW	1	1	37.0 ± 0.0	0.4 ± 0.0
LW	3	2	54.5 ± 9.5	1.5 ± 0.8
AL	1	1	60.0 ± 0.0	0.4 ± 0.0
IN	1	1	670.0 ± 0.0	n/a

Table 23. YT-24 Creek mixing zone fish metrics (fork length and weight, ± SE) from August sampling, 2018.

Species captured	Total fish captured	Fish measured	Average fork length (mm ± SE)	Average weight (g ± SE)
CH	13	13	76.8 ± 1.1	4.7 ± 0.2
CCG	3	3	54.7 ± 7.4	2.2 ± 0.3

CH = Chinook salmon; CCG = slimy sculpin

The two sampling events in the Yukon River (in proximity to YT-24 Creek) were markedly different between the two time periods, likely because the location was changed between sampling events (from upstream of the mixing zone in July to across from the creek mouth in August). During the July sampling, when seine hauls were completed upstream of the mixing zone on the Yukon River, only a single juvenile Chinook was captured (Table 24). The seining conditions upstream of the mixing zone were quite poor, with deep fast flowing water and steep banks. Seining was completed at these sites again in August, but after several failed attempts, the site was moved to be on an island across from the mouth of YT-24 on an exposed gravel bar, approximately 40 m away (visible in Photo 16). The results across from the creek mouth were more similar to what they had been in the YT-24 mixing zone in July, with six species being captured (Table 25). In addition, there were substantially more juvenile Chinook captured at this location (n = 44) than in the other non-mixing zones sites sampled on the Yukon River. Possible explanations for this include the close proximity to Halfway Creek and/or the eddy habitat that was present at this area. It is possible that juvenile Chinook and other fish prefer eddy habitat due to the lower velocities, allowing for less energy expenditure while rearing. Future research should include a component to sample fish in eddy habitats along the shore of the Yukon River that are not in close proximity to creek mouths. This could further assess the role of eddy lines and fish presence, with results being compared back to abundances in mixing zones, to ultimately provide information on whether fish are drawn to clear water mixing zones specifically, or eddy habitats (which typically form at stream mouths).

Table 24. Yukon River (upstream from YT-24 Creek) fish metrics (fork length and weight, ± SE) from July sampling, 2018.

Species captured	Total fish captured	Fish measured	Average fork length (mm ± SE)	Average weight (g ± SE)
CH	1	1	68.0 ± 0.0	3.0 ± 0.0

CH = Chinook salmon

Table 25. Yukon River (across from YT-24 Creek) fish metrics (fork length and weight, ± SE) from August sampling, 2018.

Species captured	Total fish captured	Fish measured	Average fork length (mm ± SE)	Average weight (g ± SE)
CH	44	15	77.5 ± 1.3	4.5 ± 0.3
GR	1	1	55.0 ± 0.0	1.5 ± 0.0
CCG	3	3	24.0 ± 1.5	n/a
RW	1	1	45.0 ± 0.0	0.5 ± 0.0
LW	1	1	83.0 ± 0.0	n/a
LSU	3	3	55.7 ± 12.7	2.3 ± 0.3

CH = Chinook salmon; GR = Arctic grayling; CCG = slimy sculpin; RW = round whitefish; LW = lake whitefish; LSU = longnose sucker

The CPUE of juvenile Chinook and Arctic grayling were compared between the YT-24 mixing zone and the Yukon River reference site (the proposed north barge landing site; YUK51.2). The juvenile Chinook CPUE

results in the YT-24 mixing zone did not show as strong of a relationship as the Halfway Creek results between the two sampling periods. The July results indicate the YT-24 mixing zone had a higher juvenile Chinook CPUE than the Yukon River reference site (Table 26, Figure 13). During the August sampling event, comparatively few juvenile Chinook were captured in the mixing zone (13 as compared to 139; Table 22, Table 23). The YT-24 mixing zone CPUE was still greater than the Yukon River reference site, but by a substantially smaller margin than in July (Table 26, Figure 13). The greatest number of juvenile Chinook captured in a single seine haul was 68 and occurred during the July YT-24 mixing zone sampling; in the same collection of seine hauls, another seine collected 60 juvenile Chinook (Table 22).

The Arctic grayling findings were similar to those for the Halfway Creek sampling, in that their distribution was patchy and they were caught in low numbers with low CPUE. Arctic grayling were only captured in the YT-24 mixing zone in the July sampling (Table 26). In August, they were not captured in the mixing zone, although were captured in low numbers in the Yukon River reference site (north barge landing).

Table 26. Mean CPUE (± SE) of juvenile Chinook salmon and Arctic grayling in the YT-24 Creek mixing zone, Yukon River sites in proximity to the mixing zone, and reference Yukon River site during summer 2018.

Site name	Location	Sampling event	No. of hauls	Juvenile Chinook salmon		Arctic grayling	
				Average CPUE (fish/100m² ± SE)	Range	Mean CPUE (fish/100m² ± SE)	Range
YT24_MZ	YT-24 Creek mixing zone	July	4	33.1 ± 18.5	1.9 – 80.0	0.2 ± 0.2	0.0 – 0.7
YUK51.2	Yukon River reference (north barge landing)	July	3	1.0 ± 0.6	0.0 – 2.0	0.0 ± 0.0	0.0 – 0.0
YT24_MZ	YT-24 Creek mixing zone	August	4	6.9 ± 4.0	0.8 – 18.8	0.0 ± 0.0	0.0 – 0.0
YUK51.2	Yukon River reference (north barge landing)	August	3	4.6 ± 2.5	0.0 – 8.3	2.1 ± 1.2	0.0 – 4.2

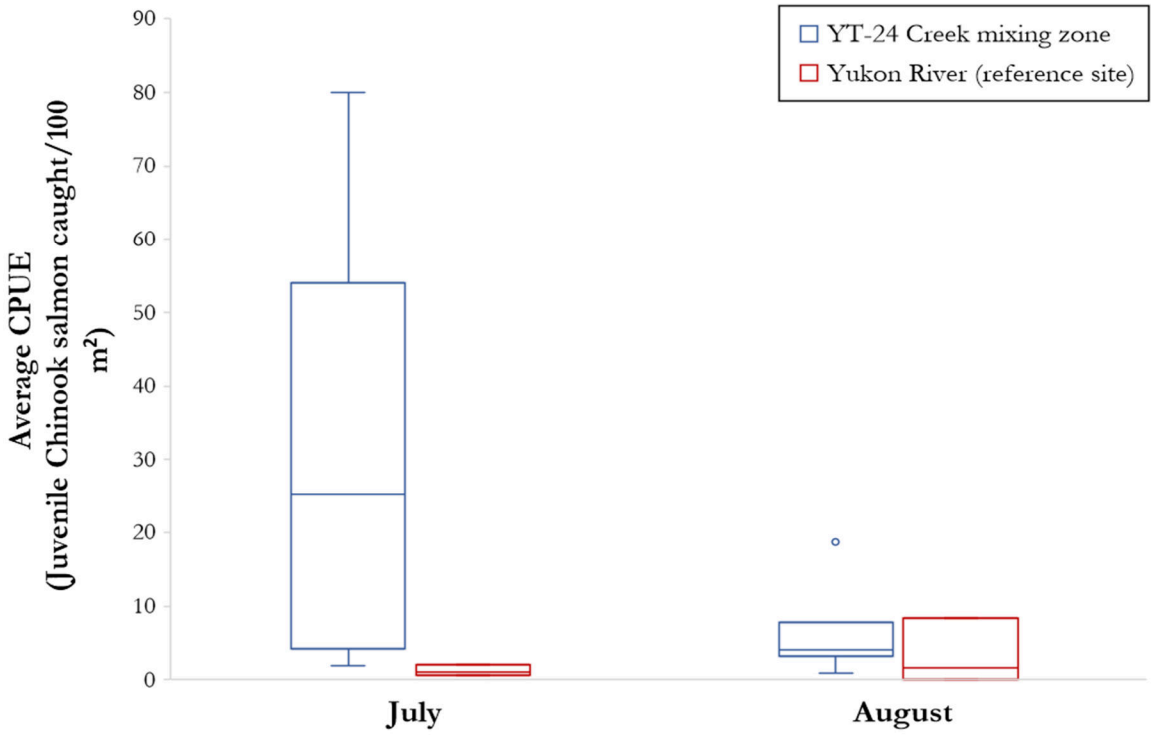

Figure 13. Average CPUE of juvenile Chinook caught in the YT-24 Creek mixing zone and a farther upstream Yukon River reference site in July and August 2018.

Photo 16. Eddy line of where the YT-24 Creek outlet surged into the Yukon River on August 9, 2018. The island where August sampling occurred is visible across the channel.

In both Halfway Creek and YT-24, the species diversity was generally higher in the mixing zone than elsewhere in the Yukon River. The exception to this is the low numbers captured in the YT-24 mixing zone in August, although this was somewhat made up for by the high species diversity at the site across from the YT-24 creek mouth, which may have been in close enough proximity to the mixing zone to receive mixing zone characteristics. Notably, inconnu were caught in the mixing zones of both creeks; these fish have not been caught during any other sampling events within the Mine Study Area. A larger diversity of species captured at mixing zones than in other locations along the Yukon River suggests that these areas provide unique value to nearby fish communities. Species abundance and number of individuals is often cited as higher at creek mouths than elsewhere in creeks or lakes (Willis and Magnuson 2000), a finding that our results support, particularly with respect to juvenile Chinook salmon. One potential explanation behind the apparent preference of juvenile Chinook for the mixing zone is increased opportunistic feeding opportunities. While both Halfway and YT-24 creeks are quite low in nutrients and invertebrates (EDI 2017, 2018), there may still be some benefit of concentrated drift feeding opportunities or increased foraging success in clearwater areas. Additionally, the presence of a thermal refuge with less predation and velocity as compared to deep-water thermal refuges may be an attractive quality of mixing zones; these thermal refugia may be important during the summer months when the surrounding nearshore water can occasionally exceed 18 °C. Feeding behaviour of predatory species which feed on juvenile salmonids also increases in higher water temperatures (Sauter et al. 2001, Richter and Kolmes 2005), potentially offering further explanation for the higher densities of juvenile Chinook in these cooler mixing zones. Additionally, the mixing zone provided a substantial backwater and/or eddy area along the edge of the creek input in the Yukon river; juvenile salmonids have been observed to prefer backwater areas on large rivers (Beechie et al. 2005). These areas provide a lower velocity refugia, in addition to the potential for drift-feed items being circulated a number of times. The mixing zone areas also present the possibility for higher predation pressure (as evidenced by inconnu in the area), although this is likely partially mitigated by the shallow-water nature of the mixing zone areas and other anti-predator behaviours such as shoaling (Pitcher 1986). Future research should consider sampling sites that have nearshore eddy lines, without the influence of creek outlets, in order to discern whether high fish abundances and diversity occur due to mixing zones specifically, or whether eddy line refugia provide similar benefits.

3.4. FISH HABITAT ASSESSMENTS

Fish habitat assessment survey results are summarized by creek in the following sections, with detailed survey data and photos affixed as appendices (APPENDIX D, APPENDIX E).

3.4.1. HALFWAY CREEK

During 2018 monitoring a FHAP survey was conducted on a 600 m section of lower Halfway Creek (Figure 14). Twenty-seven distinct habitat units were identified during the survey (Table 27). Habitat units identified include glides, pools, riffles (<5% grade), and steep riffles (≥5% grade). No cascade habitat was identified during the survey.

The surveyed section of Halfway Creek was dominated by riffle and steep riffle habitat that together comprise 80% of surveyed habitat units by length (Photo 17; Table 27). While steep riffle habitat units occurred more frequently than riffle habitat units, the average length of riffle habitat units (53.7 m) was nearly twice that of the average length of steep riffle habitat units (26.6 m; Table 27). Boulders and undercut banks were the dominant sources of cover for fish in these habitat types. There were relatively few glides and pools, which together comprised the remaining 20% of habitat units by length. Pools comprised 6% of habitat units by length in Halfway Creek and had an average residual pool depth of 0.6 m. This is the largest percentage of pool habitat units by length of the three creeks surveyed during 2018 fieldwork. The surveyed section of Halfway Creek did have some secondary (side channel) steep riffle habitat approximately 12 m in length that is accessible during most hydraulic conditions. A tertiary (within channel) pool 2.6 m in length was also identified during the survey.

The frequency and extent of habitat units in the surveyed section of Halfway Creek represents relatively low-quality, low complexity fish habitat with a low frequency of pool and glide habitat units (< 30% by area), and little instream cover and functional large woody debris (LWD; Johnston and Slaney 1996). The average bankfull width over all habitat units in Halfway Creek was 5.64 ± 0.36 m (mean ± SE), with an average wetted width of 4.0 m and an average water depth of 0.39 m during the survey.

Table 27. Summary of habitat units identified during the FHAP survey of Halfway Creek, August 2018.

Habitat type	No. of units	Average length per unit (m ± SE)	Total length in survey extent (m)	Percent of total survey extent
Cascade	0	-	-	0 %
Glide	7	12.2 ± 2.6	85.1	14 %
Pool	4	8.5 ± 0.3	34	6 %
Riffle (<5% grade)	4	53.7 ± 16.1	214.7	36 %
Steep riffle (≥ 5% grade)	10	26.6 ± 5.1	266.4	44 %
Secondary steep riffle	1	11.5 ± 0.0	11.5	n/a
Tertiary pool	1	2.6 ± 0.0	2.6	n/a
Total	**27**	**24.0 ± 4.3**	**600.2**	**100 %**

3.4.2. YT-24 CREEK

During 2018 monitoring a FHAP survey was conducted on a 545 m section of lower YT-24 Creek (Figure 15). Fifteen distinct habitat units were identified during the survey (Table 28). Habitat units identified included cascades, pools, riffles (<5% grade), and steep riffles (≥5% grade). No glide habitat was identified in the surveyed section.

The surveyed section of YT-24 was dominated by riffle and steep riffle habitat which comprised 49% and 45% of surveyed habitat units by length respectively (Photo 18; Table 28). The average length of riffle (44.3 m) and steep riffle (49.3 m) habitat units were similar. Boulders were the dominant source of cover in these habitats. There were few cascade and pool habitat units, which together comprised the remaining 6% of habitat units by length. The surveyed portion of YT-24 did not contain any secondary (side channel) or tertiary (within channel) habitat.

The frequency and extent of habitat units in this section of YT-24 Creek represents relatively low-quality, low complexity fish habitat given the low frequency of pool (<30% by area), the lack of glide habitat, and little instream cover (Johnston and Slaney 1996). The average bankfull width over all habitat units in YT-24 was 6.06 ± 0.65 m (mean ± SE), with an average wetted width of 3.6 m and an average water depth of 0.24 m in the survey extent.

Table 28. Summary of habitat units identified during the FHAP survey of YT-24 Creek, August 2018.

Habitat type	No. of units	Average length per unit (m ± SE)	Total length in survey extent (m)	Percent of total survey extent
Cascade	3	9.5 ± 0.4	28.4	5 %

3.4.3. LATTE CREEK

During 2018 monitoring a FHAP survey was conducted on a 662 m section in the middle of Latte Creek (Figure 16). Twenty-two distinct habitat units were identified during the survey (Table 29). Habitat units identified include cascades, glides, pools, riffles (<5% grade), and steep riffles (≥5% grade).

The surveyed section of Latte Creek was dominated by riffle and steep riffle habitat which comprised 71% and 22% of surveyed habitat units by length respectively (Photo 19; Table 29). Riffle habitat units were also nearly twice as long as steep riffle habitat units on average (47.1 and 29.0 m respectively). Instream boulders and cobbles were the dominant source of cover in these habitats. In the upper section of the survey, the last five habitat units were all riffle habitat, but were separated because of changes to the stream bankfull width. Two of the five sections were noticeably wider, approximately 10 m in width compared to the preceding and following habitat units which were approximately 5 m in width (Figure 16; APPENDIX E). There were relatively few cascades, glides, and pools, which together comprised the remaining 7% of habitat units by length in Latte Creek. The average residual depth of pool habitat in Latte Creek was 0.4 m, slightly less than the average residual pool depth in both Halfway and YT-24 creeks (0.6 m). The surveyed section of Latte Creek did have one secondary side channel which at the time of the survey was dry. The side channel habitat was approximately 50 m in length and was dry and thus only accessible during periods of high flow.

The frequency and extent of habitat units in this section of Latte Creek represents relatively low-quality, low complexity fish habitat with a low frequency of glide and pool habitat (<30% by area), few pieces of functional LWD, and little instream cover (Johnston and Slaney 1996). Past studies have documented higher quality habitat (with more pools and glides) in the lower section of Latte Creek (LC3.5, formerly LC2.7; (EDI 2017). The average bankfull width over all primary habitat units in Latte Creek was 5.13 ± 0.45 m (mean ± SE), with an average wetted width of 4.1 m and an average water depth of 0.46 m during the survey.

Table 29. Summary of habitat units identified during the FHAP survey of Latte Creek, August 2018.

Habitat type	No. of units	Average length per unit (m ± SE)	Total length in survey extent (m)	Percent of total survey extent
Cascades	1	3.1 ± 0.0	3.1	0.5 %
Glides	2	11.0 ± 0.2	22.0	3 %
Pools	3	7.0 ± 1.8	20.9	3 %
Riffles (<5% grade)	10	47.1 ± 6.9	511.6	71 %
Steep riffles (≥ 5% grade)	5	29.0 ± 14.7	104.3	22 %
Secondary channel (dry)	1	50.0 ± 0.0	50.0	N/A
Total	**22**	**31.5 ± 5.9**	**661.9**	**100 %**

3.5. CHINOOK SPAWNING SURVEYS

No adult Chinook salmon, carcasses or salmon redds were observed during any of the Chinook spawning surveys in 2018. Also, there were no observations of wildlife such as bears or eagles which typically feed on salmon during the spawning season. These results are consistent with data collected in previous years (EDI 2017, 2018).

4. RESULTS AND DISCUSSION – NORTHERN ACCESS ROUTE STUDY AREA

Results and discussion for the Northern Access Route Study area are described in the below sections.

4.1. BARGE LANDINGS

Past work at the proposed barge landing sites on the Yukon and Stewart rivers have indicated these areas contain typical riverbank habitat associated with large rivers (EDI 2018). Sampling in the form of beach seining was conducted to provide information on fish species presence and abundance in the vicinity of the proposed NAR barge landings. Juvenile Chinook salmon, Arctic grayling, longnose sucker, round whitefish, and slimy sculpin were captured in both the Yukon and Stewart rivers during 2018 sampling. Lake whitefish and northern pike were only captured in the Yukon River, whereas lake chub were only captured in the Stewart River during sampling of proposed barge landings in 2018.

4.1.1. BARGE LANDINGS – YUKON RIVER

4.1.1.1. Yukon River North Barge Landing – YUK51.2

The Yukon River North proposed barge landing (right downstream bank) is located at a slight outside bend in the river where the river bank is actively eroding into the river (Photo 20). Due to the eroding river bank and deep water, beach seining could not be completed at the proposed barge landing site. Instead beach seining was completed approximately 75 m downstream of the proposed barge landing in habitat more conducive to successful beach seining, similar to 2017 sampling (EDI 2018). During both July and August, several beach seines were conducted to gain an understanding of fish assemblages (sampling effort was 600 m^2 and 412 m^2, respectively).

Photo 20. **Upstream view of the proposed Yukon River north barge landing site (mid-photo) and proximity of the sampling area (boat location, moving downstream) on the Yukon River on August 9, 2018.**

A total of six species were captured during 2018 fieldwork near the proposed Yukon River north barge landing site (Table 30). Juvenile Chinook salmon were the most frequently captured species during sampling and consistently comprised more than half of caught individuals in July and August (55% and 60%, respectively). Longnose sucker and slimy sculpin were also captured during both July and August sampling events. Juvenile Chinook exhibited the same size pattern observed in other parts of the Yukon River, increasing in size and weight between sampling periods (Table 30).

Table 30. **Yukon River north proposed barge landing (YUK51.2) fish metrics summary, July and August 2018.**

Sampling event	Fish measured	Average fork length (mm ± SE)	Average weight (g ± SE)
July	CH – 6 CCG – 2 LSU – 2 LW – 1	CH – 61.5 ± 3.7 CCG – 36.0 ± 4.0 LSU – 172.5 ± 69.5 LW – 125.0 ± 0.0	CH – 2.5 ± 0.4 CCG – 0.7 ± 0.3 LSU – 97.0 ± 84.7 LW – 36.1 ± 0.0
August	CH – 18 GR – 8 CCG – 2 RW – 1 LSU – 1	CH – 76.8 ± 1.0 GR – 135.4 ± 16.9 CCG – 62.0 ± 0.0 RW – 75.0 ± 0.0 LSU – 72.0 ± 0.0	CH – 5.0 ± 0.3 GR – 34.1 ± 11.6 CCG – 2.3 ± 0.3 RW – 3.5 ± 0.0 LSU – 3.5 ± 0.0

CH = Chinook salmon; GR = Arctic grayling; CCG = slimy sculpin; RW = round whitefish; LW = lake whitefish; LSU = long-nose sucker

4.1.1.2. Yukon River South Winter Road Access – YUK51.2

The Yukon River south (left downstream bank) proposed winter access road crossing is located on the far side of a vegetated island in the Yukon River directly across from the proposed north barge landing site. The area has gently sloping, low river banks and is partially sheltered from the main river current by the upstream extent of the island. The riverbank bed material is comprised of cobbles imbedded in a mix of fines (Photo 21). This location was sampled in July with a sampling effort of 450 m^2.

Photo 21. View of the proposed Yukon River winter road crossing and location of sampling on July 14, 2018.

Juvenile Chinook salmon were the most frequently capture species, with slimy sculpin and round whitefish being the next most frequently captured species (Table 31). Juvenile Chinook salmon comprised 80% of the species captured.

Table 31. Yukon River south winter road access (YUK51.2) fish metrics summary, July 2018.

Sampling event	Fish measured	Average fork length (mm; ± SE)	Average weight (g; ± SE)
July	CH – 12 CCG – 2 RW – 1	CH – 62.0 ± 1.7 CCG – 64.0 ± 6.0 RW – 41.0 ± 0.0	CH – 2.7 ± 0.2 CCG – 2.7 ± 0.9 RW – 0.6 ± 0.0

CH = Chinook salmon; CCG = slimy sculpin; RW = round whitefish

4.1.1.3. Yukon River South Barge Landing – YUK47.6

The Yukon River south proposed barge landing (left downstream bank) is located in an area with uniform, high banks, and a steadily sloping shoreline (Photo 22). The shoreline bed material is comprised primarily of small cobbles and gravels with limited amounts of fines. This site was sampled in August with an effort of 234 m^2.

Photo 22. View of proposed Yukon River south barge landing site on the left downstream bank of the Yukon River on August 9, 2018.

Five species were captured at the proposed Yukon River South barge landing site (Table 32). Juvenile Chinook salmon were the most frequently captured species during 2018 sampling and comprised 48% of captured individuals (Table 32). Slimy sculpin were the second most abundant species captured, followed by Arctic grayling, northern pike and round whitefish.

Table 32. Yukon River south proposed barge landing (YUK47.6) fish metrics summary, August 2018.

Sampling event	Fish measured	Average fork length (mm; ± SE)	Average weight (g; ± SE)
August	CH – 12	CH – 72.9 ± 1.7	CH – 4.3 ± 0.3
	GR – 3	GR – 75.0 ± 2.5	GR – 3.5 ± 0.5
	CCG – 8	CCG – 36.4 ± 4.7	CCG – 1.0 ± 0.3
	NP – 1	NP – 160.0 ± 0.0	NP – 28.0 ± 0.0
	RW – 1	RW – 54.0 ± 0.0	RW – 1.0 ± 0.0

CH = Chinook salmon; GR = Arctic grayling; CCG = slimy sculpin; NP = northern pike; RW = round whitefish

4.1.1.4. Yukon River Existing Barge Landing – YUK46.1

The existing Yukon River barge landing site (left downstream bank) is located immediately adjacent to the current Coffee Gold exploration camp. The gently sloping riverbed is primarily comprised of a mix of gravels, fines, and a few small cobbles (Photo 23). The barge landing site is partially sheltered from the main river current by a large bend in the river and slightly protruding upstream bank. The existing barge landing was sampled in July with a sampling effort 410 m^2.

Photo 23. View of the current barge landing on the Yukon River at the Coffee Gold exploration camp on July 11, 2018.

Three species were captured at the current barge landing, including juvenile Chinook salmon, lake whitefish, and round whitefish during 2018 sampling (Table 33). Juvenile Chinook salmon were the most frequently captured species, accounting for 61% of caught individuals, similar to other proposed barge landing sites.

Table 33. Existing Yukon River barge landing (YUK46.1) fish metrics summary, July 2018.

Sampling event	Total fish captured	Fish measured	Average fork length (mm; ± SE)	Average weight (g; ± SE)
July	CH – 11 LW – 4 RW – 3	CH – 9 LW – 4 RW – 3	CH – 60.9 ± 2.1 LW – 61.3 ± 34.7 RW – 40.7 ± 0.9	CH – 2.4 ± 0.3 LW – 2.1 ± 0.2 RW – 0.5 ± 0.0

CH = Chinook salmon; LW = lake whitefish; RW = round whitefish

4.1.2. BARGE LANDINGS – STEWART RIVER

4.1.2.1. Stewart River North Barge

The Stewart River north proposed barge landing (right downstream bank) is located along a stretch of river with low, moderately sloping banks (Photo 24 from 100m downstream of the proposed barge landing). This riverbank substrate is primarily comprised of a mix of fines with few imbedded cobbles. The proposed barge landing is located in a partial eddy created by upstream bedrock and is partially sheltered from the main river current. The proposed barge landing site sits between some short but steep rock bluffs immediately upstream and a gravel bar downstream. This site was sampled in July with an effort of 480 m^2.

Photo 24. Upstream view 100m downstream of the proposed barge landing site on the north bank of the Stewart River on August 11, 2018.

Juvenile longnose sucker was the most frequently captured species during 2018 sampling (Table 34). The next most frequently captured species were slimy sculpin, lake chub, and round whitefish. Longnose sucker comprised 55% of individuals captured during the July 2018 sampling event. No juvenile Chinook were captured, contrasting Yukon River results where they were captured at all seining locations.

Table 34. Stewart River north proposed barge landing (right downstream bank) fish metrics summary, July 2018.

Sampling event	Total fish captured	Fish measured	Average fork length (mm; ± SE)	Average weight (g; ± SE)
July	LSU – 20 CCG – 9 LKC – 6 RW – 1	LSU – 14 CCG – 9 LKC – 6 RW – 1	LSU – 101.6 ± 7.4 CCG – 47.1 ± 2.5 LKC – 88.5 ± 4.6 RW – 179.0 ± 0.0	LSU – 12.7 ± 2.7 CCG – 1.1 ± 0.2 LKC – 7.6 ± 1.0 RW – 67.9 ± 0.0

LSU = longnose sucker; CCG = slimy sculpin; LKC = lake chub; RW = round whitefish

4.1.2.2. Stewart River South Barge Landing

The Stewart River south proposed barge landing site (left downstream bank) is located along a uniform stretch of river with steep eroding banks and a gently sloping shoreline and riverbed (Photo 25). The riverbed is comprised primarily of cobbles and gravel with some fines. This site was sampled in July with an effort of 400 m^2.

Photo 25. Upstream view 300m downstream from the proposed barge landing site on the left downstream bank of the Stewart River on July 12, 2018.

Juvenile Chinook salmon were the most frequently captured species during 2018 sampling (Table 35). Longnose sucker was the second most frequently captured species, followed by Arctic grayling and lake chub. Juvenile Chinook salmon comprised 75% of individuals captured during the July 2018 sampling event.

Table 35. Stewart River South proposed barge landing (left downstream bank) fish metrics summary, July 2018.

Sampling event	Fish measured	Average fork length (mm; ± SE)	Average weight (g; ± SE)
July	CH – 15 LSU – 3 GR – 1 LKC – 1	CH – 67.8 ± 1.5 LSU – 92.7 ± 13.4 GR – 99.0 ± 0.0 LKC – 75.0 ±0.0	CH – 3.5 ± 2.1 LSU – 8.9 ± 4.4 GR – 9.2 ± 0.0 LKC – 7.0 ± 0.0

CH = Chinook salmon; LSU = longnose sucker; GR = Arctic grayling; LKC = lake chub

4.2. BARGE WAKE INVESTIGATIONS

Waves observed from passing barges (n = 4) washed 20-75 cm onto shore. Measurements were taken as the distance waves washed up onto shore from the waters edge prior the barge passage. Observed waves were either small plunging/spilling waves (Photo 26) or surging waves (Photo 27). Barges passed 60 m or more from shore (estimated 60-240 m) during all observations (Table 36). In comparison, a 14 ft boat with a 25 hp motor driven by on-step approximately 40 m from shore (Site 1) created a wake that washed 30-50 cm onto shore.

Table 36. 2018 barge wake investigation details.

Site	Date	Bed material	Shore slope	Distance from shore (m)	Direction of travel	Wave run out (cm)
Site 1	August 9, 2018	Cobbles, gravels, and boulders	Low - moderate	60	upstream	~55
Site 2	August 9, 2018	Fines (sand/silt) with some cobbles.	Low gradient	50-60	downstream	30-40, 70-80
Site 3	August 12, 2018	Cobbles and fines (silt), and vegetation and fines (silt)	Low gradient	>100	upstream	~20 to 40-50
Site 4	August 15, 2018	Cobbles, gravels, and fines	Moderate gradient (15°)	240[1]	upstream	45-53

[1]Measured using a range finder; other distances were visual estimates.

Turbidity measurements were collected at the second barge passing observation (Site 2; Figure 9). The river bank at this site has a low gradient and was primarily comprised of small cobbles and fines. Turbidity was monitored to characterize the magnitude and length of disturbance from waves. Before the barge passed the site, background turbidity was 9.35 NTUs. Three minutes after the barge passed and waves reached shore turbidity spiked to 150 NTUs. After the three-minute mark turbidity dropped to 68.4 NTUs, then after seven minutes turbidity was close to background levels at 14.53 NTUs. Waves from passing barges increased turbidity in an extremely localized area up to a maximum of one meter from shore.

Larger waves have a higher potential to cause shoreline erosion. The size of waves produced by a vessel is a factor of the vessel size, weight, hull shape, and speed (Maynord 2001). The size of waves that reach shore, and their erosion potential, is further dependent on the vessels distance from shore, the depth of water, the presence or absence of shoreline vegetation, and the nearshore profile and substrate composition (Maynord et al. 2008, Bilkovic et al. 2017). The likelihood that waves from vessels will contribute to shoreline erosion can also depend on water level and the frequency, timing, and location of vessel traffic (Maynord et al.

2008). The waves observed during August 2018 fieldwork were generally small, low energy waves that created short-lived, localized disturbances. An Alaska study indicated that while waves from vessels did cause some shoreline erosion, the magnitude of the disturbance was minimal compared to large flood events (Maynord et al. 2008). Much of the shoreline of the Yukon River is armored against erosion from barge induced waves at normal and low water levels due to the presence of cobbles on riverbanks.

Photo 26. **A small plunging/spilling breaking wave at Site 1, note the sediment suspended in the turbulent wave on August 9, 2018.**

Photo 27. **A surging wave at Site 4. Note the portion of the meter stick that is underwater was previously at the waters edge (approximately 50 cm) on August 15, 2018.**

4.3. STEWART RIVER BACK CHANNEL INVESTIGATIONS

The Stewart River back channel adjacent to the proposed NAR was investigated for connectivity, suitable fish habitat, and fish presence using beach seining techniques in early July 2018. Unlike previous investigations on the back channel in October 2016 and September 2017 (EDI 2017, 2018), the channel was wetted up to approximately 600 m from the Stewart River. The mouth of the back channel was fairly wide and partially filled with water (Photo 28, Photo 29); there was evidence of the water level having been much higher earlier in the summer or spring, with vegetation in the branches of trees and woody debris along the banks (Photo 30). Nearly the entirety of the channel was characterized by a reed grass (suspected to be bluejoint reedgrass; *Calamagrostis canadensis*) that was present within the wetted area, as well as covering much of the unwetted bankfull channel. The channel was primarily narrow with fallen trees and other woody debris for the first 500 m (Photo 31). At approximately 500 m upstream from the Stewart River, the channel became wider and deeper with less cover, and also less of the aforementioned tall grass (Photo 32). This widened open channel continued until the end of the investigation at approximately 600 m, at which point the back channel severely narrowed and was inundated by woody debris with very little water (Photo 33).

Photo 28. View of the back channel facing upstream from the Stewart River on July 11, 2018.

Photo 29. Upstream view of the Stewart River back channel near the mouth of the outflow to the Stewart River on July 11, 2018.

Photo 30. Downstream view and evidence of a larger channel at high water on July 12, 2018.

Photo 31. Downstream view of a typical narrow section of the Stewart River back channel on July 11, 2018.

Photo 32. Upstream view of the Stewart River back channel in the wider and deeper stretch approximately 500 m upstream of the Stewart River on July 12, 2018.

Photo 33. Upstream view of the Stewart River back channel at the top of the NAR encroachment area, 600 m from the mouth on July 12, 2018.

The areas that were beach seined varied in wetted width from 1-6 m, and depth varying from 0.3-1.2 m (Photo 34). Fish were captured in six of the ten seine hauls that were conducted in the Stewart River back channel (Table 37, Table 38). The species captured included burbot, northern pike, and lake whitefish (Table 37, Table 38). There were more than 100 larval fish (species could not be determined) captured in the first seine haul (SR_BC1); they were not fully enumerated or measured in an effort to reduce mortality, although were estimated to be < 15 mm (Table 38; Photo 35). The larval fish weren't able to be identified; however, they would have been YOY from spring spawners, potentially lake chub. Not including the larval fish, lake whitefish had the highest CPUE, followed by northern pike and burbot (Table 38). Lake whitefish were spot-seined and all captured in a single seine haul, approximately 600 m upstream from the Stewart River. Lake whitefish had a CPUE range of 0.0-95.0 fish/100 m^2 (Table 37, Table 38; Photo 36). Northern pike were captured in five of the ten seine hauls and CPUE varied from 2.8-20.0 fish/100 m^2 (Table 37, Table 38; Photo 38). Burbot were caught in four of the ten seine hauls, and CPUE varied from 0.0-20.0 fish/100 m^2 (Table 37, Table 38; Photo 37).

Photo 34. Field crews beach seine in the Stewart River back channel on August 11, 2018.

Table 37. Stewart River back channel beach seining and fish metrics summary.

Waterbody	Sample effort	Total fish captured	Fish measured	Average fork length (mm ± SE)	Fork length range (mm)	Average weight (g ± SE)	Weight range (g)
Stewart River back channel	10 beach seine hauls	BB – 12 NP – 15 LW – 19	BB – 12 NP – 15 LW –10	BB – 33.4 ± 1.4 NP – 43.5 ± 5.0 LW – 45.2 ± 2.1	BB – 27-44 NP – 7-73 LW – 34-54	BB – 0.4 ± 0.0 NP – 1.3 ± 0.3 LW – 0.8 ± 0.1	BB – 0.2-0.8 NP – 0.1-3.3 LW – 0.4-1.1

BB = burbot; NP = northern pike; LW = lake whitefish

Table 38. Catch-per-unit-effort summary of fish captured in the Stewart River back channel, July 2018.

Sampling site	Lake whitefish CPUE (fish/100m²)	Northern pike CPUE (fish/100m²)	Burbot CPUE (fish/100m²)
SR_BC1[1]	0.0	5.6	6.7

SR_BC10	95.0[2]	0.0[3]	0.0
Average ± SE	**9.5 ± 9.5**	**6.7 ± 2.6**	**3.9 ± 2.1**

[1]Over 100 unidentified larval fish were captured in this seine haul but were not fully enumerated or measured in an effort to reduce mortalities.
[2]These fish were first visually observed but were not able to be positively identified; therefore, they were spot-seined, resulting in the high CPUE from a relatively small seine haul.
[3]Three juvenile northern pike were observed but not captured.

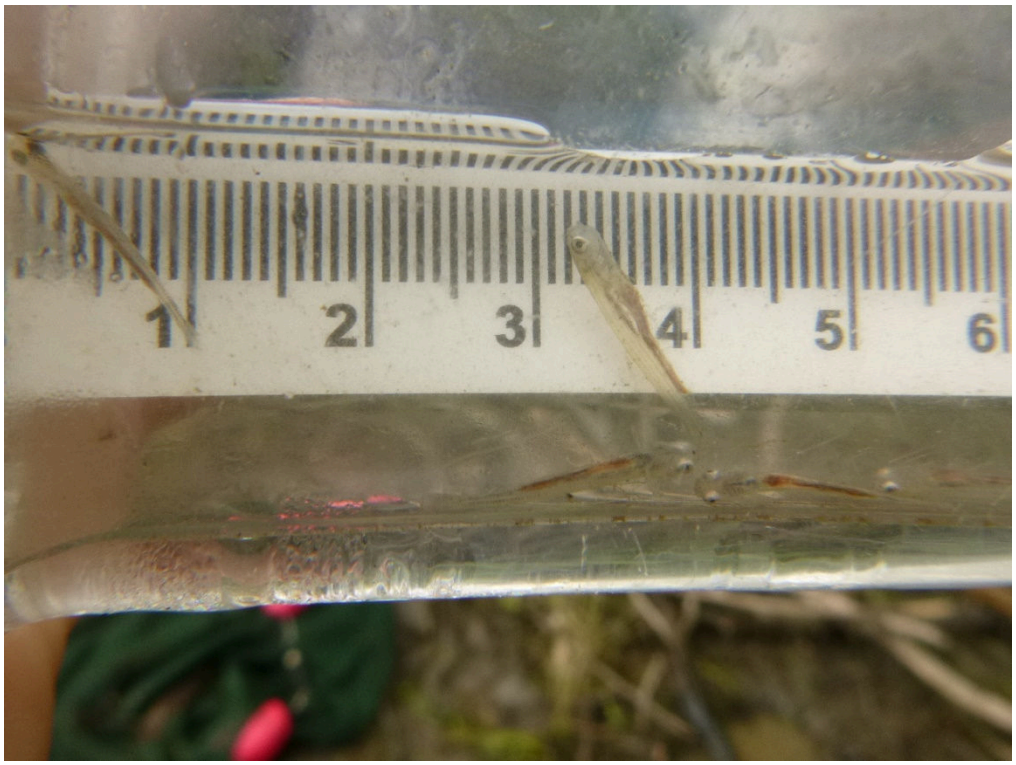

Photo 35. Unidentified larval fish captured in SR_BC1 on July 11, 2018.

Photo 36. Juvenile lake whitefish captured approximately 600 m from the mouth of the Stewart River back channel on July 12, 2018.

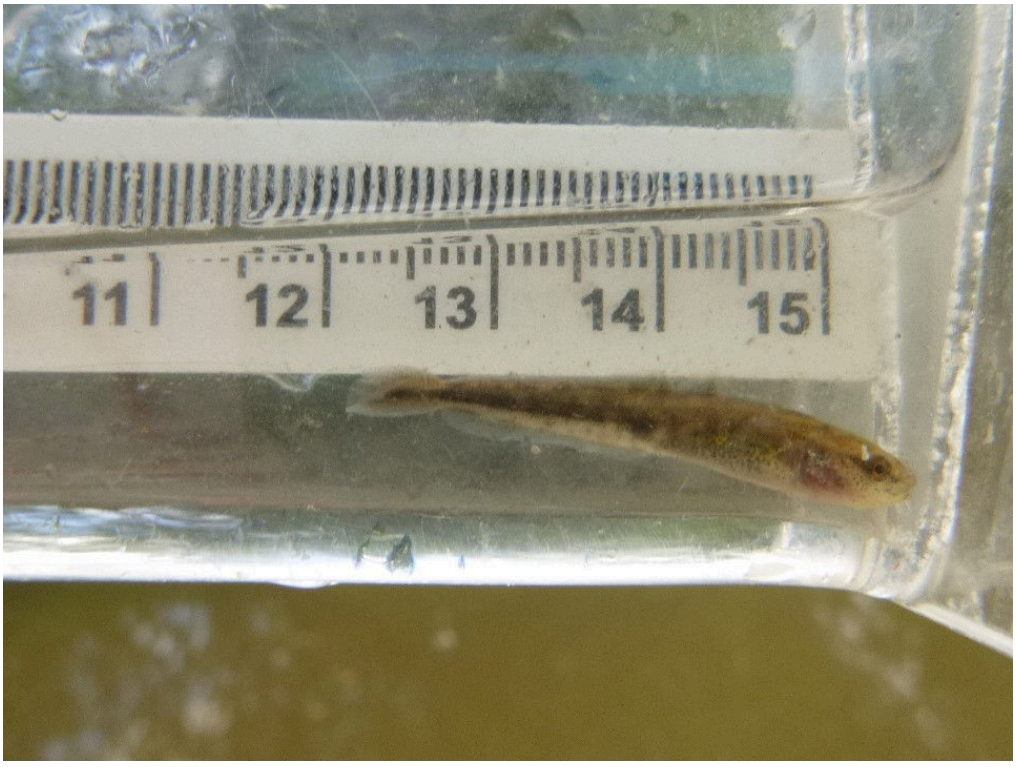

Photo 37. A juvenile YOY burbot captured in seine haul SR_BC1 on July 11, 2018.

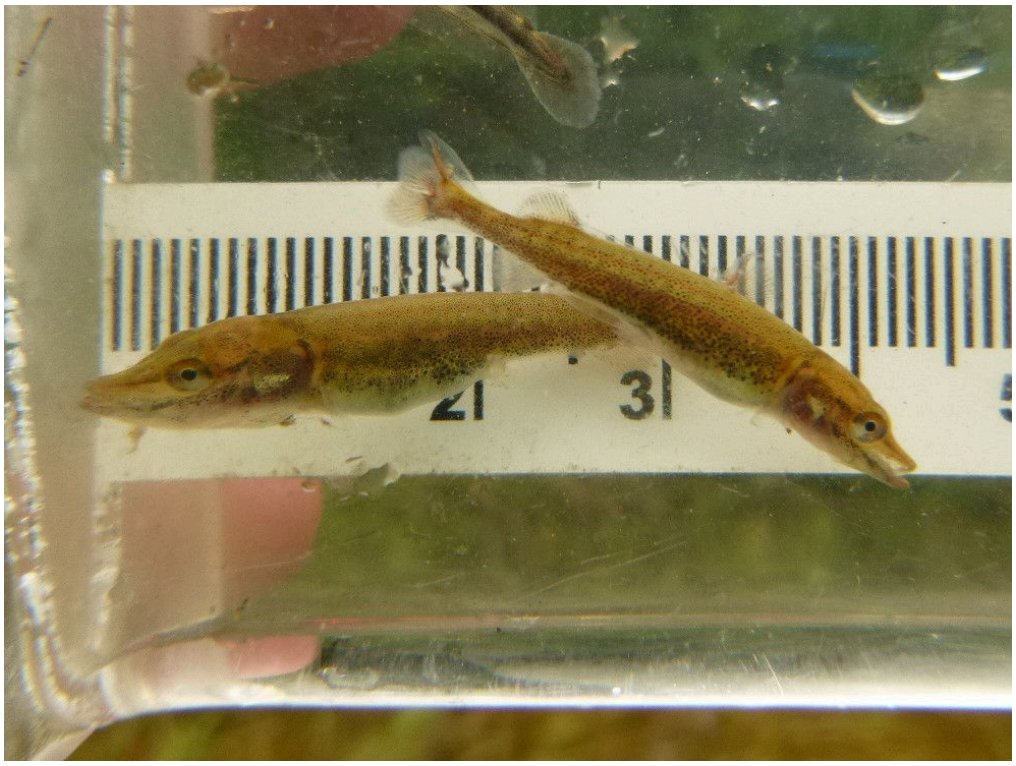

Photo 38. Two juvenile YOY northern pike captured in SR_BC7 on July 12, 2018.

It was common to capture both juvenile burbot and northern pike in the same seine hauls, with burbot occurring in four out of the five hauls that northern pike were caught in, and northern pike in all of the hauls that captured burbot (Table 38). The beach seining results from the back channel indicate that at the water levels sampled, this back channel is being used nursery habitat for juvenile YOY burbot, northern pike, and lake whitefish. Seasonally flooding back water areas provide vital habitats for juvenile burbot and northern pike (Casselman and Lewis 1996, Worthington et al. 2012). These juvenile fish also have a very patchy distribution, making it difficult to classify different parts of the back channel area as more or less important habitat (Cucherousset et al. 2009). Based on their life history and spawning preferences, it is a possibility that northern pike spawn in the back channel. However, in the case of burbot and lake whitefish is it likely that they spawn elsewhere and use the back channel as a nursery habitat (given the channel is expected to be dry during their spawning period). It is also important to note that this back channel is only seasonally flooded, and would be expected to be cut off from the Stewart River once water levels on the river drop approximately 0.5 m from the river level when fish sampling occurred (Figure 17). The water depth at the first seine haul was approximately 0.4 m; by the last week of July water levels would have likely dropped enough to isolate the back channel from the Stewart River (Figure 17). The early August high rainfall events contributed to the subsequent high water levels, but by end of September the water levels would have dropped again to the point that would dry up the back channel (Figure 17). Primary water levels at the mouth of the Stewart River were 27.007 m when sampling occurred on July 11, 2018. At this time it isn't known if these juvenile YOY fish emigrate out of the back channel before connectivity is lost with the Stewart River, or whether stranding occurs. At the July 11, 2018 water levels, it is estimated the NAR

encroachment would not have reached the water edge; the encroachment would only occur for a short period likely during the freshet and subsequent high water.

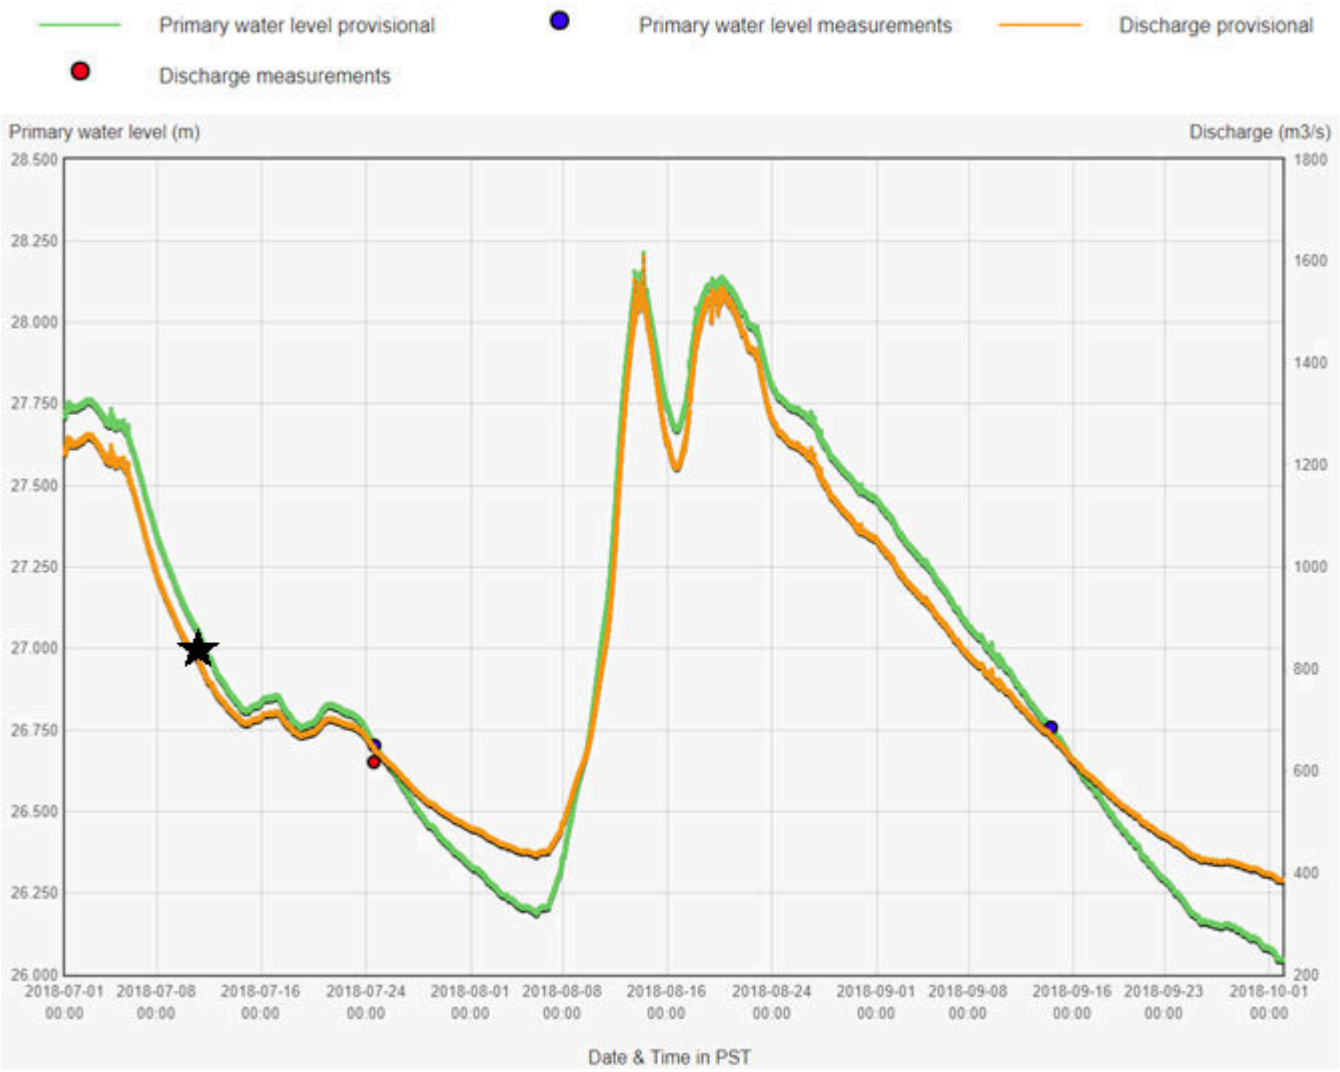

Figure 17. Water level on the Stewart River from July 1 to October 1, 2018. The star denotes levels when fish sampling occurred in 2018 (modified from Environment Canada 2019).

