Whitehorse, Yukon Y1A 2J9

Executive Summary

Introduction

The Government of Yukon (YG) Assessment and Abandoned Mines (AAM) and the Government of Canada (Canada), as represented by Aboriginal Affairs and Northern Development Canada (AANDC), are continuing to prepare a final remediation plan for the Faro Mine Complex (FMC). While preparing the Faro Mine Remediation Plan (FMRP), YG and AANDC will continue activities similar to those that have taken place at the FMC since mine operations ceased in 1998. These interim activities, called the Faro Mine Interim Works (IW), will continue for up to 10 years until YG and AANDC have completed the design, permitting, approvals and procurement for the FMRP. The IW are the subject of this Interim Works Project Proposal (IWPP) and have two main purposes:

1. To control and reduce the effects of the existing FMC on human health and safety, and the environment
2. To compile sufficient site and environmental information to support design, assessment and permitting for the FMRP

Proposed Project

The proposed IW include the following components:

1. Site Operations

Site operations are the ongoing site activities that prevent adverse effects of the FMC on persons, property, or the environment, and that mitigate adverse effects that occur. These include care and maintenance activities, as well as the implementation of comprehensive risk assessment, monitoring, and adaptive management programs. Because of changing conditions at the FMC, the site operations scope includes the implementation of responses that arise from the adaptive management plan (e.g., interim groundwater collection systems).

2. Site Investigations

Site investigation activities will occur throughout the site and extend over the duration of the proposed IW to support the development of the FMRP and the design of remediation and closure elements. Site investigation activities will include the following types of activities:

- Soil and rock sampling
- Geotechnical investigations
- Aquifer testing
- Environmental monitoring
- Field trials
- Vegetation sampling
- Wildlife surveys
- Aquatic studies
- Geophysics

Specific investigation requirements and locations will evolve to address site conditions, the results of sequential investigations, and design requirements.

3. Down Valley Interim Hydraulic Upgrades

The Down Valley Interim Hydraulic Upgrades (DVIHU) are intended to improve the flood routing capacity for the Down Valley Tailings Area. The Intermediate Dam (ID) spillway and the Rose Creek Diversion will be upgraded so that both facilities can convey the estimated flow for a 1-in-500-year flood event (115 cubic metres per second), the minimum suitable inflow design flood for these facilities to meet the guidelines in the Canadian Dam Association Dam Safety Guidelines (2007). The proposed upgrades will reduce flood-related risks during the 10-year IW duration, before construction of more robust upgrades as part of the FMRP. The DVIHU includes the following:

- Increasing the depth of the ID spillway
- Improving erosion protection in the ID spillway
- Constructing a temporary raise of the ID
- Increasing the capacity of the Rose Creek Diversion

DRAFT

It is likely that the ID interim upgrades will not experience flow during the IW period because they provide secondary flood-routing capacity. Primary flood routing is provided by the Rose Creek Diversion.

4. Ancillary Activities

Ancillary activities are also needed to support the site operations, site investigations and DVIHU tasks, and include the following activities:

- Site security and access control
- Emergency response
- Facilities and equipment
- Existing borrow areas
- Worker accommodations
- Supplies and energy sources
- Waste materials
- Fresh water
- Septic systems

Current Conditions

The FMC consists of the Faro Mine Area, the Rose Creek Tailings Area, and the Vangorda/Grum Area. The 14-kilometre Haul Road connects the Faro Mine Area and Vangorda/Grum Area.

- The Faro Mine Area includes the Faro Pit, approximately 30 waste rock dumps, ore processing and handling facilities, the Emergency Tailings Area, and the Faro Creek Diversion. It also includes contaminated water management facilities, including the S-Wells and ETA Seepage Interception Systems, and contaminated water pumping, conveyance, and treatment facilities.
- The Rose Creek Tailings Area covers an area of over 200 hectares in the original valley of Rose Creek. It comprises four dams – the Original, Secondary, Intermediate and Cross Valley Dams – and the Rose Creek Diversion. The Original, Secondary, and Intermediate Dams retain a total of 55 million tonnes of tailings in the Rose Creek valley. The Cross Valley Dam retains a pond that is used for final polishing of treated water.
- The Vangorda/Grum Area includes the Vangorda Pit, the Grum Pit, the Vangorda Waste Rock Dump, the Grum Waste Dump, the Grum Overburden Dump, the Grum Ore Transfer Pad, the Vangorda Creek Diversion, the Vangorda Water Treatment Plant, and the Little Creek Dam. There are no tailings stored at the Vangorda/Grum Area because all ore was processed in facilities at the Faro Mine Area.

The FMC is a legacy mining project that presents long-term chemical and physical stability risks. Much of the waste material at the FMC is acid-generating. Tailings, waste rock, and pit walls continue to oxidize and release contaminants. Water infiltration has led to contaminated seepage and groundwater downgradient of some waste rock dumps, and seepage interception systems currently operate in some areas. Contaminants from the tailings are migrating into the Rose Creek Alluvial Aquifer, which flows beneath the tailings. None have reached concentrations that are ecologically significant to warrant collection and treatment. Because of the contaminant load associated with the tailings, the physical stability of the structures in the Rose Creek Tailings Area is critical to protect the downstream environment. In their current configuration, the dams achieve suitable factors of safety for seismic and static stability for the IW period. The flood routing capacity for the Rose Creek Tailings Area warrants improvement and will be addressed by the proposed DVIHU.

Since the mine ceased operating, YG and AANDC have conducted extensive monitoring programs and investigations to characterize environmental conditions at and around the FMC. These programs have collected, compiled, and analyzed data to characterize site conditions, reference (i.e., background) conditions, and mine effects. The results of these programs have been used to define the current baseline conditions for geology, soils, climate, air quality, groundwater, surface water, fish, fish habitat, wildlife and wildlife habitat.

As part of the closure planning process over the past 10 years, YG and AANDC have engaged with communities with the intent to be open and transparent and to provide information to support community understanding and involvement. Further research in 2013 provided supporting information to help define the current baseline conditions for First Nations and communities that may be affected by the proposed IW. The Devolution Transfer

DRAFT

Agreement (Public Works and Government Services Canada, 2001), lists the Affected First Nations for the Faro Type II mine site:

- Ross River Dena Council
- Liard First Nation
- Selkirk First Nation
- Kaska Dena Council

The Town of Faro is considered an affected community because of proximity and reliance on the project. It is the closest community to the FMC.

Environmental and Socio-economic Effects Assessment

The environmental and socio-economic effects assessment employed a valued-component (VC) -based approach to focus the assessment on key interactions between the project and the environment or people. The following VCs, selected by considering the environmental and socio-economic context and the type and scale of activities proposed for the IW, were assessed:

- Air quality
- Surface water quality
- Fish and fish habitat
- Wildlife and wildlife habitat
- Economy and employment
- Community stability and well-being
- Infrastructure and services
- Land use and access
- Culture and heritage
- Human health and safety

The environmental and socio-economic assessment used two main steps to identify and characterize effects. The first step identified potential interactions between IW activities and the VCs, then classified potential interactions according to the following criteria to create a matrix of project activities and VCs:

- “0” = No Interaction: no measurable interaction that could cause an effect
- “1” = Minor Interaction: minimal interaction where measureable effects are possible, but the effects will be avoided or suitably mitigated through compliance with regulatory requirements and application of standard best management practices
- “2” = Major Interaction: potential interaction where measurable effects are likely even with application of best management practices, or where understanding the scale or magnitude of effects requires detailed analysis

The second step characterized the “Major” interactions to define and describe the potential effects, and evaluate their significance.

The assessment addressed Minor interactions by identifying specific regulatory requirements and best management practices that will eliminate or suitably mitigate potential effects. For each Major interaction, the assessment followed a systematic approach to understand the interaction pathways, predict the effects, identify appropriate mitigation measures, evaluate the significance, and design monitoring plans.

The evaluation of significance of effects considered direction, magnitude, likelihood, duration, geographic extent, probability/frequency, reversibility and socio-economic context, as appropriate for each VC. Ratings of High, Moderate, or Low were established for each criterion, and for overall significance. Any interaction with a High rating for overall significance was deemed to be a significant effect that would require further mitigation. The project definition proceeded iteratively to address any potential significant adverse environmental or socio-economic effects.

DRAFT

Results and Conclusion

For air quality, the major potential effects of the IW are associated with release of dust from the FMC. The assessment evaluated the significance of the potential effects by comparing predicted concentrations of total suspended particulates, particulate matter (PM_{10} and $PM_{2.5}$), and metals against provincial and territorial air quality criteria.

For surface water quality and fish and fish habitat, the major potential effects of the IW are associated with release of contaminants of concern to receiving water. The assessment evaluated the potential effects of sulphate, cadmium, cobalt, iron, lead, manganese, and zinc. The evaluation of significance of potential effects compared predicted concentrations of contaminants for both normal and adverse conditions against water quality guidelines and aquatic toxicity thresholds.

For wildlife and wildlife habitat, the major potential effects arise from the permanent or temporary destruction or alteration of habitat, metals uptake through feeding or exposure, entrapment or drowning in site facilities, vehicle collisions or equipment-related trauma, or sensory disturbance (i.e., visual, olfactory, or auditory). The assessment evaluated effects on moose, Thinhorn sheep, grizzly bear, avian nesting habitat, waterfowl and small mammals. The evaluation of significance compared the expected effects of the IW against ecological objectives for habitat loss, mortality, local habitat use, and metals uptake.

For economy and employment, the major potential effects arise from the increased employment and spending. The assessment characterized the potential changes in business development, economic diversification, employment and income levels, and education and training.

For infrastructure and services, the major potential effects arise from the influx of workers. The assessment characterized potential effects on roads and traffic, housing, health services, emergency services, and community infrastructure.

For land use and access, the major potential effects arise from two pathways: (1) increased access to currently undisturbed areas during site investigations, and (2) changes in access to the area by local users, resulting from changes in access management at the FMC. The assessment characterized potential effects on traditional land use, hunting and fishing, recreation, tourism, and forestry.

For community stability and well-being, potential effects may arise from the potential influx of workers for certain IW activities. The assessment characterized potential effects on demographics, social cohesion and cultural well-being.

No major potential effect were identified for culture and heritage, and human health and safety. In addition, extreme events including floods, earthquakes, forest fires, and malfunctions and accidents are not expected to cause significant adverse environmental or socio-economic effects during the IW.

None of the ratings of overall significance are High, and therefore none of the potential effects exceed the defined threshold for overall significance. YG and AANDC have concluded that the IW will not cause significant adverse environmental or socio-economic effects.

DRAFT

SECTION 1

Introduction and Overview

The Government of Yukon (YG) Assessment and Abandoned Mines (AAM) and the Government of Canada (Canada), as represented by Aboriginal Affairs and Northern Development Canada (AANDC), are continuing to prepare a final remediation plan, the Faro Mine Remediation Plan (FMRP), for the Faro Mine Complex (FMC). While the FMRP is being prepared, YG and AANDC will continue their activities on the FMC to protect and minimize risks to human health and safety and the environment, as well as to support the development of the FMRP. These interim activities, collectively referred to as the Interim Works (IW), are the subject of this Project Proposal and include the following tasks:

1. Ongoing site operations
2. Site investigations in support of design and environmental characterization for the FMRP
3. The Down Valley Interim Hydraulic Upgrades (DVIHU) that comprise improvements in flood routing capacity for the Rose Creek Tailings Area (RCTA)
4. Ancillary activities associated with completing these activities

This Project Proposal is referred to as the Interim Works Project Proposal (IWPP). The IWPP is intended to meet the requirements for a Designated Office Evaluation under the *Yukon Environmental and Socio-economic Assessment Act* (YESAA) for the activities associated with the IW for up to 10 years.

1.1 Proponent Information

The governance and management structures for the FMRP are defined in the *Faro Mine Remediation Project, Project Charter: Bi-lateral Governance* (the Project Charter) (YG and AANDC, 2012a). Section 2 of the Project Charter confirms that YG and AANDC are co-proponents for the YESAA assessment for the FMRP. This same approach applies for the IW. AANDC represents the federal government as the IW funder. YG manages environmental and engagement aspects of the IW in conjunction with AANDC. YG leads and directs the design, planning, procurement, construction, and operations at the FMC, and is the main contact for the IWPP:

Energy, Mines and Resources Assessment and Abandoned Mines Branch Box 2703, K-419 Whitehorse, Yukon Y1A 2C6	Contact: Ms. Patricia Randell, Manager, Assessment and Type II Phone: 867-667-3208 Email: patricia.randell@gov.yk.ca

YG and AANDC have shared responsibility for managing the FMC since April 1, 2003, when the Yukon Northern Affairs Devolution Transfer Agreement took effect. Upon devolution, YG assumed administration and control of public lands, including abandoned mine sites. Canada remained responsible for unfunded liabilities related to major sites including the FMC (YG and AANDC, 2013). In March 2009, YG and AANDC assumed more direct responsibility for daily FMC operations, taking over when the interim receiver (appointed in 1998 under the *Companies' Creditors Arrangement Act*) concluded its responsibilities. At that time, YG agreed to direct and lead FMC site operations. YG engages contractors with appropriate expertise to support its responsibilities at the FMC. Currently, these include the following firms:

- Tłı̨chǫ Engineering and Environmental Services Ltd. (TEES) - responsible for operations, maintenance, site management and environmental monitoring.
- CH2M HILL Canada Limited (CH2M HILL) – responsible for designing remediation measures and preparing assessment and regulatory applications.

DRAFT

The governance structure for the FMRP includes two mechanisms to independently review project execution. The Independent Peer Review Panel (IPRP), comprising experts in mine site reclamation, is responsible for reviewing designs and technical issues, reviewing regulatory submissions, and providing subject-matter expertise on technical issues. The Independent Engineer (IE) is responsible for monitoring the FMRP's performance, progress, and quality. The IPRP and the IE are both accountable to the Management Board that includes senior representatives from YG and AANDC (YG and AANDC, 2013).

1.2 Project Purposes and Objectives

The IW is a continuation of activities that have taken place at the FMC since mine operations ceased in 1998. These activities will continue until the FMRP is implemented, and have two main purposes:

1. To control and reduce the effects of the existing FMC on human health and safety, and the environment.
2. To compile sufficient site and environmental information to support design, assessment and permitting for the FMRP.

As part of the IW, ongoing site operations and the DVIHU are intended to achieve the first purpose by completing the following activities:

- Managing clean and contaminated water
- Maintaining, repairing, and monitoring mine facilities and structures
- Implementing site security measures
- Monitoring site and environmental conditions
- Responding to changes in accordance with an adaptive management plan (AMP) and risk assessment

Site investigation activities for the IW are intended to achieve the second purpose of compiling sufficient site and environmental information to support development of the FMRP.

Past mining activities left a legacy of waste storage facilities (e.g., waste rock dumps [WRDs] and tailings dams), water management structures (e.g., stream diversions and dams), and mine infrastructure over the FMC. The IW are being proposed to manage significant chemical and physical stability risks as a result of this legacy. In the long term, the FMRP will remediate conditions at and near the FMC and protect humans and the environment from these risks, by working to achieve the following overarching objectives (YG and AANDC, 2013):

- Protect human health and safety.
- Protect and, to the extent practicable, restore the environment including land, air, water, fish and wildlife.
- Return the mine site to an acceptable state of use that reflects pre-mining land use where practicable.
- Maximize local and Yukon socio-economic benefits.
- Manage long-term site risk in a cost-effective manner.

The design, permitting, and procurement for the FMRP will take several years. During this time, the IW are intended to manage effects and risks at the FMC; however, the overarching objectives will be fulfilled most effectively by the FMRP. For example, geochemical conditions at the FMC are deteriorating, leading to increased contaminant mobilization. The IW may include constructing seepage interception systems in accordance with the AMP, which will prevent contaminants from migrating to the receiving environment. While these measures help protect human health and the environment, they alone do not provide the degree of remediation and contaminant control that will produce suitable long-term conditions. Consequently, other long-term source control measures (e.g., covers) are planned as part of the FMRP to further reduce mobilization and transport of contaminants. The IW move towards reaching the overarching objectives, while the FMRP will be the main instrument for fulfilling those objectives in the long-term.

DRAFT

SECTION 2

Assessment and Regulatory Requirements

2.1 Requirement for YESAA Assessment

The *Proponent's Guide to Project Proposal Submission to a Designated Office* (Yukon Environmental Socio-Economic Assessment Board [YESAB], 2010) identifies three criteria (from YESAA s.47) that together require a project to undergo an assessment and receive a decision document under YESAA before the project is undertaken. YG and AANDC have concluded the IW requires assessment, as it meets all of these criteria and that they are Decision Bodies under YESAA, as shown by the following:

1. The project is located in Yukon.
2. The IW include activities that are identified, and not excepted, in Schedules 1 and 2 of the *Assessable Activities, Exceptions and Executive Committee Projects Regulations* (the Regulations) (Canada, 2005). For example, the proposed site operations, site investigations, DVIHU, and ancillary activities include activities that fall within the following items in the Regulations:
    - Part 1, Item 3: Construction, operation, modification, decommissioning, or abandonment of, or other activity in relation to, a mine.
    - Part 9, Item 1: Drilling, operation, modification, decommissioning, abandonment of, or other activity in relation to, a well for the extraction of groundwater.
    - Part 9, Item 2: Construction, operation, modification, decommissioning, abandonment of, or other activity in relation to, a facility or installation for the extraction of groundwater.
    - Part 9, Item 3: Direct use of water.
    - Part 9, Item 4: Construction, modification, decommissioning or abandonment of, or other activity in relation to, a watercourse crossing that is 5 metres (m) or more in length.
    - Part 9, Item 9: Construction, modification, decommissioning or abandonment of, or other activity in relation to, a structure for flood control.
    - Part 9, Item 12: The deposit of waste into water.
    - Part 13, Item 3: Earth drilling using power-driven machinery that has an operating weight exceeding 500 kilograms (kg).
    - Part 13, Item 12: On Crown land, moving earth or clearing land using a self-propelled power-driven machine.
    - Part 13, Item 13: On Crown land, levelling, grading, clearing, cutting or snow plowing of a: (a) trail, (b) right-of-way of a road, or (c) route that provides access to land for the purposes of a geophysical, geological or engineering survey.
    - Part 13, Item 15: On Crown land, the extraction of sand, gravel or stone.
    - Part 13, Item 16: Operation, or expansion of a gravel or sand pit or stone quarry.
3. YG and AANDC are co-proponents of the IW and many of the activities (e.g., earth drilling) would require authorization if a private individual undertook them. The use of water and deposit of waste into water also meet the criteria for licensing under the *Waters Act*.

The activities proposed as part of the IW are not identified in Schedule 3 of the Regulations. As a result, YG and AANDC have concluded in accordance with YESAA Subsection 50(1) that they are obliged to submit the IWPP to a Designated Office.

DRAFT

2.2 Current Operating Authority

On February 28, 2009, at the same time as the Ontario Superior Court discharged Deloitte and Touche Inc. from its responsibilities as interim receiver and YG assumed responsibility for day-to-day management of the FMC, the site water licence expired. Since then, YG has conducted its activities at the FMC under the authority of a Minister's Determination granted in accordance with Subsection 37(1) of the *Waters Act*. This Subsection provides the Minister with authority to take "any reasonable measures to prevent, counteract, mitigate, or remedy any resulting adverse effect on persons, property, or the environment" if the effects may arise from an abandoned site. The Minister's Determination for the FMC issued in late February 2009, provides authority for AAM to take reasonable measures to protect persons, property and the environment (especially surrounding waters) from effects that may be caused by the facilities and conditions at the FMC.

While many of the activities that make up the IW fall within the scope of the Minister's Determination, YG and AANDC recognize that some activities are not directly related to preventing, mitigating, or remedying adverse effects on persons, property, or the environment. As such, they have chosen to proceed with a YESAA assessment for the IW. At the same time, the conditions at the site require continued operation and adaptation at the FMC under the current operating authority granted by the Minister's Determination. Once the YESAA assessment and licensing processes are complete, the Minister's Determination will no longer provide the sole authority for all activities that will be undertaken at the FMC.

DRAFT

SECTION 3

Project Location, Background and Engagement

3.1 Project Location

3.1.1 Geographical Location

The FMC is located in the Yukon Territory approximately 200 kilometres (km) north northeast of Whitehorse, approximately 15 km north of the Town of Faro, and approximately 50 to 65 km northwest of Ross River (Figure 3-1). The mine Access Road extends approximately 22 km from the Town of Faro to the FMC, gaining over 400 m in elevation.

The FMC consists of three main areas: the Faro Mine Area, the RCTA, and the Vangorda/Grum Area (Figure 3-2). The 14-km Haul Road connects the Faro Mine Area and Vangorda/Grum Area. The Faro Mine Area and RCTA are in the Rose Creek watershed, and the Vangorda/Grum Area is in the Vangorda Creek watershed. Rose Creek flows to Anvil Creek, a tributary of the Pelly River, while Vangorda Creek flows directly to the Pelly River.

The disturbed area of the FMC is generally oriented southeast to northwest, with the following geographic extents:

- 62 degrees (°) 14’30.8” N to 62°21’59.1” N
- 133°10’57.5” W to 133°29’3.8” W

The FMC is found primarily on National Topographic System Map 105K/6, with a small portion on 105K/3. The FMC is located within the Southeast YESAA Assessment District. The Designated Office for the Southeast District is located in Watson Lake.

3.1.2 Traditional Territories and Affected Yukon First Nations

The FMC is located in the traditional territories of the Ross River Dena Council (RRDC) and the Liard First Nation (LFN), members of the Kaska Dena. The Selkirk First Nation (SFN) traditional territory extends upstream on the Pelly River to a few kilometres downstream of the confluence with Anvil Creek (Figure 3-3). The Yukon Northern Affairs Program Devolution Transfer Agreement (Canada and YG, 2001) identifies the RRDC, LFN, Kaska Dena Council (KDC), and SFN as Affected First Nations for the FMC.

Neither RRDC nor LFN has finalized a land claim agreement but several land selections surrounding the FMC are subject to interim protection for the RRDC (Figure 3-3). RRDC R12-B follows the left banks of Rose Creek and Anvil Creek, beginning approximately 5 km downstream of the FMC and continuing to the mouth of Anvil Creek. RRDC R21-A follows the right bank of Anvil Creek for several kilometres upstream from the mouth of the creek. RRDC S11-B is located on the right bank of Rose Creek immediately downstream of the FMC, within Order in Council (O.I.C.) 2008/168, which withdraws the FMC from staking, and Internal Yukon Government Reserve of Land 2008-2582.

3.1.3 Land Tenure

The FMC is located entirely on Crown land administered by YG. Much of the Vangorda/Grum Area falls within the municipal boundary for the Town of Faro (Figure 3-4). YG holds Internal Yukon Government Reserve of Land 2008-2582 for the FMC and surrounding area, effective November 8, 2013 (Figure 3-4). This reserve provides the following restriction:

> *“Any land use activities planned for the reserve area must be provided to Assessment and Abandoned Mines for approval prior to the activity being authorized.”*

The entire FMC and areas that may be subject to disturbance as a result of the FMRP are subject to O.I.C. 2008/168 (Figure 3-4). The O.I.C. prohibits staking and prospecting under both the *Quartz Mining Act* and the *Placer Mining Act*. YG established the O.I.C. to prevent future conflicts between FMC closure/remediation activities and mineral exploration activities.

DRAFT

A sheep range wildlife reserve, encroaches on parts of the Vangorda/Grum Area and the Haul Road (Figure 3-4). The FMC falls within Group Trapping Concession 405 that is managed by the Ross River Dena Council and used by First Nation members. It also falls within Outfitting Concession 9, held by Deuling Stone Outfitters Ltd. Outfitting Concession 8, held by MacMillan River Adventures, overlaps with Anvil Creek and the lower portion of Rose Creek, downstream from the FMC.

The FMC is located in the Kaska Land Use Planning Region established by the Yukon Land Use Planning Council. A planning commission has not been appointed for this planning region, and the regional land use planning process has not been initiated.

3.2 Project Background

3.2.1 Site History

Before ore bodies were discovered in the Vangorda and Rose Creek watersheds, people of the Kaska Nation, specifically the Ross River Dena and their ancestors, used the land where the FMC is located. Weinstein (1992) describes the use of the area by the Ross River Dena in *Just Like People Get Lost: A Retrospective Assessment of the Impacts of the Faro Mining Development on the Land Use of the Ross River Indian People.* The Dena moved across the landscape to where the resources were available in a seasonal "round." The FMC area was an important part of the traditional seasonal round in the Mount Mye area for several Kaska extended families:

> *"The people for whom the Mye Mountain/Anvil Creek/Blind Creek areas were primary resource lands at the time of development included the direct descendants of the earlier generation of people from that country. These included Selkirk Billy, Aklack, Billy Atkinson, Long Hair John, Gumbala, Nahlier, Pat Johnnie (Peter Ladue's maternal grandfather), and Sue Bill (Jack Ladue's first wife's father) and their spouses. The group also included people who married into these families or who were invited to join these groups. During the period prior to the mine construction, Joe Ladue, Hoole McLeod, Jack Sterriah, Old Man Jules and Jack Ollie's wife and some of their family members regularly trapped in the affected areas."*
>
> Weinstein, 1992 - pp. 87-88

In the seasonal round, people gathered at fish camps (e.g., Blind Creek, Pelly River at Faro, and Fish Hook near the mouth of Anvil Creek) in late July and early August. After the salmon run, people travelled to Mount Mye area to hunt arctic ground squirrels and hoary marmot, and to pick berries. With the fall moose rut, people moved to lower elevation areas to hunt moose, and dry and cache supplies of meat. Following the moose hunt, people walked back to the trading post at Ross River to purchase supplies for the winter, and then returned by raft to the Mount Mye area, where they dispersed to trapping areas around the mountain and its streams. After the winter trapping season, families converged at Swim Lakes to trap lynx and for the spring fishery. In late spring, men would travel to Sheldon Lake for the spring beaver hunt, while women and children remained at Swim Lakes to continue to prepare stocks of dried fish. In late May, families would walk to Ross River to trade the supply of furs, where they remained until the round began again with the salmon fishery (Weinstein, 1992). Figure 3-5 shows key locations.

The development of the FMC displaced traditional land uses, and damaged an environment that was steeped in family and cultural history. The words of Arthur John, a respected elder of Ross River, as quoted by Weinstein, convey the depth of loss experienced from the mining project:

> *"Now no one goes there. The mine tore up half the mountain now. People from that country try other areas, could not find anything as good. After that, just like people get lost, don't know where to go. They tried back in there, up that way. Not as good as down there no more. So people don't get good living like long time ago."*
>
> Weinstein, 1992

Al Kulan, with the assistance of Kaska prospectors Jack Ladue, Robert Etzel, Joe Etzel, Art John, and Jack Sterriah, discovered and staked the Vangorda deposit in 1953. While this deposit was considered too small and remote for

DRAFT

development at the time, it led to the 1965 discovery of the Faro deposit by Dynasty Explorations. The Grum deposit was discovered in 1973.

Mining at the FMC began in 1969 and continued until 1998, with several temporary cessations of varying lengths. Anvil Mining Corporation opened the Faro Mine in 1969 and continued operations, under the name Cyprus Anvil Mining, until 1982 when economic conditions forced a shut down. Operations at the Faro Mine resumed under Curragh Resources Ltd. in 1986. Curragh continued mining the Faro Mine while seeking approvals and constructing infrastructure for the Vangorda and Grum Mines. Mining at Vangorda Pit began in 1990 and continued, concurrent with mining at Faro Pit, until mid-1992, when resources in the Faro Pit were depleted. In late 1992, Curragh sought bankruptcy protection and ceased mining operations. Curragh began stripping overburden and waste rock from the Grum Pit in 1991, but did not begin ore production before the 1992 shut down.

Anvil Range Mining Corporation (ARMC) purchased the FMC from the interim receiver and resumed operations in 1994 with a Grum Pit pre-stripping program. Ore production began at the Grum Pit in August 1995, followed by resumed production at the Vangorda Pit. ARMC terminated mining operations in late-1996 for economic reasons and, following a financial restructuring, restarted in 1997. Mining continued until early 1998 when ARMC sought bankruptcy protection.

After the mine shut down in 1998, Deloitte and Touche Inc. undertook FMC care and maintenance (C&M) activities, serving as the interim receiver for ARMC under the *Companies' Creditors Arrangement Act*. Deloitte and Touche Inc. continued in this role until early 2009, when it was discharged from these duties and YG assumed management responsibility. In 2003, YG and the federal government acknowledged that mining at the FMC was no longer economically viable and began planning for the site to be permanently remediated. Since the mine shut down in 1998, AANDC has provided funding for C&M and closure planning activities.

As part of initial mine development, Cyprus Anvil Mining constructed the Town of Faro near the confluence of Vangorda Creek and the Pelly River, about 22 km by road from the mill facilities at the FMC. Construction began in 1968, but a forest fire destroyed most of town in June 1969. In 1970, the population in the Town of Faro was about 800 people, and it grew slowly over the years as the mine expanded, until 1981 when the population was just under 2,000. In 1985, with the mine shut down, the population reached a low point with only 97 Faro residents remaining. After the mine closed permanently in 1998, many Faro residents remained, with a few continuing to work at the closed mine. Today, the Town of Faro has approximately 400 inhabitants, with tourism identified as a major economic growth factor (Town of Faro, 2013).

3.2.2 Faro Mine Complex – Site Overview

As Section 3.1 stated, the FMC consists of the Faro Mine Area, the RCTA, and the Vangorda/Grum Area. The 14-km Haul Road connects the Faro Mine Area and Vangorda/Grum Area. This section provides an overview of the current site conditions; Section 6.1 provides additional detail.

3.2.2.1 Faro Mine Area

The Faro Mine Area (Figure 3-6) includes the following components:

- The Faro Pit (1,675 m long, 975 m wide, and 335 m deep, containing approximately 15 million tonnes of tailings)
- Approximately 30 WRDs (totalling approximately 260 million tonnes that cover approximately 335 hectares)
- Ore processing and handling facilities
- The Emergency Tailings Area (ETA)
- The Faro Creek Diversion (FCD)

It also includes contaminated water management facilities, including the S-Wells and ETA Seepage Interception Systems (SIS), and contaminated water pumping, conveyance, and treatment facilities. A second pit at the Faro Mine Area, the Zone II Pit, was filled with waste rock during subsequent mining. Dewatering the Zone II Pit prevents contaminated water from accumulating and discharging.

Much of the waste material at the FMC is acid-generating, whereby oxidation of sulphide minerals releases sulphuric acid that mobilizes metal contaminants. Waste rock and pit walls at the Faro Mine Area continue to oxidize and release contaminants. Although sulphide cells, low/medium-grade ore stockpiles, and oxide fines stockpiles contain the most consistent highly mineralized wastes, the waste rock at the Faro Mine Area is generally poorly segregated.

Water infiltration has led to contaminated seepage and groundwater downgradient of some WRDs at the Faro Mine Area. Seepage interception systems currently operate at the S-Wells and the ETA to collect contaminated water for treatment. Contaminant migration in additional areas is managed through the practices described in the AMP (Appendix 5C). The Faro Pit serves as a contaminated water storage reservoir, providing storage capacity to support seasonal water treatment and to reduce site water management risks. Water treatment at the Faro Mine Area relies on lime precipitation technology. The existing water treatment plant (WTP) is located in the former mill building, but will no longer be used due to concerns about safety and reliability. Planning is underway for establishment of an Interim Water Treatment System that will operate throughout the IW and be located near the former concentrate load-out facility. Discharge from the treatment system flows to the CVD Pond before discharging into the North Wall Interceptor Ditch and eventually Rose Creek.

3.2.2.2 Rose Creek Tailings Area

The RCTA (Figure 3-7) covers an area of over 200 hectares in the original valley of Rose Creek, just downstream of the confluence of the North Fork Rose Creek (NFRC) and South Fork Rose Creek (SFRC). The RCTA comprises four dams – the Original, Secondary, Intermediate and Cross Valley Dams – and the Rose Creek Diversion (RCD). The Original, Secondary, and Intermediate Dams retain a total of 55 million tonnes of tailings in the Rose Creek valley. The Cross Valley Dam (CVD) retains a pond that is used for final polishing of treated water. Sludge cells on the Original Tailings provide storage for water treatment sludge from the Faro Mine Area water treatment system.

Contaminants from the acid-generating Rose Creek Tailings are migrating into the Rose Creek Aquifer, which flows beneath the tailings. While concentrations of some contaminants are increasing in groundwater downgradient of the RCTA, none have reached levels that are ecologically significant to warrant collection and treatment. Planning and design have been initiated for seepage interception downstream of the CVD. The AMP will guide the construction and implementation of an SIS. Assessment and regulatory requirements will be addressed before construction.

Contaminated surface water accumulates in the Intermediate Dam (ID) Pond. Site operations includes collecting and treating this water at the Faro Mine Area water treatment system. The RCD conveys clean water in Rose Creek around the RCTA.

Because of the contaminant load associated with the tailings, the physical stability of the structures in the RCTA is critical to protect the downstream environment. YG and AANDC have engaged qualified engineers to evaluate the seismic and static stability of the tailings dams and RCD Dike, as well as the flood routing capacity of the RCD. In their current configuration, the dams achieve suitable factors of safety for physical stability for the IW period. However, the RCTA's flood routing capacity warrants improvement to reduce risks associated with floods. These improvements are addressed by the DVIHU component of the IW (described in Section 5), which involves upgrading the hydraulic capacity of both the ID spillway and the RCD to provide capacity for the system to convey a 1-in-500-year flood event.

3.2.2.3 The Vangorda/Grum Area

The Vangorda/Grum Area (Figure 3-8) includes the Vangorda Pit (1,150 m long, 350 m wide, and 150 m deep), the Grum Pit (1,100 m long, 700 m wide, and 200 m deep), the Vangorda Waste Dump, the Grum Waste Dump, the Grum Overburden Dump, the Grum Ore Transfer Pad, the Vangorda Creek Diversion (VCD), the Vangorda WTP, and the Little Creek Dam (LCD). There are no tailings stored at the Vangorda/Grum Area because all ore was processed in facilities at the Faro Mine Area.

Almost all waste from the Vangorda Pit is acid-generating. To address this issue, the Vangorda Waste Dump was designed and constructed with a seepage collection system. Seepage from the Vangorda Waste Dump flows into Little Creek Pond, where it is pumped to the Vangorda Pit and eventually to the Vangorda WTP.

The mine plan for the Grum Pit included placing sulphide waste in a sulphide cell within the Grum Waste Dump. In 2010, YG and AANDC placed a geosynthetic cover over the Grum Sulphide Cell (GSC) to reduce infiltration and contaminant migration. Seepage and surface flows from the Grum Waste Dump historically flowed into a natural depression referred to as Moose Pond, where they exfiltrated to ground on their way to Vangorda Creek. Downgradient well monitoring continues to confirm that contaminant concentrations have not reached ecologically significant levels. However, the physical stability of Moose Pond in high flow events has led to the construction of an SIS for the Grum Waste Dump. This SIS operates seasonally, pumping water into the Vangorda Pit and eventually to the Vangorda WTP.

Both the Vangorda and Grum Pits serve as contaminated water reservoirs, providing for seasonal water treatment at the Vangorda WTP. The WTP was constructed in 1990 as part of the initial mine development, relying on lime precipitation technology to reduce concentrations of contaminants of concern. Historically, sludge from the Vangorda WTP was stored in sludge cells on the Grum Overburden Dump or in the Vangorda Pit. Discharge from the WTP flows into the Grum Northeast Interceptor Ditch and through the Sheep Pad Ponds (SPP) before discharging into Vangorda Creek.

The VCD conveys clean water around the highly contaminated Vangorda Pit, relying primarily on a half-culvert flume. The VCD was constructed with capacity to convey the estimated peak flow for a 1-in-100-year flood, but the facility presents maintenance challenges, because of icing and the condition of the flume. There are also risks associated with the stability of the nearby Vangorda Pit wall.

3.2.3 Current Care and Maintenance Activities

After active mine operations ceased at the FMC in 1998, the site transitioned to a C&M phase. YG assumed management responsibility at the FMC in 2009, and began overseeing the C&M activities. Currently, YG engages TEES under a contract to carry out the following activities:

- Operate, maintain, and repair the following components:
  - Fresh water systems
  - Contaminated water systems
  - Pumping systems
  - Collection ditches
  - Dams and diversions
  - Contaminated water containment areas
  - Contaminated water treatment systems
  - Equipment
  - Site buildings and infrastructure
  - Electrical distribution systems
  - Roads and culverts
- Perform sludge management
- Perform tailings dust management
- Implement the preventative maintenance plan
- Provide emergency response capability and respond to emergencies
- Provide security, health, and safety for the FMC
- Purchase and manage use of electricity, fuels, and lubricants
- Maintain all permits and licences as required
- Implement an Affected Yukon First Nation (AYFN) and Yukoner Participation Plan
- Provide site management and administration services
- Comply with specified environmental standards
- Conduct environmental and site monitoring.

Continued C&M is part of the site operations component of the proposed IW.

DRAFT

3.2.4 Closure Planning Status

In 2003, YG and AANDC acknowledged the FMC would not reopen, and initiated a process to develop an overall closure and remediation plan. YG, AANDC, RRDC (on behalf of the Kaska Nation), and the SFN agreed to establish a joint project Oversight Committee. The Oversight Committee's role was to provide strategic leadership in the identification and development of a recommended approach to long-term site closure and remediation. The LFN joined the Oversight Committee in 2007. The Oversight Committee provided a forum for the direct participation of the affected First Nations in defining, evaluating and selecting remediation options for the FMC.

In early 2009, the Oversight Committee selected a preferred option that would form the basis for the long-term closure and remediation plan. This selection considered input from the following sources:

- Hundreds of technical studies conducted by a multidisciplinary team of engineers and scientists
- Consultations with First Nations and communities
- The IPRP, comprising nine leading experts in various facets of mine closure
- A multiple accounts-decision analysis that compared a range of options against the project objectives, conducted by a group comprising community members, technical consultants, and government representatives

The preferred option emphasizes the need to stabilize contaminants, rather than remove them from the FMC. Key features of the FMRP include upgrading dams so tailings remain in place, re-sloping waste rock, installing engineered soil covers over tailings and waste rock, upgrading stream diversions, and installing state-of-the-art water collection and treatment systems.

Once the Oversight Committee reached consensus about the long-term closure and remediation plan, the focus of remediation planning efforts shifted to the design, assessment, and permitting for the chosen option. In 2011, YG and AANDC selected CH2M HILL as the main technical designer for the FMRP, to provide engineering and scientific support for this phase of the remediation planning. The site investigation component of the IW will be a major contributor to the documentation needed to support design, assessment, and permitting. YG and AANDC currently anticipate submission of a Project Proposal for the FMRP in May 2017 (Figure 3-9). To achieve this schedule, plans include a substantial field investigation program in 2014, as described in Section 5 of this IWPP.

3.3 Community and Regulatory Engagement

3.3.1 Overview and Intent

This section provides an overview of the engagement activities that have occurred for the FMRP with specific reference to how these engagement activities relate to the IWPP. Appendix 3A, Supporting Documentation of Engagement Activities, includes specific documentation for these sessions, such as meeting agendas, presentations, and notes.

Over the past 10 years, the community and regulatory engagement process for the FMRP has included, in order, the following phases:

- Initial 2003-2008 5-year closure planning and options selection process that included engagement with First Nations, other governments, communities and other stakeholders. To support effective participation in this process, YG and AANDC established funding agreements with the AYFN communities.
- Since 2008, development and implementation of an AYFN Participation Strategy and other engagement meetings related to the FMRP.
- In 2013, IWPP-specific discussions.

YG and AANDC structured the process with the intent to be open and transparent and to provide information to support community understanding and involvement.

DRAFT

3.3.2 Parties Considered

Section F of Appendix H (Inventory of Sites) of the Devolution Transfer Agreement (PWGSC, 2001), lists the Affected First Nations for the each of the Yukon Abandoned Type II mine sites. The Faro Type II mine site has the following four AYFN governing bodies that represent First Nation Citizens affected in the communities of Watson Lake, Ross River and Pelly Crossing:

1. RRDC, centred in Ross River
2. LFN, centred in Watson Lake
3. SFN, centred in Pelly Crossing
4. KDC, centred in Lower Post British Columbia and established by five Kaska First Nations in Yukon and British Columbia

The Town of Faro is also considered an affected community because of proximity and reliance on the project. It is the closest community to the FMC.

Figure 3-1 shows the location of these communities in relation to the FMC.

3.3.3 Approach

3.3.3.1 Closure Planning (2003-2008)

From 2003-2005, potential environmental issues at the mine site were characterized through technical studies and assessments, and technical workshops were held with communities from the AYFNs and the Town of Faro and with regulatory agencies to provide information on the project and to gather input on different approaches to mine remediation to address the overarching closure objectives (Section 1.2). Meetings also took place over the same period with other interested parties, including the Yukon Chamber of Mines, Yukon Chamber of Commerce, Yukon Conservation Society, Canadian Parks and Wilderness Society, Yukon Fish & Wildlife Management Board, the Yukon Salmon Committee, and members of the general public.

In the spring of 2006, additional community consultation meetings were held to provide an overview of the project and potential remediation alternatives. With the findings of the technical studies, 12 “example alternatives” were identified to represent the spectrum of what was potentially technically feasible to address the environmental issues present at the site and address the overarching closure objectives. These alternatives were reviewed by an IPRP, and the IPRP findings (along with feedback from two rounds of community consultations in fall 2006/spring 2007) led to the 12 alternatives being refined to five final closure options: three for the Faro Mine Area (pit, tailings, and waste rock areas) and two for the Vangorda/Grum Area.

In 2007, the community, regulators, technical consultants, and government representatives further evaluated the five short-listed options against the project objectives, using a multi-attribute utility analysis method. A summary of this process up this juncture is provided in the January 2008 presentation ‘Faro Mine Closure: Arriving at Closure’ (refer to Appendix 3A, Attachment 3A-1). In November 2008, the findings of the assessment and evaluation process were presented to the Faro Mine Oversight Committee, which reviewed the findings and agreed on a preferred option that is the overall closure and remediation plan for the FMC.

3.3.3.2 AYFN Funding Agreements and Governance

AAM has held funding agreements with both the RRDC (representing KDC) and SFN since 2003, and with the LFN since 2007. Initially, the purposes of these funding agreements were to cover costs for engaging representatives from these AYFN in participating in the Faro Mine closure planning process (particularly in the selection and endorsement of a final closure option) and for each AYFN to have a dedicated FMRP office with a Community Coordinator (and assistant in some cases) to provide community communications, community meetings/workshops and technical advice related to the FMRP. Once the closure option was selected, the scope and budgets of the funding agreements expanded with the change in roles and responsibilities to include projects related to Traditional Knowledge), community socio-economic planning for remediation, projects aimed at increasing awareness of youth, and mine site tours for youth and elders.

The 2011/12 YG proposed modifications to funding agreements to address community participation on technical issues of the project, and include both the hiring of Community Coordinators to inform the communities of

project updates and training and employment opportunities through contractors working on the FMRP, and the formation of a Technical Advisory Committee (TAC). Only SFN entered into a funding agreement. The SFN TAC was comprised of representatives of different facets of the SFN community to encourage greater communication and knowledge within the community about the project, and to seek greater community input into the project.

Meetings and discussions have taken place since 2010 with representatives of the AYFNs and the Governments of Canada and Yukon, to develop a proposed governance structure for the FMRP. A final governance structure is still to be developed.

In August 2012, the KDC notified AAM that they no longer wished to be represented on the FMRP through RRDC and would represent themselves in future negotiations and discussions.

In May 2013, letters were sent to all the AYFNs to initiate the process for drafting the 2013/14 funding agreements. As of December 2013, SFN is the only AYFN to have entered into an agreement.

3.3.3.3 AYFN and Yukoner Participation Strategy

In accordance with the Devolution Transfer Agreement, the Yukon Government Contracting Policy, and the policy objectives of the Northern Contaminated Sites Program and the Government of Canada Contracting Policy, AAM has adopted a three-pronged AYFN and Yukoner Participation Contract Strategy (herein referred to as the Participation Strategy). Following that, contractors working on the FMRP must develop specific Participation Plans with targets to demonstrate how they will maximize AYFN and Yukoner participation on the FMRP through the following:

- Training and capacity building
- Contracting and subcontracting
- Direct employment

In 2008, the overall Participation Strategy was first developed with the Chiefs of the SFN and RRDC to address the C&M contract at the FMC, and has subsequently been adopted by AAM for inclusion in all major contracts where reasonable opportunities exist for AYFN and Yukoner participation. The contractors' performance is to be assessed based on agreed upon performance outcomes of their specific Participation Plans and any mitigating circumstances that may have hindered the ability to meet those targets.

As part of their Participation Strategy responsibilities, the C&M contractor meets with the communities to provide a project status update (as it relates to training and onsite activities). While these meetings may be quarterly, the timing and frequency depends on the ability of the contractor to schedule around community activities. AAM has participated in some of these meetings to provide other project updates where appropriate, as follows:

- In May 2010, the Kaska communities of Ross River, Lower Post, and Good Hope Lake were visited and an FMRP update was provided that included a discussion on the Participation Strategy (see Appendix 3A, Attachment 3A-2 PowerPoint presentation).
- At a November 2011 community meeting with the LFN in Watson Lake related to the FMRP, the C&M contractor and AAM (1) provided an update on the project (including surface water and wildlife surveys and site operations contracting efforts), (2) reinforced the message of the Community Coordinators being points of contact regarding the FMRP, and (3) advised of the ongoing governance structure discussions for the FMRP that were being developed with the AYFN Chiefs (see Appendix 3A, Attachment 3A-3 poster and PowerPoint presentation).
- An April 2013 community meeting with the SFN in Pelly Crossing was used to provide a project update on activities that had been completed on the site from 2010 to 2012 and on activities planned for 2013, including data collection for the IWPP (see Appendix 3A, Attachment 3A-4 PowerPoint presentation).

DRAFT

In 2010, YG hired an AYFN/Community Affairs Project Manager to further enhance AYFN and Yukoner participation coordination efforts in the FMRP. The key role and responsibilities for this position are as follows:

- Liaise with Community Coordinators to attempt to foster a participatory relationship between the AYFN communities and AAM through mechanisms such as weekly update meetings.
- Assist Community Coordinators in fulfilling funding agreement obligations such as quarterly and annual reports to ensure funding is available to continue working level relationships.
- Liaise with C&M contractors and the Community Coordinators on projects with AYFN involvement to assist in fulfilling the project objective of maximizing local and Yukon socio-economic benefits.
- Draft annual funding agreements from work plans submitted by the Community Coordinators or other AYFN representatives.
- Provide input on upcoming large contracts (such as C&M) to maximize socio-economic benefits through such actions as the hiring of a dedicated AYFN Training Coordinator as part of C&M.
- Assist AAM project managers with AYFN involvement where necessary.

3.3.3.4 Engagement Activities (2009 to 2013)

Following the identification of the preferred option for the overall closure and remediation plan for the FMC, engagement sessions were held in the communities in February 2009 to present the recommended closure option. In May to August 2009, meetings were held with the Environmental Assessment/Socio-economic Assessment Working Group, a group formed with representatives of the communities to discuss and provide feedback on the environmental and socio-economic aspects of the FMRP. In 2010 and 2011, AAM and AANDC were in discussion with AYFN Chiefs about a proposed governance structure for the FMRP.

In late 2011/early 2012, discussions on the engineering, environmental, and socio-economic aspects of the FMRP resumed. This section provides an overview of the key community and regulatory engagement activities around these FMRP discussions with an emphasis on how these activities relate to the IWPP.

Table 3-1 provides a summary of the engagement activities discussed in this section that occurred from 2011 to 2013 and includes reference to where the supporting activity documentation can be found in Appendix 3A.

Community Engagement

In addition to the community meetings that have been held in Ross River, Watson Lake, and Pelly Crossing in conjunction with the C&M contractor meetings (as discussed in Section 2.3.3.3), there have been four other meetings with the SFN (Table 3-1) to provide project updates (in conjunction with the C&M contractor). Two other meetings were SFN TAC meetings focused on technical issues with specific concerns around how the FMRP and IWPP will affect water quality.

Regulatory – Yukon Socio-Economic Board

Four meetings were held with YESAB from October 2011 through to July 2013 (Table 3-1). The first two meetings in late 2011 were held to introduce members of the FMRP team to YESAB and to discuss the FMRP scope and assessment approach. The third meeting was held in April 2013 to discuss the IW project scope and confirm that YG and AANDC would submit the IWPP to the Watson Lake Designated Office for an evaluation. YG also convened a site tour for YESAB members and staff in July 2013. Documentation for these meetings can be found in Attachments 3A-5 to 3A-8 in Appendix 3A, Supporting Documentation of Engagement Activities.

Regulatory – Government Agencies

A meeting was held with Yukon Environment in January 2012 (Table 3-1) to discuss wildlife information requirements (particularly for caribou, moose, sheep and grizzly bear) to prepare a YESAB Project Proposal for the overarching FMRP. It was agreed in the meeting that no further investigations were required for caribou and sheep information, and that it would be confirmed whether additional work would be required for moose (a late winter moose survey) or grizzly (denning habitat mapping). In 2013, the information needs from this meeting

were then reviewed for the purposes of the IWPP, and given the scope of the IWPP it was decided to use existing information for these species. The meeting notes can be found in Attachment 3A-9 in Appendix 3A, Supporting Documentation of Engagement Activities.

Government agencies have also been engaged on an as-needed topic basis. For example, YG consulted with Fisheries and Oceans Canada (DFO) and YESAB before conducting the fish telemetry surveys to review the plan and seek input. Posters were developed on the program and Community Coordinators posted these around waterbodies. YG also engaged the Northern Contaminants Program in 2011 to look more closely at the issue around containment effects on wildlife, and developed a wildlife monitoring program that included an organ collection program for hunted caribou, moose and sheep.

The poster for the Hunted Wildlife Organ Collection Program can be found in Attachment 3A-10 in Appendix 3A, Supporting Documentation of Engagement Activities.

3.3.4 Issue and Concern Themes and Response

There have been four main issue and concern themes raised during the engagement sessions:

1. Contamination of wildlife (namely moose) from tailings dust
2. Effect of water quality on fish
3. Employment and contracting opportunities
4. Dam risks and safety

These issues and concerns have been addressed as follows:

1. YG engaged a biologist in 2011 to look more closely at the issue around containment effect on wildlife and developed a wildlife monitoring program that included a sample organ collection program for hunted caribou, moose, and sheep.
2. A variety of monitoring programs have taken place (monthly water quality and benthic invertebrates monitoring, specific salmon studies, and a 2012/13 fish telemetry program) to characterize water quality conditions and to support the evaluation of effects. YG funded an SFN Pelly Aquatics Study from 2005 to 2010 whereby the water was sampled and monitored at approximately 20 locations upstream and downstream of the site. Since 2011, AAM has funded the program through a local contractor.
3. There is an AYFN and Yukoner Participation Strategy to maximize AYFN and Yukoner participation on the FMRP through providing training and capacity building, contracting and subcontracting, and direct employment opportunities. This was implemented for the Grum Sulphide Cell project, where the contractor funded training opportunities geared towards increasing the capacity of the communities and individuals who may wish to work on the FMRP, and it continues to be implemented by the C&M contractor.
4. The DVIHU that are part of the scope of the IW are designed to address the risks related to dam safety and major flood events.

DRAFT

TABLE 3-1
FMRP and IWPP Engagement Activities 2011 to 2013
Faro Mine Interim Works

Date	Event	Location	Community/ Organization	Purpose	Issues/Concerns Raised or Decisions Made	Documentation	Appendix 2A Reference
October 7, 2011	Meeting	Whitehorse (YESAB Office)	YESAB	To introduce members of the Faro Project Design Team to YESAB and discuss proposed approach and schedule for the Remediation Project Proposal.	No issues raised. Request for a follow-on meeting to review project at a conceptual level and alternatives analysis, and further discussion on consultation requirements. Meeting scheduled for November 16, 2013.	Agenda	2A-5
November 16, 2011	Meeting	Whitehorse (YG-AAM Office)	YESAB	To provide a project overview, describe alternatives analysis, and discuss consultation requirements.	No issues raised. Request for a follow-on meeting to further discuss the assessment methodology and establishment of a Regulatory Working Group. A follow-up meeting was not scheduled as FMRP Project Proposal was put on hold.	Agenda PowerPoint presentation	2A-6
November 29, 2011	Meeting	Watson Lake	LFN / Watson Lake	To provide an update on the project (specifically data collection programs and contracting efforts and introduce the new Community Coordinators).	No issues or actions.	Poster PowerPoint presentation	2A-3
January 19, 2012	Meeting	Whitehorse (YG-AAM Office)	Yukon Environment	To discuss wildlife information requirements for the Remediation Project Proposal.	No issues raised. Follow-on actions for Yukon Environment to confirm need for late winter moose survey and grizzly bear denning habitat survey.	Meeting notes	2A-9
January 17, 2013	Meeting	Pelly Crossing	SFN	To provide a project update (5-Year Plan, C&M Activities, Project Design Team [CH2M HILL], and Pelly Aquatics Study).	No issues or actions.	N/A	No attachment
January 21, 2013	Community Meeting with C&M Contractor	Ross River	RRDC	To provide a Q3 2013 project and C&M update.	No issues or actions.	N/A	No attachment
March 8, 2013	Meeting (TAC)	Whitehorse	SFN	A meeting to review of interim works project, particularly how site water affects the local environment.	No issues or actions.	N/A	No attachment
April 9, 2013	Meeting	Whitehorse (YESAB Office)	YESAB	To discuss the scope of the interim works project to confirm the level of assessment for the IWPP as AAM requested in a February 14, 2013, letter to YESAB.	No issues raised. Confirmed in meeting that, with the described scope, the interim works project appears to require a Designated Office-level Project Proposal.	February 14, 2013, letter from AAM to YESAB	2A-7
April 17, 2013	Meeting (TAC)	Whitehorse	SFN	A meeting to discuss Pelly Aquatics and water monitoring.	No issues or actions.	N/A	No attachment
April 22, 2013	Community Meeting with C&M Contractor	Pelly Crossing	SFN	To provide a project update on activities that had been completed on the site from 2010 to 2012 and on activities planned for 2013.	No issues or actions.	10-page presentation	2A-4
May 2, 2013	Meeting	Whitehorse	SFN	To provide a memory stick with data relating to water quality.	No issues or actions.	N/A	No attachment
July 23, 2013	Site Tour	Faro Mine	YESAB	To provide a site orientation and an overview of the IWPP.	No issues or actions. Several questions and comments for consideration in preparing the IWPP.	Agenda Site tour maps	2A-8
August 14, 2013	Site Tour	Faro Mine	KDC	To provide a site orientation and overview.	No issues or actions.	N/A	No attachment

SECTION 4

Project Purpose and Alternatives

4.1 Project Purpose

As stated in Section 1.2, the purposes of the IW are as follows:

1. To control and reduce the effects of the existing FMC on human health and safety, and the environment.
2. To compile sufficient site and environmental information to support design, assessment and permitting for the FMRP.

The IW are temporary activities that are intended to minimize effects and manage risks at the FMC while YG and AANDC complete the design, permitting, procurement and implementation of the FMRP. The FMRP will be the subject of its own YESAA assessment and regulatory processes currently scheduled to begin in May 2017. The following sections discuss alternatives for each of the main IW components, including the following:

- Site operations
- Site investigations
- DVIHU

4.2 Alternatives

4.2.1 Site Operations

Site operations activities are the primary mechanism for addressing the first purpose of the IW, to control and reduce the effects of the existing FMC on human health and safety, and the environment. Because the conditions and facilities at the FMC present substantial chemical and physical stability risks, there is no alternative but to continue site operations. The operations, maintenance, and management activities are critical to controlling and reducing effects of contaminants from the site, and maintaining the physical integrity of site infrastructure. Without these measures, the FMC would cause unacceptable effects on the local environment.

4.2.2 Site Investigations

Site investigation activities are the primary mechanism for addressing the second purpose of the IW, to compile sufficient site and environmental information to support design, assessment and permitting for the FMRP. Implementation of the FMRP is the mechanism for addressing the long-term issues and risks at the FMC, and fulfilling the overarching objectives (Section 1.2). Failure to complete the proposed site investigations may compromise YG's and AANDC's ability to complete design, assessment and permitting for the FMRP. As such, there are no alternatives to completion of the site investigations.

As described in Section 5, the site investigations proposed for 2014 were defined based on the results of a detailed gap analysis. The gap analysis and subsequent field planning exercise considered alternative means of collecting the necessary environmental and engineering information. Methods were selected to maximize the effectiveness of data collection programs while minimizing adverse effects. For example, initial investigations of potential borrow areas use non-intrusive methods to narrow down the areas that may be subject to more intrusive investigations.

4.2.3 Down Valley Interim Hydraulic Upgrades

The DVIHU component of the IW is intended to address flood-related risks for the RCTA, thereby helping to reduce the likelihood of potential adverse effects on the environment. Section 5 provides a detailed description of the proposed DVIHU that entails upgrading the hydraulic capacity of both the Intermediate Dam spillway and the RCD to provide capacity for the system to convey a 1-in-500-year flood event.

DRAFT

YG and AANDC considered three alternatives to addressing the flood risk before selecting the proposed DVIHU as part of the IW. Those three alternatives included:

- Maintain the RCD and Intermediate Dam spillway in their current configuration: Continue to maintain the existing facilities without substantial improvements in flood routing capacity.
- Construct the permanent flood routing facilities for the RCTA: As proposed in the FMRP, construct enhanced flood routing capacity for the RCTA to provide capability to convey the probable maximum flood (PMF).
- Construct the proposed DVIHU: interim upgrades to reduce flood-related risks for a period of several years, while planning and design for the FMRP are completed.

Based on annual operational risk assessments, YG and AANDC concluded that maintaining the current flood routing configuration for the RCTA presents an unacceptable risk. *Medium Term Plan, Faro Mine Remediation Project* (YG and AANDC, 2013b) describes the rationale for this conclusion:

> *"Despite the ID being rated as a "Very High" to "Extreme" risk dam based on the Canadian Dam Association (CDA) Dam Safety Guidelines 2007 (CDA, 2007), the existing spillway (capacity of 32 m3/sec) cannot safely pass a moderate or major flood event without potentially failing the dam. ID dam failure may cause an environmentally damaging discharge of metals-laden tailings to the Rose Creek Valley, Anvil Creek, and the Pelly River that would result in a significant or major loss of critical fish and wildlife habitat that would be impractical or impossible to restore. Failure of the Secondary Dam in 1975 within the Rose Creek Valley resulted in a loss of wildlife habitat, with little recovery evident more than 35 years later."*
>
> YG and AANDC, 2013b

YG, AANDC, and their design team have expended significant effort in evaluating options for permanent flood routing at the RCTA capable of conveying flows up to the PMF. Enhanced flood routing facilities constructed as part of the FMRP will have the capacity required for dams that have "Very High" or "Extreme" risk classifications. However, PMF spillway construction is a major undertaking that is impractical to implement within the timeframe necessary to respond to current flood-related risks, due to requirements for field investigations, design, funding and approvals.

YG, AANDC, the IPRP, the IE, and the design team met at a workshop in 2012 to review and evaluate alternatives for permanent routing the of the PMF flood through the Rose Creek Valley. While the group recommended construction of the permanent spillway facilities as soon as reasonably possible, they also agreed about the impracticality of timely completion of the permanent facilities and recommended interim upgrading of the hydraulic capacity of flood routing facilities. (YG and AANDC, 2013)

The DVIHU have been designed as an option that can be completed in a timely and cost-effective way, thereby providing suitable risk management for the IW period prior to construction of the permanent flood routing facilities. The proposed works are described in detail in Section 5, but generally include the following:

- Increase the existing ID spillway capacity by increasing the depth of the existing spillway channel.
- Relocate existing piping and lime mix tank that have been placed within the ID spillway.
- Increase the height of the ID embankment crest by installing a geomembrane layer to extend the core to the dam crest and by addition of gabion mattresses.
- Protect the ID spillway channel from erosion by installing gabion mattresses.
- Increase the RCD capacity to pass the 1-in-500-year flood event, by removing vegetation, repairing raveled slopes on the dike and cut slope, and by filling in low spots on the dike crest.