4.4. CHUM SPAWNING SURVEYS

During the 2018 chum spawning survey, both the Yukon and Stewart River had low water levels, which allowed for ideal surveying conditions and water clarity. However, due to such low water conditions, many of the side channels where spawning chum salmon were previously identified during past surveys were completely dewatered (Photo 39). There was little formation of pancake or shore ice on either river, and where ice was present in the side channels that hadn't dewatered, the water clarity and absence of snow allowed for effective surveying through the ice (Photo 40).

Photo 39. Dewatered side channel on the Stewart River October 13, 2018.

Photo 40. Spawning chum salmon under ice on the Yukon River on October 13, 2018.

During the survey of the Yukon River approximately 457 live chum, 90 redds, and five carcasses were observed. No live chum, carcasses, or evidence of spawning activity (redds) was observed on the Stewart River in 2018. When comparing these numbers to previous results, it is prudent to consider the relative size of the respective chum spawning runs. The 2018 run totals were fairly inline with recent years, with the exception of the 2017 chum spawning run which far surpassed the five-year average (2012-2016: 165,810; Figure 18). These results are also reflected in previous EDI chum spawning surveys (Table 39).

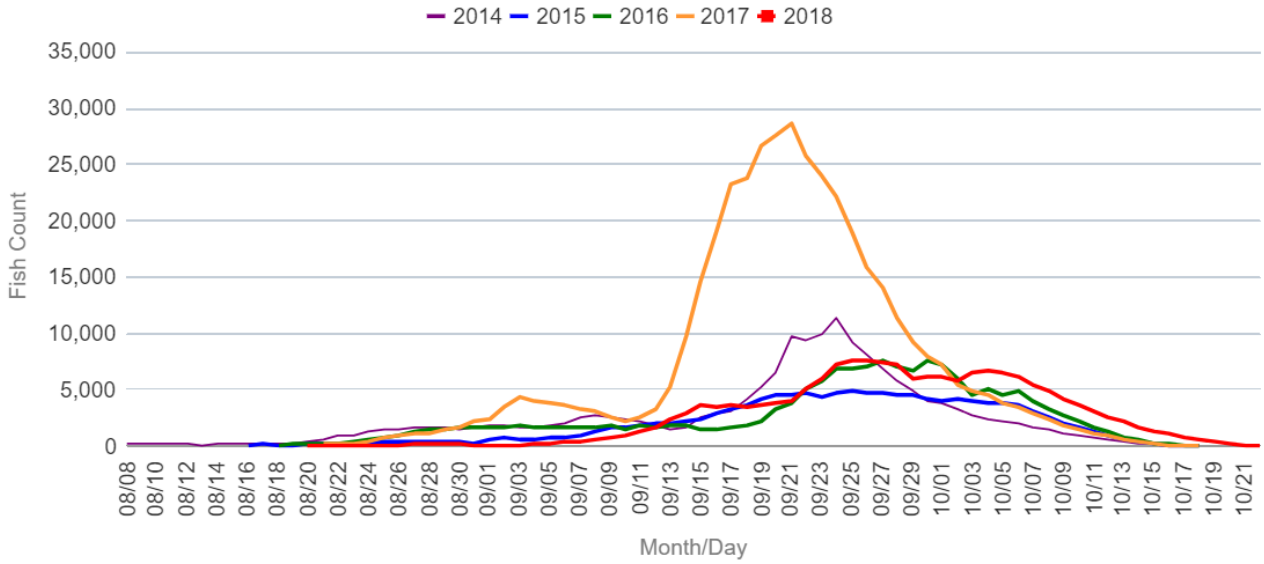

Figure 18. Eagle Sonar (Yukon/Canadian Border) historical daily passage of chum salmon (Alaska Department of Fish and Game, 2018).

Table 39. Spawning live chum salmon survey results from 2016-2018 (EDI Environmental Dynamics Inc. 2017, 2018).

	2016	2017	2018
Yukon River	263	907	457
Stewart River	3	102	0

The chum spawning surveys over the past three years have provided variable results, as a product of run size, environmental conditions (e.g., water level, ice conditions), survey timing, and gaining knowledge on spawning areas (Table 39). During the 2017 survey period there were substantially more fish observed on both the Yukon and Stewart River than in 2018, albeit the run was approximately 250,000 larger in 2017 (Alaska Department of Fish and Game 2018). Live chum salmon were observed in the same areas as in 2016 and 2017 (Figure 19). Conversely, there were more chum redds observed in 2018 than in 2017 (90 and 38, respectively; Figure 20). The redds were in more concentrated areas and didn't have the same spatial distribution as the 2017 results; good water clarity and snow-free ice cover of the channels allowed for a clear view of redds. Lastly, very few carcasses were observed during the 2018 survey; the survey occurred approximately seven days earlier than the 2017, which likely accounted for fewer carcasses (Figure 21).

5. IMPLICATIONS

Field work from the 2018 field season provided valuable information for moving forward in future research and monitoring programs. Several programs assessed in the 2018 field season had noteworthy conclusions or implications:

- Halfway Creek and YT-24 Creek mixing zones indicated higher diversity and abundance than elsewhere on the Yukon River. The only exception to this is the sampling that occurred across from the mouth of YT-24 Creek, which also had high species diversity and abundance (particularly of juvenile Chinook). This finding raised the question of whether fish abundance and diversity were high due to the proximity (and potential influence) of the creek mouth, or whether there was some effect of an eddy where sampling occurred across from the creek mouth. Future research will extend sampling to mixing zones, average shoreline areas on the Yukon River (no eddies, no mixing zones), as well as shoreline areas on the Yukon River that have an eddy (but no influence of a nearby creek mouth).

- Opportunistic barge wake investigations indicated that the effects of barge-induced wave break on shore are minimal and localized close to the shore, and fish stranding is unlikely to be a concern for the barges currently being used.

- The Stewart River back channel provides nursery habitat for YOY northern pike, burbot, lake whitefish, as well as unidentified larval fish (progeny of spring spawners). Based on the habitat, the back channel may also provide potential spawning habitat for northern pike in the early spring. Future research will include a spring survey of the channel.

- Three years of aerial chum spawning surveys have indicated that spawning occurs annually in the Yukon River, and when conditions allow (i.e., wetted side channels), they have also been observed spawning in the Stewart River.

APPENDIX D. HABITAT UNIT PHOTOGRAPHS

This page is intentionally blank.

Halfway Creek Habitat Units

Photo 1. Downstream view of glide habitat on Halfway Creek (0+488; August 14, 2018).

Photo 2. Upstream view of pool habitat on Halfway Creek (0+388; August 12, 2018).

Photo 3. Upstream view of riffle habitat on Halfway Creek (0+063; August 14, 2018).

Photo 4. Left downstream bank view of steep riffle habitat on Halfway Creek (0+217; August 14, 2018).

Photo 5. Downstream view of steep riffle habitat on Halfway Creek (0+492; August 14, 2018).

Photo 6. Right downstream bank view of tertiary pool habitat on Halfway Creek (0+460; August 14, 2018).

YT-24 Habitat Units

Photo 7. Upstream view of cascade habitat on Creek YT-24 (0+429; August 13, 2018).

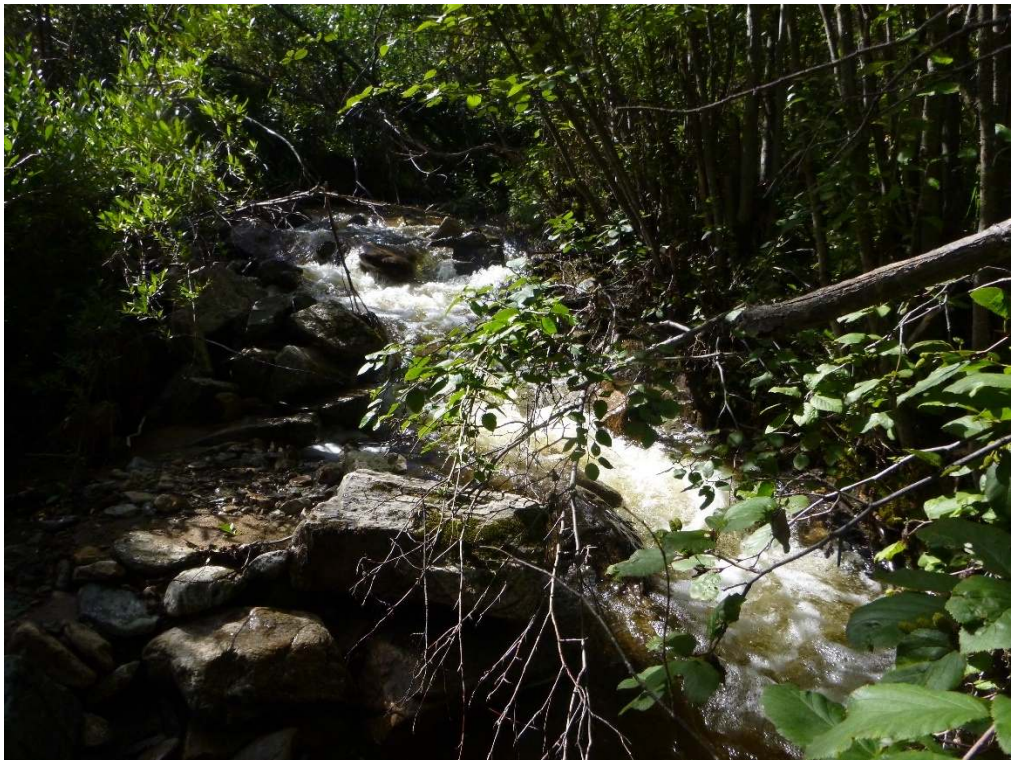

Photo 8. Example of cascade habitat on Creek YT-24 (0+525; August 13, 2018).

Photo 9. Upstream view of pool habitat on Creek YT-24 (0+100; August 13, 2018).

Photo 10. Upstream/ left downstream bank view of pool habitat on Creek YT-24 (0+100; August 13, 2018).

Photo 11. Downstream view of riffle habitat on Creek YT-24 (0+030; August 13, 2018).

Photo 12. Upstream view of riffle habitat on Creek YT-24 (0+051; August 13, 2018).

Photo 13. Upstream view of steep riffle habitat on Creek YT-24 (0+438; August 13, 2018).

Photo 14. Upstream view of steep riffle habitat on Creek YT-24 (0+314; August 13, 2018).

Latte Creek Habitat Units

Photo 15. Downstream view of cascade habitat on Latte Creek (0+074; August 10, 2018).

Photo 16. Upstream view of cascade habitat on Latte Creek (0+074; August 10, 2018).

Photo 17. Upstream view of glide habitat on Latte Creek (0+346; August 10, 2018).

Photo 18. Downstream view of glide habitat on Latte Creek (0+346; August 10, 2018).

Photo 19. Upstream view of pool habitat on Latte Creek (0+181; August 10, 2018).

Photo 20. Downstream view of pool habitat on Latte Creek (0+181; August 10, 2018).

Photo 21. Upstream view of riffle habitat on Latte Creek (0+192; August 10, 2018).

Photo 22. Downstream view of riffle habitat on Latte Creek (0+590; August 10, 2018).

Photo 23. Downstream view of wide riffle habitat on Latte Creek (0+411; August 10, 2018).

Photo 24. Downstream view of wide riffle habitat on Latte Creek (0+552; August 10, 2018).

Photo 25. Upstream view of steep riffle habitat on Latte Creek (0+300; August 10, 2018).

Photo 26. Downstream view of steep riffle habitat on Latte Creek (0+260; August 10, 2018).

EXECUTIVE SUMMARY

The Coffee Gold Project (the Project) is a proposed gold mine in west-central Yukon owned by Newmont Goldcorp Corp. (previously Goldcorp Kaminak Ltd.). The Project was submitted to the Yukon Environmental and Socio-economic Assessment Board (YESAB) Executive Committee in 2017 for review under the *Yukon Environmental and Socio-Economic Assessment Act* (YESAA). Several reports have been submitted to YESAB detailing field studies (2014 to 2016), baseline surveys, and the Project effects assessment for fish and fish habitat. In 2018 and 2019, supplementary studies and monitoring programs were conducted in the Project area to supplement existing baseline knowledge, address questions raised during Project review, and refine proposed fish monitoring programs in anticipation of future monitoring requirements.

Aquatic data have been collected for several years at the Project, with EDI Environmental Dynamics Inc. (EDI) collecting baseline and monitoring data annually since 2016. Fieldwork in 2019 was intended to supplement existing pre-project data and provide additional monitoring data to allow for future comparisons following mine operation. The 2019 field season occurred over the months of May, July, and August within the Mine Study Area (MSA) and the Northern Access Route (NAR).

The following activities took place within the MSA: fish sampling in creeks within and adjacent to the Project area, sampling in the mixing zones within the Yukon River, fish habitat assessment procedures (FHAP), and aerial surveys for Chinook salmon spawning. Within the NAR, the 2019 field study focussed on barge landing and barge wake investigations, as well as the Stewart River back channel.

Investigations occurred within the MSA in July and August 2019. Specifically, minnow trapping was completed on Coffee Creek, and electrofishing was performed on Halfway and YT-24 creeks. Minnow traps were set at Carlisle, Excelsior, and Los Angeles creeks, adjacent to the MSA, to find a suitable control for Coffee Creek juvenile Chinook salmon. Beach seining was conducted in the Halfway and YT-24 Creek mixing zones within the Yukon River (i.e., where the outlet of the creeks flow into the Yukon River). The FHAPs were conducted on two sites on Carlisle Creek, as well as Coffee Creek and an unnamed tributary one creek upstream of YT-24. Similar to previous years, Coffee and Independence creeks had aerial Chinook salmon spawning surveys completed in August and a ground survey took place on Coffee Creek.

The NAR investigations occurred over a one-day visit in May, as well as the July and August field trips. In July and August, the proposed barge landing sites were beach seined on the Yukon and Stewart rivers. In July, an opportunistic barge wake investigation was completed on the Yukon River with a focus on wake extent along the shore. During the May visit, the Stewart River back channel was investigated for the presence of spawning pike and was beach seined; it was visited again in July and August with site conditions documented.

Pertinent results from the 2019 field season include:

- Juvenile Chinook salmon were captured in Coffee Creek, but none in Carlisle, Excelsior, or Los Angeles creeks.
- Arctic grayling were captured in high numbers in Halfway Creek, particularly during the August visit.

- YT-24 Creek had approximately 60 m of dry creek 190 m upstream from the mouth during the July visit; also during the July visit, the creek did not contain enough water to flow into the Yukon River, drying up 3.5 m from the Yukon River. These areas were wetted during the August survey.
- The Yukon River mixing zones on Halfway and YT-24 creeks contained higher species diversity and abundance than did the Yukon River reference site. However, a site immediately downstream of the reference site in identical habitat had a catch-per-unit-effort more similar to the creek mixing zones. During the July visit, YT-24 Creek did not have a mixing zone as the water did not reach the Yukon River, but the area still contained a high species abundance and diversity.
- No evidence of spawning activity was found during Chinook salmon spawning surveys in Coffee and Independence creeks.
- Barge landing sampling on the Yukon River indicated that the north and south proposed barge landing sites had fairly low species diversity and abundance. However, the existing barge landing on the Yukon River adjacent to Coffee Camp had the highest species diversity and abundance since sampling of the site began in 2017. The barge landing is being used more frequently in the open water months and based on the sampling in August it does not appear to be deterring juvenile fish from rearing in the area.
- The barge landing sampling on the Stewart River produced the highest species diversity and abundance of any sampling within the NAR in 2019.
- Little wake or lasting impact was detected during barge wake investigations. The waves reaching shore came up 11 to 35 cm; waves came up higher on gently sloping silt or sand portions than on cobble. The turbidity was higher and lasted longer in back eddy areas with considerable silt.
- During the May visit of the Stewart River back channel, adult northern pike were observed and captured in the wetted portion of the back channel. Juvenile longnose sucker were also captured in low numbers within the back channel. The back channel was dry during the July and August field visits.

ACKNOWLEDGEMENTS

Jennie Gjertsen, Environmental and Permitting Manager, and Jasmin Dobson, Environmental Superintendent for the Project, managed EDI's work on the Project on behalf of Newmont Goldcorp Corp. (Newmont Goldcorp). Other members of Newmont Goldcorp's environmental staff, including Carolyn Johns, Kate Titterington, Alex Charron, and Andrew Taylor provided field support for numerous surveys and local insight into the environmental conditions. Ryan Head and Christopher Alves, Camp Managers, provided logistical support to help our field crews complete the work in an efficient and effective matter. EDI would also like to thank the various pilots with Horizon Helicopters who provided exceptional support for our aerial survey work and safely transported our crews to and from remote work sites.

1 INTRODUCTION

The Coffee Gold Project (the Project) is a proposed gold mine in west-central Yukon, located 130 km south of Dawson City. Gold was initially discovered at Coffee Creek in 2010, and exploration activities have been ongoing since. Baseline environmental studies began in 2010 and were expanded in the following years in anticipation of future regulatory requirements.

The proposed Project will consist of an open pit gold mine and heap leach facility. The projected mine life is ten years with an 18-month construction period. The feasibility study proposes four open pits mined by conventional shovel and truck methods. The mine and associated activities will generally be located on a relatively high elevation ridge top and will not extend into the lower elevations where the larger streams are located. The mine footprint does include the upper part of some headwater watersheds (including Halfway Creek, YT-24 and unnamed tributaries to Latte Creek). Most prominently, the main proposed Waste Rock Storage Facility will be positioned in the upper Halfway Creek watershed.

The Project will be accessed by road from Dawson City via a 214-km single-lane, gravel road with pull-outs. The initial part of this route, from the Klondike Highway to Sulphur Creek uses a government-maintained gravel road. Beyond Sulphur Creek, the Northern Access Route (NAR) mainly follows existing placer mine roads that will be upgraded to provide all-season access to supply vehicles. Approximately 30 km of new road will be constructed (Figure 1). Electricity is planned to be generated on site by diesel-powered generators. Most mine staff will access the site by air.

The Project is located on Crown land within the Traditional Territory of the Tr'ondëk Hwëch'in and the asserted traditional territory of the White River First Nation. A portion of Goldcorp's claim block is located in the Traditional Territory of the Selkirk First Nation and the proposed access road also overlaps with the Traditional Territory of the First Nation of the Na-Cho Nyak Dun.

The proposed Project is currently going through an Executive Committee Screening from the Yukon Environmental and Socio-economic Assessment Board (YESAB) and will require a Type A Water License issued by the Yukon Water Board and a Quartz Mining License issued by the Yukon Government, among other permits and licences.

1.1 STUDY PURPOSE AND SCOPE

Palmer Environmental Consulting Group collected baseline data around the mine in 2014 and 2015 (PECG 2017) and along the access road in 2015 (PECG 2016). EDI Environmental Dynamics Inc. (EDI) collected additional baseline data in 2016 to 2018 around the Mine Study Area (MSA) and NAR and summarized all data collected to date (EDI 2017, 2018, 2019). The study conducted in 2018 was intended to expand the baseline (both spatially and quantitatively), support the effects assessment for the Project, and provide pre-project information that can be used for effects monitoring. Fieldwork conducted during the 2019 field season provides additional fish and aquatic resource baseline conditions and pre-project monitoring information.

Project components for the MSA (Figure 2) 2019 field studies included:

- fish sampling on various creeks in the MSA, and within mixing zones of the Yukon River;
- barge landing fish sampling and investigations,
- fish habitat assessments; and,
- Chinook salmon (*Oncorhynchus tshawytscha*) spawning surveys.

Project components for the NAR Study Area (Figure 3) 2019 field studies included:

- barge landing fish sampling and investigations; and,
- fish habitat investigations in a back channel of the Stewart River.

1.2 BASELINE SAMPLING STATION CONCORDANCE

To promote consistency among groups working on aquatic and fisheries work within the Project area, a new station naming system was developed in 2018, and followed during the 2019 field season. To rectify previous sampling stations with the new system, a table of concordance is provided (Table 1). The new naming system allows for easy determination of station location and the addition of new stations, if and where needed:

1. Each station ID designation begins with a two or three letter code for each creek in the MSA. Three letter codes are used for unnamed tributaries to named creeks; therefore, LCC corresponds to Latte Creek, Tributary C.

2. Following the creek letter code is a numeric designation that represents the stream distance (kilometres) of a sampling station from its major confluence (i.e., following the meandering of the creek).

3. For stations in the Yukon River, the naming convention follows the number of kilometres from the confluence with the White River.

Table 1. Concordance table of Project fisheries and aquatic field sampling station identifiers.

2 METHODS

Methods are presented for the MSA and the NAR Study Area in separate sections below. The MSA includes controls inside and outside of the mapped MSA.

2.1 MINE STUDY AREA

Aquatic sampling during the 2019 field season included fish sampling on Coffee, Halfway, YT-24, Carlisle, Los Angeles, and Excelsior creeks, as well as fish sampling in the mixing zone of the Yukon River at the mouths of Halfway and YT-24 creeks. Fish sampling consisted of beach seining, electrofishing, and minnow trapping. Fish Habitat Assessment Procedure (FHAP; Johnston and Slaney 1996) surveys were completed on Coffee Creek, upper Halfway Creek, an unnamed tributary upstream of YT-24, lower Carlisle Creek, and a tributary of upper Carlisle Creek. Lastly, Coffee and Independence creeks had Chinook salmon spawning surveys completed. In-situ water quality was measured at all sampled sites (Appendix A).

2.1.1 FISH SAMPLING AND HABITAT INVESTIGATIONS

Fish sampling was conducted on several creeks and rivers within the MSA. Fish sampling occurred during two field events, spanning July 8 to 14 and August 7 to 13, 2019 (Figure 4). The objective of fish sampling was to add to existing baseline fisheries information, particularly for fish distribution and assemblages in several select streams within the MSA. The fish sampling method used at each site depended on physical stream features and suitability of the method for the targeted species. The sampling methods used included electrofishing, beach seining, and minnow trapping. Captured fish were identified to species, with the remaining fish enumerated before all fish were released back at their site of capture.

A Smith Root 12-B POW electrofisher was used for open-site single-pass electrofishing on appropriately sized creeks. The beach seine was 10 m in length, 1.5 m deep and constructed of a 5 mm mesh, with a buoyant float line and sinking lead line. Beach seine hauls were conducted with field crews of two members and consisted of varying lengths, widths, and depths dependent on the stream environment. Minnow traps were placed in areas of good cover and suitable depth and stream velocity. Each minnow trapping site had three small mesh gee type minnow traps (0.6 cm mesh size) baited with cured roe in a perforated bag and were positioned along stream margins in slow water habitats. Water depth, site characteristics, and photos were recorded for each trap and traps were left to soak overnight. A YSI ProSOLO was used to collect in situ water quality parameters (temperature, dissolved oxygen, specific conductivity) at all fish sampling sites; during August a pH pen was also used. Digital photos and GPS coordinates were taken of all sites sampled for fish.

For electrofishing, the fishing effort was enumerated on the device and given in total seconds of active electrofishing as well as the approximate distance from the electrofishing starting GPS point. Beach seining efforts were measured by the length and width of a seine haul (i.e., area seined; m^2). Total minnow trapping effort was enumerated based on the number of traps multiplied by soak times (HH:MM). Ten of each species were weighed (g) and measured to fork length (mm; e.g., Chinook salmon, whitefish) or total length (mm; e.g., slimy sculpin; *Cottus cognatus*) at every site for each sampling method. In some instances, weight could not be

recorded because fish were either too big or too small for the scale. The mean fork length and weight (± standard error; SE) was calculated for each group of fish per species, per sampling event. In cases where no weight was taken, fish length was still used in calculations. Catch-per-unit-effort (CPUE) was also considered at each site, where appropriate. Fish catch data are provided (Appendix B).

2.1.1.1 Coffee Creek

Coffee Creek was visited during both July and August 2019 (Site CC5.6). Minnow trapping occurred on July 11 and August 9, with the primary objective of targeting juvenile Chinook salmon. Three minnow trapping sets occurred at CC5.6, containing three traps per set (n = 9; Figure 4). Minnow traps were set late in the afternoon and pulled early in the morning (mean soak time = 15.19 ± 0.04 hr). The results were presented using an average catch of all the sets, to provide an average for the site. Coffee Creek investigations also included a ground spawning survey, two aerial Chinook spawning surveys conducted in August (see Section 2.1.4), and a fish habitat assessment (see Section 2.1.3).

2.1.1.2 Halfway Creek

Fisheries investigations at Halfway Creek were conducted July 8 and 10, as well as August 7, 9, and 10, 2019. Halfway Creek was sampled for fish with the objective of supplementing and supporting findings from previous years. Electrofishing occurred from 0.2 km to approximately 1.2 km upstream from the confluence with the Yukon River (Table 2; Figure 4). The known logjam approximately 1 km from the mouth had photos and measurements taken. Sampling continued above this perceived barrier (HC1.1) to ascertain whether fish had successfully passed it during the 2019 season. Beach seining took place at the mouth of Halfway Creek to compare species assemblages and abundances in mixing zones of the Yukon River (see Section 2.1.2).

Table 2. Halfway Creek electrofishing methods summary from July and August 2019.

Sampling site	Date	Distance (m)	Fishing effort (seconds)	Electrofisher settings	Duty cycle (%)
HC0.2	July 8, 2019	150	1,189	300 V, 50 Hz, 4ms	20
HC0.2	August 9, 2019	150	1,122	400 V, 60 Hz, 6 ms	36
HC0.7	July 10, 2019	150	1,300	400 V, 50 Hz, 4 ms	20
HC0.7	August 7, 2019	150	936	400 V, 60 Hz, 6 ms	36
HC1.1	July 10, 2019	180	1,124	300 V, 50 Hz, 4ms	20
HC1.1	August 7, 2019	170	956	400 V, 60 Hz, 6 ms	36

2.1.1.3 YT-24 Creek

YT-24 Creek was investigated on July 14 and August 10, 2019. During the July visit, the flow in YT-24 was too low to electrofish. Electrofishing occurred in August on the lower 200 m of the creek (Table 3; Figure 4). The mouth of YT-24 Creek was also beach seined to compare species assemblages and abundances in mixing zones of the Yukon River (see Section 2.1.2).

Table 3. YT-24 Creek electrofishing methods summary from August 2019.

Sampling site	Date	Distance (m)	Fishing effort (seconds)	Electrofisher settings	Duty cycle (%)
YT0.2	August 10, 2019	150	950	400 V, 50 Hz, 3 ms	15

2.1.1.4 Carlisle, Excelsior, and Los Angeles Creeks

Carlisle, Excelsior, and Los Angeles creeks were sampled in either July or August 2019 (Table 4). Minnow trapping occurred at one site on each creek, with the primary objective of targeting juvenile Chinook salmon to act as a control site and compare with Coffee Creek (Figure 4). Three minnow trap sets were deployed at each site, and each set included three traps (i.e., n = 9). Traps were left to soak overnight and occasionally into the day (Table 4). Carlisle Creek also had a fish habitat assessment conducted in August (see Section 2.1.3).

Table 4. Minnow trapping summary on Carlisle, Excelsior, and Los Angeles creeks in July and August 2019.

Sampling site	Creek	Date	Mean soak time (± SE hr)	Distance from Independence Creek (km)
CL7.9	Carlisle Creek	July 12, 2019	26.6 ± 0.01	4.9 km downstream
EX2.9	Excelsior Creek	August 10, 2019	14.9 ± 0.01	27.5 km upstream
LAX4.6	Los Angeles Creek	August 11, 2019	23.6 ± 0.02	9.5 km downstream

2.1.2 YUKON RIVER MIXING ZONES

As suggested by the Selkirk First Nation, fish sampling was completed for the second year at the mixing zones of both Halfway and YT-24 creeks with the Yukon River. Sampling at the Halfway Creek mixing zone occurred on July 12 and August 9, and at YT-24 on July 14 and August 10, 2019. The mixing zone is defined as the immediate area where the creek flows into the Yukon River and the two water masses mix. Sampling involved three successive beach seine hauls, beginning in the Yukon River at the creek mouths and continuing downstream (Figure 5). During each sampling event, three seine hauls were completed, beginning at the mouth of the creek and going progressively downstream on the Yukon River. Beach seine hauls were conducted with field crews of two members for a length of approximately 15 m, although lengths ranged depending on conditions and riverbed morphology (mean = 15.5 ± 1.5 m; range = 8 – 25 m). Fish captured were enumerated, and a subset of ten fish per species had their length and weight taken from each seine haul. Fish measurement metrics were summarized (fork length and weight, ± SE) for all species captured.

2.1.3 FISH HABITAT ASSESSMENTS

Fish habitat surveys were conducted on three drainages during July and August 2019 following the FHAP survey methodology (Table 5). The FHAP survey documents the characteristics and frequency of different fish habitats by enumerating different habitat units (e.g., pool, riffle, glide), and measuring various parameters (e.g., average depth, width, length). A detailed methodology is outlined in the FHAP guide (Johnston and Slaney 1996). The length of habitat units was measured using a laser range finder for all creeks assessed, whereas wetted widths, bankfull widths, and depths were measured with a measuring tape and/or metre stick for the unnamed tributary upstream of YT-24 (herein referred to as 'Unnamed Tributary') and both Carlisle Creek sites; Coffee Creek used the range finder for wetted and bankfull widths due to its size. Results were considered as average ± standard error (SE).

Table 5. Summary of fish habitat assessments in July and August 2019.

Creek	Date	Distance (m)	Latitude	Longitude
Unnamed Tributary	July 9, 2019	516	62.923359	-139.220304
Coffee Creek	July 12, 2019	1,091	62.878546	-139.107593
Carlisle Creek	July 13, 2019	1,117	62.977835	-139.569427
Carlisle Creek tributary	August 11, 2019	561	62.928957	-139.738841

2.1.4 CHINOOK SALMON SPAWNING SURVEYS

Chinook salmon spawning surveys were completed in areas where Traditional Knowledge indicated past presence (Tr'ondëk Hwëch'in 2012) and in watersheds that appear to have habitat to support spawning Chinook salmon; as such, Coffee Creek and Independence Creek have been investigated and surveyed for spawning Chinook salmon annually since 2014. During the 2019 field season, Coffee and Independence creeks had two aerial surveys completed. Coffee Creek investigations also included a ground survey (stream walk) to record any evidence of Chinook salmon spawning (Figure 6).

During the 2019 aerial surveys, two field crew members were positioned on the right side the helicopter, with one observer in front of the other. The pilot flew the helicopter over the river at an angle approximately 40-45 m above the creek. Surveys were completed in the early afternoon. To reduce glare, the creeks were flown starting upstream and continuing downstream towards the Yukon River. Observers also wore polarized glasses to reduce glare from the water. Weather was sunny for the first survey and overcast with some sun during the second survey.

The first set of aerial surveys on Coffee and Independence creeks was conducted on August 8, 2019, with very good visibility and a flight time of 30 and 33 minutes, respectively. The second set of surveys occurred on August 13, 2019, lasting 33 minutes on Coffee Creek, and 36 minutes on Independence Creek, with good visibility. Water levels in the creeks were slightly lower during the second survey than the first.

On August 13, 2019, a stream walk was completed on Coffee Creek to look for any sign of spawning activity. A field crew of two walked Coffee Creek from the confluence with Latte Creek downstream to approximately 4.0 km from the Yukon River. Conditions were good for observing living adult salmon, carcasses, redds or associated wildlife (i.e., eagles, bears). The crew was able to walk the channel either in or alongside the wetted portion of the creek.

2.2 NORTHERN ACCESS ROUTE

During the 2019 field season, proposed and existing barge landings were sampled, an opportunistic barge wake investigation took place on the Yukon River, and the Stewart River back channel was investigated.

2.2.1 BARGE LANDING INVESTIGATIONS

Locations of proposed barge landings on the Yukon and Stewart rivers were visited and sampled for fish during July and August 2019. Fish sampling was conducted using beach seining along the banks of the proposed barge landings. The Yukon River was sampled July 14 and August 8, 2019, and the Stewart River was sampled on July 11 and August 10, 2019. During July sampling, a total of six beach seine hauls were completed at/near the proposed barge landing sites (north and south) on the Yukon River, and another six were completed between the two proposed barge landings on the Stewart River. The same amount of effort was completed during the August field visit, with the addition of three seine hauls on the Yukon River at the existing barge landing near the Coffee Camp (Figure 7).

Information collected for each beach seine haul included seine haul dimensions (length, width, depth). Fish were identified and enumerated; a random ten individuals from each species were weighed and had fork length measured for each seine haul. Fish measurement metrics were summarized (fork length and weight, ± SE) for all species captured.

All seine hauls were conducted at the site of the proposed barge landings, with the exception of the Yukon River north bank proposed barge. The Yukon River north bank barge landing has steep eroding banks and deep water; as such, the seine hauls were completed 75 m downstream.

2.2.2 BARGE WAKE INVESTIGATIONS

EDI field crews conducted one river barge wake investigations from shore on July 10, 2019, at the mouth of Halfway Creek. This investigation was completed opportunistically while a crew was working along the Yukon River and a barge was approaching. Photos and videos were taken before, during, and after the barge passing. The distance of the barge from the shore was recorded, together with load content based on visual appearance, and other pertinent observations. After the barge had passed, the wave runout extent (i.e., slope distance waves travelled up the previously dry shoreline) was recorded.

2.2.3 STEWART RIVER BACK CHANNEL INVESTIGATIONS

2.2.3.1 Spring

The Stewart River back channel was visited May 24, 2019, to further investigate fish presence, particularly adult northern pike, in support of the 2018 findings of young-of-the-year juvenile northern pike. The back channel was walked and beach seined at nine sites, in addition to the uppermost site, which was the uppermost extent with water. Beach seine hauls were conducted with two field crew members for variable seine lengths depending on conditions and water depth (mean = 7.9 ± 1.2 m; range = 1 – 15 m). Fish captured were enumerated, and a subset of ten fish per species had their length and weight measured from each seine haul.

Fish measurement metrics were summarized (fork length and weight, ± SE) for all species captured. Digital photos and GPS coordinates were taken of all sites.

2.2.3.2 Summer

The back channel was investigated again on July 11, 2019. A YSI ProSOLO was used to measure in situ water quality parameters (temperature, dissolved oxygen, and specific conductivity). Digital photos were taken and GPS coordinates were recorded. On August 10, 2019, the Stewart River back channel was observed from the air and photos were taken.

3 RESULTS AND DISCUSSION

Results and discussion for the MSA and NAR are presented per project component in the following sections.

3.1 MINE STUDY AREA

Fish sampling occurred in both July and August 2019. Creek levels were very low during the July sampling, while during August sampling creek water levels were higher and fast-moving.

3.1.1 FISH SAMPLING AND HABITAT INVESTIGATIONS

3.1.1.1 Coffee Creek

Coffee Creek was sampled using minnow trapping techniques in July and August 2019. Both juvenile Chinook and slimy sculpin were captured during each sampling event. Juvenile Chinook salmon increased in size and weight between the July and August sampling events (Table 6). Catch-per-unit-effort was lower for juvenile Chinook salmon during the July sampling event (1.0 ± 0.6) than in August (12.4 ± 6.5; Table 6). Slimy sculpin were captured in low numbers during both sampling events. Due to the differences in habitat suitability of each minnow trap set, catches were variable between sets (e.g., large CPUE standard error for juvenile Chinook in August).

Table 6. Coffee Creek fish metrics (fork length and weight, ± SE) and catch-per-unit-effort (fish/100 m² ± SE) summary, July and August 2019.

Month	Average sampling effort per set (hrs)	Species	Total fish captured	Average fork length (mm ± SE)	Fork length range (mm)	Average weight (g ± SE)	Weight range (g)	Average CPUE (fish per 24 hr ± SE)
July	54.1	CH	7	66.3 ± 1.6	61 – 72	3.4 ± 0.3	3.8 – 14.7	1.0 ± 0.6
		CCG	11	84.7 ± 3.3	69 – 110	7.4 ± 0.9	2.6 – 4.4	1.6 ± 0.5
August	45.6	CH	71	78.0 ± 0.8	69 – 89	4.9 ± 0.2	3.4 – 7.8	12.4 ± 6.5
		CCG	4	80.3 ± 4.3	60 – 90	6.6 ± 1.0	2.1 – 8.8	0.7 ± 0.3

CH = Chinook salmon; CCG = slimy sculpin; CPUE = catch per unit effort

3.1.1.2 Halfway Creek

Halfway Creek was electrofished at several sites during the July and August sampling events. The two sites (HC0.2 and HC0.7) below the previously identified logjam barrier[2] (located 1.0 km from the mouth) were sampled for 150 m during both events, while the site above the logjam (HC1.1) was sampled for 180 m in July and 170 m in August. All sampling durations ranged from 936 – 1,300 (± 56.7) seconds. During the July field visit Arctic grayling (*Thymallus arcticus*) were captured at both the lower sites in moderate numbers (Table 7). In addition to those captured at HC0.2 and HC0.7 (n = 5 at both sites), another three were observed but not captured. No Arctic grayling were captured above the logjam (Site HC1.1).

[2] Logjam barrier is not considered permanent; other impediments have been identified upstream .

During the August visit to Halfway Creek, Arctic grayling were captured at both the lower sites in high numbers, as well as juvenile Chinook salmon in the lower 200 m (Table 7). At the lower site (HC0.2) there was a total of 22 Arctic grayling electrofished. Additionally, two juvenile Chinook salmon were captured in the lower 200 m of Halfway Creek (Table 7). Similar to the July sampling event, no fish were observed or captured above the logjam barrier at HC1.1 (Table 7).

Table 7. Halfway Creek fish metrics (fork length and weight, ± SE) and catch-per-unit-effort (fish/100 m² ± SE) summary, July and August 2019.

Date	Sampling site	Species	Total fish captured	Average fork length (mm ± SE)	Fork length range (mm)	Average weight (g ± SE)	Weight range (g)	CPUE (fish per 1000 EF seconds)
July 2019	HC0.2	GR	5	160.8 ± 20.5	124 – 235	56.8 ± 23.8	17.9 – 147	4.21
	HC0.7	GR	5	213 ± 17.0	178 – 255	119.6 ± 22.7	77.5 – 188	3.82
	HC1.1	NFC	0	-	-	-	-	0.00
August 2019	HC0.2	GR	22	164.5 ± 12.5	72 – 303	61.4 ± 12.0	5.5 – 174	19.6
	HC0.2	CH	2	67.5 ± 2.5	65 – 70	4.7 ± 0.1	4.6 – 4.8	1.8
	HC0.7	GR	1	170 ± 0.0	170	n/a	n/a	1.1
	HC1.1	NFC	0	-	-	-	-	0.00

NFC = no fish captured; CH = Chinook salmon; GR = Arctic grayling; EF = electrofishing; CPUE = catch per unit effort

The previously identified logjam was measured during the July field visit, at which point there were three locations with water flowing over drops (Table 8). The logjam is approximately 15 m wide in a series of drops and shallow pools; broadly, a drop occurred at the right and left banks (facing downstream), with another mid-channel. The drop on the right had the deepest pool depth, but was little more than a trickle over fallen logs, and had very minimal pool depth above the drop (Table 8, Photo 1). In the middle of the channel, the drop was in the form of a sieve and had shallow pools both above and below the drop (Table 8, Photo 2). The left drop was also in the form of a sieve and had very shallow pools above and below (Table 8, Photo 3). Each of the drop also had small and large woody debris overlaying them.

Table 8. Halfway Creek potential fish barrier (HC1.1) measurements, July 2019.

	Downstream pool depth (m)	Upstream pool depth (m)	Drop height (m)	Drop width (m)
Right bank	0.76	0.05	0.80	1.0
Mid-channel	0.27	0.35	0.50	1.6
Left bank	0.10	0.15	0.40	1.2

Due to the shallow pools below and above the drops, it is unlikely for a fish (e.g., Arctic grayling) to have the space to burst for the necessary propulsion required to make it up and over the obstructions. An Arctic grayling seen below the right bank drop during the July sampling (Photo 4), but none were captured above the barrier in either July or August 2019.

Photo 1. Halfway Creek potential fish barrier right bank drop, July 2019.

Photo 2. Halfway Creek potential fish barrier mid-channel drop, July 2019.

Photo 3. Halfway Creek potential fish barrier left bank drop, July 2019.

Photo 4. Arctic grayling spotted in the right bank pool below the drop, July 2019.

3.1.1.3 YT-24 Creek

YT-24 Creek was visited during both the July and August field event. The creek was first visited on July 10, 2019, when a dry stretch of creek was discovered. Approximately 60 m of the creek was entirely dry, between 190 and 250 m from the mouth (Photo 5, Photo 6). In situ water quality parameters indicated the area below the dry portion of stream had lower temperature and dissolved oxygen compared with above the dry portion, but similar specific conductivity (Table 9). Investigating the banks did not indicate any obvious springs; however, due to the substantially lower temperature and dissolved oxygen, it is possible that the lower flowing portion of the stream was being sourced through groundwater upwelling.

Table 9. In situ water quality parameters above and below the dry portion of YT-24 Creek on July 10, 2019.

	Temperature (° C)	Dissolved oxygen (%)	Dissolved oxygen (mg/L)	Specific conductivity (µS)
Below dry portion	2.5	50.0	6.81	257.6
Above dry portion	5.0	95.4	12.18	264.4

The creek was again visited on July 14, 2019. Due to continued dry conditions, YT-24 Creek did not contain enough water to reach the Yukon River, drying up approximately 3.5 m from the mouth (Photo 7).

During the August visit, considerably more water was present in the creek and was sampled 200 m from the mouth for 150 m and 950 seconds of electrofishing at site YT0.2. No fish were observed or captured during this time.

Photo 5. A dry portion of YT-24 Creek between 190 and 250 m from the mouth on July 10, 2019.

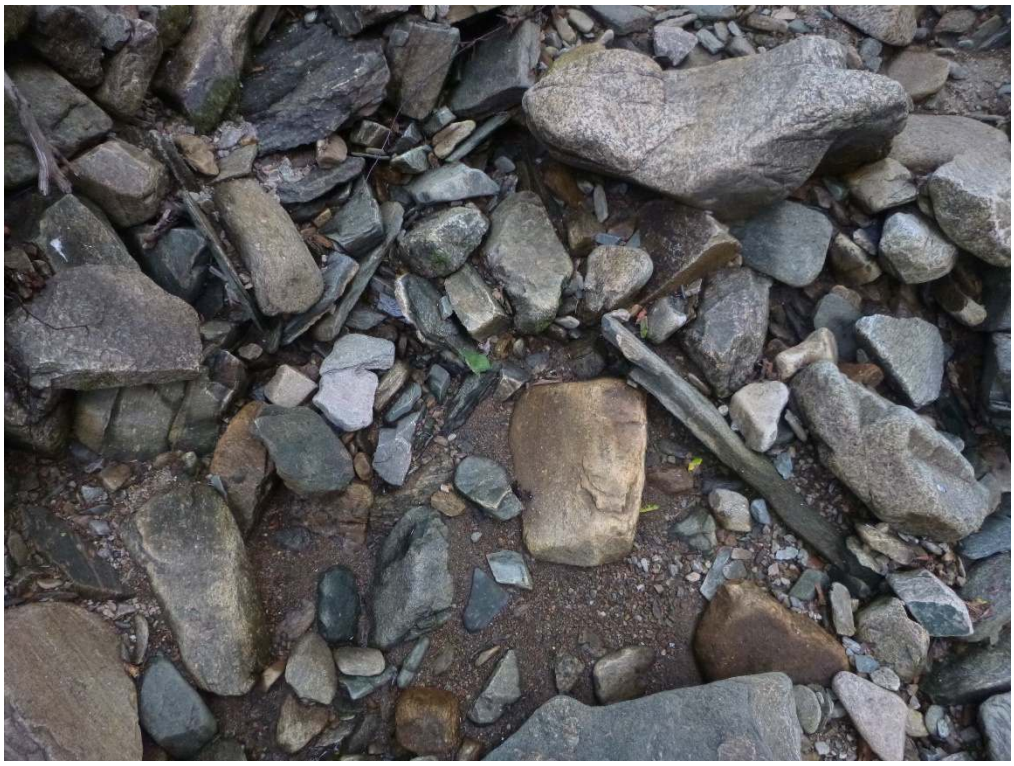

Photo 6. Dry interstitial spaces in YT-24 Creek on July 10, 2019.

Photo 7. The mouth of YT-24 drying up before reaching the Yukon River on July 14, 2019.

3.1.1.4 Carlisle, Excelsior, and Los Angeles Creeks

Carlisle Creek was sampled in July, while Excelsior and Los Angeles creeks were sampled in August. All sites were sampled using minnow traps with the purpose of capturing juvenile Chinook salmon. The minnow traps did not capture any fish at any of the three creeks, and no juvenile Chinook salmon were observed. Arctic grayling were observed in high numbers in Carlisle Creek, and a few were spotted in both Excelsior and Los Angeles creeks. These results indicate that these sites are not deemed suitable control sites to compare juvenile Chinook growth rates with those captured in Coffee Creek.

3.1.2 YUKON RIVER MIXING ZONES

Both Halfway and YT-24 creeks were sampled in their mixing zones during July and August sampling; the same Yukon River reference site from 2018 was used for comparison (YUK51.2, north barge landing). Due to the low water levels in July, the mixing zone of Halfway Creek was limited in size. No discharge from YT-24 into the Yukon River occurred during July sampling, therefore no true 'mixing zone' existed; however, the site was still sampled.

Similar species were captured in the Halfway Creek mixing zone in July and August (Table 10). In July, juvenile Chinook, Arctic grayling, slimy sculpin, and juvenile round whitefish (*Prosopium cylindraceum*) were captured; in August, all but slimy sculpin were captured (Table 10). During the July sampling a total of 69 juvenile Chinook salmon were captured, compared with 32 during the August sampling event. Alternatively, there were substantially more Arctic grayling captured in August than in July (n = 57 and n = 6, respectively; Table 10).

Table 10. Halfway Creek mixing zone fish metrics (fork length and weight, ± SE) July and August sampling, 2019.

Month	Species captured	Total captured	Total measured	Fork length (± SE; mm)	Weight (± SE; g)
July	CH	69	28	69.4 ± 1.1	3.9 ± 0.2
	GR	6	6	161.2 ± 19.6	51.7 ± 20.2
	CCG	4	1	6.5 ± 0.0	3.5 ± 0.0
	RW	3	3	62.7 ± 2.3	2.2 ± 0.2
August	CH	23	14	78.1 ± 1.5	5.1 ± 0.3
	GR	57	23	100.5 ± 7.9	10.4 ± 2.1
	RW	2	2	106.0 ± 28.0	13.2 ± 9.2

CH = Chinook salmon; GR = Arctic grayling; CCG = slimy sculpin; RW = round whitefish

Despite the lack of a visible mixing zone on YT-24 Creek in July, the species diversity was the highest of any mixing zone or reference site sampling completed in 2019 (Table 11). Six species were captured, with longnose sucker (*Catostomus Catostomus*; n = 40) and juvenile Chinook salmon (n = 32) being the most abundant (Table 11). An adult inconnu (*Stenodus leucichthys*) was observed but was not successfully captured during July sampling.

Water levels were higher in August, which allowed for YT-24 to discharge into the Yukon River, creating a mixing zone. The August sampling period had high species diversity having five species captured (Table 11), with juvenile Chinook (n = 20) and Arctic grayling (n = 19) being the most abundant. During both July and August sampling, lake whitefish (*Coregonus clupeaformis*) was the least abundant species captured (n = 1; Table 11, Table 12).

Table 11. YT-24 Creek mixing zone fish metrics (fork length and weight, ± SE) from July sampling, 2019.

Month	Species captured	Total captured	Total measured	Fork length (± SE; mm)	Weight (± SE; g)
July	CH	32	20	68.4 ± 1.7	3.9 ± 0.2
	GR	5	5	71.8 ± 15.9	6.9 ± 5.0
	CCG	9	1	51.0 ± 0.0	1.9 ± 0.0

	CCG	7	6	32.7 ± 2.2	<1.0
	RW	2	2	81.5 ± 0.5	4.4 ± 0.2
	LW	1	1	94.0 ± 0.0	7.6 ± 0.0

CH = Chinook salmon; GR = Arctic grayling; CCG = slimy sculpin; RW = round whitefish; LW = lake whitefish; LSU = longnose sucker

The same Yukon River reference site (YUK51.2) was used to compare the mixing zone results. Both during July and August sampling, fewer species were captured at the Yukon River reference site than in the mixing zones. In July, only juvenile Chinook salmon and Arctic grayling were captured; in August three species were captured, including juvenile Chinook salmon, Arctic grayling, and slimy sculpin (Table 12).

During the July sampling of the Yukon River reference site, fish activity was observed directly below where the initial sampling had occurred, in very similar habitat to the reference site. Field staff opted to sample one site directly downstream of where the reference site sampling occurred. A total of 51 juvenile Chinook salmon were captured, which was similar to the numbers caught in the mixing zones (Table 13).

Table 12. Yukon River reference site (YUK51.2) fish metrics (fork length and weight, ± SE) from July and August sampling, 2019.

Month	Species captured	Total captured	Total measured	Fork length (± SE; mm)	Weight (± SE; g)
July	CH	8	8	63.8 ± 8.1	4.4 ± 0.3
	GR	1	1	136.0 ± 0.0	22.2 ± 0.0
August	CH	22	11	78.2 ± 1.3	5.6 ± 0.3
	GR	10	10	135.2 ± 9.7	28.9 ± 3.5
	CCG	2	1	47.0 ± 0.0	1.6 ± 0.0

CH = Chinook salmon; GR = Arctic grayling; CCG = slimy sculpin

Table 13. Directly below the Yukon River reference site (YUK51.2) fish metrics (fork length and weight, ± SE) from July sampling, 2019.