The work is proposed for completion as soon as possible because the DVIHU are intended to provide temporary protection of the ID until implementation of the final closure plan (YG and AANDC, 2013).

DRAFT

SECTION 5

Project Description

5.1 Interim Works Project Scope

This section describes the components and related activities that make up the IW and identifies activities the scope of the proposed project excludes, and rationales for their exclusion. In general, the IW consists of works and activities that are required to protect human health and the environment from the ongoing effects associated with the legacies of mining activities at the FMC, and to manage risks associated with those legacies. The following four areas make up the IW environmental and socio-economic assessment scope:

- Site operations (Section 5.3)
- Site investigations (Section 5.4)
- DVIHU (Section 5.5 and detailed in Appendix 5I)
- Ancillary activities associated with completing site operations, site investigations and the DVIHU (e.g., worker accommodation and borrow source investigation and development) (Section 5.6).

As a fundamental part of the above activities, preventing and counteracting mining effects and managing site risks requires the ongoing implementation of comprehensive monitoring and adaptive management plans and of a risk assessment process. All of these project components are also described in this section. The monitoring and adaptive management plans are described in more detail in Appendix 5B, Environmental Monitoring, Surveillance and Reporting Plan, and Appendix 5C, the AMP.

In conjuction with the above activities, the project requires application of a series of management plans that are intended to mitigate potential effects. These are also described in this section and detailed in the following appendices:

- Appendix 5A Environmental Management Plan
- Appendix 5D C&M Risk Assessment Report
- Appendix 5E Spill Prevention and Response Plan
- Appendix 5F Emergency Management Plan
- Appendix 5G Access Management Plan
- Appendix 5H Heritage Resource Management Plan

The environmental and socio-economic assessment presented in subsequent sections considers the consolidated effects of all works and accessory activities.

5.1.1 Site Operations

Site operations are the ongoing site activities required to prevent the FMC from adversely affecting persons, property, or the environment, and to counteract, mitigate, and remedy adverse effects that do occur. The site operations scope for the IW includes the following components:

- Water management operations, including operating, maintaining, repairing, and monitoring water management systems and facilities at the FMC, as follows:
    - Fresh water conveyance diversions and facilities
    - Contaminated water collection, conveyance, and storage facilities
    - Water treatment at the Vangorda WTP and the Interim Water Treatment System at the Faro Mine Area, and associated sludge storage facilities
    - Dams and spillways

DRAFT

- Operation, maintenance, repair, and monitoring activities required to understand and maintain safety and functionality, and manage the physical and chemical risks to the stability of site components, facilities, and equipment:
  - Pits, waste rock storage facilities, ore stockpiles, tailings (e.g., dust suppression), and tailings storage facilities
  - Ditches, culverts, and stream crossings
  - Roads, trails, and access routes
- Environmental management and monitoring, adaptive management, and risk management activities:
  - Adhering to the prescriptions of the Environmental Management Plan (Appendix 5A), which was developed so appropriate environmental management practices are carried out during the IW.
  - Conducting extensive monitoring programs to evaluate and understand environmental conditions, and the FMC's physical and chemical stability
  - Implementing an AMP to assure timely evaluations of site uncertainties, and equally timely responses, as necessary
  - Implementing a risk assessment program to continually re-evaluate risks to health, safety, and the environment

The site operations scope includes the implementation of interim responses that are identified in the AMP, provided those do not require major upgrades of site facilities or major changes to operational activities. For example, the assessment's scope includes the implementation of interim groundwater collection systems that the AMP triggers during the IW, providing implementing the system does not require major upgrades to the water treatment facilities.

5.1.2 Site Investigations

Developing the FMRP and designing remediation and closure elements requires extensive site investigation programs. These programs are anticipated to take place throughout the IW. The requirements for specific investigations will evolve as site conditions change, the results of sequential investigations become available, and design requirements are identified. Site investigations to be conducted during the IW include land use activities listed below.

- Sampling soil and rock and establishing monitoring wells and installations using various types of drilling equipment
- Conducting geotechnical investigation programs, including test pitting, reconnaissance, drilling, and sampling
- Constructing temporary access to investigation locations, including stream crossings.
- Using water for a variety of programs, including aquifer testing
- Establishing, maintaining, and operating various monitoring facilities, including wells, flow measurement facilities, and meteorological stations
- Establishing, maintaining, and operating test facilities to support reclamation research, including cover trials and vegetation trials
- Collecting vegetative material to support re-vegetation test programs
- Conducting reconnaissance programs, which may include use of helicopters
- Using heavy equipment to test remediation methods
- Test pitting, drilling, and sampling to support contaminated site assessment, and to identify and quantify borrow sources

DRAFT

- Completing heritage and archaeological assessment programs
- Completing water treatment test programs
- Conducting field surveys for wildlife and habitat, as well as aquatic organisms and habitat
- Completing geophysics and seismic refraction programs
- Completing sampling programs including water, soil, rock, flora, fauna, and air
- Conducting surveying activities with associated line cutting, and establishing survey markers

5.1.3 Down Valley Interim Hydraulic Upgrades

The DVIHU provides improvement of flood routing capacity to the ID, where the current capacity does not meet the minimum standards specified in the CDA Dam Safety Guidelines (CDA, 2007). The RCTA contains approximately 55,000,000 tonnes of acid-generating tailings, whose release may cause adverse environmental effects. The existing ID spillway capacity (32 cubic metres per second [m^3/sec]) is smaller than the 1-in-500-year flood event (115 m^3/sec), required by the expired water licence. The DVIHU includes works to increase the capacity of the ID spillway. It also includes minor upgrades and maintenance to increase the capacity of the RCD to convey the 1-in-500-year flood event, with freeboard.

Upgrading the facilities to safely pass a 1-in-500-year event would provide acceptable risk management for the 10-year duration of the IW. The co-proponents acknowledge that planning for the FMRP has taken place on the basis of requirements established by the previous water licences. These have specified that the final remediation for the Rose Creek Tailings Area will (1) provide flood routing capacity for the PMF and (2) be able to withstand the maximum credible earthquake. The FMRP will include additional upgrades to achieve these design criteria. The co-proponents anticipate the FMRP flood-routing upgrades at the ID will require significant additional work.

It is likely that the interim upgrades at the ID will not experience flow during the IW because the design of the RCTA provides primary routing through the RCD for floods up to 1-in-500-year event. In addition, because the spillway will likely be redesigned to carry the PMF as part of the FMRP, the proposed interim hydraulic upgrade is designed as a temporary, rather than permanent structure.

The DVIHU scope includes the following:

- Increasing the capacity of the existing ID spillway by making it deeper and raising the crest height of the dam by addition of a geomembrane and gabions to raise the effective core of the dam
- Relocating piping and structures currently located within the ID spillway
- Constructing erosion protection in the expanded ID spillway (gabions and gabion mattresses)
- Increasing the RCD's capacity by removing vegetation, repairing slopes, and filling low spots on the dike crest

5.1.4 Ancillary Activities

The IW requires a number of ancillary activities associated with the activities presented in Sections 5.1.1 through 5.1.3. To address the environmental and socio-economic assessment of the IW, the IW includes the following ancillary activities:

- Maintaining site security by providing an ongoing site presence, establishing security facilities and programs, and managing site access as needed to secure the FMC and manage health and safety risks
- Maintaining and operating an office and gatehouse building at the FMC
- Providing emergency response capabilities and responding to emergencies
- Implementing preventative maintenance programs
- Maintaining buildings, site infrastructure, and utility systems (e.g., electrical distribution system maintenance and a waste-oil heating system)

- Maintaining stationary and mobile equipment
- Expanding existing borrow sources to supply aggregate and construction materials for C&M and DVIHU activities
- Providing onsite accommodations for site workers, including temporary camps (e.g. construction activities, field investigation programs)
- Maintaining and operating employee housing within the Town of Faro
- Maintaining existing roadways
- Procuring supplies and energy sources for the FMC (e.g. lime for water treatment and fuel)
- Transporting goods and equipment to and from the FMC (e.g., providing the materials listed herein and removing hazardous waste)
- Using existing solid waste disposal facilities at the FMC
- Managing special wastes (this includes operating a waste-oil heating system)
- Withdrawing and using fresh water for domestic purposes
- Using, maintaining, and repairing existing septic systems at the FMC
- Performing additional ancillary activities to complete the IW activities

5.2 Project Stages and Lifespan

As described in Section 3.2.4, a preferred closure option was selected in 2009 to provide the basis for the long-term closure and remediation of the FMC. These long-term closure and remediation activities make up the FMRP. However, more data are needed to further develop and design the remediation and closure elements. Therefore, planning efforts to design, assess, and permit the FMRP include additional site investigation programs to collect these data. The IW consist of these site investigation programs, as well as the existing operations and limited interim (i.e., DVIHU) activities to minimize risks at the FMC until the FMRP can be implemented. The IW are temporary activities, intended to minimize effects and manage risks at the FMC while the project team completes the design, permitting process, and procurement for implementation of the FMRP.

Site operations (Section 5.3) are ongoing and will be undertaken continuously throughout the IW. On an annual basis, activity levels generally increase between May and October and decrease between November and April.

Site investigations will take place throughout the IW period. An extensive site investigation field program is planned for the 2014 field season; however, additional site investigation activities will take place in subsequent years. The scope of the ongoing investigations will be determined based on the project's design requirements and the results of the initial investigations and studies.

The DVIHU is planned to be initiated and completed within 3 fiscal years. Final design will be completed during the 2014/2015 fiscal year, procurement will take place during the 2015/2016 fiscal year, and construction will be completed during the 2016/2017 fiscal year.

The IW is scheduled to take place over 10 years, from 2014 to 2024. This duration is based on an estimated 2 to 4 years to prepare the FMRP Project Proposal and another estimated 4 to 6 years to complete assessment and permitting processes, develop the final design, prepare contract documents, and initiate the implementation of the final closure measures.

FMRP construction will be initiated after the IW. The FRMP activities will have different effects than the IW activities; in the long-term, the FMRP will mitigate effects at the site. However, FMRP activities require additional planning before they can be defined sufficiently to predict their long-term effects.

DRAFT

The FMRP will undergo a YESAA assessment before it proceeds, and YG and AANDC currently anticipate the Remediation Project Proposal will be submitted in 2017. The assessment for the FMRP will consider its potential effects, combined with the continuing effects of the IW after its proposed 10-year scope.

5.3 Site Operations

As described in Section 5.1.1, site operations are the ongoing site activities required to (1) prevent the FMC from having adverse effects on persons, property, or the environment and (2) counteract, mitigate, and remedy adverse effects. Site operations will be managed in accordance with the established Environmental Management and Monitoring Plans (Section 5.3.3 and Appendices 5A and 5B), the AMP (Section 5.3.4 and Appendix 5C), and the Risk Assessment (Section 5.3.5 and Appendix 5D).

The site operations activities have specific objectives:

- Minimize the amount of clean water that enters contaminated areas of the site and subsequently requires treatment
- Maximize the capture of contaminated water for treatment
- Store and treat contaminated water
- Manage treatment residuals (sludge)

The following major components of site operations are described in this section:

- Water management operations
- Routine operation, maintenance, and repair activities
- Environmental management and monitoring plans
- Adaptive management plan
- C&M risk assessment

5.3.1 Water Management Operations

Water management is the most important site operations activity at the FMC. These include:

- Conveying clean water around the FMC
- Collecting contaminated water
- Treating non-compliant water
- Providing storage capacity for non-compliant water and unforeseen events

Water management operations include operating, maintaining, repairing, and monitoring the following water management systems and facilities at the FMC:

- Fresh water conveyance diversions and facilities
- Collection, conveyance, and storage facilities for contaminated water
- Vangorda WTP
- Interim Water Treatment System
- Water treatment sludge storage facilities
- Dams and spillways

FMC water management operations establishes operational targets so that the contaminated water storage systems have capacity to store forecasted non-compliant water, and additional water resulting from unforeseen events, unusual environmental conditions, and operational upsets. To accomplish this, site water management and site operations are reviewed annually. These reviews note changes to water management systems and site conditions. A site water balance model is used to inform the annual assessment. Based on this review, end-of-season water operational targets are revised, if required.

DRAFT

5.3.1.1 Faro Mine Area and the Rose Creek Tailing Area

Fresh Water Conveyance

Before mining development, several creek systems traveled through FMC. To facilitate development and protect these systems from mine-related contamination, these creeks were routed around the mine development areas via diversions, flumes, and ditches. There are three primary diversions in the Faro Mine Area (Figure 5-1):

- The FCD diverts Faro Creek around Faro Pit into the NFRC.
- The RCD diverts Rose Creek around the RCTA.
- The North Wall Interceptor Ditch collects runoff from the catchment areas north and northwest of the Faro Pit and routes it around the west side of the pit to Rose Creek downstream of the RCTA.

Faro Creek Diversion

The FCD will continue to be used and maintained during the IW to route Faro Creek water around Faro Pit and into the NFRC. The West Valley Interceptor Ditch is a component of the FCD that collects runoff from the west hillside above Faro Creek and directs the flow into the diversion. The FCD passes close to the northeast wall of Faro Pit.

Within the Faro Pit, the northeast pit wall is gradually ravelling into the pit. The rate of crest retreat is anticipated to be similar to the rates observed during the last few years. Only localized erosion, sloughing, and ravelling have been recently observed (Appendix 6C). During the IW, the crest of the pit wall is not anticipated to compromise the FCD. Water level targets in the Faro Pit consider water storage requirements in case the FCD does fail. The stability of the pit wall will continue to be assessed throughout the IW as part of the site geotechnical monitoring program described in the C&M Environmental Monitoring, Surveillance and Reporting Plan (Appendix 5B).

The following maintenance activities are proposed for the FCD:

- Clear ice, accumulated sediment, and debris, as necessary, so that flows are properly routed.
- Clear sloughed bank material.
- Upgrade portions of the channel to minimize leakage to Faro Pit and provide erosion protection
- Replace damaged geotextile and liners in the diversion channel and cover exposed liner material with rock armour.
- Repair or upgrading the containment dike.

North Wall Interceptor Ditch

The North Wall Interceptor Ditch will continue to divert runoff from Upper Guardhouse Creek and the slopes north of the Rose Creek Valley around the north abutment of the CVD. The following maintenance activities are proposed for the North Wall Interceptor Ditch:

- Clear ice, accumulated sediment, and debris, as necessary, so that flows are properly routed.
- Clear sloughed bank material.
- Clear vegetation along the upper and middle constructed channel reaches, as well as access roads and berms along the channel, to facilitate channel inspections.
- Clear excessive sediment accumulation upstream and downstream from the well access road crossing.
- Clear ice and debris from the twin culverts in the outfall section at Station X5.
- Maintain the Guardhouse Creek diversion dam.
- Maintain or upgrade the culvert road crossing near the CVD Pond.

DRAFT

Rose Creek Diversion and Canal Dike

The RCD is the most significant water management structure within the RCTA, and routes the entire flow of Rose Creek around the south side of the RCTA and the CVD Pond. The diversion dike flanks the north side of the diversion channel and separates the RCD from the tailings, the ID Pond, the ID, and the CVD Pond. The RCD has a design capacity of 140 m^3/sec, without freeboard, which is slightly more than the 1-in-500-year flood event (Appendix 6B). Vegetative growth and other channel-maintenance-related issues have decreased the RCD flow capacity to less than the 1-in-50-year flood flow. The proposed DVIHU (Section 5.5) include modifications to the RCD that will provide capacity to allow the diversion to pass the 1-in-500-year flood event with freeboard. These include:

- Removing vegetation
- Repairing ravelled slopes on the dike and cut slope
- Filling in low spots on the dike crest
- Raising the fuse plug (overflow structure)

The following routine maintenance activities are proposed for the RCD:

- Clear ice, debris, and vegetation.
- Repair or upgrade the backslope.
- Install or replace new monitoring instrumentation, as required.

As discussed in Appendix 5B (the EMSRP), the proposed geotechnical monitoring program for the RCD includes semi-annual [spring and autumn] reading of the geotechnical instrumentation located at the RCD. These include thermisters, piezometers, and slope indicators. A professional geotechnical engineer will inspect the dike and backslope annually. This inspection will include a review of the geotechnical instrumentation data. The monitoring program will be updated annually, as necessary, in response to recommendations from a professional engineer.

Contaminated Water Collection, Conveyance, and Storage

Contaminated water is managed through collection, storage, and treatment at the Faro Mine and Vangorda/Grum Areas. At the Faro Mine Area, contaminated water is collected or stored in six areas: (1) the Zone II Pit, (2) the S-Wells SIS (3) the ETA, (4) the ID Pond, (5) the Faro Valley Dump Pond, and (6) the Faro Pit.

Zone II Pit

The backfilled Zone II Pit collects contaminated water from its immediate catchment area. If water in the Zone II Pit rises above 1,128 metres above sea level (masl), it will seep over the buried rim, towards the NFRC. In 1991, a water management plan was implemented for the Zone II Pit. This plan involved seasonal (summer) dewatering to the Faro Pit via a down-hole pump installed in a well (X26) within the Zone II Pit. Water was pumped, as needed, to maintain the water level below 1,116 masl and thereby reducing groundwater migration towards the NFRC. The pump intake was limited to an elevation of approximately 1,103 masl. However, operating to this target water level elevation left a hydraulic gradient from the pit towards NFRC (CH2M HILL, 2012a).

In 2012, a new well was installed (CH12-Z2-PW01) with a screened interval between 1,091.7 and 1,114.0 masl and a sump extending to 1,088.6 masl. In 2013, a submersible variable speed pump with a capacity of 5 litres per second (L/s) was installed. The pump discharge line is fitted with a digital flow meter with data logger, a sampling port for Zone II Pit water, and a gate valve so the pump discharge can be adjusted manually (if required). The pump controls and monitoring instruments at the well head are enclosed in a heated container (sea-can) to allow winter operation. Pumped water discharges to Faro Pit (30 m below surface) via an insulated and heat-traced high-density polyethylene (HDPE) pipeline, for year-round operations.

The water level in the Zone II Pit will now be maintained by operating the new Zone II pumping system year-round, with a target elevation of 1,096 masl. The old Zone II pumping well will remain available as a back-up system. The old pumping well will only operate during summers.

DRAFT

S-Wells Seepage Interception System

The S-Wells SIS is located at the base of the Intermediate Dump, adjacent to the NFRC. It intercepts contaminated seepage and groundwater from the Main and Intermediate Dumps. The S-Wells SIS includes two main components (CH2M HILL, 2012a; SRK Consulting Engineers and Scientists [SRK], 2010a): (1) two pumping wells within the Deep Aquifer (SRK08-SPW1 and SRK08-SPW2) and (2) a shallow aquifer interception trench. The interceptor trench consists of a 25-m trench installed in February 2009 and a 15.4-m eastern extension installed in November 2009. A Bentomat liner was installed on the downstream face of the western 10 m of the trench and in the bottom and downstream faces of the eastern extension. An Enviro-liner was used for the remainder of the trench (SRK, 2010a). Within the trench, a 2.1-m-diameter central sump (PW3) cross-cuts the shallow aquifer, a 15-horsepower (HP) pump is positioned 0.6 m below the base of the shallow aquifer, at 1,083.3 masl (approximately 7.6 m below ground surface) (SRK, 2010a). Figure 5-2 provides a schematic of the S-Wells SIS.

Pumping well SRK08-SPW1 is not currently operational, because of excessive precipitate formation. The S-Wells SIS collects water year-round. This water is pumped to the Faro Pit, where it is discharged approximately 30 m below the pit lake water level. There are two pipes for conveying the water to Faro Pit:

- A 5.1-centimetre (cm) (2-inch) insulated HDPE pipeline (operating flow of 2.9 L/s) with heat–trace and a vacuum break at the pipeline high point
- A parallel uninsulated 10.3-cm (4-inch) HDPE pipeline, used during spring freshet (operating flow of 4.1 L/s)

An 8-foot-by-10-foot sea-can is installed over the sump, complete with all piping, valves, meters, controls, and discharge pipeline. Data loggers within the sea-can control housing record flow rates, cumulative pumped volumes, and water levels. An electrical line from the Faro Pit area provides the S-Wells area with power.

Since the system was modified in November 2009, the S-Wells SIS has intercepted, collected, and routed approximately 68,000 cubic metres (m^3) of water to the Faro Pit each year (Denison Environmental Services [DES], 2012; TEES, 2013a).

The S-Wells SIS does not have specific operational targets, but the general objective is to collect as much water as possible, based on the system capacity, to limit the amount of contaminated water entering the receiving environment. The S-Wells SIS will continue to operate this way during the IW. Contingency measures for the S-Wells SIS include repairing system components as soon as practical, when required.

Emergency Tailing Area Collection System

The ETA has been shown to contribute a significant contaminant load to the Rose Creek Alluvial Aquifer (RCAA) under the RCTA, through seepage and groundwater migration (Robertson GeoConsultants [RGC], 2007). In response, an SIS was installed in winter 2006/07 to collect waters on a seasonal basis draining to the ETA. The ETA collection system consists of the following components:

- Cut-off trench
- Sumps with 30-HP pumps
- Piping to pump to the Faro Pit or to the Interim Water Treatment System

The ETA collection system does not have specific operational targets, but the general objective is to collect as much water as possible, based on the system capacity, to limit the amount of contaminated water flowing downgradient to the ID Pond and potentially to the underlying RCAA. The ETA collection system will continue to operate seasonally during the open water season and will be activated as early as possible in the spring, pending suitable ice-free conditions. It will operate through the summer and autumn, until freezing temperatures occur. Typically, the ETA collection system will operate from May through October of each year, pumping up to 1,000 litres per minute (L/min) (CH2M HILL, 2012a). Contingency measures for the ETA include repairing system components as soon as practical, when needed.

During periods that the ETA collection system does not collect water, during operational upsets and during the winter season, it is routed to the ID Pond.

Intermediate Dam Pond

Water and tailings are retained behind the ID, and the ID Pond collects contaminated runoff water from the tailings, ETA, and Lower Guardhouse Creek. As part of the IW, water from the ID Pond will continue to be pumped seasonally to either the Faro Pit or Interim Water Treatment System. The water level in the ID Pond will be managed to maintain the water level elevation between 1,045.2 masl (top of the lower riprap) and 1,044.2 masl (bottom of the lower riprap). This will limit the potential for erosion to the upstream face of the dam. On a contingency basis only, operations may occur outside this range, to prevent uncontrolled releases of water from the ID Pond. When the dam operates below the bottom of the lower riprap (1,044.2 masl), its face will be monitored for erosion. If necessary, maintenance (i.e., erosion repair and riprap replacement) will be carried out. In addition, the stability of the riprap layer will be monitored and the water level drawdown will be suspended, if required.

Two 150-HP stainless-steel pumps, mounted on a floating barge, currently pump water via using a 350-millimetre (mm) -diameter HDPE pipeline. The current capacity of the ID Pond pumping system is 8,200 L/min. To provide sufficient storage capacity for snowmelt and spring freshet, the ID Pond will be pumped as early as practical in the spring. Pumping will continue throughout the summer and autumn to maintain the pond elevation within the recommended range. The ID Pond's drawdown is limited to a daily maximum of 40 mm to avoid potential instability related to rapid drawdown conditions. (Klohn Crippen Berger Ltd.[KCB], 2012a; CH2M HILL, 2012b).

Faro Valley Dump Pond

The Faro Valley Dump Pond is the area of ponded water that accumulates from local runoff along the alignment of the original Faro Creek channel, upstream from the Faro Valley Waste Dump. To reduce seepage into the Faro Pit, the ponded water will be periodically pumped to the FCD, provided it meets suitable discharge target water quality (currently set at 0.3 milligrams per litre [mg/L] for total zinc). Currently, data for the ponded water indicates the water quality does not meet the discharge target.

Faro Pit

The Faro Pit is an important reservoir for the active water management program at the FMC. It receives groundwater seepage, direct precipitation, runoff, FCD seepage, and water from managed sources such as the ID Pond, the S-Wells, the Zone II Pit, and the ETA. Until the fall of 2012, the water level in Faro Pit was maintained well-below the pit overflow elevation, within the prescribed operating range that has been in place since 1998. The purpose was to prevent an uncontrolled release of non-compliant water from Faro Pit to the receiving environment. Using this water management regime, the maximum recommended water elevation for the Faro Pit was set at 1,144.3 masl, which is approximately 14 m below the lowest point in the pit perimeter (1,158 masl), the point at which Faro Pit water could seep to the Zone II Pit.

The freeboard below the overflow in the Faro Pit was determined to provide sufficient storage capacity to prevent water from the Faro Pit from overflowing into Zone II Pit during an unforeseen event; specifically, a breach of the FCD for a 1-week PMF event (RGC, 1996). The minimum recommended elevation for the Faro Pit was set at 1,139 masl, based on the lower limit of the hinge range for the pumping barge. The Faro Pit water level was maintained within this prescribed range through a seasonal (summer) pumping program by pumping from the pit to the existing Faro Mill WTP. The objective of the summer pumping program was to draw the pit water level down to a pre-determined target elevation, set as 1,141 masl. This elevation allows capacity for seasonal recharge during winter, when pumping is not feasible. From 2004 until 2012, the water-level elevation in Faro Pit was maintained between approximately 1,140 m and 1,143 masl.

The Faro Pit pumping system included the following primary components (DES, 2011a):

- A floating steel barge with a walkway to the shore
- Three electric submersible pumps mounted on the barge
- Barge-mounted valving, flex hose, and header to combine flow from all pumps to one pipeline

- A 760-cm (30-inch) HDPE pipeline from the barge to the Faro Mill WTP, with flexible sections (flex hose) near the barge to prevent damage to the pipeline
- A transformer and electrical control house on shore, adjacent to the barge
- An overhead power line (4,160 volt), running from the Faro Mill substation to a transformer adjacent to the pumping barge

Each 225-HP barge-mounted pump could deliver between 7.6 cubic metres per minute (m^3/min) (approximately 2,000 United States gallons per minute [USgpm]) and 19 m^3/min (approximately 5,000 USgpm) of water to the existing Faro Mill WTP. On the barge, a manually operated valve controlled the flow rate. Typically, one pump was operated to deliver water, as the Mill WTP could only treat 19 m^3/min (approximately 5,000 USgpm). However, pumps could be run in tandem to supply more water to the Mill WTP, if required.

The existing Faro Mill WTP is located in the old Faro Mill Building and was constructed using existing ore-processing equipment adapted for water treatment. The existing Faro Mill WTP began to operate in 2001, and its original design life was intended to be 5 years (CH2M HILL, 2012c). In 2012, the existing Faro Mill WTP was assessed, and it was determined that there was an increasing risk of major equipment failure in the WTP (CH2M HILL, 2012c). In addition, a safety assessment of the existing Faro Mill WTP determined that the facility should not be operated until serious health and safety issues could be assessed and resolved (AMEC Environment and Infrastructure Limited, 2013). Consequently, the existing Faro Mill WTP ceased operations at the end of the pumping program in fall 2012. In spring 2013, the Faro Pit pumping barge was detached and relocated. Starting in summer 2013, contaminated water in the Rose Creek watershed was pumped to Faro Pit for storage.

Because the existing Faro Mill WTP was not used in 2013, the water-level elevation in the Faro Pit rose above the end-of season target (1,141 masl) to its water-level elevation of 1,148.3 masl as of January 27, 2014. The pumping system will be re-established as early as possible in 2014, and seasonal dewatering of the Faro Pit will resume through treatment at the Interim Water Treatment System when construction is completed in the summer of 2014.

The barge system will be replaced with a skid-mounted pump that will be moved as the water level lowers. The rate of dewatering will be set to a rate high enough to control and reduce the water level in the Faro Pit with the objective to achieve the end-of-season target of 1,141 masl as soon as practicable. Based on current site conditions, the water balance model predicts that the water level in the Faro Pit will return to the operational end-of-season target by summer 2016. For the remainder of the IW, the water-level elevation in the Faro Pit will be managed within the prescribed operating range outlined above.

Water Treatment at the Faro Mine Area

The Interim Water Treatment System will seasonally treat water from the Faro Pit, the ETA, the ID Pond, and other contaminated water sources at the Faro Mine Area and the RCTA. Treated effluent from the Interim Water Treatment System will discharge to the CVD Pond for clarification (solids removal) before discharge to Rose Creek. Water that complies with the proposed discharge limits (Table 5-2) will be discharged seasonally from the CVD Pond to Rose Creek through a siphon system located at Monitoring Station X5.

Interim Water Treatment System

The Interim Water Treatment System will be a modular lime-neutralization system that can treat up to 32,700 cubic metres per day (m^3/day) (6,000 USgpm). The system is expected to operate seasonally (May to September), though it could be operated at other times if necessary. As planned, the system will include modular equipment for the following operations:

- Lime storage, slurry makeup, and feed
- Mine-water neutralization and metal precipitation
- Primary clarification, with polymer- and microsand-assisted settling
- Sludge wasting to the tailings sludge ponds or into the Faro Pit

The Interim Water Treatment System will consist of mobile and skid-mounted equipment, connected by rigid and flexible piping. It will be located on the existing concrete pad in the Mill Yard, just south the Mill Building (Figure 5-3). This pad was used as a load-out area for zinc concentrate during mill operations.

Influent will be split between two 16,350 m^3/day (3,000 USgpm) treatment trains from a header pipe connected to existing pipelines from the Faro Pit, the ID Pond, and the ETA. Feed to the Interim Water Treatment System will consist of either a single, blended influent source from Faro Pit, or of influent from each individual source. Flow meters will be used to measure and record the flow split between the two treatment trains.

The treatment system described here is currently being developed to meet treatment requirements in early 2014. However, the system may be refined throughout the IW, as necessary, to provide effective water treatment.

Lime slurry will be made using a Porta Batch portable lime-slaking system from Lhoist North America. Either influent or effluent will serve as the water source for the slurry. A 20-tonne container of quicklime will be used each time a batch of lime is slaked. First, the Porta Batch will be filled with the required volume of water, and then a lime blower will pneumatically convey the 20 tonnes of quicklime into the Porta Batch while it mixes. Dust will be controlled because the lime will be discharged below the liquid surface. After slaking is completed, about 60 to 75 minutes, the slurry will be about 30 to 40 percent solids by weight. To maximize pH control, the slurry will be diluted in a mix tank to provide 10 to 15 percent lime slurry.

Figure 5-4 provides a process flow diagram of the Interim Water Treatment System. Once the influent is split between the two trains, it enters a mixed reactor tank configured into three compartments, in series. From there, it will flow into a second, similar mixed reactor tank, which in turn will flow into an Actiflo clarification skid. Polymer will be added to adhere the metal precipitates to microsand to facilitate rapid settling in the lamella clarifier. The settled sludge will be pumped to a cyclone, where the precipitates will be separated from the microsand. The microsand will be recirculated for reuse and the precipitates will be discharged to a sludge mix tank. Makeup microsand will be required periodically, as recovery is not 100 percent.

A variable-speed pump will be used to pump waste sludge via the existing piping to the tailings sludge ponds. The waste sludge is expected to be between approximately 3 and 4 percent solids by weight (Laliberte, 2013, Personal Communication). Wasting will take place as needed. Approximately 210 m^3/day of sludge will be wasted, based on a treatment rate of 32,700 m^3/day (6,000 USgpm). A portion of the sludge will flow by gravity to another sludge mix tank for mixing with lime slurry. The amount of additional lime slurry will be controlled automatically via pH feedback from pH probes in the two mixed reactor tanks. A variable-speed pump will pump the lime slurry from the lime slurry mix tank will take place via a recirculation loop. The lime/sludge mixture will then be pumped to the first compartment of the first mixed reactor tank. Figure 5-3 shows a preliminary layout of the Interim Water Treatment System.

Clarified overflow from the Actiflo clarifiers will flow by gravity to the CVD Pond. The turbidity of clarifier overflow will be continuously measured and recorded. Additional clarification will take place in the CVD Pond, similar to the existing Faro Mill WTP's operations. Lime slurry will be added to the clarified overflow as needed, to maintain a high pH in the CVD Pond. This will enhance solids removal before discharge. Effluent will discharge from the CVD Pond to Rose Creek via the CVD Pond siphon system at the X5 Monitoring Station. Using this approach, the Interim Water Treatment System effluent will meet the proposed effluent limits outlined in Table 5-2. If necessary, a flow baffle will be installed within the CVD Pond to increase settling time, or mobile filtration equipment will be used to supplement solids removal at the CVD Pond.

All tanks and vessels, except for the Porta Batch and Baker mix tank, will be housed within a heated building (i.e., a Sprung-type building). The Porta Batch and lime slurry mix tanks are designed for outdoor operation, and will be winterized. A construction-type trailer located outside the Sprung-type building will house the programmable logic controller and the human-machine interface, and will serve as a control room. The Sprung-type building will house 1,000-kg bags of polymer, as well as equipment to make and feed the polymer. Lime will be stored onsite in 20-tonne shipping containers to provide sufficient inventory for uninterrupted water treatment.

Interim Water Treatment System performance will be operated and monitored according to the FMC Operations Manual, under development. The Interim Water Treatment System will undergo routine maintenance and repairs, as required, to optimize its performance

Interim Water Treatment System Sludge Management

Sludge generated in the Interim Water Treatment System will either be deposited (1) in the existing tailings sludge ponds in the Original Impoundment or (2) in the Faro Pit via a new pipeline. For placement in the existing tailings sludge ponds, at the end of each treatment season, once partially frozen, the sludge will be excavated from the ponds and placed in windrows next to the ponds, similar to the past operations. After placement, water will be decanted off the solids as they thicken and routed to the ID Pond, where it will enter the treatment circuit. If the sludge is disposed in the Faro Pit, a new pipeline will be constructed. This pipeline will run from the Interim Water Treatment System to the pit ramp, down the pit ramp, and into the pit below the surface at sufficient depth to convey the sludge to the lower elevations of the pit lake.

Cross Valley Dam Pond

The CVD Pond will continue to be part of the active water management system at the FMC, by removing solids before effluent discharges to Rose Creek. Water that complies with the proposed discharge limits (Table 5-2) will primarily discharge seasonally (April to October) from the CVD Pond to Rose Creek at Monitoring Station X5. The existing siphon system has a maximum discharge capacity of 27,000 L/min. The current fall target water level elevation in the CVD Pond is 1,027.5 masl. This elevation provides maximum storage capacity, while considering the elevation of the sludge beds in the pond (670,000 m^3) (3.18 m freeboard), between the target level and lower spillway (1,030.68 masl). This elevation provides space to store typical winter inflows from October until March without the water level reaching the spillway elevation (approximately 173 days) Limiting the water level in the CVD Pond to 1,027.5 m also prevent its sludge beds from being exposed, potentially resulting in sludge re-suspension, which could impact the pond's water quality.

Water will be discharged from the CVD Pond to Rose Creek primarily during the open water season. Discharge will be initiated as early as practical in the spring and will continue throughout the summer and autumn, as necessary, until the target elevation is reached. Once the target elevation is reached, the discharge rate will transition to match inflow rates for the remainder of the discharge season. Between April and October, discharge from the CVD Pond is limited by a maximum drawdown of 100 mm per day to avoid rapid drawdown conditions at the dam (BGC Engineering [BGC], 2008). Winter discharges (October to March) will only take place as necessary and as conditions allow. Water quality in Rose Creek will further limit the volume of waster discharged from the CVD Pond. Specifically, the volume of water that can be released from the CVD Pond in winter is controlled to achieve acceptable water quality in Rose Creek at X14. Currently, a water quality target of 0.15 mg/L of total zinc is applied to Monitoring Station X14. If low-flow discharges last longer than 4 days, a lower internal target of 0.1 mg/L will be applied. As site conditions evolve, the water quality target at Monitoring Station X14 may be updated, as part of the AMP (Appendix 5C).

Dams and Spillways in the Faro Mine Area

Original and Secondary Dams and Impoundments

The dams that created the Original Impoundment are now almost entirely enclosed by the Secondary Tailings Impoundment. Today, only the Secondary Dam is functional. The Original and Secondary impoundments do not retain water near their surfaces. Surface runoff from these two upper impoundments, into the Intermediate Impoundment, is observed rarely, during extreme precipitation events.

During the IW, maintenance activities are not planned for the Original and Secondary Tailings Dams or Impoundments. The Secondary Dam will be monitored during IW as part of the geotechnical monitoring program described in Section 5.2.2 of Appendix 5B (Environmental Monitoring, Surveillance and Reporting Plan).

DRAFT

Intermediate and Cross Valley Dams

The ID and CVD are critical to the protection of the downstream environment. The ID spillway will be upgraded during the IW to increase its capacity (as described in Section 5.5). Routine maintenance will be necessary, as well as additional maintenance recommended through dam safety inspections. Typical maintenance that may be required includes repairing erosion rills on its downstream face, removing granular material collected on the road surface covering the gravel drain, and maintaining rip rap and the gabion mattresses.

The major physical structure stability evaluation concluded the CVD meets the design criteria for earthquake and flood loading for the IW period (Appendix 6C). As such, the CVD will be monitored and maintained. Monitoring activities will focus on maintaining the water level in the CVD Pond within the operational range. The ID depends on the CVD Pond to provide a counterbalancing hydrostatic head, which contributes to its geotechnical stability. Monitoring is also required during discharge from the CVD, so that the maximum daily drawdown rate is not exceeded and discharge does not affect the geotechnical stability of the CVD.

Appendix 5B, the EMSPR, prescribes weekly and monthly monitoring protocols for the ID and CVD, which include the following activities:

- Monitoring the water level in the ID Pond so it remains within the operational range
- Monitoring the water level in the CVD Pond so it remains within the operational range
- Monitoring seepage flow and water quality at the toe of the CVD (X11, X12, X13, and Weir 3)
- Performing detailed inspections of dam crests and toes
- Monitoring the function of ID and CVD spillways and siphons
- Recording observations of dam instability (e.g. erosion, cracking, bulging, or wet spots)

The following maintenance and repairs may be required:

- Repairing surficial cracks
- Replacing rip rap and other erosion protection measures
- Repairing surficial erosion rills on the downstream slopes

The ID and CVD will undergo formal geotechnical inspections as part of the broader formal geotechnical monitoring program. A qualified engineer will complete the formal inspection program semi-annually (in the spring during freshet and in the fall). Section 5.2.2 of Appendix 5B describes the components of the formal geotechnical monitoring.

5.3.1.2 Vangorda/Grum Area

Fresh Water Conveyance

In the Vangorda/Grum Area, Vangorda Creek is diverted around the Vangorda Pit via the VCD (Figure 5-5). Diverted water is routed back to the original creek, downstream of the FMC. Onset runoff from the north side of the FMC, upstream from Grum Pit, is routed around Grum Pit via the Grum Interceptor Ditch (GID), through the SPP, and into Vangorda Creek. The Vangorda Northeast Interceptor Ditch and the Vangorda Northwest Interceptor Ditch capture and divert freshwater around the Vangorda Pit.

Vangorda Creek Diversion

The VCD is the major water management structure in the Vangorda/Grum Area. Before the Vangorda Pit was mined, Vangorda Creek flowed directly over the Vangorda deposit. The VCD was constructed in 1991 to capture the creek and route it along the northwest rim of the pit. The VCD currently consists of the following components (Appendix 6B):

- Headworks comprising an 8-m-high earth dam and a 1.5-m-diameter culvert within the dam that directs the water into an 800-m-long, 2,400- mm-diameter, half-round corrugated-steel pipe (CSP) culvert section
- A plunge pool or stilling basin located at the end of the culvert sections

- A 3,000-mm-diameter drop-box structure, a 2,000-mm CSP culvert, and a 600-mm outfall culvert conveying the discharge from the plunge pool beneath the Haul Road back into Vangorda Creek
- Two 1,000-mm-diameter culverts at the headworks to provide an emergency spillway (installed 2005) to the Vangorda Pit for events that exceed the 1-in-100-year flood event

The VCD was designed with capacity to divert a 1-in-100-year flood event, and since it has been constructed it has generally been successful in conveying Vangorda Creek flows around the pit during normal runoff events (Appendix 6B). In the last 10 years, the VCD has experienced two flood events that caused significant damage. It has also experienced slope failures and ice-build up, which have compromised its condition and resulted in extensive maintenance activities. Similar activities are expected as part of the IW:

- Clearing ice from VCD and defrosting it throughout winter months to prevent overflow
- Excavating ice from the drop box structure to maintain adequate flow
- Clearing debris at the trash racks (located at the entrance to the drop box inflow culvert) and at the flume headworks to maintain capacity
- Repairing flume sections, including cross-braces and holes in the structure after freshet, resulting from ice damage
- Repairing VCD rock and soil backslopes to prevent slope stability
- Removing debris from flume sections

Vangorda Northeast and Northwest Interceptor Ditches

The Vangorda Northeast Interceptor Ditch conveys uncontaminated surface runoff water that would originally have flowed directly to Vangorda Creek, around the east and south sides of the Vangorda Pit and the Vangorda Waste Dump. The diverted water is routed into Dixon Creek. Flow in the Vangorda Northeast Interceptor Ditch is intermittent. The Vangorda Northwest Interceptor Ditch is an open ditch. It was excavated from the native soils and surficial bedrock upstream from the VCD flume, at the top of the northwest wall of the Vangorda Pit. The water is routed around the northwest area of the pit and re-enters Vangorda Creek at the VCD plunge pool. The maintenance activities related to the Vangorda Northeast Interceptor Ditch and Vangorda Northwest Interceptor Ditch include clearing debris, vegetation, and sloughed material, as necessary, so flows are properly routed.

Vangorda Watering Hole

Natural runoff water collects in the old Vangorda Creek, immediately upstream from the Vangorda Pit. The Vangorda Watering Hole is a natural depression in the old Vangorda Creek channel. Without intervention, this surface runoff naturally flows into Vangorda Pit. Since 2002, a sump at this location has collected water and pumped it to the VCD during the open water season. The objective of this seasonal pumping program is to limit the volume of clean water entering Vangorda Pit. The Vangorda Water Hole is dewatered as early as practical in the spring and continues throughout the summer and autumn. Key activities related to the Vangorda Watering Hole include the seasonal installation, operation, and decommissioning of the pumping system.

Grum Interceptor Ditch

The GID passes runoff water and compliant effluent from the Vangorda WTP around the Grum Overburden Dump and into the SPP. The ditch consists of three sections:

- The upper 900-m section upslope of Grum Pit, used to divert clean water away from the pit
- The middle 900-m section along the northeast toe of the Grum Overburden Dump
- The lower 650-m section that conveys flow to SPP

The ditch includes some steep sections cut into the native soil, which can provide a source of suspended sediment. The ditch was upgraded in 2001 by excavating sloughed soil, widening the ditch, flattening the side slopes, and placing geotextile and rip rap. This type of maintenance and repair work will continue, as needed,

during the IW, to maintain the ditch in good operating condition. This work will be accompanied by routine inspections to monitor potential erosion of the Grum Overburden Dump into the GID.

Sheep Pad Ponds

The two SPP, are part of the active water management system at the FMC. They are located south of the Grum Overburden Dump. The SPP collect runoff from upslope areas, including the Grum Overburden Dump and the GID (which includes compliant effluent from the Vangorda WTP). Water from the SPP that meets discharge limits is discharged to the VCD at location V25BSP.

Runoff from the Grum Overburden Dump introduces a significant amount of suspended solids during spring freshet. To help mitigate this issue, a portion of the runoff from the Grum Overburden Dump is now routed to Grum Pit. This practice is expected to continue through the IW. In addition, during spring freshet (when SPP water contains total suspended solid (TSS) levels above discharge standards), water will be routed to Vangorda Pit via siphon instead of being discharged to receiving environment. General maintenance of the SPP includes placing rip rap on the upstream section of the spillway channel. Routine visual monitoring will take place for erosion, or potential erosion, from the Grum Overburden Dump into the SPP.

Contaminated Water Collection, Conveyance, and Storage

Within the Vangorda/ Grum Area, contaminated water is collected or stored at five locations: (1) the Grum Pit, (2) the GSC, (3) the V15/Moose Pond Area, (4) the LCD, and (5) Vangorda Pit.

Grum Pit

The Grum Pit is located near a drainage divide, and its catchment area is approximately 1.5 square kilometres (km^2). Approximately one-third of the surface drainage above the Grum Pit is directed around the east side of the pit in the GID, and then into the Vangorda Creek drainage (Appendix 6C). Grum Pit receives groundwater seepage, direct precipitation, and seepage from the GID. Since mining operations ceased, the water level in the Grum Pit has been steadily rising. On average, it increases by approximately 3 m per year (DES, 2012). The previous AMP for the FMC established a threshold level of 1,210.8 m (Gartner Lee Limited [GLL], 2004). This elevation was selected to provide 1 to 1.5 years to implement management strategy for Grum Pit water, before the water reached the maximum recommended level (1,213.4 masl). The maximum recommended elevation was selected to provide enough storage for a 1-week probable maximum flood before the water would reach the overburden-bedrock contact (1,216 masl) near the Grum Slot (DES, 2011b).

In October 2011, the water-level elevation in Grum Pit surpassed the AMP trigger level of 1,210.8 masl. This prompted the development of a response plan to actively manage in the Grum Pit. In 2013, the Grum Pit water was actively managed by pumping water from the Grum Pit to the Vangorda Pit on a seasonal basis. The Grum Pit water management aims to prevent contaminated water from reaching the downstream receiving environment. It does so by providing enough storage capacity to retain water in the Grum Pit and route excess water to the Vangorda Pit. Once the water reaches the Vangorda Pit, it undergoes treatment and discharges through the Vangorda WTP. The current target water-level elevation for Grum pit is 1,213.4 masl. The 2013 water transfer was initiated in August and shut down in mid-October. This transfer did not achieve the target water-level elevation. The water-level elevation of Grum Pit is 1,216.32 masl, as of January 27, 2014.

In 2014, water will be transferred from Grum Pit to Vangorda Pit as early as practical. The rate of dewatering will be set high enough to control and reduce the water level in the Grum Pit, to achieve the target of 1,213.4 masl as soon as possible. For the remainder of the IW, the water-level elevation in the Grum Pit will either be managed to the target-end-of season water level elevation (currently set at 1,213.4 masl), or to a revised target that prevents contaminated water from migrating to the downstream receiving environment.

Grum Sulphide Cell Sediment Control System

In 2010, an engineered cover was placed over the GSC to limit infiltration. Initially, runoff from the GSC discharged to Moose Pond, along with runoff from upgradient areas (CH2M HILL, 2013a). During the 2011 spring freshet, high flows eroded portions of the soil cover. As a result, a significant amount of silt was deposited in Moose Pond and

non-compliant, silt laden water was released to the receiving environment (CH2M HILL, 2012a). In response, a series of surface water management upgrades took place during autumn, 2011. These included implementing erosion mitigation measures and constructing the following sediment control structures, surface water storage and conveyance structures:

- HDPE-lined sediment pond (8,000-m^3 capacity (BGC, 2012)
- Unlined contingency storage area (9,000-m^3 capacity) (BGC, 2012)
- Skid-mounted diesel pump and 8-inch HDPE pipeline to pump water from the sediment pond to Vangorda Pit at a rate of 13,000 m^3 per day (Rainey et al, 2013)

In 2013, a ditch was constructed along the north and east perimeters of the GSC, to intercept and redirect runoff generated in the catchment upstream from the GSC. This runoff is directed to the ditch along the Haul Road, where it flows by gravity to Vangorda Pit.

The objective of water management for the GSC is to limit contact water from entering the receiving environment. Combined, the pumping system and the lined pond can manage 21,000 m^3/day (Rainey et al., 2013). A spillway in the lined pond provides more capacity by overflowing to the contingency storage area. When water starts to flow into the lined pond, the pumping system from the lined pond to Vangorda pit is activated as soon as practical.

V15 and Grum Creek Pumping System

Seepage and runoff from the Grum Waste Dump surfaces at V15 and Grum Creek, downgradient from the waste dump on the southeastern side. In 2007, a collection ditch was installed to convey seepage from V15 into an existing ditch that routes Grum Creek water to Moose Pond, away from lower Grum Creek. In 2011, in response to continued increasing contaminant levels at V15 and to manage peak spring runoff conditions, the V15 and Grum Creek Pumping System was installed. The pumping system is located east of the Grum Waste Dump and consists of an insulated and heat-traced 76-mm HDPE pipeline, a power supply, and pump. The system can redirect seepage from the Grum Waste Dump (V15, Grum Creek, or both) to the Vangorda Pit year-round. When the system is not operated, discharge flows to Moose Pond. The goal of the V15 and Grum Creek pumping system is to limit contaminated water from seeping to the downstream receiving environment. Currently, the system only operates during peak freshet and storm event flows; hence, Moose Pond receives “normal” (non-storm) flows. When the system is not operating, water flows to Moose Pond and exfiltrates to the ground, where downgradient monitoring confirms attenuation is occurring before the water is released into Vangorda Creek. Routine maintenance activities associated with the V15 and Grum Creek Pumping System include the prevention and removal of ice and sediment buildup, and upgrades to maintain the system’s conveyance capacity.

Moose Pond

Moose Pond is a natural depression on top of a gravel bank, on the northwest side of Vangorda Creek. In 1995, it was prepared for use as a settling pond for Grum Creek water. Seepage and runoff water from the Grum Waste Dump discharges into Moose Pond when the V15 and Grum Creek Pumping System is not operating. Water in Moose Pond infiltrates into the ground, ultimately discharging into Vangorda Creek. Downgradient monitoring confirms contaminant attenuation takes place along the groundwater flow path. Routine maintenance activities associated with Moose Pond include the prevention and removal of ice and sediment buildup in the inlet ditch to maintain the system’s conveyance capacity. Physical stability will be monitored, as described in Appendix 5B, the EMSRP.

Little Creek Dam Pond

The LCD Pond currently collects seepage and runoff from the Vangorda Waste Dump. Periodically, during the open water season, water is pumped from this pond into the Vangorda Pit for treatment. The dam crest is about 10 m above natural ground, ranging in elevation from 1,114.5 masl to 1,120 masl (Appendix 6C). The target end-of-season water-level elevation for the LCD Pond is 1,108 masl. Since 2010, the water-level elevation in LCD Pond has been managed around 1,106.5 (CH2M HILL, 2013a). Each spring, water will be pumped from the LCD Pond as

soon as practical after it begins to receive water. Active management will depend on seasonal constraints, but will take place until the target level has been reached.

The LCD is an important environmental protection structure. It retains water that would have a severe impact on the downstream receiving environment if it were released. Therefore, routine maintenance and repair is critical to maintain the LCD. The proposed C&M activities include monitoring for physical stability, as described in Appendix 5B, Section 5.2.2, the Formal Geotechnical Monitoring Program, and implementing maintenance activities required to maintain the structure in good condition, as follows:

- Investigating and repairing surficial cracks, if appropriate
- Upgrading or replacing riprap and other erosion protection measures
- Repairing surficial erosion rills on the downstream slopes
- Reconstructing or upgrading the crest, spillways, or other features to the initial design configurations where erosion and site related activities have altered those structures

Vangorda Pit

The Vangorda Pit receives groundwater seepage, direct precipitation, runoff, and VCD seepage, along with water from managed sources such as the LCD Pond and the GSC Pond. Starting in 2013, additional sources were routed to Vangorda Pit; these include Grum Pit water, inflows from the V15 and Grum Creek Pumping System, and discharge collected in the ditch around the northeast perimeter of the GSC. Vangorda Pit water is non-compliant with the proposed effluent discharge limits. To prevent an uncontrolled release of Vangorda Pit water to Vangorda Creek, the water level in Vangorda Pit is maintained well-below the overflow elevation of 1,122.5 masl through a seasonal pumping program. The maximum recommended water level elevation proposed for Vangorda Pit is 1,091.8 masl, approximately 30.5 m below the elevation at which water would overflow from the pit to Vangorda Creek. This elevation considers the elevation of the base of the surficial till, and the recommendation is based on providing enough freeboard to provide emergency storage of an unforeseen event such as a breach of the VCD. This emergency storage volume provides approximately 3 million cubic metres (Mm^3) of storage capacity. The operational end-of-season target for Vangorda Pit is 1,083 masl. This target elevation at the end of the pumping season allows enough storage to accommodate winter and spring inflows (natural and transfers).

As of January 27, 2014, the Vangorda Pit water-level elevation was at 1,086.6 masl, and above the end-of-season target of 1,083 masl. In 2014, pumping of Vangorda Pit will begin as soon as possible. Dewatering will be set to a rate high enough to control and reduce the water level in the Vangorda Pit. The goal will be to achieve the end-of season target of 1,083 masl as soon as possible. For the remainder of the IW, the water-level elevation in the Vangorda Pit will either be managed to the target-end-of season water level elevation of 1,083 masl, or to a revised target that achieves the objectives. When activated, the pumping program will typically run from May/June to late summer, pumping water from the pit up to the Vangorda WTP for treatment. A longer pumping season would be considered, if necessary, to address unusual, elevated inflow.

The current pumping system will pump water from the pit. This system includes the following primary components:

- A barge with fixed walkway and pivoting anchor point
- A pumping system comprising a 350-HP pump at the barge and a 350-HP pump at the booster station, each with a pumping capacity of 8,500 L/min
- Approximately 4 km of piping from the barge to the Vangorda WTP

Water Treatment including Sludge Storage Facilities

Vangorda Water Treatment Plant

The Vangorda WTP was constructed in 1990 as part of the initial development of the Vangorda/Grum Area. It is a conventional lime treatment system, designed to treat 10,900 m^3/day (2,000 USgpm). The system involves

agitation with lime slurry, the addition of flocculent, and the settlement of solids in an associated open air sludge pond. The WTP comprise the following primary components:

- A lime delivery and transfer system to deliver lime into the storage silo
- A lime storage silo
- A freshwater supply for reagent mixing
- A lime slurry mixing system (does not include any grinding or heat-controlled slaking), storage tank, and addition system
- Dual lime conditioning tanks, providing approximately 14 minutes of mixing at maximum design flow
- Flocculant mixing and addition systems (can be managed manually or by automated control circuitry)
- A flocculant agitation tank (provides 2 minutes' light mixing at maximum design flow)
- The Vangorda WTP Sludge Pond and influent pipe
- The Vangorda WTP Sludge Pond effluent discharge pipe

Compliant effluent from the WTP is discharged from the sludge pond into the GID and subsequently into Vangorda Creek at V25BSP, via the SPP.

During the IW, the Vangorda WTP will continue to be operated in this fashion to treat water pumped from the Vangorda Pit during the summer months. Operations and monitoring of the Vangorda WTP performance will take place according to the FMC Operations Manual. Routine maintenance and repairs of the Vangorda WTP will take place, as required, to optimize the WTP's performance.

Between 2004 and 2013, partially frozen sludge was removed from the sludge pond by suction truck or excavation. It was then deposited in an interim sludge disposal facility located within a containment berm on the Grum Overburden Dump. Starting in the 2014 treatment season, the sludge will be dredged from the pond and discharged into the southern end of the Gum Pit via pipeline. The annual volume to be deposited into Grum Pit is expected to range between 5,000 and 10,000 m^3 (average of about 7,500 m^3). Dredging will take place concurrently with treatment, as well as at the end of the treatment season.

Dams and Spillways at the Vangorda/Grum Mine Area

Little Creek Dam

The LCD is an important environmental protection structure. It retains water that would have a significant impact on the downstream receiving environment if it were released. Based on the observations from periodic dam safety reviews and the annual dam safety inspections, the LCD appears to be stable.

The proposed routine C&M activities are monitoring for physical stability (as described in Appendix 5B, the EMSRP) and implementing general maintenance activities to maintain the dam structure's condition, as follows:

- Investigating and repairing surficial cracks, if appropriate
- Repairing surficial erosion rills on the upstream and downstream slopes

5.3.1.3 Water Use and Proposed Discharge Effluent Limits

IW water usage is primarily related to pumping and treating contaminated water, and discharging compliant water to the receiving environment. Table 5-1 presents the estimated average annual water use for the IW site operations, based on the results of the FMC water quality model (GoldSim model V2.) as presented in Appendix 7B.

TABLE 5-1
Summary of Estimated Site Operations Water Use – 2014 to 2024
Faro Mine Interim Works

Water Use	Annual Volume Transferred/Discharged (m^3)
ID Pond to Interim Water Treatment System or Faro Pit	781,371
ETA SIS to Interim Water Treatment System or Faro Pit	99,961
S-Wells SIS to Faro Pit	80,245
Zone II to Faro Pit	73,002
FP to Interim Water Treatment System	2,815,937
X5 (discharge from CVD Pond)	4,356,117
LCD to VP	108,147
Grum Pit to Vangorda Pit	465,356
GSC – Vangorda Pit	19,255
Grum/V15 to VP	24,029
Vangorda Pit to Vangorda WTP	916,809

Table 5-2 presents the proposed effluent discharge limits for the IW. These are based on the expected future performance of the Interim Water Treatment System, and the past performance of the Faro Mill and Vangorda WTPs. For comparison, Table 5-2 also presents the predicted water quality at the discharge locations, V25BSP and X5, as well as the current site effluent discharge standards, based on the effluent limits set out in expired Water Licence QZ03-059.

TABLE 5-2
Median Water Quality Discharge Data
Faro Mine Interim Works

Analyte	Proposed Discharge Limit (mg/L)	Predicted X5 Discharge (mg/L)	Predicted V25 BSP Discharge (mg/L)	Current Effluent Discharge Standards (mg/L)
pH	6.5 – 9.5	6.5 – 9.5	6.5 – 9.5	≥6.5
TSS [a]	15	15	15	15
Ammonia-N[1]	1.3	1.0	0.4	1.3
Antimony	0.1	0.0002	0.0001	0.1

DRAFT

5.3.2 Routine Operation, Maintenance, and Repair Activities

In addition to site operations activities associated with water management, additional activities are required to maintain and monitor the functionality and performance of site components, facilities, and equipment.

5.3.2.1 Contaminated Water Pumping Systems

The FMC contaminated-water pumping systems described in Sections 5.3.1.1 and 5.3.1.2 will be operated and maintained to assure contaminated water is pumped to the WTPs. Currently, most pumping systems (including the following) are installed, operated, maintained, and decommissioned on a seasonal basis:

- ID Pond
- Faro, Grum, and Vangorda pits
- ETA
- GSC Pond
- LCD Pond
- V15 and Grum Creek Pumping System

The Zone II Pit pumping system, S-Wells SIS, and V15 and Grum Creek Pumping System are year-round pumping systems, although the latter is currently only operated to route peak flows. The contaminated-water pumping systems will be operated to meet the prescribed target water-levels or operational objectives. The seasonal pumping systems will be decommissioned before winter and commissioned in spring. Before commissioning in the spring, winter deterioration will be repaired so the systems are fully functional at start-up.

The contaminated-water pumping systems will be monitored to prevent the collective water inventory from exceeding the capacity of the treatment plant(s) and storage ponds. The water elevations of all pits and ponds will be measured on a weekly basis during the treatment season, to confirm freeboard is available. The pumping systems will be modified, as required, to manage new sources or extend the operating season.

Maintenance of the pumping systems will be implemented, as appropriate, on a preventative or repair basis. Maintenance activities may include the following:

- Inspection
- Repair or replacement of well pumps
- Installation of new pumping wells
- Repair or replacement of overland pipelines
- Repair or replacement of pumping barges, or modifications to barge anchor points
- Installation of an alternate pumping configurations
- Installation of automated switching and water level monitoring devices, or other appropriate activities.