Month	Species captured	Total captured	Total measured	Fork length (± SE; mm)	Weight (± SE; g)
July	CH	51	30	72.5 ± 0.8	4.8 ± 0.2
	GR	1	1	136.0 ± 0.0	27.9 ± 0.0
	LSU	2	2	84.0 ± 0.0	6.4 ± 0.1

CH = Chinook salmon; GR = Arctic grayling; LSU = longnose sucker

Juvenile Chinook salmon and Arctic grayling CPUE was calculated for both mixing zones and the Yukon River reference (YUK51.2) site in July and August, and the site below the Yukon River reference site in July (Table 14, Figure 8). Overall, the mixing zones had higher CPUE than the reference site, although often with

very high variance (i.e., standard error). This is a product of the variability associated with beach seining for shoaling groups of fish. In both July and August on YT-24 Creek, there was a large haul as well as a haul yielding no fish – this resulted in a large CPUE, but also high variability (Table 14; Appendix B).

To further explain the inherent catch variability of beach seining, a site directly downstream of the Yukon River reference site was sampled in July. The Yukon River reference site did not yield a high number of fish (specifically juvenile Chinook salmon; Table 12), but directly downstream field staff could observe jumping juvenile Chinook salmon. Habitat characteristics between the two sites appeared to be identical. The site directly adjacent to the low yield Yukon River reference site had a substantially higher CPUE of juvenile Chinook salmon (Table 14). It is important to consider the natural variability in catch numbers and CPUE (both spatially and temporally) when interpreting mixing zones and the Yukon River reference site.

Table 14. Catch-per-unit-effort (fish/100 m² ± SE) of juvenile Chinook salmon and Arctic grayling captured in the Halfway and YT-24 Creek mixing zones, and the Yukon River reference site in July and August 2019. A site downstream of the Yukon reference site was also considered in July.

Month	No. of hauls	Location	Juvenile Chinook salmon		Arctic grayling	
			Mean CPUE (fish/100m²) ± SE	CPUE range (fish/100m²)	Mean CPUE (fish/100m²) ± SE	CPUE range (fish/100m²)
July	3	Halfway Creek mixing zone	14.5 ± 8.5	2.4 – 30.8	1.7 ± 1.7	0.0 – 1.7
		YT-24 Creek mixing zone	19.4 ± 14.4	0.0 – 47.5	1.9 ± 1.0	0.0 – 3.3
		Yukon River (reference location)	1.5 ± 0.9	0.0 – 3.0	0.3 ± 0.3	0.0 – 0.8
		Yukon River (downstream of reference location)	12.2 ± 3.5	7.5 – 19.2	0.2 ± 0.2	0.0 – 0.6
August	3	Halfway Creek mixing zone	6.3 ± 4.4	0.9 – 15.1	17.5 ± 11.4	2.9 – 40.0
		YT-24 Creek mixing zone	16.1 ± 14.5	0.0 – 45.0	9.4 ± 7.8	0.0 – 25.0
		Yukon River (reference location)	8.2 ± 5.4	1.4 – 18.9	3.3 ± 2.3	0.0 – 7.8

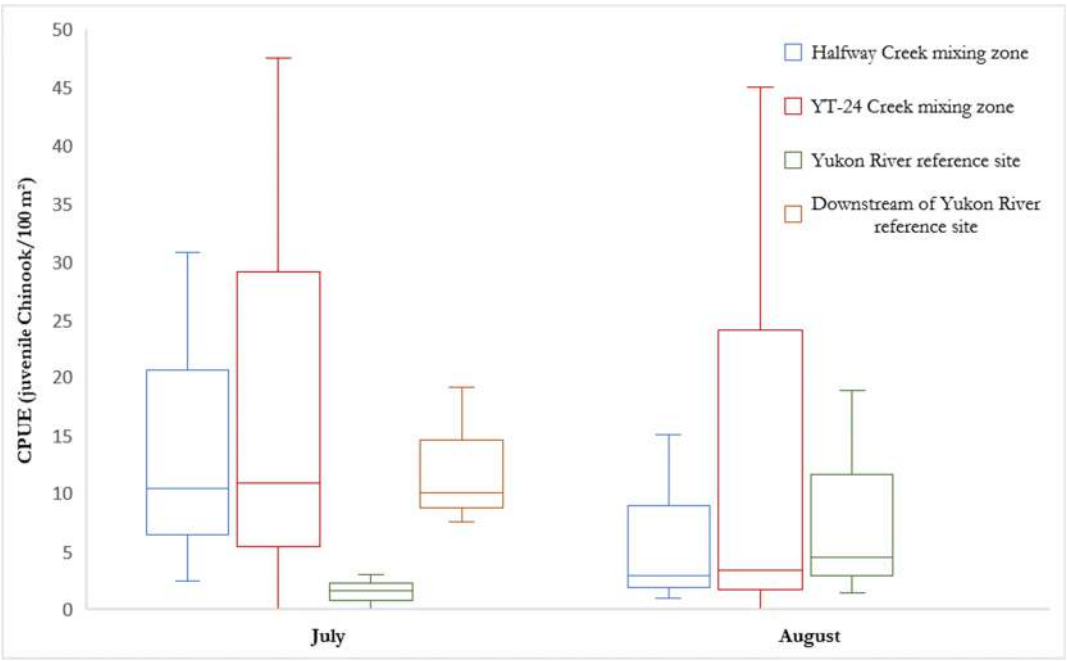

Figure 8. A box-and-whisker plot comparison of CPUE of juvenile Chinook salmon between Halfway and YT-24 mixing zones, and the Yukon River reference site (YUK51.2) in July and August 2019. A site directly downstream of the reference site was also included during July sampling.

The mixing zones appeared to consistently have a higher species diversity than the Yukon River reference site or the site directly downstream of the reference site. The species diversity of the mixing zones was similar to results from the 2018 field season; however, in 2018, the Yukon River reference site contained the same species diversity as the mixing zones (EDI 2019). The catch numbers of juvenile Chinook salmon and Arctic grayling were also higher during 2018 sampling – however, when considering catch data, it is important to consider the inherent variability of sampling shoaling species, as was exemplified in the site adjacent to the Yukon River reference site.

3.1.3 FISH HABITAT ASSESSMENTS

Fish Habitat Assessment Procedure (FHAP) survey results are summarized by sampling location in the following sections, with detailed survey data affixed as an appendix item (Appendix C).

3.1.3.1 Coffee Creek

During July 2019 monitoring, a FHAP survey was conducted on a 1,088 m section of Coffee Creek (Figure 9). Twenty-four distinct habitat units were identified during the survey, comprised of three habitat unit types: pools, riffles, and glides (Table 15). No steep riffle[3] or cascade habitat units were identified during the survey.

The surveyed section of Coffee Creek was dominated by glide habitat, which comprised 58 % of all habitat units by length (Table 15; Photo 8). The average length of glide habitat units was 64.6 (± 10.7) m and ranged

[3] While not listed in the FHAP manual, EDI has added habitat type of 'steep riffle' as it separates regular low gradient riffles from ones with higher gradients (> 5 %).

from 14.7 to 105.7 m in length. Large cobbles and overhanging vegetation were the dominant forms of instream cover, providing 8 % of cover on average in glide hatibat. The remaining habitat was comprised of riffle (32 %) and pool (10 %) habitat units by length. Habitat units in Coffee Creek generally alternated between long glides and riffles, with pools interspersed throughout either as primary or tertiary habitat units (Figure 9). The average bankfull width over all habitat units in Coffee Creek was 17.5 (± 1.1) m with an average wetted width of 10.3 m and an average water depth of 0.33 m during the July 2019 survey.

Fish habitat assessment procedure surveys were designed to be conducted on streams with less than a 15 m wide bankfull width (Johnston and Slaney 1996). As streams increase in size, they tend to exhibit large channel morphology characteristics. While the average bankfull width of Coffee Creek was greater than 15 m (17.5 ± 1.1 m), the creek does not exhibit large river channel morphology characteristics. Additionally, habitat units including glides, riffles, and pools are easily identified and delineated.

The frequency and extent of habitat units in the surveyed section of Coffee Creek represent relatively low quality salmon rearing (< 40 % pools by area), and moderate to good quality migrating adult holding habitat (Johnston and Slaney 1996). A total of four pool habitat units (primary and tertiary) were identified in the surveyed section of the creek, all of which were deep and had residual pool depths of at least one metre (Table 15). While few pool habitat units were identified by area, when pool habitat does occur, it could provide suitable holding habitat for migrating adult salmon (Johnston and Slaney 1996).

Table 15. Summary of habitat units identified during the Fish Habitat Assessment Procedure survey of Coffee Creek on July 12, 2019.

Habitat type	No. of units	Average length (± SE; m)	Total length in surveyed extent (m)	Percent of total survey extent
Cascade	0	-	-	0.0 %
Glide	10	64.6 ± 10.7	645.5	59.0 %
Pool	2	35.2 ± 4.5	70.3	6.0 %
Riffle (<5 % grade)	9	41.3 ± 7.9	372.0	34.0 %
Steep riffle (>5 % grade)	0	-	-	0.0 %
Tertiary glide	1	19.0 ± 0.0	19.0	n/a
Tertiary pool	2	25.0 ± 1.1	49.9	n/a
Total	**24**	**51.8 ± 6.5**	**1,087.8**	**100.0 %**

3.1.3.2 Unnamed Tributary Upstream of YT-24

During July 2019 monitoring, a FHAP survey was conducted on a 519 m section of an Unnamed Tributary upstream of YT-24 (Table 16). Twenty-nine distinct habitat units were identified during the survey, comprised of five habitat unit types: cascades, pools, riffles, steep riffles, and glides (Table 16).

The surveyed section of the Unnamed Tributary was dominated by riffle habitat, which comprised 62 % of habitat units by length (Table 16; Photo 9). The average length of riffle habitat units was 35.1 (± 10.4) m and ranged from 7.5 to 104 m in length. The dominant form of instream cover in riffle habitat was provided by boulders and deep pools. The remaining habitat was comprised of steep riffle (26 %), cascade (7 %), glide (3 %), and pool (1 %) habitat units by length. Cascade habitat units were generally short, 2.0 to 14.6 m in length and had an average gradient of 15.4 %. A 6.0 m long secondary (side channel) cascade was also identified during the survey and was the only side channel habitat identified during the survey. Habitat units in the Unnamed Tributary generally had long stretches of riffles separated by steep riffles, with cascades and glides occurring less frequently (Figure 10).

The frequency and extent of habitat units in the surveyed section of the Unnamed Tributary represent relatively low-quality, low complexity fish habitat with a low frequency of pool and glide habitat units (<20 % by area), and little instream cover (Johnston and Slaney 1996). The two pool habitat units were generally short (3.3 and 4.0 m, respectively; Table 16). The average bankfull width over all habitat units was 3.6 (± 0.1) m, with an average wetted width of 2.2 m and an average water depth of 0.12 m during the survey.

Table 16. Summary of habitat units identified during the Fish Habitat Assessment Procedure survey of Unnamed Tributary on July 9, 2019.

Habitat type	No. of units	Average length (± SE; m)	Total length in surveyed extent (m)	Percent of total survey extent
Cascade	7	6.2 ± 2.0	43.7	7.0 %
Glide	4	4.3 ± 0.6	17.1	3.0 %
Pool	2	3.7 ± 0.4	7.3	1.0 %
Riffle (<5 % grade)	9	35.1 ± 10.4	315.5	62.0 %
Steep riffle (>5 % grade)	7	19.3 ± 4.3	135.4	26.0 %
Secondary cascade	1	6.0 ± 0.0	6.0	n/a
Total	**29**	**18.3 ± 4.1**	**519.0**	**100.0 %**

3.1.3.3 Carlisle Creek

During July 2019 monitoring, a FHAP survey was conducted on a 1,088 m section of Carlisle Creek (Figure 11). Forty-five distinct habitat units were identified during the survey, primarily comprised of riffles and glides with a few pools and a cascade (Table 17). No steep riffle, tertiary, or secondary habitat units were identified during the survey.

The surveyed section of Carlisle Creek was dominated by glide and riffle habitat, which comprised 52 % and 43.5 % of habitat units by length respectively (95.5 % combined; Table 17; Photo 10, Photo 11). The average length of glide habitat units was 28.5 (± 4.5) m and ranged from 3.0 to 74.8 m in length. Similarly, riffle habitat units were on average 21.5 (± 3.6) m and ranged from 3.5 to 77.6 m in length (Table 17). Cascade and pool habitat units comprise the remaining 4.5 % of habitat units by length (0.5 and 4.0 % for cascade and pool habitat units, respectively). Large cobbles and boulders are the dominant forms of instream cover for both glide and riffle habitat. Additionally, usable coarse woody debris is frequently present and distributed evenly throughout the surveyed extent. Habitat units in Carlisle Creek generally alternated between glides and riffles, with other habitat units occurring infrequently (Figure 11).

The frequency and extent of habitat units in the surveyed section of Carlisle Creek represents relatively low-quality, low complexity fish habitat with a low frequency of pool habitat units (<30 % by area) (Johnston and Slaney 1996). However, glide habitat occurs regularly throughout the surveyed extent and likely provides some resting and holding habitat function for species like Arctic grayling or juvenile Chinook salmon. There is moderate instream cover and usable coarse woody debris distributed evenly throughout the surveyed extent (Johnston and Slaney 1996). The average bankfull width over all habitat units was 10.9 (± 0.3) m, with an average wetted width of 6.2 m and an average water depth of 0.27 m during the survey.

Table 17. Summary of habitat units identified during the Fish Habitat Assessment Procedure survey of Carlisle Creek on July 13, 2019.

Habitat type	No. of units	Average length (± SE; m)	Total length in surveyed extent (m)	Percent of total survey extent
Cascade	1	5.5 ± 0.0	5.5	0.5 %
Glide	20	28.5 ± 4.5	569.4	52.0 %
Pool	2	20.2 ± 9.0	40.4	4.0 %
Riffle (<5 % grade)	22	21.5 ± 3.6	472.6	43.5 %
Steep riffle (>5 % grade)	0	-	-	0.0 %
Total	**45**	**24.2 ± 2.7**	**1,087.9**	**100.0 %**

3.1.3.4 Carlisle Creek Tributary

During August 2019 monitoring, a FHAP survey was conducted on a 562 m section of the Carlisle Creek tributary (Figure 12). Twenty-one distinct habitat units were identified during the survey, comprised of glide, riffle, and steep riffle habitat units (Table 18). No cascade, pool, secondary, or tertiary habitat units were identified during the survey.

The surveyed section of the Carlisle Creek tributary was dominated by steep riffle habitat, which comprised 57 % of habitat units by length. Riffle and glide habitat units, which comprise 37 % and 6 % of habitat units by length respectively, comprise the remaining habitat units. The average length of steep riffle habitat units was 35.3 (± 16.1) m and ranged from 8.4 to 160.4 m in length. Carlisle Creek tributary habitat units commonly alternated between riffle and steep riffle habitat units (Figure 12).

The frequency and extent of habitat units in the surveyed section of the Carlisle Creek tributary represents relatively low-quality, low complexity fish habitat with a low frequency of pool and glide habitat units (<30 % by area), and little instream cover and functional large woody debris (Johnston and Slaney 1996). The average bankfull width over all habitat units was 4.7 (± 0.3) m, with an average wetted width of 6.2 m and an average water depth of 0.2 m during the survey.

Table 18. Summary of habitat units identified during the Fish Habitat Assessment Procedure survey of Carlisle Creek tributary on August 11, 2019.

Habitat type	No. of units	Average length (± SE; m)	Total length in surveyed extent (m)	Percent of total survey extent
Cascade	0	-	-	0.0 %
Glide	4	8.7 ± 1.4	34.6	6.0 %
Pool	0	-	-	0.0 %
Riffle (<5 % grade)	8	26.2 ± 3.7	209.7	37.0 %
Steep Riffle (>5 % grade)	9	35.3 ± 16.1	317.8	57.0 %
Total	**21**	**26.8 ± 7.2**	**562.1**	**100.0 %**

3.1.4 CHINOOK SALMON SPAWNING SURVEYS

No living adult Chinook salmon, carcasses or salmon redds were observed during any of the Chinook spawning surveys conducted on Coffee and Independence creeks in 2019. There were no observations of feeding wildlife (e.g., bears or eagles), which typically feed on salmon during the spawning season. The only wildlife detected was a female moose observed in Coffee Creek during the second survey. These results are consistent with data collected in previous years (EDI 2017, 2018, 2019).

3.2 NORTHERN ACCESS ROUTE

3.2.1 BARGE LANDING INVESTIGATIONS

3.2.1.1 Yukon River North Barge Landing – YUK51.2

The Yukon River north proposed barge landing (right downstream bank) is located in an outside bend of the river, the bank is actively eroding (Photo 13). As a result, beach seining was completed approximately 75 m downstream from the proposed barge landing site, similar to the 2017 and 2018 field seasons (Photo 14; EDI 2018, 2019). During both July and August 2019 several beach seines were conducted to gain an understanding of fish assemblages; sampling effort was 400 m^2 and 250 m^2, respectively.

Photo 13. View of the proposed Yukon River north barge landing on August 8, 2019.

Photo 14. Area downstream from the proposed Yukon River north barge landing where sampling occurred on July 14, 2019.

Two species were captured in July, and three in August (Table 19). In July, juvenile Chinook salmon and Arctic grayling were captured, and in August there were juvenile Chinook salmon, Arctic grayling, and slimy sculpin. Juvenile Chinook salmon made up the highest proportion of the catch both months (89 % and 65 %, respectively; Table 19). The sampling from 2018 yielded a higher species diversity than in 2019, with four species in July and five in August (EDI 2019).

Table 19. Yukon River fish metrics (fork length and weight, ± SE) from YUK51.2 sampling, July and August 2019.

Month	Species captured	Total captured	Total measured	Fork length (± SE; mm)	Weight (± SE; g)
July	CH	8	8	63.8 ± 8.1	4.4 ± 0.3
	GR	1	1	136.0 ± 0.0	22.2 ± 0.0
August	CH	22	11	78.2 ± 1.3	5.6 ± 0.3
	GR	10	10	135.2 ± 9.7	28.9 ± 3.5
	CCG	2	1	47.0 ± 0.0	1.6 ± 0.0

CH = Chinook salmon; GR = Arctic grayling; CCG = slimy sculpin

3.2.1.2 Yukon River South Barge Landing – YUK47.6

The Yukon River south proposed barge landing (left downstream bank) is located in an area with uniform high banks, and a steadily sloping shoreline (Photo 15). The shoreline bed material is comprised primarily of small cobbles and gravels with limited amounts of fines. This site was sampled in July and August 2019, with a sampling effort of 260 m^2 and 230 m^2, respectively.

Three different species were captured at the south barge landing in July and August (Table 20). In July, juvenile Chinook salmon, lake whitefish, and slimy sculpin were captured; in August, the catch composition was made of juvenile Chinook salmon, Arctic grayling, and slimy sculpin. In contrast to the proposed north barge landing, fewer juvenile Chinook were captured during both months at the proposed south barge landing (20 % and 13 %). The site does not appear to provide good rearing habitat for juvenile Chinook salmon, as there is a very steep bank and fast-moving water. At the time of July sampling, a barge was parked immediately upstream, which provided a substantial eddy (Photo 16); however, this did not seem to improve the habitat quality for juvenile Chinook salmon.

Table 20. Yukon River fish metrics (fork length and weight, ± SE) from YUK47.6 sampling, July and August 2019.

Month	Species captured	Total captured	Total measured	Fork length (± SE; mm)	Weight (± SE; g)
July	CH	1	1	70.0 ± 0.0	4.6 ± 0.0
	LW	2	1	50.0 ± 0.0	1.2 ± 0.0
	CCG	4	0	Approximately 20 mm	<1.0 g
August	CH	2	2	82.5 ± 8.5	6.4 ± 1.5
	GR	6	6	110.7 ± 52.4	21.9 ± 9.4
	CCG	7	7	27.5 ± 3.1	0.5 ± 0.5

CH = Chinook salmon; GR = Arctic grayling; CCG = slimy sculpin; LW = lake whitefish

Photo 15. Downstream view of the proposed Yukon River south barge landing on July 14, 2019.

Photo 16. Eddy caused by a parked barge upstream of the proposed Yukon River south barge landing on July 14, 2019.

3.2.1.3 Yukon River Existing Barge Landing – YUK46.1

The existing Yukon River barge landing site (left downstream bank) is located immediately adjacent to the current Coffee Gold exploration camp. The gently sloping riverbed is primarily comprised of a mix of gravels, fines, and a few small cobbles (Photo 17). The barge landing site is partially sheltered from the main river current by a large bend in the river and slightly protruding upstream bank. The existing barge landing was sampled in August 2019 with a sampling effort of 315 m^2.

A total of six species of fish were captured at the existing barge landing on the Yukon River in August 2019 (Table 21). The most abundant species were juvenile Chinook salmon (n = 38) and longnose sucker (n = 37), followed by slimy sculpin (n = 18) and Arctic grayling (n = 14); two juvenile round whitefish and lake whitefish were captured as well. Juvenile Chinook salmon made up 34 % of the catch composition.

Table 21. Yukon River fish metrics (fork length and weight, ± SE) from YUK46.1 sampling, August 2019.

Month	Species captured	Total captured	Total measured	Fork length (± SE; mm)	Weight (± SE; g)
August	CH	38	15	76.5 ± 1.8	5.1 ± 0.4
	LSU	37	25	36.7 ± 0.9	0.4 ± 0.0
	GR	14	14	80.3 ± 6.4	6.1 ± 2.1
	LW	2	2	72.0 ± 4.0	3.7 ± 0.9
	CCG	18	14	47.4 ± 4.7	1.4 ± 0.4
	RW	2	2	73.0 ± 3.0	23.8 ± 4.6

CH = Chinook salmon; GR = Arctic grayling; CCG = slimy sculpin; RW = round whitefish; LW = lake whitefish; LSU = longnose sucker

This site is currently being used as a barge landing for Coffee Camp, with barges arriving every few days during the spring/summer/fall. Sampling at this location in 2019 identified the highest species diversity and highest catch number at the existing barge landing since the site was first sampled in 2017 (EDI 2018, 2019).

Photo 17. View of the existing barge landing on the Yukon River at the Coffee Gold exploration camp on August 8, 2019.

3.2.1.4 Stewart River North Barge Landing

The Stewart River north proposed barge landing (right downstream bank) is located along a stretch of river with low, moderately sloping banks (Photo 18). The river bed material is primarily comprised of a mix of fines with few embedded cobbles. The proposed barge landing is located in a partial eddy created by upstream bedrock and is partly sheltered from the main river current. The Stewart River had higher water levels during July sampling than in August, and with the gently sloping riverbed the haul depths varied between months (average of 1.15 m in July and 0.6 m in August). The proposed barge landing site sits between some short but steep rock bluffs immediately upstream and a gravel bar downstream. This site was sampled in July and August 2019 with an effort of 560 m^2 and 460 m^2, respectively.

Photo 18. Upstream view of the proposed barge landing site on the north bank of the Stewart River, July 11, 2019.

The Stewart River proposed north barge landing had the highest species diversity of any site beach seined within the MSA or the NAR in 2019. During the July 2019 sampling, six species were captured, and in August, eight species captured (Table 22). In both July and August the most abundant fish were Arctic grayling (n = 20; n = 74), longnose sucker (n = 18; n = 33), and slimy sculpin (n = 12; n = 21; Table 22). During the August seine juvenile northern pike and inconnu were captured (Photo 19). In both July and August, juvenile Chinook salmon were captured in low numbers and made up a small portion of the total catch composition (12 % and 5 %, respectively).

Table 22. Stewart River north barge landing fish metrics (fork length and weight, ± SE) from July and August 2019.

Month	Species captured	Total captured	Total measured	Fork length (± SE; mm)	Weight (± SE; g)
July	CH	7	7	67.7 ± 2.0	3.8 ± 0.4
	GR	20	19	67.7 ± 8.9	6.4 ± 1.5
	LSU	18	15	43.1 ± 7.1	2.0 ± 0.7
	CCG	12	10	41.8 ± 5.6	1.2 ± 0.4
	LKC	2	2	71.5 ± 0.5	4.1 ± 0.0
	RW	1	1	50.0 ± 0.0	1.3 ± 0.0
August	CH	8	8	83.1 ± 1.9	6.4 ± 0.6
	GR	74	29	66.4 ± 3.6	4.9 ± 1.6
	LSU	33	23	68.1 ± 5.4	5.1 ± 1.2
	CCG	21	11	46.2 ± 4.2	1.3 ± 0.3

	RW	1	1	61.0 ± 0.0	2.0 ± 0.0
	NP	1	1	154.0 ± 0.0	37.1 ± 0.0
	IN	1	1	153.0 ± 0.0	27.9 ± 0.0

CH = Chinook salmon; GR = Arctic grayling; CCG = slimy sculpin; RW = round whitefish; LW = lake whitefish; LSU = longnose sucker; LKC = lake chub; NP = northern pike; IN = inconnu

Photo 19. Juvenile inconnu captured in a seine haul at the Stewart River proposed north barge landing on August 10, 2019.

3.2.1.5 Stewart River South Barge Landing

The Stewart River south proposed barge landing site (left downstream bank) is located along a uniform stretch of river with steep eroding banks and a gently sloping shoreline and riverbed (Photo 20). The riverbed is comprised primarily of cobbles and gravel with some fines. This site was sampled in July and August 2019, both with an effort of 460 m^2.

Photo 20. Upstream view of the proposed barge landing site on the south bank of the Stewart River, July 11, 2019.

Six species were captured during the July sampling and four during August (Table 23). Few juvenile Chinook salmon were captured in July (n = 2) and none were captured during August sampling. Arctic grayling were captured during both sampling periods (n = 5 and n = 18, respectively), as were longnose sucker (n = 12 and n = 10; Table 23).

Table 23. Stewart River south barge landing fish metrics (fork length and weight, ± SE) from July and August 2019.

Month	Species captured	Total captured	Total measured	Fork length (± SE; mm)	Weight (± SE; g)
July	CH	2	2	76.0 ± 2.8	4.9 ± 0.1
	GR	5	5	37.2 ± 2.9	0.5 ± 0.07
	LSU	12	12	37.9 ± 5.4	1.0 ± 0.4
	CCG	1	1	36.0 ± 0.0	0.3 ± 0.0

	LSU	10	10	38.6 ± 1.4	0.5 ± 0.1
	CCG	3	3	33.0 ± 7.2	1.0 ± 0.5
	LKC	1	1	31.0 ± 0.0	0.4 ± 0.0

CH = Chinook salmon; GR = Arctic grayling; CCG = slimy sculpin; RW = round whitefish; LSU = longnose sucker; LKC = lake chub

3.2.2 BARGE WAKE INVESTIGATIONS

One barge investigation was completed on July 10, 2019, at approximately 17:00. The passing barge was passing in a downstream direction and was not loaded (Photo 21); this was not the same barge docked at the Coffee Gold Project during the July field visit (shown in Photo 23). The entire channel was 440 m across, and the passing barge was 280 m from shore. The waves reaching shore came up 11 to 35 cm; waves came up higher on gently sloping silt or sand portions than on cobble (Photo 22). Turbidity along the nearshore area (1.0 m into the river from the waters edge) increased locally for approximately twelve minutes, with turbidity increasing more and for longer at sheltered sites with banks comprised of fines compared to locations with shorelines comprised of rocky substrate. Water flowing from sites with higher turbidity was observed flowing downstream along the margin of the river after the barge had passed.

Photo 21. A passing barge adjacent to Halfway Creek on July 10, 2019.

Photo 22. Waves created by the passing barge on July 10, 2019.

Photo 23. The new barge being used at the Coffee Gold Project, loaded at the existing barge landing on July 15, 2019.

3.2.3 STEWART RIVER BACK CHANNEL INVESTIGATIONS

3.2.3.1 Spring

The Stewart River back channel contained water during the May field visit (Photo 24). Eight sites along the Stewart River back channel were beach seined for fish, along with one seine in the adjacent side channel of the Stewart River (Site 9). Juvenile longnose sucker and adult northern pike were each captured in two of the eight back channel sites sampled (Table 24; Figure 13; Photo 25). Longnose sucker and lake chub were captured at Site 9 in the Stewart River side channel (Table 24; Figure 13). The highest upstream portion of the back channel that contained water (Photo 26) was near the upstream most NAR encroachment area. Site 1 was the most upstream site that was sampled with sampling progressing downstream, with Site 9 being downstream of the mouth of the back channel (Photo 27). The channel wetted width was approximately 5 m at its widest, with the deepest part of the channel being 0.7 m (Photo 28). No barriers to fish existed from the mouth of the back channel up to where it dried up, indicating that fish would be able to travel the length of the wetted portion of the back channel. Generally, water temperature and dissolved oxygen levels increased at the sites closer to the mouth (Table 25).

In 2018, the capture of young-of-the-year pike in this back channel led to speculation of pike spawning in or near this channel. While adult pike were captured in the channel in 2019, these fish did not appear to ripe and given turbid water clarity, observations of pike activity could not be made. Pike spawning in this channel or the downstream side channel is possible.

The highest water at the Stewart River mouth between January 1 to December 31, 2019, occurred on June 1, 2019, at a primary water level of 27.809 m. During the May 24 visit, the water level was 27.286 m at the Stewart River mouth. In previous years it has been surmised that water levels at the mouth of the Stewart River would need to be approximately 27.0 m for the Stewart River back channel to receive water (EDI 2019). The only time the Stewart River mouth exceeded 27.0 m was between May 21 to June 8, 2019 (Environment Canada 2020), suggesting the Stewart River back channel had little connectivity to the Stewart River during the open water season.

Table 24. Fish sampling results from the Stewart River back channel on May 24, 2019.

Site	Species	Total captured	Fork length (± SE; mm)	Notes
1	NFC	-	-	NFC
2	LSU	1	32.0 ± 0.0	Juvenile.
3	LSU	1	42.0 ± 0.0	Juvenile.
4	NFC	-	-	NFC
5	NP	1	470.0 ± 0.0	Adult.
6	NFC	-	-	NFC
7	NFC	-	-	NFC; observed splashing nearby – likely adult pike.
8	NP	1	490.0 ± 0.0	Did not appear ripe.
9	LSU	12	47.4 ± 5.2	Below the mouth of the back channel, in a side channel of the Stewart River; fines and emergent vegetation.
	LKC	10	44.2 ± 7.8	

DNS = did not sample; NFC = no fish caught; LSU = longnose sucker; LKC = lake chub

Table 25. Water quality data at sites along the Stewart River back channel on May 24, 2019.

Site	Temperature (° C)	Dissolved oxygen (%)	Dissolved oxygen (mg/L)
Site 1	10.0	31.6	3.56
Site 2	11.5	31.6	3.43
Site 3	10.9	21.5	2.30

Photo 28. Upstream view of the Stewart River back channel at Site 5 on May 24, 2019.

3.2.3.2 Summer

The Stewart River back channel was visited on July 11, 2019, at which point the mouth had dried up entirely (Photo 29). The back channel remained dry for approximately 700 m with a dry mud bottom (Photo 30). Shortly beyond 700 m there were two small pools of murky standing water, both less than 0.5 m in depth (Photo 31, Photo 32). The water quality indicated it was likely stagnant surface water with very low dissolved oxygen levels, which is poor for fish rearing (Table 26). An active forest fire was burning on a slope facing the back channel, approximately 2 km away.

Table 26. Water quality parameters of the two pools found in the Stewart River back channel on July 11, 2019.

	Temperature (°C)	Dissolved Oxygen (%)	Dissolved Oxygen (mg/L)	Specific Conductivity (µS/cm)
Pool 1	13.1	19.6	2.06	431.9
Pool 2	13.8	32.0	3.31	491.5

Photo 29. View of the dry mouth of the Stewart River back channel on July 11, 2019.

Photo 30. Upstream view of the mouth of the Stewart River back channel on July 11, 2019.

Photo 31. Downstream view of one of the isolated pools containing water on July 11, 2019.

Photo 32. Upstream view of the other isolated pool containing water on July 11, 2019.

The site was visited from the air again on August 10, 2019. The channel still appeared to be entirely dry from the mouth (Photo 33), with one of the pools still visible from the air (Photo 34). There was evidence of the July forest fire encroaching on the back channel (Photo 35).

The Stewart River level at the mouth was 25.868 m during the July visit and 26.062 m in August (Environment Canada 2020), which was below the approximate 27.0 m required for connectivity between the back channel and the Stewart River (EDI 2019).

Photo 33. View of the dry mouth of the Stewart River back channel and downstream side channel on August 10, 2019.

Photo 34. Overhead view of the dry Stewart River back channel; one of the isolated pools can be discerned in the upper middle of the photo on August 10, 2019.

Photo 35. Downstream view towards the Stewart River on August 10, 2019. The extent of the July forest fire can be seen on the right of the photo.

4 SUMMARY

Fieldwork from the 2019 field season provided additional baseline information for the Coffee Gold Project within the MSA and NAR. Several components in the 2019 field season had noteworthy findings which are presented below.

- More Arctic grayling were captured in Halfway Creek than previous years and their upstream extent increased slightly (from 600 m upstream of the mouth in previous years to 1000 m this year). No fish were captured upstream of the logjam barrier located 1 km upstream of the mouth.
- Fish sampling in Carlise, Excelsior, and Los Angeles Creeks creeks were not deemed useful control sites for comparison of juvenile Chinook salmon growth rates in Coffee Creek.
- Halfway and YT-24 creek mixing zones generally had higher diversity and abundance than the Yukon River reference site (YUK51.2). However, a site directly adjacent to the Yukon River reference site had comparable CPUE to the mixing zone sites, highlighting the high variability when targeting shoaling fish species (i.e., juvenile Chinook salmon). Additionally, YT-24 Creek did not have a mixing zone in July as the creek did not reach the Yukon River; despite the lack of a mixing zone, there was a high CPUE and species diversity.
- A considerable amount of fish habitat (FHAP) data (2017 – 2019) is now available for streams downstream of the mine site as well as control streams. Resurvey of these areas may be warranted depending on time of mine development.
- Chinook spawning surveys did not find any evidence Chinook spawning in Coffee or Independence Creek. No Chinook spawning has been detected in these creeks despite surveys being completed for seven consecutive years (2013 – 2019).
- A considerable amount of fish presence data has been collected at the barge landing sites and the results are generally consistent from year to year.
- Little wake or lasting turbidity was detected during barge wake investigations. The waves reaching shore came up 11 to 35 cm. Typically waves came up higher on gently sloping silt or sand portions of river bank than on steeper sections or those with cobble. The turbidity was higher and lasted longer in back eddy areas with considerable silt.
- Based on the recommendation in the 2018 report, the Stewart River back channel was investigated for the presence of spawning northern pike. Two adult northern pike were captured and others were visually observed. While there was no direct evidence of pike spawning, there is potential for it to occur in the back channel and/or in the adjcacent downstream side channel of the Stewart River. Additional spring sampling may be able provide more clarity, especially in a year when water levels are higher.

RE: Summer 2020 - Stewart River Back Channel Fieldwork

This letter provides a summary of the work completed and the data collected during summer 2020 fieldwork in the Stewart River back channel.

June 17, 2020

An EDI crew visited the Stewart River back channel on June 17, 2020, to assess fish and fish habitat. Water levels on the Stewart River were very high at the time (28.505 m) and there was flow through the back channel (WSC 2020). Due to the high-water and associated unwadable conditions, the crew could not complete the planned fish sampling. In situ water quality measurements and field observations were collected (Photo 1 to Photo 4; Table 1), in situ measurements were collected using a YSI Pro Solo multimeter, Oakton pH Testr pen, and an Oakton T-100 turbidimeter.

Table 1. In situ water quality parameters from the Stewart River back channel collected during June 17, 2020, fieldwork.

Site	Location Coordinates (Decimal Degrees)		Temperature (°C)	pH	Dissolved Oxygen		Specific Conductivity (µS/cm)	Turbidity (NTUs)
	Northing	Easting			mg/L	%		
Site 1	63.23074	-138.82615	12.6	7.84	9.68	91.2	268.4	75.4
Site 2	63.23059	-138.82824	11.5	-	2.34	21.8	233.1	-
Site 3	63.23019	-138.82798	12.9	-	3.07	29.2	190.4	-
Site 4	-	-	12.6	-	8.63	81.1	269.7	-
Site 5	63.22984	-138.82839	12.6	-	9.63	88.1	268.9	-

µS/cm = microsiemens per centimeter, NTU = nephelometric turbidity units.

August 27, 2020

An EDI crew visited the Stewart River back channel on August 27, 2020, to collect baseline fish and fish habitat data. The water level in the Stewart River was still relatively high (27.493 m; WSC 2020), and the

back channel was wetted for its entire length where it parallels the base of the hillside (Photo 5, Photo 6). There was no discernable flow in the back channel during sampling.

The crew recorded in situ water quality measurements using a YSI Pro Solo multimeter, an Oakton pH Testr pen, and an Oakton T-100 turbidimeter at some of the sampling locations along the length of the back channel (Table 2). Orange-brown algae was present in the upper half of the back channel (Photo 7). In situ water quality reflected poor habitat conditions in the top half of the back channel (low dissolved oxygen) and conditions improved closer to the mouth of the back channel and the Stewart River (Table 1). Water clarity (turbidity) improved and then decreased as the influence of the Stewart River backwatering the back channel became more pronounced (Photo 8).

Table 2. In situ water quality parameters from the Stewart River back channel collected during August 27, 2020, fieldwork.

Site	Location Coordinates (Decimal Degrees)		Temperature (°C)	pH	Dissolved Oxygen		Specific Conductivity (µS/cm)	Turbidity (NTUs)
	Northing	Easting			mg/L	%		
Haul 1	62.22934	-138.82878	5.0	8.60	4.88	38.6	521.0	31.3
Haul 2	62.22631	-138.82899	-	-	-	-	-	-
Haul 3	62.22894	-138.82910	-	-	-	-	-	-
Haul 4	63.22831	-138.82896	6.2	7.59	5.60	45.3	471.3	38.1
Haul 5	63.22726	-138.82909	7.5	7.64	6.90	57.6	481.0	2.70
Haul 6	63.22642	-138.82932	-	-	-	-	-	-

Haul 8	63.22510	-138.82938	10.5	7.91	7.33	66.5	418.0	18.0

µS/cm = microsiemens per centimeter, NTU = nephelometric turbidity units.

Fish sampling involved seining with a 10 m long by 1.5 m deep beach seine constructed of 5 mm mesh. Seining sampled the wetted width of the Stewart River back channel at regular intervals. A total of eight seine hauls were conducted starting at the top of the back channel, where isolated pools were previously identified (EDI Environmental Dynamics Inc. 2019), and working back towards the mouth of the back channel. Northern pike (*Esox Lucius*), burbot (*Lota lota*), and lake whitefish (*Coregonus culpeaformis*) were captured during sampling (Photo 9 to Photo 11; Table 3). Fish were only captured in the lower half of the Stewart River back channel (Table 3). An adult and juvenile Northern pike were captured in the lower half of the Stewart River back channel (Photo 9; Table 3). Juvenile burbot and lake whitefish were also captured in the lower half of the back channel (Photo 10, Photo 11; Table 3). No fish were captured or observed in the portion of the back channel with orange-brown algae.

Table 3. Fish sampling results, capture data, and relative abundance in the Stewart River Back Channel during August 27, 2020 fieldwork.

Sample Site	Area Sampled (m^2)	Location Coordinates (Decimal Degrees)		Distance from Mouth[1] (m)	Fish Captured (Spp. - number)	Length[2] (mm)	Catch Per Unit Effort; CUPE (# fish/100m^2)
		Northing	Easting				
Haul 1	15	63.22934	-138.82878	500	NFC	-	-
Haul 2	11.3	63.22931	-138.82899	490	NFC	-	-
Haul 3	60	63.22894	-138.82910	450	NFC	-	-
Haul 4	140	63.22831	-138.82896	380	NFC	-	-
Haul 5	150	63.22726	-138.82909	260	NFC	-	-
Haul 6	150	63.22642	-138.82932	170	NP - 1	112 mm	0.67
Haul 7	200	63.22588	-138.82928	110	NP - 2 BB - 1	75, 98 mm 87 mm	1.00 0.50
Haul 8	320	63.22510	-138.82938	25	NP - 2 LW - 1	130, 590 mm 139 mm	0.63 0.31

NFC = no fish captured; NP = Northern pike; BB = burbot; LW = lake whitefish.

1 Distance from the mouth of the Stewart River back channel is approximate and estimated from google earth imagery and sample waypoints.

2 Fish length was measured as either fork length for NP and LW and total length for BB.

If you have any questions or concerns please contact me or Pat Tobler at 1-(867)-393-4882.

Yours truly,

RE: 2021 Halfway Creek Fish Investigations

This letter provides a summary of the work completed and data collected during summer 2021 aquatics fieldwork in Halfway Creek, on behalf of Newmont for the Coffee Gold Project.

Fish sampling last occurred in Halfway Creek in 2019, when electrofishing was conducted from 0.2 km to approximately 1.2 km upstream from the confluence of the Yukon River. Photos and measurements were taken at a logjam approximately 1 km upstream of the mouth of the creek (HC1.0), which was suspected to be a fish barrier. No fish were captured upstream of the suspected barrier during previous sampling from 2013 to 2019 (EDI Environmental Dynamics Inc. 2017, 2018, 2019, 2020). The shallow pools below and above the barrier were unlikely large enough to provide the space required for fish (e.g., Arctic grayling; *Thymallus arcticus*) to create the necessary propulsion to make it up and over the obstruction (EDI Environmental Dynamics Inc. 2020). However, Halfway Creek is a dynamic watershed, and can change from year to year. In addition, the Coffee Gold Project's proposed Waste Rock Storage Facility will be located in the upper Halfway Creek watershed. It is therefore important to understand fish use of and distribution within the watershed, so additional fish sampling was completed in Halfway Creek in 2021, with particular focus on sampling above and below the suspected fish barrier.

Methods

Electrofishing was conducted at three locations in Halfway Creek on August 14 and at two additional locations on September 5 (Table 1). Fish sampling was completed with a Smith-Root LR-24 electrofisher. Electrofishing effort was counted on the electrofisher in total seconds of active electrofishing as well as by the approximate distance from the electrofishing starting GPS point. All captured fish were enumerated and identified to species, and ten of each species were weighed (g) and measured to fork length (mm; Arctic grayling) or total length (mm; slimy sculpin [*Cottus cognatus*]). A calibrated YSI water quality meter was used to collect in situ water quality parameters (temperature and dissolved oxygen in August; temperature, dissolved oxygen, pH, and specific conductivity in September) at each fish sampling location.

On August 14, photos and measurements were taken at the suspected fish barrier located approximately 1 km upstream of the mouth of Halfway Creek (HC1.0).

Table 1. Fish sampling details for Halfway Creek in August and September 2021.

Sampling Site[1]	Start Location (Latitude, longitude)	End Location (Latitude, longitude)	Date	Distance Sampled (m)	Fishing Effort (seconds)	Electrofisher Settings
HC0.2	62.94371°, -139.24921°	62.94345°, -139.25050°	August 14	150	1219	350 V, 60 Hz, 30% duty cycle
HC0.7	62.94128°, -139.25972°	62.94124°, -139.26065°	August 14	160	1123	350 V, 60 Hz, 30% duty cycle
HC1.1	62.94017°, -139.26472°	62.93909°, -139.27222°	August 14	400	1138	350 V, 60 Hz, 30% duty cycle
HC2.0	62.93858°, -139.28038°	62.93654°, -139.28780°	September 5	500	1044	380 V, 50 Hz, 30% duty cycle
HC6.8	62.91264°, -139.33960°	62.90928°, -139.34587°	September 5	500	1060	380 V, 50 Hz, 30% duty cycle

[1]Sampling site location corresponds with distance in kilometers from the confluence of Halfway Creek with the Yukon River; for example, HC2.0 is located 2.0 km upstream of the confluence.

Results and Discussion

Fish sampling in Halfway Creek occurred at three sites on August 14. At site HC0.2 (200 m upstream of the confluence with the Yukon River), only slimy sculpin (n=13) were captured (Table 2, Photo 1). The slimy sculpin were all captured within approximately 240 m of the confluence with the Yukon River. While electrofishing at site HC0.2, the crew thought they saw a larger fish (presumably an Arctic grayling) but could not confirm their observation. The crew then sampled site HC0.7, which is located approximately 700 m upstream of the confluence with the Yukon River but downstream of the suspected fish barrier at HC1.0. No fish were caught. The crew proceeded to sample site HC1.1, which is approximately 100 m upstream of the suspected fish barrier. Two adult Arctic grayling were captured (Photo 2, Photo 3); no other species were caught.

Given that no fish had previously been captured this far up in Halfway Creek, additional sampling was completed on September 5 at sites HC2.0 and HC6.8 to investigate fish distribution higher in the watershed; however, no fish were captured nor did the crew make any visual observations of fish. All sampling durations ranged from 1044–1219 seconds.

Table 2. Fish captured in Halfway Creek in August and September 2021.

Site	Date	Species	Total fish captured	Fork length range (mm)[1]	Weight range (g)
HC0.2	August 14, 2021	Slimy sculpin	13	48–86	1.0–6.0
HC0.7	August 14, 2021	No fish captured	0	-	-
HC1.1	August 14, 2021	Arctic grayling	2	186–310	90–185
HC2.0	September 5, 2021	No fish captured	0	-	-
HC6.8	September 5, 2021	No fish captured	0	-	-

[1] Total length for slimy sculpin.

The previously suspected fish barrier was originally measured in July 2019 and again in August 2021 (Table 3). The logjam is approximately 15 m wide, with three distinct drops where water flows down into small pools—one drop near the left downstream bank, one at the right downstream bank, and another mid-channel (Photo 4Photo 5 and Photo 6). Each drop is comprised of large and small woody debris. Comparatively, the measured downstream pool depths appear similar in 2021 to those measured in 2019, but the measured upstream pool depths have increased since 2019. The drop heights have also decreased substantially since 2019. Halfway Creek is a very dynamic stream that sees high freshet flows, which may have dislodged parts of the logjam and increased upstream pool depth. Such changes likely explain how fish were able to pass upstream in 2021.

Table 3. Comparative measurements of the suspected fish barrier at HC1.0 in July 2019 and August 2021.

	Downstream Pool Depth (m)		Upstream Pool Depth (m)		Drop Height (m)		Drop Width (m)	
	2019	2021	2019	2021	2019	2021	2019	2021
Right Bank	0.76	0.62	0.05	0.32	0.80	0.55	1.0	2.06
Mid-Channel	0.27	0.28	0.35	0.54	0.50	0.11	1.6	0.58
Left Bank	0.10	0.18	0.15	0.39	0.40	0.19	1.2	0.43

Summary and Closure

Sampling has occurred in Halfway Creek on several occasions since 2013. Sampling results in the lower portion of Halfway Creek are variable from year to year in terms of species and numbers captured. This was the first year that slimy sculpin were captured upstream of the immediate mouth of the creek. Winter surveys have shown that the stream freezes to bed in the lower portions, so it is not suspected that the sculpin will remain in this portion of the stream.

Plans to construct a Waste Rock Storage Facility in the upper Halfway Creek watershed have warranted thorough investigations of fish use of and distribution within the creek. Results from 2021 show that the former suspected fish barrier changed enough to allow Arctic grayling to pass in 2021, but they seem to exist

only sporadically past the HC1.0 mark and have so far not been found upstream of HC2.0. Past studies have documented many impediments to fish passage between HC1.0 and the location of the Waste Rock Storage Facility (EDI Environmental Dynamics Inc. 2018), which may limit fish presence in the upper watershed.

If you have any questions or concerns, please contact Annina Altherr or Pat Tobler at (867) 393-4882.

Yours truly,

EDI Environmental Dynamics Inc.

1 INTRODUCTION

1.1 Project Location and Background

The Coffee Gold Project (the Project) is a proposed open-pit gold mine owned by Goldcorp Kaminak Ltd., a subsidiary of Newmont Inc. (Newmont). The Project is in west-central Yukon, approximately 130 km south of Dawson City, 140 km west of Pelly Crossing, 95 km south-west of Beaver Creek, and 330 km northwest of Whitehorse (Figure 1.1). The Project is located wholly within the traditional territory of Tr'ondëk Hwëch'in, partially within the traditional territory of the Selkirk First Nation and the First Nation of Na-cho Nyäk Dun, and partially within the asserted territory of the White River First Nation. The Project contains several gold occurrences within an exploration concession covering an area of more than 600 km^2. The mine site will be accessed by road from Dawson City via a 214-km all-season, gravel road with pull-outs, referred to as the Northern Access Route (NAR). The NAR includes upgrades to portions of the existing road and construction of 37 km of new single-lane, forestry-type access road. The NAR includes seasonal barge crossings on both the Stewart and Yukon rivers with ice bridges in winter months.

Gold was initially discovered in Coffee Creek in 2010 and baseline environmental studies were initiated shortly thereafter. The Coffee Project was originally owned and evaluated by Kaminak Gold Corporation (Kaminak). Under the direction of Kaminak, the Coffee Project underwent a detailed Feasibility Study in 2015, with project engineering and design progressing in consideration of environmental conditions within the project area. Kaminak was acquired by Goldcorp Inc. in 2016 and Goldcorp issued a Project Proposal and supplementary information package under the *Yukon Environmental and Socio-Economic Assessment Act (YESAA)* in December 2017 (Goldcorp 2017). This initiated project review and screening at the Yukon Environmental and Socio-Economic Assessment Board (YESAB) Executive Committee level. In 2019, Goldcorp was acquired by Newmont and the Project underwent further refinement (the Coffee Mine Update Study; CMUS). Over the 2018 to 2021 period, YESAB issued Information Requests to the Proponent, who provided detailed responses to YESAB. The YESAB Executive Committee screening was completed in October 2021 with a recommendation that the Project proceed under Section 58(1)(b) of YESAA (YESAB 2021). Subsequently (November 2021), the federal decision bodies referred the screening report and recommendation back to the Executive Committee for reconsideration of NAR decommissioning, NAR access control, the influence of other developments on water quality objectives, and language utilized in the consideration of cumulative effects (Transport Canada 2021).