5.3.2.2 Collection Ditches

In addition to the diversions and ditches described in the previous sections, there are several collections ditches at the FMC:

- Vangorda Waste Dump Seepage Collection Ditch
- Below the Grum Waste Dump, including along the V15 access road
- Along the north side of the S-Wells SIS access road
- Below the CVD

Collection ditches require regular monitoring and maintenance to assure flows are routed as intended. In addition to the maintenance measures described in previous sections, the following generic maintenance measures will be performed, as required:

- Clearing debris, accumulated sediment and excessive ice build-up
- Repairing any damaged or deteriorating channel lining, including flumes, culverts, geo-synthetic liners, rip rap and pipes, as necessary

DRAFT

- Maintaining and repairing, as necessary, V-notch weirs including those at the Vangorda Waste Dump Seepage Collection Ditch
- Periodically re-armouring channels and side-slopes

5.3.2.3 Roads, Trails and Access Routes

All FMC roadways and associated infrastructure will be maintained to a standard that would prevent, counteract, or mitigate adverse effects to persons, property, or the environment. The following routine maintenance will be carried out as part of IW:

- Maintenance of road surfaces, including snow removal
- Maintenance of roadside safety berms as required by the Yukon Workers' Compensation Health and Safety Board
- Maintenance, including clearing of blockages and debris, of road-side ditches and culverts to maintain conveyance capacity and minimize the risk of road wash-out or sediment release to the environment
- Culvert steaming during winter, as required to prevent runoff from flowing over top of roadways

Two culvert crossings located on the mine Access Road are under the overall management of the Yukon Government Department of Highways and Public Works, but are monitored and maintained by site personnel because of their potential to impact water quality in the SFRC.

Haul Road

The Haul Road connects the Vangorda/Grum Area and the Faro Mine Area. It was developed for use by heavy duty off-road trucks hauling ore from the Grum Ore Transfer Pad to the Faro Mill. The road was constructed as a dumped rockfill structure, largely from mine waste rock selected for its non-acid generating characteristics. The road surface is approximately 30 m wide, with a 2-m-high safety berm on each side of the road.

Runoff from portions of the Haul Road enters the West Fork Vangorda Creek, and elevated sediment loads have been associated with precipitation events. Water quality is monitored in West Fork Vangorda Creek as part of the Pelly Aquatic Monitoring Program. In addition to the routine maintenance described herein, physical monitoring of the Haul Road consists of visual monitoring of drainage cutouts in the safety berms to identify and respond to surface runoff that may enter directly into creeks.

North Fork Rock Drain

The North Fork Rock Drain (NFRD) comprises clean waste rock at the base of the Haul Road structure, where the road crosses the NFRC. The NFRD has capacity to convey the flow of NFRC through the void space. The IW will include monitoring on a weekly basis, to confirm flows are passing normally and sediment build-up is not impeding flow-through. Sediment or debris will be removed, as required. Monitoring will also take place for sloughing that may affect the capacity of the NFRD, and material will be removed, as needed.

K-8 Rock Drain

The K-8 Rock Drain is located approximately 2.5 km east of the NFRD and drains water flowing from the northern reach of K-8 Creek through the Haul Road. The Haul Road at the creek crossing is approximately 55 m high, with a 25-m-wide crest, and is constructed of coarse waste rock fill (Appendix 6B).

The crest and side slopes of the mine Haul Road at the K-8 Rock Drain appear to be stable and the downstream drainage condition acceptable (KCB, 2012b).

The K-8 will also be monitored on a weekly basis to confirm flows are passing normally and sediment build-up is not impeding flow-through. Sediment or debris will be removed, as required. In addition, signs of sloughing will be monitored and will be maintenance as needed.

DRAFT

5.3.2.4 Waste Dumps

Other than periodic physical inspections, as outlined in the EMSRP (Appendix 5B), there are no planned maintenance activities specifically associated with the waste dumps at the FMC. Routine monitoring of seepage and groundwater associated with waste dumps will be carried out as part of the EMSRP. As part of the AMP, the progression of waste rock chemistry will be assessed, as it relates to potential impacts to the receiving environment and need for intervention.

5.3.2.5 Grum Overburden Dump

The Grum Overburden Dump is not considered to present a risk of acid generation or metal leaching, as it contains primarily overburden materials. Monitoring and maintenance of the Grum Overburden Dump will be limited to routine visual monitoring of erosion, and potential for erosion to the GID.

5.3.2.6 Dust Management

Contaminant transport in dust from the exposed tailings surface is an ongoing issue at the FMC, particularly during periods of dry weather. To mitigate this, a dust control program has been implemented in portions of the RCTA since 2008, by applying a surface adhesive agent. Dust management at the FMC will continue as part of IW and will include the following activities:

- Monitoring of the surface tailings and identification of areas where tailings are being eroded by wind and dusting is occurring
- Monitoring of areas where surface adhesive agent has been applied previously to confirm treatment effectiveness
- Applying a surface adhesive agent to tailings surface, in accordance with the Dust Management Plan, to reduce wind erosion of the tailing surface

5.3.3 Environmental Management and Monitoring Plans

Site operations during the IW period will adhere to the prescriptions of the Environmental Management Plan (Appendix 5A), which was developed so that appropriate environmental management practices are carried out during the IW. The Environmental Management Plan is a framework document that outlines the key elements of monitoring and mitigation plans. These plans describe which measures should be applied to avoid or minimize adverse environmental effects and risk to public health and worker safety. The Environmental Management Plan will be refined, as required, during the IW to reflect site modifications, changes in environmental conditions or new management protocols arising from unforeseen events, or the implementation of adaptive management measures. The Environmental Management Plan currently contains the following plans:

- Sediment and Erosion Control Plan
- Environmental Monitoring and Surveillance Plan
- Emergency Response Plan
- Spill Contingency Plan
- Tailings and Water Management Structures Plan
- Emergency Response and Preparedness Plan
- Operations, Maintenance and Surveillance Manual
- Waste Management Plan
- Wildlife and Habitat Management Plan
- Heritage Resources Management Plan
- Occupational Health and Safety Plan

Source loads of environmental contaminants pose risks to the receiving environment, and so does the increasing risk of instability from certain FMC water and tailings-retaining earth structures. In light of these risks, along with the Environmental Management Plan, an extensive and comprehensive EMSRP (Appendix 5B) has been designed to monitor conditions at the FMC and in the receiving environment. By the consistently implementing the monitoring requirements of this program, environmental risks and hazards will be identified so they can be prevented or minimized. The EMSRP will provide data and site characterization information to assist in risk assessment and adaptive management activities.

DRAFT

The EMSRP defines the monitoring objectives, monitoring design, and reporting to support the IW. The ERMSP outlines the anticipated environmental monitoring and reporting requirements for the IW related to water quality, meteorology, aquatic environment, wildlife, and vegetation. The primary objectives of the environmental monitoring program are as follows:

- Confirmation monitoring, to define environmental conditions for comparison with future monitoring efforts. It is also used to describe natural conditions in areas not impacted by mine site operations.
- Performance monitoring, to evaluate the changes in environmental conditions resulting from any action or operation carried out as part of the IW. The monitoring data collected in these areas will support the evaluation of system effectiveness, as well as support the design, of potential improvements to system operations. Performance monitoring also includes, where applicable, compliance monitoring to assure the site operations are meeting conditions set out in the Water Licence.
- Adaptive management monitoring, to understand how environmental conditions in a particular area are changing and whether a response is needed to address these changes and to protect human health and the environment.

The ERMSP also outlines portions of the Geotechnical Monitoring Program that will take place to protect the safety and integrity of the various physical site structures, including dams, diversions, and dikes.

The main site components will be monitored according to the EMSRP. Table 5-3 shows the monitoring program(s) associated with each FMC component.

In addition to the main FMC components, the EMSRP sets forth water quality, biological, and flow monitoring requirements for reference sites not impacted by the FMC, and for receiving sites downstream from FMC and IW activities. This program includes internal and perimeter-type monitoring sites that are assessed to obtain early indications of deteriorating water quality or biological conditions. The EMSRP provides additional descriptions of these programs, including water quality monitoring parameters, and proposed study designs to monitor benthic

invertebrates and fish populations. The EMSRP also contains details of the proposed meteorological, wildlife, and vegetation monitoring programs.

5.3.4 Adaptive Management Plan

In addition to water and site facilities that will be actively managed during the IW, there are waters and facilities at the FMC that represent potential environmental risks but do not require immediate intervention. The IW includes an AMP (Appendix 5C) that will provide appropriate responses to these risks.

The AMP provides the site operator with a pre-planned framework within which decisions can be quickly and efficiently made. It also provides regulators with the security of a consistent and predictable approach to unforeseen events. The AMP framework has been developed to provide an overview of the AMP process for the IW.

The AMP takes the Precautionary Principle Approach: it provides a mechanism to identify potential environmental risks as they emerge, and to allow for a management response before an environmental effect occurs. To be effective, the AMP is linked to a monitoring program that is designed to indicate when management intervention is necessary. This assures the necessary data for the assessment of environmental conditions is being collected for evaluation against predetermined triggers or thresholds.

Because the specific environmental conditions addressed by the AMP are, by definition, unknown, the AMP does not provide detailed description of specific management responses. The AMP provides general descriptions of a range of possible responses that may be adapted or otherwise used to guide the design of an appropriate response that best suits the needs of the specific environmental conditions. This approach is inherent to the fundamental purpose of the AMP, which is to provide a framework for responding to unforeseen changes in environmental conditions.

Areas with uncertain site conditions, or where possible future conditions could lead to unacceptable environmental effects, have been identified. The AMP framework provides a strong adaptive management approach that will be used to monitor, detect, and respond to changing conditions. The AMP includes the following key components:

- Proactive monitoring to detect changing conditions in areas of expected uncertainty within a timeframe that allows for effective response
- Clear triggers that will ensure timely implementation of effective responses
- Appropriate measures that can be undertaken to address unacceptable conditions and performance

The following three broad types of uncertainty for the IW will be addressed through the AMP:

- When implementation of specific management responses will be required. For example, interception and collection of seepage water from the Zone II Outwash area is not required until water quality in the vicinity begins to show signs of deterioration. The timing of when this might occur is not known.
- Where implementation of specific management responses will be required. Depending on groundwater and seepage pathways, it is unclear where potential future contaminant sources could emerge.
- Performance adequacy of measures/mitigations that have been implemented. For example, the S-Wells SIS is currently intercepting contaminated water from the area immediately downgradient of the Intermediate Dump. Depending on downstream water quality, this system may not be performing adequately to ensure the ongoing protection of NFRC.

There are eight discrete events that comprise the AMP framework for the IW, which represent anticipated environmental conditions that may decline over the 10-year period of the IW to the point that they require a management response. These events specifically focus on areas where deteriorating water quality conditions may affect receiving environments. If required, additional events will be developed as part of the final AMP to incorporate issues/concerns raised during the Environmental Assessment process.

DRAFT

The following eight events are included in the AMP framework:

1. Degraded groundwater quality in the RCAA
2. Degraded water quality in NFRC below S-Wells SIS
3. Degraded water quality in NFRC below NFRD
4. Degraded water quality in NFRC above NFRD
5. Degraded water quality in seepage from the Northwest WRDs
6. Degraded water quality in Rose Creek downstream of mine site facilities
7. Degraded water quality below the Grum/V15 Collection System
8. Degraded water quality in Vangorda Creek downstream of mine site facilities

Appendix 5C describes the conceptual AMPs for each of these proposed events individually. Table 5-4 summarizes the proposed events. The final IW AMP will be developed and finalized as part of the water licensing process; this will include defining the specific thresholds or triggers for each AMP event.

TABLE 5-4
Summary of Adaptive Management Plan Framework
Faro Mine Interim Works

AMP Event	Narrative Trigger(s)	Possible Consequences
1. Degraded groundwater quality in the RCAA	**Component 1:** Monitoring of the contaminant fronts in the tailings and underlying soils indicates that the zinc front has arrived at the tailings/aquifer interface. **Component 2**: Monitoring of indicator parameters indicates that the water quality in the RCAA is degrading and there is an increasing trend in contaminant concentrations in the aquifer, at target locations upstream from the ID. **Component 3**: Monitoring of indicator parameters indicates that the water quality in the RCAA is degrading and there is an increasing trend in concentrations of indicator parameters in the aquifer, at target locations downstream from the CVD.	Exposure of aquatic resources, terrestrial resources and human resource users to increased levels of contaminant in Rose Creek, Anvil Creek, and the Pelly River.
2. Degraded water quality in NFRC below S-Wells SIS	Monitoring of surface water downgradient of the S-Wells SIS in NFRC indicates that water quality is starting to degrade or change and contaminants are advancing towards receiving environments. Monitoring locations and indicators will be selected, where appropriate, for early detection.	Potential exposure of aquatic resources, terrestrial resources and human users of these resources to increased levels of contaminants in NFRC, RCD Channel, and, possibly, further downstream in Rose Creek, Anvil Creek, and the Pelly River.
3. Degraded water quality in NFRC below NFRD	*The development of AMP Event 3, as part of the IW AMP framework, is pending completion of the ongoing investigation of the source load.*	Potential exposure of aquatic resources, terrestrial resources and human users of these resources to increased levels of contaminants in NFRC, RCD Channel, and, possibly, further downstream in Rose Creek, Anvil Creek, and the Pelly River.
4. Degraded water quality in NFRC above NFRD	Monitoring of indicator parameters indicates that the water quality in NFRC is degrading with increasing concentrations of indicator parameters, and there is an increasing trend in concentrations at target seep and groundwater monitoring locations downgradient of the Zone II Outwash area and/or the Northeast WRDs.	Potential exposure of aquatic resources, terrestrial resources and human users of these resources to increased levels of contaminants in NFRC, RCD Channel, and, possibly, further downstream in Rose Creek, Anvil Creek, and the Pelly River.
5. Degraded water quality seepage from the Northwest Waste Dumps	Monitoring of indicator parameters indicates that water quality in seeps associated with the Northwest Waste Dumps is degrading and there is an increasing trend in concentrations at target seep locations associated with the Northwest Waste Dumps.	Potential future water quality effects associated with seepage from the Northwest Waste Dumps to Upper Guardhouse Creek, Rose Creek, Anvil Creek, and the Pelly River.

TABLE 5-4
Summary of Adaptive Management Plan Framework
Faro Mine Interim Works

AMP Event	Narrative Trigger(s)	Possible Consequences
6. Degraded water quality in Rose Creek downstream of mine site facilities	Monitoring of surface water quality in Rose Creek downstream from the FMC indicates that the downstream water quality is starting to degrade or change and acid rock drainage products are advancing towards receiving environments.	Potential exposure of the aquatic resources, terrestrial resources, and human resource users to increased levels of contaminants in Rose Creek, Anvil Creek, and the Pelly River.
7. Degraded water quality below V15 and Grum Creek Seepage Collection system	Monitoring of surface water, groundwater and seepage water quality at target locations downgradient of the V15 Grum Creek Seepage Collection System or Moose Pond indicates that water quality downgradient is starting to degrade or change and contaminants are advancing towards receiving environments.	Potential exposure of the aquatic resources, terrestrial resources, and human resource users to increased levels of contaminants in Vangorda Creek and the Pelly River.
8. Degraded water quality in Vangorda Creek downstream of mine facilities	Monitoring of surface water quality in Vangorda Creek downstream of the FMC indicates that the downstream water quality is starting to degrade or change and acid rock drainage products are advancing towards receiving environments.	Potential exposure of the aquatic resources, terrestrial resources, and human resource users to increased levels of contaminants in Vangorda Creek and the Pelly River.

5.3.5 C&M Risk Assessment

YG and AANDC conduct annual qualitative risk assessments to identify and characterize physical and operational risks at the FMC. The risk assessment approach is described in Appendix 5D. It consists of (1) ongoing identification and characterization of site risks and (2) development and implementation of appropriate responses to address the risks. Annual qualitative risk assessments are conducted to identify and characterize physical hazards and operational risks. The qualitative risk assessment approach is a form of Failure Modes Effects Analysis, which incorporates a systematic and comprehensive accounting of potential events and scenarios consisting of failure modes that could adversely affect human health and safety and the environment. The Failure Modes Effects Analysis characterizes the consequences of failure and the likelihood of failure for specific failure modes, thereby providing a framework for informed decision-making and prioritizing remedial activities.

The annual qualitative risk assessment is used as a guide to work planning efforts for site operations. YG and AANDC track ongoing risk evaluations and responses in a database that records changes in risks over time, as well as mitigation responses. The risk assessments provide rationale for annual work plan budgets associated with site operations (e.g., monitoring requirements and changes in water management approaches), site investigations to address evolving areas of concern (e.g., drilling programs in areas of evolving groundwater conditions), mitigation measures to address risks (e.g., replacement or re-alignment of piping), or equipment replacement (e.g., water treatment equipment or heavy mobile equipment).

5.4 Site Investigations

The IW site investigation activities are intended to collect additional data to support adaptive management during the IW, and to provide data to support the preparation of the FMRP. Site investigations proposed for the 2014 field season are well-defined and are described separately from site investigation activities that are likely to be undertaken subsequently. These subsequent site investigations, while similar to those proposed for the 2014 season, are not as well-defined and will depend on the results of the preceding investigations and studies. Over the timeframe of the IW, the scope of the field investigations will be refined as additional information is collected to further understand the site conditions or remedial design plans. In addition, field investigations could be required during the IW, in response to evolving geochemical conditions.

This section first describes the types of site investigation activities that will likely take place during the IW in preparation of the FMRP. Next, it describes specific site investigation activities planned for the 2014 field season. Figures 5-6 to 5-11 show field investigations planned for the 2014 field season, to illustrate their general locations.

DRAFT

5.4.1 General Description of Proposed Site Investigations Activities

A range of site investigation activities are required to collect data to support the FMRP design. A large volume of borrow material will be required for the FMRP and investigations will take place to identify, delineate, characterize, and quantify potential sources of borrow material within or close to the FMC. Site-wide field investigations are also proposed to collect the data needed to further establish baseline conditions, and to enable assessment of effects on valued components in the FMRP proposal. Investigation activities will occur across the FMC both within the existing footprint in disturbed areas and in areas that have not been previously disturbed. Likely site investigation activities for the IW can be divided into two broad categories: (1) surface geotechnical and environmental investigations and (2) subsurface geotechnical and environmental investigations.

5.4.1.1 Surface Geotechnical and Environmental Investigations

Site investigation activities required to collect additional surface geotechnical and environmental information include reconnaissance programs and field surveys, monitoring and sampling programs, aquifer test activities, and reclamation test plots and trials, along with heritage and archaeological assessment programs. Each of these investigations is described in more detail in the following subsections.

Reconnaissance Programs and Field Surveys

Reconnaissance programs will generally involve field mapping geological and geomorphological features, or performing geological hazard identification, resulting in minimal land disturbance. Field surveys will be used to collect more detailed information to establish or further define baseline conditions of wildlife, aquatics, vegetation, soils, water, and air quality.

Wildlife and habitat surveys will focus on collecting data about the usage, timing, and location of wildlife species. For example, investigations may include the use of remote camera field study within key corridor areas to better define the characteristics of movements through the site (i.e., the timing, direction, seasonality, and group sizes/composition). Water birds and waterfowl studies will be aimed at documenting bird use, behaviour, and residency in the FMC area. Wildlife and bird surveys will be conducted in accordance with permit requirements.

Surveys will be undertaken to collect information on aquatic organisms and habitat, including data collection on periphyton, aquatic macrophytes, and benthic invertebrates. Sediment and fish tissue samples will be taken for analysis of metals, and water and sediment for toxicity testing, if and where possible. Fish and fish habitat survey activities may include electrofishing, seining, and angling in creeks within, upstream, or downstream of the FMC. All fish collection programs will be conducted in accordance with DFO permit requirements.

Surveys will likely be undertaken to collect information about vegetation and soil during the IW and, if required, are proposed to follow BC terrestrial ecosystem mapping protocols, or similar methodology. Vegetation and soil surveys may include sample collection for analyses and toxicity screening. Rare plant surveys may also be undertaken.

Field surveys will also include surface and groundwater monitoring and sampling programs. These programs may involve establishing, maintaining, and operating such various monitoring facilities as surface water flow gauging stations and meteorological stations. Air quality monitoring programs may be initiated for collection of particulates and metals data in specific areas or across the FMC.

Examples of other field studies that may be performed during the IW include human health and ecological risk assessment (HHERA) studies, hazardous material and waste characterization, and heritage and archaeological assessments. HHERA may include data collection from small mammals for tissue-chemical concentrations analyses, which would be undertaken only in accordance with any permit requirements. Hazardous material and waste characterization surveys will identify existing hazardous materials and wastes stored at the FMC. Heritage and archaeological assessment programs will evaluate heritage values for areas that may be disturbed by remediation related activities.

Reconnaissance programs and field surveys may include helicopter use to provide access to areas within the local or regional study areas. Helicopters will be operated in accordance with practices recommended in *Flying in Sheep Country* (YG, 2006).

Surface Geophysical Surveys

Surface geophysical surveys are conducted to non-intrusively identify subsurface conditions, including depth to bedrock and the depth of geologic unit contacts. Ground penetrating radar, electrical resistivity, and seismic refraction and/or reflection programs are among the geophysical surveys that may be used.

Seismic surveys require an energy source to generate a compression wave in the subsurface, which is commonly achieved by detonating a small explosive charge or impacting a strike plate with a sledgehammer. In areas where geophysical surveys are required that have not been previously disturbed, line cutting may be necessary. When necessary, line cutting will be performed with hand tools and trails cut will be less than 1.5 m in width. Lines require the removal of trees and shrubs along the route, but do not involve the removal or disturbance of the vegetative mat.

Bathymetric Survey

During the IW, bathymetric surveys may be performed from boat or barge on pits and man-made ponds within the FMC (e.g., CVD Pond, ID Pond, Faro Pit, Grum Pit, and Vangorda Pit).

Field trials of Remedial Measures

Field trials of remedial measures such as vegetation plots and cover trials are planned during the IW. Where used, field trials will occur in areas of the site that have already been disturbed (e.g., RCTA or WRD). Heavy equipment (e.g., excavator, bull dozer, or haul truck) will be used to construct remedial cover trials and re-grade surfaces before vegetation trials. Remediation trials will be maintained and operated to support reclamation research and evaluation. Cover trials may include use of different borrow material types and construction of lysimeters to monitor performance. Collection of vegetative material may be required to support revegetation test programs, unless commercial seed stock is used. Vegetation plots may receive application of different amendments to evaluate plant growth.

Aquifer Test Activities

Aquifer tests are planned during the IW. Aquifer tests typically involve installation of a submersible pump into an existing well and pumping the well for a set period of time while recording the aquifer response. Water extracted during aquifer tests will be managed to prevent environmental effects, in accordance with the Environmental Management Plan (Appendix 5A). Groundwater quality monitoring will be undertaken before, and during, the aquifer tests to identify the appropriate management practices for pumped water. If the water contains elevated concentrations of constituents of concern, such as zinc, it will be contained or directed in hoses to discharge in areas of the site where water is collected for treatment (e.g., ID Pond or Faro Pit), or to a storage tank for transfer to these areas or treatment facilities. If the water may contain suspended solids greater than the discharge criteria (i.e., TSS greater than 15 mg/L) in the absence of other constituents of concern, it will be directed to areas where these suspended solids can settle before release to the environment (e.g., a sump, a constructed sediment basin, or a vegetated areas away from a receiving water body). Erosion prevention measures will be in place to limit additional sediment entrainment in areas where discharge occurs. A generator will likely be used to run the pump; refueling practices will follow those described in the Environmental Management Plan, as discussed further in the section below on drilling activities.

Groundwater-surface Water Interaction Studies

Groundwater-surface water interaction studies are planned during the IW. Personnel will enter the stream on foot to hand-install temporary narrow diameter piezometers with a post pounder, to record vertical hydraulic gradients between the stream and shallow groundwater underlying the stream. Water samples may be collected from the piezometers installed into the shallow groundwater.

Water Treatment Test Programs

Studies to support the design of a new WTP will likely occur over the duration of the IW. Studies may include characterization of relevant water streams and bench or pilot tests (or both) to evaluate performance.

DRAFT

5.4.1.2 Subsurface Geotechnical and Environmental Investigations

Subsurface geotechnical and environmental investigations will consist of advancing boreholes for the purpose of soil/rock classification, sample collection, and instrument installation, as well as excavating test pits for soil classification and sample collection. These investigations include drilling using a variety of different methods (e.g., roto-sonic, air rotary, hollow-stem auger, and rock coring), advancing test pits with excavators, and sampling soil and rock. Boreholes may be completed with monitoring well installations, or other data collection instruments such as vibrating wire or pneumatic piezometers, thermistors, soil-gas monitoring ports, or slope inclinometers. Whether instrumentation is installed or not, boreholes will be backfilled or sealed in accordance with best management practices to prevent surface water migration into the boring. Well development will be performed on monitoring and pumping wells following installation. Techniques used may include overpumping, bailing, air surging, or other practical methods. Water generated during well development will be managed in accordance with the practices for handing investigation-derived waste described in the Environmental Management Plan.

While excavating test pits in areas where there is a vegetative mat or organic soils, these materials will be segregated and replaced in the same sequence during backfill. Excavated test pits would typically be not more than 5 m long by 2 m wide and will extend less than 6 m in depth. Test pits will be backfilled immediately following logging and sampling activities.

Additional accessory activities which may be needed to support these investigations include access development, drill pad clearing, water usage, management of investigation-derived waste, fuel use, refueling, and spill prevention. Each of these activities are described in more detail in the following subsections.

Access Development and Drill Pad Clearing

Although many areas of potential investigation have been previously disturbed by mining activities, access trails and drill pad clearing may be required for investigation activities that are located in undisturbed areas. Access trails would be limited to the width necessary for drill-rig or excavator being used and would typically be less than 4 m wide. The area required for drill pads would also be dependent on the drilling equipment used, with the largest area to accommodate truck-mounted drill rigs requiring a pipe-truck support vehicle, such as roto-sonic, dual-rotary or air rotary drill-rigs. These activities would require a cleared area of about 30 m by 10 m. However, investigations in areas away from established roads would more likely be conducted with smaller track-mounted drill-rigs better suited to access conditions. The drill pad for a track-mounted drilling rig would require a cleared area of about 15 m by 10 m. Access trails and drill pad would require removal of trees and shrubs along the access route, but do not require the removal of the vegetative mat. It is anticipated that fill materials would be placed over the vegetative mat to provide access to the drill site. Before conducting clearing activities, heritage investigations and bird and rare plant surveys will be conducted or reviewed as necessary, in accordance with the Environmental Management Plan.

In selecting access trails, the priority will be to avoid stream crossings where possible. Alternatives will be explored before using a temporary stream crossing to access required investigation locations. Potential alternatives include using heli-portable drilling or excavating equipment, selecting longer access routes from a different approach, or timing investigations activities for winter when access impacts can be mitigated. If winter crossing is performed, a DFO operational statement regarding ices bridges and snow fills will be followed. In some instances, temporary stream crossings will be unavoidable. For example, design of a diversion channel east of NFRC will require subsurface investigation along the eastern slope as illustrated on (Figure 5-8). Any such temporary stream crossings will be conducted in accordance with best management practices and regulation (e.g., DFO operational statements for stream crossings [DFO, 2014] or water licence).

Water Usage

Drilling methods commonly require water to improve drill cutting recovery and productivity. If water is used for drilling, it will be pumped from onsite creeks. The volume of water potentially required will vary depending on the borehole diameter, borehole depth, and formation drilled. The volume of water used will be dependent on conditions encountered, but will be the minimum necessary to complete the work.

Investigation-derived Waste

Investigation-derived waste (e.g., soil cuttings, purge water, and equipment decontamination water) will be managed in accordance with the Environmental Management Plan. It is anticipated that waste generated during the investigation work will consist of excavated materials removed from boreholes and test pits, material generated during drill rig access pad construction, material excavated for installation of surface water monitoring structures, and water pumped from monitoring wells. A large majority of this work will be in areas previously disturbed during mining activities. In these previously disturbed areas, erosion-control measures will be implemented to prevent the migration of sediment or contaminated waters into adjacent water courses that are not part of the contaminated water circuit. These measures will occur in conjunction with run-on and runoff control, and will be put in place before the work being initiated. It is anticipated that earth materials removed during drilling activities for investigations in disturbed and undisturbed areas can be left onsite, adjacent to the boring. Tailings, waste rock, or other products will be replaced as practical in the borehole or test pit. These will be smoothed or blended into the existing topography once the investigation work is complete. Test pits will be backfilled with excavated materials in a similar order as removed and tamped in place.

Water quality data will be reviewed with respect to management of purge or well-development-derived water. This may involve reviewing historical water quality of nearby monitoring locations. Water that does not meet the effluent discharge criteria will not be discharged to water courses or areas where it can enter water courses. Instead, it will be discharged to an acceptable area such as one of the existing pits or a point where it will be captured and conveyed for treatment. Releases to non-contaminated surface waters will meet the effluent discharge criteria specified for the FMC.

Task-specific water management such as during aquifer test activities will follow specific effluent discharge procedures prepared in advance of these activities.

Fuel use and refueling

Refueling practices will include the use of the appropriate spill prevention equipment (e.g., drip pans and secondary containment), maintaining ready access to spill response supplies (e.g., spill kits), and will occur at least 30 m from water bodies.

5.4.2 2014 Site Investigations

Field investigations planned for the 2014 field season are shown on figures to illustrate the general locations of proposed field investigations (Figures 5-6 through 5-11). Field investigations are planned for the three main areas of the FMC, as follows:

- Faro Mine Area
- RCTA
- Vangorda/Grum Area

There are also site-wide investigations and investigations to support the regulatory process that are planned to occur across the entire FMC or in areas outside of the FMC. The following subsections present key field investigations proposed for the 2014/15 season.

Faro Mine Area

- Engineering geological field reconnaissance, geophysical and traditional surveys, along with subsurface investigations to collect data for design of surface water diversions at Faro Creek, North Wall Interceptor Ditch, and Lower Guardhouse Creek.
- Engineering geological field reconnaissance and subsurface investigations to support remedial planning and design for the WRDs (including the oxide fines and low-grade ore stockpiles). Investigations will support material delineation and characterization and will provide data to evaluate resloping or relocating material and cover design.

DRAFT

- Engineering geological field reconnaissance, geophysical and traditional surveys, along with subsurface investigations in the ETA to support remedial planning and design, including potential re-location of tailings, installation of groundwater and surface water collection systems and cover design.
- Engineering geological field reconnaissance, geophysical and traditional surveys, along with subsurface investigations to evaluate groundwater collection system designs for the Zone II Outwash area and S-Wells area, as well as relocation of Zone II outwash material and design of a cut-off wall to limit contaminant migration to NFRC.
- Geophysical and traditional surveys, along with subsurface investigations to assess and characterize soil in the mill site and surrounding area.

Rose Creek Tailings Area

- Engineering geological field reconnaissance, geophysical, and bathymetric surveys, along with instrumented cover trials and subsurface investigations to support remedial closure planning and design for the dams and tailings in the RCTA.
- Engineering geological field reconnaissance, geophysical, and traditional surveys, along with subsurface investigations to support final closure design for the RCD.

Vangorda/Grum Area

- Engineering geological field reconnaissance and subsurface investigations (borings and test pits) to support remedial planning and design for the Vangorda WRDs (including in-pit WRD) and Grum WRDs (including Grum Ore Transfer Pad). Investigations will support material delineation and characterization along with providing data to evaluate resloping or relocating material and cover design.
- Engineering geological field reconnaissance, geophysical, and traditional surveys, along with subsurface investigations to support final closure design for the Vangorda Creek Diversion.
- Geophysical, traditional, and groundwater/surface water interaction surveys, along with subsurface investigations to support the design of groundwater collection systems downgradient of the Grum and Vangorda WRDs.

Site-wide

- Engineering geological field reconnaissance and subsurface investigations to support borrow material characterization, delineation, and development.
- Field surveys and studies to collect baseline data on soils, vegetation, aquatics, and wildlife.

The following provides a summary of the 2014 field investigation plan, providing an indication of the scale of the investigation activities. The numbers presented are approximate but were reached based on field planning for the proposed investigations. Proposed field investigations for 2014 include the following:

- Drilling of about 200 boreholes using various techniques, potentially including hollow-stem auger, diamond-drill coring, ODEX, air rotary, and roto-sonic, with boring diameters between 25 mm and 355 mm. Some of the borings are proposed to extend to depths of up to 100 m.
- Of these borings, about half are proposed to be completed as monitoring wells, pumping wells, or piezometers.
- In addition, about another 70 direct-push investigation locations are proposed to be advanced which includes the use of cone penetrometer tests, dynamic cone penetrometer tests, or similar.
- Excavation of over 200 test pits by an excavator, which generally would extend to a depth of about 4 to 5 m.
- There are an additional 50 shallow soil samples proposed to be collected by shovel or hand auger.
- Approximately 17,000 m of surface geophysical survey work is proposed; of this, about 10,000 m may require line cutting.

DRAFT

These activities may require access road creation to allow access to borehole or test pit investigation locations. The majority of this work will occur within the disturbed areas of the mine site, but about 25 percent of the borehole and test pit investigation locations are located in undisturbed areas (Figures 5-6 through 5-11).

5.5 Down Valley Interim Hydraulic Upgrades

The DVIHU works and activities relate to the improvement of flood routing capacity for the RCTA. As summarized in Section 5.1.3, the current flood routing capacities for the ID spillway and the RCD do not meet the minimum standards specified in the CDA Dam Safety Guidelines (CDA, 2007). The existing ID spillway capacity (32 m^3/s) is much smaller than the 1-in-500-year flood event, which was the criterion specified in the now expired water licence. The RCD requires some minor upgrades and maintenance to restore its capacity to convey the 1-in-500-year flood event.

The proposed DVIHU include modifications to the ID and to the RCD, including increasing the capacity of the ID spillway, raising the height of the ID crest, and restoring the capacity of the RCD. Along with increasing the capacity of the ID spillway, erosion protection will be installed and current infrastructure within the spillway alignment will be removed or relocated.

These proposed activities provide an upgrade of the hydraulic capacity of the ID spillway and the RCD to allow both to safely pass the 1-in-500-year flood event, which is calculated as 115 m^3/s (including attenuation of flood flows through the NFRD and by the ID Pond). The work will be performed as part of the IW to provide temporary protection of the ID (and therefore the environment) until the FMRP can be implemented. The design criteria for the FMRP are further discussed in the Appendix 5I, Down Valley Interim Hydraulic Upgrades, which was prepared to support 60 percent design of the IW upgrades. The following paragraphs provide an overview of the activities to be completed as part of the DVIHU; additional details about the DVIHU project, including the current conditions, design criteria, hydrotechnical analyses, and modelling are presented in Appendix 5I.

Rationale for DVIHU

Approximately 28.6 Mm^3 of tailings were deposited in the RCTA between 1969 and 1998. The tailings are contained by a series of three dams (i.e., the Original, Secondary, and Intermediate Dams constructed across the Rose Creek Valley, with the ID (constructed in 1981) providing the final containment for the tailings and accumulated contaminated water (i.e., ID Pond) (Figure 5-12).

The ID has an emergency spillway channel on the right (north) abutment, constructed as a rock-lined channel in natural overburden material. The current capacity of the ID spillway is about 32 m^3/s when the ID Pond water elevation reaches the top of the core zone of the dam (Northwest Hydraulic Consultants Ltd. [NHC], 2006a). This is insufficient capacity to pass moderate or major flood events. The ID spillway discharges into the CVD pond. As the sulphide-bearing minerals remaining in the tailings oxidize, water with low pH (acidic) and elevated concentrations of sulphate, zinc, lead, copper, and other trace metals is released. The tailings and water contained within the tailings are potentially toxic to aquatic and terrestrial life. Failure of the ID as a result of not being able to safely pass a large storm event may cause discharge of metals-laden tailings, which would adversely affect water quality in the Rose Creek Valley and further downstream. This could result in a significant loss of fish and wildlife habitat. A failure of the Secondary Dam in 1975 within the Rose Creek Valley resulted in a loss of wildlife/aquatic habitat, with recovery ongoing for more than 35 years later.

An enhanced ID spillway will be constructed as part of the FMRP. That facility is expected to be designed to convey the PMF. However, the co-proponents of the project (YG and AANDC) wish to minimize risks associated with the current spillway capacity and condition because it is projected to require more than five years to design, plan and secure approvals for implementation of the FMRP. Therefore, the co-proponents propose to increase the capacity of the existing ID spillway and the RCD as soon as possible.

The RCD, on the south side of the valley, diverts water from Rose Creek around the RCTA (Figure 5-12). The total length of the existing diversion is approximately 4,700 m. The diversion was initially designed to carry a 1-in-50-year flood event (approximately 79 m^3/s) while maintaining 1 m of freeboard. It was subsequently modified to carry stream flows equivalent to slightly more than the 1-in-500-year flood event (BGC, 2006; NHC, 2006a). The

current condition of the RCD is such that vegetative growth and other channel maintenance related issues have decreased its flow capacity to less than the 1-in-50-year flood flow before overtopping.

5.5.1 Description of DVIHU

The main purpose of the DVIHU is to protect the ID until implementation of the FMRP, and it consists of the improvements to the ID spillway, the ID crest, and the RCD.

ID Spillway

The ID spillway capacity is proposed to be increased by:

- Increasing the effective depth of the existing spillway channel by excavating a maximum of about 2 m
- Increasing the effective height of the ID crest by about 0.5 m

Excavation of the existing ID spillway is estimated to require the removal of about 20,000 m^3 of soil and rock. The excavated ID spillway channel is proposed to be protected from erosion by installing gabion mattresses along the bottom and gabion retaining structures along the sides of the spillway, or other similar protective measures. Rock required for the gabions is proposed to be sourced from the existing Rose Creek Borrow Area (Figure 5-12). The initial estimates of the volume of rock required for the gabion mattresses and retaining structures is approximately 10,000 m^3. Section 5.6.16 provides additional detail on borrow requirements.

ID Crest

Modifications to the ID to increase the effective height will include installing a geomembrane to extend seepage cutoff to the dam crest from the dam core and adding a lined temporary crest berm to increase storage and freeboard. Glacial till will be placed in the installation trench, and the material excavated from the trench will be used for backfill where appropriate. The crest surfacing will be reinstated using a layer of gravel and sand at the crest. The temporary crest berm is proposed to be constructed from gabions.

Before excavation of the interim emergency spillway conflicting existing facilities require relocation, protection, or removal. The following existing pipeline and treatment systems located in or near the spillway construction zone will be affected:

- WTP effluent pipeline - Portions of the existing effluent pipeline will be removed and replaced to facilitate the interim emergency spillway channel. The replacement segment will be located on the north side of the access road then cross under the access road and spillway to reach the existing discharge structure at the CVD Pond.
- ID pond conveyance system – This conveyance system pumps water from the ID Pond to the WTP. Components of the conveyance system include floating barge pumps, pipelines, motor control center, and overhead power lines. A floating silt curtain will be installed to protect pumps during construction.
- Siphon Lime Mixing System - The mixing system is expected to be removed from service before construction of DVIHU and will be removed before construction begins.

RCD Modifications

The proposed RCD modifications will restore the capacity to allow the diversion to pass the 1-in-500-year flood event, with freeboard. The modifications to the RCD include removing vegetation, repairing raveled slopes on the dike and cut slope, filling in low spots on the dike crest, and raising the fuse plug.

Trees and other woody vegetation on the dike slopes can have a detrimental effect on the stability and function of the dike. It is therefore proposed that this type of vegetation be removed from the dike. Based on the results of hydraulic modelling (Appendix 5I) and considering that the left side of the channel is not a critical seepage barrier between the diversion and tailings impoundment, only the right side of the diversion is proposed to have vegetation removed.

Hydraulic modelling results (Appendix 5I) were used to determine the locations and extents of dike crest and overflow weir raises necessary to prevent overtopping of the overflow weir during a 1-in-500-year flood event (zero freeboard condition) and to prevent overtopping of the dike during a 1-in-500-year flood event (0.5 m

freeboard downstream of the overflow weir). The maximum required raise of the dike is about 0.8 m. The raise will be performed using sand and gravel for the upper 0.5 m, which is the freeboard distance. The required sand and gravel is proposed to be sourced from the existing Rose Creek Borrow Area. Compacted glacial till material is proposed to be used to extend the seepage barrier to the 1-in-500 year flood event elevation, and appropriate riprap erosion protection should be added to the top of the raised dike. The required glacial till material is proposed to be sourced from the existing Rose Creek Haul Road Borrow Area (Figure 5-12). Angular riprap required to repair the slopes along the RCD is proposed to be sourced from the Grum Dump Rock Quarry or the Granitic Outcrop Borrow Area.

Visual inspection of the existing RCD slopes and comparison with hydraulic modelling results confirmed the need for restoring the existing channel slope geometry and establishing uniform erosion protection to safely pass the 1-in-500-year flood event. It is anticipated that the most-common remediation technique will be removing vegetation and accumulated organic matter, performing localized minor regrading of the dike berm, and placing or augmenting riprap erosion protection material. The modifications do not include any in-stream work.

In summary, the specific activities associated with the proposed DVIHU are as follows:

- Install temporary silt and water management protection infrastructure
- Remove and relocate the existing pipeline
- Excavate and grade the existing spillway channel
- Screen and haul rock to build and set the gabion mattresses and sidewall supports
- Excavate trench on ID crest and install geomembrane and temporary berm
- Remove overgrown vegetation from RCD
- Remove bank slough from RCD and repair dike as required.

5.5.2 Design Components and Criteria

Until the closure conveyance strategy and structures are agreed upon and implemented, the DVIHU will upgrade existing conveyance structures so they are capable of safely conveying the 1-in-500-year flood event. This capacity is consistent with the requirements of the expired water licence (Water Use Licence QZ03-059), which states:

> *40. The Rose Creek Diversion shall have a capacity to carry a 1:500 year design flow.*
>
> *41. The spillways on the Intermediate Dam and the Cross Valley Dam shall have a capacity to carry a 1:500 year design flow of Rose Creek.*
>
> *42. The overflow structure on the Rose Creek Diversion Dam shall be maintained to ensure that peak flows can freely pass through it.*

The combined effect of deepening the spillway channel and raising the crest will allow the ID spillway to safely pass a 1-in-500-year flood event with about 1.0 m of freeboard. It is very unlikely that this flow rate would be reached during the IW because both of the following scenarios would have to occur at the same time in order for the full flow rate to be conveyed over the spillway:

1. None of the flood flow would continue down the RCD and all of the flow would be conveyed onto the tailings.
2. The duration of the 1-in-500-year flood event peak flow would be of sufficient length to fill the ITA to about elevation 1,049 m. Based on hydraulic modelling (Appendix 5I), starting from an assumed water surface elevation in the impoundment of 1,046.5 m, discharge over the spillway would reach 115 m^3/s while maintaining the minimum freeboard, during a 72-hour duration flood event that represents a peak input flow of 121 m^3/s.

Based on these considerations, it is unlikely that the flow over the ID spillway will reach the same magnitude as the inflow into the RCD during a moderate or major flood event. Additional discussion regarding the design criteria for each structure is provided in Appendix 5I.

DRAFT

5.5.3 Schedule for Construction and Sequencing

The DVIHU construction scope includes the following items:

- Mobilizing to the site
- Performing surveying and layout
- Removing or relocating existing piping and structures that are within the existing ID spillway
- Increasing the depth of the existing spillway channel
- Protecting the excavated spillway channel from erosion by installing gabion mattresses
- Increasing the height of the ID crest by installing a geomembrane to extend the core to the dam crest and by adding a temporary berm
- Increasing the RCD capacity by removing vegetation, repairing raveled slopes on the dike and cut slope, and filling in low spots on the dike crest
- Performing demobilization

The work will be initiated and completed within 3 fiscal years. Final design is planned to be completed in the 2014/2015 fiscal year, procurement during the 2015/2016 fiscal year, and construction in 2016/2017 fiscal year. The RCD work is proposed to be accomplished during low water conditions in September through November. Further details on the schedule are presented in Appendix 5I.

5.5.4 Environmental Management Plans for Construction Period

Best management practices will be followed for construction works around water (Environment Yukon [EY], 2011). Relevant aspects of the Environmental Management Plan included in Appendix 5A will be adhered to during all construction activities part of the DVIHU. The specific requirements will be defined in a project-specific environmental management plan prepared before construction begins.

5.6 Ancillary Activities

The completion of the works and activities associated with the IW requires a number of ancillary activities that are associated with one or more of the main undertakings described in the preceding sections. The ancillary activities described in the following subsections will take place at the FMC to support the IW.

5.6.1 Site Security and Access

A security gate is present at the Guardhouse to control access according to the Site Security and Health and Safety Plan. Active security personnel are onsite 24 hours a days, 7 days a week from April to October. From October to March, the security personnel are present 8 hours a day, 7 days a week. The gate is locked at all other times. The site operator is responsible for the following:

- Maintenance of security systems (e.g., gates, fences, locks, and building access)
- Conducting security training/meetings
- Ensuring all visitors are approved, sign-in, and have the required Personal Protective Equipment (PPE)
- Maintenance of security records (i.e., staff, visitors, equipment, and materials)
- Updating the Site Security Plan, including reporting of site visitors, incidents, or issues
- Conducting an annual review and audit of the Site Security Plan

AAM is responsible for the management of the FMC and, as such, needs to be able to ensure the health and safety of those that use the area, while maintaining environmental protection. As outlined in Section 3.1.3, the FMC area is covered by O.I.C. 2008/168, as well as covered by a land reserve. AAM recognizes that there are many traditional and contemporary activities that take place in the O.I.C. and reserve, or that require people to pass through them en route to other areas. An Access Management Plan has been developed to maintain access to the FMC for those with legitimate access requirements, while restricting access for unauthorized users (Appendix 5G).

DRAFT

Authorized users are members of the public (such as hunters, hikers, all-terrain vehicle riders, and snowmobilers) who wish to access the FMC for existing known uses, providing they are within identified known areas or crossing the site at designated points to access areas beyond. People holding or using trapping and guiding concessions are also considered authorized users. Non-authorized users are those that either do not have a specific purpose or are not accessing an area known for recreational, traditional, or big game outfitting purposes within or outside the area. Further details on the specifics of the Access Management Plan are provided in Appendix 5G. The Site Access Crossing Points map provided in Appendix 5G identifies the designated crossing points and known use areas.

5.6.2 Preventative Maintenance Plan

The FMC Preventative Maintenance Plan sets out a process designed to minimize equipment failures and breakdowns and retain the value of the assets to the extent possible considering requirements for service. The PMP applies to the following:

- Mobile and stationary equipment
- Infrastructure
- Faro Housing

The Preventative Maintenance Plan sets out a program of work activities that includes, but is not limited to, the following:

- Monitoring and inspecting equipment to determine the need for preventative maintenance
- Scheduling maintenance tasks
- Conducting all scheduled preventative maintenance
- Conducting all repairs and replacement of consumable components
- Provision of a monthly summary of maintenance activities
- Maintaining Preventative Maintenance Plan records and documents

The Preventative Maintenance Plan will continue to be implemented as part of IW.

5.6.3 FMC buildings and infrastructure

There are a number of buildings at the FMC that are currently used to support operational activities of the mine located at the Faro Mill site and at the Vangorda/Grum site. Site operations personnel operate, maintain, and repair, as required, the following buildings at the Faro Mill site:

- Mill Building
- Warehouse
- Norcan shop
- Lube storage building
- Cold storage
- Reagents building
- Crusher and coarse ore storage
- Guardhouse
- Dry and lunch room
- Concentrate load-out building
- FMC Laboratory

The majority of these buildings have been in place for more than 40 years, and several have been secured against access. The Mill Building, which houses the existing Faro Mill WTP, was deemed unsafe for workers in 2013 and has since been closed and barricaded against public or worker access. Similarly, the primary crusher and coarse ore storage areas are also closed and barricaded against access. The concentrate load out has mostly been removed, with only the foundation remaining.

The Guardhouse is located at the entrance to the FMC. It is occupied by security staff year-round with offices that are used during the week. There are three trailers attached to the Guardhouse: the Dry facilities, lunch room, and

DRAFT

FMCL. The Dry trailer contains a men's and women's dry with ten showers, three toilets, and a small laundry facility with one washing machine.

The office and warehouse facility located adjacent to the Mill Building is generally not used except for storage. Although the whole warehouse is accessible, only the garage bays are used for storage. The second-floor offices are not used or maintained.

A heavy duty equipment repair shop, tire shop, and light vehicle repair shop are used on a regular basis for onsite equipment maintenance and repairs.

The following buildings are located in the Vangorda/Grum mine area:

- Grum office/dry complex
- Grum shop building
- Vangorda WTP

The office/dry complex is a 735 square metre (m^2s) two-storey wood frame construction on a concrete slab with a total floor space of approximately 1,500 m^2. The exterior cladding is sheet steel. The adjacent shop building is approximately 1,092 m^2 and of similar construction. These two buildings are owned by the Town of Faro.

The Vangorda WTP is housed in a steel-frame building on a concrete pad. The site also includes a lime bin and related structures and a few small temporary buildings or shed used for storage, office, and lunchroom space. The Vangorda WTP building and associated accessory buildings are the only buildings in the Vangorda area that are operated, maintained, and repaired by site operations personnel.

All site buildings and related infrastructure currently used will be operated, maintained, and repaired as required as part of IW.

5.6.4 Faro Mine Complex Laboratory

Operational water quality samples are analyzed at the FMC Laboratory, which is located in a trailer attached to the FMC Guardhouse. The use of the onsite laboratory provides for quick turnaround of water quality results to support operational needs. The FMC Laboratory contains an Inductively Coupled Plasma dual-view Optical Emission Spectrometer, which is used as the primary instrument for metals analysis. The laboratory also contains an Atomic Absorption Spectrometer, which is currently used as a backup method for analysis.

The FMC Laboratory is operated in accordance with very stringent contamination procedures and a quality assurance/quality control program implemented to help ensure the accuracy of results and ongoing compliance with Canadian Association for Laboratory Accreditation proficiency requirements.

5.6.5 Lime Delivery and Storage

Lime, specifically calcium oxide or quicklime, is used for the treatment of water at the FMC. Lime is delivered to site and stored in 20-tonne sea containers pending emptying of the containers at the Interim Water Treatment System and Vangorda WTP. At the Vangorda WTP, there is a lime silo with approximately 36 tonnes storage capacity. The specific method of delivery and storage may vary through the IW period, depending on the costs and other aspects of delivery. For example, lime may be delivered in bulk trailers that are offloaded directly into the treatment systems or that are stored onsite and exchanged for an empty trailer. Regardless of the specific delivery and storage method, lime will be handled onsite according to operational procedures that provide for worker health and safety. The handling and storage of lime is also subject to contingency spill response procedures described in the site Spill and Response Plan (Appendix 5E). Annual lime consumption for the IW period for the Interim Water Treatment System and Vangorda WTP is estimated to be approximately 780 tonnes and 350 tonnes, respectively.

5.6.6 Temporary Camp

A temporary camp may be required in order to provide facilities for accommodation of workers for various components of the IW including construction activities and field investigation programs. If required, the proposed location for this temporary camp is the old Pelly Camp area, located off the Grum Access Road. Potable water

supply for this temporary camp would be provided by a well located adjacent to the Grum Office Building. There is an existing septic system in place at the old Pelly Camp that has sufficient capacity to handle potential sewage flows generated by the temporary camp.

5.6.7 Town of Faro Housing

The site operator is responsible for the maintenance of four houses in the Town of Faro. Maintenance personnel are required to report the condition of each house on an annual basis.

5.6.8 Drinking water and septic system

Potable water for the FMC is shipped to the site from Yukon Springs in Whitehorse. There is a potable water system onsite, but it is currently not used for drinking water because of the conditions of the pipes in the Guardhouse. Water for this system is provided by a 66-m well located approximately 350 m northeast of the Guardhouse. This water system is currently only used for water for showering and washing in the Dry facility.

In 2005, a new septic system was installed to treat an increased volume of wastewater discharge from the Guardhouse/Dry facilities associated with additional seasonal activities. The septic system is comprised of a septic tank and siphon, and an absorption bed north of the Guardhouse. The existing septic system will continue to be used for IW period. The septic system is permitted under the *Sewage Disposal Systems Regulation* pursuant to the *Public Health and Safety Act.*

5.6.9 Fuel transport and storage

There are three aboveground storage tanks on the mine site used for storing and dispensing diesel and gasoline at the FMC. There are two single-walled diesel tanks, each with a 40,000-litre (L) capacity. The diesel tanks are located inside a lined, bermed containment area that is sized to store 110 percent of the tank volume, in accordance with the Yukon Government's *Storage Tank Regulations* and *Environmental Code of Practice for Aboveground storage Tank Systems Containing Petroleum Products*. The gasoline tank is a double-walled enviro-tank with a capacity of 30,000 L. The tanks are permitted under the Yukon Government's *Storage Tank Regulations,* and operating procedures are in place that provide for monitoring of storage tank levels and security control of dispensing. Gasoline and diesel fuel are handled according to applicable regulations (i.e., Transportation of Dangerous Goods) and diligently managed for protection of the environment, public safety and worker health and safety. Mobile tanks will be used to fuel equipment remotely or during special projects where procedures for additional tanks are expressly incorporated into the project work plan. Any active mobile tanks will be located within secondary containment berms. The handling and storage of fuels is also subject to contingency spill response procedures described in the site Spill and Response Plan (Appendix 5E).

5.6.10 Electrical distribution system

Electrical power is supplied to the Faro site via a 38-kilovolt power line connected to the Whitehorse-Aishihik-Faro grid. Transformers at the Faro Mill step the power down for onsite distribution. A 27-kilovolt overhead power line runs from the Faro Mill site to the Vangorda/Grum site, and there are electrical substations located at both sites. If required, backup power can be provided using the diesel generator located in the Town of Faro.

5.6.11 Access route and trails construction and maintenance

The mine access road from the Town of Faro to the FMC is maintained by Yukon Government Department of Highways and Public Works. This has included localized resurfacing, grading, patching, steaming culverts, and snow clearing, activities which will continue throughout the IW period.

All FMC roadway and associated infrastructure will be maintained to a standard that would prevent, counteract, or mitigate any adverse effects on persons, property, or the environment. The following routine maintenance will be carried out as part of IW:

- Maintenance of road surfaces in a condition that is suitable for travel that is commensurate with the frequency of use and type of vehicle commonly used

DRAFT

- Maintenance of road side safety berms as required by the Yukon Workers' Compensation Health and Safety Board
- Maintenance of roadside ditches and culverts to minimize the risk of road wash-out or sediment release to the environment
- Culvert steaming during winter, as required to prevent runoff from flowing over top of roadways

5.6.12 Solid waste management

Solid waste disposal is authorized by Waste Management Permit No: 81-001 and is managed in accordance with the terms therein. The permit is currently held by TEES and is effective until December 31, 2014. Under this permit, there are two permitted facilities at the FMC: the Demolition Dump, located directly southwest of the Faro Pit, and the Operations Dump, located directly south of the Demolition Dump. Both dumps are located within the area of the Main and Intermediate Waste Dumps.

The scope of authorization of the Waste Management Permit includes the following:

- Operation of the dumps for the disposal and burial of solid waste generated at the FMC
- Generation, storage, and handling of waste oil, waste batteries, waste antifreeze, and waste lubricants
- Operation of equipment for the incineration of special waste (waste oil) for the purpose of space heating
- Offsite transfer of solid waste

Solid waste generated at the FMC is disposed of in these two permitted facilities, other than domestic-type waste and material containing contaminants in excess of the industrial land use standards in the *Contaminated Sites Regulation*, O.I.C. 2002/17. The domestic-type waste is taken for disposal at the Town of Faro dump. This includes food waste and garbage associated with routine operations at the Guardhouse and Dry facility.

The handling and storage of solid and special waste is also subject to contingency spill response procedures described in the site Spill and Response Plan.

5.6.13 Waste-oil heating

The FMC warehouse, welding, and maintenance building is heated by means of incineration of waste oil. Site C&M personnel are responsible for commissioning, operating, maintaining, and decommissioning the waste-oil heaters. Waste oil is consolidated from equipment maintenance and from a number of storage tanks in a safe and environmentally secure manner and processed in the waste-oil burners as necessary to provide heat.

Incineration of waste oil is conducted in accordance with the terms of the FMC Waste Management Permit No. 81-001. Specifically, the permit sets out limits on contaminant levels of waste oil and prohibits the incineration of waste oil that exceed these thresholds.

5.6.14 Special/Hazardous Waste Management

Special (including hazardous) wastes are stored and handled onsite in accordance with Section 7 of FMC Waste Management Permit No. 81-001. Section 7 sets out a list of mandatory criteria that includes specifications for storage structure and location, segregation of special waste from other wastes, storage container labeling, mixing and dilution prohibition, and standards for storage containers.

The permittee is prohibited from transporting or transferring special wastes, other than within the site. Special waste is transported offsite by a carrier permitted in the Yukon, to an appropriate special waste management facility.

5.6.15 Borrow Sources for IW

Borrow material is required for various components of IW. The following provides a summary of the borrow material requirements for two components of IW: site operations and DVIHU. In addition, the proposed investigations for the identification of borrow sources for the FMRP are summarized.

Borrow Material for Site Operations

Site operations will required borrow material for activities such as road repair, erosion protection, or minor construction purposes. The current borrow material available and its source area is as follows:

- Gabbro rock from the Grum Dump Rock Quarry located west of the Grum waste rock dump
- Sand and gravel from the Haul Road Borrow located south of the Haul Road at NFRC
- Sand and gravel from the Rose Creek Borrow Area located northwest of the RCTA

Heavy equipment is used to extract and transport the borrow material sourced from these areas. Material is screened to acquire a specific grain-size fraction if required.

Borrow Material for DVIHU

Borrow material requirements for the DVIHU are described in Section 5.5. The DVIHU requires approximately 10,000 m^3 of rock to construct gabion mattresses and retaining structures. The proposed source of this material is the existing Rose Creek Borrow Area. Heavy equipment will be needed to extract and transport the required borrow material. Material will be screened to acquire the grain-size fraction specified in the engineering design.

Minor amounts of angular rip rap (1,500 m^3) are required to repair the slopes along the RCD. The Rose Creek Borrow Area does not provide a suitable borrow source of angular riprap. The Grum Dump Rock Quarry or the Granitic Outcrop Borrow Area, have been identified as potential source areas of angular riprap. The Grum Dump Rock Quarry is an active quarry at the site. Heavy equipment is used to extract the borrow material. The Granitic Outcrop Borrow Area would be developed in an existing cut on the south side of the Haul Road. The quarry will be drilled and blasted to meet rip rap size requirements. The blasted rock will then be sorted and loaded into trucks using hydraulic excavators or with large loaders. If the Grantic Outcrop Borrow Area is used, best management practices for rock quarries will be followed and all required permits and certification for storing and using explosives will be in place.

Borrow Material Requirements and Investigation

Additional borrow material will be required for elements of the FMRP. Various material types are required for specific reclamation uses, including the following:

- Low permeability silt and clay (till) for covers and as a growth medium
- Organic rich soils for top cover to improve vegetation growth
- Granular sand and gravel for concrete aggregate, drainage, backfill, and grading/ fill
- Coarse rip-rap (competent cobbles and boulders) for lining watercourses

As described in Section 5.4, Site Investigations, additional investigation of potential borrow areas is required to identify, delineate, and quantify potential borrow material sources. This investigation work will also help to determine geochemical/ geotechnical characteristics of source materials at each potential deposit and to determine fertility/salinity parameters of low permeability and organic soils that affect vegetation for use as potential growth medium, or evapotranspirative cover, or both. Borrow materials must be relatively non-reactive and free of potential leachable contaminants.

Potential priority borrow areas, and material type(s) within the Faro Mine Area, RCTA, Haul Road, and Grum/Vangorda Area include the following:

Faro Mine Area

- Rose Creek Borrow (Granular)
- Rose Creek Haul Road (Low permeability/growth medium)
- RCD Quarry (Schist bedrock)
- Haul Road Borrow (Granular)
- Pump House Borrow (Granular)

DRAFT

Haul Road Area

- Faro Mine Access Road Granitic Outcrop (Granite bedrock for rip-rap)

Vangorda/ Grum Area

- Grum Overburden Dump (Low permeability/growth medium)
- NE Area of Grum Pit (Low permeability/growth medium)
- Grum Creek Borrow/Moose Pond Borrow (Granular)
- Grum Dump Rock Quarry (ripable Gabbro bedrock)

As part of the IW, targeted areas will be evaluated for their potential to be developed into an economically feasible borrow source, but only the sources specifically identified in above and in Section 5.5 will be used during the IW. Many potential borrow locations are located in undisturbed areas. As part of the FMRP, plans to rehabilitate the selected borrow areas will be completed. Reclamation planning of borrow sources will include a revegetation plan, which requires input from baseline data collection, volumes of borrow material to be removed, and information about fertility and salinity parameters. This planning work is ongoing; therefore, it is included for context but not described in further detail at this time.