1.2 Project Description

The Coffee Project will have four distinct phases over its life span as follows:

1. Construction Phase: 2½ years (Q2 of Year -3 to the end of Year -1);
2. Operation Phase: 10 years (Year 1 to end of Year 9);
3. Reclamation and Closure Phase: 11 years (Year 11 to end of Year 21, including a 6-year Post-Mining Closure Stage and a 5-year Active Closure Stage); and
4. Post-Closure Phase: Year 24 onwards as required.

Several mine activities will continue from one phase to another as mine site development advances. When areas that support mine operations are no longer required, they will be progressively reclaimed. Detailed activities are subject to change depending on mine planning, operational initiatives, and the receipt of authorizations.

The Coffee Project, which has been optimized over time to improve economics and meet environmental protection commitments, is comprised of four open pits (Latte, Double-Double, Supremo, and Kona) and one permanent Waste Rock Storage Facility (WRSF; Figure 1.2; Newmont Goldcorp 2019). The projected ore production rate is between 7.0 and 7.5 million tonnes (Mt) per year. Ore will be crushed at an average rate of approximately 28,000 tonnes per day up to a maximum of 40,000 tonnes per day in peak mining years, producing an estimated total of 60.1 Mt of heap leach feed over the 10-year Operation Phase. The conceptual-level estimate for waste material to be moved over the life of mine (LOM) is 300 Mt based on an average strip ratio of 5.0:1. The ore will be transported to a Crusher System for crushing and screening and then transported to and stacked on a lined heap leach facility pad using an overland conveyor or trucks for nine months of the year. During the three coldest months of winter, run-of-mine (ROM) ore will be stockpiled in the ROM stockpile. Waste rock will be transported to the alpha waste rock storage facility, backfilled into the pits, or used as construction materials where appropriate.

Up to nine million tonnes of ore will be stacked on the heap leach pad annually. Gold will be leached from ore at the heap leach facility (HLF) using a weak sodium cyanide solution. As the barren sodium cyanide solution percolates through the heap leach, gold will react with the cyanide and dissolve into the solution. This gold-bearing solution (referred to as the pregnant solution) will be collected at the base of the heap leach pad. The pregnant solution will then be transported by pipe to the process facility, where it will be processed using conventional gold recovery methods at an on-site adsorption, desorption, and recovery (ADR) carbon plant. The end product of the ADR plant is poured doré bars, which will be shipped off-site by aircraft for further refining.

Mine Infrastructure, Newmount Coffee Gold Project

Date: December 2021
Project 217202.0074

minnow environmental inc.

Figure 1.2

Document Path: C:\Users\MLaPalme\Trinity Consultants, Inc\Newmont - 217202.0074 - 2021 Coffee Project AEMP\D - GIS\Report\21-74 - Figure 1.2 Coffe Mine Site Infrastructure.mxd

Conceptual design indicates a total of approximately 60.1 Mt of mined ore containing 2.6 million ounces of gold.

A water treatment plant will be constructed during the Operation Phase to treat excess process water (e.g., water produced during rinsing of the heap leach as part of mine closure activities) and will be operated through the Reclamation and Closure Phase. The treatment plant will also allow for progressive rinsing and reclamation of the heap leach facility during operations and will discharge to Halfway Creek. The treatment process will include oxidizing residual cyanide and metals removal using a biological reduction process targeting uranium. The biological reduction process will also treat numerous other metals in the heap leachate including arsenic. The process will also remove nitrate from heap solutions, anticipated to be elevated due to *in situ* cyanide degradation. Treated water from the water treatment plant will initially be used for additional rinsing of the heap leach. Treated excess water in the heap leach facility will be discharged to Halfway Creek once it meets effluent discharge quality standards.

In addition to the open pits, HLF, WRSF, process plant, and water treatment plant, the Plant Site will include a reagent storage area, assay laboratory, truck shop, warehouse buildings, a power plant (including power generation and distribution), Liquid Natural Gas (LNG) storage and bulk fuel storage tanks with a fuel distribution system. A mine camp complex will include camp facilities for 400 persons with associated potable water and wastewater treatment, fire suppression systems, mine dry, office, and emergency response and training buildings, and a waste management facility. Additional project infrastructure will include a bulk explosive storage area, emulsion plant, and blasting accessories storage, mine site roads and haul roads, and site water management infrastructure including conveyance structures, several ponds specific to the HLF, a pond and dam at the foot of the WRSF (the Alpha Pond and Dam), clean water diversions, and sediment ponds. Ancillary components include the NAR, airstrip, laydown areas, a freshwater pipeline, Coffee exploration camp and Java exploration/construction camp, and waste management facilities. Some minor or ancillary facilities may be relocated, modified, or added as detailed design is completed but are not expected to affect the overall Project footprint.

When mining or processing activities have been completed or when areas are no longer needed for mining, reclamation and closure activities will be undertaken, either progressively during the Operation Phase or subsequently during the Reclamation and Closure Phase. Reclamation and closure planning, which has been a primary consideration from the onset of mine planning and design, has focused on achieving short- and long-term erosion control, ensuring that future land use is compatible with surrounding lands, and returning the area to a landscape that is compatible with original land uses.

1.3 Aquatic Environmental Setting

The Coffee Project mine infrastructure is located along a ridgetop straddling three watersheds (Figure 1.2). Two of the watersheds (Halfway Creek and YT-24), drain directly to the Yukon River. The third watershed (Latte Creek) drains to Coffee Creek, then on to the Yukon River. All three watersheds have the potential to be influenced by the Coffee Project through changes in water quantity and/or water quality associated with watershed configuration changes and site water discharge, and water quality objectives and effluent quality standards will be developed for all three creeks. Halfway Creek will receive direct discharge from the Coffee Project water treatment plant. The potential effects of the Project on hydrology, water quality, and aquatic life were evaluated in detail in the Project Proposal and have been the subject of refinement through the YESAB review and screening (e.g., Lorax 2017a,b; EDI 2017a; Minnow and EDI 2017). Briefly, the physical presence of the Coffee Project within these three watersheds will result in modest loss of watershed area and consequent changes in water flow, principally confined to the upper reaches of Halfway Creek, YT-24 Creek, and Latte Creek. Flow changes in Latte Creek are negligible, while those in Halfway Creek are modest (i.e., maximum 15% change in mean annual discharge; Lorax 2017a). Project operations will have some influence on water quality of Halfway Creek, YT-24 Creek, and Latte Creek through erosion and sedimentation, leaching from disturbed mine materials and waste, leaching of nitrogen residues from blasting, discharge of treated camp water, heap leach facility residues, groundwater and surface water interactions and seepage, and atmospheric deposition (Lorax 2017b). Water treatment plant effluent and water from the Alpha Pond will be directed to Halfway Creek, although small volumes of pit dewatering will be routed to YT-24 Creek, and small volumes of pit dewatering, plant site runoff, and sewage treatment plant effluent will be routed to Latte Creek (Lorax 2019). Detailed evaluation of the influence of the project on water quality indicated some modest Project-associated influences on concentrations of arsenic, nitrate, and sulphate in Halfway Creek, arsenic in YT-24 Creek, and arsenic, uranium, and nitrate in Latte Creek and Coffee Creek (Lorax 2019). Most recent evaluation of water quality under the CMUS indicated a potential for sulphate concentrations in Halfway Creek to exceed water quality objectives (WQO), but no exceedances for any other parameter (Lorax 2019). This evaluation also indicated no exceedances of any WQO in YT-24 Creek or Latte Creek (Lorax 2019).

Evaluation of the potential influence of the Project on aquatic biology indicated no major expected changes to fish or fish habitat (EDI 2017a), and only very subtle changes in the taxonomic composition and/or productivity of periphyton and benthic invertebrate communities (Minnow and EDI 2017). The latter differ slightly by water body, with changes deemed most likely to occur in Halfway Creek, in the form of subtle changes in periphyton community composition, a modest increase in periphyton productivity (in association with nitrogen input and

temperature changes), subtle changes in benthic invertebrate community composition, and a modest increase in benthic invertebrate productivity (Minnow and EDI 2017). In YT-24 Creek and Latte Creek, the only predicted changes are minor, low probability changes in periphyton community composition (Minnow and EDI 2017).

1.4 Aquatic Life Baseline Update Objectives and Design

This Aquatic Life Baseline Update Report provides an update to previously reported data on baseline periphyton and benthic invertebrates (and supporting physical and chemical environmental data) within the catchments potentially affected by the Coffee Project (PECG 2017; EDI 2017b, 2018; Minnow and EDI 2017). This report is focused exclusively on the Project site subject to the Project operations as described in Section 1.3 and does not include the NAR (i.e., it is focused on the Halfway Creek, YT-42 Creek, and Latte Creek/Coffee Creek watersheds; Figure 1.2). The report also includes baseline data collected from reference areas outside of these three watersheds. These data were collected over the period from 2017 to 2021 (as described in detail in Section 3).

The fundamental objective of this Aquatic Life Baseline Update Report is to provide a detailed quantitative documentation of periphyton, benthic invertebrate community, benthic invertebrate tissue quality, and supporting aquatic environmental variables for creeks that may potentially be affected by the Coffee Project and for associated "future" reference creeks. The collection of additional aquatic life baseline data considered the specific findings of the environmental assessment (e.g., Minnow and EDI 2017) as summarized above. In addition, the design took future needs into consideration, including the provision of high-quality data in order to: 1) effectively support environmental assessment and permitting; 2) facilitate optimal design of an Aquatic Environmental Monitoring Program (AEMP; alternately entitled Fisheries and Aquatic Life Monitoring Program); and 3) provide replicated data that can be used in future analysis of AEMP data using an optimal study design (Before-After Control-Impact; BACI). This update seeks to provide the periphyton, benthic invertebrate community, benthic invertebrate tissue quality, and supporting aquatic environmental data collected from 2017 to 2021 in a clear manner that can be easily picked up and used in future data analyses and includes presentation and discussion of baseline differences among areas that must be considered in future evaluation of potential mine-related influences and effects.

1.5 Report Organization

In addition to this introduction to the Periphyton and Benthic Invertebrates Baseline Update Report, a brief review of periphyton and benthic invertebrate community data collected from 2014 to 2017 is provided in Section 2. All methods used in the collection, analysis, and

interpretation/reporting of baseline periphyton, benthic invertebrates, and supporting physical and chemical data are outlined in detail in Section 3. Sections 4 to 8 provide data and discussion associated with each of the main components of the Periphyton and Benthic Invertebrates Baseline collected from 2017 to 2021: supporting habitat and water quality, periphyton/productivity, benthic invertebrate community, benthic invertebrate tissue chemistry, and sediment quality. Section 9 provides conclusions and a brief discussion the use of baseline data to support monitoring program design and the interpretation of future monitoring data and some recommendations for future monitoring. All references cited throughout the document are listed in Section 10.

2 PREVIOUS AQUATIC BASELINE STUDIES (2014 to 2017)

2.1 Overview

Baseline aquatic data collections in support of the Coffee Project were initiated as early as 2010. Intensive baseline data collection was completed from 2014 to 2017 in support of the Project Proposal (Table 2.1; Figure 2.1). This included focused collection of aquatic biological baseline data in 2014 and 2015 (PECG 2017), and in 2016 and 2017 (EDI 2017b, 2018; Minnow and EDI 2017). Aquatic environmental baseline data collection included:

- habitat and water quality;
- sediment quality;
- periphyton / primary productivity;
- benthic invertebrate community;
- benthic invertebrate tissue quality;
- fish community and populations; and
- fish habitat and habitat use evaluations.

With the exception of fish and fish habitat data (which are presented in a separate report), the results of the 2014 to 2017 aquatic baseline studies are briefly reviewed in the following sections.

2.2 Habitat and Water Quality

The aquatic environmental setting of the Coffee Gold Project is described in detail in the Project Proposal and in previous environmental baseline reports (PECG 2017; EDI 2017b, 2018). This section provides a brief overview of the aquatic environmental characteristics relevant to periphyton and benthic invertebrates.

The topography of the Project area is consistent with Yukon unglaciated ecozones and is characterized by deep soil weathering and strong erosional patterns linked to precipitation and snowmelt (Grods et al. 2012). Creeks that could potentially be influenced by the Project (Halfway Creek, YT-24 Creek, Latte Creek, and Coffee Creek) are predominantly erosional with rocky substrate that varies from cobble and boulder in upper reaches to cobble and gravel in lower reaches. Upper Creek areas are typically comprised of cascade-pool or step-pool sequences, whereas lower/larger creek areas are typically comprised of riffle-run sequences. Pool habitat is limited in all creeks except for Coffee Creek. Creek geomorphology is consistent with high gradients in the Upper Creek areas (commonly >8%) and moderate gradients (≤4%)

Table 2.1: Aquatic Biological Baseline Studies at the Coffee Project, 2014 to 2017

Study Name	Study Purpose, Duration and Spatial Boundaries
Coffee Gold Mine Fish and Aquatic Resources Baseline Report (PECG 2017)	**Study Purpose:** Detailed baseline characterization of fish and aquatic resources of the Project area.
	Timing: August and October 2014; March, June, July, and September 2015.
	Periphyton and Benthic Invertebrate Data: Periphyton and benthic invertebrate sampling at sites in Latte Creek, Coffee Creek, YT-24 Creek, Halfway Creek, Independence Creek, Isaac Creek, and Los Angeles Creek. Periphyton endpoints included biomass (ash-free dry mass), chlorophyll-a, and community composition (to the phylum/division [algae] or class [diatoms] level). Benthic invertebrate community endpoints included abundance, taxon richness, biodiversity, evenness, and community composition (to the lowest practical level).
	Additional Aquatic Environmental Data: Sediment quality, fish habitat, fish distribution, fish community, fish population (size, age, condition), and fish tissue quality. Fish sampling and habitat investigations in lower reaches of Coffee, Halfway, and Independence creeks; salmon spawning survey in a 31 km section of the Yukon River in the vicinity of the Project area and lower Coffee and Independence creeks.
Coffee Gold Mine: Fisheries and Aquatic Resource Baseline Update (EDI 2017b)	**Study Purpose:** Supplementary baseline characterization of fish and aquatic resources of the Project area. Additional data collection and synthesis with traditional and scientific knowledge and previously collected data.
	Timing: March, July, August, and October 2016
	Periphyton and Benthic Invertebrate Data: Periphyton chlorophyll-a and benthic invertebrate tissue sampling at sites in Latte Creek, Coffee Creek, YT-24 Creek, Halfway Creek, Independence Creek, and Los Angeles Creek.
	Additional Aquatic Environmental Data: Additional baseline characterization of fish and fish habitat including environmental DNA sampling, winter studies, summer fish and fish habitat assessments, chinook salmon spawning surveys, fish tissue quality, and stream gradient modeling around Project area.
Coffee Gold Project: Fish and Aquatic Resources Studies - 2017 (EDI 2018)	**Study Purpose:** Continued baseline characterization of fish and aquatic resources of the Project area.
	Timing: March, August, and October 2017
	Periphyton and Benthic Invertebrate Data: Periphyton chlorophyll-a and ash-free dry mass (AFDM), benthic invertebrate community sampling (CABIN methodology) at sites in Latte Creek, Coffee Creek, YT-24 Creek, Halfway Creek, Independence Creek, and Los Angeles Creek.
	Additional Aquatic Environmental Data: Additional baseline characterization of fish and fish habitat including fish usage surveys, habitat and fish passage (barrier) assessment, environmental DNA sampling, winter studies, summer Chinook salmon spawning surveys, and fish tissue quality assessment around the Project area.
Coffee Gold Project Supplementary Periphyton and Benthic Invertebrate Community Studies (Minnow and EDI 2017; Appendices A and B)	**Study Purpose:** Supplementary baseline characterization of fish and aquatic resources of the Project area.
	Timing: August 2017
	Periphyton and Benthic Invertebrate Data: Replicated benthic invertebrate sampling in two areas: a “future-exposed area” on Halfway Creek and a matched reference area located on a tributary to Carlisle Creek. Benthic invertebrate community endpoints included density, taxon richness, biodiversity, evenness, community composition (to the lowest practical level), habitat preference groups, and functional feeding groups. Periphyton and benthic invertebrates were also sampled at sites in Latte Creek, Coffee Creek, YT-24 Creek, Halfway Creek, Independence Creek, and Los Angeles Creek. Periphyton endpoints included biomass (ash-free dry mass), chlorophyll-a, and community composition (to the phylum/division [algae] or class [diatoms] level). Benthic invertebrate community endpoints included abundance, taxon richness, biodiversity, evenness, and community composition (to the lowest practical level).
	Additional Aquatic Environmental Data: Additional baseline characterization of stream sediments at the same sites as periphyton and benthic invertebrates. Fish tissue in Halfway Creek (near the mouth) and in Independence Creek.

Periphyton and Benthic Invertebrate Sampling Locations (Pre-2018)

Date: December 2021
Project 217202.0074

minnow environmental inc.

Figure 2.1

Document Path: C:\Users\MLaPalme\Trinity Consultants, Inc\Newmont - 217202.0074 - 2021 Coffee Project AEMP\D - GIS\Report\21-74 - Figure 2.1 Periphyton and BI Sampling Locations.mxd

in the lower/larger areas/creeks (EDI 2018). Complete winter ice cover occurs in the Upper Creeks, with aufeis (thick sheet ice that forms due to the successive flows of ground water at freezing temperatures) observed in Coffee, Latte, YT-24, and Halfway Creeks (EDI 2017b, 2018).

The hydrology of Project area creeks tends to be flashy and is surface water driven during freshet and groundwater driven at other times of year (Lorax 2017a,b). Seasonality in hydrology and water chemistry is more pronounced upstream in the upper catchments. Total suspended solids concentrations are typically low, although elevated total suspended solids are associated with peak flow events. Baseline aqueous concentrations of several metals (aluminum, arsenic, cadmium, chromium, copper, iron, selenium, and uranium) have been observed at concentrations greater than water quality guidelines (Lorax 2017b). In general, seasonal patterns include greater concentrations of some metals during low-flow conditions (e.g., uranium) and of others during high suspended solids events, as occurs during spring freshet (e.g., total arsenic, total cadmium, total copper, total chromium, total selenium). Peak flows also typically include annual maximum concentrations of total suspended solids, dissolved organic carbon, dissolved aluminum, and particulate-bound metals. During winter low-flow periods, uranium concentrations have consistently been above corresponding water quality guidelines.

Most tributary streams in the Project area are nutrient-poor and have cool water temperatures (e.g., all creeks except Coffee Creek remained lower than 5°C during baseline summer sampling in 2014 and 2015; PECG 2017), which limit their overall productivity.

2.3 Sediment Quality

Although the creeks potentially influenced by the Project are predominantly erosional and do not support substantive sediment accumulation, some sediment sampling has been completed (PECG 2017; EDI 2018). Samples collected in 2014 and 2015 were predominantly sand, but chemical analysis of their finer fractions indicated that the silt and clay components contained concentrations of cadmium, chromium, copper, and mercury greater than Canadian Council of Ministers of the Environment (CCME) Interim Sediment Quality Guidelines (ISQG; CCME 1999) in Latte Creek and/or Coffee Creek, and of arsenic in Halfway Creek, YT-24 Creek, Kona Tributary, and Independence Creek (PECG 2017). Sampling in 2017 indicated that baseline concentrations of arsenic and chromium were consistently greater than ISQG across the Project area, and that arsenic concentrations in Latte Creek, Halfway Creek, and YT-24 Creek were also greater than the Probable Effect Level of the CCME (EDI 2018).

2.4 Periphyton / Primary Productivity

Periphyton sampling between 2014 and 2017 generally indicated that streams have very low primary productivity (e.g., chlorophyll-a concentrations of ≤0.088 mg/m^2; PECG 2017;

EDI 2017b, 2018), which is common of low nutrient, northern watercourses. Baseline periphyton sampling within the Project area included Latte, Coffee, Halfway, and YT-24 creeks as well at reference stations (Independence, Los Angeles, and upper Coffee creeks; Figure 2.2). Ash-free dry mass (AFDM) ranged from 3.5 to 8.1 g/m² in 2014 and 3.2 to 14 g/m² in 2015, while mean AFDM ranged <0.42 to 25 g/m^2 in 2017 (Figure 2.2). There was little variation in AFDM among stations in 2014 and 2015, but large variation, both among and within stations, in 2017 (Figure 2.2).

Mean chlorophyll-a concentrations were very low in all watersheds within the Project area (PECG 2017; EDI 2017b, 2018), which is typical of northern, nutrient poor aquatic habitats. Laboratory holding times were exceeded during chlorophyll-a sampling in 2014 and 2015, and therefore, chlorophyll-a concentrations were expected to represent an underestimation during this time. Chlorophyll-a sampling was conducted again in 2016 and 2017, and sampling met all lab holding times and requirements. Chlorophyll-a concentrations ranged from 0.79 to 3.5 mg/m² in 2014, and 0.96 to 2.5 mg/m² in 2015 (Figure 2.3). Maximum chlorophyll-a concentrations in these years occurred at Isaac Creek (IS0.1; 3.5 mg/m^2) and at the downstream YT-24 Creek station (YT0.0; 2.5 mg/m^2) in 2014 and 2015, respectively. Mean chlorophyll-a concentrations in 2016 and 2017 ranged from 1.4 to 8.8 mg/m^2 and <0.42 to 11 mg/m^2, respectively (Figure 2.3). These concentrations are within the range of oligotrophic streams (<20 mg/m^2; Dodds et al. 1998) and are well below the short-term maximum British Columbia guideline for the protection of aquatic life (100 mg/m^2; BCMOCCS 2021). In 2016, chlorophyll-a was generally lower at upstream compared to downstream stations across the watershed[1], including Coffee Creek (5.7 and 8.8 mg/m², respectively), Latte Creek (1.4 and 2.7 mg/m², respectively), YT-24 Creek (6.1 to 7.6 mg/m², respectively), and Halfway Creek (3.0 to 7.0 mg/m², respectively). In 2017, this was only observed for Latte Creek, while chlorophyll-a was higher upstream compared to downstream in YT-24 Creek. Chlorophyll-a concentrations were generally higher in 2016 than in 2017, which simply reflects temporal variability. The maximum mean chlorophyll-a concentrations in 2016 and 2017 were observed at the downstream (CF3.9; 8.8 mg/m²) and upstream (CF10.0; 3.0 mg/m²) Coffee Creek stations (Figure 2.3).

The baseline periphyton community was dominated by blue-green algae (Cyanophyta), which typically make up approximately 80% of the community (PECG 2017; EDI 2017b, 2018). Periphyton community taxon richness was similar among stations and years and varied between 8 and 14 taxa (Figure 2.4). Taxon richness was lower upstream than downstream in Coffee and

[1] under the naming convention for baseline sampling stations, higher numbers indicate greater distance from the creek mouth at the Yukon River. For example, HF0.2 is 0.2 kilometers upstream of the mouth of Halfway Creek and HF6.3 is 6.3 kilometers upstream of the mouth of Halfway Creek.

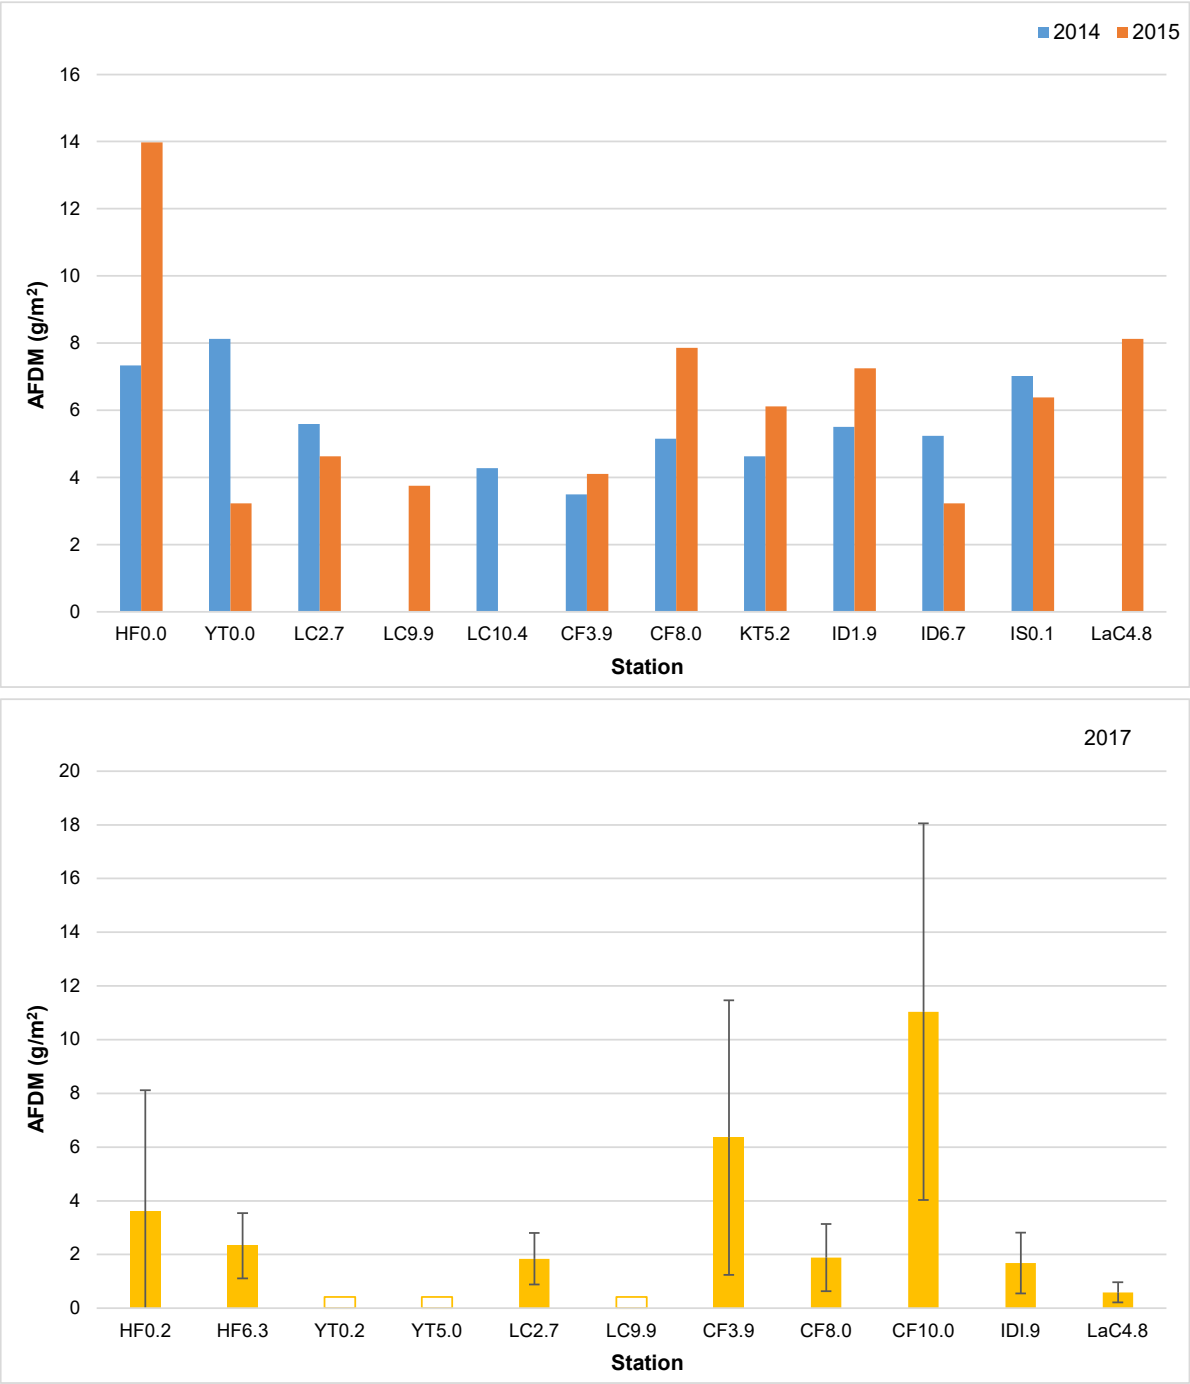

Figure 2.2: Periphyton Ash-Free Dry Mass (AFDM) per Square Meter, 2014, 2015, and 2017

Notes: Open bars indicate mean values below the method detection limit (MDL). For 2017, mean ± standard deviation are reported for 4 to 6 replicates per station. Mean and standard deviation were estimated using the survfit function in the survival package in R (R Core Team, 2016) using the methods for censored data described in (Helsel 2012). HF = Halfway Creek, YT = YT24 Creek, LC = Latte Creek, CF = Coffee Creek, ID = Independence Creek, LaC = Los Angeles Creek.

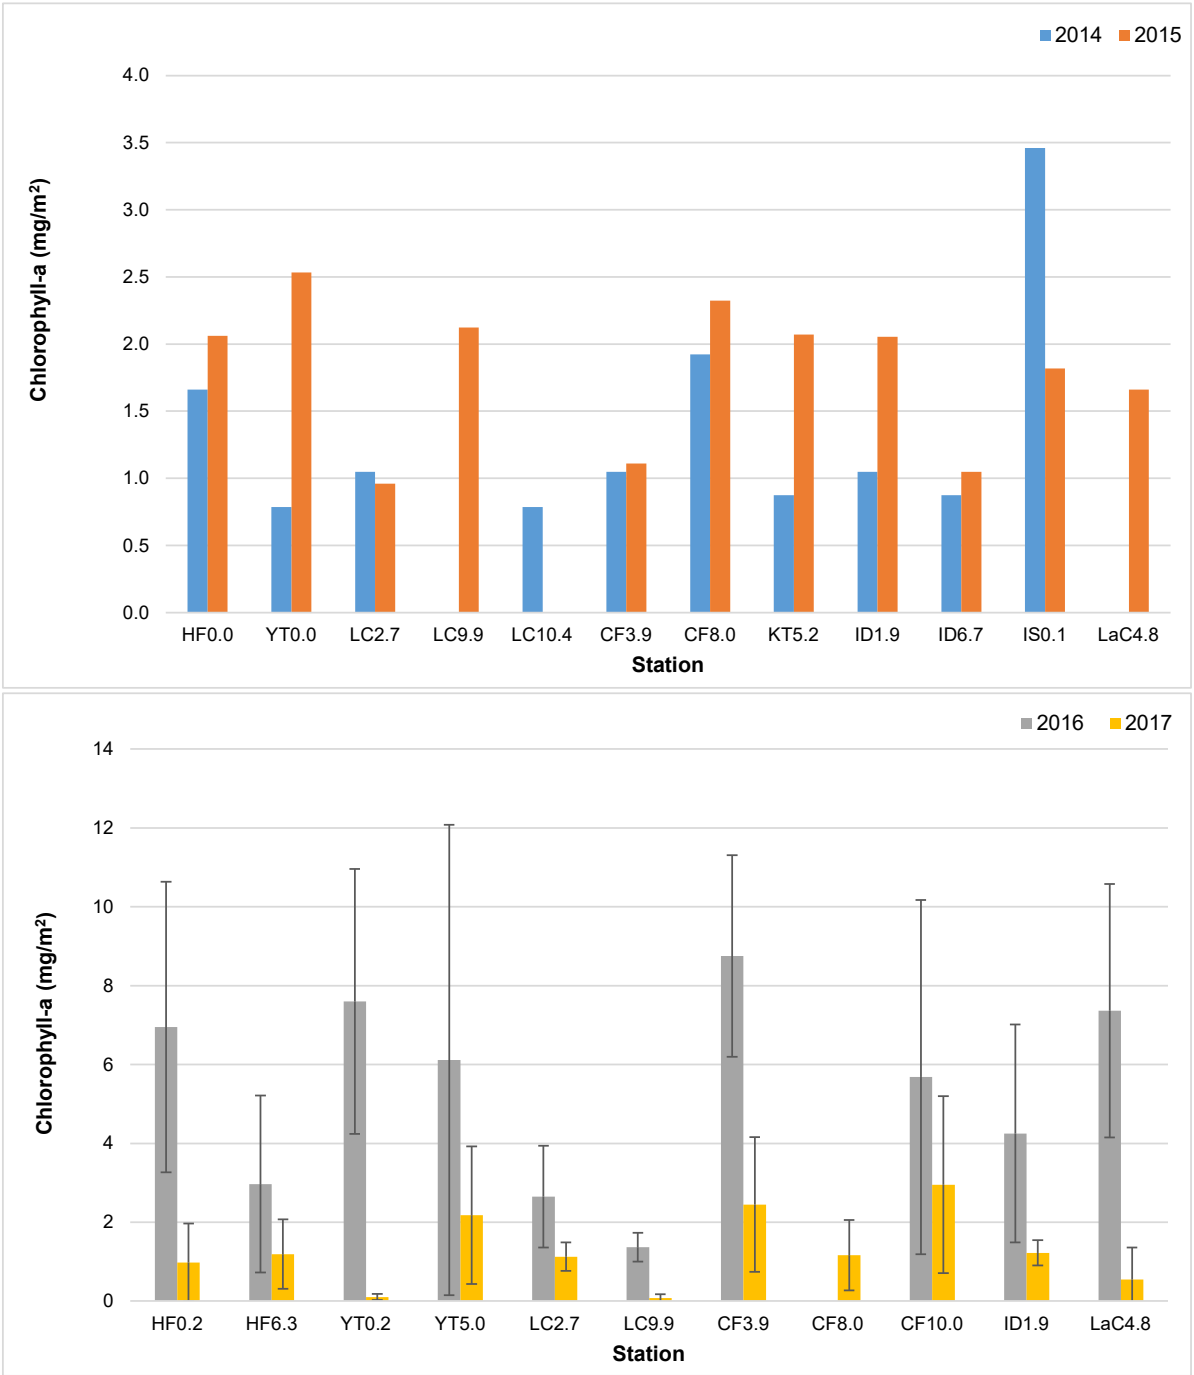

Figure 2.3: Periphyton Chlorophyll-a Concentrations, 2014 to 2017

Notes: For 2016 and 2017, mean abundance ± standard deviation are reported for 5 to 6 replicates per station. Mean and standard deviation were estimated using the survfit function in the survival package in R (R Core Team, 2016) using the methods for censored data described in (Helsel 2012). HF = Halfway Creek, YT = YT24 Creek, LC = Latte Creek, CF = Coffee Creek, ID = Independence Creek, LaC = Los Angeles Creek.

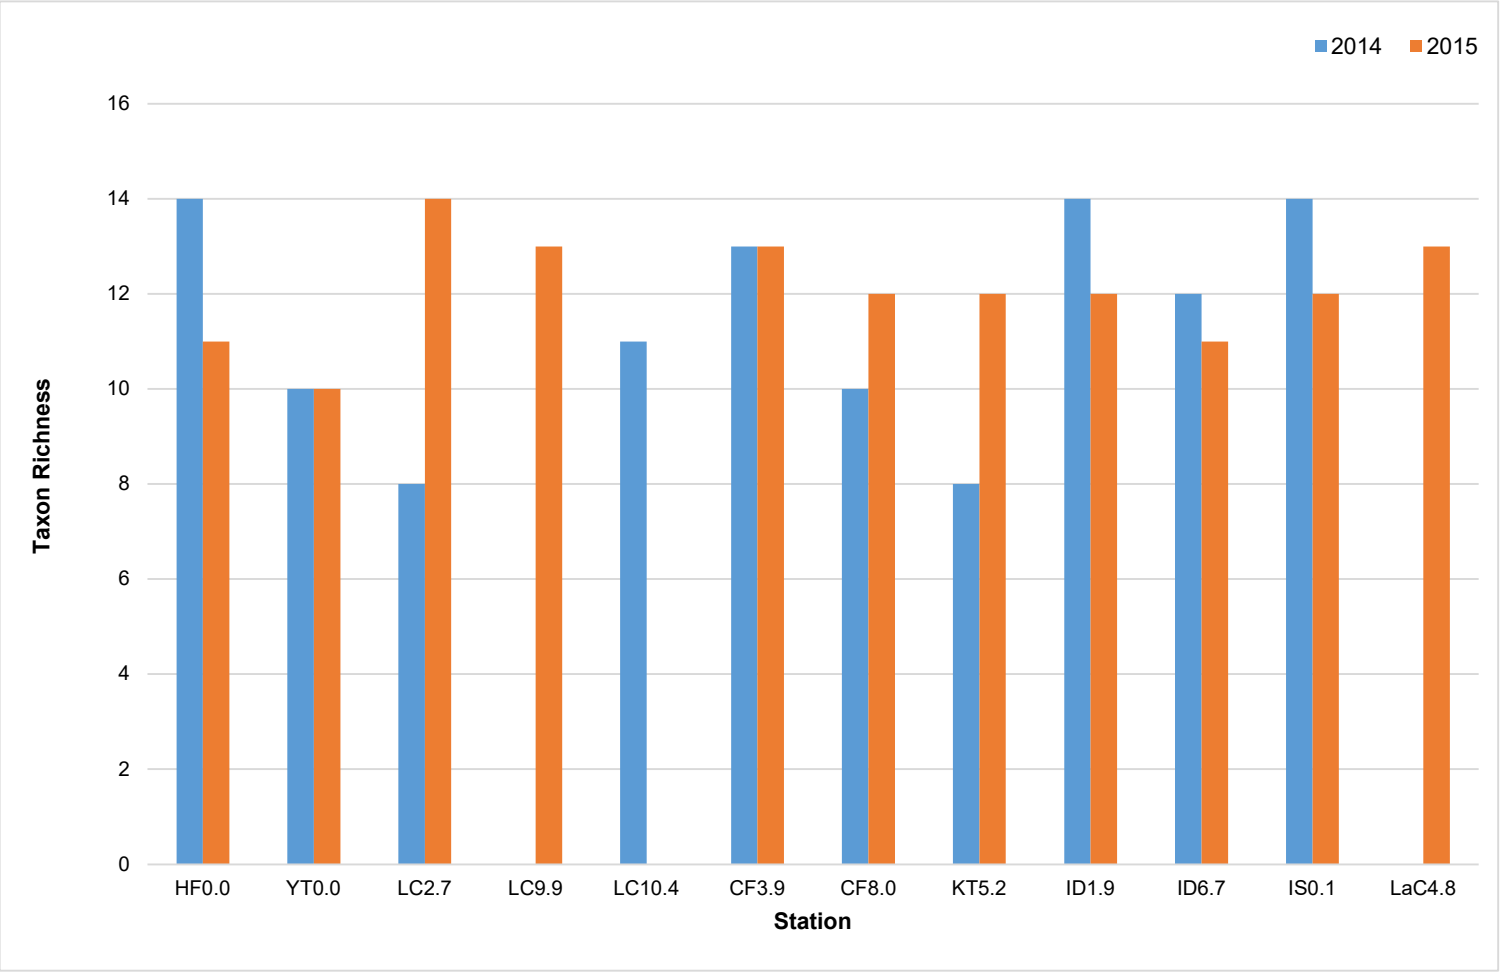

Figure 2.4: Periphyton Taxon Richness in 2014 and 2015

Notes: HF = Halfway Creek, YT = YT24 Creek, LC = Latte Creek, CF = Coffee Creek, KT = Kona Tributary, ID = Independence Creek, IS = Isaac Creek, LaC = Los Angeles Creek.

Independence creeks, while the opposite was observed for Latte Creek (Figure 2.4). Cyanophyta (blue-green algae) were the dominant periphyton taxon group at all stations and in all years except for Isaac Creek in 2014, where Bacillariophyta (diatoms) were dominant (Figure 2.5). Periphyton communities at all stations in 2014 and 2015 were dominated by blue-green algae (72% and 89%, respectively), followed by diatoms (24% and 8%, respectively), and green algae (Chlorophyta; 4% and 3%, respectively). Rhodophyta (red algae) were only observed at Isaac Creek in 2014 and were a minor component of the periphyton community (1.9%).

2.5 Benthic Invertebrate Community

Benthic invertebrate communities of the Coffee Project area are also typical of nutrient-poor, erosional, northern watercourses, with 18 to 34 taxa observed in Project area sampling sites, dominated by dipterans (mainly chironomids [non-biting midges]), mayflies, and stoneflies (PECG 2017; EDI 2017b, 2018). Most baseline benthic invertebrate community data was collected using a kick-and-sweep method (Environment Canada 2012b). This method collects one sample per site and does not provide an estimate of variability within the site. Kick-and-sweep benthic invertebrate community sampling was undertaken in 2014, 2015, and 2017 at Independence, Kona, Isaac, Los Angeles, Latte, Coffee, Halfway and YT-24 creeks. Highest mean abundances (organisms per 3-minute kick-and-sweep) across all years (2014 to 2017) were observed in Los Angeles Creek (4,590), Independence Creek (2,510), and Coffee Creek (991), followed by Kona Creek (893), YT-24 Creek (813), Latte Creek (758), Halfway Creek (644), and Isaac Creek (391). Total abundance generally increased in a downstream direction within YT-24 Creek and Independence Creek watersheds. The highest mean taxon richness across all three years was observed in Coffee, Latte, and Isaac creeks (24), Halfway Creek (23), followed by YT-24, Independence, and Los Angeles creeks (19), and Kona Creek (16). Unlike abundance, there was no apparent pattern in taxon richness from upstream to downstream.

Dominant benthic invertebrate taxon groups included Ephemeroptera (mayflies) and Plecoptera (stoneflies) in 2017, whereas Plecoptera, Chironomidae (non-biting midges) and/or Simulidae (black flies) were dominant in 2014 and 2015 (Figure 2.6). In 2017, Ephemeroptera and Plecoptera made up much of the benthic invertebrate community in Coffee Creek, Latte Creek, Halfway Creek, YT-24 Creek, and Los Angeles Creek. Abundance of EPT taxa (Ephemeroptera, Plecoptera, and Trichoptera) fluctuated among years and was comprised mostly of Ephemeroptera (mayflies) in Coffee Creek, Latte Creek, Independence Creek, Isaac Creek, and Los Angeles Creek, and Plecoptera (stoneflies) elsewhere. Trichoptera (caddisflies) only made up a small average proportion of the total community, and were only observed in Coffee

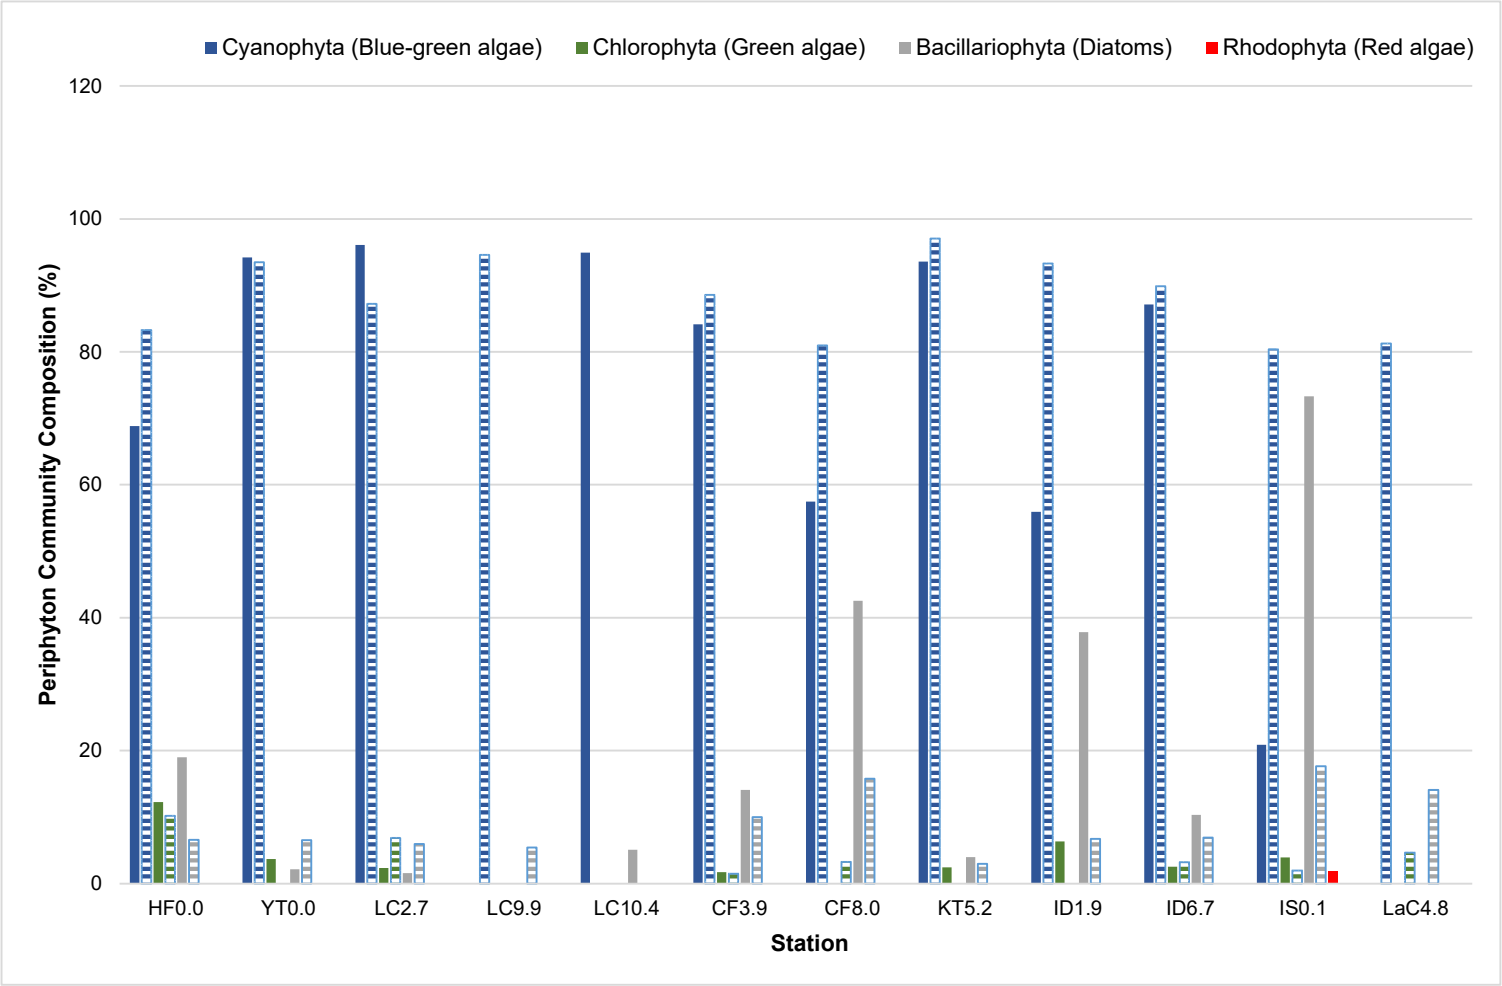

Figure 2.5: Periphyton Community Composition (% of total cells/m^2) in 2014 (Solid Bars) and 2015 (Hatched Bars)

Notes: HF = Halfway Creek, YT = YT24 Creek, LC = Latte Creek, CF = Coffee Creek, KT = Kona Tributary, ID = Independence Creek, IS = Isaac Creek, LaC = Los Angeles Creek.