5.7 Workforce Requirements

5.7.1 Employment Expectations

Employment expectations for the components of the IW, including the timing the labour force is required, skill level of workers and number of positions, are provided in this section. This includes details on the employment levels, broken down by month and job type.

Site operations are ongoing and are expected to continue with similar staffing levels as in the recent past. Site operations occur year-round; however, between about April and October, the staffing levels increase (Figure 7-1). Average monthly employment is expected to range between 36 and 52 employees for site operations from April until October.

Currently there are no significant changes anticipated to the number of site operations staff during the IW. Staffing requirements are indicated on Figure 7-1, and include WTP operators, environmental technologists, security/safety personnel, skilled labourers/equipment operators and unskilled labours, along with supervisors and forepersons.

As has been described in the preceding sections, extensive site investigations will occur in 2014, with reduced levels of investigation activities likely to occur in subsequent years. Average monthly employment during 2014 is expected to range between 13 and 41 employees for site investigations from May to October (Figure 7-2) and are anticipated be at the lower end of that range in subsequent years. Staffing requirements are indicated on Figure 7-2, and include drillers, field engineers/scientists, surveyors, and managers.

Activities at the FMC to construct the DVIHU are limited to one season (anticipated to be in 2016), and average monthly employment is expected to range from 6 to 26 employees from April to September (Figure 7-3). Staffing requirements are indicated on Figure 7-3, and include equipment operators, labourers, engineers, and forepersons.

5.7.2 Accommodation Requirements

There is one hotel in the Town of Faro (the Studio Hotel) and at least three bed and breakfasts (B&Bs) (Bears Den B&B, Far-O-Way Guest House, and the Valley B&B) that offer potential accommodation for the seasonal-workforce. During the IW, there are several periods when staffing levels may exceed the supply of rooms available in Faro. In addition, it is understood that there are competing demands for the available accommodations. Visitors and service providers who travel to the community, such as health care providers or non-FMC related construction workers (e.g., highways crews or forest fire crews), also require lodging.

This competition for accommodation is highlighted by the same seasonal use requirements by the IW workforce as the seasonal use for tourism and non-FMC construction work. Therefore, the seasonal non-local workforce will likely be housed in a mix of hotel/B&B accommodation and leased or rental housing in the Town of Faro.

Consultation with the Town of Faro is occurring to assess the availability of possible rental units and other housing accommodation solutions to the anticipated accommodation needs. One additional option to meet the accommodation requirements is the construction of a temporary camp, as described in Section 5.6.7.

5.7.3 Worker Health and Safety Programs

The site operations contractor is required to have a site-specific Occupational Health and Safety (OHS) manual to manage health and safety at the site and protect the health and safety of the employees. TEES, the current site operations contractor, has prepared a FMC OHS manual, last updated in 2013. In addition to the OHS manual, all employees are responsible for complying with the requirements of the Yukon Occupational Health & Safety Act and Regulations and the Yukon Workers' Compensation Health and Safety Board.

The FMC OHS manual provides a means to communicate the health and safety culture, rules, regulations, policies, procedures, and criteria for site operations employees, as well as other contractors, subcontractors, and visitors. The OHS manual includes information on the following:

- Policies
- Roles and responsibilities
- Hazard identification and risk control
- Safe work practices and job procedures

5.7.4 Yukon and Local Opportunities

As referenced in Section 5.1, one of the overarching objectives of the FMRP closure and remediation work is to maximize local and Yukon socio-economic benefits. This objective is carried through the IW. Yukon and local opportunities will be developed or identified and implemented for AYFN and Yukoner participation with a view to build capacity toward longer-term participation and socio-economic benefits for the project. Opportunities and socio-economic benefits for AYFN and Yukoners will include opportunities for direct employment and for the provision of services, goods, and supplies from AYFN and Yukon businesses. Opportunities for engagement will continue to evolve during the IW based on participation, lessons learned and as new opportunities are identified.

A wide range of Yukon-based contractors, suppliers, and vendors were engaged to support 2012 and 2013 site operations, site investigations and development of the IW, and similar or other opportunities will continue to be available during the IW. This includes engagement of external technical consultants, drilling contractors, surveyors, electricians, truck rentals, piping and pumping supplies, transport and expediting services, potable drinking water, communication systems, and accommodations.

Table 5-5 provides a detailed list of the Yukon-based subconsultants, suppliers, and vendors retained for the 2013 field programs and development of the IWPP. Similar engagement is anticipated to support activities during the IW.

In general, IW activities likely provide limited long-term employment opportunities for the local communities (Town of Faro, Ross River, Pelly Crossing, and Watson Lake), beyond the current employment opportunities needed to sustain site operations. While the three main IW activities potentially provide employment opportunities for a range of job types, many of these jobs require specialized skillsets. As a result, the local area is expected to capture a relatively small portion of the employment opportunities. The workforce is anticipated to combine non-local technical experts with Whitehorse-based and local support.

DRAFT

Similarly, beyond current opportunities for purchase of materials and supplies, the activities conducted as part of the IW offer limited additional local business development opportunities. As most of the materials and equipment will be imported into the project area, limited potential for economic diversification is anticipated. However where possible and practical, local resources will be used. It is expected that for some supporting services and suppliers demand will exceed the existing local capacity. Opportunities for potential engagement by local business include house rental, shuttle services, catering, housekeeping, restaurant, grocery, and fuel supply.

TABLE 5-5
Yukon-based Subconsultants, Local Suppliers, and Vendors for Field Programs and development of the IWPP
Faro Mine Interim Works

Name	Service Provided
A-1 Delivery	Shippers
Acklands Grainger	Field supplies
Air North	Air transport and freight
Alkan Air	Air charter transport
Aurora Geosciences	Geophysical surveys
Bill Slater Environmental Consulting	Technical consulting services (Regulatory Lead role)
Bears Den B&B	Faro Accommodation
Challenger Geomatics	FMC surveys and aerial photography targets
Capital Helicopters	Helicopter transport
The Chocolate Claim	Catering
Driving Force	Truck rentals
Dynamic Electric	Electrician
EDI Environmental Services, Inc. (EDI)	Fish tagging and telemetry
ELR	Technical consulting services
Energy North	Technical consulting services
Faro Studio Hotel	Accommodation
FMTX	Field suppliers
Glacier Water	Potable drinking water
Hemmera (Whitehorse Office)	Technical consulting services
Laberge Environmental Services	Pit Lake Sampling
northSense	Technical consulting services
NorthWest Vacuum Service	FMC portable toilets
Northwestel	Cable and internet
Midnight Sun Drilling Ltd.	Drilling services
SLR (Whitehorse Office)	Technical consulting services
Sunset Septic Services	Septic service
Tait Custom Trailer	Trailer rental
The Brick	Lab equipment
Territorial Expediting	Expediting
Total North	Radio and satellite communications hardware and setup
Trans North Helicopters	Helicopter transport
Valley B&B	House rental and Faro accommodations

DRAFT

5.7.5 Training and Skills Development Programs

Various programs to provide training and skill development have been offered in the past and will likely continue during the IW. Training and capacity building initiatives are intended to develop skills and capabilities that will meet labour resource needs during the IW and ultimately for the FMRP. The training and education strategy will preferentially support AYFN work force development and training opportunities.

Examples of training programs that occurred recently include the following:

- The site operations contractor offers a training and development program for AYFN residents. Training and development initiatives include work experience opportunities, job shadowing, role cross-training, and formal training courses. In 2012, six AYFN trainees (including participants from Ross River and Watson Lake) and in 2013, eight AYFN trainees (including participants from Faro, Ross River, and Watson Lake) completed this training program.
- CH2M HILL participated in the YG-sponsored Student Training and Employment Program (STEP), which provides summer employment opportunities to full-time post-secondary students or recent post-secondary graduates who were Yukon residents before attending school.

Table 5-6 provides a list of AYFN participation activities planned for 2014. It is anticipated that these, or similar activities, will continue during the remainder of the IW. Table 5-7 provides a list of Yukoner participation activities planned for 2014. It is anticipated that these, or similar activities, will also continue during the remainder of the IW. Lessons learned related to local skill development and training opportunities from the IW activities will be applied to the FMRP.

TABLE 5-6
Proposed November 2013–November 2014 AYFN Participation Activities
Faro Mine Interim Works

Opportunity	Description	Participation Type	Schedule
Visit First Nation Communities	Road trip to Pelly, Ross River, and Watson Lake to discuss opportunities for training employment and contracting opportunities	Training and capacity building	November–December 2013
Youth Job Fairs	CH2M HILL attendance at local job fair-type information sessions (Pelly, Ross River, Watson Lake)	Training and capacity building	February 2014
Dechen La' Youth Program Support	Meeting with N. Barichello to discuss the 2014 summer program	Training and capacity building	February–June 2014
Project Delivery Assistant for the FMC Field Office	Direct-hire 2 AYFN candidates to work in FMC Field Office as key team members	Direct employment	Summer 2014
AYFN Trainee Program/TEES	Coordinate work with TEES to use job training and mentoring for apprentices CH2M HILL to offer specialized 'young worker' health and safety training programs that are more age-sensitive	Training and capacity building	2014 field season
Contracting	Award field support services to local vendors, including heavy equipment services, vending, and logistics	Contracting and Procurement	2014 field season

SECTION 6

Description of Existing Environmental and Socio-economic Conditions

This section describes the existing conditions at the FMC and the assessment study areas, as follows:

- Existing Site Conditions (Section 6.1)
- Environmental Conditions (Section 6.2)
- Socio-economic Conditions (Section 6.3)

The existing conditions serve as the baseline for the assessment of effects presented in Section 7.

6.1 Existing Site Conditions

This section describes existing site conditions at the three main areas of the FMC: the Faro Mine Area, the RCTA and the Vangorda/Grum Area (as illustrated in Figures 5-1 and 5-5), and the associated main facilities. It focuses on issues and components that result in requirements for the proposed IW. It describes the existing geochemical and physical stability conditions associated with the FMC facilities. As stated in Section 3.3.2, the FMC presents long-term chemical and physical stability risks that require on-going monitoring and long-term management. Current geochemical and physical stability conditions are characterized by the following documents, provided as appendices to this document:

- Appendix 6A, Geochemical Characterization Report
- Appendix 6B, Hydraulics Characterization of Existing Facilities
- Appendix 6C, Stability of Major Existing Facilities

6.1.1 Faro Mine Area

An overview of the Faro Mine Area and RCTA is provided in Figure 5-1. It shows the following main facilities:

- Freshwater diversion systems
- Faro Pit and backfilled Zone II Pit
- Faro WRDs
- S-Wells area, ETA, and associated SIS
- The Faro Mill WTP
- The RCTA

6.1.1.1 Freshwater diversion systems

Historically, a number of streams and creeks conveyed runoff through the Faro Mine Area. However, to prevent potential surface water contamination associated with mining activities, many of these systems were re-routed via diversions, flumes, and ditches. North of the Faro Pit, runoff drains through Faro Creek, a natural channel carrying unimpacted surface water to the southwest. Faro Creek was diverted from its original flow path and now flows around the northeast side of Faro Pit through the FCD, to the NFRC natural channel. Clean runoff is collected from the hillsides northwest of the Faro Pit and redirected to the FCD via the West Valley Interceptor Ditch. The NFRC flows southwest and adjacent to the Northeast WRD and Intermediate Dump, and through the Haul Road via the NFRD to its confluence with the SFRC. Water from the NFRC and SFRC flows into the upper section of the RCD, a straight constructed channel that diverts water around the south side of the RCTA. The RCD is described in detail in the section below describing the RCTA. Rose Creek ultimately flows to Anvil Creek, a tributary of the Pelly River.

The North Wall Interceptor Ditch intercepts runoff from the north side of the Rose Creek Valley and diverts it around the CVD to Rose Creek. Upper Guardhouse Creek, a natural channel located northwest of the Faro Pit, collects runoff from the catchment north of the FMC, as well as seepage from the Faro Northwest Waste Dump (Northwest WD), and conveys the flow to the North Wall Interceptor Ditch.

DRAFT

Throughout the FMC, clean surface water continues to be managed using various fresh water conveyance diversions and facilities to minimize the amount of clean water that enters the impacted areas of the site and subsequently requires management and treatment.

6.1.1.2 Faro Pit

The Faro Pit was mined from 1969 until 1982, and from 1986 until 1992. Excavation began along the northwest side of the pit and expanded to the west and south until the pit reached its maximum open length of approximately 1,600 m and maximum width of approximately 975 m, crest to crest. The top of the slope at the northwest end of the pit is approximately 1,320 masl, and the top of the slope along the east side of the pit is approximately 1,296 masl. The bottom of the pit is currently under water, but is estimated to be 975 masl (RGC, 1996). The side slopes are intact where benched, with overall slopes varying between 30 and 45 degrees. The steepest slopes are located around the northwest end of the pit, and the gentler slopes are located along the eastern wall. Two slope failures have been identified along the east slope of the Faro Pit: the North and South Instability Zones (Golder, 2013). For the interim period, there is a low risk of the Faro Pit slopes experiencing a large-scale failure (Appendix 6C). The Faro Pit Instability Zones are monitored periodically.

Underground mining also took place through the southwest wall of the Faro Pit, but its extent is not well-defined. During these operations, approximately 3.4 million m^3 of mine rock were dumped into the Faro Pit. The pit also contains approximately 15 million tonnes of net acidic, alkaline-bearing tailings received from the Mill starting in 1992. Portions of the pit's south and east walls are covered by waste rock and contribute a significant amount of contaminants to the pit lake.

Faro Pit is part of the active water management program at the site and receives groundwater seepage, direct precipitation, runoff, FCD seepage, pit wall seepage, and water from managed sources such as the ID Pond, S-Wells, Zone II Pit, and ETA. The Faro Pit has the capacity to store water pumped by various water interception systems year-round, making it possible to operate the WTP seasonally. Until the fall of 2012, to prevent an uncontrolled release of non-compliant water from Faro Pit to the receiving environment, the water level in Faro Pit has been managed through seasonal pumping and treatment. Each year the water level was maintained at least 15 m below the elevation at which water could overflow into Zone II Pit, through seasonal (summer) pumping and treating of water from the pit in the Faro Mill WTP.

In 2012, the Faro Mill WTP was assessed and it was determined that there was an increasing risk of major equipment failure in the WTP (CH2M HILL, 2012c). In addition, a safety assessment of the existing Faro Mill WTP determined that the facility should not be operated until health and safety issues could be assessed and resolved). Consequently, operation of the Faro Mill WTP ceased at the end of the pumping program in the fall of 2012. During 2013, without operation of the Faro Mill WTP, the water-level elevation in the Faro Pit rose above the end-of season target (1141 masl) to its current water-level elevation of 1148.3 masl (as of January 2014). In 2014, as early as possible, seasonal dewatering activities will resume at the Faro Pit using the Interim Water Treatment System, with the objective to manage the water-level elevation in the Faro Pit within the prescribed operating range. Based on current site conditions, it is anticipated that the water level in the Faro Pit will return to the operational end-of-season target in 2016.

6.1.1.3 Zone II Pit

A smaller pit, the Zone II Pit, was excavated immediately southeast of the Faro Pit. This pit was mined from 1969 until 1982, and was approximately 100 m deeper than the original ground surface (RGC, 1996). During the 1980s, this pit was backfilled entirely with waste rock; however, there is a continuing need to extract contaminated water from the backfilled pit. The back-filled Zone II Pit collects contaminated water from its immediate catchment area. If water in Zone II Pit rises above 1,128 masl, it will seep towards NFRC. Since 1991, a water management plan for Zone II Pit has been in place involving seasonal (summer) dewatering into the Faro Pit via a down-hole pump installed in a well (X26) located in Zone II Pit on an as-required basis to maintain the water level and to minimize the migration of groundwater from the pit towards the NFRC. In 2013 a new well (CH12-Z2-PW01) replaced X26, enabling groundwater levels in Zone II Pit to be managed to lower levels, below the elevation of water in the NFRC. In addition the system was upgraded to enable year-round operation.

DRAFT

6.1.1.4 Faro Waste Rock Dumps

Within the Faro Mine Area, waste rock was deposited in a series of dumps surrounding the Faro Pit. There are approximately 260 million tonnes of waste rock in the Faro Waste Rock Dumps, covering approximately 335 hectares of surface area. There are roughly 30 separate dumps, each with a unique history and composition.

The Faro Waste Dumps' geochemistry has been studied extensively in the recent past (SRK 2004a, 2006a) and most recently to as part of the current assessment (Appendix 6A). The main waste dumps at the Faro Mine Area include Northwest, Faro Valley, Main, Intermediate, Northeast, Zone II, and near pit dumps, and the Low-Grade and Oxide Stockpiles. The Faro Mine Area waste dumps are shown in Figure 6-1.

At the broadest level, it is helpful to characterize three groupings of waste rock. The most mineralized material occurs in a series of low-grade ore and oxide fines stockpiles. Although that material represents less than 10 percent of the total volume of waste, it has a high metals content and is therefore a significant source of contaminants. The next most mineralized material is found in three sulphide cells, which are areas within the Main Dump, Intermediate Dump and Northeast WRD, where some sulphide waste was purposefully segregated. The sulphide cells are not as well-delineated as the low grade ore and oxide fines, so volumes are more difficult to estimate. But the material's relatively high metals content and acid-generating potential suggest the sulphide cells are also disproportionately large sources of contaminants. The remainder of the waste rock dumps are variable in composition. In general, most dumps contain areas of acidic and metal-leaching waste, and none of the dumps can be considered completely benign.

Geochemical loading from the FMC WRDs is largely controlled by the waste rock material's composition, as well as how it was placed, relative to the paleotopography. Previous borehole data and historical geological information indicate the FMC WRDs are underlain by generally thin (less than 10-m-thick), discontinuous deposits of glacial till, glaciofluvial sediments, and low-permeability bedrock (RGC, 1996). When the FMC WRDs were established, the relatively coarse waste rock material (which has a fairly high hydraulic conductivity) was placed over the native soil, which is less permeable. As a result, water infiltrating the waste rock either continues to infiltrate into the native soil or will travel along the paleosurface at the base of the WRD until it daylights at the toe of the waste rock. Contaminated water which infiltrates the native soil and into the groundwater leads to groundwater contamination in the Faro Mine Area. Groundwater contamination is expected to increase significantly in the future (Appendix 6A).

Seepage water that emerges at the toe of the WRDs can impact surface water quality directly. Currently, the majority of poor-quality seepage water is collected through interception systems for treatment. Most of the seepage occurs at these locations after freshet or large precipitation events. It takes place over a fairly short timeframe, based on observations during the CH2M HILL 2012 field program (CH2M HILL, 2013b), as well as the historical seep sampling program (SRK, 2010b). However, several seeps (generally located in pre-mining drainage channels), flow year-round. As part of the FMRP, the seepage from perennial seeps at the toe of the waste dumps will likely be managed further by placing covers to minimize infiltration through the waste dump. SISs will control seepage that still emanates from the toe of the waste dumps (i.e., after the covers are in place).

6.1.1.5 S-Wells and Emergency Tailings Area Seepage Interception Systems

The S-Wells area is an area of identified groundwater contamination. It is located at the southernmost extension of the Main WRD, where it branches off to the Haul Road (Appendix 6A). Groundwater and surface water quality investigations in the S-Wells area indicated high levels of contaminants near the NFRC, with a component of the contaminated groundwater discharging to the creek. Increasing trends in contaminant levels were also evident within the creek, particularly in the winter low-flow period. In early 2009, a first-phase groundwater interception system was installed in the S-Wells area and upgraded in the autumn of 2009. Since then, the collected water from the S-Wells has been pumped to the Faro Pit on a year-round basis.

Significant groundwater contamination has also been identified in the ETA, located downgradient of the Mill and stockpiles (Appendix 6A). The ETA has been shown to contribute a significant contaminant load to the RCAA under the RCTA through seepage and groundwater migration. As the name suggests, the area was used for emergency deposits of tailings, but studies have shown that groundwater contamination results at least in part from the

DRAFT

waste rock located upgradient of the tailings. The ETA is also the only portion of the Faro Mine Area with significant surface water seepage from the waste rock (other seeps are ephemeral or internal). Measures to capture the ETA surface and groundwater and send it directly to water treatment were implemented in 2007, providing for seasonal collection and treatment. Flow not captured by the ETA SIS flows into Faro Creek Canyon, the pre-mine Faro Creek channel located downgradient of the Mill Area and ETA. Most of this flow discharges to the Intermediate Impoundment of the RCTA, where it is pumped to the Faro Pit or directly for treatment when the WTP is operating. A small percentage of this flow, however, seeps into the RCAA through the unlined conveyance ditch draining Faro Creek Canyon to the Intermediate Impoundment.

6.1.1.6 Faro Mill Water Treatment Plant

The Faro Mill WTP, which began operation in 2001, is located in the old Faro Mill Building and was constructed using existing ore-processing equipment adapted for lime water treatment. Treated effluent from the Faro Mill WTP was discharged to the CVD Pond for polishing clarification (solids removal) prior to discharge, via siphon, to Rose Creek.

In 2012, the Faro Mill WTP was assessed and it was determined that there was an increasing risk of major equipment failure (CH2M HILL, 2012c). In addition, a safety assessment of the Faro Mill WTP determined that the facility should not be operated until health and safety issues could be assessed and resolved. Consequently, operation of the existing Faro Mill WTP ceased at the end of the pumping program in the fall of 2012.

Since 2006, sludge generated in the Faro Mill WTP was deposited in a series of cells (ponds) excavated in the Original Impoundment. At the end of each treatment season, once partially frozen, the sludge is excavated from the ponds and placed in windrows next to the ponds. During operations, water decanted off the solids is routed through existing ditches to the ID Pond, where it blends with those waters and is eventually pumped back for treatment.

6.1.2 Rose Creek Tailings Area

6.1.2.1 Rose Creek Tailings Area Dams

Figure 5-1 shows the RCTA, which consists of four dams; the Original Dam, Secondary Dam, ID, and CVD. The RCTA contains about 28.6 million m^3 of tailings (about 55 million tonnes). Throughout most of the operating periods at the FMC, tailings were deposited in the three impoundments that make up the RCTA:

- The Original Impoundment was used from 1969 to 1975; it has a surface area of 41.7 hectares, and holds approximately 6,300,000 m^3 of tailings.
- The Secondary Impoundment was used from 1975 to 1982 and again in 1986; it has a surface area of 54.5 hectares and contains approximately 10,400,000 m^3 of tailings.
- The Intermediate Impoundment was used from 1986 to 1992; it has a surface area of 99 hectares and contains approximately 11,900,000 m^3 of tailings.

Between 1992 and 1998, tailings were deposited in the Faro Pit as described previously.

The tailings impoundments were created by the series of dams and associated dam raises. The dams that created the Original Impoundment are now almost entirely enclosed by secondary tailings and no longer function as dam structures. The Secondary Dam and ID function as tailings and water retention structures.

The Secondary Dam comprises an East and a West Limb. The East Limb of the Secondary Dam is a low retention dike constructed of compacted fill. It runs parallel to the south Rose Creek Valley wall, and only rises about 4 m above the natural topography. The West Limb of the Secondary Dam is a curved portion of the dam that crosses the Rose Creek Valley in a roughly north–to-south direction. It was raised using centerline construction and compacted fill to a maximum height of 27 m, about half of which is now covered by the intermediate tailings. Tailings were deposited behind this dam from 1975 until 1982, and again for approximately five months in 1986.

The ID is a zoned earthfill embankment with a sloping upstream low-permeability core and a downstream random fill shell. In 1981, the ID was constructed across the Rose Creek Valley to contain supernatant water and tailings

DRAFT

solids. It was raised in 1988, 1989, and 1991 to a final crest elevation of 1,049.8 masl, to a maximum height of about 32 m above the old Rose Creek channel. The ID spillway on the right (north) abutment is a rock-lined channel in natural overburden material. The ID spillway discharges into the CVD Pond.

The CVD is located about 500 m downstream from the ID. It has a maximum height of about 19 m, is approximately 500 m long, and creates the CVD Pond which holds treated water prior to discharge to Rose Creek. The embankment is a zoned dam with core and filters, constructed as a conventional water-retaining dam with no retained tailings. A toe berm was constructed at a later date (after the original construction was completed) to address seepage that appeared near the toe of the dam. The crest of the dam is 1,034 masl and the downstream toe is 1,016 masl (nominal).

Sampling to date has identified contaminants migrating from the acid-generating Rose Creek tailings to the RCAA, an essentially continuous aquifer of sand and gravel outwash that underlies the tailings. The tailings contain an excess of acid-generating sulphide minerals, with very high levels of soluble metals and acidic conditions. Precipitation picks up some of the soluble contaminants and transports them down into the underlying tailings and soils. However, groundwater contamination is limited and is not ecologically significant at this time because the contamination has not reached surface receiving waters. Testing of soil and water from the RCAA demonstrates that the metal contaminants are being temporarily held within the organic and alluvial sediments underlying the tailings. In the future, groundwater contamination is expected to increase significantly below the tailings (Appendix 6A).

6.1.2.2 Rose Creek Diversion

The RCD is located about 2.5 km southwest of the Faro Pit and was designed to convey Rose Creek around the RCTA. The RCD is approximately 4,700 m long, with a slope ranging from 0.23 to 5.0 percent. Numerous drop weirs are present at the downstream portion of the diversion.

The RCD was developed in two stages: the upper section and the lower section. The upper section was constructed in 1974, in conjunction with the construction of the Secondary Impoundment, and is approximately 900 m long. It is predominantly a straight channel constrained by natural slopes on the south side and by a constructed dike on the north side. The channel includes drop weirs, as well as rip rap for erosion protection.

The lower section of the RCD was constructed in 1980 and 1981, in conjunction with the Intermediate Impoundment development. It passes water along the south side of the Intermediate Impoundment and returns flow into the natural Rose Creek Channel, downstream of the CVD. The lower section includes a series of boulder-lined drop structures and a sharp bend at the downstream end. It is constrained by natural slopes on the south side and by a till dike on the north side.

The crest of the diversion dam (also known as the overflow weir) which diverts flow from the upper section to the lower section of the RCD, was constructed approximately 1 m lower than the crest of the adjacent diversion canal dike, and was armoured with rip rap. This was done to facilitate overflow at this location to the Intermediate Impoundment during an event in excess of the 1-in-500-year flood design capacity. In 2004, the containment dike (roadway) was rebuilt along portions of the lower RCD to restore freeboard to safely pass the design flood. Slumping and encroachment of excessive vegetation in the containment dike has limited the success of this rebuild, and the RCD's capacity remains below the intended design flood capacity.

6.1.3 Vangorda/Grum Area

An overview of the Vangorda/Grum Area is provided in Figure 5-5. It shows the following main facilities:

- Fresh water diversions and facilities
- Vangorda and Grum Pits
- Vangorda and Grum Waste Dumps (including the GSC)
- Little Creek Dam
- V15 and Grum Creek Pumping System
- Grum Overburden Dump
- Vangorda WTP and Sludge Pond

6.1.3.1 Fresh water conveyance diversions and facilities

The Vangorda/Grum Area is characterized by two localized groundwater sinks (the Grum and Vangorda Pits) and regional groundwater flow toward Vangorda Creek, which drains the area and flows south toward the Pelly River. The major water management structure in the area is the VCD. Before mining began, Vangorda Creek flowed directly over the Vangorda deposit. Vangorda Creek is now diverted from its original path via a 1,200-m-long flume that flows west of the Vangorda Pit and discharges back into Vangorda Creek downstream of the Vangorda Pit. Design of an upgraded VCD is currently underway because the current diversion only has capacity for a 1-in-100-year flood event, and it requires extensive ongoing maintenance to maintain performance.

There are also a number of small ditches and sediment ponds around both the Grum and Vangorda Pits. The GID diverts Grum Creek in a rip rapped channel around the upper perimeter of the Grum Pit. It discharges the flow into the sedimentation SPP built to capture sediment from the GID before discharging into Vangorda Creek.

6.1.3.2 Little Creek Dam

The LCD is located directly south of the Vangorda Pit. The LCD was constructed in 1992 to collect water pumped from the Vangorda Pit, and runoff and seepage from the Vangorda Waste Dump. During operations, water stored in the LCD Pond was conveyed to the water treatment plant. Once mine operations ceased, water management at the FMC changed. Currently, only runoff and seepage from the Vangorda Waste Dump collects behind the LCD. Runoff and seepage are conveyed to the LCD Pond by the Vangorda Waste Dump Seepage Collection Ditch; an open ditch along the south, west and north sides of the Vangorda Waste Dump which intercepts runoff and seepage that would otherwise enter Vangorda Creek directly. Several transverse drains were constructed beneath the till berm surrounding the Vangorda Waste Dump to direct the seepage toward the perimeter collection ditch and LCP. Water accumulates in the LCD Pond and is pumped seasonally to the Vangorda Pit and eventually to the Vangorda WTP for treatment.

6.1.3.3 V15 and Grum Creek Pumping System

Seepage and runoff from the Grum Waste Dump surfaces at V15 and Grum Creek, downgradient from the waste dump on the southeastern side. A collection ditch, installed in 2007, conveys seepage from V15 into a ditch that routes Grum Creek water to Moose Pond, away from lower Grum Creek. In 2011, site operators installed the V15 and Grum Creek Pumping System in response to continued increasing contaminant levels at V15, to manage peak spring runoff conditions, and to protect the physical integrity of Moose Pond. The pumping system, located east of the Grum Waste Dump, consists of an insulated and heat-traced, 76-mm HDPE pipeline, a power supply, and pump. The system can redirect seepage from the Grum Waste Dump (V15, Grum Creek, or both) to the Vangorda Pit year-round. Currently the system is operated during peak freshet and storm event flows only, with Moose Pond receiving ‘normal” flows. When the system is not operated, discharge flows to Moose Pond, where it exfiltrates to ground. Sampling of Moose Seep and Moose Well No. 2, downgradient of Moose Pond, confirm that losses from Moose Pond (via exfiltration) flow towards Vangorda Creek with contaminant attenuation provided along the groundwater flow path.

6.1.3.4 Vangorda and Grum Pits

The Vangorda Pit is about 1,150-m-long and 375-m-across at its widest point. The southeast half of the pit is narrower and shallower, and includes a ramp, and ore and waste stockpiles. The deepest point in the pit is about 150 m from the crest. Vangorda Pit receives groundwater seepage, direct precipitation, runoff, VCD seepage, along with water from managed sources such as LCD Pond and the GSC Pond. Starting in 2013, additional sources were routed to Vangorda Pit including Grum Pit water, inflows from the V15 and Grum Creek Pumping System, and discharge collected in the ditch around the northeast perimeter of the GSC. Pit wall rock and waste rock release contaminants to the pit lake. Vangorda Pit water is currently non-compliant with the proposed effluent discharge limits.

The water level in Vangorda Pit is maintained through a seasonal pumping program. When activated, the pumping program typically runs from May/June to late summer/autumn, pumping water from the pit up to the Vangorda WTP treatment.

DRAFT

The Vangorda Pit walls are considered stable and with a low risk of large-scale failure. Slope movement, however, has been identified along the southwest pit wall and could eventually affect the safety berm along the Haul Road.

The Grum Pit is oval in shape, oriented with the long axis in a north to south direction. The pit is approximately 1000 m in length (north to south), and 625 m wide (west to east), measured crest to crest. The Grum Pit receives water from surface runoff within the Grum Pit catchment, as well as groundwater inflow from the surrounding thalweg aquifer (Appendix 6A). Since the mine operations were shut down, the water level in the Grum Pit has been steadily rising. In 2013, active management of water Grum Pit was initiated through seasonal pumping of water from Grum Pit to Vangorda Pit. The Grum Pit was operated as an in situ biological treatment system (algal-based bioreactor) by adding nutrients over approximately 8 years. However, the treatment process was discontinued in 2012 due to limited effectiveness.

Slope failure within the glacial till materials overlying the rock of the Grum Pit East wall occurred during a temporary shutdown in 1997/98. The slope failure has since increased in size and has potential to affect the GID and electrical substation. Continuing displacement is occurring within the instability zone, but the rate and the magnitude of these displacements are unknown. There is a risk that the blocks of soil hanging at the top of the slope could break free at any time (Appendix 6C). In addition, the North wall of the Grum Pit is a till slope that is gradually sliding into the pit.

6.1.3.5 Vangorda and Grum Waste Dumps

Figure 6-2 shows the three waste dumps in the Vangorda/Grum area: the Vangorda Dump, the Grum Waste Dump, and the Grum Overburden Dump. There are a number of much smaller waste deposits in the area, such as above the Vangorda Pit ramp and on the Ore Transfer Pad northwest of the Grum Pit. Depending on the sub-catchment location, seepage from the waste dump may flow to the Grum Pit, the Vangorda Pit, Vangorda Creek, or West Fork Vangorda Creek.

The Vangorda Waste Dump was constructed on a topographic high point south of the Vangorda Pit. It contains about 16 million tonnes of material and covers about 40 hectares. Despite more rigorous segregation practices followed when the Vangorda Pit was mined, the waste dumps associated with the Vangorda Pit generally contain sulphide-rich waste rock with little neutralization potential available to buffer acid generation processes. Waste rock generated from the Vangorda Pit area contains some of the greatest percentages of sulphide at the FMC (SRK, 2006b). As a result, water draining from its waste dump can be poor quality (SRK, 2010b). The contaminant load from the Vangorda Waste Dump is expected to continue increasing over the next few decades, and water will require treatment for several centuries.

The Grum Waste Dump contains about 28 million tonnes of waste that covers about 128 hectares. The south-central portion of the Grum Waste Dump contains sulphide-dominant waste rock in an area called the GSC, and has some of the greatest potential at the FMC for generating acid and leaching metals. To minimize downgradient impacts, the GSC was strategically placed during active mining, and in 2010 it was capped with a low-permeability cover (60-mil single-sided textured HDPE liner covered with 1 m of till [Rainey et al, 2013]). Although the GSC contains strong acid-generating material, the remainder of the Grum Waste Dump contains only pockets of acidic material. Seepage water quality downgradient of the Grum Waste Dump has begun to deteriorate. Groundwater contamination downgradient of the Grum Waste Dump is expected to increase in the future (Appendix 6A).

The Grum Overburden Dump is southeast of the Grum Pit. It covers about 46 hectares and contains overburden and till that was stripped from the surface of the Grum deposit.

6.1.3.6 Water Treatment Plant

The Vangorda WTP, located north of the Grum Pit, was constructed in 1990 as part of the initial development of the Vangorda/Grum Mine Area. Annually, during the open water season, water is pumped from Vangorda Pit to the Vangorda WTP for treatment. The Vangorda WTP is a conventional lime treatment system with discharge to a sludge disposal pond. Compliant effluent is discharged from sludge pond into the GID and from the GID into Vangorda Creek at V25BSP via the SPPs. Prior to 2013, sludge from the Vangorda WTP Sludge Pond was removed from the sludge pond by suction truck or by excavation, when partially frozen, and deposited in an interim sludge disposal facility located on the Grum Overburden Dump. In 2013 the sludge was hydraulically dredged and piped

into Vangorda Pit. Starting in the 2014 treatment season, the sludge will be dredged from the pond and discharged into the southern end of the Grum Pit.

6.1.4 Site-wide Conditions

6.1.4.1 Geochemical Characterization of Waste Materials

The Geochemical Characterization Report, (Appendix 6A), presents the geochemical conditions at the FMC in detail. The report provides cumulative results of historical and recent field characterization programs and describes geochemical processes with the potential to impact water quality at the FMC during the IW. Characterization results not otherwise cited in the following section are sourced from the Geochemical Characterization Report (Appendix 6A). All other source information and data is cited appropriately.

The following section provides a broad summary of the results of analyses, and highlights sources of contaminant-loads requiring management throughout the proposed IW period. It also includes general information about predicted water quality effects on receiving subcatchment zones in the FMC.

There are three main contaminant-load contributors at the FMC:

1. **Waste Rock Dumps (including the backfilled Zone II Pit)**

- The main source of contaminants in the FMC is sulphide-containing waste rock stored in several waste dumps. Oxidation and leaching of the mineralized waste rock results from precipitation, which migrates through relatively coarse waste rock material. The resulting contaminated seepage water either infiltrates through the less permeable underlying native soil to groundwater or flows to the toe of the waste dump, where it can impact surface water directly. The infiltration of precipitation through waste dumps has led to the contamination of certain groundwater aquifers, and is causing increasing contaminant levels in some surface waters. Groundwater contamination is expected to increase significantly in the future. This contamination will impact surface water quality if the waste dumps and seepage are not adequately managed.

2. **Faro Pit, Grum Pit, and Vangorda Pit (including discrete inputs into the pits [i.e. pit walls, surface runoff])**

- A secondary source of contaminant load is confined to the lake waters of the three open pits. Each pit lake has unique geochemical properties. Predicting future water quality conditions in each of the pits is an ongoing process.
- The main controlling factors in the Faro Pit water chemistry is seepage through pit walls, the FCD and Faro Waste Dumps, and water pumped from the S-wells SIS, ETA SIS, the Zone II Pit, and the ID Pond. The Faro Pit also contains tailings received from the Mill. Tailings are not expected to become acid-generating or a significant source of metals, because subaqueous disposal limits contact with oxygen.
- The Vangorda Pit chemistry is driven by seepage and runoff water from within its catchment and water pumped from the Grum Pit, the LCD Pond and the V15 and Grum Creek Pumping System.
- The Grum Pit future chemistry will be mainly controlled by sulphidic pit wall oxidation and the composition of the influent seep chemistry.
- Additional remedial system waters that may be pumped to the pits in the future, would further impact the lakes' water quality (SRK, 2010b).
- Disposal of WTP sludge into Grum Pit will begin in 2014. The sludge will have a higher pH than the pit water. Metal leaching from the sludge is not expected to be significant. Any leaching that may occur would be treated along with the Vangorda and Grum Pit water in the WTP.

3. **Tailings (RCTA)**

- Approximately 55 million tonnes of tailings generated from ore processing at the mill were deposited in the RCTA. The rate of oxidation within the tailings was evaluated testing samples from the RCTA. The results showed an oxidation front moving through the tailings deposits over time (RGC, 2012). As this oxidation front migrates through the largely sulphidic tailings material, acidity and high concentrations of metals will be

released to the pore water. Over time, the pore water will be displaced by precipitation infiltration, driving impacted water into the underlying RCAA.

- Once the tailings-impacted water reaches the RCAA, it reacts with the alluvial aquifer sediments and attenuation occurs. The alluvial material's attenuation results in a delayed, sequential release of contaminants. Sulphate, which is largely unattenuated, is the first contaminant to migrate from the RCTA source area. Zinc, iron, and other metals are retained through changes in pH that cause precipitation, coprecipitation, and adsorption. As the aquifer material's attenuation capacity declines, either by metals occupying adsorption sites or through decreased pH (which can result in metal desorption), metals (e.g., zinc) are transported downstream of the RCTA, arriving later than the sulphate front.
- Recently, elevated sulphate has been observed in groundwater at the downstream end of the RCTA, at the toe of the CVD. However, trace metals such as zinc, lead, and cadmium are being actively attenuated by existing and newly precipitated oxyhydroxides and by organic material, maintaining concentrations well-below levels of concern in the downgradient portion of the RCTA.

Concentrations of sulphate and zinc were used to assess relative levels of contamination at the FMC. Sulphate is a good indicator of acid rock drainage and zinc represents the metal leaching potential of other trace metals released during the drainage. The relative levels of contamination are categorized according to the concentrations listed below for use in illustrating figures and differentiating areas of impact within the text.

- Not impacted or minimally impacted: sulphate less than or equal to (≤) 40 mg/L and zinc ≤ 0.05 mg/L.
- Slightly impacted: sulphate greater than (>) 40 mg/L and ≤400 mg/L, or zinc > 0.05 mg/L and ≤ 0.5 mg/L.
- Moderately impacted: sulphate > 400 mg/L and ≤ 4,000 mg/L, or zinc >0.5 mg/L and ≤5 mg/L. This corresponds to sulphate and zinc concentrations one order of magnitude greater than the "slightly impacted" range.
- Highly impacted: sulphate >4,000 mg/L or zinc >5 mg/L. This corresponds to sulphate and zinc concentrations one order of magnitude greater than the "moderately impacted" range.

Faro Mine Area Constituent Loading

Depending on the subcatchment location of a waste dump, seepage from the waste dumps near the Faro Pit may flow to the Faro Pit, Zone II Pit, NFRC, Faro Creek Canyon, Upper Guardhouse Creek, Lower Guardhouse Creek, RCAA, RCTA or Rose Creek.

Constituent Loading to the Faro Pit

The following sources contribute influent waters that affect water quality in the Faro Pit:

- Seepage from the Faro Valley Waste Dump (Faro Valley North [FVN] and Faro Valley South [FVS])
- The Northeast Faro WRDs (Upper Northeast [NEU], Lower Northeast [NEL], East Sulphide Cell [NELS], and Outer Northeast [NEO])
- Pumping from the Zone II Pit (X26)
- Pumping from the S-wells area
- Pumping from the ID Pond and ETA

Faro Pit lake water quality can be described as buffered acid rock drainage. It has a neutral pH and is highly impacted based on concentrations of zinc. Dissolved sulphate concentrations have been consistent in recent years, and zinc concentrations have been increasing over time (Appendix 6A). As the alkalinity is consumed, the acidity will rise, resulting in an increase in acid-mine drainage products.

Seepage flowing through the Faro Valley Waste Dumps (FVN and FVS) enters the Faro Pit through the north pit wall. Flow through the area of the dumps is high, and the high flux of oxygenated water may be causing relatively acidic conditions in this area, relative to other seepage areas. The seepage water is highly impacted with a low pH

and moderate concentrations of sulphate (545 mg/L) and high concentrations of zinc (47.3 mg/L). The observed general decrease in alkalinity over time and increased sulphate concentrations indicate much of the available NP in this area has been consumed. The data also indicate a net acid generation effect on seepage from the monitoring location on the north pit wall (A30) reporting to the Faro Pit lake.

Seepage from the Northeast WRDs flows either to the Faro Pit or to the NFRC along a pre-mine surface drainage divide. The most highly impacted waters are generally downgradient from the NELS, located towards the centre of the Northeast WRD. Two main flows from the Northeast WRDs report to the Faro Pit lake. The first flow originates west of and topographically lower than the NELS, and is characterized as highly impacted water with high concentrations of iron (10.8 mg/L), zinc (40 mg/L), and sulphate (1,060 mg/L). The second flow is a moderately impacted, higher volume flow that follows a pre-mine drainage just north of the former Zone II Pit. Geochemical characterization of the Northeast WRDs' waste rock materials indicates substantial potential for long-term acid generation.

In general, very little seepage flows from the south and west pit walls into the Faro Pit. The only other main inputs into the Faro Pit are from groundwater pumped from the Zone II Pit and the S-wells SIS area. Groundwater from the Zone II Pit is highly impacted, with high sulphate (3,320 mg/L) and zinc concentrations greater than 20 mg/L. Seepage water collected by the S-wells SIS is highly impacted and the S-Wells area is expected to be a large contributor to increased contaminant loads through time with sulphate and zinc concentrations greater than 5,000 mg/L and 300 mg/L, respectively, in water quality observed in SRK08-SPW3. Alkalinity in SRK08-SPW3 has decreased over time, from 587 mg/L to 401 mg/L, but has remained present to neutralize acidic drainage. The numerous contaminant sources that contribute to the S-Wells area are attributed to the pre-mine topography. The current conceptual site model (CSM) indicates pre-mining drainage patterns are focusing seepage water from the Intermediate and Main Dumps, towards the S-Wells SIS area and ETA, respectively (CH2M HILL, 2012e).

Although surface water quality downgradient of the S-Wells SIS improve, groundwater quality in the S-wells area downgradient of the SIS did not improve as expected with the installation of the SIS, with no notable change in groundwater quality (better or worse). Contaminant concentrations were neither shown to increase, nor to decrease, in groundwater downgradient of the S-wells SIS. Increased concentrations of sulphate and zinc in groundwater monitored by wells southeast of the S-wells SIS indicate the SIS may not be capturing a portion of the waste dump seepage.

The ETA is also a source of contamination to the Faro Pit. A seasonal pumping system located above Faro Creek Canyon captures 80 percent of contaminated surface water seepage and groundwater, and pumps this flow to the Faro Pit. Water quality is monitored at station X23, and is characterized as highly impacted. The most recent (September 2013) concentrations of sulphate (8,750 mg/L) and zinc (1,380 mg/L) were some of the largest concentrations measured at the FMC. Concentrations of iron at X23 were also indicative of highly impacted water, at 613 mg/L. As described above, this contaminant load is unique to the site in that the source of contaminants are both from waste rock surface water seepage and from groundwater contaminated by waste dumps in the ETA.

The ID Pond is part of the active water management program on site and functions as a reservoir for contaminated water held for pumping to the existing Faro WTP for treatment or, in 2013, to the Faro Pit for storage. The ID Pond receives flows not captured by the ETA SIS via Faro Creek Canyon, as well as Lower Guardhouse Creek, a catchment area adjacent to the Intermediate Impoundment.

Constituent Loading to North Fork Rose Creek

Seepage water that flows east from the Northeast WRDs and from the former Zone II Pit area (i.e. water that is not captured by the pumping well) contributes to the NFRC, upstream of the NFRD and is represented by the water quality measured at monitoring stations SRK- FD21, SRK-FD05, SRK-FD06, NE1, NE2, and NE3. Seepage from SRK-FD21 (located within the NEL waste dump) is highly impacted, with concentrations of sulphate and zinc at 3,200 mg/L and 36.7, respectively. Highly impacted seepage water has also been observed emanating from the west side of the Northeast Waste Dump at SRK-FD05. SRK-FD05 and SRK-FD06 represent a widespread perennial seep located near the base of the west face of the Northeast Waste Dump. Observed water quality at SRK-FD05

indicates seasonal fluctuations in concentrations of sulphate (692 mg/L [September 2012] to 904 mg/L [June 2013]) and zinc (5.9 mg/L [September 2012] to 8.3 mg/L [June 2013]), with greater concentrations observed in the spring than in the fall, and an overall trend of increasing concentrations through time (SRK, 2010).

Seepage water in the waste dumps adjacent to the Zone II Pit that is not captured by the Zone II pumping well continues along a flowpath toward the Zone II Outwash and is further influenced by waste dump seepage (RGC, 2012). Wells in this area indicate that highly impacted groundwater is flowing toward the NFRC with sulphate concentrations of approximately 3,000 mg/L and zinc concentrations greater than 100 mg/L.

Downstream from the Zone II Outwash, the NFRC flows southwest at the base of the Intermediate Dump, underneath the Haul Road through the NFRD, and past the S-Wells area. The S-wells area is characterized by highly impacted water that is collected and pumped to the Faro Pit. However, water not captured by the S-wells SIS continues down the flowpath toward NFRC and its confluence with the SFRC.

In the autumn of 2013, a new load source to the NFRC developed in the area of the NFRD, which resulted in zinc concentrations in the NFRC (NF2, X2) and at X14, above concentrations previously measured at these locations. Consistent with the current site AMP, a detailed monitoring program was implemented to delineate the source of this new load. Based on the results of that program, the source of the increased zinc loading to the NFRC is believed to be seepage from the Intermediate Sulphide Cell. The increased loading associated with this source is most likely due to breakthrough of a natural seep, possibly due to depletion of attenuation along the flow path, in a drainage channel beneath the NFRD (YG, 2013). As per the site AMP, a response plan has been developed and is currently being implemented to locate and intercept this source.

Constituent Loading to Faro Creek Canyon

Water quality at Station X23, which is the surface expression of groundwater flow along the pre-mine Faro Creek Canyon, is characterized as highly impacted mine water. Seepage water from X23 flows across the eastern edge of the ETA and into old Faro Creek Canyon, just south of the Haul Road. Drainage from the Mill area also contributes to flow across the ETA. Along these flowpaths, water interacts with the ETA tailings material before discharging into Faro Creek Canyon. The ETA SIS at the head of Faro Creek Canyon, just below the Access Road, is designed to seasonally capture the bulk of X23 and Mill area flows, as well as subsurface flows from the ETA, before the flow reaches Faro Creek Canyon, the ID Pond, and seeps into the RCAA. The intercepted flow is pumped to Faro Pit or directly to the treatment facilities. Flow not captured by the ETA sump (approximately 20 percent of the flow when operating in the summer, and 100 percent of the flow in the winter) flows through Faro Creek Canyon and continues down an unlined earthen ditch along the northern side of the Intermediate Impoundment, flowing out over the western end of the Intermediate Impoundment and into the ID Pond, or seeping into the RCAA.

The most recent (September 2013) concentrations of sulphate (8,750 mg/L) and zinc (1,380 mg/L) were some of the largest concentrations measured at X23. The highly impacted water quality at X23 is not unexpected as the pre-mine Faro Creek Canyon south of Faro Pit includes waste dumps with some of the highest metal and sulfide content in the Faro Mine Area, such as the Low-grade Stockpiles “A” and “C” (LGSPA, LGSPC), the Oxide Fines Stockpile (OXSP), Medium-grade Stockpile (MGSP), Stockpiles Base (SPB), Chrusher Stockpile (CHSP), and the Main Dump (MDE, MESC, MDW).

Constituent Loading between S-Wells and X23

The S-wells area and the X23 seepage area are hot spot seepage areas south of the Main and Intermediate Dumps. While there are no significant surface seepage locations between these two areas, one well (SRK08-P9) provides an indication of the groundwater conditions flowing from the Faro waste dumps towards the RCAA in this area. Samples collected in 2012 suggest this area is moderately impacted with sulphate (1,160 mg/L), but not impacted with zinc (0.01 mg/L).

Constituent Loading to Upper and Lower Guardhouse Creek

Upper Guardhouse Creek flows through mainly unimpacted terrain, yet collects several seeps originating from the Northwest WRDs. These seeps have maintained a slightly impacted status over the past 10 years, with sulphate

DRAFT

concentrations generally less than 50 mg/L and zinc concentrations of about 0.1 mg/L. Increasing concentrations from these seeps indicate the possibility of future water quality impacts to Upper Guardhouse Creek.

Lower Guardhouse Creek collects mine-influenced seepage emanating from waste dumps, draining to the ID Pond. Concentrations of sulphate (3,020 mg/L) and zinc (87.7 mg/L) observed at SRK-FD01 are increasing and reflect highly impacted water.

Contaminant concentrations have been steadily increasing in Lower Guardhouse Creek, with seepage from the south toe of the Northwest Lower waste dump contributing 50 percent of Lower Guardhouse Creek flow. This seepage is highly impacted, with trends of decreasing alkalinity (from 386 mg/L [September 2002] to 151 mg/L [September 2013]) and increasing sulphate (from 3,810 mg/L [September 2002] to 6,300 mg/L [September 2013]) and zinc (from 51 mg/L [September 2002] to 257 mg/L [September 2013]).

Constituent Loading to Rose Creek Tailings Area, Rose Creek Alluvial Aquifer, and Cross Valley Dam

The RCTA generally receives clean groundwater from the south and southeast, and receives impacted waters from the Faro Mine Area to the north (Appendix 6G, Groundwater Baseline Report). Locally, tailings contribute to groundwater contamination in the RCTA. Contaminant loads may be mobilized by precipitation infiltrating through the tailings, or by discharge from the ETA migrating downward into the underlying RCAA (Appendix 6G). The unlined ditch that conveys ETA water not captured in the ETA sump may also be contributing a substantial source of contamination to the northern RCAA underlying the RCTA. This possibility is supported by increasing trends in sulphate (from about 1,000 mg/L [January 2006] to about 3,500 mg/L [June 2012]) and zinc (from about 0.1 mg/L [January 2006] to about 11 mg/L [June 2012]), observed in the RCAA underlying the Secondary Impoundment downgradient of the Faro Creek Canyon. The greatest concentrations of sulphate and metals of interest were observed in tailings porewater in the southeastern and northwestern sections of the Secondary Impoundment. Conversely, the lowest concentrations of contaminants occur in groundwater in the southwestern section of the Secondary Impoundment (Appendix 6G, Figure 6G-28) (RGC, 2012). In the RCAA area, downgradient from the Faro Creek Canyon and towards the ID Pond, observations over the past 10 to 12 years have noted a gradual increase in sulphate, followed by a lagging increase in zinc (RGC, 2012).

The southern portion of the RCAA is generally less impacted than the northern portion because of “clean” water leaking from the RCD. The exception is the southeastern corner of the RCTA, where oxidation appears to be more rapid in the Secondary Impoundment and seepage from the tailings appears to be impacting the RCAA. Significant increases in sulphate and zinc concentrations were observed in wells in the Secondary Impoundment: P03-03 (sulphate from about 1,000 mg/L to about 5,000 mg/L and zinc stable at about 0.01 mg/L in P03-03-06) and P03-05 (sulphate from about 400 mg/L to about 800 mg/L and zinc from about 0.01 mg/L to about 10 mg/L in P03-05-02) (RGC, 2012). Site operations personnel have observed iron stains in the ice covering the RCD during the low-flow winter months when groundwater input contributes the most flow. This suggests metal-rich groundwater from the RCTA is reaching the RCD during this time.

In addition to the impacts to the RCAA, groundwater in the underlying weathered bedrock downgradient of the CVD shows signs of impact by magnesium and sulphate, especially on the northern side of the valley (RCG, 2012). Metal plumes (i.e., zinc and iron) currently remain upgradient of the CVD (RGC, 2012). Zinc, lead, and cadmium concentrations in alluvial groundwater, downgradient of the Secondary Impoundment and beneath the ID and CVD, however, are being actively attenuated by adsorption to iron oxyhydroxides and carbonates and also to adsorption to organic matter near the CVD (CH2M HILL, 2013c).

Vangorda/Grum Area Constituent Loading

Depending on the subcatchment location of a particular waste dump in the Vangorda/Grum Area, seepage from waste dumps may flow to the Grum Pit, the Vangorda Pit, or Vangorda Creek.

Constituent Loading to Grum and Vangorda Pits

The Grum Pit receives water from surface runoff within the Grum Pit catchment, as well as groundwater inflow from the surrounding thalweg aquifer. Seepage water quality is characterized by alkaline pH, and is slightly impacted with sulphate concentrations and zinc. The Grum Pit lake’s water quality is characterized by alkaline pH

(7.84) and moderately impacted mine water, based on sulphate and zinc concentrations (435 mg/L and 3.14 mg/L, respectively) from June 2013.

The Vangorda Pit lake is largely the product of surface runoff within the pit catchment area and groundwater flow. The Vangorda Pit also receives constituent loading from pumped water from the Grum Pit, as well as water collected by the V15 and Grum Creek Pumping System, and LCP. The current water quality is characterized by a slightly acidic pH (6.24) and highly impacted mine water, based on concentrations of sulphate and zinc (857 mg/L and 52.5 mg/L, respectively) measured in June 2013. Concentrations of sulphate and zinc in the Vangorda Pit lake have been increasing steadily during the period of record (CH2M HILL, 2013b). Seasonal fluctuations were observed in the water quality of the Vangorda Pit lake, with decreased sulphate and zinc concentrations during freshet and increased concentrations during low-flow conditions (DES, 2012; CH2M HILL, 2013a).

Grum Waste Dump

The easternmost flank of the Grum Waste Dump was built over the former Grum Creek channel, whose drainage water flows toward two contiguous perennial seep locations (SRK-GD01 and SRK-GD02). These two seeps indicate moderately impacted water quality, based on sulphate (1,578 mg/L) and zinc (2.3 mg/L) concentrations.

Water quality at V15 showed moderately impacted water, based on zinc concentrations (4.1 mg/L) measured before the low-permeability cover was installed on the GSC; concentrations have somewhat stabilized (to observed 2010 concentrations) since the cover has been placed (DES, 2012).

Seepage water quality at the southern toe of the Grum waste dump, differs from other seepage water at the FMC because of its abundant algal growth and hard-white, crusty deposits. This seepage is characterized by neutral to alkaline pH and is moderately impacted with sulphate (2,330 mg/L) and zinc (2.95 mg/L).

Westward-flowing seepage from the western toe of the southwest Grum Waste Dump ultimately flows to West Fork Vangorda Creek drainage. This seepage indicates neutral to alkaline pH and moderately impacted drainage, based on concentrations of sulphate (1,140 mg/L) and zinc (0.23 mg/L).

Seepage from the Ore Transfer Pad, which is northwest of the Grum Pit, ultimately flows into the West Fork Vangorda Creek drainage via AEX Creek. Seepage water quality is characterized by neutral pH and minimally to moderately impacted drainage, based on concentrations of sulphate (522 mg/L) and zinc (0.45 mg/L) (Appendix 6A).

Vangorda Waste Dump

The Vangorda Waste Dump is composed of sulphide-rich waste rock. Four monitoring wells monitor seepage beneath the Vangorda Waste Dump drainage ditch (Appendix 6G). Water quality at these locations is characterized by high pH with slightly-to-moderately elevated dissolved sulphate and zinc concentrations (Appendix 6A). Observed increases in sulphate concentrations in all four wells suggest that some groundwater from the Vangorda Waste Dump is bypassing the seepage collection system (Appendix 6A and Appendix 6G).

Several transverse drains extend beneath the till berm surrounding the waste dump; these direct the seepage toward the perimeter collection ditch and LCD Pond. Water quality in the LCD Pond is highly impacted, based on sulphate and zinc concentrations. Water quality in the five transverse drains is also highly impacted, with low pH and elevated concentrations of sulphate and zinc. Values of pH in the transverse drains range from 2.71 to 5.84. Concentrations of sulphate and zinc range from 1,740 mg/L to 87,400 mg/L, and 0.73 mg/L to 87.3 mg/L respectively. These concentrations identify the till berm area around the waste dump as one of the most mine-affected areas of the FMC. Monitoring of the Vangorda transverse drains will continue to support future water collection and treatment options.

Currently, Vangorda Creek and its tributaries are monitored at nine monitoring stations. Water quality is characterized by pH ranging from neutral to alkaline, with minimal impacts to water quality. These characteristics suggest Vangorda Creek has experienced minimal impacts from mining activities to date. However, increasing concentrations of mine-related contamination and evidence of affected waters bypassing the seepage collection system indicate future impacts are possible (Appendix 6G and CH2M HILL, 2013e).

DRAFT

6.1.4.2 Physical Stability of Dams

The major civil structures at the FMC are part of an ongoing program monitoring and evaluating physical stability. The results of these evaluations have recently been compiled in Appendix 6C, which describes the current conditions of the major civil structures at the FMC, and provides recommendations to for interim measures to reduce associated potential risks to human health and safety, and the environment during the IW period. The following sections provides a summary of this compilation. Due to the potential for detrimental consequences from the release of contaminated water and tailings to the receiving environment associated with dam failure, this section focuses on the stability assessment of the dams and hydraulic conveyance structures. Appendix 6C describes the physical stability of additional FMC major physical structures.

The following subsections summarize the main findings of this evaluation, focussing on the recommended design criteria for dams for the IW. Also summarized is a stability evaluation of major conveyance structures and dams under various hydraulic and seismic loading conditions.

Hazard Classification of Dams

Each dam at the FMC poses a different level of hazard; the RCTA dams are considered the most hazardous. Based on the potential incremental losses associated with environmental and cultural values, each of the dams at the FMC were assigned a hazard rating according to the CDA Dam Safety Guidelines (CDA, 2007). For reference, the CDA dam classification is provided in Table 6C-1 of Appendix 6C.

Intermediate Dam

The most severe consequences of a dam breach are associated with the ID, which contains more than 11.9 Mm^3 of tailings and water that are toxic to aquatic and terrestrial life. The total tailings volume in all three impoundments (Original, Secondary, and Intermediate) is 28.6 Mm^3 (RGC, 1996). Failure of the ID could result in a significant or major loss, or deterioration of critical fish or wildlife habitat downstream of the FMC within Rose Creek, Anvil Creek, and possibly extending to the Pelly River.

Currently it is estimated that the ID has a High risk classification, although this estimate was made in the absence of a formal dam breach and inundation study. A dam breach and inundation study for the ID and the CVD will be carried out in conjunction with the 2014 dam safety evaluation. These studies will assess downstream consequences of dam failure and may result in a modification of the hazard classifications for these facilities. Considering the CDA dam safety guidelines and noting that a large spill would likely make restoration or compensation impractical or impossible, it is likely that the hazard classification may change once these updated studies have been completed.

Cross Valley Dam

The CVD has the same hazard classification as the ID: High risk classification. The main hazards from a CVD breach include the uncontrolled release of water from the CVD Pond, as well as a sudden release of the polishing pond, which could cause significant danger to the ID. The ID does not have filter and drainage systems in the lower part of the embankment, below the downstream bench. It depends on the polishing pond to provide a counter balancing hydrostatic head to reduce seepage and the need for filtering. A sudden drawdown of the pond is likely to result in significant seepage from the saturated ID downstream slope. This could lead to progressive sloughing, even more seepage, possibly backward erosion, and could eventually result in piping or loss of the crest from larger slope stability failures.

Secondary Dam

A breach of the Secondary Dam could also lead to a loss of tailings into the environment, but the magnitude of such a tailings loss would be much smaller and more contained than the tailings loss associated with an ID breach. Whereas the ID and CVD need to accommodate hydraulic (flood) loading, as well as seismic loading, the Secondary Dam only needs to be designed for seismic loading. Seismic loading could cause liquefaction of the dam foundation, specifically where Rose Creek sediments occur. At the West Limb, which is the curved portion of the Secondary Dam that crosses the valley roughly north to south, there are intermediate tailings on the downstream toe of the Secondary Dam. These intermediate tailings would prevent the dam from failing during seismic loading,

even if the foundation soils liquefy. Even if some tailings are lost along this portion, the Intermediate Impoundment is likely to contain the tailings.

A breach of the East Limb of the Secondary Dam, which is parallel to the RCD and does not contain tailings at the toe, could result in tailings flowing into the RCD. Note, the upper layers of the secondary tailings are not saturated and the East Limb's crest is relatively low, at about 4.6 m. Given that a breach of the East Limb of the Secondary Dam could result in tailings loss into the RCD and from there into the areas downstream of the tailings areas, it can be conservatively assumed that the Secondary Dam has the same risk classification as the ID, which is High.

Little Creek Dam

The LCD is typically not operated at full supply level. Because it contains a small volume of potential water release, it is assigned a Low risk classification, based on the fact that (1) there would be relatively small economic loss, (2) there is limited infrastructure or services downstream, and (3) there would be loss of marginal habitat only or restoration or compensation in kind would be possible.

Stability Evaluation of Dams

The dam stability evaluation includes two components: (1) the adequacy of the associated conveyance structures (such as spillways and diversions) to pass the inflow design flood (IDF) and (2) the structural stability of the dams under normal, flood loading, and earthquake loading conditions.

Structural Stability of Dams under Hydraulic Loading Conditions

The general approach to assess whether the existing dams could withstand the design hydraulic loads for each conveyance structure during the IW included the following steps:

1. Assemble the 1-in-500-year IDF estimates for each conveyance structure based on routing scenarios and area-based hydrologic estimates.
2. Compare the existing capacity of the specific conveyance structure with the IDF. The existing capacity is determined by hydraulic modelling and the development of rating curves for the structures.
3. Identify required modifications to address insufficient conveyance capacity.

The following sections describe the capacity of conveyance structures and indicate proposals for interim modifications.

<u>North Fork Rock Drain</u>

Based on review of the design and construction records, uncertainty exists pertaining to the flow-through capacity of the rock drain and its hydraulic capacity during extreme storm events. Flood routing of a 500-year storm event indicates that, assuming low flow-through capacity and some debris accumulation, a significant flood pool may form against the Haul Road embankment and NFRD, possibly destabilizing the haul road (Appendix 5I). In such a case, the performance of the rock drain and the embankment, and their stability under these conditions, is uncertain. Concerns exist with respect to piping of materials, internal erosion, and destabilizing resulting in erosion of the downstream face of the embankment.

<u>Rose Creek Diversion</u>

Hydraulic modelling results predict the existing configuration of the RCD does not provide adequate capacity to convey the 1-in-50-year flood flow of 71 m^3/sec before overtopping the overflow structure. Design criteria dictate that the RCD maintain 0.5 m freeboard at the 500-year flow. As such, the crest of the RCD dike must be raised to meet freeboard criteria. In addition to raising the crest of the RCD dike, vegetation needs to be removed from the dike and rip rap, and slope sloughing needs to be repaired at some locations. These activities are proposed as the DVIHU component of the IW.

<u>Overflow Weir in Rose Creek Diversion Dike</u>

To prevent flows in excess of the 500-year event from damaging the RCD downstream of the overflow weir, the elevation of the overflow weir must be raised to 1,057.82 masl, which corresponds with the predicted water

surface elevation to convey the 500-year flow (elevation 1,058.0 m) plus a 200-mm thick layer of native sand and gravel covering the crest to provide a road surface (i.e. the structure will have a freeboard of 0.2 m).

Intermediate Dam Spillway

The existing ID spillway does not have the capacity to safely pass a moderate or major flood event without overtopping and potentially failing the dam and releasing tailings to the downstream environment.

Planned improvements of the ID spillway capacity are part of the DVIHU.

The ID is a secondary flood-routing facility; therefore, there is a considerable chance that it will not experience flow during the IW. As a result, the Interim Hydraulic Upgrades design for the ID does not focus on permanent capacity. Permanent capacity will be designed into the FMRP.

Cross Valley Dam Spillway

According to NHC (2006b), the CVD spillway has a capacity of 300 m^3/sec, which is sufficient to convey the IDF.

Structural Stability of the Dams Under Seismic Loading Conditions

Numerous studies have been undertaken by different firms over the last 10 years to assess the stability of the dams. These included seismic stability assessments by Golder (2004) and Klohn Crippen Consultants (later Klohn Crippen Berger) for the tailings dams and the CVD; other studies (NHC, 2006b, etc.) were performed to assess the flood vulnerability of the ID and CVD. The results of these studies formed the basis for evaluating the embankment slope stability under static and seismic loading conditions, for the interim period.

Intermediate Dam

Extensive seismic stability assessments were performed to determine the liquefaction potential in the ID foundations and to evaluate seismic slope stability (KCB, 2006a; KCB, 2006b). Results showed that the terrace or glaciofluvial deposits that form most of the uppermost foundation soils of the ID (Appendix 6C, Figure 6C-23), the northern foundation of the West Limb of the Secondary Dam, and most of the foundation of the East Limb of the Secondary Dam, are not liquefiable.

However, it was found that the recently deposited Rose Creek sediments were generally liquefiable under MCE loading (for example, beneath the West Limb of the Secondary Dam and the southeast corner of the East Limb). The only exception was beneath the maximum section of the ID, where the recent Rose Creek alluvial sediments were found to be not liquefiable.

Since the design earthquake for the interim period has a recurrence interval of 1-in-500 years, with ground motions much smaller than the MCE motions (1-in-10,000-year motions), the ID should be stable for this level of shaking, and permanent seismic displacements should be small.

Cross Valley Dam

KCB (2007) performed seismic stability analyses of the dam for the 1-in-500-year earthquake. Ground motions from the Atkinson (2004) study were used for those analyses. The results of the analyses showed that the foundation soils do not liquefy under the 1-in-500-year motions, and that the dam would be able to withstand the 1-in-500-year earthquake. KCB (2007) noted that there will still be seismic deformations of the dam during an earthquake event of this magnitude. Such movements will be permanent but should be small and will not lead to the release of the reservoir, provided the freeboard is more than 1.5 m.

The analyses performed in 2007 (KCB, 2007) used the ground motions from the Atkinson (2004) study, which are significantly higher than the ground motions of the recent updates to the seismic hazard assessment (Atkinson and Assatourians, 2013). It is therefore concluded that the CVD is stable under the design seismic loading for the interim period.

Secondary Dam

Analysis results showed no liquefaction in the foundation soils (including the recent Rose Creek sediments) for a 500-year seismic event. Results also showed that the dam will be stable with factors of safety of 1.5 or greater

under all considered load cases, including static, pseudo-static and post-seismic loading. It is anticipated that small deformations will occur and such deformations would be tolerable; the dam will not breach and no tailings would be released.

Little Creek Dam

Based on the observations from periodic dam safety reviews and the annual dam safety inspections, the LCD appears to be stable.

In summary, most of the major existing facilities meet the design criteria for physical and hydraulic stability during the IW. However, some of the existing flood conveyance structures are undersized and inadequate to convey the IDF for the interim period (500-year return period flood event). The current flood routing capacities for the ID spillway and the RCD should be improved so that they can safely convey the inflow design floods. Planned improvements for the ID spillway capacity and RCD are part of the DVIHU.

6.2 Environmental Conditions

This section describes the environmental conditions of the FMC and assessment study areas, including the physiography, geology and soils, atmospheric environment, water resources, aquatic ecosystems, terrestrial resources and heritage resources. Details are documented in the following appendices:

- Appendix 6D Climate Baseline Report
- Appendix 6E Air Quality Baseline Report
- Appendix 6F Hydrology Baseline Report
- Appendix 6G Groundwater Baseline Report
- Appendix 6H Aquatic Baseline Characterization Report
- Appendix 6I Vegetation and Soil Baseline Report
- Appendix 6J Wildlife and Wildlife Habitat Baseline Report
- Appendix 6K Heritage Resource Impact Assessment

6.2.1 General Physiography

The FMC is located in the Yukon Plateau-North Ecoregion in the Boreal Cordillera Ecozone. The Yukon Plateau-North Ecoregion is the largest ecoregion located entirely in the Yukon Territory (YT) and it encompasses the Stewart Plateau, the Macmillan Highlands, and the Ross Lowlands (Smith et al., 2004). This ecoregion was once entirely glaciated by the Cordilleran Ice Sheet, as well as local glaciers from the South Ogilvie Mountains and cirque glaciers from other peaks in the ecoregion. This intense glaciation has resulted in rolling highlands, till-covered plateaus, thermokarst lakes, and discontinuous permafrost.

The FMC is located on the Vangorda Plateau, a northwest-to-southeast-oriented rolling upland located between 1,000 and 1,400 masl, and is surrounded by the Anvil Range to the north and east, and Rose Mountains to the south. The Anvil Range rises to a series of peaks over 2,000 masl, including Mount Mye (east of the Vangorda/Grum area) and Mount Aho (north of the Faro Mine area). Faro Peak and Sheep Mountain are two key features occurring to the south of the FMC. Generally, the FMC area is typical of a mountainous region that has been influenced by multiple past glaciations, consisting of broad U-shaped valleys, rounded hills, rough mountain peaks, as well as deposits of glacial till and glaciofluvial materials.

The Vangorda Plateau parallels the Tintina Trench, which is a regionally dominant feature of the Tintina Fault that lies just south of the FMC. This ancient fault contains deposits from at least seven Pleistocene glaciations and numerous wetlands and sloughs (Smith et al., 2004). The Tintina Trench, in the vicinity of the FMC, lies at approximately 600 masl.

Two local watersheds encompass the FMC: Rose Creek and Vangorda Creek, both of which form part of the Pelly River drainage. The Pelly River is regionally dominant and flows northwesterly within the Tintina Trench. The Pelly River is a major tributary to the Yukon River and drains more than 49,000 km^2 of land.

The Rose Creek watershed encompasses the Faro Mine Area portion of the FMC and drains west to the Pelly River via Anvil Creek. Rose Creek is fed by two tributary forks that join within the FMC: the NFRC and the SFRC. The NFRC drains south from the Anvil Range and is partially fed by Faro Creek and other small tributaries. The SFRC originates further east and drains northwest along the Vangorda Plateau, joining the NFRC just east of the RCTA. From 1969 to 2003, the Freshwater Supply Dam held back the flow of the SFRC, retaining water for mine operations. That dam was removed in 2003, and the SFRC again flows in its original channel. Downstream from the confluence of the NFRC and SFRC, the main stem of Rose Creek was diverted around the tailings impoundment in 1974. The subsequent expansion of tailings facilities in 1982 required a further extension of the Rose Creek Diversion. Rose Creek still flows via the Rose Creek Diversion to beyond the RCTA, where it rejoins its original channel just northwest of the CVD. Rose Creek flows into Anvil Creek approximately 13 km northwest of the FMC; Anvil Creek then flows into the Pelly River, approximately 33 kilometres west of the Faro Mine Area.

The Vangorda Creek watershed encompasses the Vangorda/Grum Area of the FMC, with a total drainage area of approximately 90 km^2. Vangorda Creek is fed by Grum Creek and several smaller tributaries within the FMC, and drains to the Pelly River to the southwest, near the Town of Faro.

The Pelly River, Anvil Creek, Rose Creek, and the lower reaches of Vangorda Creek all provide fish habitat. Species recorded in these watercourses include Arctic grayling (*Thymallus arcticus*), slimy sculpin (*Cottus cognatus*) and Chinook salmon (*Oncorhynchus tshawytscha*). Anvil Creek, Rose Creek and lower Vangorda Creek provide habitat for juvenile Chinook salmon, as well as some occurrences of spawning adults. The NFRC and SFRC provide a variety of spawning, rearing, and overwintering habitat for slimy sculpin and Arctic grayling.

Vegetation in the FMC area is typical of the boreal and subalpine zones of the encompassing ecoregion. Vegetation in the boreal zone largely consists of forest and wetland associations, most of which are linked to morainal and glacio-fluvial terrain and are influenced by fire. The dominant forest type in moist and cool aspects is typically black spruce (*Picea mariana*) with moss dominating in moist understories, which is often associated with permafrost soils, and lichens dominating in drier areas. Drier slopes and warmer aspects frequently are dominated by white spruce (*Picea glauca*) with occasional stands of trembling aspen (*Populus tremuloides*), and less frequently lodgepole pine (*Pinus contorta*). Vegetation in the subalpine zone is largely dominated by tall shrub vegetation, with some scattered open spruce and fir forests. Dwarf birch (*Betula nana*) and scattered white spruce and subalpine fir (*Abies lasiocarpa*) dominate the overstory, with lichens occurring in drier sites and mosses and graminoids in wetter areas. In the wetlands, bogs, and lakes, various willows, sedges, and aquatic plants are typical with riparian areas being comprised of black spruce.

The FMC supports many of the typical boreal forest wildlife species, including a wide variety of resident and migratory birds, moose (*Alces alces*), woodland caribou (*Rangifer tarandus caribou*), grizzly bear (*Ursus arctos*), and Fannin sheep (*Ovis fannini*). The Tintina Trench is an important migratory corridor for large numbers of sandhill cranes (*Grus canadensis*) and waterfowl that breed on the North Slope of the YT and the northern tundra. Many of the wetlands, lakes, and ponds in and around the FMC are valuable breeding and staging areas for a variety of waterfowl, including American wigeons (*Anas americana*), surf scoters (*Melanitta perspicillata*), and horned grebes (*Podiceps auritus*), as well as several species of mergansers.

6.2.2 Geology and Soils

Introduction and Study Areas

The following sub-sections describe bedrock geology, surficial geology, terrain and soils of the FMC. These descriptions are based on information obtained from previous CH2M HILL studies, geological and geochemical data gathered during the CH2M HILL field programs of 2012 and 2013, published technical papers, and documents prepared by others, including SRK and RGC. Further information is also available in Appendix 6G, Groundwater Baseline Report, which provides a description of the geologic setting, and in Appendix 6I, Vegetation and Soils Baseline Report, which provides details on the soil conditions at the FMC.

The local study area (LSA) is illustrated on Figure 6I-1 (Appendix 6I) and is defined as the area encompassing all FMC facilities, infrastructure, and road corridors, with the addition of a 1- km buffer. The resulting LSA area is 8,122 hectares.

A regional study area (RSA) was established within which to describe more broad geographic features of surficial geology, bedrock geology, and terrain features. The RSA is shown on Figure 6I-2 (Appendix 6I) and includes geological units of the YT interior that are separated by the northwest trending, right-lateral Tintina Fault Zone, with distinct geological properties: a relatively homogeneous region to the northeast composed of a thick, older sequence of sedimentary rocks (miogeocline), and a more heterogeneous region to the southwest comprising several younger, litho-tectonic terranes of varying rock types that amalgamated and accreted to the stable sedimentary package. In addition, the northern component of the RSA includes portions of the Anvil plutonic suite, which forms the core of the Anvil Arch, a structural high within the RSA.

6.2.2.1 Bedrock Geology

Regional Bedrock Geology

The FMC is located within the Anvil District, between the Rose Mountains and the Anvil Range. The Anvil District contains the westerly exposures of the Selwyn Basin, a large area of central Yukon in which deep-water clastic rocks, chert, and minor carbonate accumulated along the ancient North American continental margin (convergent plate boundary between the oceanic Pacific Plate and the continental North American Plate) during the Neoproterozoic and early Paleozoic eras (miogeocline) (Lowe et al., 1994; Wheeler et al., 1991). Locally, the Anvil District consists of a structurally thickened sequence of late-Precambrian to upper Paleozoic poly-formed, poly-metamorphosed, meta-sedimentary, and meta-volcanic schists and phyllites (Jennings and Jilson, 1986) of the miogeoclinal assemblage.

The northwest trending, right-lateral Tintina Fault Zone separates the older relatively homogeneous miogeoclinal geology of the Selwyn Basin from several younger, litho-tectonic terranes of varying rock types (locally the Slide Mountain and Yukon-Tanana Terranes). These younger, heterogonous, litho-tectonic terranes likely once formed a Paleozoic-to-early-Mesozoic fringe to North America before accretion to the stable continent (Colpron et al., 2007). Regionally, the Tintina Fault Zone is mapped for over 1,000 km, trending northwest from Watson Lake at the Yukon/British Columbia border to its termination into a series of splay faults in the Yukon Flats area of Alaska (Snyder et al., 2005).

During the Cretaceous Era, the southwestern portion of the miogeoclinal Selwyn Basin meta-sediments of the region were intruded by two large intrusive suites: the Anvil and Tay plutonic suites. The Anvil plutonic suite (104 to 109 million years ago [Ma]) are the oldest recognized granitic intrusive rocks in the Anvil District and consist of biotite±muscovite granite of sedimentary protolith-derived geochemical affinity. The Anvil plutonic suite forms the Anvil Batholith that cores the northwest-trending Anvil Arch (Pigage, 2004). The Anvil plutonic suite is cross-cut by the Tay River plutonic suite (97 Ma), consisting of intrusives of biotite-hornblende granodiorite to granite composition (Pigage, 2004). The igneous protolith-derived Tay Suite forms the large Orchay Batholith at the southeast margin of the District and numerous dikes and sills throughout the District. The plutonic suite's geochemical signature and age indicate it is the subvolcanic equivalent of the South Fork volcanics that outcrop immediately to the northeast.

There are 108 mineral occurrences listed in Yukon Minfile (a database of mineral occurrences in the Yukon) for the 1:250,000 NTS Mapsheet Index 105K (Tay River) map area (as listed by the YGS Online Map Viewer on November 15, 2013), which encompasses the FMC. The majority of the occurrences are strataform lead-zinc showings and deposits that occur in Selwyn Basin sedimentary rocks. Most of these occurrences are found within a broad belt, parallel and adjacent to the Tintina Fault Zone. The dominant deposits are the significant zinc-lead-silver-barite pyritic sulphide sedimentary-exhalative-type deposits of the Anvil Range (Jennings and Jilson, 1986; Pigage, 1990), of which the FMC deposits are a component.

Local Bedrock Geology

Locally, the Mount Mye and Vangorda formations represent the lower part of the late Proterozoic and early Paleozoic sequence and are the most important with respect to the FMC site geology as the mineral deposits of the FMC occur on or near the geological contact between these formations. The Cambrian-aged Mount Mye formation is the oldest unit exposed in Anvil District (Jennings and Jilson, 1986). It is extensively exposed on the lower slopes of both the north and south sides of Mount Mye. Cross sections on the north side of Mount Mye

indicate a minimum present-day thickness of approximately 2,000 m (Pigage, 2004). Typical Mount Mye formation is a medium to dark grey, noncalcareous, moderately soft to soft, fine-grained, micaceous phyllite; close in composition to an average shale. Interbands of marble, calc-silicate rock, and chloritic phyllite or hornblende amphibolite occur in lesser amounts.

The Cambrian- and Ordovician-aged Vangorda formation is a widespread unit in the Anvil District that overlies the Mount Mye Formation. It is characterized as a pale silvery grey, calcareous, recessive phyllite (Jennings and Jilson, 1986). Lesser interbedded rock types include limestone/marble, carbonaceous phyllite/schist, dolomitic siltstone, and chloritic phyllite/amphibolite. At higher metamorphic grade, the Vangorda formation consists of thinly banded, resistant, pale cream and dark brown calc-silicate rock. The unit is exposed both north and south of intrusions that make up the Anvil Batholith. Thickness estimates for the Vangorda formation from cross sections range from 700 to 2,200 m. Jennings and Jilson (1986) suggested an average thickness of 1,000 m.

The Ordovician-aged Menzie Creek formation is present as a thick, resistant, grey-weathering, basaltic volcanic unit that conformably overlies the Vangorda formation (Jennings and Jilson, 1986). Massive and pillowed, locally amygdaloidal flows are interbedded with volcaniclastic rocks, which consist dominantly of monolithic basalt breccia with lesser conglomerate, sandstone, and siltstone. South of the Anvil Batholith, the Menzie Creek formation consists of a medium green, pervasively foliated, noncalcareous to slightly calcareous chloritic phyllite (Pigage, 2004). The phyllite commonly contains pale tan to white calcite amygdules.

Overlying the Menzie Creek formation is the Duo Lake Formation. It is present onsite as a black, carbonaceous, silty argillite with lesser siltstone, sandstone, and limestone. It is documented as generally poorly exposed, but with significant continuity along strike (Pigage, 2004).

A higher degree of metamorphism is generally observed in the local miogeoclinal lithology with proximity to the Anvil Batholith contact. The strata of the metamorphic sequence dip northeast and southwest, away from the Anvil Batholith. The degree of metamorphism within sedimentary and volcanic strata range from moderate (schist) to low (phyllite).

Locally, the zinc-lead-silver deposits of the FMC occur as stratiform horizons within a 150-m stratigraphic interval that straddles the geological contact between the Vangorda and Mount Mye formations. The Faro deposit is in the phyllite and schists of the Mount Mye formation. Numerous local structural faults intersect this ore body.

The Grum and Vangorda Mine deposits are predominantly hosted in the Vangorda Formation, which consists predominantly of calcareous phyllite and calc-silicate rocks banded with meta-igneous greenstone and chloritic phyllite, carbonaceous phyllite, and minor limestone (AECOM, 2009). The Grum deposit intersects the Mount Mye Formation at its base.

6.2.2.2 Surficial Geology and Soils

Regional Surficial Geology

The FMC is located within the Yukon Plateau physiographic subdivision, bound by the Pelly Mountains and Tintina Fault to the southwest, and the Tay River to the north. The local physiography is dominated by the northwest trending Tintina Fault Zone, which coincides with a linear valley known as the Tintina Trench. The surficial geology of the area is controlled by three physiographic features: the Anvil Arch, the intermediate upland surface of the interconnected valleys known as the Vangorda Plateau, and the Tintina Trench (Bond, 2001).

As many as six glaciations during the Pleistocene are recorded in the stratigraphy of Tintina Trench near Dawson City (Bond, 2004). The last glaciation to affect central Yukon is the late Wisconsinan McConnell Glaciation, which began sometime after approximately 25 to 15 thousand years ago (Bond, 2001). The Anvil District is overlain by sediments originating from this glacial period.

Ice flow through the district was controlled by topography, except in areas of low relief. Glacial ice advanced into the Tintina Trench and followed the topographic lineament northwest into central Yukon. Ice flow was largely from east to west, becoming more northwesterly upon intersecting the Vangorda Plateau. With the exception of a few unglaciated summits (nunataks), the entire area was covered by the Selwyn Lobe of the Cordilleran ice sheet (Jackson, 1986). The relatively rapid ice flow through areas adjacent to the Tintina Trench resulted in extensive

glacial erosion and later deposition upon deglaciation. Till deposits on the Vangorda Plateau and in the Swim Basin to the southeast range in thickness from less than 1 m to 200 m.

Much of the Vangorda Plateau is underlain by a thin veneer (less than 1 m thick) of colluvium and soil over bedrock; however, portions of the plateau are underlain by discontinuous deposits of glacial till and glacio-fluvial deposits. Important exceptions are a buried valley filled with up to 100 m of overburden over the subcrop of the Grum deposit and a ridge of highly compacted till up to 40 m thick overlying the Vangorda deposit (RGC, 1996). Thick till and fluvial deposits also occur in the Rose Creek, the west fork of Vangorda Creek, and in the Blind Creek valleys.

Upland areas are generally covered by colluvium with exposed rock and felsenmeer (where the top layer of rock outcrop that has been broken up by freeze-thaw action) above approximately 1,770 m above sea level (masl). These areas include Mount Aho, Mount Mye, and Rose Mountain. Rock outcrop and felsenmeers also exist at lower elevations on these mountains on north- and west-facing slopes, where nivation processes are common. In the alpine valleys of Mount Mye, till sediments are derived from local ice sources and the Cordilleran ice sheet.

Local Surficial Geology

Typical native soils at the FMC consist of thin discontinuous deposits of glacial till and glacio-fluvial deposits overlying phyllitic bedrock. Local surficial geology is described below, according to FMC area.

Faro Mine Area

The Faro Mine Area includes the Faro Pit, NFRC, Zone II Pit, S-Wells, the ETA and extensive waste dumps. Before the Faro Pit was developed, the area comprised a veneer of glacial till and glacio-fluvial deposits, intermixed with slope-derived colluviums. The Faro Creek Valley and the former Faro Creek Channel contain thicker colluviums and fluvial deposits. The NFRC (including Zone II Outwash and S-Wells) consists of alluvial/outwash materials over bedrock, ranging in thickness from 5 m to 20 m. In the S-Wells area, till and weathered bedrock underlay the sand and gravel. The Zone II Pit has been backfilled with waste rock produced during mining operations. The ETA overlies the former Faro Creek Channel, which is presently composed of tailings ranging between 6 m and 20 m deep.

Rose Creek Tailings Area

The RCTA includes the Original and Secondary Impoundments and the Intermediate Impoundment, as well as the RCD and the CVD and CVD Pond. Within the RCTA, there is approximately 55 million tonnes of tailings, generally comprised of coarse-grained fractions at the zones of deposition on the northern/central edges of the original and second impoundments, and finer-grained fraction near the impoundment dam faces. Tailings deposits range from 250 m wide to 800 m wide and up to a maximum thickness of 25 m.

Beneath the tailings and along the periphery of the Rose Creek Valley, sands and gravels of fluvial and glacio-fluvial origin are interspersed with till deposits. Within these sands and gravels there are areas of inter-layered fine-grained silts and clays, typical of backwater or glaciolacustrine deposits. The fluvial and glacio-fluvial deposits vary throughout the Rose Creek Valley, and reach depths of 50 m in the centre of the valley. The glacial till extends to a depth of 25 m at the edges of the valley. Surficial deposits in the valley are largely fluvial deposits from Rose Creek and its tributaries. The alluvial unit is composed of a heterogeneous mix of silt, sands, gravels, and cobbles. The alluvial deposits are thickest in the centre of the valley.

Vangorda/Grum Area

Up to 100 m of till overburden overlaid the Grum deposit; the overburden thinned out to less than 40 m in the northeastern and southeastern portions of the pit (RGC, 1996). Similar to the Faro Pit, the area around the Grum Pit had a glacial till unit overlying bedrock. Investigations to the south and west of Grum Pit reported by SRK (2010b) typically identified calcareous phyllite of the Vangorda Formation underlying silty to sandy glacial till in both areas. East of the Grum Waste Dumps, Grum Creek and several tributaries drain towards Vangorda Creek. Generally, alluvium material is found over till material with varying amounts of sand, gravel, and clay. Weathered bedrock, transitioning to competent bedrock, provides the foundation.

DRAFT

Similar to Grum Pit Area, three primary units appear to be identifiable in the Vangorda Pit Area. However, at the latter there is an overlying overburden unit composed of silty, sandy glacial till (about 30 m thick) that sits atop a sand and gravel unit overlying weathered bedrock that transitions into competent calcareous phyllite. Several fault zones have been identified in the bedrock (RGC, 1996).

Immediately to the west and south of the Grum Pit, there are about 28 million tonnes (14.4 Mm^3) of overburden and waste rock covering 1.48 km^2 of surface area. This includes a sulphide cell covering a surface area of about 0.28 km^2. This waste rock is underlain by thin colluvium and bedrock. Southwest of the Vangorda Pit there are approximately 16 million tonnes (8.2 Mm^3) of waste rock occupying about 0.4 km^2 of area. In addition, there is a 5,900 tonne (11,400 m^3) stockpile of the fines of the oxidized ore or baritic fines (RGC, 1996).

Previous Surficial Geology/Soil Studies

The characterization of soil baseline conditions has been compiled and described based on studies completed in the FMC and the RSA. The results for the FMC have been completed on areas that were either disturbed when the study took place, or if undisturbed, were identified as potential future disturbance areas.Table 6-1 summarizes studies that provide information about near-surface soil conditions by mine area.

6.2.2.3 Seismic and Terrain Hazards

Regional Seismicity

Earth-shaking events can trigger various natural hazards, including landslides, avalanches, liquefaction of saturated soils, and surface ruptures. Findings from a 2013 CH2M HILL seismic hazard assessment summary showed that there is little documented evidence of recent displacements along the Tintina Fault zone in this region of the Yukon. There appears to be a small concentration of epicentres aligned along the Tintina fault; however, these are minor earthquakes (less than Magnitude [M] 5). Furthermore, most of the activity has been at the northern end of the Tintina Fault zone, close to the Alaskan border (Cassidy et al., 2005).

A GPS-based deformation study by Leonard et al. (2008) associated the Tintina fault zone with low-level seismicity (up to M5) and calculated a maximum right-lateral strike-slip rate of only 0.5 millimetres per year (mm/year), suggesting that the fault no longer accommodates significant seismic deformation. In contrast, the zones with the highest deformation rates are those that most directly represent the North America plate boundaries with the Pacific plate and/or Yakutat block: the Fairweather fault zone (27.3 mm/year) and the southern St. Elias zones (3.6 to 18.3 mm/year) (Leonard et al., 2008), located more than 400 km southwest of the FMC.

Through the interior of the Yukon, there are only three focal mechanisms from recent moderate (less than M5) earthquakes near the Tintina fault system (Cassidy et al., 2005; Leonard et al., 2008). They are a mixture of right lateral strike-slip and thrust earthquakes and do not align with the orientation of the Tintina fault system. Furthermore, there has been no evidence found for active faulting along the Canadian segments of the Tintina fault zone or the Denali fault system (Cassidy et al., 2005).

Local Seismicity

Data on recent earthquakes that occurred within about 250 km of the FMC site (62.2°N and 133.2°W) from September 1985 to November 2012 were extracted from the Earthquakes Canada/GSC database. No earthquakes with magnitude greater than 5 have occurred within approximately 220 km of the site. Within a 50-km radius of the FMC, approximately 38 earthquakes have been recorded since 1985. Only one event, an M4.6 event occurring in November 2002 in the Pelly Mountains, exceeded M4. The closest documented event, an M2.2, occurred about 15 km northwest of the FMC on Christmas Day, 1986.

Mass Movement Processes

The most likely terrain hazards identified in a 2002 Indian and Northern Affairs Terrain Hazard Assessment of the Tay River Map Area (105K), which covered the region that includes the FMC, are snow avalanches and rock mass movements (Doherty et al., 2002).

The peaks of Mount Mye, Mount Aho, and Rose Mountain are subject to a high snow-avalanche-mass movement hazard. Avalanches can contain large volumes of boulders and debris and are considered the most hazardous mass movement process to the FMC (Doherty et al., 2002).

Rock mass movements are most often related to thawing permafrost resulting from denuded soils or the erosion of soft glacio-lacustrine and glacio-fluvial sediments on river banks.

Solifluction lobes and slope creep are also common on the slopes of Mount Mye, Mount Aho, and Rose Mountain, but pose a less severe risk to works at the FMC. Solifluction is common above the tree line and is enhanced in moisture-rich soils on north- and west-facing slopes (Lipovsky and Bond, 1999).

Permafrost

The FMC lies within the discontinuous permafrost zone (Duk-Rodkin, 1999). Low to moderate ice content permafrost is likely extensive at higher altitudes within colluvial and morainal deposits. Valley bottom sediments may have a higher ice content, including large ice inclusions such as ice wedges, ice veins, and tabular ice bodies, especially in the fine-grained alluvial and glaciolacustrine sediments. Variations in permafrost distribution are also controlled by surface sediment composition, soil moisture, slope aspect, and snow depth. Within areas mantled by till, permafrost is more common on north-facing slopes and in old growth forests because these sites typically receive reduced solar radiation.

Previous drilling at the Little Creek Dam in the Vangorda/Grum area identified discontinuous permafrost at about 11 m below ground surface; however, the vertical extent of this permafrost is unknown (SRK, 2010b). Discontinuous zones of permafrost have also been noted in drilling records from the NFRC Area and in the shallow subsurface from drilling and test pitting for the Faro Creek Diversion realignment.

Patterned ground, palsas, thermokarst, and frost boils are commonly associated with the glaciolacustrine deposits in the alpine valleys of Mount Mye. Thermokarst is also present on alluvial plains where streams are eroding fine-grained surficial deposits. Similarly, the removal of the organic blanket will often result in the melting of the permafrost and excess water will be allowed to flood the surface, creating poorly drained soil conditions (Doherty et al., 2002). Other evidence of permafrost activity occurs in the alpine and subalpine zones and includes frost shattering, stone stripes, and solifluction (Bond, 2001).

6.2.2.4 Geochemistry

Geochemistry of Potential Borrow Areas – CH2M HILL Studies

Detailed geochemistry for the mine wastes and FMC site are addressed in the Geochemical Characterization Report (Appendix 6A).

CH2M HILL conducted investigations in 2012 and 2013 to characterize soil and rock geochemical information for several potential borrow areas at undisturbed locations in the FMC (outside of the existing footprint areas).

In 2012, samples were collected at 15 shallow (i.e., 0 to 0.15 m below ground surface) locations including areas north of Rose Creek, downstream of the Cross Valley Dam Pond, west of the Faro Pit, several locations along the Haul Road, and east of the Grum Pit. Some samples from the Faro Mine Area had slightly elevated arsenic and nickel concentrations (compared to Canadian Council for Ministers of the Environment [CCME] *Soil Quality Guidelines for the Protection of Environmental and Human Health, Parkland*). These results suggested the shallow samples were within an acceptable range given their intended use for cover, drainage material, and as a growth medium for the FMRP.

Additional sampling was conducted in 2013 in undisturbed areas identified as potential sources of bedrock and soils. This program included advancing 24 boreholes, conducting 47 test pits, and field mapping nine areas. The following samples were submitted for laboratory analysis:

- 123 samples for soil/rock geochemistry
- 66 samples for soil fertility
- 34 samples for soil geotechnical properties
- 16 samples for rock geotechnical properties

The laboratory analytical program is still in progress and results were not available when this report was developed.

Previous Site Till Geochemistry Studies

In 1998 and 1999, a study was conducted by the Yukon Geology Program, a jointly managed program with the Department of Indian Affairs and Northern Development and the Yukon Government Department of Economic Development to conduct detailed surficial geological mapping and till geochemistry over the Anvil District of central Yukon to assess the potential for an undiscovered buried massive sulphide deposit and to better quantify the background geochemical values for the district (Bond, 2001). Regional till sampling was carried out in four areas adjacent to the known massive sulphide deposits in the Faro area, including those of the FMC. Results from these sampling programs highlighted anomalies in lead, zinc, and copper.

The till geochemistry on approximately 140 samples from a 12-km^2 till grid sampled northwest of the Faro Mine indicated a broad dispersion plume for lead, zinc, and copper extending more than 5 km west of the Faro lead/zinc deposit and into a tributary valley of the Rose Creek Valley-oriented transverse to estimated glacial ice flow.

A total of 20 till samples were taken north of Mount Mye on the north side of the Anvil Batholith. An anomalous lead value exceeding 43.2 parts per million (ppm) lead was obtained from a natural exposure (head-scarp exposure of a small landslide). Additional anomalous lead values are present to the east, in upper North Rose Creek Valley. Three samples returned values ranging between 25 and 27 ppm lead. Two anomalous zinc values collected from samples taken in stream cuts were identified along upper Rose Creek.

Twelve samples were taken within the Anvil Creek Valley along a continuation of Anvil stratigraphy west of the Faro deposits that revealed only minor anomalies.

To the southeast of the FMC, elevated lead and zinc values were identified in the Swim Basin and on the Vangorda Plateau from a till sampling program of 123 samples. Elevated zinc values include anomalies west of Swim Lake, Moose Lake (ainc: 208 ppm and 622 ppm), in upper Blind Creek (ainc: 149 ppm), and marginal to the Pelly River.

Analyses of the till geochemistry vertically in an exposure over the Vangorda massive sulphide deposit showed that the lead concentration is a better indicator of the nearby deposit than zinc because of the greater abundance of zinc compared to lead within the regional bedrock. Six of twenty samples exceeded 138 ppm zinc (the 90th percentile). The data showed concentrations of zinc increase rapidly near the bedrock contact. Eighteen of twenty samples exceeded 24 ppm lead (the 90th percentile). Samples taken within 3 m of bedrock returned values exceeding 66 ppm (the 99th percentile of the regional data set).

In 2006, Gartner Lee Limited (GLL, 2006a) completed a soil geochemical investigation as part of a terrestrial effects study. This investigation examined 168 samples (by depth and parent material) for 29 elements, to evaluate whether elevated elemental levels attributed to mine-generated airborne deposition could be due instead or in part to the influence of underlying mineralized soil materials. Sampling focused on the Faro Mine Area, Vangorda/Grum Area, and on Rose Creek downstream of the Faro Mine Area. Out of the 29 elements evaluated, the study found patterns of elevated lead and zinc concentrations in surface organic soil similar to patterns found in surface lichen, but no similar pattern of elemental concentrations in subsurface organic or mineral soils.

This study suggested that the spatial pattern of elevated elemental levels observed in the study area are the result of deposition from the FMC (called the Anvil Range Mine Complex in *Anvil Range Mine 2005 Investigation of Hydrocarbon-contaminated Soils* [GLL, 2006a]) and eliminates the possibility that these levels can be attributed to natural effects or conditions present before mining.

6.2.3 Atmospheric Environment

6.2.3.1 Climate

General Climate

The FMC is located in the Yukon Plateau-North ecoregion of the Boreal Cordillera Ecozone, approximately 22 km north of the Town of Faro. The climate around the FMC is typical of sub-arctic continental areas in that it is subject to significant annual temperature ranges and moderate amounts of precipitation. Because of prominent terrain features such as the Vangorda Plateau, Anvil Range Mountains, and the Macmillan Highlands that surround the FMC, the site experiences significant seasonal temperature fluctuations and precipitation levels. Cold winters and warm summers are typical for this region. Temperature inversions are frequent because of the mountainous terrain; valley bottoms experience winter temperatures about 10 degrees Celsius (˚C) cooler than higher elevations. Summer temperatures in the valley bottoms are frequently warmer than upper elevations. This is consistent with the environmental lapse rate (i.e., the rate atmospheric temperature decreases with an increase in altitude) (Janowicz et al., 2005).

Temperature

Regional Temperature Normals and Extremes

Regional daily average temperatures, normals, and extremes were collected from the Environment Canada Faro AUT Weather Station, as well as the Faro Airport Station (Faro A Station). During the winter, the lowest daily average temperature of -24.6˚C typically occurs in January. During the summer, the highest daily average temperature of 21.0˚C typically occurs in July. The daily temperature varies by 12˚C in summer and by 8˚C in winter. Regionally, historical Environment Canada data shows a warming trend, where the extreme minimum temperatures in winter have risen by 0.3˚C and the extreme maximum temperatures in summer have risen 2.4˚C between 1981 and 2010 (AECOM, 2009).

Local Temperatures

Two FMC weather stations are located at the FMC; one at the Faro Waste Dump (Faro Dump Station), and the second formerly at the Grum Waste Dump, but now located at a former gravel pit north of that area (Grum Dump Station) (Figure 6D-2 of Appendix 6D, Climate Baseline Report). Temperature measurements at these stations have been collected at each station every 5 seconds, with averages logged hourly, and monthly mean temperatures calculated using these data. Average temperatures at the Faro Dump Station range from 12.3˚C in summer to -15.6˚C in winter, while the corresponding average temperatures at the Grum Dump Station range from 12.1˚C to -15.5˚C. A comparison of concurrent temperature data from the Faro Airport weather station indicates that summer temperatures experienced at the FMC are generally cooler than those measured at Faro. This difference is expected because of the elevation difference between the airport and the FMC. Inversions in such mountainous terrain likely cause recorded winter temperatures at the Faro Airport weather station to be up to 10˚C lower than temperatures at the Faro Dump Station. While there are no complete, long-term datasets from the FMC weather stations, a strong correlation has been observed between temperatures measured at the Faro Airport and those registered by FMC weather stations (Figure 6D-6 of Appendix 6D; AECOM 2009).

DRAFT

Precipitation

Precipitation characteristics for the FMC are described based on data collected and summarized by Environment Canada between 1981 and 2010 at the Faro A Station and are referred to as climate normals for that location. During this time period, mean total annual rainfall was 218.4 millimetres (mm) and mean total annual snowfall was 114 cm, corresponding to a mean snow water equivalent of 101.3 mm. The total annual precipitation ranged between 166 mm (1988) and 355 mm (1990), with an average of 320 mm per year (Appendix 6D).

Monthly rainfall was generally highest between May and September, when snowfall was at a minimum. The wettest months were July and August, with monthly average rainfalls totalling 56.1 mm and 47.5 mm, respectively. Snow-free months were restricted to June and July, with all other months experiencing snowfall from as little as 0.636 cm in May to as much as 21.7 cm in November (or 0.6 mm and 19.2 mm snow water equivalent for May and November, respectively).

Wind Speed and Direction

Surface wind speed and direction at the FMC were assessed for a 5-year period between 2006 and 2010 using measurements collected from the Faro A Station and the two FMC stations. This series of years was chosen for the air quality effects assessment and are considered to present a representative summary. Onsite wind speeds averaged 2.13 metres per second (m/s) at the Faro Dump Station and 2.49 m/s at the Grum Dump Station. In comparison, wind speeds at the Faro AUT Station averaged 2.21 m/s. Annually, more frequent periods of calm winds were observed at the Faro AUT station (approximately 5.3 percent of the recorded hourly wind speeds) than the Grum Dump Station (less than 1 percent of recorded hourly wind speeds).

Seasonally, summer wind speeds between May and September averaged 2.35 m/s at the Faro Dump Station and 2.38 m/s at the Grum Dump Station. In comparison, summer winds at the Faro AUT Station averaged 2.21 m/s. Winter wind speeds from October to April averaged 1.96 m/s at the Faro Dump Station and 2.57 m/s at the Grum Dump Station. Comparatively, winter wind speeds at the Faro AUT Station averaged 2.21 m/s.

At the Faro Airport Station, the prevailing summer wind directions are from the southeast and northwest, while winter winds originate predominantly from the southeast. At the Faro Dump Station, the prevailing summer wind directions are from the northeast and southwest, while prevailing winter winds are from the southeast. The Grum Dump Station experiences summer winds predominantly from the northwest and winter winds from both the southeast and the northwest.

Solar Radiation

While solar radiation is not a published component of the Environment Canada stations at Faro, the FMC stations did record solar radiation data from December 2003 to July 2009. Five complete years of data, 2004 to 2008, were used to characterize onsite solar radiation. Average daily solar radiation calculated using this dataset ranges from the lowest detected levels of 0.129 kilowatts in December to a high of 5.599 kilowatts in June. Highest daily solar radiation levels occurred between April and July, with the lowest daily solar radiation experienced between November and January.

Relative Humidity

Relative humidity (RH) data for the site were based on data collected at the Faro A Station between 1981 and 2010. During this time, RH readings were collected twice daily during the summer months (April through October; 06:00 and 15:00), and once daily for the remainder of the year (15:00). The annual average RH at the Faro A Station taken at 15:00 is 62.69 percent with monthly mean values ranging from 41.44 percent (June) to 81.17 percent (November). RH was generally higher in morning readings, ranging from 74.6 percent (May) to 89.99 percent (September), with an annual average of 81.92 percent.

6.2.3.2 Air Quality

Overview

Air quality in the FMC area is considered to be an important consideration and a primary goal for the IW, and therefore is selected as a valued component (VC) for the IW. Air quality is selected as a VC because of its intrinsic

importance to the health and well-being of humans, wildlife, and vegetation. The following subsection provide an overview of existing air quality conditions in relation to the FMC site, as detailed in Appendix 6E.

Existing air quality for the IW is characterized by ambient concentrations of the following key air quality indicators:

- Nitrogen oxides (NO_x)
- Sulphur dioxide (SO_2)
- Carbon monoxide (CO)
- Ozone (O_3)
- Particulate matter (PM)
- Particulate based metals

Greenhouse gases were not characterized as part of the existing environment because the IW is scheduled for completion within 10 years. The IW is therefore not expected to contribute measurably to global climate conditions during this time.

Study Area

The study area chosen to assess air quality for the IW is the aerial extent of potential effects from project related emissions, including the sensitive receptors closest to the FMC. This study area was established as a 100- km-by-100-km square area approximately centred on the FMC.

Factors Affecting Air Quality

The following sources currently influence ambient air quality near the FMC and are expected to remain as contributors during the IW:

- Airborne dust from vehicle traffic on unpaved roads
- Fugitive emissions from material handling
- Wind-blown dust emissions from the tailings storage facilities
- Combustion of diesel and other fuels (heavy equipment, power generation, and heating)

Additionally, criteria air contaminants resulting from regional sources may influence ambient air quality, and are expected to remain as contributors during the IW.

Data Sources

Ambient air quality was evaluated in order to serve as a benchmark to which project related emissions could be compared in order to assess potential effects. Both local and regional ambient air quality data were compiled to characterize baseline conditions. Data from locally established monitoring stations were used to characterize particulate matter and particulate based metals; whereas regional sources provided data for contaminants not explicitly measured during on-site monitoring programs.

In 2008, SENES Consultants Limited (SENES) established on-site monitoring stations at the FMC and conducted an ambient air monitoring program for total suspended particulates (TSP), particulate matter with aerodynamic diameter of less than 10 microns (PM_{10}), and particulate metals. Samples were collected at eight sites within the FMC and one site in the Town of Faro. A one-in-six day sampling schedule was used during the period of July to October 2008 to capture 13 24-hour-average concentrations (Senes, 2009). Sample sites were grouped in the Faro Mine Area and Vangorda/Grum Area to provide data for specific areas as well as the overall FMC (as shown in Figure 6E-3, Appendix 6E).

Regional ambient air quality data were obtained for the nearest Environment Canada National Air Pollution Surveillance (NAPS) stations in Whitehorse, YT, and Norman Wells, Northwest Territories (Figure 6E-2, Appendix 6E). 2010 and 2011 NAPS data for criteria air pollutants were reviewed, which consisted of hourly monitoring data for O_3, SO_2, CO, NO_x, NO_2 and very fine particulate matter ($PM_{2.5}$; particulate matter with aerodynamic diameter of less than 2.5 microns). Mean annual concentrations for O_3, SO_2, CO, NO_x, NO_2, and $PM_{2.5}$ were also reviewed (Environment Canada, 2013a).

Particulate and criteria air pollutant data were compared with government air quality standards from the Yukon, British Columbia, or Ontario, where applicable. Yukon Ambient Air Quality Standards (AAQS) (YG, 2010) were the preferential standard and were used where available, otherwise standards from other jurisdictions were used.

Existing Air Quality Conditions

The following section describes baseline ambient air quality conditions, established through analysis and review of available data, including both local and regional monitoring results.

Criteria Air Contaminants (Other than Particulate Matter)

Background ambient air quality concentrations for non-particulate criteria air contaminants including NOx, CO, SO_2, and O_3 are shown in Table 6-2, while detailed data are provided in Table 6E-3 in Appendix 6E. These data were derived from the Whitehorse NAPS station except for SO_2, which was characterized based on the Norman Wells station, as it is not measured at the Whitehorse station. Background ambient air quality concentrations for all criteria air contaminants were found to be below Yukon AAQS standards (YG, 2010).

It is recognized that air quality values derived from the regional monitoring stations are likely higher than those for the FMC because there is more human activity near the NAPS stations. Because data on certain criteria air pollutants is lacking for the FMC, these values are still considered useful for estimating baseline levels for the FMC.

TABLE 6-2
Proposed Ambient Air Quality Baseline Levels – Criteria Air Contaminants
Faro Mine Interim Works

Contaminant	Averaging Time	Baseline Concentration	Yukon AAQS
NOx	1-hour	31 (ppb)	213 (ppbv)
	24-hour	26 (ppb)	106 (ppbv)
	Annual	12.4 (ppb)	32 (ppbv)
CO	1-hour	1.1 (ppm)	13 (ppm)
	8-hour	0.8 (ppm)	5 (ppm)
$PM_{2.5}$ (TEOM)	24-hour	7 (µg/m^3)	30 (µg/m^3)
PM_{10}	24-hour	7.1 (µg/m3)	50 (µg/m^3)[a]
TSP	24-hour	11.7 (µg/m^3)	120 (µg/m^3)
SO_2	1-hour	1.5 (ppb)	172 (ppbv)
	24-hour	1 (ppb)	57 (ppbv)
	annual	0.00 (ppb)	11 (ppbv)
O_3	8-hour	47 (ppb)	65 (ppbv)

Notes:

[a] BC Ambient Air Quality Objectives
µg/m^3 = micrograms per cubic metre
ppbv = parts per billion, volumetric
TEOM = Tapered Element Oscillating Microbalance

Particulates

Background ambient air quality conditions for particulate matter were generated using both local and regional data. Measurements taken at nine local monitoring stations (eight at the FMC and one in the Town of Faro) were used to characterize baseline concentrations of TSP and PM_{10} (Senes, 2009). $PM_{2.5}$ data were derived from the Whitehorse NAPS station. Based on a 24-hour averaging time, baseline ambient concentrations of 7 µg/m^3 for $PM_{2.5}$, 7.1 µg/m^3 for PM_{10} and 11.7 µg/m^3 for TSP are proposed. Background ambient air quality concentrations for particulates were all found to be below Yukon AAQS standards (YG, 2010). Baseline ambient concentrations

for particulates are presented in Table 6-2, above, while detailed data are presented in Tables 6E-3 and 6E-5 in Appendix 6E.

Particulate-Based Metals

Monitoring data for 22 particulate-based metals based on maximum observed 24-hour concentrations were below Ontario ambient air quality guidelines for metals (Table 6E-6 in Appendix 6E). Ontario standards (Ministry of the Environment, 2005) were used in the case of particulate-based metals, as neither Yukon AAQS nor BC Ambient Air Quality Objectives were available.

Proposed baseline ambient concentrations for particulate-based metals developed based on 24-hour average concentrations are presented in the context of Ontario ambient air quality criteria (AAQC) in Table 6-3.

DRAFT

6.2.4 Water Resources

6.2.4.1 Hydrology

Introduction

The FMC is located within the regional Vangorda Creek and Rose/Anvil Creek watersheds. The watercourses within these basins are all tributaries to the Pelly River: Vangorda Creek flows directly to the Pelly River through the town of Faro, and Rose Creek is a tributary to Anvil Creek, which in turn discharges to the Pelly River approximately 46 km north of Faro. Within the FMC, a number of hydrological modifications or conveyance features were developed to facilitate mining operations. During mining and post-mining operations, considerable effort was exerted to monitor stream flow and meteorological conditions at the FMC. Data continues to be collected at existing monitoring locations, as part of site operations, to maintain an active database of hydrological conditions. In addition, information on the regional hydrology is available through federal and YG data collection programs.

The hydrology information provided in the following subsections is directly related to the requirements for the IW. The hydrology-related information provides a description of the watershed boundaries, drainage areas, connectivity to adjacent watercourses, and drainage patterns. The analysis of flow records for the FMC provides estimates of peak, minimum, seasonal, and annual average flows. Baseflow estimates are provided for the Rose Creek and Vangorda Creek catchment areas that cover the FMC. More detailed information about site hydrology is provided in the Hydrology Baseline Report, attached as Appendix 6F.

Regional Hydrology

Precipitation, annual snowmelt, air temperature, evaporation, and evapotranspiration influence the region's hydrology. Details on regional and local climate parameters are provided in Section 6.2.3.1 and in the Climate Baseline Report (Appendix 6D). Overall, the region is characterized by large snowmelt runoffs that peak between late May and early June. Stream flows then generally taper off through the summer months. Stream and river flows increase during periods of heavy rainfall throughout the summer and fall, until freeze-up in October. The larger watercourses, such as the Pelly River, maintain significant baseflows throughout the year, while small to medium streams tend to have lowest flows from December to March or April when the groundwater table is lowest.

Local Hydrology

Faro Mine Complex Major Hydrological Features

A number of hydrological features within the FMC are important from a surface water hydrological perspective and are monitored as part of ongoing remediation efforts. These include pre-mining sections of local watercourses, stream diversions, and surface water impoundments that were developed to facilitate mining operations. Table 6-4 lists these features.

TABLE 6-4
FMC Hydrology-related Features
Faro Mine Interim Works

FMC Feature	Description	Hydrological Relevance
Faro Pit	Main excavated pit in Faro Mine Area	Receives local surface water and pumped water from the ETA, ID Pond and groundwater from the Zone 2 wells and S-wells No direct contribution to surface water hydrology
Various Waste Dumps	Waste rock from pit excavation	Potential surface water runoff during extreme rainfall events; contributes to surface flow quantity
Intermediate Dam Pond	Containment of contaminated surface water behind intermediate dam	Water pumped to the Faro Pit. Spillway from dam is being upgraded as part of IW
Various seepage collection systems	Collect potentially contaminated seepage	Contained and pumped for treatment

TABLE 6-4
FMC Hydrology-related Features
Faro Mine Interim Works

FMC Feature	Description	Hydrological Relevance
Cross Valley Dam Pond and CVD	Surface water containment area behind CVD	Pond acts as a water treatment polishing pond
RCD	Diversion of Rose Creek around tailings area	Requires minor upgrades to convey 1-in-500 year design rainfall event
NFRC	Tributary of Rose Creek conveying surface water and seepage from waste dumps	Conveyance of regional flows
North Wall Interceptor Ditch	Collects uncontaminated surface water from north side of Rose Valley and Upper Guardhouse Creek	Conveyance of local runoff
NFRD	Haul road crossing of NFRC	Creates a surface water retention area upstream from drain and limits flow
Upper Guardhouse Creek	Collects local uncontaminated surface water and directs to North Wall Interceptor Ditch	Conveyance of local runoff
Lower Guardhouse Creek	Collects potentially contaminated mill area surface water	Conveys flow to the Intermediate Pond where it is pumped for treatment
Faro Zone II Pit	Collects contaminated groundwater	Collected and pumped to Faro Pit
Faro Creek	Undisturbed section of Faro Creek collecting uncontaminated surface water	Conveyance of regional flows
Faro Creek Diversion	Diversion of Faro Creek around Faro Pit	Conveys uncontaminated surface water around Faro Pit
Pumphouse Pond and Dam	Collects surface water from South Fork Rose Creek and part of NFRC	Discharges into Rose Creek
Vangorda Pit	Excavated mine pit in Vangorda/Grum Area	Receives local surface water and seepage Receives pumped water from Little Creek Pond, Grum Pit, Grum V15, and Grum Sulphide Cell Surface Water Collection Ponds
Grum Pit	Excavated mine pit in Vangorda/Grum Area	Collects local surface water
Vangorda Creek	Undisturbed section of Vangorda Creek conveying surface water	Conveyance of regional flows
VCD	Diversion of Vangorda Creek around Vangorda Pit	Conveys uncontaminated surface water around Vangorda Pit
Moose Pond	Small pond collecting local surface water and seepage from Grum Waste Dump.	No surface water discharge. Connected via groundwater to Vangorda Creek system
Sheep Pad Ponds	Collects Grum Interceptor Ditch water for solids settling	Discharges to Vangorda Creek
Grum Interceptor Ditch	Collects uncontaminated surface water and discharges to Vangorda Creek via Sheep Pad Ponds	Collects local surface water and receives discharge from Vangorda water treatment plant
Little Creek Dam and Little Creek Dam Pond	Collects water from Vangorda Waste Dump	Pond water is pumped to Vangorda Pit
Dixon Creek	Conveys local uncontaminated surface water	Tributary of Vangorda Creek

DRAFT

Faro Mine Complex Sources of Data and Information

A considerable amount of information exists to characterize the hydrological conditions at the FMC. The majority of site-specific data was collected during the post-mining maintenance period. These data are available through a variety of compiled sources, including annual reports generated through FMC care and maintenance activities.

Meteorological and stream flow data for the regional area relevant to the FMC are available from government agency monitoring locations. Climate data are available through the Environment Canada Climate Archive (http://climate.weather.gc.ca/). Flow monitoring data are available through the Environment Canada water survey database (http://www.ec.gc.ca/eau-water).

These data and other available information are detailed in Appendix 6F, which also details the methodology for data review and the results of historical and current FMC hydrological investigations.

Vangorda Creek and Rose Creek Watersheds and Catchment Areas

For analyzing hydrology at the site, the Vangorda Creek and Rose Creek watersheds are subdivided into 13 catchment areas: five catchments in the Vangorda watershed and eight catchments in the Rose Creek watershed. Appendix 6F provides corresponding watershed figures and describes the catchment delineation methodology. The watershed catchments are summarized in Table 6-5, below.

TABLE 6-5
Surface Water Catchments
Faro Mine Interim Works

Catchment ID	Description	Area (hectares)	Mean Elevation (masl)
Rose Creek Regional Catchments (Tributary to FMC X14 monitoring location)			
RC1	NFRC (Upper) – includes the extent of the NFRC to the confluence with the FCD. The flow contributed to the FMC hydrology is monitored by the R7 station.	9,874	1,480
RC2	Faro Creek and FCD –includes both the Faro Creek and FCD to its confluence with the NFRC.	1,589	1,540
RC3	NFRC (Lower) – includes the area tributary to the NFRD at the Haul Road.	992	1,110
RC4	SFRC – includes the extent of the area tributary to the SFRC to the confluence with the NFRC (just south of the NFRD) and is bound by the Vangorda Creek catchment to the east.	7,253	1,450
RC5	RCD – RC5 is tributary to RC6 and represents the NFRC between the NFRD and confluence with the SFRC.	124	1,220
RC6	RC6 represents the RCD around the tailings area.	1,842	1,310
RC7	Upper Guardhouse Creek and North Wall Interceptor Ditch – includes the extent of the area tributary to the Upper Guardhouse Creek and North Wall Interceptor Ditch before the confluence with Rose Creek.	637	1,290
RC8a	Faro Pit –includes the area tributary to the Faro Pit. The pit is considered a water storage location in the context of surface water hydrology.	305	1,140
RC8b	Tailings Area – includes the area between the Faro Pit and tailings area; the flow within this area is monitored by the X23 station. This catchment outlets to the Rose Creek Catchment by the Siphon at the CVD.	539	1,130
RC9	Rose Creek west of the FMC – includes the remaining area tributary to the Rose Creek, upstream from the X14 monitoring location. Water exiting this catchment flows to Anvil Creek and, eventually, the Pelly River.	2,974	1,380
Vangorda Creek Regional Catchments			
VC1	Vangorda Creek and VCD – includes the extent of the area tributary to Vangorda Creek upstream from the VCD; flow through this catchment is represented by the V1 monitoring location.	2,007	1,460

TABLE 6-5
Surface Water Catchments
Faro Mine Interim Works

Catchment ID	Description	Area (hectares)	Mean Elevation (masl)
VC2	Vangorda Creek and Shrimp Creek – Includes the area tributary to the Vangorda Pit (not captured by VCD) and the area Northwest of Vangorda Creek (GSC/V2/Moose Pond) downstream from the haul road to the V27 monitoring location.	842	1,180
VC3	Grum Pit – represents the area tributary to the Grum Pit.	176	1,310
VC4	Shrimp Creek/Dixon Creek – includes the extent of the area tributary to Shrimp/Dixon Creek upstream from the confluence with Vangorda Creek and the V27 monitoring location.	1,360	1,210
VC5	Vangorda Creek – includes the remaining areas tributary to Vangorda Creek upstream from the V8 monitoring location.	4,430	1,240

Hydrological Conditions

Recurrence Interval Event Stream Flows

A number of studies used the available FMC hydrological, meteorological, and physical site data to determine baseline hydrological conditions. The available data were reviewed and integrated into the baseline analysis through a quality assurance/quality control process that determined the most suitable data for inclusion in the analysis. The data analysis carried out to develop baseline hydrological data, the steps applied during the review and quality assurance/quality control process for each relevant data set are discussed in Appendix 6F.