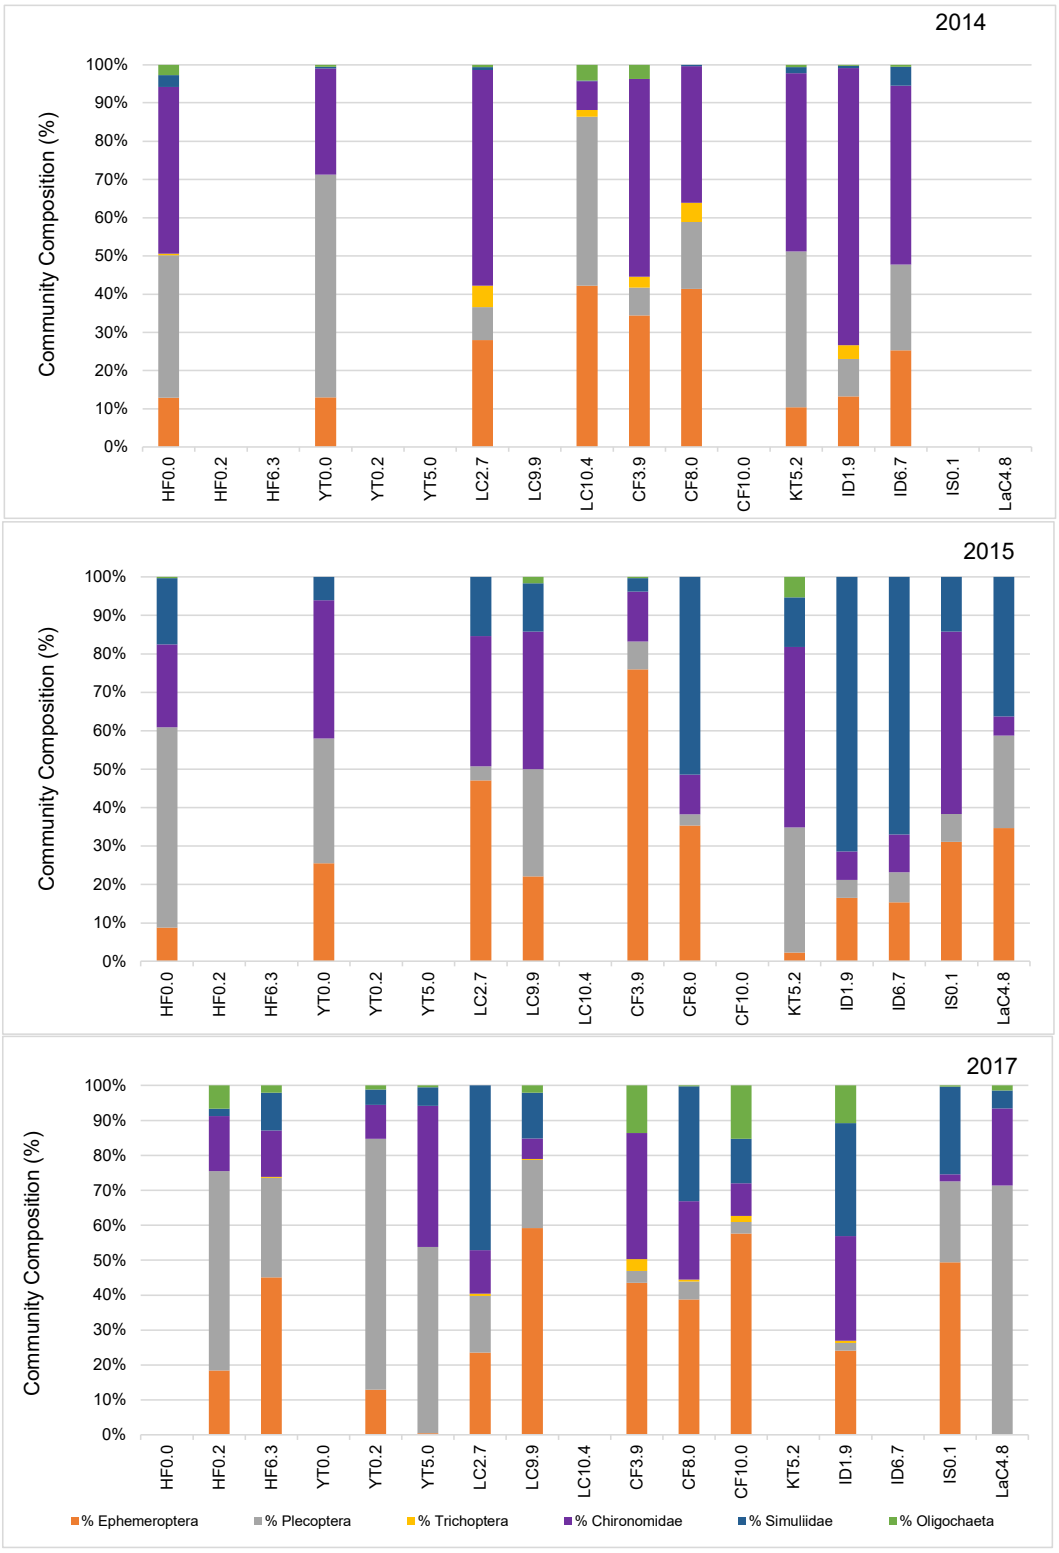

Figure 2.6: Percent Composition of Major Benthic Community Groups

(3.5%), Latte (3.5%), Halfway (0.4%), and Independence (1.8%) creeks in 2014, and in Coffee (1.9%), Latte (0.4%), Halfway (0.2%), and Independence (0.5%) creeks in 2017. Trichoptera were not present in samples collected in 2015. In 2017, Dipterans (true flies; mainly Chriomonidae and Simuliidae) represented a large proportion of the community at creeks sampled within the local study area except for Independence Creek, where Ephemeroptera and Plecoptera were the dominant groups (Figure 2.6). Among dominant taxa, the Simuliidae (black flies) showed the greatest variability in relative abundance within- and among-watercourses and study years (Figure 2.6), potentially reflecting variability in emergence, habitat, and/or sampling artifacts. In general, Ephemeroptera were typically present in higher relative abundance in upstream creek areas. The relative abundance of metal-sensitive chironomids[2] was generally low across all sites over the three sampling years.

Functional feeding group (FFG, as defined by Mandaville 2002) composition showed relatively minor variability among the three sampling years at individual local study area (LSA) creeks and was largely represented by collector gatherers (Figure 2.7). Differences in the proportions of filterers and shredders were observed among sampling years, which depending on the sampling year, made up the next largest proportion of FFG in the community at most LSA creeks (2014 –-shredders, 2015 – filterers, 2017 – shredders). The proportion of FFG scrapers and predators was generally low (i.e., less than 10% of the community), and was higher in 2014 compared to 2015 and 2017. Habitat Preference Group (HPG, as defined by Merritt et al. 2008) composition appeared was dominated by sprawlers in most years, although dominance of clingers was observed at some locations in 2015 and 2017 (Figure 2.8). Consistent with the erosional habitat sampled, burrowers predominantly represented by Oligochaetes (aquatic worms) were found in low numbers in all three years of baseline sampling.

In 2017, benthic invertebrates were also collected using a Hess sampler at a future mine-exposed area (Halfway Creek) and at a potential reference area (Area 129/CR24.5, a tributary to Carlisle Creek), with replication of five stations per area (Minnow and EDI 2017). The average density of organisms was lower at Halfway Creek (839 org/m^2) than at Area 129 (2,079 org/m^2), but average taxon richness was similar between these creeks (Halfway Creek = 18.8; Area 129 = 19.6; Table 2.2). Simpson's Evenness and Shannon-Weiner Diversity were higher at Halfway Creek than at Area 129 (Table 2.2). The mean proportion of EPT was similar between areas (Halfway Creek = 24.4%; Area 129 = 25.7%); however, Halfway

[2] Specific to this study, this group includes *Micropsectra* sp., *Stempellinella* sp., *Tanytarsus* sp., *Arctodiamesa* sp., *Psuedokiefferiella* sp., *Diamesa* sp., *Pagastia* sp., *Pottastia gaedii*, and *Pseudodiamesa* sp.; members of the metal-tribe Tanytarsini and subfamily Diamesinae (Kraft and Sypniewski 1981; Clements and Kiffney 1995; Clements et al. 2000).

Notes: T= t-test; Tunequal = t-test for unequal variances; MW = Mann-Whitney test; log = logarithm base 10. The observed effect size is calculated on the transformed scale when the data were transformed for analysis. No effect size is reported for the Mann-Whitney test.

[a] For transformed data, the back-transformed mean is reported; for ranked data, the median is reported.

[b] Reference area on a tributary to Carlisle Creek also known as CR24.5.

Creek had similar proportions of Ephemeroptera (33.4%) and Plecoptera (37.3%), whereas Area 129 was dominated by Plecoptera (67.9%; Table 2.2). Neither area had a high density of Trichoptera, as was also observed in the kick-and-sweep sampling (PECG 2017; EDI 2017b, 2018). Chironomidae made up a greater proportion of the community at Halfway Creek (12.8%) than at Area 129 (6.4%); however, they only accounted for small proportions of the community overall at both sites. Of the taxa present at Halfway Creek, 9.0% were metal sensitive and 67% of the chironomids present were metal sensitive.

As with the Canadian Aquatic Biomonitoring Network (CABIN) data from 2017 and previous years, the Hess FFG data showed that collector/gatherers and shredders made up the largest percentages of the community at Halfway Creek (Table 2.2). This was also observed at Area 129, but data showed a much greater proportion of shredders relative to collector/gatherers. Again, for Halfway Creek, Hess and CABIN mean data both indicated that HPG were largely made up of clingers and sprawlers in similar proportions. Area 129 was largely dominated by sprawlers (74.0%), with clingers and burrowers in similar, smaller proportions (13.4% and 12.6% respectively; Table 2.2). Statistical comparisons between the two areas using two sample t-tests indicated that Halfway Creek was significantly different from Area 129 based 13 of 19 endpoints examined despite similar physical characteristics (Table 2.2). This is indicative of spatial variability even under baseline conditions.

The differences observed between Halfway Creek and a reference area (Carlisle Creek tributary) even in baseline (i.e., statistically significant differences in density, evenness, diversity, taxonomic composition, functional feeding group composition, and habitat preference group composition; Table 2.2) highlight the importance of not relying on simple exposed reference (control impact or CI) comparisons for future evaluation of potential Project-related effects.

2.6 Benthic Invertebrate Tissue Quality

Benthic invertebrate tissue samples were collected in Latte, Coffee, Halfway, YT-24, Independence and Los Angeles creeks in March and/or August of 2016 and in August 2017, and analyzed for total metal concentrations (EDI 2017b, 2018). Of the metals with elevated baseline concentrations in water (e.g., aluminum, arsenic, cadmium, chromium, copper, iron, selenium, and uranium), baseline concentrations in benthic invertebrate tissue collected in 2016 were generally higher in the spring (March 2016) than in the summer (August 2016). Mercury results were evaluated against the CCME guideline for the protection of piscivorous wildlife (0.033 µg/g ww; CCME 2000) and no exceedances were observed (maximum 0.023 µg/g ww in a sample collected from Coffee Creek in March; EDI 2018). Selenium concentrations were not specifically evaluated in the original reports but reported baseline concentrations in 2016 exceeded the interim British Columbia guideline for dietary exposure to fish

(invertebrate tissue; 4 µg/g dw) in several samples in Latte, Coffee, Halfway, Independence, and Los Angeles creeks (EDI 2017b). Maximum recorded concentrations of selenium in benthic invertebrates were 7.6 µg/g dw in a sample collected from Coffee Creek and 7.3 µg/g dw in a sample collected from Coffee Creek in March 2016.

3 METHODS

3.1 Design Overview, 2018 to 2021

Benthic invertebrate and periphyton monitoring in support of the Coffee Project's conceptual Fish and Aquatic Life Monitoring Program (FALMP) is designed to monitor for potential (although not predicted) physical disturbance and toxicity effects, and for predicted stimulation of primary and secondary productivity. A Fish and Aquatic Life Adaptive Management Plan (FAL-AMP) has been developed for the Coffee Project to ensure that, similar to water quality results, the results of the FALMP follow an Adaptive Management Plan (AMP) framework (*i.e.*, are specifically used to trigger appropriate responses), and that links between the Water Quality Adaptive Management Plan (WQ-AMP) and Aquatic Life Adaptive Management Plan (AL-AMP) are established (Newmont 2021). The latter includes the use of FALMP and FAL-AMP results to inform the Water Quality Management Plan (WQMP) and WQ-AMP, and vice-versa. As with the WQ-AMP, the FAL-AMP includes predetermined thresholds that trigger monitoring and/or management responses to threshold exceedance.

Periphyton and benthic invertebrate community monitoring under the preliminary FALMP includes "future-exposed" creek areas and matching reference creek areas. Areas designated as future-exposed were selected because it is anticipated that the Project may cause direct or indirect effects in those creeks, including changes to water chemistry and nutrient enrichment (Newmont 2021), whereas the matching reference areas are not expected to be influenced by the Project.

The inclusion of both area types was selected to support the future application of a BACI design, which is considered the optimal design for environmental effects assessment and to specifically support the AL-AMP thresholds (*e.g.,* Green 1979; Mellina and Hinch 1995). Unlike the standard before-after (BA) or control-Impact (CI) approach, which asks the questions "does after differ from before (baseline)?" and "does exposed differ from reference?" (respectively), the BACI asks a question that is more powerful in determining potential mine-related change: "if there is a change from baseline in an exposed area, is that change larger than observed at the reference area?." Application of BACI controls for natural differences among areas and temporal variability to provide optimal resolution of potential mine-related effects. Upper Creek and Lower Creek "future-exposed" sampling areas were established at locations of anticipated Project influence to ensure FALMP monitoring satisfies future monitoring needs (*e.g.*, for Environmental Effects Monitoring [EEM] under the Metal and Diamond Mining Effluent Regulations [MDMER]; Environment Canada 2012; Newmont 2021).

A key consideration in the AL-AMP is which indicators to select as subject to AMP. Much like the WQ-AMP focusses on key analytes (parameters of concern) identified in the environmental and socio-economic assessment process, key indicators have been identified for use in the AL-AMP. Measurable Parameters were selected primarily based on an analysis of potential and predicted Project-associated physical and chemical changes reviewed in the analysis of periphyton and benthic invertebrates as part of environmental assessment (Minnow and EDI 2017). In selecting Measurable Parameters to use as key indicators, one consideration was to limit the number of key indicators in order to effectively capture those that are quantitative, reproducible, and sensitive to the potential changes identified in environmental assessment, while at the same time not including so many indicators that the AL-AMP becomes unmanageable or that there is redundancy in the indicators. Considering too many indicators results in an increased likelihood of finding a statistically significant difference when testing multiple hypotheses (*i.e.*, potential false positives, *e.g.*, Somers *et al.*, 2019) and can also result in redundancy (Rice and Rochet 2005). Redundant indicators that are influenced by similar generating processes (*e.g.*, effects on flow or effects on water chemistry) may overestimate impacts if used collectively (Sutherland *et al.,* 2016).

Based on consideration of these factors, the AL-AMP does not include triggers for periphyton (due to high variability in measurable parameters / indicators and trophic “distance” from the fundamental valued component [fish]). Monitoring endpoints and interpretation, therefore, include those identified as key indicators as well as additional parameters not assessed as potential future triggers for AL-AMP response (Table 3.1).

The following key indicators have been selected for AL-AMP:

- benthic invertebrate community biomass;
- benthic invertebrate community taxon richness; and
- percent EPT taxa in the benthic invertebrate community.

For each of these key indicators, thresholds are based on statistical contrasts of exposed area results versus reference area results (Table 3.2). If the key indicators do not differ from baseline and reference, or if the BACI interaction term does not differ from reference, then no AMP response is required. If statistically significant differences are observed at p=0.10, the AL-AMP framework is triggered.

Table 3.1. Rationale for Inclusion of Periphyton and Benthic Invertebrate Measurable Parameters in the Coffee Project FALMP and for the Selection of Key Indicators for the Aquatic Life Adaptative Management Plan (AL-AMP)

Monitoring Component	Subcomponent	Measurable Parameters	Units	Rationale for Inclusion in the FALMP	AL-AMP Key Indicator and Rationale
Periphyton	Productivity	Chlorophyll-a	Chlorophyll-a mg/m^2	potential stimulation by nutrients/temperature; impairment by sedimentation or toxicity,	**YES.** Indicator of nutrient enrichment (BCMECCS 2021; Dodds et al. 1998) .
		Biomass	Dry weight (mg/m^2) and Ash-Free Dry Mass (mg/cm^2)	potential stimulation by nutrients/temperature; impairment by sedimentation or toxicity	**NO.** Periphyton data are typically more variable than benthic invertebrate data and are more distant link (relative to benthic invertebrates) to the Valued Component (fish)
	Community	Taxonomic Richness	number of taxa per sample (station)	potential impairment by nutrients/temperature, sedimentation, or toxicity	
		% green algae	percent of total organisms	potential decrease with flow, nutrients, temperature, metal concentrations	
		% blue-green algae	percent of total organisms	potential increase with flow, nutrients, temperature, metal concentrations	
		% diatoms	percent of total organisms	potential increase with flow, nutrients, temperature, metal concentrations	
Benthic Invertebrates	Productivity	Biomass	dry weight (g/m^2)	potential stimulation by nutrients/temperature; impairment by sedimentation	**YES.** Highly quantitative and sensitive to potential stimulation and flow regime change.
	Community	Density	total organisms per m^2	potential stimulation by nutrients/temperature; impairment by sedimentation or toxicity	**NO.** Recapitulates biomass; considered a supporting metric to biomass.
		Taxon Richness	number of taxa per sample (station)	potential impairment by nutrients/temperature, sedimentation, or toxicity	**YES.** Highly quantitative and sensitive to potential stimulation, flow regime change, and toxicity.
		% EPT [a]	percent of total organisms	metal sensitive - potential decrease with elevated metals	**YES.** Highly quantitative and sensitive to potential stimulation, flow regime change, and toxicity.
		% mayflies	percent of total organisms	metal sensitive - potential decrease with elevated metals	**NO.** Recapitulates % EPT; considered a supporting metrics to % EPT.
		% HPG (burrowers v. clingers)	percent of total organisms	potential increase in burrowers under sedimentation	**NO.** Limited specificity to mine-related stressors.
		% FFG (collector-gatherer v. filterer v. scraper)	percent of total organisms	potential increase in collector-gatherers with sedimentation, lower filterer and scraper and higher clingers with flow augmentation	**NO.** Limited specificity to mine-related stressors.
		Simpson's Evenness	unitless; scale from 0 to 1	potential decrease with flow, nutrients, temperature, metal concentrations	**NO.** Can be naturally variable and somewhat recapitulates taxon richness.
		Simpson's Diversity	unitless; scale from 0 to 1	potential impairment by nutrients/temperature, sedimentation, or toxicity	**NO.** Recapitulates taxon richness.
		Bray Curtis Index of Dissimilarity	unitless; scale from 0 to 1	difference from baseline or reference	**NO.** Provides a yes/no evaluation of difference without description of the difference.
	Tissue Quality	Tissue Metals	mg/kg dry tissue weight	potential increase with aqueous metal concentrations	**NO**. Indicator of exposure, not of effects.

[a] EPT taxa = invertebrate taxa from the insect orders of Ephemeroptera (mayflies), Plecoptera (stoneflies), and Trichoptera (caddisflies).

Table 3.2. Statistical Contrasts and Outcomes for Periphyton and Benthic Invertebrate Monitoring Key Indicators under the Coffee Project FALMP and Triggers to the FAL-AMP

Statistical Contrast	Statistical Test	Question	Outcome and Associated Response under the FALMP	Trigger under to AL-AMP Action
Exposed versus Baseline (Before-After)	ANOVA	Does the key indicator differ from baseline?	No difference from baseline; no additional action required.	None
			Significant difference from baseline; proceed to 2-way ANOVA	None if the BACI analysis is supported; rely on the BACI analysis outcome. If the BACI analysis is not supported, a difference from baseline triggers the AL-AMP framework.
Exposed versus Reference (Control-Impact)	ANOVA	Does the key indicator differ from reference?	No difference from baseline; no additional action required.	None
			Significant difference from baseline; proceed to 2-way ANOVA	None if the BACI analysis is supported; rely on the BACI analysis outcome. If the BACI analysis is not supported, a difference from reference triggers the AL-AMP framework.
2-Way (Current-Baseline-Exposed-Reference) (Before-After-Control-Impact)	2-Way ANOVA	Is an observed "exposed area" difference from baseline (after versus before) greater than the equivalent reference area difference from baseline?	The difference from baseline at the exposed area is consistent with reference; no additional action required.	None
			Significant difference from baseline at exposed area relative to reference suggests a mine-related change.	AL-AMP framework triggered

3.1.1 Sampling Frequency and Study Area Locations

Benthic invertebrate and periphyton baseline field sampling at Project FALMP areas was conducted by Minnow Environmental Inc. (Minnow) biologists in August 2018, 2019, and 2021[3] (Table 3.3; Figure 3.1). Sampling in 2017 was only conducted at one future-exposed (HC6.8[4]) and one potential reference (CR24.5[4]) area as a preliminary step towards establishing sampling areas and protocols for a more comprehensive monitoring program. Sampling in 2018, 2019, and 2021 was conducted in a manner consistent with the conceptual FALMP, to ensure that three years of baseline data were collected in manner that can be optimally used for future detection of potential mine-related effects to aquatic life (Newmont 2021).

The FALMP monitoring program is designed around three "future-exposed" creeks (or creek groupings in the case of Latte/Coffee):

- Halfway Creek;
- YT-24 Creek; and
- Latte Creek/Coffee Creek.

Each of these three creeks has been further divided into an Upper Creek monitoring area and a Lower Creek monitoring area to account for a possible future gradient of effects due to proximity to Project development (Table 3.3; Figure 3.1). The monitoring program design includes two reference areas for the Upper Creek "future-exposed" areas and two reference areas for the Lower Creek "future-exposed" areas.

Conceptually, the frequency of periphyton and benthic invertebrate monitoring under the FALMP varies by location and project stage. Upper and Lower Creek areas were both monitored annually for three years (with the exception of 2020) of baseline collection from 2018 to 2021 (Tables 3.3 and 3.4). During mining operations, the Upper Creek areas will be monitored at a greater frequency than Lower Creek areas, reflecting greater mine influence relative to creek size. Upper Creek areas will be monitored at an initial frequency of annually for the first three years of operations, followed by every two years thereafter. Periphyton and benthic invertebrate monitoring of Lower Creek areas will be at a frequency of every 2 years during mine operations.

[3] The additional baseline monitoring was initially planned for 2018, 2019, and 2020, but monitoring in 2020 could not be completed due to site closure associated with the COVID-19 pandemic.

[4] FALMP sampling area names were revised in 2019 to more accurately reflect their proximity to each creek's mouth at the Yukon River. For previous area/station names see Appendix Table A.1.

Table 3.3: Coffee Project FALMP Periphyton, Benthic Invertebrate, and Sediment Sampling, 2017, 2018, 2019, and 2021

Area Type	Area Description	Area Name	Stations per Area	Habitat and *in situ* water	Periphyton			Benthic Invertebrates			Sediment

Table 3.4. Periphyton and Benthic Invertebrate Monitoring Areas, Methodology, Indicator Endpoints, Frequency, and Timing under the Fish and Aquatic Life Monitoring Program (FALMP) for the Newmont Coffee Project

Area Type	Future-Exposed Creeks	Reference Creeks	Periphyton		Benthic Invertebrates		Frequency	Timing
			Method Summary	FAL-AMP Indicator Parameters[a]	Method Summary	FAL-AMP Indicator Endpoints[ab]		
Upper Creek Areas	Upper Halfway (HC6.8)	Upper Carlisle (CR24.5) and Upper Coffee (CC23.7)	**Productivity:** sample periphyton with razor blade from a measured surface area of five randomly selected rocks, freeze two samples (one for AFDM and one for chlorophyll-a). **Community:** sample periphyton with razor blade from five randomly selected rocks, preservation with Lugol's solution.	**Productivity:** dry weight per (mg/cm^2)and chlorophyll-a (mg/m^2) **Community:** taxon richness, %green algae, %blue-green algae, %diatoms	**Productivity and Community:** Hess Sampler with 500 µm mesh (3 sub-sample composite); taxonomy to lowest practical level **Tissue Quality:** kick-and sweep and by hand (overturning rocks), taxon composition representative of community	**Productivity:** dry weight per (mg/m^2) **Community:** density, taxon richness, Simpson's Evenness, Simpson's Diversity, Bray-Curtis Index of Dissimilarity, %EPT taxa, %mayflies, %HPG, %FFG **Tissue Quality:** metal concentrations	**Baseline:** Annually for 3 years **Construction:** once **Operations:** Annually for years 1-3, every 2 years starting year 5. **Reclamation and Closure:** every 2 years	Mid-late August
	Upper YT-24 (YT4.3)							
	Upper Latte (LC10.2)							
Lower Creek Areas	Lower Halfway (HC0.2)	Lower Creek East of Excelsior (EX0.2) and Lower Stream South of YT-24 (SYT0.6)					**Baseline:** Annually for 3 years **Construction:** once **Operations:** every 2 years **Reclamation and Closure:** every 2 years	
	Lower YT-24 (YT0.2)							
	Lower Coffee (CC5.6)							

[a] The identification of FAL-AMP Trigger Parameters does not preclude interpretation based on additional Parameters. This is particularly true for community data, for which additional interpretive parameters will be calculated and contrasted (e.g., proportion of other taxonomic groups and ordination such as Correspondence Analysis).

[b] EPT = Ephemeroptera (mayflies), Plecoptera (stoneflies), and Trichoptera (caddisflies); HPG = Habitat Preference Group (sprawlers, burrowers, and clingers); FFG = Functional Feeding Group (collector-gatherers, filterers, scrapers, shredders, and predators).

Three future-exposed areas have been established in upper reaches of creeks in the vicinity of the Project, as well as three areas in corresponding lower reaches (Figure 3.1; Tables 3.3 and 3.4; Appendix Table A.1). The future-exposed areas are:

- Upper Halfway Creek (HC6.8);
- Upper Latte Creek (LC10.2);
- Upper YT-24 Creek (YT4.3);
- Lower Halfway Creek (HC0.2);
- Lower Coffee Creek (CC5.6); and
- Lower YT-24 Creek (YT0.2).

Reference areas were selected based on Geographic Information System (GIS) comparisons of regional creeks with future-exposed creeks, focused on creek morphology, hydrology, and proximity to the project (i.e., access logistics). Reference areas were selected to be as similar as possible to future-exposed areas according to criteria including elevation, stream order, and stream width. Similarity of reference areas with future-exposed areas is important to ensure applicability of the BACI design. The four reference areas selected are:

- Upper Coffee Creek Tributary (CC23.7);
- Upper Carlisle Creek Tributary (CR24.5);
- Creek South of YT-24 (SYT0.6); and
- Creek east of Excelsior (XE0.2).

Areas were divided into five replicate sampling locations (stations) for benthic invertebrate and periphyton sample collection (Appendix Table A.1). This level of replication was selected to provide adequate statistical power for application of state-of-the-science data collection and interpretation methodologies. Stations were selected in creek habitats to ensure within-creek and overall among-creek sample comparability, selecting riffle habitats with similar substrate (gravel and small cobble), similar flow velocity (~0.5-0.8 m/s), and similar depth (~20 cm) characteristics. Distances among stations were generally approximately 50 to 100 m as (i.e. maximum distance from Station 1 to Station 5 less than 500 m) but varied among areas depending on availability of suitable habitat, and safe access. Effort was made to establish stations in separate riffles wherever possible. Station replicates were numbered from 1 to 5 with 1 being the farthest upstream and 5 being the farthest downstream.

A number of sampling areas for which some historical baseline data exist were not included in the current study design including Independence Creek, Isaac Creek, Los Angeles Creek, various

areas along Coffee Creek (e.g., CC5.7 and CC8.0), and the Yukon River (EDI 2018; PECG 2017). The decision to exclude these historical sampling areas was generally the result of those areas being sub-optimal reference areas due to poor comparability with areas selected for the FALMP or due to changes within that area (e.g., initiation of placer mining activity).

3.2 Supporting Habitat and Water Quality

3.2.1 Habitat Features

Habitat assessment and *in situ* water quality measurements were completed at all stations sampled during the 2017, 2018, 2019, and 2021 field programs (Table 3.3). Habitat assessments included the following variables at all periphyton and benthic invertebrate monitoring stations:

- station location coordinates recorded in Universal Transverse Mercator (UTM) units;
- mean flow velocity (averaged across a 3-5 point transect in the vicinity of the Hess samples placements, m/s; measured using a HACH FH950 handheld flow meter [HACH Company, Loveland, CO]);
- water depth (meters [m]) measured using a meter stick at each Hess subsample location;
- habitat types present (i.e., pool/pond, riffle, run);
- creek gradient (by clinometer);
- creek width (bankfull and wetted, m)
- bank condition;
- substrate type(s);
- substrate size (cm, average of intermediate axis measurements for 50 randomly selected pebbles within the vicinity of the Hess sampler placements and for every 10th pebble an estimate of the degree of embeddedness in surrounding materials was recorded).
- amount and types of dominant aquatic vegetation;
- adjacent vegetation types (e.g., grasses, shrubs) and land use, including potential anthropogenic influences; and
- representative photos.

3.2.2 Supporting Water Quality Measurements

Water quality samples for laboratory analysis were not collected as part of this monitoring program, as routine baseline water quality monitoring has been conducted by Coffee Project staff

as well as Lorax Environmental Services Limited (Lorax) for the Coffee Project Water Quality AMP (WQ-AMP).

Supporting *in situ* measurements of water temperature, pH, specific conductance, and dissolved oxygen (DO) were recorded at each station using a YSI EXO™ handheld portable field meter equipped with YSI EXO2™ Sonde. *In situ* measurements were taken approximately 5 centimeters (cm) below the water surface.

The water quality meter was calibrated daily and maintained according to manufacturer instructions. Calibrations for DO were completed multiple times per day on days when there was movement among low- versus high-elevation areas.

3.2.3 Data Analysis

Habitat and water quality variables specifically identified as drivers of change in periphyton and benthic invertebrates due to Project operation (flow velocity and temperature; Minnow and EDI 2017), as well as remaining *in situ* water quality variables, were tabulated and plotted as time-series figures for Upper and Lower Creek areas. *In situ* water quality data were screened against available CCME water quality guidelines (pH and DO). Values for DO (concentration and saturation) from area HC6.8 in 2019 were unusually high compared with the range of values for other areas and other years at HC6.8. Those values were included in plots and data summary tables but excluded from statistical analyses.

Habitat and *in situ* water quality data were also integrated into correlation analyses of periphyton community, periphyton productivity, and benthic invertebrate community. Correlation testing is used to establish whether any spatial or temporal variability in biotic variables may be correlated with variability in any habitat or water quality variables.

Habitat and *in situ* water quality variables were compared spatially and temporally from 2018 to 2021 using a two-way analysis of variance (ANOVA) with factors *Area* and *Year* and their interaction. The significance of the main effects and interaction terms of the ANOVA were assessed using an α of 0.05, and the results of these determined which post-hoc comparisons were then conducted. Specifically, when the interaction between *Year* and *Area* was significant it indicated that the differences between the areas changed over time and post-hoc comparisons were conducted to 1) test for differences between the first year of sampling and each subsequent year for each area, and 2) test for differences between the exposed and reference areas in each year. For all significant post-hoc temporal comparisons, a magnitude of difference (MOD) between years was calculated as:

$$MOD_{Year} = \frac{MCT_{recent\ year} - MCT_{older\ year}}{MCT_{Older\ year}} \text{ x } 100\%$$

For significant spatial comparisons a MOD was calculated between the exposed and reference areas within each year as:

$$MOD = \frac{MCT_{Exposed} - MCT_{Reference}}{MCT_{Reference}} \text{ x } 100\%$$

The measure of central tendency (MCT) was calculated as back-transformed estimated marginal means or medians for rank-transformed data. When the interaction term (*Year* x *Area*) was not significant, post-hoc spatial comparisons and MOD calculations were conducted pooling over year and temporal comparisons were conducted pooling over stations.

3.3 Periphyton/Primary Productivity

3.3.1 Sample Collection

Periphyton community, chlorophyll-a, and ash-free dry mass (AFDM) sampling was completed in 2018, 2019, and 2021 (Table 3.3). One sample was collected for each periphyton parameter at each station (n=5 per area[5]) by selecting five representative submerged rocks for processing on shore as described below. A concerted effort was made to ensure that habitat characteristics (water depth, velocity, and substrate characteristics) were comparable among sampling stations and areas to minimize natural influences on the variability of community and productivity endpoints. Rocks were selected to be as close to benthic invertebrate community sampling locations as possible.

Creeks within the Project area are characterized as having very low productivity, and therefore the volume of periphyton for collection is very low and biomass distribution is patchy. Most randomly selected submerged rocks have no visible or tangible algal growth (Figure 3.2), which can bias collection towards rocks/sections of rocks having visible assemblages with atypically high concentrations of algal growth to ensure that sample volumes are adequate for laboratory analysis. Collection of sample volume adequate for analysis, particularly with respect to meeting the minimum AFDM target mass (1 mg), required targeted selection of rocks with visible periphyton assemblages. Rocks with algal growth typically had small patches of periphytic growth relative to the overall surface area, and those patches were targeted for sampling (Figure 3.3). A completely random approach to collecting rocks for periphyton sampling in the Project area would be extremely unlikely to generate adequate samples for periphyton analysis. Unit area-based periphyton biomass estimates are therefore likely overestimates of naturally

[5] Only 3 replicate periphyton samples were collected at area CC5.6 in 2018 due to difficulty collecting samples of adequate size for analysis due to low algal coverage.

Figure 3.2: **Randomly Selected Rocks for Assessment of Periphyton, Area CC5.6, 2019**

Figure 3.3: **Rocks Selected with Algal Growth for Periphyton Sampling, Area CC5.6, 2019**

occurring representative algal coverage but will continue to be valuable for tracking spatiotemporal trends so long as rocks with the highest concentration of periphytic growth for a given area continue to be targeted for sampling. Use of this method in future is recommended to ensure consistency and comparability of data across years.

Periphyton community samples were collected by firmly placing a thin acetate template with a 2x2 cm (4 cm²)[6] opening on a section of rock with encrusting material present (whether filling the template or not) and scraping off all periphyton present within this area using a stainless-steel razor blade or scalpel. Each single composite sample represented a 0.002 m² (5 x 4 cm²; or 0.0125 m^2 in the case of n=12 out of 50 samples in 2019) surface area per endpoint. Sample material scraped from each of the five rocks was then transferred from the razor blade or scalpel to an opaque 40 mL sample cup, diluted with creek water, and preserved with Lugol's iodine solution until the sample was the colour of weak tea. Samples were stored at room temperature prior to shipment to the laboratory for taxonomic analysis.

Periphyton samples collected for productivity measures (chlorophyll-a and AFDM) were collected using the same protocols as periphyton community samples and scraped from the same five rocks whenever possible (i.e., whenever the rocks had sufficient material for three scrapings), with additional rocks collected as required. Chlorophyll-a sample material (periphyton) was transferred from the scalpel to a large (47 mm) 0.45 µm pore diameter Whatman Mixed Cellulose Ester (MCE) filter paper, which was inserted into an opaque vial for storage. Ash-free dry mass sample material was transferred to an opaque 40 mL sample cup. Chlorophyll-a and AFDM samples were then frozen prior to shipment to the laboratory for analysis.

The total area scraped at each station was recorded (0.002 m²: 5 x 4 cm², or any deviations from this surface area) to allow calculation of productivity and area-based community metrics. This process was repeated for all three periphyton parameters at each of the five stations per monitoring area.

3.3.2 Sample Processing

3.3.2.1 Community

Taxonomic identification and enumeration of periphyton community samples was completed by Biologica Environmental Services Ltd. in Victoria, BC. Briefly, samples were homogenized,

[6] In 2019, 12 of 50 periphyton samples were collected using 5x5 cm (25 cm^2) templates to assess whether a larger template would facilitate sampling using random rocks (i.e., a larger sample area could generate sample volumes adequate for laboratory analyses). It was determined that the increased template size did not guarantee adequate sample volume and targeted rock collection was still necessary even with the larger templates. This was therefore not an effective solution and in 2021 methods reverted to 2x2 cm templates exclusively.

settled in Ütermohl chambers for 24 hours, and all cells within randomly selected fields of view were enumerated until a minimum count of 300 algal units (1 unit = >1 cell for colonial or filamentous taxa) was reached. Identification was performed using an inverted phase contrast microscope, and algal taxa were identified to a minimum of genus-level (whenever possible) according to the most up-to-date taxonomic references. Periphyton density was determined using the area sampled, proportion subsampled, and the total area of the selected fields of view.

Laboratory quality assurance/quality control included a re-analysis of two samples (representing 10% of samples) and a calculation of percent agreement among results. Upon completion of the analyses, the data and quality control reports were provided by Biologica to Minnow electronically as Adobe Acrobat PDF and Microsoft Excel files (see Appendix H for complete laboratory reports).

3.3.2.2 Productivity

Laboratory determination of periphyton productivity (chlorophyll-a and AFDM) was completed by ALS Environmental (Burnaby, BC). Upon receipt, laboratory staff opened the coolers, measured temperature to verify the maintenance of cold samples, logged each sample, and assigned each sample a unique sample identification code. A sample receipt confirmation was then sent to Minnow. Analysis of chlorophyll-a followed procedures adapted from United States Environmental Protection Agency (USEPA) Method 445.0 (USEPA 1997). Briefly, chlorophyll-a concentration was determined by routine acetone extraction followed by fluorescence detection using a non-acidification procedure (a method that is not subject to interferences from chlorophyll-b). Determination of total AFDM followed procedures adapted from American Public Health Association (APHA) Method 10300 C (APHA 2010). Total AFDM was calculated as the difference between the dried sample weight and the ash weight, both determined gravimetrically. Dry weight was determined following drying at 105°C, and ash weight was subsequently determined by ashing at 500°C. Laboratory quality assurance/quality control (QA/QC) of periphyton productivity samples included reagent blanks, laboratory replicates, and laboratory accuracy measures (i.e., laboratory control samples). Upon completion of the analyses, data reports were provided by ALS Environmental to Minnow electronically as Adobe Acrobat PDF (portable document format) and Microsoft Excel files (Appendix H).

3.3.3 Data Analysis

A formal data quality review (DQR) was completed to assess the quality of the periphyton community data (Appendix G). Periphyton monitoring is focused on Measurable Parameters representing productivity and community conditions (Table 3.1). Several periphyton community metrics were identified as potential indicators of periphyton community change that could result

from Project operation although not considered key indicators for FAL-AMP response (general community composition [the relative densities of taxonomic groupings] and proportion of blue-green algae [Cyanobacteria]; Minnow and EDI 2017), and were evaluated in addition to metrics of organism density, taxonomic richness, biomass (inferred from biovolume estimates), Simpson's Evenness, and Simpson's Diversity. These metrics were calculated using taxonomy assessed at the Lowest Practicable Level (LPL). Relative densities were calculated as the density of each respective taxonomic grouping divided by the total density expressed as a percent. Taxonomic groups evaluated were diatoms, green algae (Chlorophytes), Cyanobacteria, and "Others" (all other taxa, which included golden algae [Chrysophytes], Dinoflagellates, and red algae [Rhodophytes]). All periphyton community metrics were plotted as raw values for all years sampled for every Project area, separately for Upper and Lower Creek areas. Analytes identified in Minnow and EDI (2017) as indicators of periphyton community health are assessed in detail in Section 5, whereas summary tables and plots for all other analytes are appended in Appendix C.

Periphyton productivity (in terms of periphytic chlorophyll-a and AFDM concentrations) was identified as a potential indicator of Project-related changes although not a FAL-AMP key indicator (Minnow and EDI 2017). A formal DQR was completed to assess the quality of the periphyton productivity data (Appendix G). Chlorophyll-a and AFDM sample data were converted to standard area-based measurements (mg/m^2 and mg/cm^2, respectively) and data were plotted to establish temporal and spatial conditions and variability in the Project area. Chlorophyll-a concentrations were also compared to water quality guidelines for trophic conditions (British Columbia Water Quality Guidelines [BCWQG] guideline for eutrophic conditions = 100 mg/m^2; BCMOECCS 2021), and the Dodds et al. (1998) productivity classification system for temperate streams. Endpoints were summarized by area and year, including sample size, mean, median, minimum, maximum, and standard deviation.

Changes in periphyton community endpoints from 2018 to 2021 were quantified using an ANOVA with factors *Area* and *Year* and their interaction. Response variables were transformed (log_{10} for density and log_{it} transformed for proportions) where necessary to meet the assumption of normality, which was tested using a Sharpiro-Wilks test and visually using Q-Q normal plots of the model residuals. When this assumption could not be met, response variables were rank transformed.

The significance of the main effects and interaction terms of the ANOVA were assessed using an α of 0.1, and the results of these determined which post-hoc comparisons were then conducted. Specifically, when the interaction between *Year* and *Area* was significant it indicated that the differences between the areas changed over time and post-hoc comparisons were conducted to

1) test for differences between the first year of sampling and each subsequent year for each area, and 2) test for differences between the exposed and reference areas in each year. For all significant post-hoc temporal comparisons, a MOD between years was calculated as:

$$MOD_{Year} = \frac{MCT_{recent\ year} - MCT_{older\ year}}{Pooled\ Standard\ Deviaton}$$

For significant spatial comparisons a MOD was calculated between the exposed and reference areas within each year as:

$$MOD_{Station} = \frac{MCT_{Exposed} - MCT_{Reference}}{Pooled\ Standard\ Deviaton}$$

The measure of central tendency (MCT) was calculated as back-transformed estimated marginal means. When the analysis was done on the rank-transformed scale, the observed effect size was estimated using median values instead of marginal means and the variability was estimated using the median absolute deviation (MAD).

When the interaction term (*Year* x *Area*) was not significant, post-hoc spatial comparisons and MOD calculations were conducted pooling over year and temporal comparisons were conducted pooling over stations.

To identify what characteristics may be associated with periphyton community and productivity, Spearman Rank Correlations were conducted between periphyton endpoints and *in situ* water chemistry characteristics and substrate size. Correlations were assessed for the strength of the correlation and the significance corrected using Bonferroni correction for 8 independent comparisons (corrected alpha = 0.1/8 = 0.0125).

3.4 Benthic Invertebrate Community Survey

3.4.1 Sample Collection

Samples for analysis of benthic invertebrate density, biomass, and community structure were collected in 2017, 2018, 2019, and 2021 (Table 3.3). The only FALMP area sampled in 2017 were HC6.8 and CR24.5[7] and because there are limited data for that year, integration of those data into statistical tests was not possible. Five samples were collected in erosional habitat at each of five Upper (three future-exposed and two reference) and five Lower (three future-exposed and two reference) Creek areas in 2018, 2019 and 2021 (Table 3.3).

In 2018, 2019, and 2021, samples were collected from riffle/run habitat with cobble and gravel substrate using a Hess sampler (0.1 m^2 sampling area) with 500 µm mesh. Samples were

[7] Previously referred to as I29 and HC6.3.

composites of three Hess sampler placements (0.3 m^2 area in total) at five replicate stations within each sampling area. For each sampler placement, gravel or cobble enclosed within the Hess sampler was disturbed and carefully washed (by hand rake and nail brush), while allowing the current to carry dislodged organisms into the mesh collection net. The substrate was disturbed to a depth of approximately 5 to 15 cm over a period of approximately five minutes. This procedure was repeated at new subsampling locations for the second and third grab, with all placements located as close together as possible. Positions with flow rates of 0.5-0.8 m/s, small cobble, and depths 10-20 cm were targeted.

Following collection of the third subsample, material contained in the collection net was carefully transferred to a pre-labeled 1 litre (L) wide-mouth plastic jar using a wash bottle, while working over a plastic bin to avoid any potential loss of organisms. Any organisms clinging to the sieve bag were removed using forceps and added to the sample. All samples were labeled internally (using labelled tongue depressors) and externally with the station number, area identifier, Minnow project number, date, and field personnel to ensure correct identification at the laboratory. Samples were preserved at the end of the day upon the return to camp using buffered formalin solution to a nominal concentration of 5-10% in ambient water.

3.4.2 Sample Processing

Benthic invertebrate community samples were sent to Cordillera Consulting (lead taxonomist Scott Finlayson), in Summerland, BC, for sorting and taxonomic identification. Organisms were identified to the Lowest Practicable Level (LPL; typically, genus or species). At the beginning of the sorting process, the total number of preserved organisms in each sample was estimated. If the total number was estimated to be greater than 300, then the sample was sub-sampled for sorting and enumeration using a Marchant box. Sorting efficiency and sub-sampling accuracy and precision were quantified using methods outlined by Environment Canada (2014). Total organism abundance was reported for every distinct taxon identified in each sample (see Appendix H for laboratory reports).

3.4.3 Data Analysis

Benthic invertebrate monitoring was focused on Measurable Parameters representing productivity, community condition, and tissue quality (Table 3.1). A formal DQR was completed to assess the quality of the benthic invertebrate community data (Appendix G). Community endpoints that were evaluated included key indicator endpoints for the FAL-AMP and those identified in Minnow and EDI (2017) as potential indicators of Project-related effects on benthic invertebrate communities (total density, taxonomic richness [LPL], proportional abundances [%] of taxonomic groups, % functional feeding groups, % habitat

preference groups, % metal-sensitive chironomids, Simpson's Evenness, and Simpson's Diversity), as well as Biomass. Major taxonomic groups assessed were combined orders of Ephemeroptera (mayflies), Plecoptera (stoneflies), and Trichoptera (caddisflies), collectively known as EPT, Ephemeroptera alone, Plecoptera alone, Chironomidae, Simuliidae, and Oligochaeta. Community data were tabulated as raw and summary values and plotted as time-series figures for all years available at each FALMP area for Upper and Lower Creek areas. Those analytes identified in Minnow and EDI (2017) as indicators of benthic invertebrate community health are assessed in detail in Section 8, whereas summary tables and plots for all other analytes are appended in Appendix D. Benthic invertebrate data collected in 2017 at area HC6.8 were plotted with 2018 to 2021 data.

Changes in benthic invertebrate community endpoints from 2018 to 2021 were quantified using an ANOVA, with factors *Area* and *Year*, and their interaction using the approach described in Section 3.3.3.

The Bray-Curtis Index was calculated as described in Environment Canada (2012) and updated technical guidance (Borcard and Legendre 2013). This metric considers the abundance of each taxon at each station compared to the median abundance computed from the reference station data to compute an index of the relative "distance" of each station from a hypothetical reference median station. Larger Bray-Curtis index values indicate greater dissimilarity from reference. Recently, the utility of the Bray-Curtis distance measure as calculated under EEM has been scrutinized due to the fact that using a reference median value calculated from only one area biases the outcome toward detecting a difference between two areas regardless of potential anthropogenic stressors (Borcard and Legendre 2013). This occurs because the area used to calculate the median is inherently more similar to itself than any other area (Huebert et al. 2011), even if the two areas in question are 'natural-pristine' areas. Borcard and Legendre (2013) identified that previous EEM Bray-Curtis evaluation methods were statistically invalid and suffered from inflated type 1 and type 2 error rates. They recommend use of Mantel and distance-based Redundancy Analysis (dbRDA) for evaluating effects on communities using Bray-Curtis dissimilarity (BC). Following the recommendations of Borcard and Legendre (2013), Bray-Curtis dissimilarity was calculated on ln(x+1) transformed densities. Prior to analysis, the homogeneity of group dispersion was evaluated using a betadisper test based on PERMDISP2 procedure (Anderson 2006). If the variances are considered heterogeneous, only a dbRDA test is performed, as it is considered more robust to deviations of multivariate homogeneity. If the variances are considered homogeneous, both Mantel and dbRDA tests are used. All analyses were conducted using custom R scripts and functions provided by Environment and Climate Change Canada.

The Mantel test is a distance-based correlation analysis, which compares BC to a matrix of perfectly separated sites. A significant p-value in the Mantel test suggests the observed BC is more similar to a matrix of perfect dissimilarity than would be expected by chance. The dbRDA is a special case of a permutation based multivariate ANOVA (PERMANOVA), which contrasts a principal coordinates analysis based on BC to a factor representing control and impacted sites. A significant p-value in the dbRDA indicates the factor levels explain a significant amount of variation between sites. Due to differences between the two tests (dbRDA and Mantel), the outcomes may differ under certain circumstances (one test significant, the other not). In these cases, the recommended conclusion is based on sample size (i.e., statistical power). If 11 or more samples were collected at each of control and impacted sites, the results are deemed non-significant (i.e., no observed impact, due to the high power of the tests at those sample sizes). If fewer than 11 samples were collected per site, the results are deemed significant (i.e., observed impact).

There are no criteria for BC effect size since these multivariate methods cannot be defined in terms of differences between means. There are R^2 statistics associated with Mantel and dbRDA tests that can be interpreted as measures of effect size, but they are not comparable between tests because the measures used in their calculation differ. The Mantel tests R^2 measures the link between two dissimilarity matrices, while the dbRDA R^2 measures the amount of variance explained by a factor variable representing differences between sites.

To identify what characteristics may be associated with benthic community endpoints, Spearman Rank Correlations were conducted between community endpoints and *in situ* water chemistry characteristics and substrate size following the approach described in Section 3.3.3.

3.5 Benthic Invertebrate Tissue Chemistry Survey

3.5.1 Sample Collection

Samples for analysis of benthic invertebrate tissue chemistry were collected in 2018, 2019, and 2021 at all FALMP sampling stations following collection of benthic invertebrate community samples (Table 3.3). Samples were collected using a kick net with a triangular aperture measuring 36 cm per side and a mesh (400 µm). During sampling, the technician moved across the stream channel through the erosional habitat from which the community sample was taken (from bank to bank when possible[8]) in an upstream direction. The net was held immediately downstream of the technician's feet, so the detritus and invertebrates disturbed from

[8] Complete kick transects of Coffee Creek at area CC5.6 were generally not safe due to fast-flowing water and high depth relative to other Project areas, particularly in 2018 and 2019. Accordingly, some kick transects were from shore to the location of maximum safe sampling depth/water velocity.

the substrate were passively collected into the kick-net by the stream current. Collections were not timed, and kicks were repeated until the volume of organisms collected was sufficient for analysis. The kick net was rinsed with water to move debris and invertebrates into the collection cup at the bottom of the net. The collection cup was then removed, the contents poured into a white basin, and organisms were carefully separated from sample debris using tweezers. During 2018 and 2019, collection continued until a minimum of approximately 2 g wet tissue was collected and until a minimum of 0.5 g was collected during 2021 sampling[9]. Organisms were picked from debris with the goal of approximating a representative sample of all benthic invertebrate taxa present (composite-taxa samples). Invertebrate tissue samples were then photographed to document taxa composition, placed into labelled, sterile, 20 mL scintillation vials and stored in a cooler with ice packs until transfer to a freezer later at camp at the end of the day.

3.5.2 Sample Processing

Tissue samples were transported by courier in coolers with ice packs to Saskatchewan Research Council (SRC) laboratory in Saskatoon, SK (2018 and 2019) or TrichAnalytics Inc. in Saanichton, BC (2021). Samples from 2018 sampling at one area (LC10.2; n=5) were lost en route to Saskatoon or during processing at SRC. Samples were either freeze-dried (SRC) or dehydrated (<60°C; TrichAnalytics) upon receipt by the respective laboratories. Analysis of samples submitted to SRC were analyzed using High Resolution Inductively Coupled Plasma Mass Spectrometry (HR-ICP-MS), while those submitted to TrichAnalytics Inc. were analyzed using Laser Ablation Inductively Coupled Plasma Mass Spectrometry (ICP-MS). Results for all parameters were reported on a dry weight basis along with moisture content to allow conversion to wet weight values, as required (see Appendix H for laboratory reports).

3.5.3 Data Analysis

A formal DQR was completed to assess the quality of the benthic invertebrate tissue chemistry data (Appendix G). Benthic invertebrate tissue metal concentrations were tabulated and plotted as time-series figures for all years available at each FALMP area for Upper and Lower Creek areas. Analytes assessed included metals, which have been identified in aqueous form as potential indicators of Project-related changes in creek water quality (arsenic, uranium, and zinc) and/or are present in Project area creeks at concentrations that naturally exceed water quality guidelines (aluminum, arsenic, chromium, copper, uranium, and zinc;

[9] Target collection volume was reduced following a change in benthic invertebrate tissue chemistry analysis laboratory subcontractor from Saskatchewan Research Council (SRC, Saskatoon, SK) to TrichAnalytics (Saanichton, BC) prior to 2021 field sampling. The laboratory transition was implemented to increase field sampling efficiency by reducing time spent picking insects from sample material as TrichAnalytics can generate quality data from smaller sample sizes than SRC.

Minnow and EDI 2017). Those analytes identified in Minnow and EDI (2017) are assessed in detail in Section 7, whereas summary tables and plots for all other analytes are appended as Appendix E. The follow summary statistics were reported: sample size, percent of values below the laboratory reporting limit (LRL), mean, standard deviation, minimum value, median, and maximum value.

Commonly used substitution methods (e.g., substituting values < LRL with half the LRL) for censored data introduces bias in summary statistics (Helsel 2012). Means and standard deviations were therefore estimated used the Kaplan-Meier (K-M) method. This method involves transforming the left censored (i.e., < value) dataset to a right censored (i.e., > value) dataset, and then using the K-M estimator (used to estimate the mean survival time in survival analysis) to estimate the mean. The calculation was conducted using the *survfit* function in the *survival* package (Therneau 2017) in R and involves calculating the area under the K-M survival curve. The K-M method is non-parametric and can accommodate multiple LRLs. This method of estimating the mean is equivalent to using the distribution of detectable values below the LRL to represent values that are < LRL. For example, the mean of the data set {1, 2, < 4, 5} is estimated as the mean of 1, 2, [½×1 + ½×2], and 5 which is 2.375. The value < 4 is replaced by the distribution of values below 4 (i.e., 1 and 2 with equal weight of ½). Similarly, the mean of the data set {1, 1.6, 2, 2.1, < 4, 5} is estimated as the mean of 1, 1.6, 2, 2.1, [¼×1 + ¼×1.6 + ¼×2 + ¼×2.1], and 5 which is 2.229. Again, the value < 4 is replaced by the distribution of values below 4 (i.e., 1, 1.6, 2, and 2.1 with equal weight of ¼). If the minimum value in the data set is below the LRL then it is replaced with the LRL. Therefore, if there is only one LRL and no detected values below the LRL, then the K-M estimate of the mean is equivalent to replacing the value below the LRL with the LRL (i.e., the best guess for the values < LRL is the LRL). When a standard deviation could not be estimated (e.g., when all data were below the LRL), it was not reported. When a value was reported below a poor LRL (defined as a LRL that exceeded the maximum detected value), the value was removed from the dataset.

Changes in benthic invertebrate tissue analyte concentrations from 2018 to 2021 were quantified using a censored regression ANOVA with factors *Area* and *Year* and their interaction. The model was fit with maximum likelihood and assumed a log-normal distribution for chemistry concentrations.

The significance of the main effects and interaction terms of the ANOVA were assessed using an α of 0.05, and the results of these determined which post-hoc comparisons were then conducted. Specifically, when the interaction between *Year* and *Area* was significant it indicated that the differences between the areas changed over time and post-hoc comparisons were conducted to 1) test for differences between the first year of sampling and each subsequent year for each area,

and 2) test for differences between the exposed and reference areas in each year. For all significant post-hoc temporal comparisons, a MOD between years was calculated as:

$$MOD_{Year} = \frac{MCT_{recent\ year} - MCT_{older\ year}}{MCT_{Older\ year}} \text{ x } 100\%$$

For significant spatial comparisons a MOD was calculated between the exposed and reference areas within each year as:

$$MOD = \frac{MCT_{Exposed} - MCT_{Reference}}{MCT_{Reference}} \text{ x } 100\%$$

The MCT was calculated as back-transformed estimated marginal means. When the interaction term (*Year* x *Area*) was not significant, post-hoc spatial comparisons and MOD calculations were conducted pooling over year and temporal comparisons were conducted pooling over stations.

3.6 Sediment Quality

3.6.1 Sample Collection

Sediment sampling at Project areas was completed opportunistically in 2019 and 2021 to determine the feasibility of including a robust sediment chemistry component in the FALMP (Table 3.3). Project area creeks are mostly erosional habitat, and availability of locations of deposited sediment is limited or non-existent (depending on the creek) and can vary by year. Sediment was therefore collected at areas where deposits were found of quantity and quality sufficient for analysis. Wherever possible, sediment was collected concurrent with, and adjacent to the locations of benthic invertebrate and periphyton samples. In 2019, sediment was collected at future-exposed areas HC6.8 (n=3), LC10.2 (n=3), YT4.3 (n=4), HC0.2 (n=3), and CC5.6 (n=5), as well as reference stations SYT0.6 (n=3) and XE0.2 (n=3; Table 3.2). In 2021, sediment was collected at future-exposed areas HC6.8 (n=5), LC10.2 (n=5), CC5.6 (n=5), and YT0.2 (n=5; Table 3.2). In both 2019 and 2021, the replication target for sediment chemistry was n=5, however, available sediment was not adequate to meet targets for some areas in 2019. Also, some depositional pools sampled in 2019 were not present in 2021 either due to changes in creek morphology or flow between sampling events. The most persistent depositional habitats sampled appear to be adjacent to station CC5.6-3 and downstream of station LC10.2-5.

At each sampling station, samples were collected using a stainless-steel spoon. The location was approached by foot in a manner that did not disturb the sediment prior to sampling. Surficial sediment was then collected carefully by slowly placing the spoon on the sediment surface in a manner that minimized disturbance and inserting the spoon into the sediment to capture sediment to a depth of 5 cm or less. The spoon was then moved horizontally until full,

and slowly retrieved to the surface to avoid sample washout. The content of each spoonful was inspected to ensure that it was predominantly fine sediment (i.e., silt and clay), and, if acceptable, was placed into a resealable plastic bag labeled with the project number, sample location, and collection date. Approximately 500 mL of sediment was collected per replicate to ensure adequate volume for particle size and metals analysis. Sampling equipment was rinsed between stations using site water. Following collection, samples were placed in a refrigerator at approximately 4°C until shipment to the analytical laboratory.

3.6.2 Laboratory Analysis

Laboratory analysis of sediment quality samples was completed by ALS Environmental in Burnaby, British Columbia. Laboratory analyses included particle size distribution and texture, total organic carbon (TOC), and total metal concentrations for all samples. Total organic carbon content and total metal concentrations were determined in the silt/clay fraction (< 63 µm diameter) to reduce variability associated with differences in particle size distribution (BCMOE 2016). Analysis of particle size was completed by sieve and pipette; TOC was completed combustion and titration (total carbon minus total inorganic carbon). Analysis of metals was based on the BC Strong Acid Leachable Metals digestion (SALM; BCMOE 2016), with total metals analysis completed by Collision Reaction Cell Inductively Coupled Plasma – Mass Spectrometry (CRC-ICP-MS [United States Environmental Protection Agency Method 6020B; USEPA 2014]), and mercury analysis completed by cold vapor atomic absorption spectrophotometry (CVAAS; USEPA Method 245.7; USEPA 2005). Quality Assurance and Quality Control sampling completed by the laboratory included reagent blanks, laboratory replicates, and laboratory accuracy measures (i.e., matrix spikes, laboratory control samples, and/or certified reference materials). Upon completion of the analyses, data reports were provided by ALS Environmental to Minnow electronically in Adobe Acrobat PDF and as Microsoft Excel files (Appendix H).

3.6.3 Data Analysis

A formal DQR was completed to assess the quality of the sediment chemistry data (Appendix G). Raw sediment chemistry and composition data were summarized by area by calculating mean, median, standard deviation, minimum, and maximum values for all analytes. Following the calculation of summary statistics, Upper and Lower Creek area data were tabulated and plotted as time-series figures for all sampling areas. Plots included comparison to British Columbia Working Sediment Quality Guidelines for the protection of aquatic life (BCMOE 2021) and the British Columbia Approved Working Sediment Quality Guideline for selenium in sediment (BCMOECCS 2021), collectively termed WSQG in this report. WSQGs are numerical criteria that are protective of sediment-dwelling organisms based on long-term exposed. Most WSQGs have

been adopted from the CCME (CCME 1999) or from Ontario (OMOE 1993) and have two levels - a lower WSQG and an upper WSQG. The lower WSQG is intended to represent a concentration that will protect aquatic life from adverse effects in most situations (BCMOE 2021). The upper WSQG is intended to represent a concentration that, if exceeded, will likely cause severe effects to aquatic life (BCMOE 2021). However, WSQGs - even the Upper WSQGs - are often naturally exceeded in mineralized areas. In addition, WSQGs were developed based on co-occurring bulk surficial sediment data and biological effect data (CCME 1999). Bulk sediment chemistry can differ substantially from the <63 µm fraction, and this discrepancy between measurement (<63 µm fraction) and exposed (to bulk sediment to which sediment quality guidelines [SQG] are most applicable) should be considered in interpretation as "caution should be used in interpreting the biological significance of chemical concentrations in sediments for different types based on these guidelines" (CCME 1999).

Analytes assessed included metals that have been identified in aqueous form as potential indicators of Project-related changes in water quality (arsenic, uranium, and zinc) and/or are present in Project area creeks at concentrations that naturally exceed water quality guidelines (aluminum, arsenic, chromium, copper, uranium, and zinc; Minnow and EDI 2017). Those analytes, analytes for which WSQGs exist, and general composition data, are assessed in detail in Section 8, whereas summary tables and plots for all other analytes are appended as Appendix F.

Statistical comparisons of sediment quality among lower creek areas in 2019[10] conducted using a one-way ANOVA at $\alpha = 0.05$. Assumptions of normality and homogeneity of variances were tested using a Shapiro-Wilk's test and Levene's test, respectively at $\alpha = 0.05$. Data were $\log_{10}$ transformed as necessary to meet assumptions. When the assumptions were not met, analysis was conducted using a Kruskal-Wallis test. If a parameter contained censored data, all values below the maximum censored value were replaced with the maximum censored value and analysis proceeded using a rank transformation (Kruskal-Wallis test). Post-hoc comparisons were conducted using Tukey-adjusted p-values for all pairwise contrasts. For each comparison, the magnitude of difference was calculated with the same MCT equation described in Section 3.5.3 using means for untransformed data, geometric means for $\log_{10}$ transformed data and medians for non-parametric tests.

Temporal differences in sediment quality for areas sampled in both 2019 and 2021 were tested using a two-sample t-test, with a p-value <0.10. A p-value of 0.10 was used as per suggested EEM guidelines (Environment Canada 2012). The assumption of normality was assessed using

[10] Sediment deposits were not found at any reference areas in 2021 so a statistical test of differences in sediment data from 2019 and 2021 was not feasible.

the Shapiro Wilks' test (α = 0.05) and homogeneity of variance was assessed using Levene's Test (α = 0.05). If variances were unequal, then the two-sample t-test for unequal variances was conducted (Ruxton 2006). Data that could not be normalized were log, square root, or fourth root transformed. A value of 1 was added before taking the logarithm if values of zero were in the data set. If data could not be normalized after transformation, a non-parametric Mann-Whitney test was applied. Statistical comparisons were conducted using R (R Core Team 2020). A magnitude of difference (MOD) was calculated for each community metric as:

$$MOD = \frac{\left(\bar{X}_{Exp} - \bar{X}_{Ref}\right)}{SD}$$

where the SD is an estimate of the pooled standard deviation. The estimate standard deviation was the pooled standard deviation in the two-sample t-test for equal variances when the two-sample t-test for unequal variances was applied.

The MOD for the Mann-Whitney test was calculated using medians instead of means and the pooled median absolute deviation (MAD) instead of the SD. The MAD is calculated as the median of the absolute values of the differences between each observation and the median observation for that area (and corrected by a factor of 1.4826 to scale the MAD to a comparable magnitude to the SD). A study design with two areas and n = 5 samples per area has an approximate power of 0.9 to detect a two standard deviation difference between areas using α = 0.1 (Environment Canada 2012).

4 SUPPORTING HABITAT AND WATER QUALITY

4.1 Overview

Supporting habitat variables and *in situ* water quality parameters were recorded at all Project periphyton and benthic invertebrate monitoring areas in 2018, 2019, and 2021, and at area HC6.8 in 2017 (Table 3.3; Figure 3.1). All habitat and water quality data collected with the periphyton and benthic invertebrate monitoring in 2018, 2019, and 2021 are provided in Appendix B.

4.2 Upper Creek Areas

Mean flow velocities were highest in 2018 (area means: 0.78-0.86 m/s) and lowest in 2017 and 2021 (0.44-0.52 m/s) at all Upper Creek future-exposed areas, and Upper Creek reference area CC23.7 (Table 4.1; Figure 4.1; Appendix Table B.1). Mean flow velocity was slightly higher in 2019 than 2018 at Upper creek future-exposed area CR24.5 (0.86 m/s and 0.88 m/s, respectively), but like all other Upper Creek areas was lowest in 2021 (0.47 m/s). Flow velocities at Upper Creek future-exposed areas were not significantly different from either reference area for any individual year (Appendix Table B.2).

Mean water temperatures at Project Upper Creek areas in 2018, 2019, and 2021 ranged from 1.44°C to 3.66°C (YT4.3 - 2019 and CR24.5 - 2021, respectively; Table 4.1; Figure 4.1; Appendix Table B.1). Mean water temperatures were highest in 2021 at all Upper Creek future-exposed areas, and Upper Creek reference area CR24.5. Water temperatures at Upper Creek future-exposed areas were not significantly different from either reference area for any individual year (Appendix Table B.2).

Dissolved oxygen (DO) concentrations met the CCME water quality guideline for cold water (9.5 mg/L) at all Upper Creek areas across all years sampled (Table 4.1; Figure 4.2; Appendix Table B.1). Mean DO concentration at Upper Creek areas ranged from 12.08 to 12.82 mg/L (CR24.5 - 2021 and YT4.3 – 2018, respectively) and mean saturation ranged from 89.1 to 94.4% (CC23.7 – 2019 and HC6.8 – 2021, respectively; Table 4.1). Outlier dissolved oxygen values were recorded at area HC6.8 in 2019, likely resulting from sensor failure and those values were therefore not included in statistical comparisons. Dissolved oxygen concentration and saturation was generally not significantly different between future-exposed and reference areas (Appendix Table B.3). The few comparisons for which differences were observed occurred inconsistently (i.e., no patterns in significant spatial or temporal variability between any future-exposed and reference areas), indicating good compatibility among Upper Creek areas with respect to DO.

Table 4.1. Coffee Project FALMP Mean *In Situ* Water Quality Endpoints, Upper Creek Areas, 2017 to 2021

Metrics	2017	2018					2019					2021

Notes: Green represents reference stations and blue represents future-exposed stations. Horizontal lines indicate measure of central tendency (MCT) used in the statistical analyses. Data collected in 2017 were not included in statistical comparisons but are shown for visual comparison only.

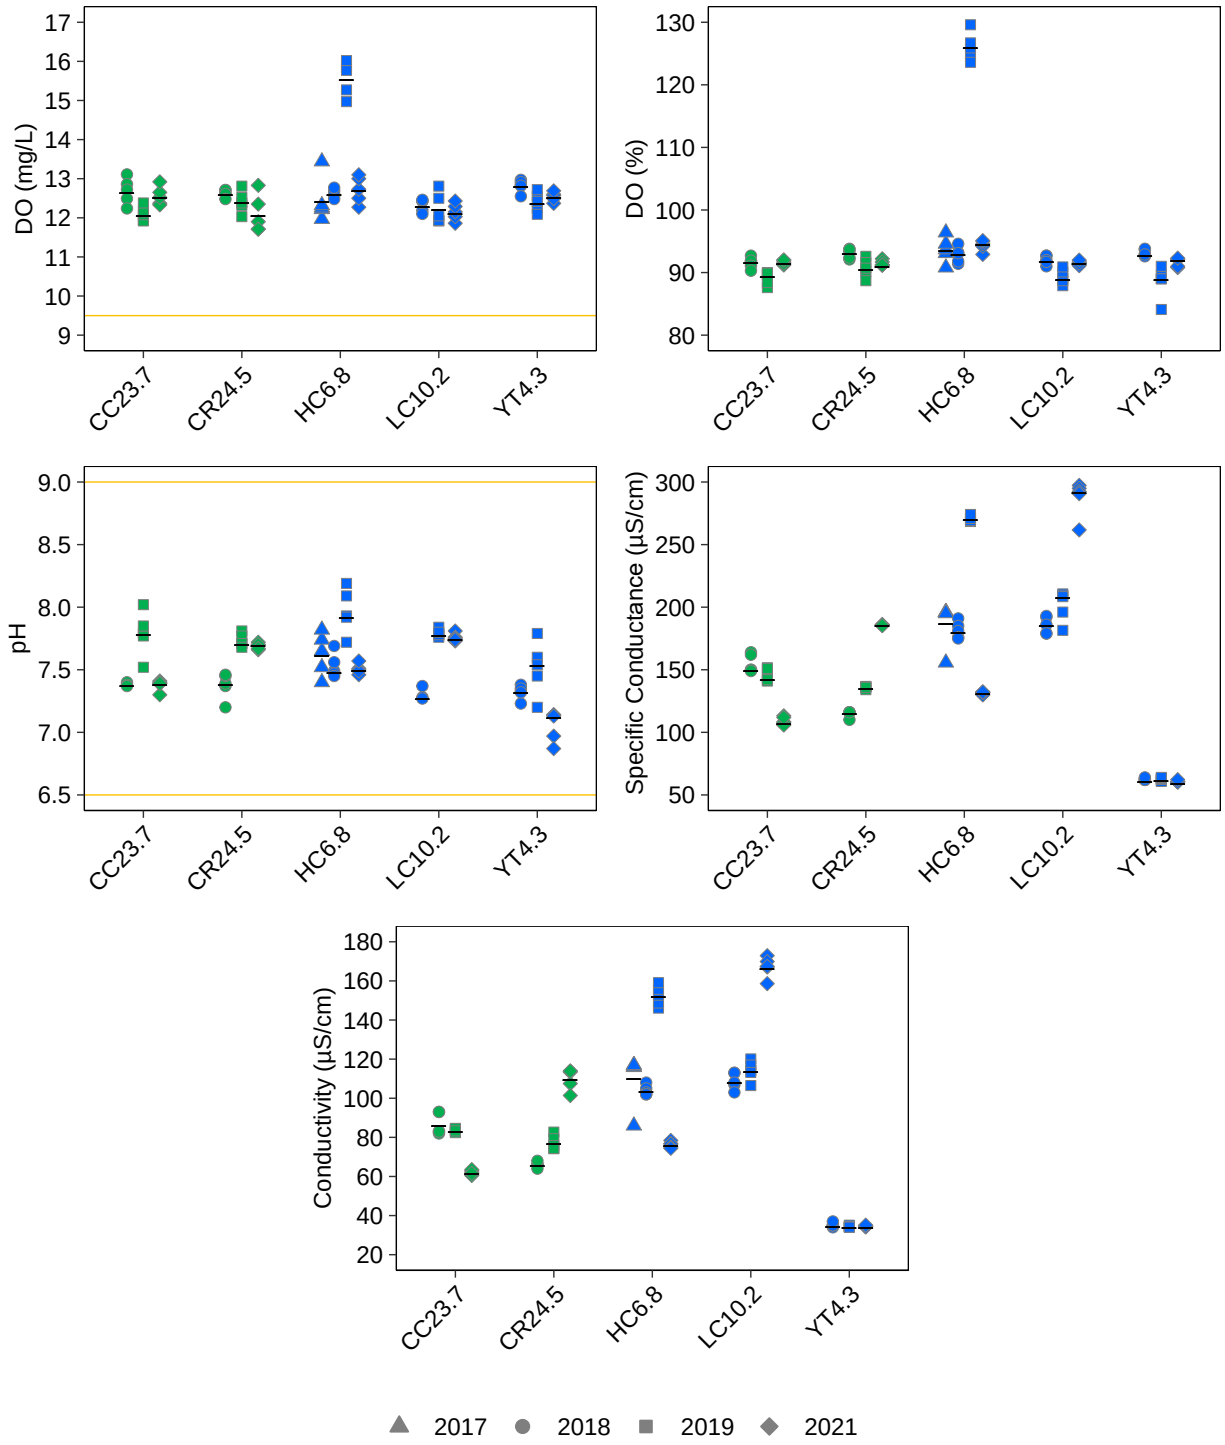

Figure 4.2: Coffee Project FALMP Upper Creek Area In Situ Water Quality, 2017, 2018, 2019, and 2021

Notes: Green represents reference stations and blue represents future-exposed stations. Horizontal lines indicate measure of central tendency (MCT) used in the statistical analyses. Orange solid lines indicate the Canadian Water Quality Guideline (CCME 2001) for cold water DO (> 9.5 mg/L) and pH (6.5 to 9.0). Data collected in 2017 were not included in statistical comparisons but are shown for visual comparison only.

All Upper Creek areas were slightly basic across all years sampled, with mean pH values ranging from 7.05 (YT4.3 - 2021) to 7.97 (HC6.8 – 2019; Table 4.1; Figure 4.2; Appendix Table B.1). All pH values at Upper Creek areas were within the CCME water quality guideline range (6.5 to 9.0) across all years sampled (Table 4.1). Mean pH was highest at Upper Creek areas in 2019 and was lowest at area YT4.3 in all years sampled. Significant differences in pH between future-exposed and reference Upper Creek areas occurred infrequently and inconsistently (i.e., no patterns in spatial or temporal variability), indicating generally good compatibility among Upper Creek areas with respect to pH (Appendix Table B.2).

Mean conductivity at Project Upper Creek areas ranged from 34.4 (YT4.3 – 2019) to 167.2 µS/cm (LC10.2 – 2021; Table 4.1; Figure 4.2; Appendix Table B.1). Mean conductivity was lowest at area YT4.3 across all years sampled, with a maximum of 35.2 µS/cm in 2018. Conductivity was generally significantly higher at future-exposed areas HC6.8 and LC10.2 than both Upper Creek reference areas (CR24.5 and CC23.7), whereas YT4.3 was significantly lower than both reference areas for all years sampled (Appendix Table B.2). High conductivity is potentially indicative of existing mineralization at the proposed Project mine site. Although there is existing variability between future-exposed and reference areas with respect to conductivity, reference area values are a good representation of regional conditions and should still provide a good basis for future comparisons (Table 4.1; Figure 4.2).

4.3 Lower Creek Areas

In the lower creek areas, mean flow velocities were highest in 2018 (0.75-0.87 m/s) and lowest in 2021 (0.40-0.55 m/s) at future-exposed areas HC0.2 and YT0.2, and at both reference areas (Table 4.2; Figure 4.3; Appendix Table B.3). Mean flow velocity was slightly higher in 2019 than 2018 at lower future-exposed area CC5.6 (0.85 and 0.84 m/s, respectively), but like all other Lower Creek areas was lowest in 2021 (0.71 m/s; Table 4.2; Figure 4.3). Flow velocities at Lower Creek future-exposed areas were not significantly different from either reference area for any individual year (Appendix Table B.4). Mean flow velocities for CC5.6 in 2018 and 2019 may be underestimates as complete creek transects could not be taken at any stations due to high flows and deep channels, which made safe crossing impossible. In 2021, complete transects were able to be safely taken at stations CC5.6-5 and CC5.6-2.

Mean water temperatures at Project Lower Creek areas in 2018, 2019, and 2021 ranged from 2.4°C to 4.7°C (XE0.2 – 2018 and CC5.6 – 2021, respectively; Table 4.2; Figure 4.3; Appendix Tables B.3 and B.4). Mean temperatures were highest in 2021 at all Lower Creek future-exposed areas, and at Lower Creek reference area CC24.5 (Figure 4.3). Water temperatures at Upper Creek future-exposed areas were not significantly different from either reference area for any individual year (Appendix Table B.4).

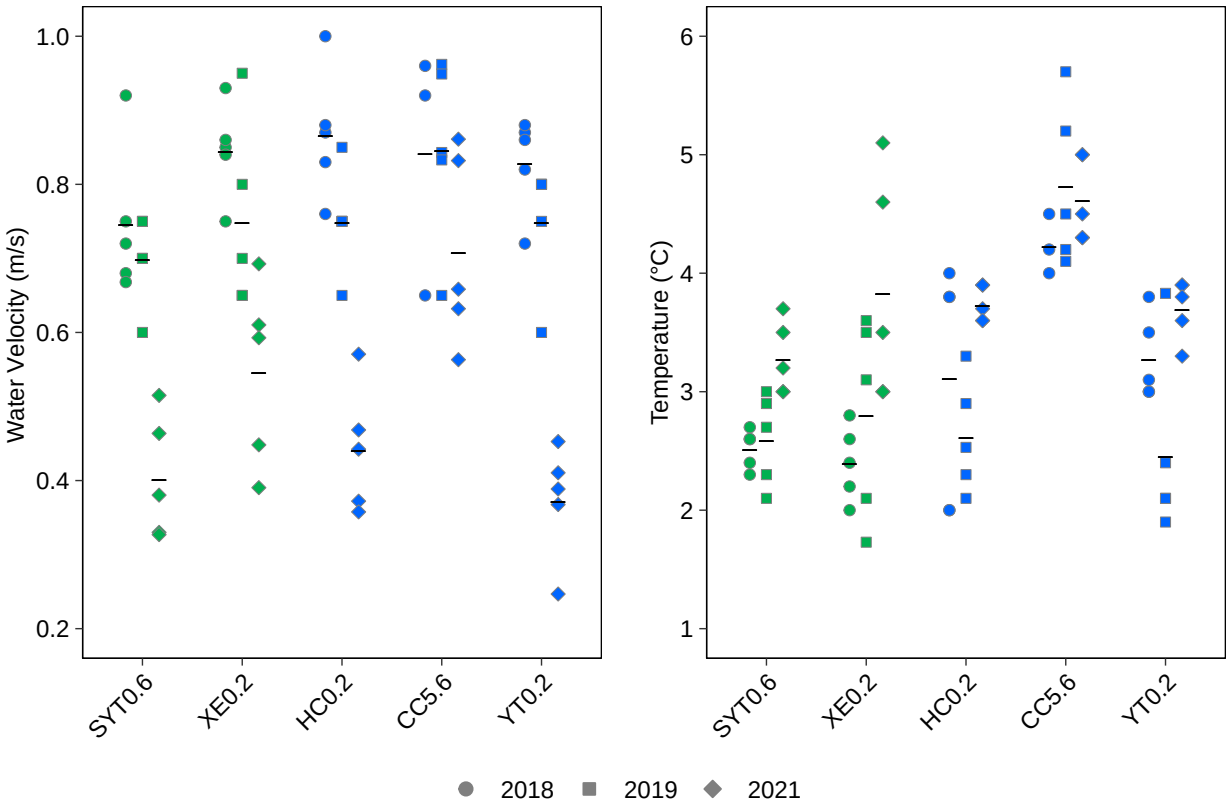

Figure 4.3: Coffee Project FALMP Lower Creek Area Water Velocity and Temperature, 2017, 2018, 2019, and 2021

Notes: Green represents reference stations and blue represents future-exposed stations. Horizontal lines indicate measure of central tendency (MCT) used in the statistical analyses.

Dissolved oxygen concentrations met the CCME water quality guideline for cold water (9.5 mg/L) at all Lower Creek areas across all years sampled (Table 4.2; Figure 4.4; Appendix Table B.3). Mean DO concentration at Lower Creek areas ranged from 11.30 (CC5.6 – 2019) to 13.40 mg/L (XE0.2 – 2019) and mean saturation ranged from 87.0% (YT0.2 – 2019) to 99.0% (XE0.2 – 2019; Table 4.2). Spatial and temporal variability in DO at Lower Creek areas was inconsistent over the baseline sampling period, with DO at all future-exposed areas lower than both reference areas in 2019, but mostly not significantly different in 2018 and 2021 (Appendix Table B.4). This indicates generally good comparability among Lower Creek areas with respect to DO.

All Lower Creek areas were slightly to moderately basic across all years sampled, with mean pH values ranging from 7.22 (CC5.6 2018) to 8.41 (XE0.2 – 2019; Table 4.2; Figure 4.4; Appendix Table B.3). All pH values at Lower Creek areas were within the CCME water quality guideline range (6.5 to 9.0) across all years sampled (Table 4.2). Mean pH at all Lower Creek areas was lowest in 2018, and highest in 2019, indicating similar interannual variability across areas. Future-exposed area pH values were significantly lower than both reference areas across all years of baseline sampling, but the magnitude of difference was consistently less than 10% (Appendix Table B.4). This indicates that although future-exposed area pH values are generally lower than reference, interannual variability should be consistent across all areas and differences should be within a consistent range. This indicates that there is a good comparability for pH among Project Lower Creek areas.

Mean conductivity at Project Lower Creek future-exposed areas ranged from 96.4 (YT0.2 2018) to 130.8 (YT0.2 and HC0.2 – 2021) µS/cm, whereas values at Upper Creek reference areas were consistently higher, ranging from 168.8 (SYT0.6 – 2018) to 370.0 (XE0.2 – 2021) µS/cm (Table 4.2; Figure 4.4; Appendix Table B.3). Conductivity at upper Creek future-exposed areas was significantly lower than both reference areas across all years sampled (Appendix Table B.4). Because observed differences in conductivity between future-exposed and reference have been consistent over the baseline sampling, there is a good basis for comparison, specifically with respect to tracking potential increases in conductivity at future-exposed areas.

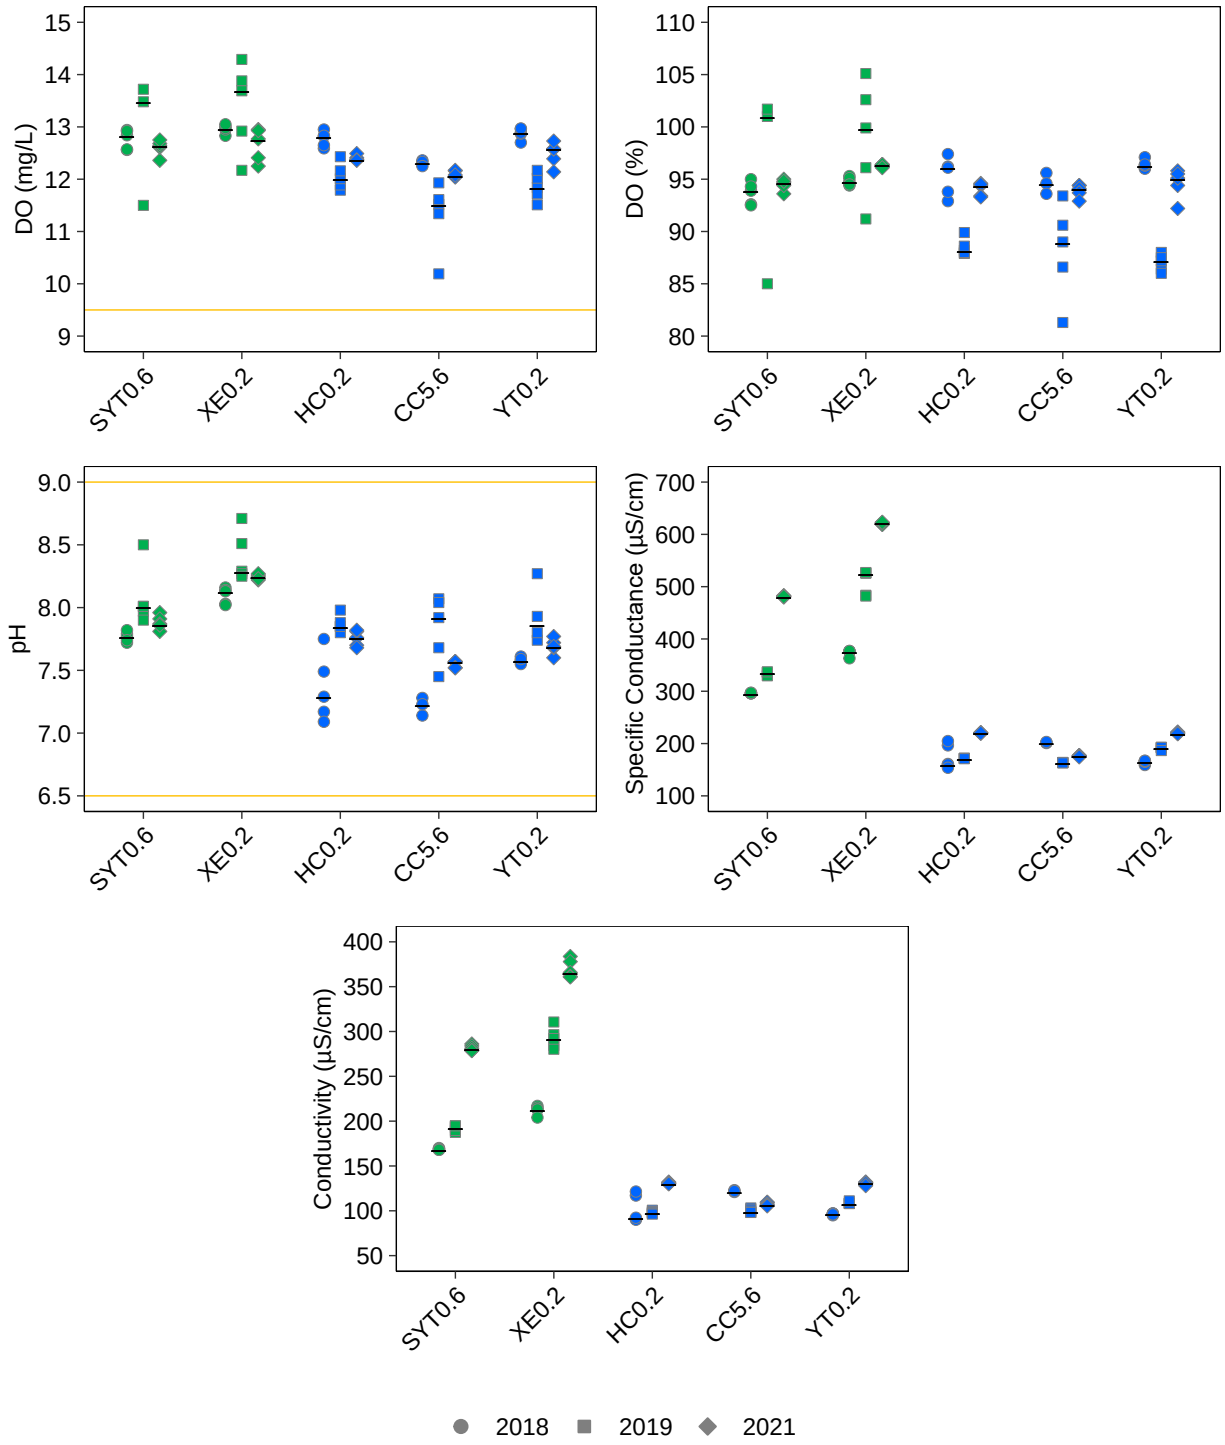

Figure 4.4: Coffee Project FALMP Lower Creek Area In Situ Water Quality, 2017, 2018, 2019, and 2021

Notes: Green represents reference stations and blue represents future-exposed stations. Horizontal lines indicate measure of central tendency (MCT) used in the statistical analyses. Orange solid lines indicate the Canadian Water Quality Guideline (CCME 2001) for cold water DO (> 9.5 mg/L) and pH (6.5 to 9.0).

5 PERIPHYTON / PRIMARY PRODUCTIVITY

5.1 Overview

Periphyton productivity and community monitoring were completed at Project Upper and Lower Creek areas during monitoring in 2018, 2019, and 2021. Results of a DQR indicate that periphyton community data collected for the Project FALMP were of acceptable quality as characterized by good accuracy, and productivity data were of good precision and accuracy. Therefore, the associated data can be used with a good level of confidence in the derivation of conclusions (Appendix G). All periphyton data collected as part of FALMP baseline monitoring in 2018, 2019, and 2021 are provided in Appendix C.

5.2 Upper Creek Areas

5.2.1 Productivity

Periphyton productivity at Project areas was assessed in terms of chlorophyll-a concentrations, AFDM, and algal biomass estimates as inferred from taxonomic data. Upper Creek area mean chlorophyll-a concentrations were lowest at future-exposed area YT4.3 (0.53 to 1.80 mg/m^2) and highest at reference area CC23.7 (3.40 to 21.50 mg/m^2) across all three years of baseline sampling (Table 5.1; Figure 5.1; Appendix Table C.1). All Upper Creek area chlorophyll-a concentrations were well below the short-term term maximum British Columbia guideline for the protection of aquatic life (100 mg/m^2; BCMOECCS 2021; Table 5.1; Figure 5.1; Appendix Table C.1). Chlorophyll-a concentrations were significantly lower at all future-exposed Upper Creek areas than reference area CC23.7, whereas they were not significantly different from reference area CR24.5 across all years of baseline sampling (Appendix Table C.2). Mean AFDM was highest at reference area CC23.7 in 2018 (2.10 mg/cm^2) and 2019 (0.77 mg/cm^2), and at reference area CR24.5 in 2021 (0.63 mg/cm^2; Table 5.1; Figure 5.1). Differences in AFDM between future-exposed and reference areas were mostly not statistically significant and occurred inconsistently (Appendix Table C.2). Spatial patterns in Upper Creek area periphyton total biomass estimates were similar to those for chlorophyll-a with CC23.7 highest in 2018 (169 mg/m^2) and 2019 (587 mg/m^2) and CR24.5 highest in 2021 (99.9 mg/m^2; Table 5.1; Figure 5.1; Appendix Table C.1). Differences in Upper Creek area total biomass between future-exposed and reference areas were observed but most were not statistically significant and any significant differences occurred inconsistently and likely reflect natural differences and supports the application of a BACI experimental design (Appendix Table C.2). All periphyton productivity indices were positively correlated with water velocity (Appendix Table C.3; Appendix Figure C.1).

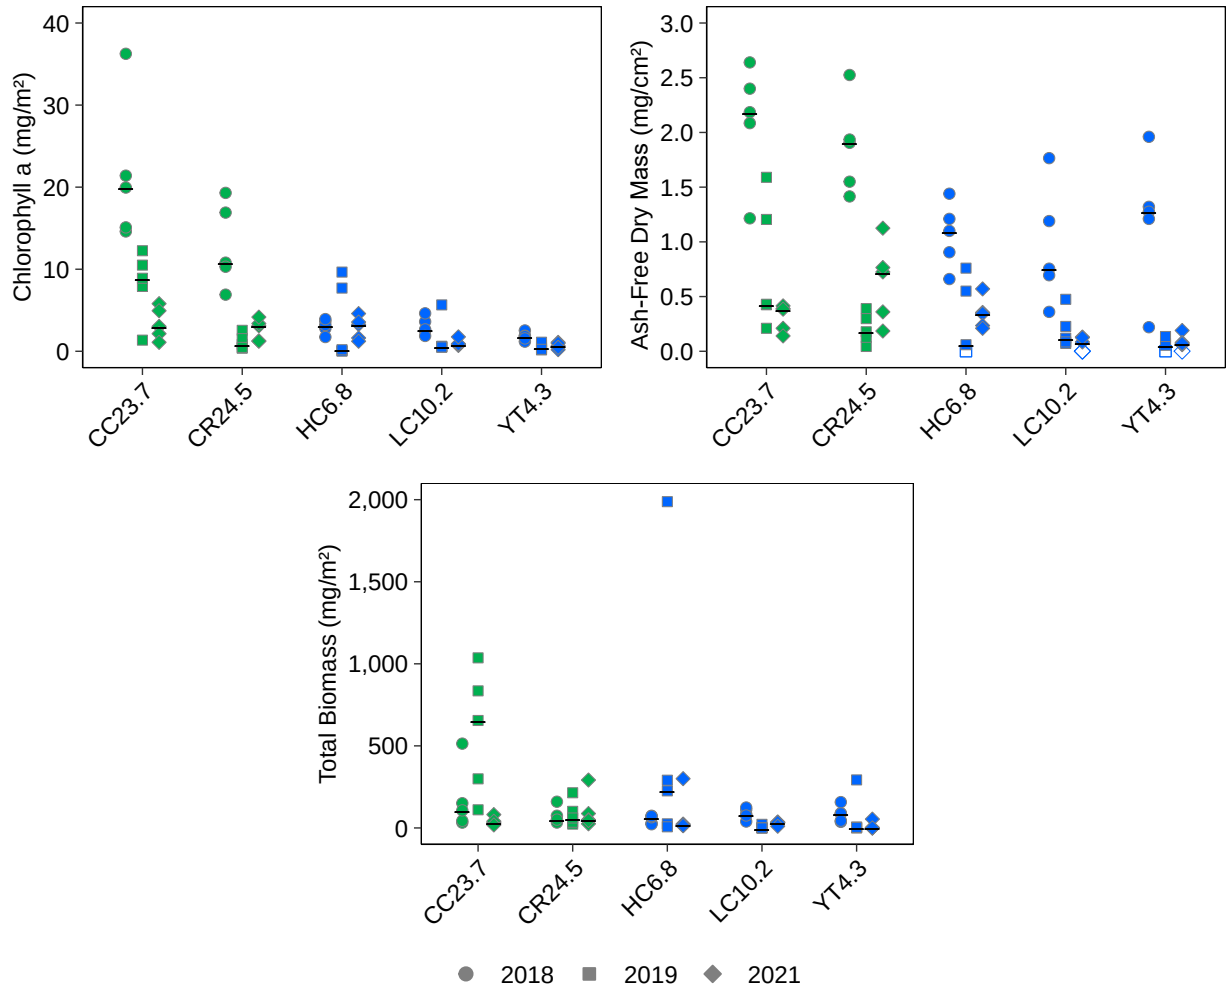

Figure 5.1: Periphyton Productivity Indicator Endpoints, Upper Creek Areas, Coffee Project FALMP, 2018 to 2021

Notes: Green represents reference stations and blue represents future-exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Horizontal lines indicate measure of central tendency (MCT) used in the statistical analyses.

Upper Creek area chlorophyll-a concentrations were generally below the threshold for mesotrophic streams outlined in Dodds et al. (1998; 20 mg/m^2), indicating that all Upper Creek areas can be classified as low productivity oligotrophic systems overall despite productivity measures likely being over-estimates of actual periphytic coverage at Project Upper Creek areas (Section 3.3.1; Appendix Table C.1). Furthermore, comparability of Upper Creek future-exposed and reference area periphyton productivity is good given the overall lack of significant differences, as well as the agreement in trends among productivity endpoints.

5.2.2 Community

Upper Creek area periphyton mean total densities were highest in 2018 at YT4.3, LC10.2, and CR24.5, and in 2019 at CC23.7 and HC6.8 and ranged from 8,479 (YT4.3 – 2021) to 6,091,910 cells/cm^2 (CC23.7 – 2019; Table 5.1; Figure 5.2; Appendix Table C.1). Periphyton mean taxonomic richness ranged from 2 (CR24.5 – 2018) to 8 (CR24.5 – 2019) taxa across all Upper Creek areas over the baseline period (Table 5.1; Figure 5.2). Periphyton total density and taxonomic richness at Upper Creek areas varied across areas and years of sampling, but significant differences between future-exposed and reference areas occurred infrequently and inconsistently (Figure 5.2; Appendix Table C.2). Similarly, there were no consistent trends in variability between Lower Creek future-exposed and reference areas with respect to community evenness, diversity, and Bray-Curtis distance, and significant differences were infrequent across all comparisons (Appendix Table C.2). Periphyton communities at Upper Creek future-exposed and reference areas were dominated by blue-green algae, with mean proportions ranging from 85.9% (CR24.5 – 2021) to 100% (LC10.2 – 2018; Table 5.1; Figure 5.2). The mean ratio of green algae to diatoms at Upper Creek areas was generally low, however, green algae and diatoms were frequently absent from baseline Upper Creek samples at both future-exposed and reference areas (Table 5.1; Appendix Table C.1). Those low values are therefore the result of the scarcity of green algae at Upper Creek areas as opposed to representing relatively high proportions of diatoms.

5.3 Lower Creek Areas

5.3.1 Productivity

Lower Creek area mean chlorophyll-a concentrations were highest at reference areas SYT0.6 and XE0.2 in 2018 (14.80 and 14.20 mg/m^2, respectively) and at future-exposed area CC5.6 in 2019 and 2021 (31.50 and 22.80 mg/m^2, respectively; Table 5.2; Figure 5.3; Appendix Table C.4). Mean chlorophyll-a concentrations were lowest at future-exposed area CC5.6 in 2018 (0.31 mg/m^2 and future-exposed area YT0.2 in 2019 and 2021 (0.79 and 2.38 mg/m^2, respectively; Table 5.2; Figure 5.3). All Lower Creek area chlorophyll-a concentrations were well below the

short-term term maximum British Columbia guideline for the protection of aquatic life (100 mg/m^2; BCMOECCS 2021; Table 5.2; Figure 5.3; Appendix Table C.4). Lower Creek area chlorophyll-a concentrations were significantly lower at most future-exposed areas than both reference areas in 2018, but in 2019 and 2021 differences among areas were inconsistent (Appendix Table C.5). Except for the unusually high chlorophyll-a concentrations for CC5.6 in 2019 and 2021, comparability of chlorophyll-a data was good among Lower Creek future-exposed and reference areas. Furthermore, despite the high values observed at CC5.6 in 2021, three of four values were still within the range of Lower Creek reference area baseline data, reinforcing that the range of chlorophyll-a concentrations resulting from natural variability is similar among all Lower Creek areas. Mean AFDM at Lower Creek areas was highest at reference area SYT0.6 in 2018 (2.83 mg/cm^2), future-exposed areas CC5.6 in 2019 (0.61 mg/cm^2), and reference area XE0.2 in 2021 (Figure 5.3; Table 5.2). AFDM values were similar among future-exposed and reference areas in general, and few statistically significant differences occurred among comparisons of future-exposed and reference areas (Table 5.2; Figure 5.3; Appendix Table C.5). Periphyton mean total biomass estimates for Upper Creek future-exposed and reference areas were highest at reference areas SYT0.6 and XE0.2 in 2018 (119 and 151 mg/m^2, respectively), and at future-exposed area CC5.6 in 2019 and 2021 (772 and 3,496 mg/m^2, respectively; Table 5.2; Figure 5.3). Total biomass estimates indicated some differences among areas, but no consistent differences between Lower Creek future-exposed and reference areas, and aside from high values for CC5.6 in 2021 the range of values for all areas across all years was similar (Figure 5.3; Appendix Table C.6). Variability in all three periphyton productivity endpoints at Lower Creek areas was not consistently significantly correlated with any one physicochemical parameter, although chlorophyll-a concentrations and AFDM were positively correlated with DO and mean substrate size (Appendix Table C.6; Appendix Figure C.2).

Lower Creek area chlorophyll-a concentrations were generally below the oligotrophic-mesotrophic boundary of 20 mg/m^2 outlined in Dodds et al. (1998) the exception being CC5.6 in 2021 (Appendix Table C.5). This indicates that all Lower Creek areas can be generally classified as low productivity oligotrophic systems however, productivity may vary by year and variability may be higher at some areas that others. It is also possible that chlorophyll-a concentrations above the boundary (including samples from CC5.6 in 2021) may reflect measures likely being over-estimates of actual periphytic coverage at Project Upper Creek areas (Section 3.3.1). Overall comparability of Upper Creek future-exposed and reference areas is good given the few significant differences as well as the agreement in trends among productivity endpoints.

5.3.2 Community

Periphyton community mean total densities at all Lower Creek areas except CC5.6 were highest in 2018 and lowest in 2021 (Figure 5.4; Table 5.2; Appendix Table C.2). At future-exposed Lower Creek area CC5.6 mean total density was lowest in 2018 and highest in 2021, and those values also represent the minimum and maximum mean density values recorded across all Lower Creek areas throughout the baseline sampling period (79,899 and 9,546,540 cells/cm^2, respectively; Figure 5.4; Table 5.2). Periphyton mean taxonomic richness was lowest at future-exposed area HC0.2 in 2018 (3 taxa) and highest at future-exposed area CC5.6 in 2021 (11 taxa; Figure 5.4; Table 5.2). Periphyton total density and richness varied among areas and over time at Project Lower Creek areas, however, significant differences between future-exposed and reference areas were infrequent and inconsistent (Appendix Table C.5). Similarly, there were no consistent trends in variability between Lower Creek future-exposed and reference areas with respect to community evenness, diversity, and Bray-Curtis distance, and significant differences were infrequent across all comparisons (Appendix Table C.5). All Lower Creek area periphyton communities were dominated by blue-green algae, and mean proportions ranged from 84.5% (HC0.2 – 2018) to 99.8% (HC0.2 – 2018; Table 5.2; Figure 5.4). The ratio of green algae to diatoms was generally low at Lower Creek areas, however, this reflects low (frequently zero) abundances of both groups (Table 5.2; Appendix Table C.2). Those low abundances, however, will make it straightforward to detect potential changes in the relative abundances of these two groups and the ratio of green algae to diatoms (which was identified as a potential mine-related change; EDI and Minnow 2017).

6 BENTHIC INVERTEBRATE COMMUNITY

6.1 Overview

Benthic invertebrate community samples were collected in 2018, 2019, and 2021 at three future-exposed (HC6.8, LC10.2, YT4.3) and two reference (XE0.2 and SYT0.6) Upper Creek Areas, as well as three future-exposed (HC0.2, YT0.2, CC5.6) and two reference (XE0.2, SYT0.6) Lower Creek Areas. Samples were also collected from FALMP areas HC6.8 and reference area CR24.5[11] in 2017. Results of a DQR indicate that FALMP benthic invertebrate data can be reliably interpreted (Appendix G). All benthic invertebrate data collected as part of FALMP baseline monitoring in 2018, 2019, and 2021 are provided in Appendix D.