Previous hydrological studies for the FMC reported in CH2M HILL (2013g) have generally focused on determining instantaneous peak flows for a range of recurrence interval events. The studies have relied on regional analyses to determine discharge yield, based on catchment area for a range of flood events. NHC and BGC (2004) conducted a regional analysis based on data obtained from seven regional gauges. During the study, the period of record represented by the gauges ranged from 14 years to 40 years. The catchment areas for the gauges ranged from 91 km^2 to 7,250 km^2. Instantaneous peak discharges were estimated for the mean annual event and for the 1-in-50-, 1-in-100-, 1-in-200-, 1-in-500-, and 1-in-1,000-year return period floods. Table 6-6 summarizes the peak discharge hydrology estimates at the R7 gauge (NFRC, upstream from the FMC), NFRD, SFRC, X14 gauge (Rose Creek downstream from FMC), and Vangorda Creek Diversion locations and indicates recurrence interval peak discharge.

Probable Maximum Flood Flows

The probable maximum precipitation (PMP) and PMF are events that occur with less frequency than once in every 1,000 years. While the PMF is not specifically relevant to the IW, it is a key design event for the Faro Mine Remediation Project (FMRP). A study performed by WMC and a committee of the Faro Mine Closure Planning Office (2006a) examined the FMC PMF event in detail. The findings of this study are included in Appendix 6F.

The probable maximum precipitation (PMP) was determined to be a 175-mm-in-24-hours, rain-on-snow event, which is most likely to occur in June. Table 6-7 summarizes the PMF findings for Rose Creek. CH2M HILL has reviewed WMC (2006a) and has found the assumptions and peer-reviewed work to be appropriately conservative.

TABLE 6-7

Base Flow Conditions

The continuous flow data sets for FMC monitoring stations R7 (NFRC) and V1 (Vangorda Creek) were examined, and base flow values were then derived from these records to represent average base flow conditions in the Rose Creek and Vangorda Creek watersheds. Based on these average monitored baseflow conditions, the average baseflow conditions in each of the Rose Creek and Vangorda Creek catchment areas was estimated. These catchment area base flow estimates are shown in Tables 6-8 and 6-9, below.

Although knowledge of surface water/groundwater interaction is somewhat limited across the site because of the limited number of data available to support the characterization of the nature of stream-aquifer interaction at the site, baseflow values monitored during periods of drought conditions are indicative of groundwater influence on the low flow conditions in the streams. Further groundwater discussions are provided in Appendix 6G.

6.2.4.2 Groundwater Quantity and Quality

Hydrogeological Setting

The study area for groundwater resources at the FMC is the aquifers underlying the Faro Mine Area and the Vangorda/Grum Mine Area. Groundwater flows within the study area are typical of mountainous environments: upland mountain areas act as groundwater recharge areas, and groundwater flows toward valley-bottom discharge areas. In general, all groundwater within the Faro Mine Area flows to the Rose Creek surface drainage (which feeds into Anvil Creek); groundwater within the Vangorda/Grum Area flows into Vangorda Creek. While pre-mining groundwater drainage patterns are assumed to have mirrored local topographic gradients, several features associated with the mine development now affect localized groundwater flow patterns (e.g., pits, tailings, and other mine-related features).

Data Collection

Existing groundwater data for the FMC was gathered from a large number of information sources, including historical field monitoring data for groundwater level and quality collected during previous consultant investigations, ongoing monitoring programs, and investigations completed in 2012 and 2013 by CH2M HILL. CH2M HILL used the data collected during various site investigations to develop groundwater flow models for the Faro Mine Area that were subsequently used for the assessment of baseline conditions. This section presents the baseline conditions for groundwater within the FMC. Additional details about groundwater baseline conditions are provided in Appendix 6G, attached.

FMC Hydrogeological Features

Two separate aquifer systems underlie the FMC; the Rose Creek aquifer system that underlies the Faro Mine Area and discharges into Rose Creek, and the Vangorda Creek aquifer system that underlies the Vangorda/Grum area and discharges into Vangorda Creek. These two groundwater systems are described in more detail below.

Faro Mine Area

Groundwater conditions in the Faro Mine Area are influenced by numerous mine-related and surface water features including the following:

- Faro Pit and various associated WRDs
- Zone II Pit adjacent to the Faro Pit

- Groundwater/surface water interaction within the NFRC drainage
- ETA and SIS below the mill and stockpile areas
- S-wells SIS adjacent to the NFRC downgradient of the Intermediate WRD
- RCTA, including the CVD, ID, Secondary Dam, Original Dam, and RCD Channel

Overall, the hydrogeology of the Faro Mine Area is characterized by two significant alluvial aquifer systems (the RCAA and the NFRC Alluvial Aquifer) underlain locally by low-permeability till deposits, a moderate to low permeability weathered bedrock unit, and a generally low permeability competent bedrock unit. Due to their significantly higher permeability, a very high percentage of the groundwater flow moving through the Rose Creek aquifer system occurs through the alluvial deposits.

The Faro Pit has a large influence on hydrogeology in the vicinity of the Faro Rock Dumps. Faro Pit generally acts as a groundwater sink, collecting groundwater seepage and subsurface inflow from the surrounding rock dumps. A small amount of outflow is believed to leave the pit in response to groundwater extraction operations within the nearby Zone II Pit. The primary inflows to Faro Pit occur as precipitation, pit wall and surface seepage from surrounding WRDs, and subsurface inflow from the aquifer system underlying the WRDs. The Faro Mine Area includes several large WRDs that act as areas of infiltration for rainfall and snowmelt. Much of this infiltrating water discharges back to the ground surface in the form of seeps contributing to surface water runoff while the remainder becomes deep percolation and recharges the groundwater aquifer system. The previously infilled Zone II Pit is located between the Northeast and Intermediate WRDs. Groundwater levels within the Zone II Pit backfill are controlled by groundwater pumping to limit potential subsurface seepage into the nearby NFRC. Groundwater is pumped from the pit to maintain groundwater elevation in the rock backfill at no greater than 1,096 masl.

The Zone II Outwash and S-Wells areas are located in the alluvial floodplain along the NFRC. The S-Wells area lies south of the Intermediate WRD while the Zone II Outwash area lies east of the Zone II Pit. The generalized stratigraphy of these areas consists of alluvial materials overlying weathered and competent bedrock, with locally limited deposits of glacial till material. In the S-Wells area however, the alluvial aquifer is separated into an upper and lower aquifer by the presence of a low-permeability aquitard, while in the Zone II area, the alluvial aquifer appears to be a single aquifer system with overlying outwash material deposited at the ground surface. Recent studies show that groundwater in both of the areas is hydraulically connected with the NFRC, and mine-impacted groundwater has the potential to discharge to the NFRC, with resulting impacts to surface water quality. Past experience in the S-Wells area has illustrated that these interactions do occur.

The ETA is located along the former Faro Creek Channel, north of the RCTA. The stratigraphy of the area is comprised of limited thicknesses of sand and gravel, underlain by weathered and competent bedrock. Disposal of tailings materials in this area during mine operations has resulted in the deposition of a 6- to 20-m-thick low-permeability tailings unit in the upstream portion of the ETA adjacent to the Mill Area and Main Rock Dump. The ETA receives water from upgradient WRDs and associated seeps, including the discharge from the X23 seep that exhibits some of the highest metals and sulfate concentrations detected across the FMC.

The RCAA is located in the Rose Creek Valley, downstream of the confluence of the NFRC and SFRC. This aquifer system is a classic fluvial depositional system deposited by the NFRC and by Rose Creek itself. The alluvial aquifer is composed of a mixture of silt, sand, and gravel, with thicknesses of up to 50 m near the centre of the valley. Alluvial deposits are now covered by up to 25 m of tailings in the central valley area. The primary hydrogeological units in the Rose Creek valley include the relatively low-permeability tailings deposits underlain by high-permeability alluvial deposits, overlying lower permeability weathered and competent bedrock. Limited discontinuous low permeability glacial till deposits have also been observed overlying the bedrock units, primarily along the valley margins.

Vangorda/Grum Area

This section describes the hydrogeology of the Vangorda/Grum area of the FMC located within the upper portions of the Vangorda Creek Drainage.

DRAFT

Grum Pit Area

Similar to the Faro Pit, the area around the Grum Pit has a low-permeability overburden (glacial till) unit overlying low-permeability bedrock. A second confined (limited extent) overburden unit, called the Thalweg aquifer, may also be present, which is composed of high-permeability sands and gravels, about 20 to 30 m thick. Above the bedrock contact, a permeable unit of unknown extent may also be present and may be connected to the Thalweg aquifer (RGC, 1996). Groundwater investigations in 2009 (SRK, 2010) in the south and west of Grum Pit identified calcareous phyllite of the Vangorda Formation underlying silty to sandy glacial till in both areas. Three hydrostratigraphic units were identified as consisting of a surficial silt, sand, and gravel unit; weathered bedrock; and competent bedrock (SRK, 2010).

West of the Grum Waste Dumps, Grum Creek and several tributaries drain towards Vangorda Creek. Generally, alluvial material is found deposited over till material with varying mixtures of sand, gravel, and clay. Weathered bedrock, transitioning to competent bedrock, provides the foundation. The thicker overburden and fluvial sediments of the Grum Creek Area have been interpreted to provide the greatest conduit for groundwater movement. At one borehole in the Grum Creek Area, two permeable water-bearing units were observed above the bedrock: a coarse-grained gravel and boulder layer and a sand and silt unit, separated by a low-permeability silt layer (RGC, 1996). Although limited data are available, a confined aquifer was identified at depths below approximately 12 m. Drainage from the Grum Waste Dump is anticipated to predominately flow towards the south/southeast, particularly in thicker overburden materials of Grum Creek and associated smaller tributaries (RGC, 1996).

Vangorda Pit Area

Similar to the Grum Pit Area, three hydrostratigraphic units appear to be identifiable in the Vangorda Pit Area. However, at Vangorda, there is an overlying confining, low-permeability overburden composed of silty, sandy glacial till (about 30 m thick) that sits atop a saturated sand and gravel unit overlying weathered bedrock that transitions into competent and lower-permeability calcareous phyllite. Several fault zones have been identified in the bedrock (RGC, 1996).

Similar to the Grum Creek Area, the greatest conduit for groundwater movement away from the Vangorda Waste Dumps is expected to be via sediments underlying the Vangorda Creek Area. Typically, overburden consisting of compact silty and sandy glacial till overlies a more permeable basal sand and gravel unit. Underlying this unit is the low permeability calcareous phyllite bedrock of the Vangorda Formation (RGC, 1996). In the investigated areas of Vangorda Creek Valley, fluvial sediments up to about 20 m thick show greater permeability. A confining unit of low-permeability till with silty to sandy composition overlies more permeable sand and weathered bedrock. The thickness of each unit varies but, combined, they are not typically greater than 30 m (SRK, 2010).

In general, water levels downgradient of the Grum/Vangorda Pits exhibit about 1 m of seasonal fluctuations. Groundwater in the alluvium appears deeper (about 7 to 10 m below ground surface) and shallower in the overburden (about 2 to 6 m below ground surface). Water levels reported for the bedrock are relatively stable, about 7 m below ground surface (AECOM, 2009).

Groundwater Quantity

To estimate groundwater flows in the Faro Mine Area, two calibrated groundwater flow models were used. Both of these models cover the entire upper Rose Creek drainage, but one is refined to perform detailed analysis in the RCTA, while the other supports refined analysis of the NFRC area.

A groundwater flow model has not been prepared for the Vangorda/Grum Area, and therefore greater uncertainty exists regarding the magnitude of groundwater flows in that area. However, the existing understanding of groundwater in the Vangorda/Grum Area is sufficient to support the assessment of IW activities because the main discharges to receiving waters for the IW period are expected to occur at the Faro Mine Area. Additional modeling for the Vangorda/Grum Area will be conducted to support the FMRP.

DRAFT

Faro Mine Area

The model refined in the NFRC area was used to estimate steady state groundwater flow conditions in the approximately 4.2- km^2 area that contains the Northeast Rock Dump, NFRC, Zone II Pit and Outwash, and S-Wells areas (CH2M HILL, 2013). Results of this modeling analysis suggest that approximately 20 L/sec of groundwater flow moves through the aquifer system beneath the NFRC in this area. The analysis further indicated that the primary sources of recharge to the groundwater system include infiltration from precipitation, streams, and pits, as well as groundwater inflow from upstream areas, while the major components of groundwater outflow are discharges to streams and pits, pumping from wells (S-Wells SIS and Zone II Pit Well), and underflow to downstream areas.

Rose Creek Tailings Area

The model refined in the RCTA was used to estimate the steady state groundwater flow conditions in the 4.6-km^2 area encompassing the RCTA and the CVD. Results from this modeling analysis estimated groundwater flow through this area to be approximately 117 L/s. The analysis further indicated that the primary sources of recharge to the groundwater system include infiltration from precipitation and streams (RCD, Faro Creek Channel, and Rose Creek downstream of the CVD), as well as groundwater inflow from upstream areas. Major components of groundwater outflow are discharges to streams and drains (drainage channels downstream of the CVD), and underflow to areas further downstream in the Rose Creek Valley.

Vangorda/Grum Area

A calibrated groundwater flow model has not been prepared for the Vangorda/Grum Area, and therefore no quantitative analysis estimating rates of groundwater flow through the area has been performed. Well monitoring at the Vangorda/Grum Mine Site during the care and maintenance period suggested that groundwater flows from the various pits and WRDs into Vangorda Creek (in a predominately southern direction).

Before development of Grum Pit, a small lake existed at this location, representative of a pre-mining water table (RGC, 1996). The Thalweg aquifer along the north-northeast portion of the pit provides recharge to the pit. Groundwater flow is estimated to be in a predominately southerly direction.

The Vangorda Pit water level elevation averages 1,085 masl and had ranged between 1,074.6 and 1,094.1 masl since 2004 (DES, 2012a). Seasonal pumping maintains Vangorda Pit as a groundwater sink. Groundwater flow in the area is expected to be toward the south/southwest, predominately sourced from the sand and gravel units associated with Vangorda Creek and its associated small tributaries. As the water level in the pit is retained below surrounding groundwater elevations (as it will be for the long term), flow may be received from all directions.

Groundwater Quality

Groundwater quality throughout the FMC is changing and evolving because of ongoing geochemical processes within the waste rock dumps, the open pits, and tailings deposits. Ongoing studies have used concentrations of sulphate and zinc to classify water quality impacts at the site according to the concentrations outlined in Table 6-10. Impacts to groundwater quality across the FMC are summarized below. The relative levels of contamination are categorized according to the concentrations listed below for use in illustrating figures and differentiating areas of impact within the text.

TABLE 6-10
Summary of Concentrations used for the Classification of Groundwater Contamination
Faro Mine Interim Works

Groundwater Quality Classification	Mean SO_4 Concentration (mg/L)	Mean Zn Concentration (mg/L)
Not Impacted / Minimally Impacted	< 40	< 0.05
Slightly Impacted	40 – 400	0.05 – 0.5
Moderately Impacted	400 – 4, 000	0.5 – 5
Highly Impacted	> 4, 000	> 5

Faro Mine Area

Faro Pit

Faro Pit water quality is highly impacted with moderate sulphate concentrations (less than 1,000 mg/L) and high zinc concentrations (above 5 mg/L) for data reviewed between 1998 and 2012 (DES, 2012b). Contaminated water from the S-Wells SIS and from the Zone II Pit is currently pumped to Faro Pit. The quality of seep water flowing to Faro Pit (discharging from the Faro waste dumps) ranges from not impacted to highly impacted, as shown in Figure 6G-21. Sulphate levels in Faro Pit water have remained steady while zinc concentrations have steadily increased over the last decade. The most current field sampling results show that similar conditions are occurring in seepage from the Main Waste Dump at X23, as quality continues to deteriorate as sulphate, manganese, and dissolved metals concentrations increased and seepage became more acidic (RGC, 2013).

Northeast Rock Dumps Area

The Northeast Rock Dumps are located to the northeast of the Zone II Pit and southeast of the Faro Pit and cover an area of about 0.51 km^2, with a maximum elevation of 1,290 masl. The near pit dumps are located immediately to the south and southwest of the pit, just north of the Main and Intermediate Dumps, and cover an area of 0.2 km^2, with a maximum elevation of 1,200 masl (RGC, 1996). Groundwater quality at areas in the vicinity of the Northeast Waste Dump can be summarized as follows:

- Areas downgradient from the Northeast Waste Dumps: Three well pairs (BH12A/B, BH13A/B, and BH14A/B) are located at the toe of the Northeast Waste Dumps and are screened mainly in weathered bedrock and deeper bedrock (Figure 6G-26, Appendix 6G). Groundwater conditions in this area have worsened substantially over the last 10 years, and zinc concentrations up to about 10 mg/L have been detected at the well pair closest to Zone II (BH14A/B; highly impacted). The well pairs located farther northeast have moderate groundwater impacts. Mine-related contamination is expected to increase in this area and additional investigation is required to evaluate the extent of contamination (RGC, 2012).
- NFRC upgradient from Northeast Waste Dumps: Three wells are located near NFRC upgradient from Northeast Waste Dumps (P09-UN1 through P09-UN3) and are screened in alluvial sediments or weathered bedrock (Figure 6G-27, Appendix 6G). Here, sulphate concentrations are less than 200 mg/L and zinc concentrations up to 1 mg/L. The moderate contamination impacts shown in this area are a result of mine-impacted groundwater flow from the Northeast Waste Dumps (RGC, 2012).

North Fork of Rose Creek

The two most extensively studied areas within the NFRC Valley are the Zone II Outwash area and the S-Wells Area. Numerous wells have been installed in both locations to characterize the alluvial thickness, depth to bedrock, groundwater flow patterns, and groundwater quality. Groundwater quality has been substantially impacted in both the Zone II Outwash and S-Wells areas because of subsurface migration of mine-affected water from waste dumps in the Zone II Pit area and from the Intermediate Waste Dump, respectively. Field investigations conducted in 2013 suggest that the NFRC is a gaining stream along the majority of its length between its confluence with the FCD and the NFRD. These conditions suggest that groundwater contamination in the vicinity of the stream represents a viable pathway for contaminants of concern to enter the stream system and degrade surface water quality. To address this concern, a seepage interception system has been installed at the S-Wells site that consists of a shallow permeable trench and a series of deeper weathered bedrock extraction wells. Recent groundwater quality data also indicate that sulphate and zinc concentrations are increasing in groundwater at the base of the Northeast Waste Dump, suggesting that this area may also represent a conduit for metals loading to the NFRC.

Zone II Pit and Outwash Area

Groundwater in the waste-rock-filled Zone II Pit is managed (pumped) to mitigate potential seepage from the pit to the Zone II Outwash area. As discussed above, groundwater contamination in the vicinity of the Zone II area may travel along two potential pathways: groundwater contamination could discharge to NFRC, in which case it would likely bypass the RCAA through the RCDC; alternatively, it may travel as subsurface underflow, resulting in continued loading to the RCAA.

Water in the Zone II Pit (well X26) is highly impacted with fairly stable zinc concentrations. Sulphate concentrations have been more variable since 2008, likely because of more aggressive pumping. However, sulphate and zinc concentrations within the pit continue to increase. Zinc and sulphate loads collected from the Zone II Pit were 5.8 tonnes per year (tpy) and 184 tpy, respectively, in 2011. Between July and September 2012, loads collected from the pit were approximately 3 tpy of zinc and 134 tpy of sulphate. Contaminant concentrations at X26 tend to be lower in the spring when meteoric water inputs are greater (RGC, 2012).

In the alluvial aquifer within the Zone II Outwash area, two wells are highly impacted, five wells are moderately impacted, one well is slightly impacted, and one well is not impacted. In the bedrock aquifer, four out of five monitored wells are moderately impacted and one is highly impacted. Most groundwater both in the shallow and bedrock aquifers in the Zone II Outwash is moderately impacted, with some highly impacted groundwater near the toe of the waste dump (locations BH2, BH6, and BH8). Concentrations have generally remained stable or show gradual increasing trends in Zone II Outwash wells over the monitoring period. Monitoring wells to the north of Zone II Outwash have had substantial mine-related contamination increases in recent years. The *2012 Groundwater Quality Review* (RGC, 2013) suggests that the breakthrough of more highly contaminated groundwater might occur in this area from the toe of the Intermediate Waste Dump to the west.

S-Wells Area

Contaminated groundwater daylights both as seeps along the Intermediate Waste Dump face to the north of the S-Wells Area and also flows south toward NFRC within alluvial, weathered bedrock, and bedrock aquifers. Groundwater contamination in this area discharges to NFRC and could contribute loading to the RCAA as leakage from the NFRC or RCD further downstream. The 2008 S-Cluster groundwater investigation (SRK, 2009) concluded "the plume of contaminated groundwater [in S-Wells Area] is likely moving underneath the NFRC in permeable materials and discharging to the NFRC at indeterminate locations."

In general, groundwater in the S-Wells Area is moderately to highly impacted, with some slightly impacted alluvial and overburden locations on the far eastern portion of the site. The shallow groundwater system generally has the highest contamination, with 11 out of 21 wells classified as highly impacted (and 8 wells classified as moderately impacted). Groundwater contamination does extend into the bedrock as well, with highly impacted groundwater detected in one bedrock well (SRK-08-SPW2) and moderately impacted groundwater detected in the remaining bedrock wells (RGC, 2012).

An SIS was constructed in 2009 to intercept contaminated groundwater flowing from the Intermediate Waste Dump before it reached NFRC. It consists of three parts (RGC, 2012):

- A shallow rock-filled interceptor trench located in the shallow aquifer (overburden) with one pumping well (SRK08-PW3).
- Two pumping wells (SRK08-SPW1 and SRK08-SPW2) screened in the deeper bedrock aquifer. However, only one well typically operates because the other well contains high iron concentrations. Addition of this flow stream containing high iron concentrations to the discharge from the other S-Wells extraction facilities has historically resulted in extensive iron fouling of the conveyance pipelines and more intensive associated operations and maintenance requirements.
- Surface water interception via a rock drain at the toe of the Intermediate Waste Dump, which diverts water to the shallow aquifer interceptor trench.

S-Wells SIS water is pumped to the Faro Pit and currently operates year-round (RGC, 2012). Zinc and sulphate loads in 2011 captured by the S-Wells SIS were 21.3 tpy and 300 tpy, respectively. Between May 2012 and December 2012, 17.8 tonnes of zinc and 272.5 tonnes of sulphate were captured at the S-Wells SIS.

Groundwater quality in wells classified as slightly to moderately impacted has relatively stable concentration trends. However, water quality in some wells along the southern toe of the Intermediate WRD continues to deteriorate gradually (SRK05-SP1A/B and SRK05-SP2). Groundwater quality in the till unit, located to the west of the SIS, also continues to degrade (this water is not captured by the SIS). Groundwater quality in the bedrock aquifer is improving

overall as a result of pumping the S-Wells SIS bedrock wells. However, operation of the shallow aquifer interceptor trench of the S-Wells SIS has not made a noticeable impact on shallow groundwater quality (RGC, 2012).

Emergency Tailings Area

The ETA has some of the most highly contaminated groundwater and surface water in the Faro Mine Area and represents a major source of contaminant loading to the RCAA (AECOM, 2009). Flow monitoring and sampling completed in 2005 and 2006 along Faro Creek below the ETA indicated that the total zinc load discharged from the ETA (surface flow and subsurface seepage discharging downstream from the mine access road) ranged from about 35 to 80 tpy (RGC, 2007). The contaminated seepage is a combination of surface flow originating as toe seepage from the Main WRD and groundwater flow from the WRD through highly permeable alluvial sediments from the Old Faro Creek. The ETA tailings also contribute significantly to the groundwater and surface water contaminant loading (SRK, 2006). Seeps discharging to the ETA at the base of the Main Waste Dump, which combine with flowing surface water across the ETA in Old Faro Creek and Mill Canyon Creek, are highly impacted and show increasing contaminant load trends as evidenced by the water quality at X23.

Surface water and groundwater qualities in the ETA show increasing trends for acidity, sulphate, and zinc, and these trend are expected to continue. Seepage from the Main WRD has become noticeably more acidic over the last 3 years, suggesting ongoing breakthrough of acid rock drainage products and a decline in the buffering capacity of the Main WRD waste rock and ETA alluvial soils (RGC, 2012). In 2006, an interim SIS was constructed at the southeast end of the ETA (downgradient from the mine access road) to collect surface water runoff and seepage (from two prominent seeps). The SIS operates during the ice-free seasons, and collected water is pumped to the Faro Water Treatment Plant or the Faro Pit. The ETA SIS intercepted an estimated 31.2 tpy of zinc and 488 tpy of sulphate in 2011 and an estimated 86 tpy of zinc and 940 tpy of sulphate in 2012. Seepage not intercepted by the SIS was observed discharging directly to the Faro Creek Canyon. Overburden and weathered bedrock groundwater quality and surface water quality downstream from the ETA is highly impacted (locations P09-ETA2 and FCS-4), and the seasonal operation of the ETA SIS does not appear to be improving this condition. However, groundwater in deep bedrock downgradient of the ETA does not show indications of mine-related contamination based on data from monitoring well P09-ETA1 (RGC, 2012).

Rose Creek Tailings Area

Generally, clean groundwater from the south and southeast flows to the RCTA, and contaminated groundwater flows from the Faro Mine to the RCTA from the north, with a significant portion of contamination associated with the Faro Creek Canyon. Locally, the tailings contribute to groundwater contamination in the RCTA as well. The extensive leakage of clean water from the RCDC (south of the RCTA) has a major influence on the spatial water quality trends in the RCAA, especially further downgradient near the CVD. In the western half of the RCTA, there is a significant spatial trend from south to north of not impacted groundwater transitioning to moderately impacted groundwater.

Groundwater quality in the Original and Second Impoundment area ranges from not impacted to highly impacted, with the highest sulphate and zinc concentrations occurring in the tailings. Higher concentrations are generally observed in groundwater in the northern portion of the RCAA likely because of contaminant discharges from the Faro Creek Canyon. The upper portions of the underlying alluvial aquifer are highly-impacted. The highest sulphate and zinc concentrations are detected in tailings porewater in the southeastern (multilevel wells P03-01 and P03-03) and northwestern (multilevel well P03-06) areas of the Second Impoundment. Zinc concentrations tend to be highest near the interface of the sand and gravel RCAA and the overlying tailings. Groundwater contamination in the far southeast section of the impoundment areas is thought to be mainly a result of direct tailings-related contamination (RGC, 2012).There are continued increases in contamination in the alluvial aquifer near the mouth of Faro Creek Canyon (multilevel well P03-06), which is a primary flow path for contamination from the Faro Mine Area to the RCTA. Groundwater in the Intermediate Impoundment Area ranges from not impacted to highly impacted as well, with the highest sulphate and zinc concentrations in the tailings. Sulphate and zinc concentrations are very high in shallow tailings porewater and have been relatively stable for the last 10 years. In contrast, alkalinity and pH have decreased substantially in the tailings porewater since 2009, indicating a breakthrough of the acid front in the Intermediate Impoundment area (RGC, 2012).

Groundwater at the toe of the ID is moderately impacted in the alluvium and till. Concentrations of mine-related contaminants have generally increased since 2001 in this area, and seepage from the coarse tailings beaches of the upgradient impoundments and input from the Faro Creek Canyon are likely sources. Conditions are expected to deteriorate in the coming years as the groundwater contamination front in the RCTA progresses. Groundwater in the southern portion of the area is generally less contaminated than in the northern portion because of the inflow of clean groundwater leaking from the RCDC to the south. However, concentrations in this area do show a significant trend of increasing sulphate, iron, magnesium, and manganese. It is believed that the mine-related total dissolved solids (TDS) plume front has reached this area.

Groundwater on the southern edge of the Rose Creek Valley, downgradient from the CVD, remains only slightly impacted by mine-related groundwater contamination. Groundwater contamination in the northern area has higher sulphate and magnesium concentrations, indicative of the leading edge of the TDS plume. Concentrations of sulphate and metals are gradually increasing in shallow groundwater along the north side of the valley downgradient of the CVD, but zinc concentrations remain low (less than 0.05 mg/L).

Groundwater farther downgradient from the CVD (wells X16A/B) is not impacted. However, the well pair upgradient from this location (X17A/B) has had increases in mine-related contamination since 2008, which is likely to continue. This water is now within the slightly impacted range, indicating continued movement of the leading edge of the TDS plume front down the valley (RGC, 2012).

Vangorda / Grum Area

Most groundwater monitoring locations in the Vangorda/Grum Area are between the toes of the waste dumps and Vangorda Creek. In general, the Vangorda/Grum Area is characterized by low-permeability materials with some higher permeability alluvial material associated with current and former stream channels. Therefore, seepage from waste dumps is expected to follow preferential flow paths.

Vangorda Pit and Area

As the Vangorda Pit is considered a groundwater sink, drainage of contaminants into Vangorda Creek is not expected so long as the pit is maintained at current or lower water levels. The pit water quality is highly impacted based on elevated zinc concentrations. Since 2000, sulphate and zinc concentrations at the surface of Vangorda Pit have been steadily increasing. Groundwater within the Vangorda WRD is moderately to highly impacted, with contaminant concentrations increasing downgradient of the WRDs despite the till berms installed to reduce seepage. The highest zinc concentrations are detected in more permeable alluvial sediments (associated with preferential flow paths) and have recently increased near the northwestern toe of the Vangorda Rock Dump (RGC, 2013). Weathered bedrock and bedrock at the toe of the Vangorda Waste Dump have slightly impacted groundwater with less sulphate than detected in the overburden (RGC, 2012).

Grum Pit and Area

Grum Pit is expected to be a groundwater sink and is not considered a source of contamination to the Vangorda Creek drainage as long as the water is kept contained. The pit water quality is considered highly impacted, based on elevated zinc concentrations. Groundwater quality in the overburden of the Grum waste rock areas is highly impacted by elevated zinc concentrations. In the underlying bedrock, sulphate concentrations are elevated, indicating the groundwater is moderately impacted in these areas. Seep and shallow groundwater collecting at the toes of the waste rock dump and within the Grum Creek channel are slightly to moderately impacted. Overall, shallow overburden and bedrock groundwater quality around the waste rock dumps continues to deteriorate, with deeper bedrock groundwater currently remaining unaffected. Sulphate and other TDS plume parameters have migrated into the Vangorda Creek Valley and do extend beyond specific drainage channels, but zinc concentrations are still low in the area (typically less than 0.05 mg/L) (RGC, 2012).

6.2.4.3 Surface Water Quality

Introduction

Physical and chemical parameters of surface water quality are important indicators of natural and mine-related geochemical processes, and affect the distribution and characteristics of vegetation and aquatic biota. Data collected

between 2008 and 2012 from various surface water monitoring stations were compiled to characterize current conditions at the FMC. Water monitoring stations within the LSA included streams within approximately 500 m of the mine disturbance footprint, incorporating parts of Rose Creek (North and South forks), Faro Creek, and Vangorda Creek. The RSA for water quality assessment encompassed the maximum spatial extent of potential, measurable, project-related influence, including the areas of Rose and Vangorda Creeks downstream of the LSA, Anvil Creek, and areas of the Pelly River immediately upstream and downstream from the mouths of Anvil Creek and Vangorda Creek.

The following sections summarize data analysis methods and results. Additional details are available in Appendix 6H, the Aquatic Baseline Characterization Report.

Water Quality Monitoring Stations

Water quality data were collected and reviewed for 7 reference stations, 20 mine-exposed stations, 4 stations on the Pelly River, and 2 First Nations drinking water stations (Figure 6-3). Reference stations were located upstream of any mine influence. Mine-exposed stations were located on the NFRC, SFRC, Rose Creek, Anvil Creek, and Vangorda Creek, where water quality is or has the potential to be influenced by surface water or groundwater draining from various waste rock piles, pits, ponds or tailings. Data from monitoring stations on the Pelly River were used to determine whether any mine-related influences on water quality from the Vangorda and/or the Anvil-Rose Creek drainages could be detected in the Pelly River. The First Nations drinking water stations were used to determine human health risks that may be resulting from mine runoff.

Water Quality Parameters

The characterization of existing water quality conditions focused on analytes that previous studies at the FMC had identified as being indicative of mine-related influence (Minnow, 2007 and 2010), as well as supporting analytes that contribute to water quality interpretation:

- 14 metals: cadmium, calcium, magnesium, nickel, potassium, silver, sodium, strontium, cobalt, iron, lead, manganese, uranium, and zinc.
- 10 non-metal parameters: alkalinity, ammonia, hardness, nitrate, sulphate, total organic carbon, dissolved organic carbon, total dissolved solids (TDS), TSS, and turbidity.
- 2 field-measured water chemistry parameters: pH and conductivity.

Data Analysis Approach

To facilitate comparisons of water quality data between mine-exposed and reference data, reference data were pooled to compute the minimum, maximum, median, mean, standard deviation, and 5th and 95th percentiles for each analyte. The 5th and 95th percentiles were considered to represent the lower and upper range of background concentrations, respectively. Data from mine-exposed monitoring stations were compared to guidelines for the protection of aquatic life. Wherever possible, the CCME *Canadian Water Quality Guidelines for the Protection of Aquatic Life* were used (CCME, 2013). Alternate guidelines were used (e.g., Environment Canada or British Columbia Ministry of the Environment) where a CCME guideline was not available, or where a more recent/applicable guideline was available. Where water quality guidelines required calculation based on water hardness, median hardness at each station was used to derive a station-specific guideline. For the First Nations drinking water stations, analytes were compared with Health Canada's Guidelines for Canadian Drinking Water (Health Canada, 2010).

Background Water Quality

Data collected from the reference stations at the FMC were summarized to characterize the background water quality (Table 6-11). Reference streams tended to be slightly basic, with a median pH of 7.7 (ranging between 5.2 and 9.15). Water hardness was relatively low, with a median concentration of 48 (mg/L expressed as calcium carbonate ($CaCO_3$), but concentrations as high as 251 mg/L were observed among individual samples. Organic carbon was relatively low and mainly in the dissolved form (dissolved organic carbon and total organic carbon concentrations were approximately equivalent), with a median dissolved concentration of 2.4 mg/L. TSS and turbidity also tended to be low (less than 1.0 mg/L and 0.5 Nephelometric Turbidity Units [NTUs], respectively), but ranged up to 400 mg/L and 6.2 NTU, respectively, typically associated with spring snowmelt or large rain events.

TABLE 6-11

Water Quality Summary Statistics for Pooled Reference Station Data (V1, VR, USFR, R7, FC, R6, W10) [a], FMC, Yukon.

Faro Mine Interim Works

	Analyte	Units	n	Minimum	Maximum	Median	Mean [b]	Standard deviation [b]	Lower Background Benchmark (5th percentile)	Upper Background Benchmark (95th percentile)
Non-Metals	Alkalinity, Total	mg/L	209	5.1	160	40.1	55.1	43.3	10.0	150

Notes:

[a] Data for individual reference stations are summarized in Attachment Tables B.2 - B.8 in Appendix 6H.

[b] values reported as less than the detection limit (DL) were used at 1/2 the DL for calculation

DRAFT

Water Quality at Mine-Exposed Areas Relative to Background Levels

Analytes that were identified in previous studies at the FMC as having elevated concentrations (in relation to background) remained elevated in at least 10 percent of monitoring samples collected at one or more of the stations located downstream of mine disturbances in 2008-2012 (Table 6-12). Alkalinity, conductivity, hardness, sulphate, total dissolved solids, calcium, cobalt, magnesium, nickel, sodium, strontium, and zinc were observed at concentrations above the background concentration range in approximately half or more of samples collected downstream of the Vangorda/Grum Area (station V8) and the Faro Mine Area (station X14, Tables 6-12, 6-13). While the FMC is the main source of many of these variables to downstream areas, natural sources (e.g., landslide on West Vangorda Creek; bank erosion) also contribute to elevated downstream water concentrations of some analytes, such TSS, turbidity, iron, and manganese.

Elevated hardness, sulphate, manganese, and potassium concentrations were detected to the mouths of both Vangorda Creek and Anvil Creek.

Water Quality Relative to Guidelines

Non-Metals

Ammonia, sulphate, nitrate, and pH concentrations were always or almost always within guidelines (Table 6-12). Guidelines for TSS and turbidity are based on a shift from mean or median background levels, rather than specific effect thresholds; detailed evaluation of the data indicated limited mine-related influence on downstream concentrations of these substances (Appendix 6H, the Aquatic Environment Baseline Report).

Metals

Cadmium, cobalt, iron, lead, manganese, uranium, and zinc were the metals found at concentrations above guidelines in 10 percent or more of samples collected at one or more stations downstream of mine disturbances (Table 6-13). The pattern of iron concentration data among stations indicated that elevated concentrations were mainly associated with sources outside of the FMC. Zinc was the mine-related metal most frequently exceeding guidelines in water samples collected from stations in the Rose-Anvil system and in Vangorda Creek. A localized source for cadmium, cobalt, iron, lead, manganese, and zinc was indicated near station NF1 on the NFRC, as fewer guideline exceedances were observed at the next station downstream (NF2). Cobalt, manganese, and zinc concentrations were also above guidelines in some samples collected at Station X14 on Rose Creek (Table 6-14).

Pelly River

Water concentrations measured at Pelly River monitoring stations were compared upstream and downstream of both Vangorda and Anvil Creeks for analytes that are reliable indicators of FMC-related disturbance on water quality (i.e., alkalinity, sulphate, manganese, and zinc). Overall, there were no significant differences in mean concentrations of alkalinity, sulphate, and zinc among stations. Mean manganese concentrations downstream from Vangorda Creek were lower than those at the upstream Pelly River reference station P1. These data indicate FMC-related influences on water quality do not currently extend into the Pelly River.

First Nations Drinking Water Stations

2008 to 2012 water quality data were reviewed for two First Nation drinking water stations, one located on SFRC (at the Access Road culvert) and a second located on a tributary to the SFRC (at the Access Road culvert). At these stations, organic carbon, turbidity, iron, and/or manganese concentrations occasionally exceeded Health Canada's Guidelines for Canadian Drinking Water (Health Canada, 2010).

DRAFT

6.2.5 Aquatic Ecosystems and Resources

6.2.5.1 Introduction and Study Areas

Aquatic environment conditions have been studied at the FMC throughout its operation, receivership, and C&M phases. Reports describing those studies were reviewed and summarized to characterize the existing aquatic ecosystem conditions for the FMC. These conditions are summarized in the following subsections and are described in detail in Appendix 6H, the Aquatic Baseline Characterization Report. Studies that included the following information were reviewed:

- Habitat characteristics and descriptions
- Stream sediment quality
- Periphyton communities
- Benthic invertebrate communities
- Fish distributions and relative abundances

These investigations have focused primarily on watercourses within a defined aquatic environment LSA (as described in Appendix 6H) that includes streams within approximately 500 m of the FMC disturbance footprint. This area includes parts of Rose Creek (North and South forks), Faro Creek, and Vangorda Creek.

Information was also reviewed for streams within the RSA, including Rose and Vangorda Creeks downstream from the LSA, Anvil Creek, and areas of the Pelly River immediately upstream and downstream from the mouths of Anvil Creek and Vangorda Creek. Figure 6-4 shows the location of these watercourses and study areas in relation to the FMC.

6.2.5.2 Stream Habitat Descriptions

Regionally, the Rose-Anvil and Vangorda Creek watersheds affected by the FMC encompass an area of 980 km^2 and 90 km^2 and contribute 2 percent and 0.2 percent of the Pelly River watershed, respectively. The Pelly River watershed has a total drainage area of 49,000 km^2.

North Fork Rose Creek

The NFRC flows through the FMC from north of the Faro Mine Area, approximately 17 km upstream from the Haul Road (Figure 6-5). It originates in a wetland area that also drains towards the Tay River watershed. Several instream ponds are located near the headwaters. The NFRC channel ranges from segments 2 to 3 m deep and less than 5 m wide to those from 0.2 to 0.8 m deep with wider flat glades with braiding (Table 6-15) (WMEC, 2005b). Generally, the upper reaches of the NFRC are dominated by large cobble and boulder habitats that transition to finer substrates closer to the confluence with the FCD. A small lake is located on a branch flowing into the NFRC, which flows out through a steep creek that is impassable to fish (WMEC, 2005b).

Downstream from the FCD, the NFRC ranges from 8 m to 12 m wide and has gradients between 0.2 percent and 2.0 percent (Table 6-15). The stream morphology within this reach is riffle-pool, and the channel is frequently confined (de Graff, 2013). An instream pond is located just upstream from the Haul Road; this pond is approximately 250 m by 115 m in spring, but becomes smaller under lower seasonal flows (WMEC, 2005a). The depths of the pond fluctuate accordingly, declining from 4 m in the spring to approximately 1 m in late summer (WMEC, 2005b). The NFRC flows beneath the Haul Road through a constructed rock drain that is impassable to fish.

Downstream from the Haul Road, the NFRC is predominantly confined, approximately 8.5 m wide, and has gradients ranging from 0.4 percent to 1.6 percent (Table 6-15). This section of NFRC is primarily of riffle-pool morphology, with an area of cascade-pool (de Graff, 2013).

Notes:

[a] data compiled from relevant tables and figures in reports presented in Attachment A of Appendix 6H.

NA = no data available

DRAFT

Downstream from the mine Access Road, the NFRC splits into two channels (Figure 6-5). The original channel joins with the SFRC after flowing through five ponds that were constructed to recharge nearby groundwater wells that supplied process water during mine operations. Culverts are present at the upper end of these ponds, which may seasonally restrict fish movement (de Graff, 2013). The second channel, the North Fork Diversion, was constructed to allow for diversion of sediment-laden water away from the Pumphouse Pond during spring freshet (GLL, 2002).

Faro Creek

North of the FMC, where it originates, Faro Creek is relatively undisturbed. Near the FMC, the creek has been diverted from its original channel around the Faro Pit and into the NFRC (upstream from the Haul Road).

South Fork Rose Creek

The SFRC originates upstream from Dixon Lake (north of the Vangorda/Grum Area), flows across the Haul Road and mine Access Road, then flows northwest along the Access Road, eventually joining with the NFRC (Figure 6-5). Habitat has not been well characterized upstream from the Haul Road; however, the stream reach immediately above the Haul Road has a measured bankfull width of 8.6 m, a gradient of approximately 4.8 percent, and morphology that is predominantly riffle (Table 6-15) (Minnow, 2009). Further upstream, a gradient of 20 percent has been reported (GLL, 2003).

Between the Haul Road and the confluence with the NFRC (a distance of approximately 10 km), the SFRC is between 5 m and 10 m wide with gradients ranging from 0.2 percent to 2.5 percent (Table 6-15). The SFRC varies in this reach from a steeper section with boulder and cobble habitat and slightly steeper gradient (2.2 to 2.5 percent) just downstream from the Access Road to a broader valley that includes the former Freshwater Reservoir (Figure 6-5) (Harder, 1991a; AECOM, 2009). Here, the channel meanders through gravels and finer particles and has a gradient of 0.2 percent (AECOM, 2009). Downstream from the former reservoir area, the SRFC has primarily riffle habitat, followed by a wetland complex, then another section of riffle habitat that extends to the confluence with the original NFRC (AECOM, 2009). Boulders and pools provide instream cover for fish throughout most of the SFRC downstream from the access road.

Downstream from its confluence with the NFRC, the SFRC flows through the 250-m-by-40-m Pumphouse Pond, and then receives flow from the North Fork Diversion. From there, the combined NFRC and SFRC become Rose Creek and flow past the RCTA.

Rose Creek Diversion

The RCD is a 5-km constructed channel located downstream from the NFRC-SFRC confluence that diverts Rose Creek around the RCTA and subsequently offsite (Figure 6-5). In the upper two-thirds of the RCD, stream gradient is typically 0.5 percent or less, with channel widths ranging from 13 m to 15 m and relatively homogenous boulder substrate interspersed with cobbles and gravels (de Graff, 2013). The lower third of the RCD has a gradient of 5 percent, with primarily boulder substrate.

Lower Rose Creek and Anvil Creek

Downstream from the FMC, Rose Creek flows 21 km to its confluence with Anvil Creek. In this reach, the channel gradient ranges from 0.5 percent to 1.5 percent, and channel widths range from 15 m to 25 m. Substrate in this reach is predominately cobble and gravel (WMEC, 2008).

After converging with Anvil Creek, the combined watercourse flows an additional 43 km to the confluence with the Pelly River. In this reach, the channel ranges from 35 m to 80 m wide, with gradients ranging from 0.7 percent to 1.9 percent and substrate consisting mainly of boulder and cobble.

Vangorda Creek

Originating near the top of Mount Mye, northeast of the Vangorda/Grum Area, the upper sections of Vangorda Creek have channel widths ranging from 4 m to 7.4 m and gradients ranging between 3.5 percent 6.8 percent

(Table 6-15). Boulder, cobble, and gravel dominate the substrate in this reach. When it reaches the Vangorda/Grum Area, the creek is diverted around the Vangorda pit in a metal half-culvert.

Downstream from the Vangorda/Grum Area, the channel is confined and consists primarily of gravel, cobble, and boulder substrate, with a gradient of approximately 4 percent (RGC, 1996). An 8-m waterfall on the main stem of Vangorda Creek (just upstream from the confluence with West Fork Vangorda Creek) is a barrier to upstream fish movement.

West Fork Vangorda Creek originates approximately 3 km upstream from the Haul Road and has channel widths ranging from 2 m to 5.6 m and gradients between 1.5 percent and 4.8 percent (Table 6-15). The substrate of West Fork Vangorda Creek is predominantly boulder, cobble, and gravel.

Downstream from the confluence with West Fork Vangorda Creek, Vangorda Creek has a channel ranging from 7.8 m to 10 m wide and gradients between 1.5 percent and 3.9 percent, with boulder, cobble, and gravel substrate (Table 6-15).

6.2.5.3 Stream Sediment Quality

Historical Studies

Sediment quality has been monitored relative to the FMC since as early as 1973 (Rose and Anvil Creeks) and 1991 (Vangorda Creek). Historical studies have varied in terms of precise sampling locations and laboratory techniques; however, sampling methods were generally comparable amongst studies. Elevated metal concentrations were reported in samples collected downstream from the FMC based primarily on analysis of the ≤0.15-mm fraction of the sediment samples. In particular, levels of arsenic, lead, and zinc were higher than the Canadian Sediment Quality Guidelines for the Protection of Aquatic Life Probable Effect Level (CCME, 2013; Minnow, 2007). Detailed data and the location of sampling stations are shown in Appendix 6H, the Aquatic Baseline Characterization Report.

Recent Studies

The most recent sediment data collections for the FMC took place in 2007 and 2008 and are considered to represent current site conditions, because water quality has been relatively stable during this time (Appendix 6H). Generally, the sediments from the FMC area are composed of sand, gravel, or larger rocks, consistent with the fast-flowing characteristics of most streams in the area. Of samples collected in the NFRC, Rose Creek, and Vangorda Creek, silt and clay fractions represented less than 5 percent combined, except at NFRC upstream from the Access Road, where the proportion of silt plus clay was 30 percent. All samples had less than 4 percent of total organic carbon.

Sediment metal concentrations collected from reference areas of Rose and Vangorda Creeks did not exceed CSQGs in either whole sediment samples or the fraction containing fine sand and smaller particles. Sediment arsenic, lead, manganese, and zinc concentrations in mine-exposed areas were elevated relative to reference levels and guidelines, and were roughly three times higher in the fine fraction versus whole sediment samples. However, sediment samples from the same areas resulted in no observable toxic effects to the amphipod *Hyallela azteca* in laboratory tests (Minnow, 2009). Appendix H provides detailed sediment metals data according to individual sampling areas.

6.2.5.4 Periphyton and Primary Productivity

Periphyton communities were characterized in 2009 along the NFRC and the RCD (de Graffe, 2013). The group of photosynthetic bacteria known as Cyanophyta dominated the communities in the NFRC just downstream from the confluence with the FCD, but a shift to diatom (Bacillariophyceae) -dominated communities occurred closer to the Haul Road and continued downstream throughout the RCD. Cyanophyte abundance declined at stations farther downstream where water quality is known to reflect increased mine influence. Through the downstream areas of the NFRC and in the RCD, periphyton communities shifted towards greater abundance and diversity of diatoms (Bacillariophyceae).

DRAFT

The highest periphyton densities were observed in the NFRC, just downstream from the mine Access Road. In this and other areas of the NFRC, the diatom *Achnanthes minutissima* was the most commonly observed species (ranging from 4 to 72 percent). *Achnanthes*, especially *A. minutissima,* is generally considered tolerant of a wide variety of environmental conditions and, in other studies, has been observed in streams affected by mining or metals (Yoshiaki et al., 2004; Ponader and Potapova, 2007).

6.2.5.5 Benthic Invertebrate Communities

More than 23 studies of the benthic invertebrate community associated with the FMC took place between 1973 and 2010.

Historical Studies

Historical surveys took place at standardized locations biannually from 1991 until 2008 (alternating between Rose and Vangorda Creeks), to meet the requirements of FMC Water Licences. The majority of these studies used artificial substrate placements, though the studies varied in terms of numbers of replicate samples and levels of taxonomic identification. Generally, these studies suggested some differences between communities in reference areas and receiving environments in both Rose and Vangorda Creeks. However, differences did not appear to be mine-related, as data did not show patterns consistent with a deleterious effect. Appendix 6H provides more details about these studies.

Recent Studies

Benthic invertebrate surveys took place annually from 2007 to 2010 using various sampling methods and analyses. The following section summarizes the methods and results of these surveys, while full details regarding the results of sampling and community analyses are provided in Appendix 6H. Several retrospective analyses were performed as part of the current baseline summary (Appendix 6H) to investigate potential trends or patterns.

Minnow (2009) compared 2007 and 2008 benthic invertebrate community data that were collected using artificial substrates, Hess sampling, and kick net sampling. Data collected by Hess and kick net sampling were found to be more sensitive than artificial substrate studies in detecting differences between reference and mine-exposed communities. The data suggested subtle effects on benthic invertebrate community characteristics in areas downstream from mine disturbances.

In 2009, de Graff (2013) assessed benthic invertebrate communities in the NFRC and RCD using kick net sampling and subsequent data analysis through Environment Canada's Canadian Aquatic Biomonitoring Network web-portal (Environment Canada, 2013b). This approach allows investigators to compare collected community data with a regional reference community data set using existing models (in this case, the January 2010 Yukon Reference Model [Bailey and Reynoldson, 2010]). The results of this analysis suggested most FMC sampling stations were within the reference condition (i.e., minimal site-related influence), except for three stations along the NFRC; only the one of these three stations, located just downstream from the mine Access Road, was considered to be conclusively different from reference (i.e., two were inconclusive).

In 2010, Laberge (2011) used kick net sampling at the FMC and compared reference and mine-exposed communities based on various endpoints such as species richness, sample abundance, percent Ephemeroptera-Plecoptera-Trichoptera, and percent chironomids. Although no statistical comparisons were conducted, the study concluded some impairment was evident at mine-exposed areas on Rose Creek (NFRC near the mine Access Road and Rose Creek downstream from the RCD). However, it also concluded that a full community recovery was evident in lower Rose Creek, just upstream from the Anvil Creek confluence.

The results from Minnow (2009) were recently reanalyzed with data from Laberge (2011) as part of the current baseline characterization (Appendix 6H). Similar to other studies, this analysis showed community samples from (1) the NFRC upstream from the mine Access Road, (2) Rose Creek downstream from the FMC, and (3) Lower Vangorda Creek were within or only slightly different from reference conditions.

In summary, recent surveys have indicated that most benthic invertebrate communities in streams adjacent to and downstream from the FMC area are similar to those in reference areas uninfluenced by mining. Exceptions were the lower NFRC, and in Rose Creek immediately downstream from the FMC.

6.2.5.6 Fish Communities and Habitat Utilization

The following section describes existing information on the fish communities and important habitat features in streams near the FMC. These data are based on various site investigations that date back to the mid-1970s, with emphasis on more recent studies describing fish species distribution and abundance. Table 6-16 summarizes fish communities according to watercourse reaches and Figure 6-5 shows habitat features described below on Rose and Vangorda Creeks, respectively.

North Fork Rose Creek

Fish migration between the upper and lower portions of NFRC is prevented by the rock drain at the Haul Road. Upstream from the Haul Road, Arctic grayling, slimy sculpin, burbot (*Lota lota*), round whitefish (*Prosopium cylindraceum*) and longnose sucker (*Catostomus catostomus*) have all been reported. Of these, slimy sculpin are most abundant. Very few burbot and whitefish have been observed in the upper reaches of NFRC. Although few Arctic grayling have been captured upstream from the Haul Road in recent studies (de Graff, 2013; EDI, 2013a), higher numbers have been observed (WMEC, 2005b). The pond created by the rock drain appears to provide important over-wintering habitat for grayling because the pond does not freeze to the bottom (EDI, 2013b). Potential spawning habitat for grayling has been identified just upstream from this pond, as well as near the ponds at the headwaters of the NFRC.

In the NFRC downstream from the Haul Road, Arctic grayling, slimy sculpin, burbot, and round whitefish have been reported. Slimy sculpin were the most abundant, though numerous arctic grayling were also present (WMEC, 2005b; de Graff, 2013; EDI, 2013b). Arctic grayling spawning and spawning habitats have been reported both in the NFRC downstream from the Haul Road and in the vicinity of the constructed ponds just upstream from the confluence with the SFRC (WMEC, 2005b; EDI, 2013a). Fish access between the constructed ponds and the lower NFRC is restricted seasonally by culverts, but the NFRC diversion provides an alternate route for fish passage from the RCD and SFRC to the NFRC.

South Fork Rose Creek

Fish populations in the SFRC upstream from the Haul Road are separated from those in the rest of the system by culverts at the Haul Road and mine Access Road and by stream gradients of more than 20 percent upstream from the Haul Road. Both of these prevent upstream migration. Arctic grayling and slimy sculpin are the only fish species that have been captured upstream from the Haul Road (Minnow and WMEC, 2009; EDI, 2013a).

Between the mine Access Road and the confluence with the NFRC, Arctic grayling, juvenile Chinook salmon, slimy sculpin, burbot, and round whitefish have either been captured or observed, although only Arctic grayling and slimy sculpin have been found in most studies (AECOM, 2009; WMEC, 2005c). In addition to the NFRC (see above), grayling spawning has been reported at the Pumphouse Pond, located at the confluence of the NFRC and SFRC (WMEC, 2005b).

Rose Creek Diversion

Generally, habitat and fish cover in the RCD is constrained by a lack of natural stream processes, homogeneous substrates, and sparse riparian vegetation. Arctic grayling, Chinook salmon, slimy sculpin, burbot and round whitefish have been found within the RCD, but only Arctic grayling and sculpin are common. Arctic grayling reside in the upper portions of the RCD throughout the year, although some Arctic grayling from this and other areas of the FMC area migrate to the Pelly River to overwinter (EDI, 2013b). Upstream migration of Arctic grayling in the steep lower portion of the RCD was recorded by EDI (2013b). Spawning Chinook salmon were observed once in the RCD (Minnow, 2010).

Lower Rose Creek and Anvil Creek

Downstream from the FMC, Arctic grayling, juvenile Chinook salmon, slimy sculpin, burbot, round whitefish, and longnose sucker have been observed or captured. Lake chub (*Couesius plubeus*) have also been captured near the Pelly River. Slimy sculpin were the most frequently captured species in previous studies.

DRAFT

The Rose-Anvil Creek system is identified as having low to moderate suitability for Chinook salmon spawning, with suitable but limited habitat for juvenile Chinook salmon (Yukon Placer Secretariat, 2010). WMEC (2010a) also concluded that Anvil Creek would be expected to support only low numbers of spawning Chinook salmon.

Vangorda Creek

There are two significant barriers to fish passage on Vangorda Creek: (1) an 8-m waterfall located 3 km upstream from the mouth of Vangorda Creek and (2) a culvert under the mine Access Road on the West Fork of Vangorda Creek (Figure 6-5). No fish have been reported in the upstream reaches of Vangorda Creek above these barriers (RCG, 1996; Minnow, 2009). Arctic grayling, juvenile Chinook salmon, slimy sculpin, burbot, round whitefish, longnose sucker, and lake chub have all been identified in the lower reaches of Vangorda Creek. Although numbers vary from year to year, juvenile Chinook salmon have been the most abundant species captured in this reach (WMEC, 2005c; WMEC, 2008). The lower portion of Vangorda Creek has moderately suitable habitat for Chinook salmon rearing (Yukon Placer Secretariat, 2010). High densities of juvenile Chinook salmon have been reported in Lower Vangorda Creek during the spring and summer months, likely moving in from Blind Creek and the Pelly River.

6.2.6 Terrestrial Resources

6.2.6.1 Vegetation

Introduction

The following subsection describe existing information on vegetation resources in the area of the FMC. This summary is based on a review of studies that focused on the FMC and local area, as well as general information describing the region that includes the FMC. The following terrestrial assessments conducted between 1996 and 2003 provided the basis for the baseline characterization:

- Several engineering reports for which soil information was collected
- A metals contamination study of vegetation and soils within the FMC (C.E. Jones and Associates Ltd., 2003)
- A terrestrial effects study related to support closure and remediation planning (GLL, 2006a)
- A mapping of vegetation zones as part of a larger abandonment plan (RGC, 1996)
- A vegetation survey and development of a 1:20,000 scale map of vegetation associations in the LSA (GLL, 2008)
- A rare plant survey (AECOM, 2008)
- A vegetation survey around the periphery of WRDs (EDI, 2008)

In addition, localized revegetation and remediation efforts have taken place at specific sites within the FMC, which undergo regular monitoring (EDI, 2009, 2010, 2013a, and 2013b).

Information about the ecology of the region surrounding the FMC was summarized based on field verification studies and territorial references, including the following:

- Ecoregions of Yukon Territory (Smith et al., 2004)
- Soils of Yukon (YG, 2013a)
- Vegetation inventory completed in 1976 by the Montreal Engineering Company Ltd (cited in RGC, 1996).
- Vegetation classification for Sheep Mountain (Staniforth, 1998)
- The 2006 GLL terrestrial effects study

Study Areas

For the IW, the geographic region around the FMC was delineated into an LSA and an RSA (Figure 6I-2 in Appendix 6I). The LSA encompasses a 1-km buffer around all FMC facilities, infrastructure, and road corridors, resulting in a total area of 8,122.8 hectares. It comprises the area in which there is reasonable potential for effects (direct and indirect) on vegetation and soils from IW activities. The RSA was defined in order to assess effects at a broader geographical scale and to gain a better regional understanding of vegetation and soils (Figure 6I-2). The RSA includes the area where contaminants have been recorded at greater than background levels (GLL, 2006a), but is limited by the Pelly River to the west. The RSA is 58,803 hectares in area.

DRAFT

Regional Study Area Vegetation

The FMC is located within the Yukon Plateau-North Ecoregion, in the Boreal Cordillera Ecozone (Smith et al., 2004). Vegetation in the RSA is typical of boreal, sub-alpine, and alpine ecosystems of this ecozone. In the boreal ecosystems of the Yukon Plateau, forests are dominated by open black spruce stands with moist moss or drier lichen understories. White spruce, occasionally with trembling aspen or lodgepole pine, grows on warmer and better-drained soils (Smith et al., 2004). The sub-alpine ecosystems, various shrubs and an abundance of lichens dominate the tundra. Low-growing ericaceous shrubs, prostrate willows, and lichens dominate the alpine. Talus slopes are also common at these high elevations, and are typically covered by crustose lichens. Where forest fires have occurred, *P. tremuloides* and balsam poplar (*Populus balsamifera*) are common.