6.2 Upper Creek Areas

Benthic invertebrate mean total density at Upper Creek areas ranged from 422 (YT4.3 – 2018) to 2,617 (CR24.5 – 2021) organisms/m^2 and mean taxonomic richness ranged from 10 (YT4.3 –-2018) to 23 (HC6.8 – 2021) taxa over the baseline sampling period (Table 6.1; Figure 6.1; Appendix Table D.1). Benthic invertebrate biomass was generally very low at Upper Creek areas, ranging from 0.08 (YT4.3 – 2018) to 0.41 (HC6.8 – 2018) g/m^2 (Table 6.1; Figure 6.1). Mean community evenness ranged from 0.18 (CR24.5 – 2018) to 0.41 (HC6.8 – 2018) and diversity ranged from 0.60 (YT4.3 – 2019) to 0.86 (CC23.7 – 2019), indicating generally low to moderate evenness[12] and moderate to high diversity[13] across all Upper Creek areas and years of baseline monitoring (Table 6.1; Figure 6.1). Those key benthic invertebrate community endpoints all varied significantly among and within areas over the baseline sampling period, however significant differences between future-exposed and reference areas were observed but were uncommon and inconsistent (Appendix Table D.2). Despite good matching among sampling areas, natural variability in benthic invertebrate communities was identified, further reinforcing the applicability of a BACI experimental design.

Variability in benthic community composition was high at Project Upper Creek areas during baseline sampling, with no areas dominated by a single taxonomic grouping across all years (Table 6.1). Upper Creek area benthic invertebrate communities were generally co-dominated by mayflies, stoneflies, chironomids, and oligochaetes in proportions varying over time among

[11] Previously Area I29 (Appendix Table A.1)

[12] Simpson's evenness index values range from 0 to 1, with a value of 1 corresponding to a perfectly even community (with respect to number of taxa and distribution of abundance among those taxa) and 0 corresponding to a highly uneven community.

[13] Simpson's diversity index values range from 0 to 1, with a value of 1 corresponding to infinite community diversity (with respect to number of taxa and distribution of abundance among those taxa) and 0 corresponding to zero diversity.

and within areas (Table 6.1, Figure 6.1). Proportions of EPT taxa ranged from 17.2% (YT4.3 –-2018) to 81.3% (CR24.5 – 2018), with no consistent pattern of spatial variability across the baseline sampling period (Table 6.1). Proportions of stoneflies and chironomids were similarly variable over the baseline period with the former ranging from 6.8% (LC10.2 – 2018) to 66.5% (YT4.3 – 2019) and the latter from 6.1% (CC23.7 – 2018) to 69.6% (YT4.3 – 2018; Table 6.1). Significant differences in key community composition endpoints (e.g., %EPT, %Plecoptera, %Chironomidae, etc.) between future-exposed and reference Upper Creek areas were rare and inconsistent (Appendix Table D.2). In general, community composition at all Upper Creek area future-exposed areas was dominated by four groups (Ephemeroptera, Plecoptera, Chironomidae, and Simuliidae), but relative proportions were variable over the baseline period. However, although differences were observed between future-exposed and references areas, variability at reference areas was similar and patterns of difference between future-exposed and reference areas were inconsistent (Figure 6.1; Appendix Table D.2).

Project Upper Creek area benthic invertebrate communities were either co-dominated by collector-gatherers, filterers, and shredders, or were dominated by shredders or by collector-gatherers (Table 6.1). No Upper Creek areas fell into one of those categories consistently across all years of baseline monitoring due to significant interannual variability in proportions of all FFGs (Table 6.1; Appendix Table D.2). Similarly, proportions of HPGs at Upper Creek areas were variable over the baseline monitoring period, with no clear dominance patterns within and/or among areas (Table 6.1; Appendix Table D.2). Significant differences in FFGs and HPGs between future-exposed and reference Upper Creek areas were observed, but were inconsistent, especially depending on which reference area (i.e., CR24.5 or CC23.7) was used as the basis for comparison (Appendix Table D.2). In general, community composition with respect to proportions of FFGs and HPGs at all future-exposed areas was similar to (and not significantly different from) at least one reference area at some point over the baseline sampling period (Figure 6.1; Appendix Table D.2).

Mean proportions of metal-sensitive chironomids varied at Upper Creek areas over the baseline monitoring period, ranging from 1.3% (CR24.5 – 2021) to 63.0% (YT4.3 – 2018); however, mean proportions were most commonly <20% (Table 6.1). Proportions of metal-sensitive chironomids at future-exposed areas were generally not significantly different than both reference areas, with significant differences occurring infrequently and inconsistently (Appendix Table D.2).

Upper Creek area benthic invertebrate communities were also assessed using BC comparisons of dissimilarity (both family-level, and lowest practicable level) of future-exposed and reference areas (Appendix Table D.3). All future-exposed Lower Creek area communities were significantly different from both corresponding reference areas for every year of baseline sampling

with the exception of one comparison (HC6.8 vs. CC23.7 – 2021), reflecting temporally consistent natural variability in community composition among Project Lower Creek areas (Appendix Table D.3).

Upper Creek area benthic community endpoints were frequently significantly correlated with physicochemical parameters (e.g., flow velocity, temperature, DO, pH, etc.), however, correlations were inconsistent (Appendix Table D.4). Variability in most benthic invertebrate community key indicator endpoints was correlated significantly with at least two habitat or water chemistry endpoints with no apparent pattern, indicating that natural variability in benthic invertebrate communities among Upper Creek areas is driven by myriad factors across Project areas (Appendix Table D.4; Appendix Figure D.1).

6.3 Lower Creek Areas

Benthic invertebrate mean density at Lower Creek areas ranged from 149 (CC5.6 – 2018) to 3,200 organisms/m^2 (SYT0.6 – 2021) and varied significantly among and within areas over the baseline sampling period (Table 6.2; Figure 6.2; Appendix Tables D.5 and D.6). Mean benthic invertebrate biomass was generally low at Lower Creek areas, ranging from 0.02 (CC5.6 –-2018) to 0.72 g/m^2 (SYT0.6 – 2021; Table 6.2; Figure 6.2). Benthic invertebrate density and biomass were generally significantly lower at future-exposed Lower Creek areas than reference areas. Although differences were observed, the range of values for both endpoints at future-exposed areas was generally within the range of density and biomass values observed at reference areas over the baseline monitoring period (Figure 6.2; Appendix Table D.6).

Benthic invertebrate mean taxonomic richness ranged from 11 (YT0.2 and CC5.6 – 2018) to 22 (XE0.2 – 2021) taxa, and while there were no significant spatial differences over the baseline sampling period, richness was higher 2019 than in 2018, as well as in 2021 relative to 2019 at all Lower Creek areas (Table 6.2; Figure 6.2; Appendix Table D.6). Mean Simpson's Diversity was generally moderate to high, ranging from 0.56 (SYT0.6 – 2018) to 0.84 (XE0.2 – 2021) and Evenness was low to moderate, ranging from 0.17 (SYT0.6 – 2018) to 0.54 (CC5.6 – 2018) at Lower Creek areas over the baseline sampling period (Figure 6.2; Appendix Table D.6). Statistically significant results for comparisons of taxonomic richness, evenness, and diversity between future-exposed and reference areas were observed but were infrequent and inconsistent despite temporal and spatial variability at and among Lower Creek areas, indicating that future-exposed and reference are data are of generally good comparability.

Lower Creek area benthic invertebrate community composition was variable within and among areas over the baseline sampling period. Lower Creek area benthic communities were generally dominated by stoneflies (future-exposed area YT0.2 and reference area SYT0.6) or co-dominated by varying proportions of EPT taxa (mostly E and P), chironomids, black flies, and oligochaetes

Notes: Green represents reference stations and blue represents future-exposed stations. Horizontal lines indicate measure of central tendency (MCT) used in the statistical analyses.

(future-exposed area CC5.6 and reference area XE0.2; Table 6.2; Figure 6.2). At Lower Creek area HC0.2 both community composition scenarios were observed, with stoneflies, chironomids, and black flies co-dominant in 2018, and stoneflies dominant in 2019 and 2021 (Table 6.2; Figure 6.2). Significant differences in community composition endpoints (e.g., %EPT, %Plecoptera, %Chironomidae, etc.) between future-exposed and reference Lower Creek areas were inconsistent and dependent on which reference area (i.e., SYT0.6 or XE0.2) was applied (Appendix Table D.6). In general, community composition at all future-exposed areas was similar to (and not significantly different from) at least one reference area at some point over the baseline sampling period (Figure 6.2; Appendix Table D.6).

Project Lower Creek area benthic invertebrate communities were either co-dominated by collector-gatherers, filterers, and shredders (XE0.2, HC0.2, and YT0.2), dominated by shredders (SYT0.6), or dominated by collector-gatherers (CC5.6), although proportions of each FFG varied over the baseline period at each area (Table 6.2; Appendix Table D.6). Proportions of scraper-grazers and predators were low relative to the other FFGs at Lower Creek areas over the baseline monitoring period. Habitat preference groups at Lower Creek areas were generally dominated by clingers (SYT0.6, HC0.2, and YT0.2) or co-dominated by all three HPGs (i.e., clingers, burrowers, and sprawlers; XE0.2 and CC5.6) in varying proportions over the baseline monitoring period (Table 6.2; Appendix Table D.6). Significant differences in FFGs and HPGs between future-exposed and reference Lower Creek areas were observed but were inconsistent, especially depending on which reference area (i.e., SYT0.6 or XE0.2) was used as a basis for comparison (Appendix Table D.6). In general, community composition with respect to proportions of FFGs and HPGs at all future-exposed areas was similar to (and not significantly different from) at least one reference area at some point over the baseline sampling period (Figure 6.2; Appendix Table D.6).

Mean proportions of metal-sensitive chironomids were relatively low at all Lower Creek areas throughout the baseline monitoring period (i.e., 0.6% to 13.4% at CC5.6 in 2018 and SYT0.6 in 2019, respectively). Proportions of metal-sensitive chironomids at future-exposed areas were generally significantly lower than both reference areas, however, differences and proportions at future-exposed areas were consistent throughout the baseline monitoring period, providing a good baseline for monitoring Project-related variation in the future (Appendix Table D.6).

The relative dissimilarity of Lower Creek area benthic invertebrate communities was also assessed using BC comparisons of dissimilarity between taxonomic composition (both family-level and lowest practicable level) of future-exposed and reference areas (Appendix Table D.7). All future-exposed Lower Creek area communities were significantly

different from both corresponding reference areas for every year of baseline sampling, reflecting consistent natural differences among Project Lower Creek areas (Appendix Table D.7).

Variability in Lower Creek area benthic community endpoints was frequently significantly correlated with changes in physicochemical parameters (e.g., flow velocity, temperature, DO, pH, etc.), however, correlations were inconsistent (Appendix Table D.8). Variability in most benthic invertebrate community key indicator endpoints was correlated significantly with at least three habitat or water chemistry endpoints, indicating that natural variability in benthic invertebrate communities among Lower Creek areas is driven by myriad factors (Appendix Table D.8; Appendix Figure D.2).

7 BENTHIC INVERTEBRATE TISSUE CHEMISTRY

7.1 Overview

Composite-taxa benthic invertebrate tissue chemistry samples were collected from all FALMP sampling stations in 2018, 2019, and 2021 following collection of benthic invertebrate community samples[14]. The results of a DQR indicate that FALMP benthic invertebrate tissue chemistry samples were associated with good analytical precision and can be reliably interpreted (Appendix G). All benthic invertebrate tissue chemistry data collected as part of FALMP baseline monitoring in 2018, 2019, and 2021 are provided in Appendix E.

7.2 Upper Creek Areas

7.2.1 Mercury

In the Upper Creek areas, mean mercury concentrations in benthic invertebrate tissue exceeded the Canadian Tissue Residue Guidelines for mercury (0.033 mg/kg ww[15]; CCME 2000) at future-exposed areas Halfway Creek (HC6.8) and Latte Creek (LC10.2), as well as reference area Coffee Creek (CC23.7; Table 7.1; Figure 7.1; Appendix Table E.1). Mean mercury concentrations in benthic invertebrate tissue samples from YT-24 Creek (YT4.3; future-exposed) and Carlisle Creek (CR24.5; reference) remained below the CCME guideline (Table 7.1; Figure 7.1). Spatially, concentrations of mercury in benthic invertebrate tissue samples indicated that baseline differences between future-exposed and reference areas were observed but were inconsistent. In the Upper Creek areas, although concentrations of mercury were significantly higher in some future-exposed areas in 2018 and 2019 compared to reference areas, no differences were observed in 2021 (Appendix Table E.2).

7.2.2 Selenium

Selenium concentrations in composite-taxa benthic invertebrate tissue samples were compared to the British Columbia Ministry of Environment Guideline for selenium (4 mg/kg dw; BCMOE 2014). In the Upper Creek areas, mean selenium concentrations in benthic invertebrate tissue only exceeded the BC guideline in future-exposed areas HC6.8 and LC10.2 (Table 7.1; Figure 7.1). Similar to mercury, spatial differences in benthic invertebrate selenium

[14] No results are available for LC10.2 in 2018 because the samples were either lost en route to Saskatoon, or misplaced during processing at SRC.

[15] Mercury concentrations were converted from dry weight to wet weight using % moisture for screening against the CCME guideline for mercury.

Value is > BCMOE and CCME Guidelines.

Notes: "-" = no data. BCMOE = British Columbia Ministry of Environment Guideline (BCMOE 2014) for Selenium (4 mg/kg dw). CCME = Canadian Sediment Quality Guideline (CCME 2001) for Mercury (0.033 mg/kg ww).

[a] 2018 Benthic Invertebrate Tissues from LC10.2 (n=5) were lost either en route to or at SRC Laboratories.

[b] Mercury concentrations were converted from dry weight to wet weight for screening against CCME Guideline for Mercury.

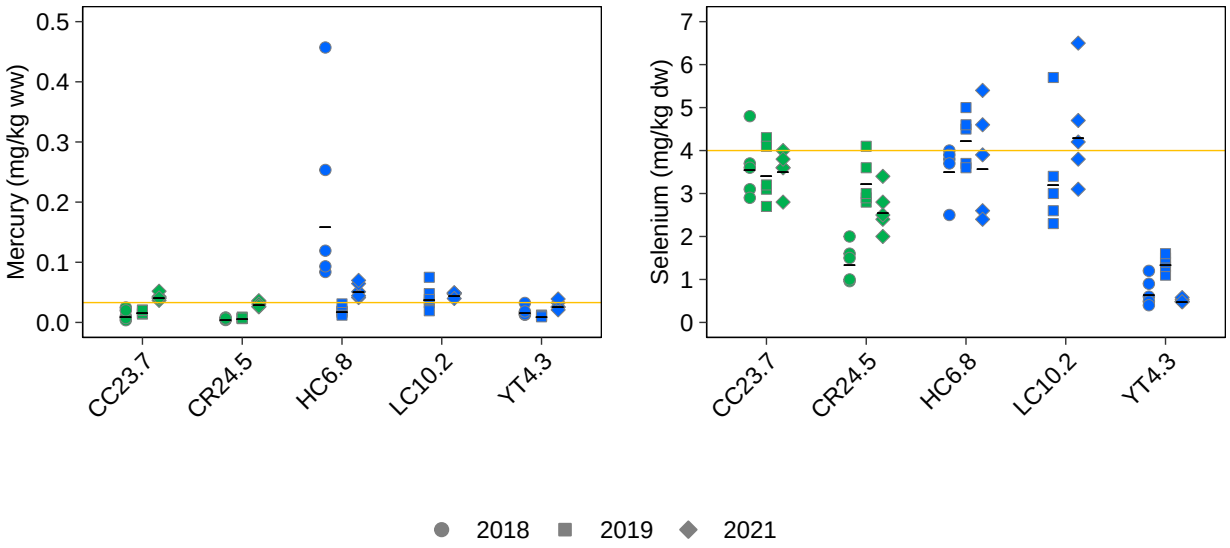

Figure 7.1: Coffee Project FALMP Benthic Invertebrate Tissue Mercury and Selenium Concentrations, Upper Creek Areas, 2018 to 2021

Notes: Green represents reference stations and blue represents future-exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Horizontal lines indicate measure of central tendency (MCT) used in the statistical analyses. Boron and tin were excluded from analyses because 100% of the data were at the LDL in 2018 and/or 2019. MCT's are not shown for these parameters. Orange solid line indicates the Canadian Sediment Quality Guideline (CCME 2001) for Mercury (0.033 mg/kg ww) and British Columbia Ministry of Environment Guideline (BCMOE 2014) for Selenium (4 mg/kg dw). Mercury concentrations were converted from dry weight to wet weight using % Moisture for screeing against the CCME guildeline for Mercury.

concentrations were not consistent among future-exposed and reference areas in the Upper Creek areas. The only consistent significant difference that was observed was significantly lower concentrations of selenium in benthic invertebrate tissue at YT4.3 compared to both reference areas; however, the magnitude of difference between YT4.3 and references was consistent across comparisons for all years (Appendix Table E.2).

7.2.3 Key Indicators

Concentrations of parameters expected to be elevated in aqueous form as a result of future mine operations (i.e., arsenic, uranium, and zinc) were also examined in benthic invertebrate tissue samples. Differences in benthic invertebrate tissue concentrations of arsenic, uranium, and zinc between future-exposed and references areas in the Upper Creek areas were observed but were inconsistent. Concentrations of benthic invertebrate tissue arsenic and uranium were significantly higher at future-exposed areas compared to CR24.5, but significantly lower compared to CC23.7 indicating reference areas capture the range of natural variability for Upper Creek areas and represent a good basis for future monitoring (Table 7.1; Figure 7.2; Appendix Table E.2). No consistent differences were observed in the concentrations of benthic invertebrate tissue zinc concentrations between future-exposed and reference areas potentially reflecting the naturally elevated concentrations of this parameter across all FALMP areas. No temporal changes in concentrations of arsenic, uranium, or zinc were apparent in any Upper Creek areas (Appendix Table E.2).

Additional consideration was given to those parameters that are also naturally enriched in the Project area in aqueous form (i.e., aluminum, chromium, and copper) but for which long-term increases due to mine operations are not expected. Differences that were observed between future-exposed and reference areas in the Upper Creek areas with respect to aluminum, chromium, and copper concentrations in benthic invertebrate tissue were not consistent spatially nor across years of baseline sampling. These results are indicative that these parameters are elevated across all Upper Creek areas and future-exposed and reference area conditions are of good comparability with respect to benthic invertebrate tissue chemistry (Table 7.1; Figure 7.2; Appendix Table E.2).

7.3 Lower Creek Areas

7.3.1 Mercury

At Lower Creek areas, mean mercury concentrations in benthic invertebrate tissue samples only exceeded the CCME guideline at the future-exposed Coffee Creek area (CC5.6 – all years; Table 7.2; Figure 7.3; Appendix Table E.3). Consistently higher mercury concentrations were observed in benthic invertebrate tissues at CC5.6 compared to both reference areas, but HC0.2

[a] Mercury concentrations were converted from dry weight to wet weight for screening against CCME Guideline for Mercury

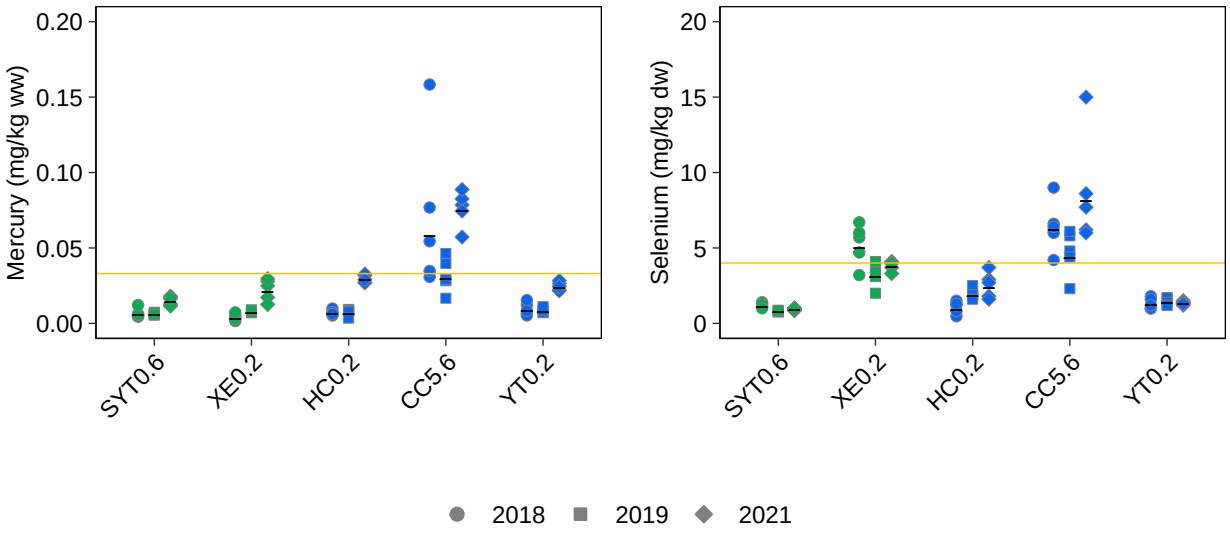

Figure 7.3: Coffee Project FALMP Benthic Invertebrate Tissue Mercury and Selenium Concentrations, Lower Creek Areas, 2018 to 2021

Notes: Green represents reference stations and blue represents future-exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Horizontal lines indicate measure of central tendency (MCT) used in the statistical analyses. Boron and tin were excluded from analyses because 100% of the data were at the LDL in 2018 and/or 2019. MCT's are not shown for these parameters. Orange solid line indicates the Canadian Sediment Quality Guideline (CCME 2001) for Mercury (0.033 mg/kg ww) and British Columbia Ministry of Environment Guideline (BCMOE 2014) for Selenium (4 mg/kg dw). Mercury concentrations were converted from dry weight to wet weight using % Moisture for screeing against the CCME guildeline for Mercury.

and YT0.2 did not differ consistently from reference (Appendix Table E.4). Similar to the Upper Creek areas, temporal differences indicated significantly higher concentrations of mercury in benthic invertebrate tissue in 2021 at all areas compared to 2018 and 2019 (with the exception of CC5.6 in 2018; Table 7.2; Figure 7.3; Appendix Table E.4). It is important to note that there was a change in laboratories used for the analysis of benthic invertebrate tissue chemistry samples in 2021 to increase field sampling efficiency by reducing time spent picking insects from sample material (SRC was used in 2018 and 2019, and TrichAnalytics was used in 2021), therefore, changes in mercury concentrations observed between 2018 and 2019 compared to 2021 may be related to differences in analytical procedures.

7.3.2 Selenium

Mean benthic invertebrate tissue selenium concentrations only exceeded the BC guideline at CC5.6 and reference area XE0.2 (all years; Table 7.2; Figure 7.3). Selenium concentrations at future-exposed areas were generally significantly higher than reference area SYT0.6 (Appendix Table E.4). Conversely, selenium concentrations in benthic invertebrate tissue from HC0.2 and YT0.2 were significantly lower than the reference area XE0.2 (Appendix Table E.4). The range of values at reference areas therefore capture regional variability in benthic invertebrate tissue selenium concentrations. No differences were observed between CC5.6 and reference area XE0.2 in either 2018 or 2019, indicating that selenium concentrations are naturally elevated at this reference area. Temporally, significantly higher selenium concentrations were observed at HC0.2 in both 2019 and 2021 compared to 2018 (Appendix Table E.4). Additionally, significantly higher selenium concentrations were noted in 2021 compared to 2019 at CC5.6 (Appendix Table E.4).

7.3.3 Key Indicators

At Lower Creek areas, arsenic was significantly higher at future-exposed areas when compared to both reference areas, potentially associated with proximity to the Project economic ore body (Table 7.2; Figure 7.4; Appendix Table E.4). Uranium was also significantly higher at all Lower Creek areas compared to reference area XE0.2. Uranium concentrations at future-exposed areas HC0.2 and CC5.6 were not significantly different from reference area SYT0.6, and uranium concentrations were significantly lower at YT0.2 than SYT0.6 (Table 7.2; Figure 7.4; Appendix Table E.4). This indicates that reference areas XE0.2 and SYT0.6 effectively capture the range of natural variability in Lower Creek area uranium concentrations (Table 7.2; Figure 7.4). No temporal changes in the concentrations of benthic invertebrate tissue arsenic, uranium, or zinc were apparent at any of areas over the baseline monitoring period (Appendix Table E.4). Similar to the Upper Creek areas, differences in benthic invertebrate tissue aluminum, chromium, copper, and zinc concentrations were variable between future-exposed and

reference areas were observed but were not consistent across years (Table 7.2; Figure 7.4; Appendix Table E.4).

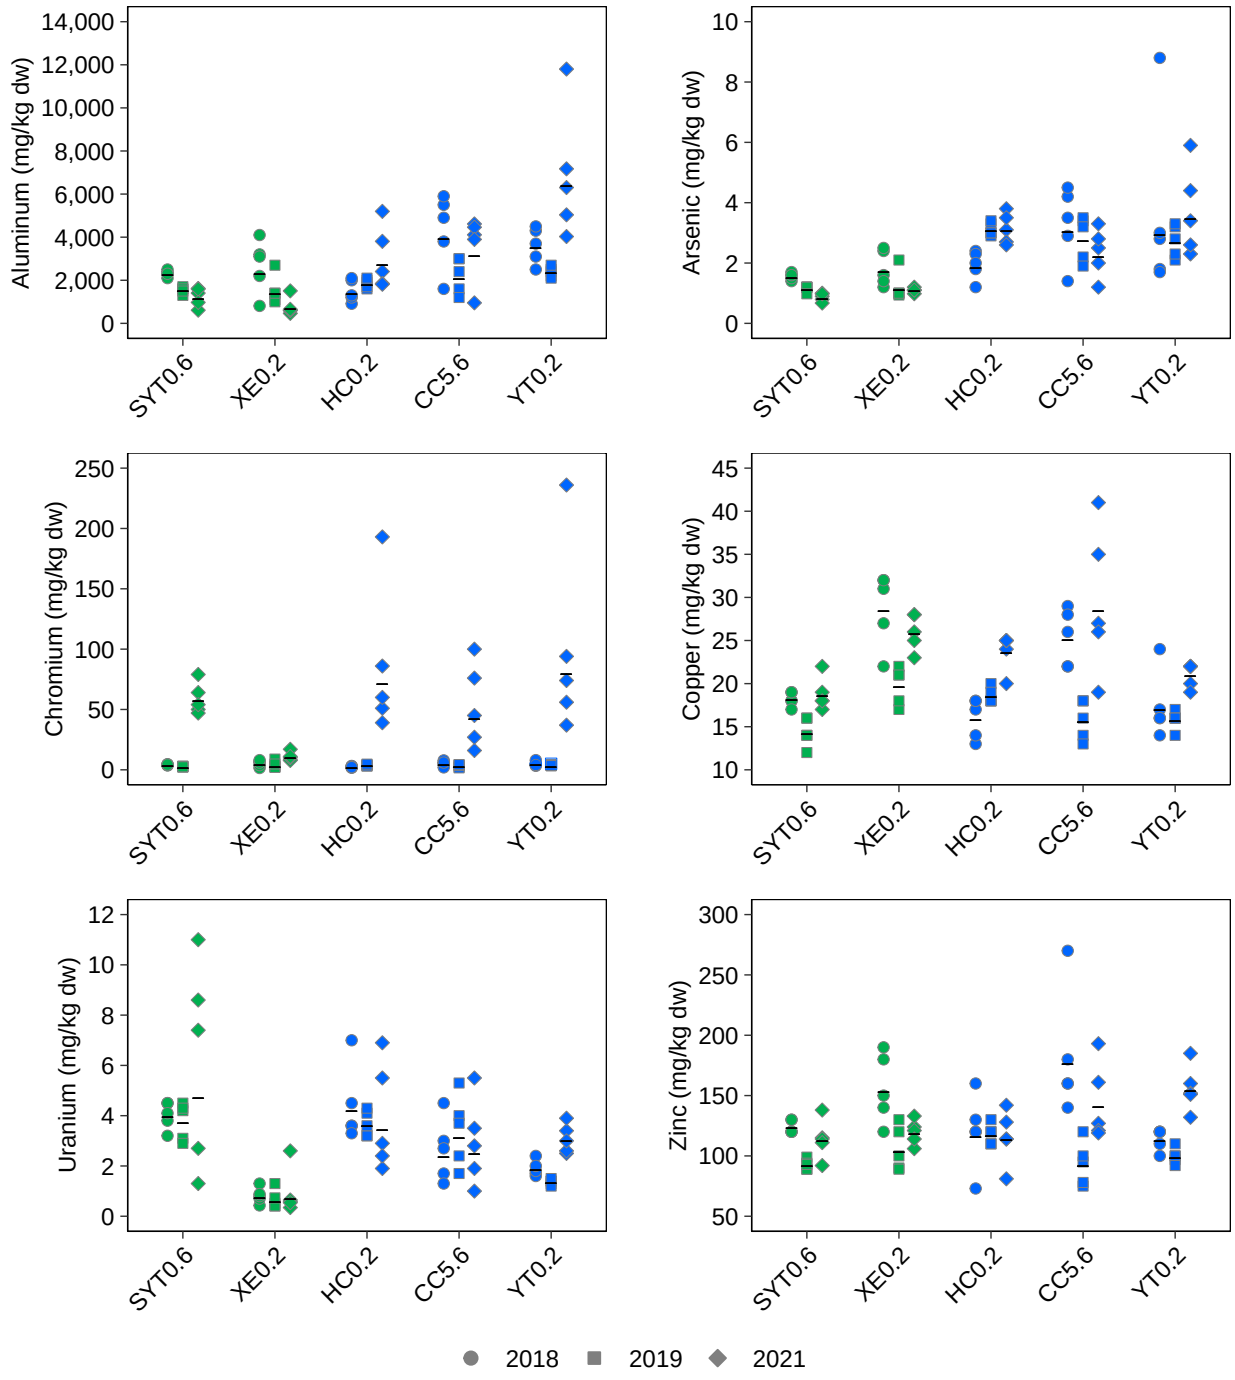

Figure 7.4: Coffee Project FALMP Benthic Invertebrate Tissue Metal Concentrations, Selected Parameters, Lower Creek Areas, 2018 to 2021

Notes: Green represents reference stations and blue represents future-exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Horizontal lines indicate measure of central tendency (MCT) used in the statistical analyses.

8 SEDIMENT CHEMISTRY

8.1 Overview

Sediment sampling was conducted in 2019 and 2021 to determine the feasibility of including a robust sediment chemistry component in the FALMP. Project FALMP Upper and Lower Creek areas are mostly erosional habitat, and availability of depositional habitat is very low or non-existent and can vary by year. Sediment was therefore collected at areas where it could be located and in whatever limited volume was available. The results of a DQR indicate that FALMP baseline sediment chemistry samples were associated with excellent analytical precision and can be reliably interpreted (Appendix G). All sediment chemistry data collected as part of FALMP baseline monitoring in 2018, 2019, and 2021 are provided in Appendix F.

8.2 Upper Creek Areas

Sediment samples were collected in 2019 and 2021 from three future-exposed Upper Creek Areas including HC6.8 (upper Halfway Creek), LC10.2 (Latte Creek), and YT4.3 (upper YT-24 Creek; only sampled in 2019). Sediment could not be collected from either Upper Creek reference area (CC23.7 and CR24.5). The sediments of Upper Creek future-exposed areas were primarily composed of silt (49 to 84%; Table 8.1; Appendix Figure F.1; Appendix Table F.1; Appendix Figure F.1) and to a lesser extent sand (12 to 41%; Table 8.1). Particles larger than sand were rare in samples collected from the Upper Creek areas (Appendix Table F.1; Appendix Figure F.1). Percent TOC varied among the Upper Creek Areas ranging from 4.8 to 8.9% at HC6.8, 2.3 to 4.0% at LC10.2, and 3.2 to 7.0% at YT4.3 (Table 8.1).

Sediment samples from the three future-exposed areas were analyzed for 35 different metals, and the results were screened against BC Working and Canadian Sediment Quality Guidelines. Of all analytes, only arsenic exceeded the upper sediment quality guideline (at two areas; HC6.8 and YT4.3; Table 8.1; Appendix Table F.1; Appendix Figure F.1), while exceeding the lower sediment quality guideline at the third area (i.e., LC10.2; Table 8.1; Appendix Table F.1; Appendix Figure F.1). Lower-level guideline exceedances were observed for four other analytes from each of the future-exposed Upper Creek areas, including chromium (Appendix Table F.1).

Sediment concentrations of TOC, arsenic, chromium, and uranium varied among future-exposed Upper Creek Areas (Appendix Table F.1; Appendix Figure 8.1). As sediment samples could not be collected from the reference Upper Creek Areas, no comparison could be made between the future-exposed and reference areas. Temporal variability was observed in several sediment chemistry analytes at the areas that were sampled in 2019 and 2021 (i.e., HC6.8 and LC10.2). At LC10.2, several analytes including aluminum, chromium, copper, uranium, and zinc were significantly higher in 2021 than in 2019 (Appendix Table F.2; Appendix Figure F.1). At HC6.8,

Value is > BC Working Sediment Quality Guideline and Canadian Sediment Quality Guideline Effect Lower Level.

Value is > BC Working Sediment Quality Guideline and Canadian Sediment Quality Guideline Effect Upper Level.

Notes: "-" = no data. BCWSQG = British Columbia Working Sediment Quality Guideline (BCMOECCS 2021) and approved BC Sediment Quality Guideline for selenium (BCMOECCS 2019c). CCME = Canadian Sediment Quality Guideline (CCME 2001). All WSQG and CCME Guidelines are the same except for selenium as there is no CCME guideline.

several analytes were significantly higher in 2021 than in 2019 (e.g., arsenic), while others were significantly lower (e.g., uranium; Table 8.1; Appendix Table F.2; Appendix Figure F.1).

8.3 Lower Creek Areas

Sediment samples were collected in 2019 from Lower Creek future-exposed areas HC0.2 and CC5.6, and reference areas SYT0.6 and XE0.2 (Table 8.1). Samples were also collected in 2021 at Lower Creek future-exposed areas YT0.2 and again from CC5.6 (Table 8.1). The sediments of two of the three Lower Creek future-exposed areas (HC0.2 and CC5.6) were primarily composed of silt (41% to 78%) and to a lesser extent sand (Table 8.1), whereas at future-exposed area YT0.2 sand was the dominant particle type (5% to 72%), and silt secondary (24 to 37%; Table 8.1; Appendix Table F.1; Appendix Figure F.1). At both reference Lower Creek areas (SYT0.6 and XE0.2) sand (62 to 72%) and silt (22 to 33%) were the primary and secondary components, respectively (Table 8.1; Appendix Figure F.1). Like the Upper Creek Areas, particles larger than sand were rare in samples collected from the Lower Creek Areas (Appendix Table F.1; Appendix Figure F.1). Percent TOC varied among both the future-exposed and reference Lower Creek Areas, ranging from 2.6 to 4.9% at HC0.2 (2019), 2.1 to 12% at CC5.6 (2019 and 2021), 2 to 4% at YT0.2 (2021), 2.9 to 4.1 % at SYT0.6 (2019), and 6.6 to 13% at XE0.2 (2019; Table 8.1; Appendix Table F.1; Appendix Figure F.1).

Lower Creek area sediment samples were also analyzed for 35 different metals, and results were screened against BC Working and Canadian Sediment Quality Guidelines. Similar to Upper Creek Areas, only arsenic exceeded the Upper Sediment Quality Guideline, which occurred at areas HC0.2 (2019) and YT0.2 (2021), while the Lower Sediment Quality Guideline was exceeded at area CC5.6 (2019 and 2021; Table 8.1; Appendix F.1; Appendix Figure F.1). There were lower-level exceedances of six other analytes among the future-exposed and reference areas, including chromium, which exceeded the lower guideline at areas HC0.2 and XE0.2, and copper, which exceeded the lower guideline at XE0.2 (Table 8.1). Sediment samples were only collected from one future-exposed Lower Creek area in both 2019 and 2021 (CC5.6). Several analytes were significantly higher in concentration in 2021 relative to 2019 at CC5.6, including aluminum, chromium, copper, uranium, and zinc (Appendix Table F.2; Appendix Figure F.1).

Lower Creek sediment chemistry differed between future-exposed and reference area for several analytes (Appendix Table F.3). Arsenic was significantly higher at future-exposed Lower Creek areas than reference areas (potentially due to ore body influence), whereas chromium was significantly lower at future-exposed Lower Creek Areas than the reference areas (Appendix Table F.3; Appendix Figure F.1). With respect to copper and zinc, concentrations at reference area XE0.2 were significantly higher than reference area SYT0.6 and both future-exposed areas sampled (HC0.2 and CC5.6; Appendix Table F.3; Appendix Figure F.1).

Finally, differences among future-exposed and reference areas in aluminum and uranium were observed but were inconsistent (Appendix Table F.3; Appendix Figure F.1).

9 CONCLUSIONS AND RECOMMENDATIONS

9.1 Conclusions

Habitat variables at FALMP monitoring areas, specifically flow and temperature, are of good comparability and have generally been similar between Project future-exposed and reference areas, as well as between Upper and Lower Creek areas over the FALMP baseline sampling period. *In situ* water quality variables, particularly temperature and DO, were also similar between future-exposed and reference areas at both Upper and Lower Creek areas. Variability in conductivity between future-exposed and reference areas (i.e., higher mean values Upper Creek future-exposed than Upper Creek reference, and lower mean values at Lower Creek future-exposed than Lower Creek reference) was generally consistent across years of baseline sampling, and the range of reference values will be a good "control" term within the BACI design. In general, habitat and water quality conditions at Upper and Lower Creek future-exposed and reference areas demonstrate good comparability.

Periphyton conditions in creeks of the Project area (Upper and Lower Creek areas) during FALMP baseline sampling were characterized by low productivity (i.e., oligotrophic conditions), blue-green algae dominance, and low variety in taxonomic groups present. Data across FALMP future-exposed and reference areas were of good comparability across all periphyton productivity and community endpoints (i.e., chlorophyll-a, AFDM, and periphyton biomass). For most periphyton community endpoints (e.g., taxonomic richness, evenness, community proportions, etc.) baseline data ranges for future-exposed and reference areas were either similar or represent a range of natural variability that occurred consistently across FALMP sampling areas and can be compared against for future monitoring during future Project development phases. Periphyton productivity was frequently lower at future-exposed areas than reference (particularly for Upper Creek areas). However, because an increase in algal productivity at future-exposed areas due to nutrient enrichment is one of the anticipated potential Project-related changes, higher values at reference areas provide a good range of naturally occurring variability for future comparisons (Minnow and EDI 2017). Upper and Lower Creek FALMP sampling areas and baseline data will be reliable for tracking Project-related changes in periphyton productivity and community in the future.

Project Upper and Lower Creek area benthic invertebrate communities were generally co-dominated by EPT taxa (particularly stoneflies), chironomids, black flies, and oligochaetes, similar to the initial 2015 to 2017 baseline assessment (Minnow and EDI 2017). Benthic invertebrate total density and biomass were frequently higher at reference than future-exposed areas, which likely results from the generally higher periphyton productivity at

reference relative to future-exposed areas. At all FALMP areas, evenness was generally low to moderate, and diversity was generally moderate to high. Most other benthic invertebrate community endpoints were comparable between Upper and Lower Creek areas and were also consistent with the 2014 to 2017 baseline work, despite the change in sampling methodology to a more quantitative method (Minnow and EDI 2017; EDI and Minnow 2021).

Benthic invertebrate community endpoints including key indicators (e.g., total density, taxonomic richness, and evenness) varied within and among all areas (i.e., future-exposed/reference and Upper/Lower Creek areas) over the FALMP baseline sampling period. However, ranges of values for most benthic invertebrate community endpoints were comparable between future-exposed and reference areas, or the complete range of values for reference areas reflected the range of future-exposed area baseline values, and therefore still provides a good basis for comparison of Project-related effects in the future. Furthermore, significant differences between future-exposed and reference FALMP area benthic community endpoints mostly occurred inconsistently. This implies that FALMP reference areas likely reflect the range of naturally occurring variability occurring at future-exposed areas. Interannual variability in benthic invertebrate community endpoints may also be driven by changes in the same physicochemical variables (i.e., habitat and *in situ* water quality parameters) at FALMP future-exposed and reference areas. However, significant correlations between those endpoints and benthic invertebrate community endpoints were too numerous and inconsistent to identify meaningful trends.

Several benthic invertebrate tissue quality analytes, including mercury, selenium, and uranium were naturally elevated at FALMP Upper and Lower Creek future-exposed and reference areas. In the case of mercury and selenium, concentrations exceeded benchmarks at future-exposed and reference areas, although mercury did not exceed the benchmark at either Lower Creek reference area. Exceedances were generally not observed consistently across all areas and years, as spatial and temporal variability was high for both analytes. Arsenic concentrations were generally higher at Upper and Lower Creek future-exposed areas than reference, potentially due to proximity to the ore body. Variability in concentrations of other key aqueous indicator analytes (e.g., chromium, copper, selenium, and uranium) between future-exposed and reference areas was inconsistent in both Upper and Lower Creek areas. Successfully identifying this range of natural variability in benthic invertebrate tissue analytes during baseline will likely be beneficial for differentiating between Project-related effects and changes related to natural variability in the future.

Sediment was collected opportunistically in 2019 and 2021 monitoring due to the scarcity of depositional habitat in FALMP Upper and Lower Creek areas. Available data indicate that several analytes (e.g., arsenic, chromium, copper, selenium, and uranium) are elevated in FALMP

Upper and Lower Creek area sediments. This result reflects results of water quality monitoring as well as FALMP benthic invertebrate tissue chemistry monitoring. A robust statistical comparison of spatiotemporal variability across FALMP areas over the baseline monitoring period similar to the ones employed for other study components (e.g., benthic invertebrate community structure and tissue chemistry) was not possible with the limited sample size available for sediment chemistry. Sediment chemistry analytes that occurred in naturally elevated concentrations at future-exposed areas (e.g., Halfway Creek and YT-24 Creek) were also elevated at associated reference areas, indicating that the current study design with respect to area selection will be effective for differentiating between Project effects and naturally elevated metal concentrations.

Overall, the application of a “future-exposed” versus reference design at the baseline stage indicated numerous differences in physical and chemical variables, in key metrics of periphyton production and community, and in key metrics of benthic invertebrate production, community and tissue quality despite careful matching of the areas. This highlights the ubiquity of natural differences even among closely matched un-impacted sampling areas and the importance of accounting for such differences to facilitate true detection of potential project/mine-related influences on aquatic life.

9.2 Recommendations for Future Monitoring and Interpretation

Given the general consistency of results between future-exposed and reference areas across all monitoring endpoints for both Upper and Lower Creek monitoring areas, it is recommended that FALMP monitoring proceed under the current conceptual design according to the schedule outlined in the FALMP (EDI and Minnow 2021). The BACI design will be optimal for detecting Project-related changes as selected reference areas are good matches for the “future-exposed” areas and baseline conditions for both are now well characterized. This design will facilitate identification of Project-related changes by providing differentiation from naturally occurring spatial and temporal variability (thereby eliminating the risk of falsely attributing a difference between an exposed area and a reference area to a mine-related effect).

Project FALMP creeks have very minimal periphytic coverage and selection of rocks for periphyton collection is generally targeted towards rocks with visible algal material. This is because selection of entirely random rocks would result in sample volumes being too low for analysis. We recommend that FALMP sampling introduce artificial substrates in order to attempt collection of algal biomass data that are as reliably quantitative as possible. Introduction of artificial substrates is proposed as a means of: 1) ensuring data are quantitative, and 2) maximizing comparability among sampling areas. We propose that at each area, n=5 modified Hester-Dendy samplers (adapted for use in shallow creek environments) are installed

for biomass analysis, and n=5 rock cages are installed (using rocks from the same area). Artificial substrates, such as Hester-Dendy samplers, will improve biomass sampling and reflect natural primary production, but communities on artificial substrates do not always reflect naturally occurring communities, which necessitates the rock cages (Porter et al. 1993). Additionally, we propose that we test comparability of data collected using tubular syringe/brush samplers for sampling in 2022 as this could potentially reduce sample loss and increase sampling accuracy (Steinman et al. 2017). This will also enable sampling from rocks having suboptimal surfaces for scraping with a scalpel, like those with rough, irregular surfaces, which occur frequently in creeks in the vicinity of the Coffee Project and are generally not scraped, potentially skewing community data. A downside of changing protocols is the potential loss of baseline productivity data; however, it is possible those data collected using the updated methods may be comparable in which case we may still be able to apply BACI, otherwise additional baseline sampling would potentially be necessary in that case.

Depositional habitats are uncommon on FALMP creeks, and their presence can vary from year-to-year, making the reliability of sediment collection as part of annual monitoring poor. For example, depositional areas have not been identified over three years of sampling at Upper Creek reference areas CR24.5 and CC23.7, and aside from CC5.6 and LC10.2, locations and presence of sediment have been variable at other FALMP areas. It is unlikely that FALMP sediment sampling will be adequate to reliably support meaningful BACI statistical comparisons in the future. Nonetheless, we recommend that sediment continue to be collected opportunistically, particularly in Project receiving area creeks (i.e., Latte, Coffee, Halfway, and YT-24 Creeks), as they have demonstrated the highest degree of reliability with respect to sediment presence over the baseline period. An alternative statistical approach may be utilized for sediment (e.g., a BA design), which would then remove collection of sediment at reference areas (as robust comparison to reference is limited already) and focus on comparisons reflecting change over time at areas with more reliable sediment deposits. Also, those data could be supplemented with periphyton tissue chemistry data, which would constitute as close an approximation as possible to the functional connection between sediment and water chemistry.

ANOVA P-value < 0.05.
Significantly Decrease in Concentration.
Significantly Increase in Concentration.

Note: "nc" indicates no comparison available; "ns" indicates not significant.

[a] Magnitude of Difference is calculated as $(MCT_{recent\ year} - MCT_{older\ year})/ MCT_{older\ year})*100$. MCT = measure of central tendency, which are median for rank transformed and back-transformed estimated marginal means for others.

[b] Magnitude of Difference is calculated as $(MCT_{Exposed} - MCT_{Reference})/(MCT_{Reference}))*100$. MCT = measure of central tendency, which are median for rank transformed and back-transformed estimated marginal means for others.

ANOVA P-value < 0.05.
Significant decrease in concentration.
Significant increase in concentration.

Note: "nc" indicates no comparison available; "ns" indicates not significant.

[a] Magnitude of Difference is calculated as $(MCT_{recent\ year} - MCT_{older\ year})/ MCT_{older\ year})*100$. MCT = measure of central tendency, which are median for rank transformed and back-transformed estimated marginal means for others.

[b] Magnitude of Difference is calculated as $(MCT_{Exposed} - MCT_{Reference})/(MCT_{Reference}))*100$. MCT = measure of central tendency, which are median for rank transformed and back-transformed estimated marginal means for others.

APPENDIX C
PERIPHYTON PRODUCTIVITY AND COMMUNITY

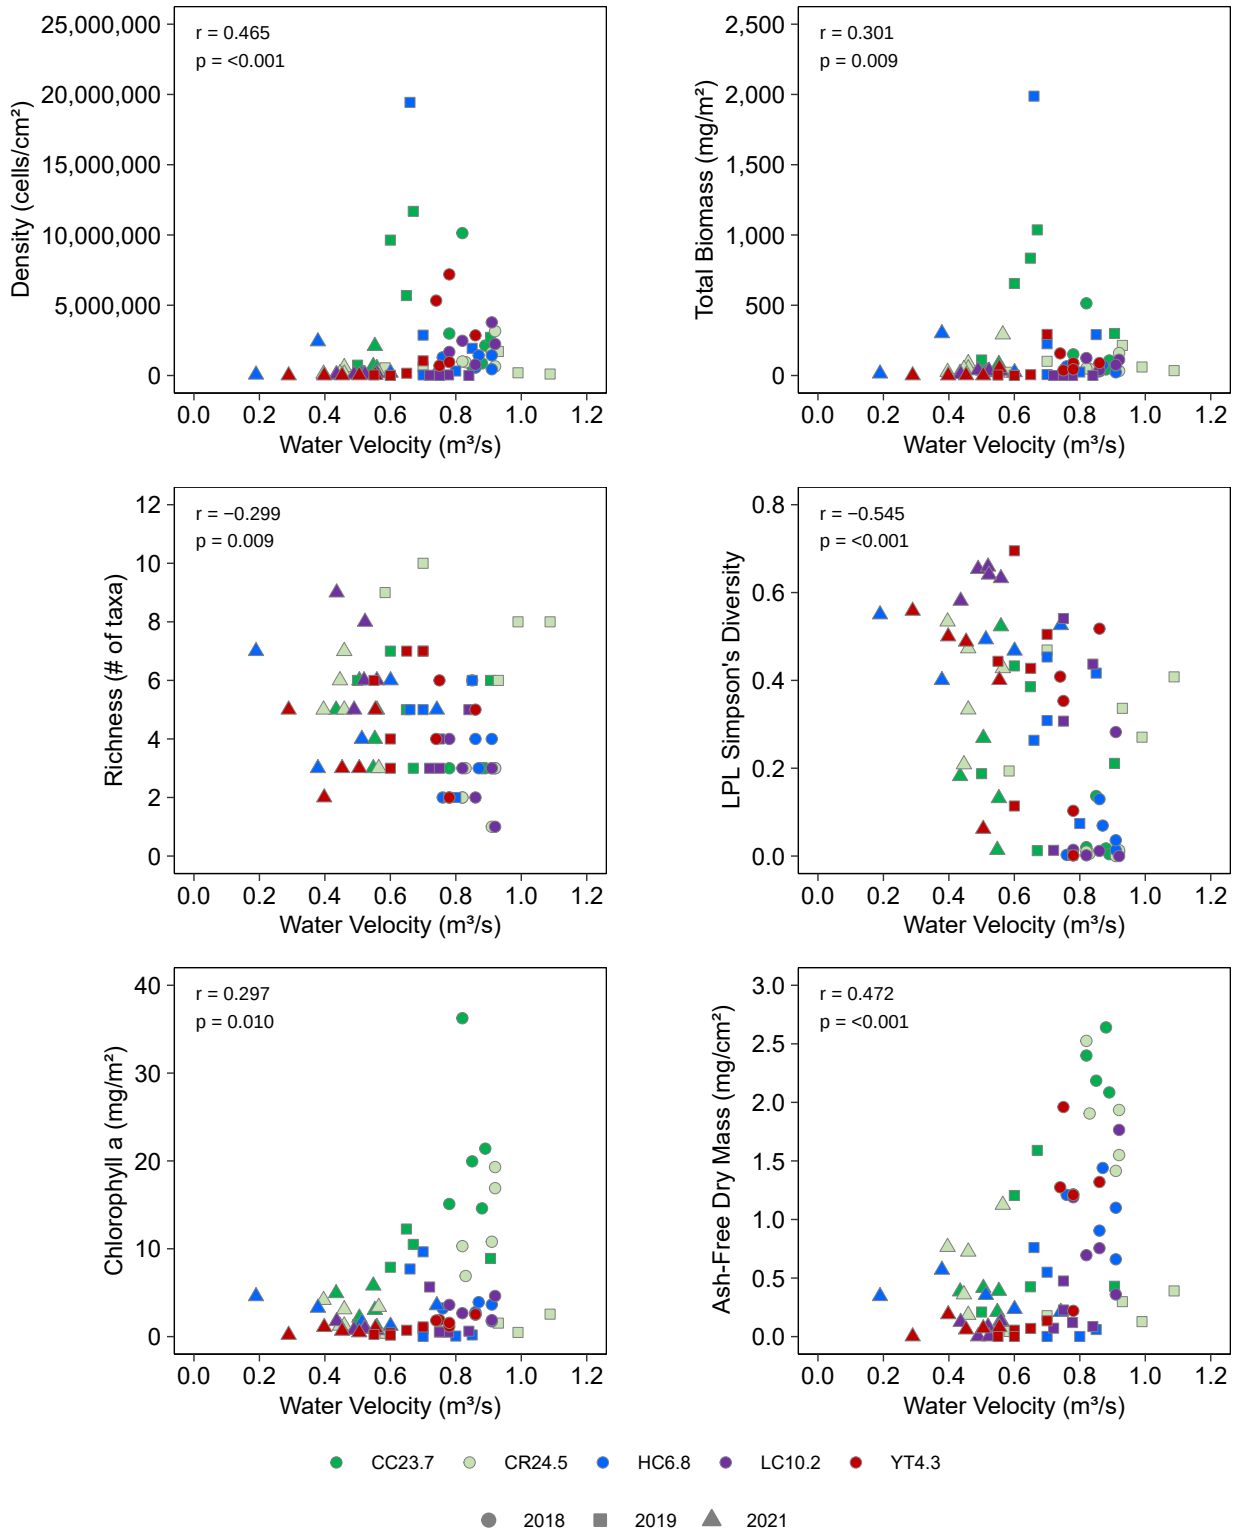

Figure C.1: Correlations between Periphton Community Endpoints and Physiochemical Parameters, Upper Creek Areas, 2018 to 2021

Notes: Stations shown in green are reference areas and all other colours are future-exposed.