Local Study Area Vegetation

Vegetation Associations

A 2007 vegetation study by GLL provides the most detailed ecological information for the LSA to date (GLL, 2008). This study identified 13 vegetation associations within the LSA, based on 17 ground plots and 59 visual plots (GLL, 2008; Table 6-17). The following paragraphs briefly discuss this study, including the total area of each association relative to the LSA (Table 6-17), and describe the characteristics of the associations. Attachment 6I-2 in Appendix 6I provides a complete discussion of the associations.

TABLE 6-17
Faro Mine Closure Project Local Study Area Vegetation Associations Baseline Area [a]
Vegetation and Soils Baseline – Faro Mine Interim Works

Vegetation Association	LSA Baseline Area	
	Area (hectares)	Percent of the LSA
Sedge/Willow	54.6	0.7
Willow/Sedge	254.7	3.1
Willow/White Spruce	326.0	4.0

[b] Project Footprint represents the disturbed areas an infrastructure of the FMC. This is not a vegetation association, but provides detail on the relative occurrence of these features within the LSA.

DRAFT

Sedge / Willow (S/W)

This wetland association is common in both boreal and subalpine zones, occurring in depressions and drainages where water collects. It covers approximately 0.7 percent of the LSA. A mixture of sedge and graminoid species dominates these areas, with water sedge (*Carex aquatilis*) being the most common. Willows, dwarf birch, and some white spruce occur around the edges of wetlands, and sphagnum mosses (*Sphagnum* spp.) are abundant throughout.

Willow / Sedge (W/S)

Approximately 3.1 percent of the LSA consists of willow / sedge associations, which are linked with standing or flowing water, along lakes, pond, and creek drainages. It is a common riparian association found at a variety of elevations throughout the LSA. The shrub layer is dominated by various willow species that include tea-leaved willow (*Salix planifolia*) and Athabasca willow (*Salix athabascensis*). Water sedge are common below the shrub layer, along with various wetland mosses.

Willow / White Spruce (W/Sw)

This vegetation association is most frequently found in riparian drainages along creeks and rivers in the boreal zone, and makes up approximately 4.0 percent of the LSA. An open canopy of mature white spruce is scattered amongst a well-developed shrub layer that includes a variety of willows and dwarf birch. The groundcover is most often a combination of shrubs, sedges, lichens, and mosses.

Willow / Dwarf Birch (W/B)

This riparian association comprises approximately 2.2 percent of the LSA. It is widespread in the lower elevations, typically occurring on gentle to steep slopes near drainages or open water in the boreal zone. Willows and dwarf birch are co-dominant, with the occasional white spruce and Labrador tea (*Ledum groenlandicum*), with sparse grasses, and forbs.

Dwarf Birch / Willow (B/W)

The birch / willow association makes up approximately 2.9 percent of the LSA. It is characteristic of slopes at higher elevations in the subalpine zone and. While dwarf birch is the dominant shrub, willow species, Labrador tea, shrubby cinquefoil (*Dasiphora fruticosa*), and bog billberry (*Vaccinium uliginosum*) are also common. A variety of ground shrubs are found in the understory, though lichens dominate the groundcover.

Dwarf Birch / Lichen / Subalpine Fir (B/L/Fa)

This vegetation association is largely a subalpine and alpine community, typical of areas with rock outcrops and windswept ridges. This association makes up approximately 4.4 percent of the LSA and is dominated by dwarf birch (0.5 m tall) and lichen species. Krumholtz subalpine fir is scattered throughout the association with bearberry (*Arctostaphylos uva-ursi*), crowberry (*Empetrum nigrum*), bog bilberry and mountain avens *(Drayas* spp.) also present.

Dwarf Birch / Subalpine Fir (B/Fa)

This association is a subalpine community that occurs on well-drained soils and slopes at the upper elevations, and comprises approximately 3.4 percent of the LSA. Dwarf birch is the dominant cover species, with subalpine firs scattered throughout the area. Willow species, Labrador tea, common juniper (*Juniperus communis*), and white spruce are present but infrequent. Low-growing shrubs include bog bilberry, bearberry, crowberry and mountain cranberry (*Vaccinium vitis-idaea*). Graminoid and lichen species are present in the groundcover.

White Spruce / Willow (Sw/W)

The White Spruce/Willow association is the most frequent vegetation association within the LSA. It occurs in both the boreal and subalpine zones on various upland and lowland slopes, and totals approximately 45 percent of the LSA. White spruce dominates the canopy, with the occasional subalpine fir. The shrub layer is dominated by willow species (1 m tall) with a low percentage of dwarf birch, Labrador tea, and shrubby cinquefoil. Dwarf shrubs include bog bilberry, bearberry, net-veined willow (*Salix reticulata*), and crowberry. Common horsetail (*Equisetum*

arvense) and various bluegrass species are also frequent. The forest floor is frequently carpeted by stair-step moss (*Hylocomium splendens*), reindeer lichens (*Cladina rangifera*), and pelt lichens (*Peltigera* spp.).

White Spruce / Feathermoss (Sw/Fm)

This association occurs most frequently on well-drained alluvial flats and on mesic sites in lowland areas throughout the boreal zone. It totals approximately 1.3 percent of the LSA. The tree canopy comprises dense white spruce, with a sparse shrub understory including various willow species, dwarf birch, shrubby cinquefoil, and low shrubs. A thick carpet of feathermoss (*Pleurozium shreberi*) is prevalent throughout.

Pine (Pl)

The pine association is dominated by a tree canopy of lodgepole pine, predominantly occurring in upland areas around the Grum and Vangorda Pits in the boreal zone. It makes up approximately 0.6 percent of the total LSA. In these areas, there are a few scattered white spruce, and the shrub layer is dominated by Sitka alder (*Alnus viridis* ssp. *sinuata*) and Scouler's willow (*Salix scouleriana*). The low shrub layer is composed of Labrador tea, prickly rose (*Rosa acicularis*), and buffaloberry (*Sheperdia canadensis*). The ground cover is minimal consisting of bog bilberry, crowberry, bunchberry (*Cornus canadensis),* bearberry, and twinflower (*Linnaea borealis*).

Mixed Coniferous-Deciduous (Mx)

The mixed coniferous-deciduous forest association is typically established on well-drained sites over a broad elevation range, and makes up approximately 8.4 percent of the LSA. These areas consist of a mix of coniferous and deciduous trees, including white spruce, trembling aspen, balsam poplar, and lodgepole pine. Soil moisture and nutrient richness determine the persistence of subalpine fir and or black spruce. In these areas, forest fires have resulted in a mixed-seral stand, where trees of various species make up both the canopy and the understory. Low-growing shrubs such as bog bilberry, crowberry, and Labrador tea are also present.

Deciduous Forests (Dd)

Approximately 3.4 percent of the LSA is a deciduous vegetation association occurring on sites regenerating from a disturbance (e.g., fire or human development). These sites tend to be located on well-drained slopes and are rich in species diversity. Most often occurring in the boreal zone, trembling aspen dominates, followed by balsam poplar on moister sites. Tall shrubs include willow species, Sitka alder, shrubby cinquefoil, Labrador tea, dwarf birch, buffaloberry and prickly rose. The ground layer is often a diverse mix of bearberry, mountain cranberry, blueberry willow (*Salix myrtilifolia*), bunchberry, bastard toad-flax *(Geocaulon lividum*), fireweed (*Epilobium angustifolium*), northern grass-of-parnassus (*Parnassia palustris*), and twin flower.

Graminoid (Gr)

The graminoid association is found in lowland areas in the boreal zone, and makes up about 0.6 percent of the total LSA. This association generally occurs in areas re-established from seed mixtures through revegetation programs at the FMC. Grasses include a variety of brome (*Bromus* spp.), reedgrass (*Calamagrostis* spp.), and fescue species (*Festuca* spp.). Sedge species, fireweed, and wormwood (*Artemesia* spp.) are also present.

Species at Risk and Rare Plants

Species at risk (SAR) are plant species considered to be extirpated, endangered, threatened, or of special concern by the federal Committee on the Status of Endangered Wildlife in Canada (COSEWIC). The federal *Species at Risk Act* (SARA) regulates SAR and legislates activities within the critical habitats of those species (Environment Canada, 2013c).

The SAR in YT are listed based on their COSEWIC standing (YG, 2013a). There are currently three plant species at risk and one under review in Yukon (Table 6-18).

DRAFT

TABLE 6-18
Plant Species at Risk Potentially Occurring in the Regional Study Area
Vegetation and Soils Baseline – Faro Mine Interim Works

Species	Common Name	COSEWIC (date listed)	SARA	NatureServe Ranking of Status in YT
Draba yukonensis	Yukon draba	Endangered (November 2011)	Not listed	S1
Micranthes spicata	spiked saxifrage	Threatened (May 2013)	Not listed	S2
Carex sabulosa	Baikal sedge	Threatened (May 2005)	Threatened	S2
Podistera yukonensis	Yukon podistera	Under Review (November 2014)	Not listed	S2

Rare plants are plant species that are uncommon or infrequently encountered, and includes both species whose status is not known and species that are of conservation concern. A registry of rare plants is maintained in Yukon by the Yukon Conservation Data Centre, including those that are termed as reportable (i.e., for which the Conservation Data Centre is actively seeking records of observations. Rare plants include, but are not limited to, SAR.

Three surveys that directly or indirectly targeted rare plants have been completed within the LSA: (1) A rare plant survey by GLL in 2008 focused on areas that are to be disturbed by rock resloping in the overall FMRP, (2) A 2007 vegetation study of the LSA that focused on vegetation associations, and (3) a vegetation study by EDI (2008) that described vegetation types at the FMC. No rare plant species listed by COSEWIC or SARA were found in these three plant surveys.

Overall, there is limited potential for rare species to be present in the LSA or the RSA. The existing footprint of the FMC (approximately 20 percent of the total LSA) has been disturbed considerably through mining activities, roads, historical trails, and waste rock storage areas. As a result, there is minimal soil accumulation, which has a limited capacity to establish vegetation. Furthermore, the classified non-footprint vegetation associations in the LSA are typical of much of the central Yukon and do not generally host rare species.

Introduced Plant Species

Because of the amount of disturbance in the FMC footprint, there is a potential for introduced plant species to be present and to further establish themselves in the future. Previous FMC vegetation surveys identified seven introduced species (YG, 2013c; Attachment 6I-1-4 in Appendix 6I). These introduced species were then further classified based on their "invasiveness" according to the Yukon Invasive Plant List (YG, 2013c; Attachment 6I-1-3 in Appendix 6I). Invasiveness rankings are detailed in Appendix 6I.

The following introduced species are known to currently occur within the LSA:

- Narrowleaf Hawk's beard (*Crepis tectorum*) – present (AECOM, 2008; EDI, 2008) and highly invasive
- Kentucky bluegrass (*Poa pratensis*) – present (EDI, 2008), but may not replace native species or change ecosystem function
- Giant bentgrass (*Agrostis alba*) – present (EDI, 2008), but currently not invasive in the Yukon
- Red fescue (*Festuca rubra*) – present (AECOM, 2008), but currently not invasive in the Yukon
- Field pennycress (*Thlaspi arvense*) – present (AECOM, 2008), but currently not invasive in the Yukon
- Herb sophia (*Descurainia sophia*) – present (EDI 2008, AECOM 2008), but has not shown to persist in Yukon
- Biennial cinquefoil (*Potentilla biennis*) – present (EDI, 2008), but not likely to persist in the Yukon

Contaminant Concentrations in Vegetation

Background

Past operations at the FMC have resulted in elevated metal concentrations in vegetation in the LSA and RSA, compared with territorial background and reference site concentrations (C.E. Jones and Associates Ltd., 2003; GLL, 2006). Studies in 2002 (C.E. Jones and Associates Ltd., 2003) indicated that elemental deposition was a result of mining operations; however, no information was provided about its timing. The terrestrial effects assessment completed by GLL (2006) measured elemental concentrations in vegetation and lichen to identify sites with the highest metals concentrations and sites where these concentrations were likely to continue to increase. Unfortunately, no pre-mining information is available; therefore, information collected from 2004 to 2005 was compared with reference sites around the Swim Lakes, approximately 9 km east of the Vangorda/Grum Area.

To consider airborne deposition of metals, natural soil mineralization, and large landscape processes, lichens were targeted as the indicator species by GLL (2006). Lichens depend entirely on airborne materials and precipitation for nutrients and are largely unaffected by mineralization of the underlying soils. A brief discussion of the trends in metal concentrations in lichens is provided herein, with a more detailed account provided in Appendix 6I.

Metals Concentrations in Lichen

Significantly Elevated Concentrations

Compared with the Swim Lake reference sites and YT reference levels, there are significantly elevated concentrations of lead and arsenic in the lichen samples from the LSA. In mine-affected areas, concentrations of lead and arsenic were up to 450 times and 250 times higher than reference sites, respectively. In total, approximately 76,900 hectares of the RSA showed lichen lead concentrations at least 3 times greater than reference sites in the Swim Lake area.

Moderately Elevated Concentrations

Concentrations of zinc, copper, iron, silver, and thallium were moderately elevated in the LSA, compared with reference sites. In mine-affected areas, maximum lichen concentrations for these metals ranged from 15 to 75 times greater than Swim Lake maxima. Equivalent-to-reference concentrations were generally reached at distances of 0 to 2 km from the Vangorda/Grum Area, northeast along the exposed (mine-side) slopes of Mount Mye, and southwest along the exposed slopes of Rose Mountain. Elevated elemental levels generally extend northeast along North Fork Rose Creek, north up and past Mount Aho, and northwest down the Rose Creek Valley.

Minimally Elevated Concentrations

Concentrations of barium, chromium, mercury and nickel were three to nine times greater in mine-affected areas than in reference sites. The zones of contamination for these elements were also generally smaller than those of lead or other elements considered highly or moderately elevated, relative to reference levels. Although selenium concentrations near the mine were 25 times the Swim Lake maximum, this element is considered to be minimally elevated because the area affected by elevated concentrations is very small.

Marginally Elevated Concentrations

There is some evidence of elevated concentrations of antimony, cadmium and cobalt in lichens within mine-affected areas when compared to reference sites. These recorded concentrations were either within reported YT reference ranges (antimony and cobalt) (Gamberg, unpublished) or were similar to levels detected in the study area that to not appear to be related to the FMC (cadmium) (GLL, 2006a).

Metals Concentrations in Vegetation

The results of studies of metals concentrations in vegetation by GLL (2006a) and AECOM (2009) provide the following trends in vegetation metals content:

High Elevation Relative to Reference Levels – Lead

Lead concentrations for all plant species groups studied were greatly elevated in the area immediately adjacent to the tailings impoundment/mill complex, which indicates the mine has affected lead concentrations in vascular plants and mushrooms, as well as in lichens and soils. Lead levels near the mine ranged from 2.5 (horsetails) to 410 (tree sap) times Swim Lake reference means. Willows, grasses, forbs, horsetails, mushrooms, and bear root all had lead levels greater than Swim Lake ranges.

Moderate Elevation Relative to Reference Levels – Zinc

Zinc levels were significantly elevated in berries, willows, and forbs collected next to the tailings impoundment/mill complex. The magnitude of elevation ranged from three times the Swim Lake reference mean (berries) to 20 times (forbs). In most zones affected by the mine, zinc levels in forbs, willow, mushroom, and bear roots exceeded documented YT background ranges (Gamberg, unpublished).

Low Elevation Relative to Reference Levels – Copper, Nickel, Silver, Mercury, and Thallium

Copper, nickel, silver, mercury, and thallium had isolated occurrences of significantly elevated concentrations compared to Swim Lake reference levels. Concentrations ranged from approximately two (copper in willows) to nine times (silver in willows and thallium in Labrador tea) those of Swim Lake reference means. There is no conclusive evidence that the elevated nickel concentration in lichens can be attributed to the presence of the FMC. The maximum nickel concentrations are within published YT background ranges.

6.2.6.2 Wildlife

Introduction

The collection of wildlife baseline data for the FMC area dates back to the 1970s, and includes a variety of local and regional studies. The description of wildlife and wildlife habitat in the following section was compiled based on field studies and previous reports, including recent local studies conducted on behalf of AAM as well as regional studies conducted by EY:

- A winter tracking survey (Ecological Logistics & Research Ltd. [ELR], 2012)
- A waterfowl study (ELR, 2013)
- A log of FMC incidental wildlife observations that has been maintained by site C&M contractors (AAM, 2013; unpublished data)
- An early winter moose survey (Clarke et al., 2012)
- A thinhorn sheep lambing survey (EY, 2013; unpublished data)

The following wildlife reports and studies were completed before AAM assumed responsibility for the site in 2009, and were also reviewed to develop the current description:

- A wildlife baseline study report (Gartner Lee Limited, 2008a)
- A thinhorn sheep summary report (Gartner Lee Limited, 2008b)

Several wildlife information datasets were also reviewed to contribute to baseline information, including breeding bird survey data, EY Wildlife Key Areas (WKA) (EY, 2009), and EY harvest records. SAR resources, including the Yukon Conservation Data Centre, the *SARA* Registry, COSEWIC, and NatureServe Canada, were also examined to identify and characterize potential or known SAR within and around the LSA and RSA. These study areas were established to characterize wildlife and wildlife habitat for the FMC and its surrounding area.

Further details about wildlife baseline conditions are provided in Appendix 6J.

Wildlife Local and Regional Study Areas

The wildlife LSA encompasses the area defined by the existing disturbance footprint, with the addition of a 1-km buffer, which represents an immediate zone of potential project effects. The LSA has a total area of 81.2 km^2 (Figure 6J-2 in Appendix 6J). The FMC footprint area is characterized by roads, mine infrastructure, engineered

waterbodies (i.e., pits and ponds), and patches of regenerating vegetation communities. Regenerating areas transition to boreal woodlands, as well as to subalpine and alpine ecosystems that are adjacent to the footprint area.

The wildlife RSA was delineated to better describe wildlife populations and assess potential effects at a broader geographical scale. The RSA was defined as an area extending 15 km beyond the FMC footprint, resulting in a total area of 1,530 km^2 (Figure 6J-2 in Appendix 6J).

Species at Risk

Several SAR have been identified as occurring or having the potential to occur within the LSA or RSA. These species are listed under *SARA* (Government of Canada, 2013) or the Territorial *Wildlife Act* (YG, 2013), or are designated by COSEWIC (2010). Table 6-19 summarizes SAR that are either confirmed or potentially occurring in the LSA and RSA.

TABLE 6-19
Species at Risk That Are Confirmed or Potentially Occurring in the LSA and RSA
Faro Mine Interim Works

Species	Confirmed or Potentially Occurring in LSA	Confirmed or Potentially Occurring in RSA	Yukon *Wildlife Act* Status	*SARA* Status	COSEWIC Status
Mammals					
Woodland caribou	Confirmed	Confirmed		Special Concern	Special Concern

Rusty Blackbird *Euphagus carolinus*	Potential	Potential		Special Concern	Special Concern

DRAFT

Abundance and Distribution of Major Wildlife Species

Moose

Moose are an important species in the Yukon. First Nation and Yukon residents value moose as a big game species, which they rely on for subsistence. Moose are ranked as secure in the Yukon (Canadian Endangered Species Conservation Council, 2011).

Important habitats for moose include riparian areas adjacent to rivers, marshes, ponds, and meandering streams; burned or logged areas; and treeline and subalpine areas with abundant shrub forage species. Moose use a range of habitats, from valley bottoms to the subalpine zone within both the LSA and RSA. There are no moose WKAs in the LSA or RSA, and the nearest WKA (moose late-winter range) lies in the Ross River Valley, 45 km east of the Vangorda/Grum Area.

The most recent population data available for moose in the FMC area was collected during a 2011 early winter moose aerial survey by EY that covered an area of 6,470 km^2 (Clarke et al., 2012) and overlaps the RSA. The study results indicated high-quality moose habitats are located throughout the study area, with a high average moose density of 364 moose per 1,000 km^2 compared to the territory-wide average of 157 moose per 1,000 km^2 (Clarke et al., 2012). Despite this, a trend analysis indicated the average moose density in the region had declined from the 2004 estimate of 397 moose per 1,000 km^2. The total moose population within the survey area was estimated to be 2,352 individuals ±23 percent, which was lower than the 2004 estimate of 2,450 ±27 percent.

Survey results suggested that Game Management Subzone (GMS) 4-45 (which overlaps the western portion of the LSA) had the highest average moose harvest rate of all the Yukon (Clarke et al., 2012; EY, 2013a). They also suggested the population within GMS 4-45 has declined at an annual rate of two percent from 2004 and a total of 28 percent since 1997 (Clarke et al., 2012). There are moderate to high hunting pressures on moose within the RSA in areas adjacent to the FMC (some of which can be accessed from the FMC Access Road).

Moose were the second most frequently observed species recorded in the FMC Incidental Wildlife Log. They were observed throughout the LSA in every month except November, with the most observations during the summer months (AAM, 2013; unpublished data). Most observations were recorded in the Faro Mine Area, including in the vicinity of the parking lot and guardhouse, the ETA, CVD Pond, ID Pond, Rose Creek, RCD, Faro Diversion, and generally in the Down Valley area. Moose were also observed along the Haul Road and periodically in the Vangorda/Grum Area. Detections of moose within the LSA during the 2012 winter tracking survey revealed that moose use nearly all habitats types found in the LSA, but that their habitat use is focused around riparian areas of Rose Creek and other riparian draws (ELR, 2012).

Thinhorn Sheep

There are two subspecies of thinhorn sheep in the Yukon: Dall's (*Ovis dalli dalli*) and Stone's (*Ovis dalli stonei*); the southern Yukon is the northern extent for the latter. Sheep in the FMC area are referred to as 'fannin' and have an intermediate pelage colour between the darker Stone's sheep and the lighter Dall's sheep, which may be the result of crossbreeding (Worley et al., 2004). Fannin sheep are reported to range only in the Pelly and Ogilvie mountains. Neither Stone's nor Dall's sheep have been listed by COSEWIC.

Fannin sheep have been observed in the FMC from May to November, and most regularly in the Vangorda/Grum Area (AAM, 2013; unpublished data). Several sheep were also observed incidentally in this area during September 2013 waterfowl surveys (ELR, 2013), and included a large group of rams, ewes, yearlings, and lambs. Beyond the FMC, most individual sheep have been observed on Mount Mye, Sheep Mountain, and Rose Mountain, with some observed on Mount Kulan and the Yukon Plateau, and in the Blind Creek and Swim Lakes areas (Gartner Lee Limited, 2008b). Thirty-one thinhorn sheep WKAs occur within the RSA and include mineral licks, seasonal ranges, and migration corridors; four of these occur within the LSA (Figure 6J-4 in Appendix 6J.

Although 2011 aerial survey results for the regional thinhorn sheep population suggest it is stable, the study noted that hunting pressures have increased in the area (particularly in GMS 4-45) because of increased access (EY, 2011). Furthermore, EY (2011; unpublished data) reported the primary management concern for the surveyed population at that time was an increase in mineral exploration activities in the area.

Caribou

All woodland caribou of the Northern Mountain population are ranked by COSEWIC and are listed under Schedule 1 of *SARA* as a species of special concern (Table 6-19).

The annual ranges of four woodland caribou (Northern Mountain population; *Rangifer tarandus caribou*) herds occur in the Faro region, including the ranges of the Tay River, Finlayson, Moose Lake, and Pelly herds (EY, 2012). Only the annual range of the Tay River caribou herd overlaps the RSA and for this reason caribou observed within the LSA most likely belong to the Tay River herd (Alain Fontaine, personal communication, 2013). The Tay River herd was last surveyed in 1996 by EY, at which time the population was estimated to be 3,750 individuals. The population is currently considered to be stable (EY, 2012).

Woodland caribou feed primarily on ground lichens and tend to use habitats in alpine and subalpine elevations that provide these forage species and vantage points to watch for predators. Winter ranges, migration corridors, and rutting areas used by woodland caribou can be habitats identified by EY as WKAs; however, there are no caribou WKAs within the LSA or RSA.

Caribou have infrequently been observed at the FMC according to the FMC Incidental Wildlife Log records (AAM, 2013; unpublished data). Over the 5 years of wildlife reporting to date, there have been 13 recorded caribou observations onsite during the months of May, June, or July. Most observations have been recorded near the Haul Road, the Rose Creek, Faro Creek Diversion and ETA, as well as near the Grum Dump meteorological station.

Grizzly Bear

Grizzly bear (*Ursus arctos*) are often considered to be a keystone species. They are referred to as ecological indicators, as they are critical to ecosystem diversity and integrity. The western population of grizzly bears is listed by COSEWIC as a species of special concern, but currently has no protection status under *SARA*.

The existing project footprint has limited habitat that is suitable for grizzly bear life requisites because of the disturbed nature of many areas. Reclaimed areas that support the growth of grasses and shrubby subalpine hillsides, however, likely provide some vegetation species for foraging (e.g., berry-producing shrubs and *Hedysarum sp.*), as well as potential prey items (e.g., ungulates and Arctic ground squirrels).

FMC Incidental Wildlife Log records include 60 grizzly bear sightings and an additional 37 bear (i.e., either black or grizzly bear) sightings from May 2009 to July 2013 (AAM, 2013; unpublished data). Pooled for all years, grizzly bears were sighted between April and October—most frequently in May (n = 21), followed by June (n = 17). Grizzly bears were consistently observed during May in all 5 years of observation records, while the timing of sightings was not consistent across observation years. Of the 60 grizzly bear records, 4 observations were of sows with either one, two, or three cubs, accounting for a total of 12 of the individual observation records. Over half of the grizzly bear observations occurred in the Faro Mine Area, including areas in proximity to the CVD Pond, RCTA and the Faro Pit and Diversion. The remaining observations occurred in the Vangorda/Grum Area (e.g., Grum Pit, Vangorda Flume, and SPP areas) and along or near the Haul Road.

Furbearers

Trapping furbearers is an important economic activity in much of the Yukon. The FMC falls within a large group trapping concession that is approximately 35,400 km^2 in area. Several furbearing species have been observed at the FMC (ELR, 2012; AAM, 2013; unpublished data):

- American marten (*Martes americana*)
- Ermine (short-tailed weasel; *Mustela erminea*)
- Mink (*Mustela vison*)
- Least weasel (Mustela nivalis)
- Fisher (*Pekania pennanti*)
- Wolverine (*Gulo gulo*)
- Canada lynx (*Lynx canadensis*)
- Red squirrel (*Tamiasciurus hudsonicus*)

Among these species, the wolverine is listed as special concern by COSEWIC but is not currently listed under *SARA*. The wolverine is believed to be stable within the Yukon (Yukon Conservation Data Centre, 2011). COSEWIC has indicated the Canada lynx is not at risk and the remaining furbearer species listed above have not been listed by COSEWIC. Appendix 6J provides more detailed information summarizing furbearer occurrences in the LSA.

Canids

Grey wolf (*Canis lupus*), coyote (*Canis latrans*), and red fox (*Vulpes vulpes*) occur throughout the Yukon in a variety of habitats. They are currently not listed by either COSEWIC or *SARA*. These canid species were all detected during the 2012 winter tracking survey at low densities (ELR, 2012). Wolf and fox sightings were the most common records among furbearing species in the FMC Incidental Wildlife Log records (AAM, 2013; unpublished data). Canids are known to use roads and linear corridors to move through the landscape. This behaviour was observed at the FMC (e.g., tracks observed along the Haul Road); however, wolf tracks were also observed in forested stands with pine and mature white spruce (ELR, 2012).

Avifauna

The areas surrounding the Town of Faro and the FMC offer suitable habitats for a wide range of avian species, including waterfowl, shorebirds, passerines, upland game birds, and raptors. Many species have been observed in the FMC area (EY, 2003); the species most commonly observed while conducting avian surveys included white-winged crossbill (*Loxia leucoptera*), dark-eyed junco (*Junco hyemalis*), common raven (*Corvus corax*), Swainson's thrush (*Catharus ustulatus*), hermit thrush (*Catharus guttatus*), gray jay (*Perisoreus canadensis*), and American robin (*Turdus migratorius*) (USGS, 2013; CWS, 2007; Tables 6J-7 and 6J-8 in Appendix 6J.

Migratory bird species are protected under the *Migratory Birds Convention Act,* and the Yukon *Wildlife Act* has provisions for non-migratory species. Specifically Section 17 of the latter refers to the protection of non-migratory species' eggs and nests. The following avian SAR have been observed at the FMC:

- Bank swallow - Threatened (COSEWIC)
- Harlequin duck - Special Concern (COSEWIC and *SARA* Schedule 1)
- Horned grebe - Special Concern (COSEWIC)
- Trumpeter swan - Specially Protected (Yukon *Wildlife Act*)

A colony of bank swallows has been observed using a small sandy cliff in a roadside cut bank north of the ID Pond (GLL, 2008a). The olive-sided flycatcher (*Contopus cooperi*) has not been observed onsite but has been recorded as occurring in the area and is associated with open areas containing, or adjacent to, mixed or coniferous mature forest with snags or tall live trees (COSEWIC, 2007). It is listed by COSEWIC and under Schedule 1 of *SARA* as a threatened species.

Waterfowl and shorebird habitats in the LSA are limited to man-made pits and ponds onsite and the altered habitats of the NFRC and the RCD. FMC Incidental Wildlife Log records (AAM, 2013; unpublished data) and a recent waterfowl survey (ELR, 2013) indicate that waterfowl and shorebirds visit the FMC during the ice-free season and have been observed to be diving, foraging, dabbling, drinking, and resting in the aquatic habitats onsite (see Appendix J). Forage availability (e.g., benthic invertebrates, and riparian and aquatic vegetation) varies among the pits and ponds, as do the concentrations of heavy metals in water, sediment, and in the tissues of potential food sources (see Appendix J). Results from total metal content analyses of sediments and aquatic and riparian vegetation indicate some sample sites (e.g., ID Pond, Little Creek Pond and CVD Pond) provide more potential for contaminant availability and uptake than other sites (e.g., SPP, Slot Cut in Grum Pit).

Small Mammals

Small mammals are ecologically important, as some species are considered furbearers (i.e., red squirrels) but most are prey species for land-based carnivores and raptors and support an ecosystem food web. Small mammal species are defined here to include snowshoe hare and porcupine, in addition to species (e.g., small rodents and squirrels) typically included within this group.

DRAFT

Several small mammal species have been observed within the LSA (GLL, 2006; AAM, 2013; unpublished data):

- Northern red-backed vole (*Clethrionomys rutilus*)
- Common shrew (*Sorex cinereus*)
- Heather vole (*Phenacomys intermedius*)
- Deer mouse (*Peromyscus maniculatus*)
- Siberian lemming (*Lemmus sibiricus*)
- Snowshoe hare (*Lepus americanus*)
- Porcupine (*Erethizon dorsatum*)
- Red squirrel

Amphibians

Five species of amphibians are known to occur in YT; however, based on their distribution, the wood frog (*Rana sylvatica*) is the only one likely to occur in the FMC area (EY, 2005). One wood frog was observed by a field crew in the Vangorda/Grum Area during a vegetation classification survey in July 2007 (Gartner Lee Limited, 2008a). Wood frogs are not at risk at the territorial or federal level and are not anticipated to be abundant at the FMC. There are no reptile species found within the Yukon (Canadian Amphibian and Reptile Conservation Network, 2012).

Invertebrates

The Canada darner (*Aeshna canadensis*), a dragonfly species, is ranked as critically imperiled in the Yukon by NatureServe (2013) and is not listed by COSEWIC. A WKA polygon for this species is located in the Swim Lakes area, approximately 8.5 km east of the LSA boundary. Specimens of this species have not been observed in other habitats appropriate for the species elsewhere in southern Yukon (Randi Mulder, personal communication, 2013).

FMC Wildlife Habitat Summary

The FMC occurs primarily within mid- to high-elevation boreal forest, which is dominated by white spruce with isolated stands of lodgepole pine and with shrub species in the understory. Subalpine vegetation communities are dominated by scrub birch, subalpine fir, white spruce, some lodgepole pine, and lichen. Above the treeline, alpine areas are characterized by rock and bluffs, low ericaceous and willow shrubs, and an abundance of terrestrial lichen (YEWG, 2004). These ecosystems surround the FMC and are in contrast to the footprint area, which is characterized by roads, mine infrastructure, engineered or altered waterbodies, and patches of regenerating vegetation communities.

Despite the altered state of the FMC, many wildlife species have been observed using LSA habitats to breed (e.g., passerine species that nest in shrubs or adjacent forest stands), migrate (e.g., waterfowl rest on pits and ponds; Fannin sheep traverse and rest in the Vangorda/Grum Area), and forage (e.g., moose feed on shrubs in riparian areas). Waterfowl and shorebird habitats within the LSA are dominated by man-made pits and ponds at the FMC; waterfowl use these habitats during migration periods and, to a lesser extent, through the summer.

Moose use a variety of habitats from valley bottoms to the subalpine zone within the LSA and RSA. Within the LSA, moose have been observed predominantly in the western portion of the FMC and in riparian draws of the Rose and Vangorda Creek systems.

Woodland caribou feed primarily on ground lichens in alpine and subalpine habitat and infrequently pass through the site. Along with other wide-ranging species such as wolverine and grizzly bear, caribou may travel through the FMC as part of larger range that includes neighbouring mountains and valleys traveled to fulfill a range of life requisites. The FMC woodlands provide year-round habitat for some mustelid species, including American marten, ermine, and mink, as well as small mammals and upland game birds. Canids have been observed at the FMC and make use of both disturbed and undisturbed areas.

The disturbed nature of the FMC footprint limits the presence of key avian and wildlife habitats within the LSA to the sand cliffs such as those north of the ID Pond (that could be used by bank swallows), the thinhorn sheep WKA movement corridors that traverse the Vangorda/Grum Area, and the portion of a thinhorn sheep WKA winter

range that extends into the LSA from the slopes of Mount Mye. Within the RSA, WKAs have only been identified for thinhorn sheep and include winter range, spring lambing, and early winter rut areas and movement corridors.

6.3 Socio-economic Conditions

This section provides an overview of the baseline conditions related to the socio-economic values and their indicators for the FMC. For the full report on the results and data pertaining to the socio-economic conditions, including methodology and references, refer to Appendix 6L, the Socio-economic Conditions Report, and Appendix 6K, Historical Resource Impact Assessment. The baseline was determined from 2009 onwards, as 2009 was the year that the co-proponents took over the responsibility of the FMC from the receivers. The baseline conditions serve as a benchmark for measurement of potential changes in VCs predicted to occur as a result of the IW. The following Affected First Nations impacted by the FMC were identified in the Devolution Transfer Agreement:

1. RRDC (based in the community of Ross River; Traditional Territory to be all of Kaska Traditional Territory, encompassing FMC)
2. LFN (based in the community of Watson Lake; Traditional Territory to be all of Kaska Traditional Territory, encompassing FMC)
3. KDC (umbrella organization representing interests of Kaska people in Yukon and BC; Traditional Territory encompassing FMC)
4. SFN (based in the community of Pelly Crossing; the FMC is upstream of its Traditional Territory)

The Town of Faro was established because of the FMC in 1969, and it is the closest community to the FMC.

Consequently, the socio-economic baseline conditions are described for the Town of Faro, RRDC (primarily in Ross River), LFN (primarily in Watson Lake), KDC, and SFN (primarily in Pelly Crossing). These were chosen as representative of both those Affected First Nations identified in the Devolution Transfer Agreement (Government of Canada, 2001) and the community (Town of Faro).

Secondary data related to all VCs were collected for each of these First Nations and communities, wherever possible. Secondary data as it relates to the KDC is represented through their members, who are citizens of the RRDC or the LFN. Data collection centered on understanding the conditions of individuals, communities, and businesses as they relate to the following VCs:

- Economy and employment
- Community stability and well-being
- Infrastructure and services
- Land use and access
- Culture and heritage

For each First Nation/community, the conditions of the listed VCs were determined through secondary data, including statistics from YG and Statistics Canada, and from information gathered from community and First Nations websites and documents. Socio-economic data are generally less frequently available compared to environmental data. Best efforts have been made to gather relevant data from 2009 on, for purposes of describing community conditions; however, not all Census data from 2011 have been released. Available data from the 2011 Census were used, but data from the 2006 Census comprise most of the description of the VCs for each community.

6.3.1 Economy and Employment

The local economy (labour force by industry) in the region has historically been heavily reliant on resource development, with mining and oil and gas extraction representing the second largest source of employment in half of the communities (the largest labour force across all four communities is in public administration). More recently, communities are focussing efforts on further developing tourism as a primary economic industry. Labour-force participation is relatively high, averaging above 70 percent, with individual pre-tax incomes ranging

DRAFT

from a low of $26,061 in Ross River to a high of $34,232 in Faro and household pre-tax incomes ranging from a low of $44,069 in Ross River to a high of $59,628 in Faro (Statistics Canada, 2008).

In terms of education, for the Census 2006 survey respondents aged 15 years and older (a total of 1,420 individuals for the four communities), 50 percent (715 individuals) reported a certificate or diploma as the highest level of schooling reported. Nine percent (125 individuals) reported high school as their highest level of schooling. Approximately 6 percent (90 individuals) reported having a Bachelor's degree and only 3 percent (45 individuals) reported having a Master's degree (Statistics Canada, 2008).

The Consumer Price Index measures the cost of living experienced by communities in Canada. In terms of consumer purchasing power, the cost of living in these communities is slightly higher in comparison to Whitehorse. Individuals from these communities often travel to Whitehorse to purchase groceries and household goods or shop online or by phone. In addition, groceries are commonly supplemented by country foods such as game, berries, and fish.

6.3.2 Community Stability and Well-being

The local area supports a relatively small population, with recent estimates from 2013 showing average populations in the Town of Faro, Ross River, and Pelly Crossing to be approximately 360 people; the largest community is Watson Lake, which is home to 1,474 people (YG, 2013a). Together, these communities are comprised of a mainly non-Aboriginal population, with 35 percent identifying as Aboriginal (Statistics Canada, 2008). Communities such as the Town of Faro and Pelly Crossing have indicated trends of a growing population in recent years, contrasted with the general population change in the region, which is declining. In terms of mobility, all communities are relatively stable, with few people moving into or away from the region.

Additional demographics indicate an aging trend across all four communities, with approximately 39 percent of the total local population (Town of Faro, Pelly Crossing, Ross River, and Watson Lake) aged 50 and above. Those individuals under the age of 24 represent 28 percent of the total local population.

AANDC generates the community well-being score, which ranges from 0 to 100 and provides data on income, education, housing conditions, and labour force activity. In 2006, community well-being scores for the four communities ranged from 68 to 79, with the Town of Faro and Watson Lake both receiving scores in the high 70s.

Community crime rates between 2009 and 2012 have generally undergone little change, with the exception of Watson Lake, where crime saw a 20 percent decrease from 2009 to 2011 (YG, 2012). Following that decrease, however, crime rose again in the community from 2011 to 2012, and Watson Lake continues to have the second highest crime rate in YT (YG, 2012).

6.3.3 Infrastructure and Services

In all communities, schools provide education to students from kindergarten to grade 12, except Ross River, where schooling is to grade 10. In addition, Yukon College has local community campuses and offers post-secondary education programs to all four communities.

Access to medical and emergency services in the region is provided at nursing stations and is available 24 hours a day. Firefighting and ambulance services are provided by volunteers. People requiring complex medical and dental treatment must travel to Whitehorse or outside of the Yukon, although Watson Lake provides limited emergency services. Typically, patients requiring emergency medical attention are flown from their communities to the nearest appropriate facilities, depending on the severity of their medical condition.

Communities are accessible by both road and air, and both the Town of Faro and Watson Lake have airports. Ross River and Pelly Crossing have gravel airstrips maintained by YG. Watson Lake and the Town of Faro are municipalities responsible for delivering police, firefighting, medical, and other municipal services to residents and properties, including road maintenance. YG is responsible for providing these services in Ross River and Pelly Crossing.

DRAFT

6.3.4 Land Use and Access

Land use in the region includes resource and wildlife harvesting, particularly timber, fish, caribou, moose, and other wildlife. Before development of the FMC, the area was traditionally used by First Nations primarily for hunting and gathering (further detail provided in Section 3.2.1). Trapping within the area remains active today.

Much of the land in the region is used for recreational purposes, including the multi-use 65-km Deno Cho Trail, which connects Ross River and the Town of Faro and is now used to promote tourism and recreation in the area. A number of wildlife viewing platforms are also provided in Faro and are renowned for their vantages for sheep and sandhill cranes.

Local First Nations living in the region include citizens of RRDC, LFN, and SFN. The FMC lies within the traditional territory of the KDC, of which the RRDC and LFN are members. Citizens of these First Nations used the area for harvesting and recreation before the development of the mine. The SFN people are members of the Northern Tutchone Tribal Council, and are part of the Northern Tutchone language and cultural grouping. The FMC is not within the traditional territory of the SFN; however, SFN traditional territory extends upstream on the Pelly River to a few km downstream of the confluence of Anvil Creek. The creeks and rivers that flow through the FMC feed into the Pelly River watershed and SFN traditional territory.

There is no information indicating there is any significant freshwater fishing in the area surrounding the FMC. There are important fisheries downstream of the FMC, particularly the salmon fishery in the Pelly River (Morrell, 1991). There is one main trapping concession surrounding the FMC. Trapline concession 405 is a group trapline held by the RRDC. Trapline harvesters may use the FMC from time to time to access the concession area.

Both the Yukon-based First Nations of the KDC (RRDC and LFN) do not have a land claim agreement, and both assert unextinguished aboriginal rights in the area. The SFN has land claim and self-government agreements with Canada and Yukon.

6.3.5 Culture and Heritage

The community of Faro was established to service the FMC in the late 1960s, as such, the history and heritage of the Town of Faro is closely tied to the mining industry. While further mineral exploration in the area is important to economic stimulus, tourism has become a major focus of the community and is identified as a priority in the town's Integrated Community Sustainability Plan (Town of Faro, 2007). Each May, the Town of Faro hosts a Crane and Sheep viewing festival during the annual migration of the Sandhill cranes up the Tintina Trench. This has become a major event for the community and draws visitors from around the territory.

Aboriginal people comprise most of the population of Pelly Crossing and Ross River, with non-Aboriginal residents accounting for less than 15 percent of the total population. In comparison, Faro and Watson Lake are home to a relatively smaller population of Aboriginal people, who account for 15 percent and 35 percent of each community, respectively (Statistics Canada, 2008). Both Kaska and Northern Tutchone are spoken throughout the region; however, English is the predominant language in all communities in the FMC vicinity.

To support this IWPP, YG engaged a heritage specialist to conduct a heritage resource overview assessment followed by a more detailed heritage resource impact assessment in specific areas. The results of the more detailed assessment are described in the Heritage Resource Impact Assessment (Appendix 6K). The assessment entailed a reconnaissance survey and selected shovel testing across potential borrow areas where disturbance of previously undisturbed areas may occur. Field work was carried out in eight areas of the FMC between September 24 and September 26, 2013. These areas had been previously identified in the overview assessment. Of the eight sites three were found to contain prehistoric lithic scatters in the first 10 cm of soil. These three sites were flagged with a 30-m buffer of yellow No Work Zone flagging tape.

The field crew also recorded a modern horse corral and cabin, a single log privy, and two game hanging racks (used in the late 1900s or early 2000s) that are located within potential borrow pit areas. Due to the relatively modern age of these resources, they were not recorded with the Yukon Historic Sites Inventory.

DRAFT

SECTION 7

Potential Environmental and Socio-economic Effects and Proposed Mitigation Measures

This section describes the environmental and socio-economic assessment conducted for the Faro Mine IW. Section 7.1 provides an overview of the assessment approach, while Section 7.2 provides details about the assessment methods. The assessment of the IW's potential environmental and socio-economic effects relies on a combination of quantitative and qualitative analysis methods. Sections 7.3.1 through Section 7.3.7 detail the results of the environmental and socio-economic effects assessments as well the human health effects assessment. To address YESAA requirements, Section 7.3.8 describes the effects extreme events, including the effects of malfunctions and accidents. Section 7.3.9 provides a summary and conclusions about the significance of effects.

The following appendices provide further details about quantitative analyses that support the assessment:

- Appendix 7A – Air Quality Effects Report
- Appendix 7B – Description of Water Modelling and Results
- Appendix 7C – Assessment of Effects on Surface Water Quality and the Resulting Effects on Fish and Fish Habitat

7.1 Assessment Scope

The co-proponents' assessment team initiated the environmental and socio-economic assessment by defining an initial assessment scope to guide the team's work, and to support a comprehensive assessment that focused on key issues. As the proposal progressed, the team refined the assessment scope based on input received and changes in our understanding of conditions. This section defines the issues the assessment considered, based on YESAA guidance. It then outlines which values the assessment addresses, and the rationale for their inclusion in the proposal.

7.1.1 Matters Considered in the Environmental and Socio-economic Assessment

In accordance with the requirements of YESAA subsection 50(2), this Project Proposal addresses the following matters that must be considered in a Project Proposal submitted to a Designated Office:

- 42(1)(b) – All stages of the project: The assessment considers all stages of the IW through its 10-year period, as described in Section 5.1 – Project Scope. Additional activities will take place at the FMC after the IW. These activities will be the subject of a future YESAA assessment for the FMRP.
- 42(1)(c) – The significance of any environmental or socio-economic effects of the project that have occurred or might occur in or outside Yukon, including the effects of malfunctions or accidents: Sections 7.3.1 through Section 7.3.6 describe the results of the environmental and socio-economic assessment, and evaluate the significance of effects. Section 7.3.8 addresses effects that may arise from accidents and malfunctions.
- 42(1)(e) – Alternatives to the project, or alternative ways of undertaking or operating it, that would avoid or minimize any significant adverse environmental or socio-economic effects: Section 4 describes alternatives to the IW and alternative ways of executing it.
- 42(1)(f) - Mitigative measures and measures to compensate for any significant adverse environmental or socio-economic effects: The project team has iteratively developed mitigative measures to address potential adverse environmental and socio-economic effects. Some measures have been incorporated into the project design; these are addressed in the project description, which Section 5 provides. Subsequent parts of Section 7 address further mitigative measures.

DRAFT

In addition to considering the matters required under YESAA subsection 50(2),this Project Proposal also provides information to support the Designated Office in conducting its evaluation by providing information and considering the following additional YESAA subsection 42(1) matters:

- 42(1)(a) – The purpose of the project: Section 4.1 of this Project Proposal addresses the purpose of the IW.
- 42(1)(d) – The significance of any adverse cumulative environmental or socio-economic effects of the project or existing project that have occurred or might occur in connection with the project: While this Project Proposal does not include a cumulative effects assessment, it provides information to support evaluation of the effects of the IW in combination with the most notable other projects and activities – the past mining activities and operations at the FMC. For key environmental components, the assessment considers the absolute effects of the project – a combination of historical activities and those that will take place during the IW.
- 42(1)(g) – The need to protect the rights of Yukon Indian persons under final agreements, the special relationship between Yukon Indian persons and the wilderness environment of Yukon, and the cultures, traditions, health and lifestyles of Yukon Indian persons and other residents of Yukon: The socio-economic assessment considers effects on Valued Components (VCs) and key characteristics that are related to treaty rights (e.g. traditional land use, hunting and fishing) and the protection of cultures, traditions, health and lifestyles.
- 42(1)(h) – The interests of residents of Yukon and of Canadian residents outside Yukon: Canada and Yukon are the proponents of the IW and have considered the interests of Yukon Residents and Canadians in proposing the project. These interests are addressed in Sections 3.2 and 4.1 (Project Background and Project Purpose, respectively).

7.1.2 Valued Components

The IW effects assessment employs a VC, or VC-based, approach that is consistent with guidance provided in YESAB's *Proponent's Guide to Project Proposal Submission to a Designated Office* (YESAB, 2010). This approach focuses the assessment on key interactions between the project and the environment or people. The VCs are relevant environmental, social, or economic elements that have scientific, social, cultural, economic, historical, archaeological, health, or aesthetic importance. When combined, the selected VCs are intended to be comprehensive, providing a framework for the assessment to efficiently identify and consider the effects of the IW.

VCs were selected by considering the environmental and socio-economic context and the type and scale of activities proposed for the IW. Compared with past mining activities or the future FMRP, the IW activities are relatively minor interim measures that are unlikely to change existing conditions for some environmental, social, and economic components. Table 7-1 lists the VCs for the IW assessment and provides the rationale for their inclusion.

TABLE 7-1
Valued Components Considered in the Assessment
Faro Mine Interim Works

Valued Component	Rationale for Inclusion
Air Quality	Air quality has a direct effect on the health of humans, wildlife, and vegetation. Dust mobilization from the FMC has affected air quality in the past, and this will continue through the IW period (e.g., dust from tailings). IW construction and maintenance activities may mobilize dust. The IW includes mitigation measures to reduce dust mobilization and transport.
Surface Water Quality	Surface water quality has a direct effect on the health of humans and the aquatic and terrestrial ecosystems. Aqueous transmission is the primary pathway for contaminants to be released from the FMC. This process began during mining and will continue through the IW. Many IW activities focus on controlling contaminant transmission into the aquatic environment (e.g., contaminated water collection and treatment).

TABLE 7-1
Valued Components Considered in the Assessment
Faro Mine Interim Works

Fish and Fish Habitat	Anvil and Rose Creeks are both fish-bearing streams that provide fish habitat for various species. The lower portion of Vangorda Creek is also fish habitat for Chinook salmon rearing, among other species. The IW could result in changes to water quality and quantity, which could affect fish and fish habitat.
Wildlife and Wildlife Habitat	The FMC is a large area that provides habitat for a range of wildlife species. Some species are important because of their cultural and resource values (e.g., as a food source), while others provide valuable measures of ecological health. The IW may affect wildlife and wildlife habitat directly (e.g., traffic-related mortality) and indirectly (e.g., vegetation disturbance).
Economy and Employment	The IW may stimulate local economies, and could increase employment, skill development, training opportunities, and education in local communities. This VC evaluates the community's ability to adapt to economic growth, the effects of increased disposable income, the distribution of costs/benefits among affected people (adverse effect/income equity), and the effects on local and regional cost of living.
Community Stability and Wellbeing	The IW will use an external work force during each IW component. The presence of this workforce in the community may affect individual, family, and community health, as well as First Nations and non-First Nations cultural wellbeing. The influx of a temporary workforce during each project component may influence (1) community makeup, including changes in demographics, mobility (such as effects of migration [in and out]), and (2) changes in social and cultural conditions.
Infrastructure and Services	The influx of the workforce associated with some of the IW components may strain community infrastructure, housing, and emergency and health services. Increased traffic caused by IW activities may affect local road safety and cause wear to road infrastructure.
Land Use and Access	There are a variety of community land uses (including trails) on and around the FMC. The assessment considers potential effects of the IW on First Nations' traditional land use (for hunting, trapping, and gathering), as well as effects on access for commercial and recreational land users.
Cultural and Heritage	Before mining activities began, local First Nations used the area around the FMC. As a result, the area has cultural value and contains heritage resources. The assessment will consider potential effects of the IW on cultural, heritage, and archaeological values.
Human Health and Safety	The IW and current best management practices aim to protect human health and safety. However, Human Health and Safety is a VC for two purposes: • To continue to protect the community and worker health and safety • To identify the potential effects on both community and worker health and safety

While developing the list of VCs, the assessment team considered several additional components, but concluded these did not warrant direct incorporation as VCs because (1) they are unlikely to be measurably affected by the IW or (2) they are considered vectors for effects on identified VCs. Table 7-2 describes the rationale for excluding components from direct incorporation as VCs.

DRAFT

TABLE 7-2
Components Excluded from Direct Incorporation as VCs
Faro Mine Interim Works

Component	Rationale for Exclusion
Groundwater	The assessment does not consider groundwater as a direct VC for the IW because it accounts for groundwater's importance as a pathway for effects on the Surface Water Quality and Fish and Fish Habitat VCs. This approach is based on the existing and expected future conditions of groundwater, as well as the foundation for the proposed long-term remediation and closure methods at the FMC. Within the FMC footprint, groundwater quality and flows have already been substantially altered by mining-related site disturbance and contaminant loading. Groundwater conditions within the FMC's footprint will continue to change throughout the life of the IW and beyond. For example, groundwater quality within the FMC's footprint will deteriorate further as contaminant loads increase from mine waste sources. One of the fundamental goals of the IW and the FMRP is to prevent onsite groundwater from significantly impacting local ecosystems. As a result, the interim and long-term (contained in the FMRP) responses to changing groundwater conditions will rely on groundwater collection systems, cover installation, and pit water management, which also affect groundwater. In these circumstances, groundwater is and will be a pathway for effects on the Surface Water Quality and Fish and Fish Habitat VCs. Changes in the quantity and quality of groundwater could affect these VCs, and this assessment has addressed those effects. As a critical pathway of effects, groundwater may also be an important early indicator of conditions for these VCs, and will be a critical component of monitoring programs. The decision to exclude groundwater as a direct VC carefully considered potential direct uses of groundwater near the FMC. The nearest downgradient groundwater use is for the Town of Faro's water supply, with wells located near the mouth of Vangorda Creek. Hydrogeological investigations in this area have concluded that these wells are influenced by surface flows in Vangorda Creek and the Pelly River, depending on relative water levels. There is not a direct groundwater linkage to the FMC. In this case, surface water acts as a vector for the potential effects. As a result, the assessment of effects on surface water addresses potential concerns about these wells.
Soil and Sediment Quality	Soil and sediment quality have been affected by past mining activities via dust transported from the FMC. While the IW will continue to affect these components, changes arising from the IW activities are expected to be minimal, and are not likely to be measurable during the IW. The evaluation of effects on the Fish and Fish Habitat and Wildlife and Wildlife Habitat VCs addresses adverse effects associated with existing conditions.
Climatic Conditions	The assessment did not consider potential effects of the project on climatic conditions because of the short-term nature of the proposed IW. During the IW, its effects on climatic conditions are not likely to be measurable. However, effects on climatic conditions will be more relevant during the assessment of the FMRP.
Aesthetics	Aesthetic conditions were not identified as a VC for the IW because the activities proposed as part of the IW are unlikely to have notable effects on aesthetic conditions. The FMRP will include substantial measures that will affect aesthetic values, but these remediation activities are not part of the IW.
Noise	While the activities proposed for the IW will generate noise at the FMC, the levels of activity and noise are not substantially different from those generated during similar activities at the site since the mine closed in 1998. The FMC is located in a remote location and is home to wildlife with limited exposure to anthropogenic noise. Excessive noise from project activities could affect wildlife use patterns, but for the IW, these have been addressed through the assessment of effects on wildlife, which is a VC.
Vegetation	The activities proposed as part of the IW will have little effect on vegetation near the FMC. Much of the site has already experienced extensive vegetation disturbances, and the IW will be focused in areas of existing disturbance. While revegetation and reclamation activities will be a major component of the FMRP, the IW does not include these activities, except when they are required to mitigate direct effects of IW activities. Vegetation disturbances can affect wildlife and wildlife habitat, and these effects have been addressed through the assessment of effects on those VCs.

7.1.3 Geographic Assessment Scopes

The geographic assessment scope defines the area where IW activities may overlap environmentally, socially, or economically with each of the VCs. The area of influence varies for VCs; therefore, the IW assessment defines geographic assessment scopes separately for each VC and for some specific indicators or key characteristics. Relevant portions of Sections 7.3 describe the specific geographic scopes.

To promote consistent approaches for establishing the spatial boundaries to assess effects on different VCs, the assessment team considered the criteria described in Table 7-3.

TABLE 7-3
Criteria for Defining Study Areas (Spatial Scopes)
Faro Mine Interim Works

Study Area	Definition
Site	Existing disturbed area and immediate zone of direct project effects
Local	Area with reasonable potential for effect interactions (direct or indirect) between the IW and the relevant VC
Regional	Wider area with potential for socio-economic or cumulative effects.

7.1.4 Assessment Temporal Boundaries

The assessment temporal boundary defines the timeframe associated with the effects predictions. For the IW, the assessment considers effects within its 10-year project scope. The co-proponents recognize that effects from the FMC will extend well beyond the duration of the IW. However, there is little benefit in assessing or predicting effects of the IW beyond the proposed 10-year scope of the proposed project. The FMRP activities will be initiated to address long-term effects. The FRMP activities will be of longer duration, have different effects, and are intended to mitigate many of the ongoing effects at the site. The IW activities will be upgraded or expanded, changing their effects on VCs. The details of the FMRP activities are not yet sufficiently defined to predict their long-term effects.

The FMRP will undergo a YESAA assessment before it proceeds. According to the current schedule, the FMRP Project Proposal will be submitted to YESAA during the third year of the IW. The assessment for the FMRP will consider the potential effects of the FMRP, combined with continuing effects of the IW after its proposed 10-year scope. Therefore, the IW assessment only considers effects within its 10-year time period.

7.1.5 Baseline Condition Definition

The IW assessment compared project-related effects with current conditions at the FMC. This approach is appropriate for a project that involves interim measures to control and mitigate existing effects from a legacy project. The co-proponents' overarching objectives focus on protecting and restoring the environment and land uses, as practicable. These objectives guide overall remediation planning towards long-term outcomes which are improvements over existing conditions. During the 10-year scope of the proposed project, the IW activities will also result in some positive outcomes; for example, decreased risks to human health and safety, and to the reduction of risks to water quality.

The specific timeframes used to characterize baseline conditions vary for different environmental, social, and economic elements, depending on data availability, quality, and applicability. Please refer to Section 6 for specific timelines used to define baseline conditions.

7.1.6 External Factors That May Affect the Project

The ability of the FMC and the proposed IW to withstand external factors is an important consideration in the assessment. External factors present risks to the project, which could result in adverse environmental or socio-economic outcomes. Using a risk assessment approach, the IW assessment considers effects that may result from forest fires, floods, and earthquakes.

Global climate change could affect the long-term performance of various FMC components (e.g., diversion capacity). However, the IW assessment has not considered those effects, because of the short (10-year) duration of the proposed project. Within that timeframe, the effects of global climate change are not likely to be measurable. Using current conditions to define baseline conditions assures past effects of global climate change are incorporated into the assessment and project planning.

DRAFT

The IW assessment also excludes the effects of external socio-economic factors (e.g., limitations on access to goods and services; institutional failure), because of its short duration.

7.1.7 Effects of Accidents and Malfunctions

As Section 7.1.1 described, YESAA requires the assessment to consider the potential effects of accidents and malfunctions associated with the IW. Using a risk assessment approach, the assessment considers the effects that could arise from a variety of potential failure modes and events:

- Engineering failures (e.g., structural failure of building)
- Human error (e.g., operator error, inspector error, mischief, or vandalism)
- Prediction errors (e.g., uncertainty in geochemical predictions, or underestimates of flood events)

7.2 Assessment Methods

The co-proponents' assessment team applied a VC-based approach to the assessment, evaluating project effects on a range of VCs to identify and then characterize potentially significant effects. Section 7.1.2 describes the VCs and the rationale for their consideration in the assessment.

For the selected VCs, the environmental and socio-economic assessment teams used consistent methods comprising two main steps to identify and characterize effects. The first step broadly identified potential interactions between IW activities and the VCs, then classified potential interactions to highlight those warranting detailed evaluation. The second step characterized the important interactions to define and describe the potential effects, and evaluate their significance.

This section describes the methods used in the proposal to assess the potential environmental and socio-economic effects of the IW, and to determine their significance.

7.2.1 Step 1: Initial Identification and Classification of Project/VC Interactions

The first step in conducting the effects assessment involved a comprehensive identification of interactions between IW activities and VCs. It also classified the interactions to highlight those warranting detailed consideration in the effects assessment. This step took place during two workshops, to promote consistency in decision-making: one for environmental VCs, and one for socio-economic VCs.