ANOVA P-value < 0.1.
> 2 SD Decrease in endpoint relative to reference.
> 2 SD Increase in endpoint relative to reference.

Note: "nc" indicates no comparison available; "ns" indicates not significant. "-" indicates magnitude of difference could not be calculated when pooled standard deviation or median absolute deviation equal to 0. Logp1 indicates log10(x+1).

[a] Magnitude of Difference is calculated as $(MCT_{recent\ year} - MCT_{older\ year})/MAD_{pooled}$ for rank transformation and $(MCT_{recent\ year} - MCT_{older\ year})/SD_{pooled}$ for all other transformations. MAD_{pooled} = pooled median absolute deviation and SD_{pooled} = pooled standard deviation. MCT = measure of central tendency, which are median for rank transformed and back-transformed estimated marginal means for all others.

[b] Magnitude of Difference is calculated as $(MCT_{Exposed} - MCT_{Reference})/(MAD_{pooled})$ for rank transformation and $(MCT_{Exposed} - MCT_{Reference})/(SD_{pooled})$ for all other transformations. MAD_{pooled} = pooled median absolute deviation and SD_{pooled} = pooled standard deviation. MCT = measure of central tendency, which are median for rank transformed and back-transformed estimated marginal means for all others.

ANOVA P-value < 0.1.

> 2 SD Decrease in endpoint relative to reference

> 2 SD Increase in endpoint relative to reference

Note: "nc" indicates no comparison available; "ns" indicates not significant. "-" indicates magnitude of difference could not be calculated when pooled standard deviation or median absolute deviation equal to 0. Logp1 indicates log10(x+1).

[a] Magnitude of Difference is calculated as $(MCT_{recent\ year} - MCT_{older\ year})/MAD_{pooled}$ for rank transformation and $(MCT_{recent\ year} - MCT_{older\ year})/SD_{pooled}$ for all other transformations. MAD_{pooled} = pooled median absolute deviation and SD_{pooled} = pooled standard deviation. MCT = measure of central tendency, which are median for rank transformed and back-transformed estimated marginal means for all others.

[b] Magnitude of Difference is calculated as $(MCT_{Exposed} - MCT_{Reference})/(MAD_{pooled})$ for rank transformation and $(MCT_{Exposed} - MCT_{Reference})/(SD_{pooled})$ for all other transformations. MAD_{pooled} = pooled median absolute deviation and SD_{pooled} = pooled standard deviation. MCT = measure of central tendency, which are median for rank transformed and back-transformed estimated marginal means for all others.

ANOVA P-value < 0.1.
> 2 SD Decrease in endpoint relative to reference
> 2 SD Increase in endpoint relative to reference

Note: "nc" indicates no comparison available or comparison completed in adjacent cell; "ns" indicates not significant. Logp1 indicates log10(x+1).

[a] Magnitude of Difference is calculated as $(MCT_{recent\ year} - MCT_{older\ year})/MAD_{pooled}$ for rank transformation and $(MCT_{recent\ year} - MCT_{older\ year})/SD_{pooled}$ for all other transformations. MAD_{pooled} = pooled median absolute deviation and SD_{pooled} = pooled standard deviation. MCT = measure of central tendency, which are median for rank transformed and back-transformed estimated marginal means for all others.

[b] Magnitude of Difference is calculated as $(MCT_{Exposed} - MCT_{Reference})/(MAD_{pooled})$ for rank transformation and $(MCT_{Exposed} - MCT_{Reference})/(SD_{pooled})$ for all other transformations. MAD_{pooled} = pooled median absolute deviation and SD_{pooled} = pooled standard deviation. MCT = measure of central tendency, which are median for rank transformed and back-transformed estimated marginal means for all others.

ANOVA P-value < 0.1.

> 2 SD Decrease in endpoint relative to reference

> 2 SD Increase in endpoint relative to reference

Note: "nc" indicates no comparison available; "ns" indicates not significant. "Logp1" indicates log10(x+1).

[a] Magnitude of Difference is calculated as $(MCT_{recent\ year} - MCT_{older\ year})/MAD_{pooled}$ for rank transformation and $(MCT_{recent\ year} - MCT_{older\ year})/SD_{pooled}$ for all other transformations. MAD_{pooled} = pooled median absolute deviation and SD_{pooled} = pooled standard deviation. MCT = measure of central tendency, which are median for rank transformed and back-transformed estimated marginal means for all others.

[b] Magnitude of Difference is calculated as $(MCT_{Exposed} - MCT_{Reference})/(MAD_{pooled})$ for rank transformation and $(MCT_{Exposed} - MCT_{Reference})/(SD_{pooled})$ for all other transformations. MAD_{pooled} = pooled median absolute deviation and SD_{pooled} = pooled standard deviation. MCT = measure of central tendency, which are median for rank transformed and back-transformed estimated marginal means for all others.

APPENDIX E
BENTHIC INVERTEBRATE
TISSUE CHEMISTRY

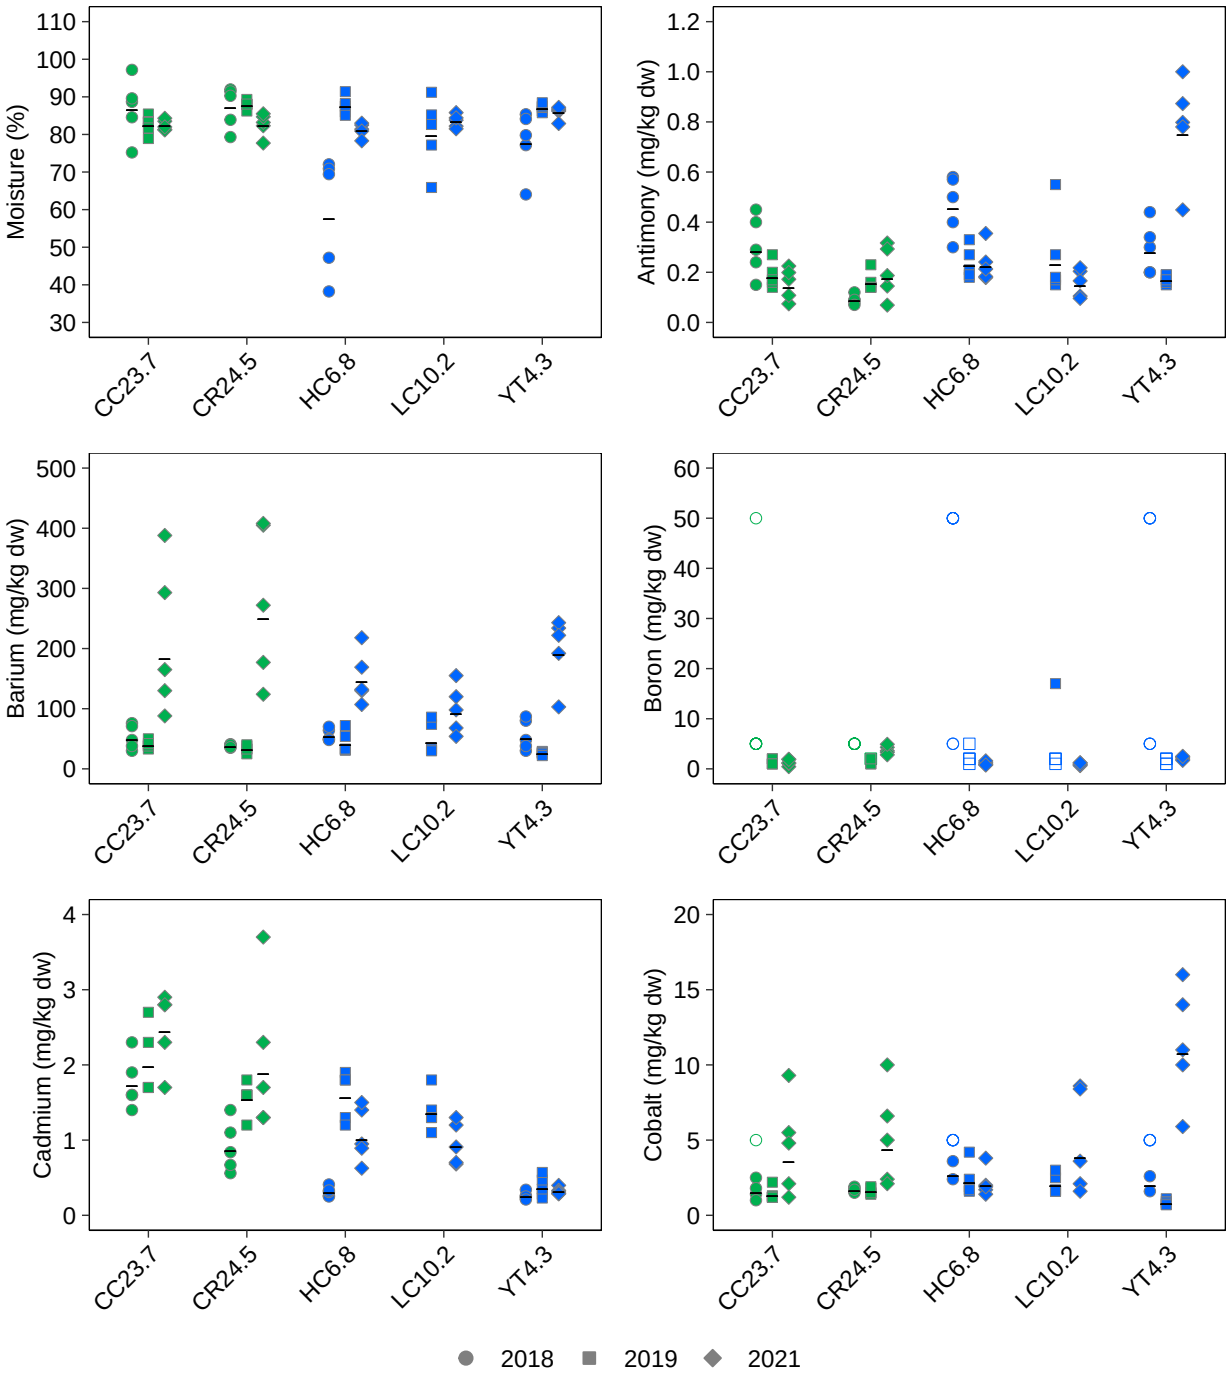

Figure E.1: Coffee Project FALMP Benthic Invertebrate Tissue Composition, Non-Key Analyte Concentrations, Upper Creek Areas, 2018 to 2021.

Notes: Plots for Key Indicator Analytes (e.g. arsenic, uranium, zinc) included in main text (see section 7). Green represents reference stations and blue represents future-exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Horizontal lines indicate measure of central tendency (MCT) used in the statistical analyses. Boron and tin were excluded from analyses because 100% of the data were at the LDL in 2018 and/or 2019. MCT's are not shown for these parameters.

Boron and tin were excluded from analyses because 100% of the data were at the LDL in 2018 and/or 2019. MCT's are not shown for these parameters.

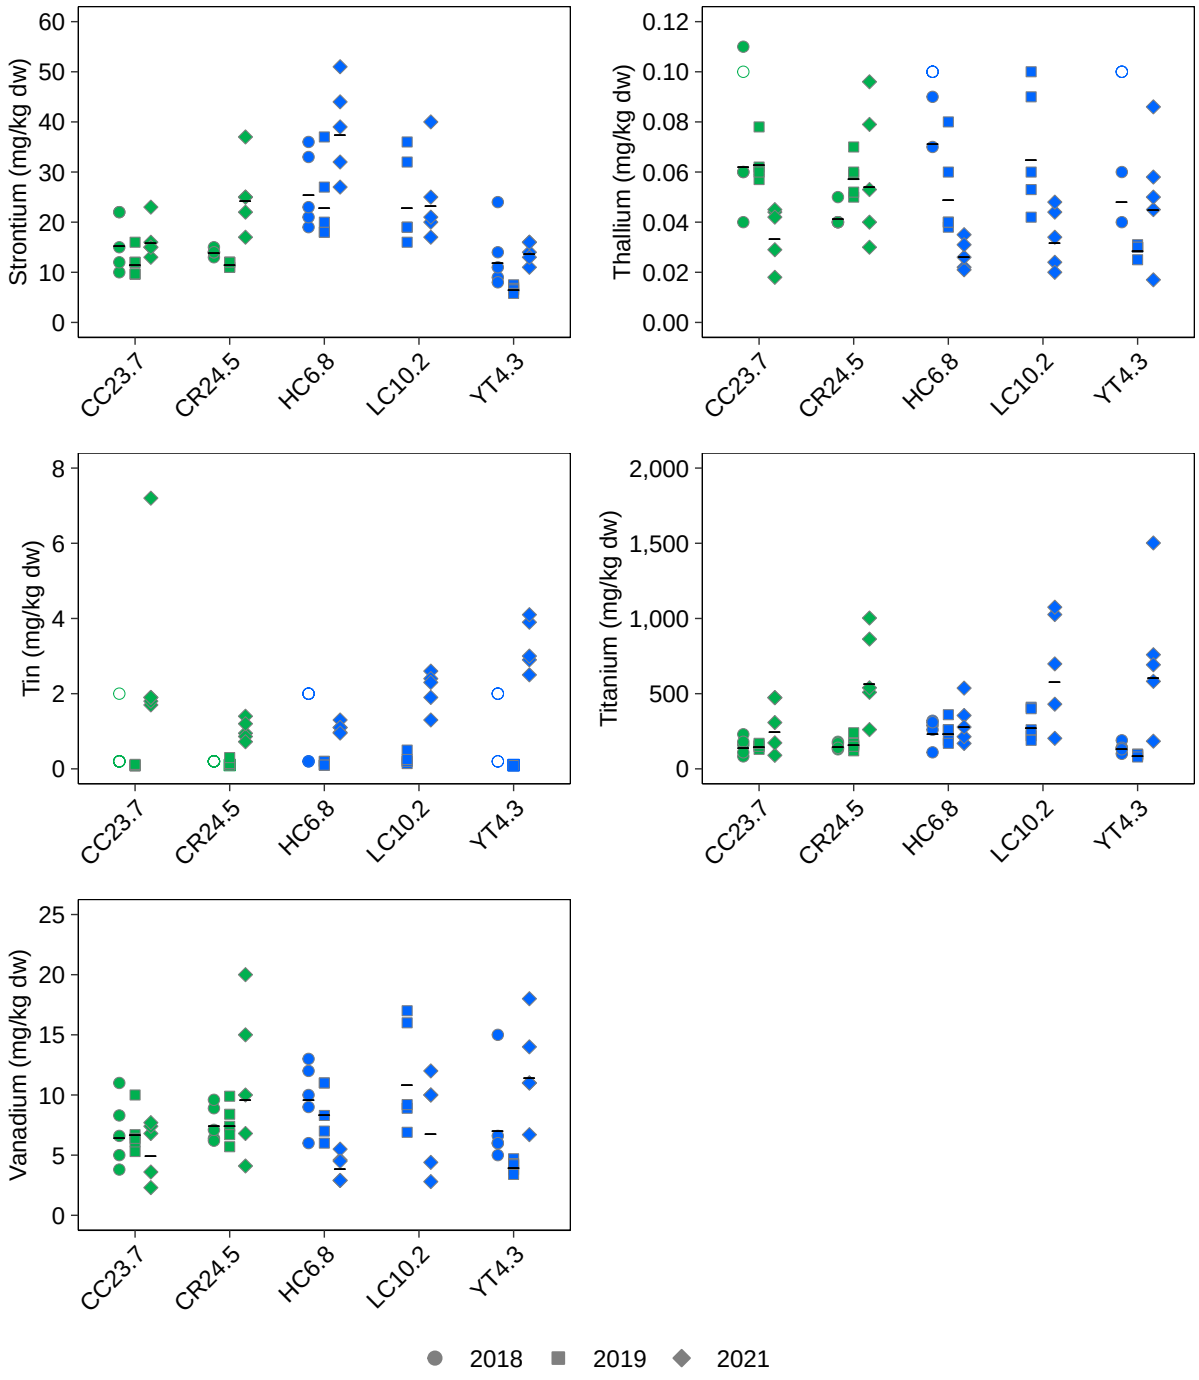

Figure E.1: Coffee Project FALMP Benthic Invertebrate Tissue Composition, Non-Key Analyte Concentrations, Upper Creek Areas, 2018 to 2021.

Notes: Plots for Key Indicator Analytes (e.g. arsenic, uranium, zinc) included in main text (see section 7). Green represents reference stations and blue represents future-exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Horizontal lines indicate measure of central tendency (MCT) used in the statistical analyses. Boron and tin were excluded from analyses because 100% of the data were at the LDL in 2018 and/or 2019. MCT's are not shown for these parameters.

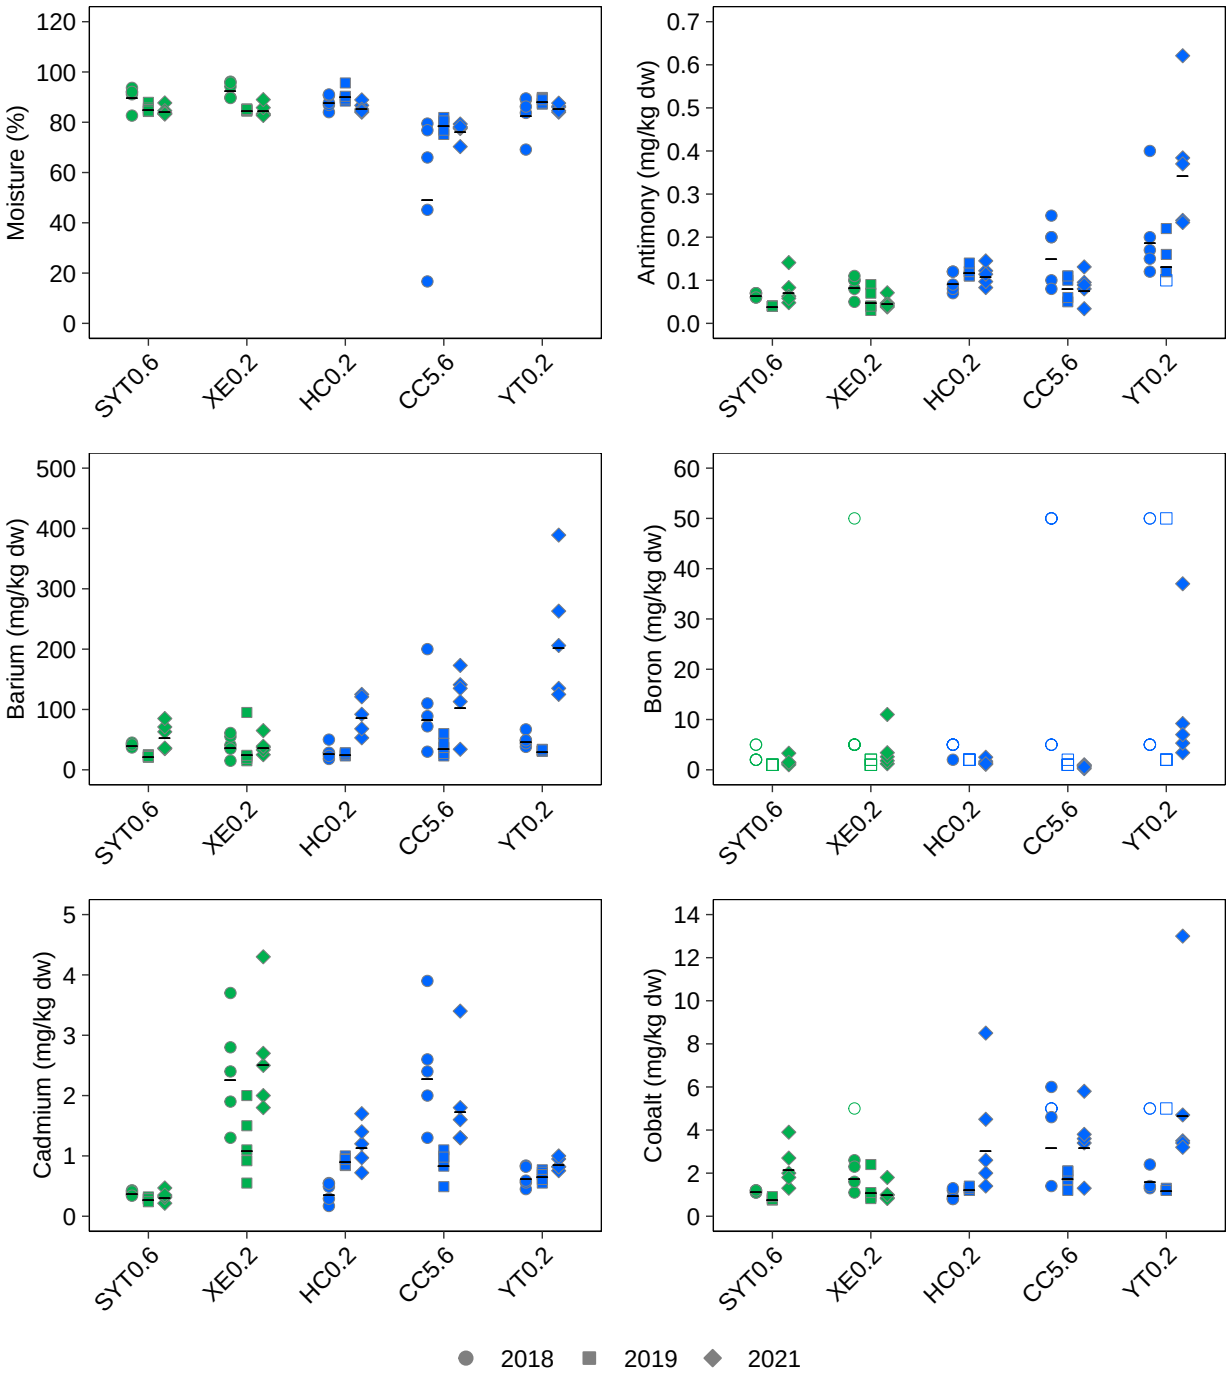

Figure E.2: Coffee Project FALMP Benthic Invertebrate Tissue Composition, Non-Key Analyte Concentrations, Lower Creek Areas, 2018 to 2021.

Notes: Plots for Key Indicator Analytes (e.g. arsenic, uranium, zinc) included in main text (see section 7). Green represents reference stations and blue represents future-exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. Horizontal lines indicate measure of central tendency (MCT) used in the statistical analyses. Boron and tin were excluded from analyses because 100% of the data were at the LDL in 2018 and/or 2019. MCT's are not shown for these parameters.

ANOVA P-value < 0.05.
Significantly Decrease in Concentration.
Significantly Increase in Concentration.

Note: "-" indicates no comparison available and no data; "ns" indicates not significant. Analysis of Variance (ANOVA) model consisted of a censored regression model with factors Year and Station and assuming a log-normal distribution. Boron and Tin were excluded from the analyses because 100% of the data were at detection limit in 2018 and/or 2019.

[a] MOD is calculated as $((year_{recent} - year_{older})/year_{older})*100$.

[b] MOD calculated as (Exposed - Reference)/(Reference)*100.

[c] 2018 Benthic Invertebrate Tissues from LC10.2 (n=5) were lost either en route to or at SRC Laboratories.

Table E.2: Statistical Temporal and Spatial Comparisons of Benthic Invertebrate Tissue Composition Data, Upper Creek Areas,

ANOVA P-value < 0.05.

Significantly Decrease in Concentration.

Significantly Increase in Concentration.

Note: "-" indicates no comparison available and no data; "ns" indicates not significant. Analysis of Variance (ANOVA) model consisted of a censored regression model with factors Year and Station and assuming a log-normal distribution. Boron and Tin were excluded from the analyses because 100% of the data were at detection limit in 2018 and/or 2019.

[a] MOD is calculated as $((year_{recent} - year_{older})/year_{older})*100$.

[b] MOD calculated as (Exposed - Reference)/(Reference)*100.

[c] 2018 Benthic Invertebrate Tissues from LC10.2 (n=5) were lost either en route to or at SRC Laboratories.

ANOVA P-value < 0.05.

Significant decrease in concentration.

Significant increase in concentration.

Note: "-" indicates no comparison available; "ns" indicates not significant. Analysis of Variance (ANOVA) model consisted of a censored regression model with factors Year and Station and assuming a log-normal distribution. Boron and Tin were excluded from the analyses because 100% of the data were at detection limit in 2018 and/or 2019.

[a] MOD is calculated as $((year_{recent} - year_{older})/year_{older})*100$.

[b] MOD calculated as (Exposed - Reference)/(Reference)*100.

APPENDIX F
SEDIMENT CHEMISTRY

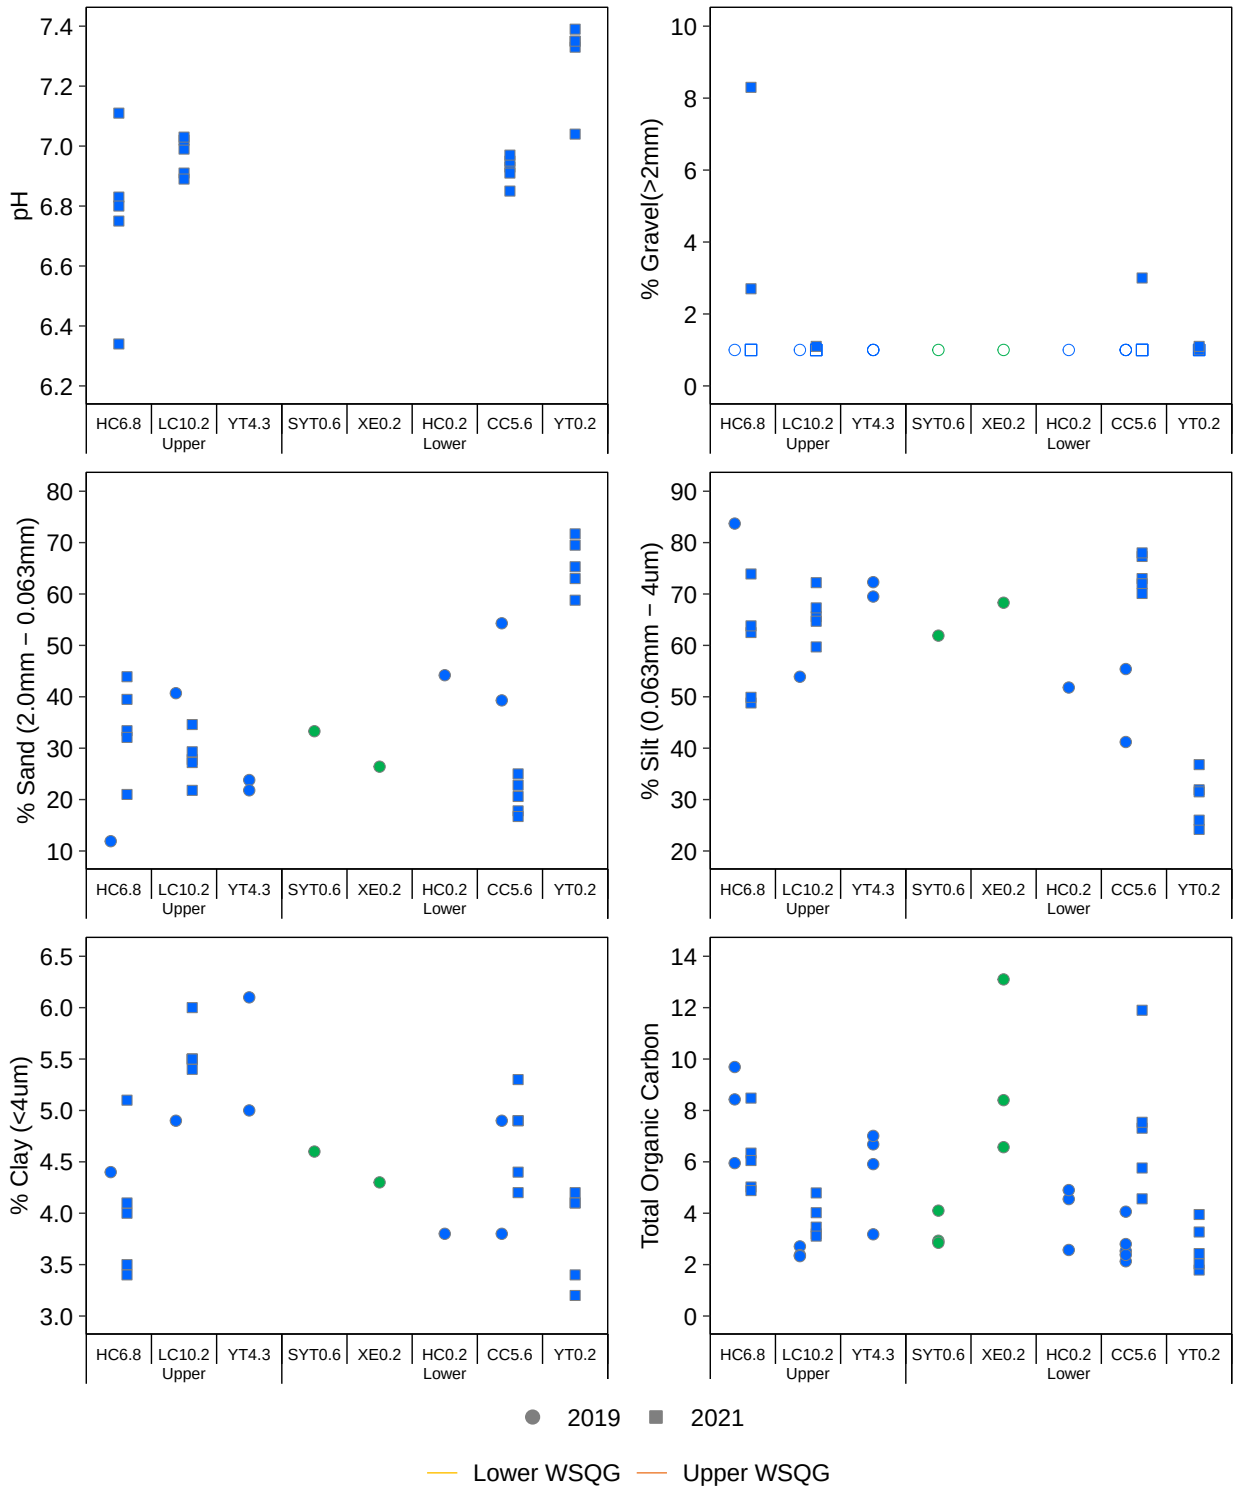

Figure F.1: Sediment Analyte Concentrations from Upper and Lower Tributaries of the Coffee Project AEMP, 2019 to 2021

Notes: Green represents future reference stations and blue represents future-exposed stations. Concentrations below the laboratory reporting limit (LRL) are plotted as open symbols at the LRL. WSQGs are British Columbia Working or Approved (selenium) Sediment Quality Guidelines (BCMOECCS 2019c, 2021). All WSQGs are consistent with Canadian Sediment Quality Guidelines (CCME 2001) with the exception of Iron, Manganese, Molybdenum, Nickel, Selenium and Silver for which there are no CCME guidelines.

Value is > BC Working Sediment Quality Guideline and Canadian Sediment Quality Guideline Effect Lower Level.

Value is > BC Working Sediment Quality Guideline and Canadian Sediment Quality Guideline Effect Upper Level.

Notes: "-" = no data. BCWSQG = British Columbia Working Sediment Quality Guideline (BCMOECCS 2021) and approved BC Sediment Quality Guideline for Selenium (BCMOECCS 2019c). CCME = Canadian Sediment Quality Guideline (CCME 2001). All WSQG and CCME Guidelines are the same except for the Iron, Manganese, Molybdenum, Nickel, Selenium and Silver that there is no CCME guideline.

P-value < 0.05.

Magnitude of Difference (MOD) > 0 and p-value < 0.05.

Magnitude of Difference (MOD) < 0 and p-value < 0.05.

Notes: "nt" = not tested when parameters had 100% concentrations recorded at the LRL. Comparisons were made using a T-Test (tequal) unless assumption of normality was violated or there were values at the laboratory reporting limit (LRL) forcing the use of a Mann-Whitney U test (M-W). MOD = Magnitude of Difference = $(MCT_{2021} - MCT_{2019})/MCT_{2019} * 100$. MCT = Measure of Central Tendency; MCT reported as mean for untransformed data, median for rank-transformed data and geometric mean for log10-transformed data. Parameters that had 100% concentrations recorded at the LRL at all three stations in two years, had less than three samples per station per year, and/or had only one year data were excluded from the analyses.

G1 INTRODUCTION

This Data Quality Review (DQR) provides an evaluation of data collected as part of the Coffee Project FALMP baseline benthic invertebrate, periphyton, and sediment sampling conducted in 2018, 2019, and 2021. The objective of the DQR is to define the overall quality of the data presented in the report, and, by extension, the confidence with which the data can be used to derive conclusions.

G1.1 Background

A variety of factors can influence the physical, chemical, and biological measurements made in an environmental study and thus affect the accuracy and/or precision of the data. Depending on their magnitude, inaccuracy or imprecision have the potential to affect the reliability of conclusions made from the data. Therefore, it is important to ensure that programs incorporate appropriate steps to control the non-natural sources of data variability (i.e., minimize the variability that does not reflect natural spatial and temporal variability in the environment) and thus assure the quality of the data. Data quality as a concept is meaningful only when it relates to the intended use of the data. That is, one must know the context in which the data will be interpreted in order to establish a relevant basis for judging whether or not the data set is adequate. A DQR involves comparison of actual field and laboratory measurement performance to Data Quality Objectives (DQOs) established for a particular study, such as evaluation of Laboratory Reporting Limits (LRL), blank sample data, data precision (based on field and laboratory duplicate samples), and data accuracy (based on matrix spike recoveries and/or analysis of standards or certified reference materials). Trusted analytical laboratories certified by Canadian Association for Laboratory Accreditation (CALA) with a rigorous internal quality assurance program was selected to ensure the highest possible data quality. DQOs were established *a priori* to reflect reasonable and achievable performance expectations. Programs involving a large number of samples and analytes usually yield some results that exceed DQOs. This is particularly so for multi-element scans since the analytical conditions are not necessarily optimal for every element included in the scan. Generally, scan results may be considered acceptable if no more than 20% of the parameters fail to meet DQOs. Overall, the intent of DQR is not to reject any measurement that did not meet a DQO, but to ensure that any questionable data received more scrutiny to determine what effect, if any, this had on interpretation of results within the context of the project.

A Data Quality Review (DQR) was conducted on all laboratory data collected as part of Project FALMP baseline data analysis. The objective of DQR is to define the overall quality of the

data presented in the report, and, by extension, the confidence with which the data can be used to derive conclusions.

A DQR involves the examination of analytical results associated with several types of Quality Control (QC) samples collected (or prepared) in the field and laboratory. General QC samples collected for this project, and a description of each, include the following:

G1.2 Types of Quality Control Samples

- **Blanks** are samples of de-ionized water and/or appropriate reagent(s) that are handled and analyzed in the same way as regular samples. These samples will reflect any contamination of samples occurring in the field (in the case of field or travel blanks) or in the laboratory (in the case of laboratory or method blanks). Analyte concentrations should be non-detectable.
- **Laboratory Duplicates** are sub-sample pairs created in the laboratory from randomly selected field samples which are sub-sampled and then analyzed independently using identical analytical methods. The laboratory duplicate sample results reflect any variability introduced during laboratory sample handling and analysis and thus provide a measure of laboratory precision.
- **Laboratory Control Samples** are created in the laboratory to have a known analyte concentration in a matrix free of interferences, such as deionized water or reference sand. The sample results are compared to the target results to confirm that the analytical method is accurate in a purified reference sample. The results are reported as the percent of the known concentration that was recovered in the analysis.

Two types of QC were only applied to benthic community samples as follows:

- **Laboratory Sorting Duplicates** are randomly selected grabs of the initially sorted community material. These samples are recounted and the number of invertebrates that were not recovered during the initial sort was determined. In order to reduce bias, the recounting was conducted by an analyst uninvolved in the initial sample processing. This check was performed on 10% of samples and determines the accuracy through assessment of recovery (sorting) efficiency and quantifies any under-estimation of organism enumeration.

One QC type was specific to benthic community and also to periphyton community samples as follows:

- **Laboratory Subsamples** are community samples prepared by the laboratory to ensure that the fraction of the total sample examined was an accurate representation of the total number of organisms. By comparing the amount recovered between at least two sub-samples, one can assess the analytical precision. In addition, comparisons of the sub-samples from the whole community sample allows for an evaluation of sub-sampling accuracy.

G2 PERIPHYTON COMMUNITY

G2.1 Laboratory Reporting Limits

Dry weight, ash weight, ash-free dry weight (AFDM), and chlorophyll-a results from 2018, 2019, and 2021 (L2157659, L2337313, and WR2101119, respectively; Appendix H) were examined to provide an inventory of analytes that were less than the LRL. All individual chlorophyll-a measures across all years were found to be above the LRL (Appendix H). All 2018 AFDM results from 2018 were above the LRL, whereas 6 (12%) and 7 (14%) were below the LRL in 2019 and 2021, respectively (Appendix H). Therefore, the achieved LRLs are appropriate for the study.

G2.2 Laboratory Blanks

Three method blank (MB) samples each from 2018 (WG2876899-1, WG2876899-3, and WG2876899-5), 2019 (WG3156219-1, WG3156219-3, and WG3156219-5), and 2021 (QC-280315-001, QC-280316-001, and QC-280317-001) were analyzed in the ALS Laboratory Reports (L2157659, L2337313, and WR2101119; Appendix G). The blank dry weight, ash weight, ash-free dry weight, and chlorophyll-a results were below the LRL and laboratory DQO for all MB samples, meaning that laboratory contamination had no observable impact on the results.

G2.3 Data Accuracy

Chlorophyll-a accuracy was evaluated based on results of five LCS samples from 2018 (WG2880159-2, WG2882403-2, WG2882403-4, WG2882444-2, and WG2882444-4), and three each from 2019 (WG3157665-2, WG3157665-4, and WG3157665-6) and 2021 (QC-280315-002, QC-280316-002, and QC-280317-002) which both met the laboratory DQO (within 20% of accepted value, L2157659, L2337313, and WR2101119; Appendix H). The accuracy achieved by the laboratory in this study can therefore be considered excellent.

G2.4 Density Accuracy

Periphyton density was re-measured in a total of five samples per year in 2018, 2019 and 2021 (10% of all samples) to evaluate sub-sampling accuracy and taxonomic consistency within the periphyton enumeration and identification laboratory report (Appendix H). Since there was a high percent of agreement between the duplicate pairs across all years (2018 mean 87%; 2019 mean 89%, 2021 mean 89%) the samples is considered to have good field subsampling precision and reproducibility (Appendix Table G.1).

G2.5 Data Quality Statement

Periphyton community data collected for the Project FALMP were of acceptable quality as characterized by good sub-sampling accuracy. Additionally, productivity measurements (dry weight, ash weight, and chlorophyll-a) results were of acceptable detectability, negligible analyte concentrations in method blanks, good laboratory precision, and good laboratory accuracy. Therefore, the associated data can be used with a good level of confidence in the derivation of conclusions.

Table G.1: Laboratory Duplicate Results for Analysis of Periphyton Total Density (cells/cm^2), 2018, 2019, and 2021

Year	Sample ID	Laboratory ID	Original Density (cells/cm^2)	Quality Assurance Density (cells/cm^2)	Percent Agreement (%)[a]

[a] Percent agreement calculated as: (100- [(difference in abundance between samples) / total abundance of original sample)] *100)%.

G3 BENTHIC INVERTEBRATE COMMUNITY

Five benthic invertebrate samples each from 2018, 2019, and 2021 were re-sorted to assess sorting efficiency. Sorting accuracy for all but one sample in 2018 (CF3.9-5) met the objective for percent organism recovery; with recovery over 90% (Table G.2). The one sample which did not meet the 90% target reached 89% sorting efficiency, missing only one organism. This low efficiency was therefore exaggerated because CF3.9-5 was a particularly depauperate sample. Of 50 benthic invertebrate community samples analyzed for each year 43 sampling in 2018, 22 in 2019, and 29 in 2021 were analyzed whole. The remaining samples were subsampled at percentages ranging from 48% to 88% in 2018, 31% to 75% in 2019, and 25% to 80% in 2021 (Table G.3). This indicates that the benthic invertebrate data can be reliably interpreted.

G4 BENTHIC INVERTEBRATE TISSUE SAMPLES

G4.1 Laboratory Reporting Limits

Eight benthic invertebrate tissue analytes each in 2018 and 2019 were below LRLs and did not meet targets: antimony (2019 - 1 of 50 samples), boron (2018 – 44 of 50 samples, 2019 -41 of 50 samples), chromium (2018 – 6 of 50 samples, 2019 - 1 of 50 samples), cobalt (2018 – 12 of 50 samples, 2019 - 1 of 50 samples), lead (2019 - 1 of 50 samples), molybdenum (2018 – 1 of 50 samples), nickel (2018 – 10 of 50 samples, 2019 - 1 of 50 samples), silver (2018 – 2 of 50 samples), thallium (2018 – 12 of 50 samples, 2019 - 1 of 50 samples), and tin (2018 – 42 of 50 samples, 2019 - 13 of 50 samples; Table G.4). No benthic invertebrate tissue analytes were below LRLs in 2021, potentially due to the change in laboratory subcontractor. Target concentrations are not guidelines but represent detection limits quoted by the laboratory. Benthic invertebrate tissue data for this project can be reliably interpreted.

G4.2 Data Precision

Laboratory duplicate benthic invertebrate tissue samples were analyzed in 2021 only and showed good agreement among all duplicate analyte concentrations (Appendix H). Benthic invertebrate tissue chemistry samples were associated with good analytical precision.

Table G.2: Percent Sorting Efficiency of Benthic Invertebrate Community Samples, 2018, 2019, and 2021

Year	Station	Initial Sort	Re-sort	Percent Sorting Efficiency [a]
2018	CF3.9-5	9	1	89%
	HFO.2-2	112	1	99%
	XE0.2-1	325	1	100%
	XE0.2-4	506	23	95%
	YT4.6-1	67	1	99%
			Average Recovery	**96.4%**
2019	CC5.6-2	125	5	96%
	XE0.2-1	392	5	99%
	YT0.2-3	226	2	99%
	SYT0.6-4	320	0	100%
	YT4.3-2	255	3	99%
			Average Recovery	**98.6%**
2021	SYT0.6-1	395	5	99%
	YT0.2-2	371	0	100%
	YT4.3-1	310	7	98%
	LC10.2-2	239	11	95%
	LC10.2-4	216	9	96%
			Average Recovery	**97.6%**

Sorting efficiency < 90%.

[a] Percent sorting efficiency = (1-(# in QA/AC re-sort / (# sorted originally + # in QA/QC re-sort)))* 100.

G5 SEDIMENT SAMPLES

G5.1 Laboratory Reporting Limits

Results for eight analytes were reported as less than LRL (7 in 2019, 8 in 2021) but only mercury, selenium, and silver had associated guidelines (Table G.5). Mercury and selenium LRLs were below the Canadian Sediment Quality Guideline (CSQG; CCME 1999; Table G.5). Analytes with guidelines detectable in the majority of samples indicating that the data can be reliably interpreted.

G5.2 Laboratory Blank Sample Analysis

All method blank samples across both years contained non-detectable analyte concentrations indicating no inadvertent contamination of samples within the laboratory during analysis (Appendix H).

G5.3 Data Precision

Agreement was achieved between all laboratory duplicate samples across both years, indicating excellent analytical precision.

Table G.4: Evaluation of < Laboratory Reporting Limit (LRL) Benthic Invertebrate and Periphyton Tissue Chemistry Results Relative to Reporting Limits, 2018, 2019, and 2021

Parameter	Units	British Columbia Interim Dietary Guidelines [a]	Range of LRLs (2018 to 2019)	LRLs[b] (2021)	2018 No. Sample Results <LRL	2019 No. Sample Results <LRL	2021 No. Sample Results <LRL
Metals							
Antimony	µg/g	-	0.01 to 0.1	0.135	0	1 (2%)	0
Boron	µg/g	-	1 to 50	0.004	44 (88%)	41 (82%)	0
Chromium	µg/g	-	1 to 5	0.356	6 (12%)	1 (2%)	0
Cobalt	µg/g	-	0.5 to 5	0.008	12 (24%)	1 (2%)	0
Lead	µg/g	-	0.5	0.001	0	1 (2%)	0
Molybdenum	µg/g	-	0.5	0.001	1 (2%)	0	0
Nickel	µg/g	-	1 to 5	0.043	10 (20%)	1 (2%)	0
Silver	µg/g	-	0.02	0.001	2 (4%)	0	0
Thallium	µg/g	-	0.01 to 0.1	0.001	12 (24%)	1 (2%)	0
Tin	µg/g	-	0.1 to 2	0.035	42 (84%)	13 (26%)	0

Note: LRL = Laboratory Reporting Limit. "-" indicates that no guideline is available.

[a] British Columbia Approved Water Quality Guidelines (BCMOECCS 2019).

[a] Detection limits changed following change in laboratory subcontractor to TrichAnalytics in 2021.

G6 DATA QUALITY STATEMENT

All data quality objectives for periphyton community and benthic invertebrate community were met. Chlorophyll-a and AFDM met all data quality objectives and was deemed acceptable. For benthic invertebrate tissue chemistry, the LRL target values were met for all analytes except for antimony, boron, chromium, cobalt, lead, molybdenum, nickel, silver, thallium, and tin in some 2018 and 2019 samples. All LRL target values were met for all 2021 benthic invertebrate tissue chemistry samples. However, all applicable guidelines could be met with the 2021 laboratory limits.

Laboratory accuracy and precision was considered excellent across all components. Where applicable, method blanks, duplicates, and laboratory control samples met the laboratory data quality objectives.

The overall quality of data for this project was considered good and can serve to meet the project objectives.

Table G.5: Evaluation of < Laboratory Reporting Limit (LRL) Sediment Chemistry Results Relative to Guidelines, 2018, 2019, 2021[a]

Analyte	Unit	BCWSG[b]		2019		2021	
		Long-term	Short-term	Maximum LRL	No. Sample Results <LRL	Maximum LRL	No. Sample Results <LRL
Particle Size							
% Gravel (>2 mm)	%	-	-	1	9 (100%)	1	14 (70%)
Metals							
Bismuth	mg/kg	-	-	0.20	23 (96%)	0.2	15 (75%)
Boron	mg/kg	-	-	5	24 (100%)	5	20 (100%)
Mercury	mg/kg	0.17	0.486	0.05	0	0.05	8 (40%)
Selenium	mg/kg	2	-	0.20	10 (42%)	0.2	10 (50%)
Silver	mg/kg	0.5	-	0.10	17 (71%)	0.1	13 (65%)
Sulphur	mg/kg	-	-	1000	23 (96%)	1000	20 (100%)
Tin	mg/kg	-	-	1.0	24 (100%)	1	20 (100%)
Tungsten	mg/kg	-	-	0.50	21 (88%)	0.5	17 (85%)

Note: "-" = no applicable guideline.

[a] Only analytes with reported values less than LRL were presented.

[b] British Columbia Working Sediment Guidelines (BCWSG; BCMOECCS 2021) and approved BC Sediment Quality Guideline for Selenium (BCMOECCS 2019).