During these workshops, the potential for specific pathways of effects between each activity in the IW and each VC was considered. This systematic approach created a matrix of project activities and VCs, promoting thorough consideration and identification of all potential interactions, regardless of scale, magnitude, or direction. Within the matrix, each project-activity/VC intersection was classified according to the following numerical criteria:

- "0" = No Interaction: no measurable interaction that could cause an effect
- "1" = Minor Interaction: minimal interaction where measureable effects are possible, but the effects will be avoided or suitably mitigated through compliance with regulatory requirements and application of standard best management practices
- "2" = Major Interaction: potential interaction where measurable effects are likely even with application of best management practices, or where understanding the scale or magnitude of effects requires detailed analysis

The assessment addressed interactions classified as "1" by identifying specific regulatory requirements and best management practices to eliminate or suitably mitigate potential effects. Sections 7.3.1 through 7.3.6 describe the results of the assessment for these interactions.

The assessment addressed interactions classified as "2" by conducting more detailed analyses of potential effects (which is Step 2 the assessment methodology). Where multiple activities could have similar effects on the same VC (e.g., effects of multiple construction-related activities on air quality), some of the interactions classified as "1" were considered in aggregate as a "2" and were subject to more detailed analyses during Step 2. Section 7.2.2 describes the methods used to conduct these assessments for environmental and socio-economic VCs.

DRAFT

7.2.2 Step 2: Evaluate Effects of Relevant Project/VC Interactions

Each interaction classified as "2" was carried forward for a more detailed assessment. Analytical processes were followed to understand the interaction pathways, predict the effects, identify appropriate mitigation measures, evaluate the significance, and design monitoring plans to confirm the validity of the assessment.

7.2.2.1 Environmental VCs

For environmental VCs, the co-proponents' assessment team applied the following general steps to evaluate project activity/VC interactions. In many cases, the assessment evaluated combined effects of multiple activities to achieve a thorough understanding of the effects of the entire project.

- Identify and describe specific pathways that may lead to effects on VCs.
- Identify indicators and metrics to characterize the interactions between the project and a specific VC.
- Develop and describe ecological objectives that define acceptable conditions and levels of changes for VCs from the baseline conditions
- Analyze project effects on VCs. Analytical methods varied for each VC and for each type of interaction, with appropriate methods selected to achieve the overall assessment goals: to predict the potential environmental conditions arising from the project, and compare the predicted conditions with the baseline and the ecological objectives. In some cases, rigorous scientific modelling approaches were applied to predict effects (e.g., water balance models, contaminant loading models, landscape models). In other cases, more holistic approaches were applied to predict project outcomes based on experience with other projects, case studies, experiments, and professional judgement.
- Develop mitigation measures. Where necessary, the assessment team identified the need for mitigation to address adverse environmental effects. This was an iterative process, resulting in refinements of the design to improve its environmental performance. For the IW, adaptive management is an important component of the project and proposed mitigation plans. Where the effects analysis identified uncertainty about potential effects from changing site conditions, AMPs were developed. AMPs are systematic plans that identify (1) events that may lead to adverse effects, (2) appropriate performance indicators, (3) detailed monitoring programs to understand status and trends of indicators, (4) triggers for actions, and (5) specific actions that will be undertaken.
- Evaluate the significance of residual effects (i.e., effects after mitigation measures are applied). Section 7.2.3 describes this methodology.
- Develop monitoring programs. The intent is to confirm assessment predictions and the performance of the project and mitigation measures.

7.2.2.2 Socio-economic VCs

The assessment team followed similar general steps to evaluate project-activity interactions for socio-economic VCs:

- Identify and describe specific pathways that may lead to effects on VCs.
- Identify key characteristics and metrics to characterize the interactions between the project and a specific VC.
- Describe baseline conditions and acceptable levels of change for VCs.
- Analyze potential project effects on VCs. Analytical methods varied for each VC and for each type of interaction, with appropriate methods selected to achieve the overall assessment goals: to predict the potential socio-economic conditions arising from the project, and compare the predicted conditions with baseline conditions. Secondary data, at best available scales, were analyzed using largely qualitative tools to predict potential socio-economic effects (e.g., comparative approach, experience with other projects, case studies, experiments, and professional judgement).

DRAFT

- Develop mitigation measures. Where necessary, the assessment team identified the need for mitigation or enhancements to existing best management practices and communication protocols, to address adverse socio-economic effects.
- Evaluate the significance of residual effects. Section 7.2.3 describes this methodology.

7.2.2.3 Extreme Events

The environmental and socio-economic assessment considered two types of risk events, external factors (i.e., floods, earthquakes and forest fires) and malfunctions and accidents. The assessment followed a series of steps to evaluate these effects:

- Identify and describe specific pathways that may lead to increased risk.
- Analyze project risks using risk assessment tools.
- Develop mitigation measures to reduce the risks and their environmental and socio-economic effects. Some risk events can be managed by reducing the likelihood of the events, while others can be addressed by mitigating the magnitude of consequences.
- Evaluate the significance of residual risks (i.e., effects after mitigation measures are applied). Section 7.2.3 describes this methodology.

7.2.3 Methodology for Evaluating Significance

As Section 7.1.1 stated, YESAA requires the consideration of the significance of identified adverse residual effects. The co-proponents' assessment team considered the following list of criteria when evaluating the significance of project activities' residual effects on VCs:

- Direction
- Magnitude
- Likelihood
- Duration
- Geographic extent
- Frequency
- Reversibility
- Socio-economic Context

The following criteria were used to determine the significance of environmental VCs:

- Direction – For all environmental VCs, direction was considered to be negative and addressed as part of the magnitude criteria.
- Magnitude/Likelihood/Duration - These criteria are related, and considered together when determining the significance of environmental VC. Magnitude is the amount of change in an indicator, relative to the existing or baseline condition, or change above an established objective. Likelihood refers to the probability that an effect will occur, and in this case, also considers how often an effect will occur (i.e. frequency of an effect). Duration addresses how long an effect may continue once it has occurred. For example, the period of time required until the VC or indicator returns to its baseline condition, or until the effect can no longer be measured or otherwise perceived. The overall duration of the IW is 10 years, so the significance of effects is assessed within this 10-year period. Effects that extend beyond this period will be considered in the assessment for the FMRP.
- Geographic Extent - This refers to the extent or proportion of a VC affected by a project activity. The geographical extent can vary from site-specific or to larger geographical areas, depending on the VC. Residual effects over larger geographical extents are more significant.
- Reversibility – Reversibility addresses the ability of an adverse effect to return to pre-project or pre-activity conditions. It considers the timeframe within which, and probability that, an effect could be reversed.

DRAFT

For each criterion, significance is measured as High, Moderate, or Low, with the understanding that criteria and significance are defined according to the specific VC and indicator being considered. In some cases, rigorous scientific modelling approaches were applied to predict effects (e.g., water balance models, contaminant loading models, landscape models) and quantify significance. In others, significance was determined based on experience with other projects and professional judgement. The rating of overall significance for each VC is based on the balance of ratings for the criteria. Before significance was evaluated, the assessment team established that if an activity had a high rating for overall significance, the activity was deemed to have significant effects and was not acceptable to proceed in accordance with YESAA requirements.

Socio-economic VCs

The criteria for socio-economic VCs are similar to the criteria for environmental VCs. However, they are defined more specifically to reflect the socio-economic conditions and indicators. The following criteria were established to evaluate the significance of socio-economic VCs:

- Direction – Socio-economic effects may differ in direction, and are therefore considered when evaluating significance. Direction is defined as the ultimate long-term trend of the socio-economic effect (neutral, positive, or negative), relative to the baseline conditions.
- Magnitude/Duration - The amount or degree of change relative to baseline conditions. The period of time required until the VC or indicator returns to its baseline condition, or until the effect can no longer be measured or otherwise perceived. In this case, duration provides a measure of reversibility as well.
- Geographic extent - The geographic area within which a socio-economic effect occurs.
- Probability/Frequency – This is considered separately from magnitude/duration to reflect the probability that an effect will occur, and how often it could occur (once, daily, weekly, monthly, continuous).
- Social-economic context –The existing socio-economic context or situation, and the additional effects the project may have on a socio-economic VC. It is a measure of socio-economic resiliency and the ability to cope/adapt.

For each criterion except direction, significance is measured as High, Moderate/Medium, or Low. Specific criteria and significance definitions reflect the specific VC and indicator under consideration. A combination of socio-economic modelling approaches, experience with other projects, and professional judgement was used to identify significance. Again, before significance was evaluated, the assessment team determined that if an activity had a rating of high for overall significance, the activity was deemed to have significant effects and was not acceptable to proceed in accordance with YESAA requirements.

Extreme Effects

Risk assessment tools are applied to evaluate the likelihood and consequences of potential extreme events. Risks are estimated using quantitative modelling or qualitative methods (e.g., comparative approach, experience with other projects, case studies, experiments, and professional judgment). If the likelihood and consequence of an extreme event was High, the project activity was deemed to have significant effects and was not acceptable.

7.3 Effects Assessment Results

7.3.1 Initial Identification and Classification of Project/VC Interactions

Table 7-4 provides the results of Step 1 of the effects assessment – the initial identification and classification of potential interactions between project activities and VCs, according to the interaction criteria described in Section 7.2.1.

Subsequent subsections address the effects of all interactions classified as Major interactions (“2”) in Table 7-4 in detail.

7.3.2 Mitigation for Minor Interactions

Table 7-4 identifies numerous potential Minor interactions ("1") where measureable effects are possible, but the effects will be avoided or suitably mitigated by complying with regulatory requirements and applying standard best management practices. For these potential effects, the project's performance relies on the development and effective application of appropriate mitigation - a series of best management practices. Appendix 5A, the Environmental Management Plan, provides mitigation and management plans. These plans describe the best management practices that will be applied during the IW. Table 7-5 identifies specific mitigation and management plans that will apply to each of the activities that make up the IW.

By effectively applying the listed mitigation and management plans, the assessment team concluded that the minor interactions, when considered individually, will not cause significant adverse environmental or socio-economic effects. Where effects of more than one minor interaction could combine to have greater effects on specific VCs, or where they combine with major interactions, the combined effects have been addressed in aggregate; subsequent sections provide more detailed assessments of these.

7.3.3 Air Quality Effects Assessment

This section describes the results of the detailed analysis of potential effects of the IW on air quality. As identified in Table 7-4, this effects assessment has only identified one Major interaction between project activities and air quality (i.e., ranked as "2" in the interaction matrix). That interaction considers the effects of storing tailings in the RCTA. Site operations include dust control measures to minimize dust release from the tailings. However, the assessment recognizes that continued dust mobilization will remain an issue until the FMRP is complete.

Several other proposed activities may also cause dust to be released at the FMC, but these are identified as Minor interactions. The assessment recognizes that although these interactions are minor, their effects may combine with that of tailings storage (the Major interaction). The air quality effects assessment considers the combined effects of all IW activities that may adversely affect air quality. Appendix 7A provides additional details about effects on air quality.

USEPA CALPUFF quantitative dispersion modelling was used in this effects assessment. This modelling estimates the dispersion of estimated project emissions throughout the IW. The dispersion modelling covers an area of 50 km from the centre of the FMC, and incorporates meteorological data. To determine project-related effects, the modelled dispersion patterns are then compared to applicable ambient air standards for particulate matter, as well as metal concentrations within particulate matter. The modelling approach and results are provided in Appendix 7A.

7.3.3.1 Air Quality – Pathways of Effects

The pathways of effects are the mechanisms through which project activities can effect air quality in the region.

Table 7-4 identifies several potential air quality interactions that fall into the following four categories:

1. Dust re-suspension from tailings stored in the RCTA
2. Dust re-suspension from vehicle traffic on roadways within the FMC
3. Dust emissions from general construction activities and earthworks being performed as part of the IW
4. Dust emissions from lime handling at water treatment facilities

Dust emissions from lime handling have not been considered further in the modelling and assessment because these will be addressed by lime handling protocols. The remaining interactions can adversely affect air quality in the study area and are the focus of the modelling and assessment.

Table 7-4 provides further detail.

7.3.3.2 Air Quality – Indicators

Four indicators are selected on which to adequately describe potential effects of the IW on ambient air quality. Changes in air quality are indicated through total suspended particulates (TSP), two size classes of particulate matter, and metals contained within the particulate matter. The two sizes of particulate matter chosen were PM_{10} and $PM_{2.5}$. Several different metal contaminants are used to characterize the metal indicator (Appendix 7A), specifically metals known to occur within the FMC and known to affect both human and environmental health. Changes in air quality are assessed by modelling the concentrations of these indicators at the identified model receptor sites, using IW emission estimates, and air dispersion modelling for all of the identified effects pathways. While metals are modelled for all pathways in order to consider the combined effects, the tailings are an overwhelming source for this indicator.

These indicators were selected based on the effects pathways identified, where particulate matter and metals released into the air as a result of IW activities are most likely to show the greatest change when compared to background ambient air quality. The indicators described formed part of the air quality model, and are shown in Table 7-6 and provided in Appendix 7A.

TABLE 7-6
Source Identification, Pathway, and Indicators Used in Air Quality Effects Assessment
Faro Mine Interim Works

Source Type	Effects Pathway	Indicators
RCTA	The re-suspension of dust from the RCTA through wind erosion.	TSP, PM_{10}, $PM_{2.5}$, metals
Site and access roads	The release of dust from project-related traffic on the various site and access roads.	TSP, PM_{10}, $PM_{2.5}$, metals
Construction activity sites	The release of dusts associated with construction activities onsite, including: • ID spillway - upgrades – Excavation of ID Spillway – Sourcing and transport of borrow material – Construction of erosion protection in spillway • ID raise (geomembrane and concrete barrier - installation) • Excavation and handling of borrow materials	TSP, PM_{10}, $PM_{2.5}$, metals

7.3.3.3 Air Quality – Ecological Objectives

The assessment compares model results to a series of AAQC developed by YT, British Columbia, and Ontario (Table 7-7). An AAQC is a desirable concentration of a contaminant in air, based on protection against adverse effects on health or the environment. AAQC are set with different averaging times (e.g., annual, 24 hour, 1 hour and 10 minutes) appropriate for the effect that they are intended to protect against. The effects considered may be health, odour, vegetation, soiling, visibility, corrosion or other effects.

The assessment preferentially relies on Yukon standards when available, in this case TSP for 24-hour and annual averages, and 24-hour average $PM_{2.5}$ concentrations. If Yukon standards were not available and more than one provincial standard exists for a particular contaminant or averaging period, the most stringent was used for comparison. For 24-hour PM_{10}, the objective from British Columbia was used, while for the metals, Ontario 24-hour average standards and guidelines were used.

Standards and guideline concentration units are in $\mu g/m^3$ unless otherwise noted.

TABLE 7-7
Summary of Ambient Air Quality Standards for All Modelled Contaminants µg/m³

7.3.3.4 Air Quality – Analysis of Potential Effects

Method of Analysis

IW activities could generate dust (including metal particulates), which may affect ambient air quality parameters at receptor sites in the study area, thereby potentially affecting the surrounding environment. Comprehensive air quality dispersion modelling considered emission sources and estimated emissions from each source area (Appendix 7A). Modelling used local meteorological data to characterize and evaluate short-term atmospheric

DRAFT

dispersion and transport of emissions released by the identified sources in the FMC. Data included wind velocities, wind direction, annual temperatures, atmospheric stability, and mixing-layer depth.

The model uses a series of receptor sites to characterize effects within the study area. Ground level contaminant concentrations for the modelling domains were calculated over the following receptor grid:

- Uniform spacing of 500 m in an area extending out to 12 km from the approximate centre of the project site
- Discrete receptors spaced at 100 m along the boundary of the O.I.C. area where the highest off-property ambient air concentrations are expected
- Uniform spacing of 1,000 m from 12 km out to 50 km from approximate centre of the FMC site

A total of 3,409 receptors were used to calculate concentrations within the entire modelling domain.

The model output predicted ambient air quality 24-hour maximum concentrations for the selected indicators, and annual averages for TSP. The model incorporates the following assumptions.

- Background ambient air quality represents effects from existing contaminant sources in the areas surrounding the FMC.
- The FMC is isolated; therefore, background levels of each contaminant are expected to be small.
- The Town of Faro and the access road from the Robert Campbell Highway likely contribute nitrogen oxide, particulate matter, and carbon monoxide from mobile combustion products, residential heating, and wood-burning.
- Deposition loss from suspended particulates is unknown because of a lack of information about dust particle size. As a result, the model is likely to predict higher ambient concentrations of particulates and metals.
- Timing, numbers and locations for vehicle use are estimated based on the types of activities proposed.
- The property line for IW activities is the boundary of the O.I.C. area (refer to Figure 3-4), which is larger than the FMC footprint. IW activities are also expected to produce emissions indistinguishable from natural variability. Based on both of these facts, concentrations at the edges of the O.I.C. are expected to be small and localized.
- Tailings will cause emissions year-round, which is unlikely due to the likely presence of snow cover during winter months, reducing the generation of fugitive dust.

Identified Potential Effects

Overall, the model predicts that IW activities will likely have a moderate effect on ambient air quality within the ID construction area and around unpaved roads and RCTA. It further predicts IW activities will result in little-to-no effect outside of the O.I.C. boundaries (Appendix 7A).

In the RCTA, wind will erode the dry tailings. This will result in a moderate effect, after the implementation of mitigation measures. Construction around the ID, specifically related to emissions from vehicles and material handling is also likely to have a moderate effect. Traffic on the FMC access and haul roads is also likely to affect local ambient air quality through vehicle emissions and dust re-suspension.

For receptors outside the O.I.C., the model predicts that maximum 24-hour and annual averages of ground level concentrations for TSP, PM, and metals will be less than applicable air quality standards (Tables 7A-9 and 7A-10 in Appendix 7A). Specifically, background concentrations of TSP are approximately 11.7 $\mu g/m^3$, and modelled 24-hour average TSP concentrations are 48 $\mu g/m^3$. The Yukon standard for TSP is 120 $\mu g/m^{3;}$ therefore, TSP is not expected to exceed standards at receptors outside the O.I.C. PM_{10} background concentrations are 7.1 $\mu g/m^3$, and maximum 24-hour average concentrations are 33 $\mu g/m^3$. These concentrations are less than the British Columbia standard of 40 $\mu g/m^3$. $PM_{2.5}$ background concentrations are 7 $\mu g/m^3$, and modelled 24-hour maximums are 3 $\mu g/m^3$. Both background and modelled concentrations are less than the Yukon guidelines of 30 $\mu g/m^3$ for $PM_{2.5}$.

For metals, the model predicts localized exceedances only for chromium and iron at locations in and near active construction areas (Appendix A, Table 7A-11). All other predicted metal concentrations meet the standards. Overall, modelled metal concentrations in particulates at receptors outside of the O.I.C. area range from less than 0.1 percent of the air quality standard for titanium, strontium, and molybdenum, to 41.5 percent for chromium and 53.7 percent for iron. Metals concentrations were estimated by using a ratio of metal to PM_{10} concentrations as described in Appendix 7A.

These exceedances consider a ratio of metal to PM_{10}, where particulate matter decreases until it is less than applicable standards beyond the O.I.C. boundary.

7.3.3.5 Air Quality – Mitigation

General mitigative strategies for dust control include the application of tackifiers, water, and other dust mitigation best management practices (BMPs) as described in the EMP. Based on model results, proposed mitigation measures will result in a 60 percent reduction of dust production. To control dust emissions from the tailings, the IW includes application of chemical tackifiers on a yearly basis to areas that are susceptible to wind erosion.

For planned IW construction activities, water spray will be used to reduce fugitive dust during dry periods. Controlling vehicle access and speeds on unpaved roads will reduce vehicle-generated dust. Work should cease during periods of high winds. Minimizing the drop distance of materials during construction activities will further reduce the likelihood and extent of materials travelling out of the construction area. Lastly, all vehicles and machinery will be washed as needed to reduce dust loads.

Environmental awareness will be a key component of the staff orientation program, particularly as it relates to IW activities that will result in increased traffic on unpaved roads). The use of fuel-efficient vehicles will reduce emissions in the local air shed. No-idling strategies and strict enforcement of speed limits will further maintain air quality parameters within applicable guidelines. Appropriate road maintenance, including water application during dry periods, will reduce dust emissions from these areas.

7.3.3.6 Air Quality – Significance of Effects

A series of significance evaluation criteria were established to assess the significance of the IW effects on ambient air quality. The development of these criteria considered magnitude and likelihood/duration, geographic extent, and reversibility (Table 7-8).

Based on these criteria, the significance of changes in air quality indicators were ranked as Low, Medium, or High. Magnitude ratings ranged from Low, indicating a minimal effect, to High, indicating a substantial effect. The ratings assume the application of appropriate mitigation measures.

7.3.3.7 Residual Effects

The results of the significance evaluation for air quality are described in Table 7-9. Particulate matter emissions from the FMC are not expected to result in offsite exceedances of applicable TSP, PM_{10}, $PM_{2.5,}$ or metal standards. The model predictions are conservative in that all emission sources were modelled simultaneously and it is unlikely that this will occur in practice. Dust suppression best management practices will be utilized wherever feasible to reduce on-property and off-property effects.

It is expected that after the appropriate dust control techniques are employed at the tailings area, construction area, and unpaved roadways, the residual effects of particulate matter emissions (including metals) at off-property locations will be negligible and concentrations will be indistinguishable from those measured during the previous monitoring campaigns. The geographic extent reversibility of air quality effects is low, and although the magnitude and likelihood of effect can be high within and close to the emission sources, a negligible effect is expected at the property line and in the neighbouring Town of Faro.

DRAFT

TABLE 7-8
Definitions for Evaluating Significance
Faro Mine Interim Works

VC	Indicator	Rationale for Selection	Measurements	Effects Attributes	Significance Ranking	Ranking Criteria
Air Quality	Contaminant Air Concentrations affected by Tailings Area, Construction, and Unpaved road traffic	Elevated pollutant concentrations can be harmful to humans, wildlife and vegetation. Ambient air quality standards will be used to assess significance of effects and these standards and guidelines are measured in terms of contaminant concentrations in air.	Modelled changes in Air concentrations for TSP, PM10, PM2.5, and metals	**Magnitude and Likelihood**	Low	Air concentrations less than applicable standards on-property, throughout the modelled year
					Medium	Air concentrations less than applicable standards off-property, throughout the year, but above on-property <25% of modelled days at any receptor
					High	Air concentrations more than standards on-property, more than 25% of days in modelled year at any receptor
				Geographic Extent	Low	Air concentrations greater than standards only on-property
					Medium	Air concentrations greater than standards off-property
					High	Air concentrations greater than standards on a regional basis (greater than 1 km from site boundary)
				Reversibility	Low	Effects are completely reversible
					Medium	Effects are reversible but with mitigation and it may takes months or years for reversal to occur
					High	Effect is non-reversible despite mitigation.

DRAFT

TABLE 7-9
Projected Air Quality Effects From IW Activities After Mitigation
Faro Mine Interim Works

IW Activity	Potential Interaction	Reversibility	Magnitude	Frequency/ Probability	Extent	Overall Level of Significance	Mitigation Plan Summary
Tailing area	Wind erosion from dried tailings material	Medium	Low	Medium	Low	Medium	Application of a chemical dust suppression compound on an annual basis or more frequently as required.
Intermediate Dam Construction	Emissions from various activities associated with vehicles, material handling, blasting etc.	Low	Medium	High	Low	Medium	Apply water spray during dry periods to disturbed areas, control of vehicle access and speeds, work stoppage under high wind events, minimize material drop distance, periodic washing of vehicles to reduce load out of dust.
FMC Access and Hauls Roads	Emissions from road dust re-suspension caused by traffic	Low	Low	Low	Low	Low	Fuel efficient vehicles, environmental awareness, proactive identification of emission sources, maintenance programs, reduced idling times, water application to roads during dry periods, snow grading on top of roads, posting and enforcement of speed limits.

DRAFT

7.3.3.8 Air Quality – Monitoring

Dispersion modelling analysis has shown the effects in the O.I.C. to be moderate when using conservative emission estimates and dust mitigation methods for the three emission source areas. Overall, significance is None to Low, outside the O.I.C. By implementing dust management according to the (Appendix 5A) effects outside the O.I.C. will be insignificant. Therefore, this document does not propose air quality monitoring.

7.3.4 Aquatic Effects Assessment

This section describes the detailed analysis results for the IW's potential effects on the aquatic VCs of surface water quality, and fish and fish habitat.

Table 7-10 identifies various minor interactions between IW activities and aquatic VCs. These minor interactions are not generally associated with the mobilization and transportation of chemical contaminants from the FMC. Rather, they are related to particulate releases (soils or sediments), which occur episodically as a result of weather (i.e., precipitation or snowmelt events) or specific work activities. Sediment effects on aquatic VCs are different than those associated with chemical contaminants. Potential effects of these interactions are addressed by mitigation and management plans identified in Section 7.3.2, rather than by predictive modelling. Additional discussion is provided in Section 7.3.4.7.

Table 7-10 also identifies a series of major interactions for aquatic VCs that are associated with existing mine waste material storage, contaminated water storage, and treated water releases. Many of the site operations of the IW are intended to minimize release of contaminants from the FMC through activities such as diverting clean water and collecting and treating contaminated water. Also, the comprehensive AMP (Appendix 5C) serves as a mechanism for the co-proponents to respond to changing conditions. Regardless, contaminant release into receiving environments is inevitable at the FMC and will continue through the IW period.

The aquatic VCs effects assessment evaluates the combined effects of chemical loadings to surface water at the FMC. The assessment considers two scenarios and applies different approaches to predict water quality changes and interpret effects. First, the assessment considers a "Normal" scenario that uses a water and load balance model to predict water quality in the streams affected by the FMC. Second, the assessment considers an "Adverse" scenario that assumes a new source or transport pathway causes a rapid increase in aquatic zinc concentrations. The adverse scenario is assumed to exist for a limited time until mitigation measures (set forth in Appendix 5C) can be implemented to return conditions to Normal. Predictions for the Adverse scenario are based on 2013 monitoring data that indicate a new zinc load to the NFRC. In addition to the summary presented below, Appendices 7B (Water Quality Modelling and Results) and 7C (Analysis of Aquatic Effects) provide additional details about the analysis of IW effects on water quality and aquatic biota.

7.3.4.1 Context

The effects of the IW on aquatic VCs must be considered in the context of the FMC as a legacy mining project that was not operated by the current co-proponents. Deterioration of water quality at the FMC is a primary driver for developing and implementing a final remediation solution (the FMRP). The proposed IW involve temporary measures to minimize effects of the FMC while the co-proponents plan, permit, procure, and implement the FMRP. Consequently, The IW do not offer a water quality outcome that would be considered acceptable for a long-term remediation plan; rather, the IW are intended to minimize effects while the FMRP is finalized.

Many of the existing site management and maintenance activities at the FMC were established to minimize contaminant releases (e.g., clean water diversion, collection and treatment of contaminated water). The continuation of these activities is a key component of the IW and a cornerstone of proposed efforts to control and minimize the effects of the FMC on human health and safety, and the environment. Despite these efforts, however, mine-related contaminant sources such as waste rock, tailings, and open pits, will continue to release contaminants into receiving environments around and downstream from the FMC during the IW. Furthermore, acid-rock drainage conditions at the FMC are progressing and contaminant mobilization from waste materials will likely increase during the IW. Contaminants will be conveyed to surface water receiving environments via surface and groundwater pathways.

TABLE 7-10
Project interactions with aquatic value components and associated mitigation and residual effects
Faro Mine Interim Works Project

Project Activities/Physical Works		Interaction Ranking		
Category	**Specific**	**Surface Water Quality**	**Fish and Fish Habitat**	**Description of Interaction**
Site Operations	Storage of tailings material in the RCTA	2	2	Contaminants will continue to be released into surface waters via treated effluent and groundwater, with potential to affect aquatic biota in downstream areas.
	Seasonal treatment and discharge of water at Interim Faro Water Treatment System	2	2	Contaminants will continue to be released into surface waters via treated effluent with potential to affect aquatic biota in downstream areas.
	Storage of waste rock	2	2	Contaminants will continue to be released into surface waters via surface runoff, groundwater, and treated effluent with potential to affect aquatic biota in downstream areas.
	Storage of contaminated water in pit lakes and backfilled pits (Faro, Vangorda, Grum and Zone II)	2	0	Contaminants will continue to be released via treated effluent and potentially through groundwater.
	Storage of contaminated water in ponds (e.g., Little Creek Pond, Intermediate Pond, Cross-Valley Pond, Sheep Pad Pond, Moose Pond, Grum Settling Pond, Vangorda Water Treatment Pond)	2	2	Contaminants will continue to be released via treated effluent and potentially through groundwater. Also potential for TSS release from some ponds, which could affect fish habitat.
	Interception, collection and transfer of contaminated water from S-Wells to Faro Pit	2	2	Contaminants will continue to be released as a result of incomplete interception. Pipeline break would result in discharge of pit water to the environment.
	Seasonal discharge of contaminated water into Moose Pond	2	2	Potential contaminant release via groundwater to Vangorda Creek
	Seasonal treatment and discharge of water at Vangorda Water Treatment System	2	2	Contaminants will continue to be released into surface waters via treated effluent and have potential to affect aquatic biota in downstream areas.
	Transfer of contaminated water from Zone II Pit to Faro Pit	1	0	Pipeline break could occur, resulting in discharge of pit water to the environment
	Interception, collection and transfer of contaminated water from ETA to Faro Pit	1	0	Contaminants released through incomplete interception. Pipeline break would result in contaminants reporting to tailings or Rose Creek aquifer.
	Seasonal transfer of contaminated water from Grum Pit, Grum Dump and Little Creek Pond to Vangorda Pit and V15	1	1	Pipeline break could occur, resulting in discharge of pit water to the environment
	Disposal of sludge from water treatment systems. Original Impoundment at Faro, and Vangorda Pit	1	0	Potential remobilization of contaminants from disposed treatment sludges.

TABLE 7-10
Project interactions with aquatic value components and associated mitigation and residual effects
Faro Mine Interim Works Project

Project Activities/Physical Works		Interaction Ranking		
Category	**Specific**	**Surface Water Quality**	**Fish and Fish Habitat**	**Description of Interaction**
Site Investigations	Boreholes/test pits	1	1	Potential TSS release and/or contaminants from water use and release during drilling
	Monitoring equipment installation including wells, thermistors, flow measurement facility	0	1	Potential TSS release and/or contaminants from water use and release during drilling
	Aquifer and pump testing	1	1	Potential TSS release and/or contaminants from water use and release during drilling
	Access route development (may include stream crossings)	1	1	Potential channel disturbances
DVIHU	Excavation of Intermediate Dam Spillway	1	0	Potential TSS release
	Sourcing and transport of borrow material	1	0	Potential TSS release
	Construction of erosion protection in spillway	1	0	Potential TSS release
	Geomembrane and dam raise (gabion) construction	1	0	Potential TSS release
	Removal of vegetation in RCD	1	1	Potential TSS release and/or stream channel disturbances
	Removal of bank sloughs in RCD	1	1	Potential TSS release and/or stream channel disturbances
	Repair of RCD dike	1	1	Potential TSS release
Accessory Activities	Transport fuel and materials	1	1	Potential fuel spill
	Transport of personnel and supplies	1	1	Potential spill of chemical supplies
	Hazardous materials storage and use (reagents, fuel and hydrocarbons)	1	1	Potential spills
	Temporary Camp	1	0	Potential for sewage contamination
	Sourcing and transport of borrow material	1	1	Potential TSS release

DRAFT

If the IW do not take place, water quality conditions have potential to deteriorate severely. This is illustrated by previous monitoring data for station X2 (NFRC at the mine Access Road), which show how adaptive management led to the detection and remediation of a new zinc load. Water quality in the NFRC improved markedly once the S-Wells SIS was established in 2009. A similar situation evolved in 2013 with monitoring data indicating a new zinc load entering the NFRC at the Haul Road (i.e., the basis of the Adverse effects scenario); this recent situation is also being remediated through adaptive management. Table 7-11 estimates zinc concentrations and loads in North Fork Rose Creek at X2 and Rose Creek at X14 (downstream from the FMC) that could have been expected in the absence of adaptive management actions. The estimates include the zinc load captured at the SIS, which would have migrated to the NFRC if the system had not been installed. The estimates also assume that no action is taken to address the 2013 increase in zinc load at the Haul Road. The data presented in Table 7-11 demonstrate that significant adverse environmental effects on the aquatic environment are very likely to occur in the absence of the proposed IW activities.

TABLE 7-11
Predicted zinc loads and receiving environment concentrations that would be occurring in the absence of contaminant collection at the S-Wells and at an additional source to the NFRC identified in 2013.
Faro Mine Interim Works

Month	X2 Zn Load (kg/mon)	X2 Zn (mg/L)[a]	X14 Zn Load (kg/mon)	X14 Zn (mg/L)[a]
January	2,246	1.74	2,254	1.45
February	2,223	2.34	2,222	2.13
March	2,127	2.23	2,127	2.09
April	2,288	1.98	2,330	1.56
May	3,816	0.39	4,048	0.20
June	2,916	0.35	3,248	0.20
July	2,483	0.50	2,828	0.28
August	2,939	0.75	3,264	0.41

November	2,674	1.71	2,700	1.11
December	2,496	1.68	2,497	1.28

Notes:

kg/mon = kilogram per month

Zn = zinc

[a] The Canadian Water Quality Guideline for zinc is 0.03 mg/L.

The water quality that led to establishment of the S-Wells SIS in 2009, combined with the recent increase in zinc loads in the NFRC (autumn of 2013), demonstrate the ongoing potential for new pathways to develop between contaminant source areas at the FMC and surface waters. The AMP (Appendix 5C) is designed to detect and respond to emerging changes. Even with this important component of the IW, months may lapse between a new condition being identified and a response being developed and implemented. In the meantime, water quality may be unavoidably degraded. This means it may not be possible to consistently control the magnitude of adverse effects, only the duration (i.e., the time between detection and remediation of a sudden change in water quality).

Based on the conditions described above, the situation at the FMC contrasts greatly with an environmental assessment at a Greenfield site, where effects would be mitigated through appropriate design. At the FMC, YG and AANDC are seeking regulatory approval for continued maintenance and management activities that will

mitigate environmental effects, to the degree practicable, while they finalize the FMRP, which will provide longer-term solutions for existing and potential effects.

7.3.4.2 Geographic Scope

Appendix 7C, Analysis of Aquatic Environment Effects, describes and illustrates local and regional study areas for aquatic VCs (Figure 7C-3). The local study area, where effects of the IW are most likely to be realized, comprises the footprint of the former FMC operations and streams within approximately 500 m of the FMC footprint. The regional study area is the maximum area with the potential for measureable project-related effects. This area comprises the drainages downstream from the local study area to the Pelly River, and includes the areas within the Pelly River immediately upstream and downstream from the mouths of Anvil and Vangorda Creeks. For the aquatic effects assessment, the local and regional study areas are not functionally separate. Therefore, the effects assessment uses the same approach to evaluate water quality conditions in both local and regional study areas.

7.3.4.3 Pathways of Effects

Table 7-10 identifies interactions between IW activities and the aquatic VCs (i.e., surface water quality, and fish and fish habitat). There are major interactions for these VCs that are associated with existing mine waste materials storage, contaminated water storage, and treated water releases. These facilities and activities can release contaminants to surface waters downstream from, the FMC via controlled surface discharges (e.g., collection systems and treated effluent), uncontrolled surface discharges (e.g., untreated seepages and runoff), and groundwater. While the IW activities focus on controlling the release of contaminants to the aquatic environment, some contaminants will continue to be released via these pathways. The aquatic effects assessment focuses on the resulting chemical effects on surface water quality and fish and fish habitat.

Table 7-10 also identifies several minor interactions for aquatic VCs that related mainly to potential particulate (soil/sediment) releases. Such releases are of concern with respect to potential physical (e.g., habitat) effects. Particulate releases tend to occur episodically as a result of weather (i.e., precipitation or snowmelt events) or to specific work activities. Such interactions will be minimized by Best Management Practices (BMPs) related to erosion or solids control as well as adherence to regulations protecting fish and fish habitat. BMPs and regulatory requirements for fuel and chemical (e.g., reagent) handling will also mitigate effects associated with fuel or chemical spills during site investigations or accessory project activities. Consequently, the types of interaction in Table 7-10 are rated as a "1." Based on experience at the FMC and professional judgment, such interactions are very unlikely to result in a significant environmental effect, either in the absence of mitigation or with the application of standard mitigation practices. Residual effects of such practices, if any, are expected to be minor, so these interactions are not assessed further.

7.3.4.4 Indicators

The aquatic effects assessment for major interactions considers the combined effects of all contaminant sources on surface water quality by using a water balance and load model that incorporates inputs from all of these sources and estimates resulting contaminant concentrations at key receiving environment locations (Appendix 7B).

Surface water quality has been evaluated by considering relevant water uses. As described in Appendix 7C, protection of aquatic life is the most relevant and sensitive water use at the FMC and in downstream areas. Also, water quality guidelines for the protection of aquatic life tend to be the most stringent of the guidelines respecting various water uses. Therefore, this approach provides a conservative basis for evaluating effects on aquatic VCs. By considering surface water quality relative to guidelines for protection of aquatic life, the surface water quality assessment also addresses potential mine-related chemical effects on fish and fish habitat. In this context, fish habitat includes the aquatic plant and invertebrate communities that contribute to ecosystem function and represent a food source for fish.

By comparison, the potential effects of the IW on the physical characteristics of fish habitats are most likely to occur through particulate loads to surface water bodies. These have potential to increase suspended solids and turbidity concentrations and sedimentation on bottom substrates. As Section 7.3.4.3 noted, interactions involving particulate loads to surface waters are judged to be relatively minor, and will be controlled through BMPs.

DRAFT

According to the baseline water quality characterization (Appendix 6H, Aquatic Environment Baseline Report), the following mine-related contaminants have been observed at concentrations greater than water quality guidelines for the protection of aquatic life at some surface water stations near, and downstream from, the FMC:

- Cadmium
- Cobalt
- Iron
- Lead
- Manganese
- Sulphate
- Zinc

Modelling described in Appendix 7B predicted future surface water quality for all of these substances except iron. Iron was excluded because elevated concentrations are usually associated with elevated particulate loads caused by snowmelt and rainfall events. This is indicated by the correlation between total iron and TSS concentrations shown in the baseline water quality characterization (Appendix 6H). The baseline characterization also concluded that TSS concentrations are strongly influenced by sources in addition to the FMC. Furthermore, mine-related particulate loads associated with the IW, along with associated iron loads, are expected to be modest and controllable through BMPs.

Therefore, the assessment of surface water quality assessment is based on evaluation of expected sulphate, cadmium, cobalt, lead, manganese, and zinc concentrations, whose downstream concentrations are mainly influenced by loads from the FMC.

Of the mine-related contaminants included in the assessment, zinc is an important indicator of future geochemical changes at the FMC and is the most likely mine-related substance to be observed at concentrations greater than water quality guidelines for the protection of aquatic life. Consequently, zinc is a separate indicator from the other mine-related variables in the effects assessment. However, concentrations of zinc and the other mine-related contaminants were assessed in a similar manner, namely by comparing them to baseline concentrations (2008 to 2012), water quality guidelines for protection of aquatic life, and toxicity data presented in the scientific literature for relevant aquatic species (Appendix 7C).

7.3.4.5 Ecological Objectives and Significance Criteria

As previously mentioned, the FMC is an abandoned mine site storing waste materials with substantial inventories of contaminants. This is an important context for determining the significance for aquatic environmental effects. As Section 1.2 of this IWPP stated, the purposes of the IW are dual, as follows:

- To control and reduce the effects of the existing FMC on human health and safety and the environment
- To compile sufficient site and environmental information to support design, assessment and permitting for the FMRP

Significant adverse environmental effects on the aquatic environment are extremely likely to occur in the absence of the proposed IW activities. The IW aims to protect aquatic VCs by avoiding significant, direct, adverse effects on fish species. Criteria were developed to allow for surface water quality effects to be ranked as Low, Medium, or High based on the magnitude, likelihood, duration, geographic extent, and reversibility of predicted changes in water quality (Table 7-12) (Appendix 7C). Magnitude and likelihood/duration are considered together because potential effects on aquatic biota depend on the combined effects of these exposure characteristics at any given location.

DRAFT

TABLE 7-12
Assessment criteria for effects on surface water quality and associated chemical effects on fish and fish habitat
Faro Mine Interim Works

Valued Components	Effects Assessment Indicator	Rationale for Selection	Measurements	Effect Attributes	Significance Ranking	Ranking Criteria
Surface Water Quality and Associated Chemical Effects on Fish and Fish Habitat	Water quality (zinc)	Protection of aquatic species is predicated on exposure to water concentrations that do not cause impairment. Water quality concentrations can be predicted and concentrations toxic to aquatic organisms have been characterized in the scientific literature. Mine-related effects on surface water quality are expected to be dominated by zinc.	Concentrations of zinc in fish-bearing reaches relative to baseline and predicted conditions, water quality guidelines, toxicity thresholds.	Magnitude and Likelihood/Duration	Low	Water concentrations, after effluent mixing in the receiver are predicted to usually meet water quality guidelines (i.e., ≥50% of months) and will rarely or never exceed fish toxicity thresholds (<50% of months) throughout the 10-year project period.
					Medium	Concentrations after effluent mixing may frequently exceed water quality guidelines (>50% of months) but will usually not exceed toxicity thresholds for relevant fish (<25% of months). Temporary exceptions may occur when a new source or pathway results in a sudden increase in zinc concentration; during this time fish toxicity thresholds may be temporarily (<1 year) exceeded while a mitigation plan is developed and implemented.
					High	Water concentrations are predicted to be above levels likely to harm fish species in >25% of samples for indefinite periods (>1 year).
				Geographic Extent	Low	"Low" water quality effects will apply to all surface waters within and downstream of the FMC footprint (local and regional study areas).
					Medium	"Medium" water quality effects described above will be limited to the Rose Creek and Vangorda Creek system (i.e., mainly confined to local study, possibly extending to mouths of both creeks). In Anvil Creek and Pelly River, water quality effects are predicted to be "low" as defined above.
					High	"High" water quality effects described above may occur within the Rose Creek or Vangorda Creek system and "medium" or "high" water quality effects described above may extend into Anvil Creek and/or the Pelly River (regional study area).
				Reversibility	Low	Periods of elevated concentrations will naturally be followed by periods of lower concentration as a result of normal seasonal cycles of contaminant release and available dilution.
					Medium	Water quality effects are likely reversible through mitigation, although it may take months for solutions to be found and mitigation to be put in place.
					High	Water quality effects are not expected to be reversible.
	Water quality (sulphate, cadmium, cobalt, lead, manganese)	Protection of aquatic species is predicated on exposure to water concentrations that do not cause impairment. Water quality concentrations can be predicted and concentrations toxic to aquatic organisms have been characterized in the scientific literature. Next to zinc, sulphate, cadmium, cobalt, lead, and manganese are the mine-related variables having greatest potential to adversely influence surface water quality.	Concentrations of sulphate, cadmium, cobalt, lead, manganese, and zinc relative to baseline and predicted conditions, water quality guidelines, toxicity thresholds.	Magnitude and Likelihood/Duration	Low	Water concentrations, after effluent mixing, are predicted to meet water quality guidelines in most (≥95% of) months and are not predicted to exceed toxicity thresholds for relevant fish species throughout the 10-year project period.
					Medium	Concentrations are predicted to often meet water quality guidelines (>50% of months) and rarely or never (<5% of months) exceed concentrations shown in the literature to be harmful to relevant fish species.
					High	Water concentrations are predicted to sometimes or often (>5% of months) exceed levels expected to be harmful to relevant fish species.
				Geographic Extent	Low	"Low" water quality effects will apply to all surface waters within and downstream of the FMC footprint (local and regional study areas).
					Medium	"Medium" water quality effects described above will be limited to the Rose Creek and Vangorda Creek system (i.e., mainly confined to local study, possibly extending to mouths of both creeks). In Anvil Creek and Pelly River, water quality effects are predicted to be "low" as defined above.
					High	"High" water quality effects described above may occur within the Rose Creek or Vangorda Creek system and "medium" or "high" water quality effects described above may extend into Anvil Creek and/or the Pelly River (regional study area).
				Reversibility	Low	Periods of elevated concentrations will naturally be followed by periods of lower concentration as a result of normal seasonal cycles of contaminant release and available dilution.

DRAFT

TABLE 7-12
Assessment criteria for effects on surface water quality and associated chemical effects on fish and fish habitat
Faro Mine Interim Works

Valued Components	Effects Assessment Indicator	Rationale for Selection	Measurements	Effect Attributes	Significance Ranking	Ranking Criteria
					Medium	Water quality effects are likely reversible through mitigation, although it may take months for solutions to be found and mitigation to be put in place.
					High	Water quality effects are not expected to be reversible.
Fish (particularly Arctic grayling, Chinook salmon, slimy sculpin), and fish habitat.	Aquatic toxicity	Potential toxicity to fish and fish habitat associated with predicted water chemistry are addressed through assessment of effects on water quality, see above.				
	Physical habitat quantity and quality	Loss of aquatic habitat can compromise the success of fish populations, particularly if the affected habitats are critical to life cycle functions and there is limited availability of such habitat. Studies have been undertaken to characterize fish populations and habitat utilization around the FMC, as well as water flows and elevations and conditions at lower trophic levels (periphyton, benthic invertebrates).	Characterize habitat disturbance in terms of size, intensity, timing, and duration of disturbance. Consider both solid habitat and water flows/elevations. Possibly also quantify aquatic productivity and/or habitat details within and around the affected area, depending on context (location and type of expected habitat effect) Periphyton chlorophyll a, taxon richness, diversity, evenness, Benthic invertebrate abundance, taxon richness, diversity, evenness, ecological tolerances	Magnitude and Likelihood/Duration	Low	No alteration, disruption, or destruction of physical aquatic habitat and minimal or no effects on water flows/elevations compared to baseline conditions.
					Medium	Minor habitat effect is possible but will be sufficiently short in duration to have no impact on critical life stages of fish.
					High	Habitat effect could be of sufficient magnitude or duration to impact critical life stages of fish.
				Geographic Extent	Low	No habitat effects are expected that would impact accessibility/utilization by fish.
					Medium	Any habitat effect will be very confined to the local study area and will not include critical habitat.
					High	Critical habitats are likely to be affected.
				Reversibility	Low	Habitat effect will be completely reversible.
					Medium	Habitat effect will be largely reversible.
					High	Habitat will be permanently affected.
	Habitat access/barriers	Another important habitat consideration is maintenance of access by fish to critical habitat for fulfilling key life functions (i.e. spawning, rearing, and over-wintering). Features such as road crossings, rock drains, and culverts, can be barriers to fish access.	Characterize habitat disturbance in context of fish passability.	Magnitude and Likelihood/Duration	Low	The project activities will not affect fish movements relative to baseline conditions.
					Medium	Project activities may temporarily affect fish passage, but will not occur during typical fish migration periods.
					High	Habitat alteration will permanently affect fish passage relative to baseline conditions.
				Geographic Extent	Low	The project activities will not affect fish movements relative to baseline conditions.
					Medium	Any habitat disruption/alteration will be very localized and will avoid critical habitat.
					High	Habitat disruption/alteration may affect critical habitats.
				Reversibility	Low	Habitat effect will be completely reversible.
					Medium	Habitat effect will be largely reversible.
					High	Habitat will be permanently affected.

DRAFT

Potential zinc effects were considered differently than those associated with the other mine-related contaminants, because zinc is the dominant contaminant of concern at the FMC and a key indicator of changing geochemical conditions. Baseline data indicate zinc concentrations in surface water around the FMC exceed water quality guidelines more often and at more stations than the other mine-related variables (Appendix 6H, Aquatic Baseline Characterization Report). Because the effects on water quality were evaluated by comparing them with guidelines for the protection of aquatic life, and aquatic toxicity thresholds, the assessment addresses chemical effects on both surface water quality, and fish and fish habitat VCs.

To evaluate effects on aquatic VCs, predicted concentrations for indicator parameters were compared with baseline concentrations at representative local and regional monitoring stations and were also compared with water quality guidelines for protection of aquatic life. Some guidelines vary based on water hardness, so station-specific guidelines were developed based on observed water hardness over the baseline period. Table 7-13 lists the guidelines applied for each parameter at each station. Appendix 7C provides details about the rationale for selection of specific guidelines.

For water quality variables listed in Table 7-13 that were predicted to exceed guidelines, the predicted concentrations were also compared with toxicity data for aquatic biota reported in the scientific literature. Data were compiled for both acute (short-term) exposures and chronic (long-term) exposures, as described in Appendix 7C. To be consistent with current Environment Canada protocols (CCME, 2007), short-term exposures were typically defined as follows, depending on the species and life-stage tested:

- Less than one day (algae)
- Less than four days (invertebrates and larval fish)
- Less than seven days (older fish)

However, long-term exposure data are generally considered most relevant and conservative for assessing potential effects of predicted concentrations, because conditions cannot be reliably predicted for periods as brief as hours or a few days. Table 7-14 lists the toxicity thresholds derived for application at the FMC for each indicator parameter, where it is predicted to exceed guidelines.

7.3.4.6 Analysis of Potential Chemical Effects

Prediction of Future Water Quality

As indicated previously, the aquatic VCs effects evaluation considers two scenarios. The assessment focuses mainly on a Normal operating scenario, which uses a water and load balance model to predict water quality conditions in the streams affected by the FMC. An Adverse scenario was also assessed; this considered a localized, rapid increase in zinc load to surface water, which is assumed to temporarily affect water quality until a mitigation solution can be developed and implemented (likely 6 to 8 months). Zinc concentrations for the Adverse scenario are based on data from recent events at the FMC and represent a realistic worst case for assessing the effects of the IW activities.

Appendix 7B describes the methods and results for water quality modelling associated with the 10-year period of the IW for the Normal scenario. Appendix 7C (Attachment Figures A.1 to A.4) shows the results of 200 stochastic simulations for representative mine-related variables (zinc, cadmium, cobalt, manganese), including predicted 5^{th}, 50^{th}, and 95^{th} percentiles for each month over the 10-year period at representative stations. Appendix 7C presents monthly summary statistics derived from all stochastic realizations of the predictions (Attachment A, Tables A.1 through A.9). Annual variations in water quality at the FMC are generally associated with three seasons: winter baseflow, spring freshet, and the summer/autumn ice-free period. Therefore, water quality predictions were further summarized according to season and compared to baseline conditions and water quality guidelines (Appendix 7C, Attachment Tables A.10 through A.18). Table 7-15 compares predicted water quality for the Normal scenario with water quality guidelines for protection of aquatic life. Shaded cells show predicted guideline exceedances.

DRAFT

TABLE 7-13
Summary of water quality guidelines relevant to selected stations at FMC
Faro Mine Interim Works

Variable	Generic Guideline	Guideline Applied to Each Station for Evaluation of Water Quality Predictions [a] (and median station hardness 2008-12)							
		NF1 (91 mg/L)	X2 (108 mg/L)	X3 (115 mg/L)	X14 (217 mg/L)	R4 (156 mg/L)	V8 (301 mg/L)	A1 (161 mg/L)	P4 (173 mg/L)
Sulphate [b]	0-30 mg/L hardness = 128, 31-75 mg/L hardness = 218, 76-180 mg/L hardness = 309, 181-250 mg/L hardness = 429	309	309	309	429	309	429	309	309

[b] Insufficient data

DRAFT

The Adverse scenario considers effects associated with development of new contaminant pathways between mine source areas and surface waters. This scenario only evaluates the effects of zinc, because historical monitoring data indicate that zinc is the most likely contaminant to be associated with the leading edge of developing contaminant source plumes that could cause aquatic effects. New pathways may result in zinc concentrations that temporarily exceed those associated with the Normal operating scenario described herein. Such a condition developed in the S-Wells area, and was detected as a rising trend in winter zinc concentrations in the NFRC, which led to installation of the S-Wells SIS. Subsequent reductions in stream zinc concentrations were apparent in monitoring results. More recently, a new load source to the NFRC has developed near the Haul Road crossing, which has increased zinc concentrations in the NFRC (NF2, X2) and at X14 such that concentrations in November 2013 were greater than the maxima predicted for the normal operating scenario (Table 7-16). For the Adverse scenario, the effects assessment evaluates the effects of the water quality conditions measured in November 2013.

A1 GoldSim low flow (L/s)	948	
P4 GoldSim low flow (L/s)	23,856	

Sulphate

Future median surface water concentrations of sulphate are expected to be less than water quality guidelines for protection of aquatic life during winter baseflow, spring freshet, and summer/autumn periods at all stations (Appendix 7C, Table 7C-4 and Attachment Tables A.10 through A.18). Even predicted 95th percentile values for sulphate are not expected to exceed the sulphate guideline (Appendix 7C, Attachment Tables A.1 through A.9). Therefore, no significant adverse effects are expected to aquatic biota as a result of exposure to sulphate, and this substance was not evaluated further.

Cadmium

Appendix 7C, Section 3.2.2 provides details of the effects assessment for the Normal scenario for cadmium. Under the Normal operating scenario, median concentrations of cadmium are predicted to be slightly higher than baseline conditions during the IW, but will still be less than water quality guidelines for the protection of aquatic life (Table 7-15). However, peak concentrations may occasionally exceed the guidelines in lower NFRC (X2), RCD (X3), in Rose Creek immediately downstream from the Faro Mine Area (X14) and in lower Vangorda Creek (V8)

DRAFT

(Appendix 7C, Attachment Tables A.2 through A.4, A.9). The probabilities of such exceedances range from approximately 3 percent at X14 to 25 percent at X2 (Appendix 7C, Figure 7C-4). However, toxicity to most aquatic species occurs at concentrations of 0.0005 mg/L or more, and fish are typically unaffected until concentrations are at or above approximately 0.0017 mg/L (Table 7-14). Concentrations are not expected to be above 0.0005 mg/L in the Rose-Anvil creek system and will be below 0.0007 mg/L in lower Vangorda Creek (Appendix 7C, Figure 7C-4). Therefore, cadmium concentrations associated with the IW are not expected to affect fish nor most other aquatic biota in either the LSA or RSA.

Cobalt

Appendix 7C, Section 3.2.3 provides details about the effects assessment for the Normal scenario for cobalt. For the Normal operating scenario, median concentrations of cobalt associated with the IW are predicted to be comparable to the range observed during the baseline period at most stations. However, these concentrations may increase in Rose Creek at X14 and R4 during the ice-free period, as well as at V8 (Table 7-15). Environment Canada (2013d) recently developed a water quality guideline for cobalt of 0.0025 mg/L to protect against effects associated with long-term exposure. Concentrations in Rose Creek at X14 and R4 are predicted to exceed the guideline in approximately 45 percent and 35 percent of months, respectively (Appendix 7C, Figure 7C-5).

Appendix 7C (Attachment Table D.3) contains the toxicity data used by Environment Canada (2013d) to derive the long-term-exposure guideline. In addition, toxicity data associated with acute exposures to cobalt were summarized by Nagpal (2004) (Appendix 7C, Attachment Tables D.1 and D.2). Based on the scientific literature, effects to sensitive invertebrates and algae have been reported at cobalt concentrations as low as 0.003 mg/L, but most organisms are not affected at concentrations below 0.02 mg/L (Appendix 7C, Attachment Tables D.1, D.3). Maximum cobalt concentrations are not expected to exceed 0.02 mg/L at any stations during the IW (Appendix 7C, Figure 7C-5). Therefore, cobalt concentrations associated with the IW are not expected to affect fish nor most other aquatic biota.

Furthermore, as Appendix 7C (Section 3.2.3.1) describes, cobalt tends to be associated with particulate phases in aquatic systems. Therefore, although cobalt released at X14 is mainly in the dissolved phase, elevated concentrations in areas farther downstream tend to be more associated with particulates (suspended solids) than the dissolved phase (Appendix 7C, Figure 7C-6). As Appendix 7C describes, metals are more bioavailable to interact with aquatic organisms when in the free ion form than when they are complexed or speciated with other components in water. Therefore, because cobalt tends to partition to suspended and bottom sediments, aquatic cobalt concentrations are expected to be increasingly less bioavailable farther downstream from the FMC.

Based on of the information presented herein, cobalt concentrations associated with the IW are expected to have negligible effects on aquatic biota in the local and regional study areas.

Lead

Future median surface water concentrations of lead are expected to be less than water quality guidelines for the protection of aquatic life during winter baseflow, spring freshet, and summer/autumn periods at all stations (Appendix 7C, Table 7C-4). Even predicted 95th percentile values for lead are not expected to exceed the lead guideline (Appendix 7C, Attachment Tables A.1 through A.18). Therefore, no significant adverse effects to aquatic biota are expected to arise as a result of exposure to lead, and this substance was not evaluated further.

Manganese

Appendix 7C, Section 3.2.4 provides details about the effects assessment for the Normal scenario for manganese. For the Normal operating scenario, manganese concentrations are not predicted to change substantially from baseline conditions, except that concentrations may decrease slightly in winter months and increase slightly in other months at Rose Creek stations at, and downstream from, X14 (Table 7-15). There is no federal water quality guideline for manganese, but British Columbia has established a guideline that varies based on water hardness (Tables 7-13 and 7-14). Manganese concentrations are predicted to be greater than the hardness-adjusted guidelines in a substantial percentage of months at X14 (65 percent) and in an increasingly lower percentage of months at stations farther downstream (Appendix 7C, Figure 7C-7).

Toxicity data for manganese, particularly for long-term exposures, are limited and there are no data for the specific fish species found near the FMC (Appendix 7C, Attachment Tables E.1-E.3). The available data suggest aquatic toxicity could occur at the manganese concentrations predicted at X14 (median 2.4 to 4.2 mg/L) (Table 7-14). However, winter manganese concentrations at X14 averaged 3.9 mg/L over the baseline period (Table 7-15) and baseline biological studies concluded that mine-related effects on aquatic biota (e.g., benthic invertebrate surveys) were undetectable or relatively minor at X14/R2 (Minnow, 2013). Also, the predicted median concentrations at X14 are unlikely to cause acute lethality to fish (Table 7-14).

As Appendix 7C (Section 3.2.4.1) notes, manganese tends to partition to particulate phases of freshwater aquatic systems. Therefore, although manganese released at X14 is largely in the dissolved phase, elevated concentrations in areas farther downstream tend to more associated with particulates (suspended solids) than the dissolved phase (Appendix 7C, Figure 7C-6). As Appendix 7C describes, metals are more bioavailable to interact with aquatic organisms in the free ion form than when complexed or speciated with other components in water. Consequently, any effects associated with manganese are expected to be limited to the area immediately downstream from X14, with gradual reduction of bioavailable manganese concentrations farther downstream as a result of partitioning to suspended and bottom sediments.

Overall, the data indicate that aquatic effects, if any, of manganese in surface waters around the FMC would be limited to the vicinity of X14 (i.e., within the LSA) and would likely be minor in magnitude.

Zinc

Appendix 7C, Section 3.2.5 provides details of the effects assessment for both the Normal and Adverse scenarios for zinc. During the baseline period, median concentrations of zinc were greater than the water quality guideline at only X14 (Table 7-15). However, for the Normal scenario during the 10-year IW period, modelling predicts that winter and summer/autumn concentrations will sometimes exceed guidelines throughout the Rose Creek system, downstream from NF1 to the mouth at Anvil Creek (R4). At these stations, probabilities of monthly guideline exceedance range from 60 percent to 80 percent (Appendix 7C, Figure 7C-8). The exceedance probability declines from 80 percent at X14 to 70 percent at the mouth of Rose Creek (R4). It declines further to 30 percent after the confluence of Rose Creek and Anvil Creek (R5), but remains close to 20 percent even at the mouth of Anvil Creek (A1) (Appendix 7C, Figure 7C-8). Predictions do not assume attenuation with distance downstream, and may therefore be overly conservative. The water quality guideline for zinc is also expected to be exceeded in approximately 30 percent of months at V8, near the mouth of Vangorda Creek, but will not be exceeded at P4 in the Pelly River downstream of Vangorda Creek and Anvil Creek (Appendix 7C, Figure 7C-8).

Aquatic toxicity data associated with water hardness around 100 mg/L indicate that toxicity to sensitive aquatic species may occur at zinc concentrations that are only slightly greater than the water quality guideline of 0.03 mg/L (Table 7-14). However, winter zinc concentrations at X14 during the baseline period averaged more than double this value, at approximately 0.08 mg/L (Table 7-15). In addition, baseline studies concluded that mine-related effects on biota (e.g., benthic invertebrate surveys) have been undetectable or relatively minor at X14/R2 (Appendix 6H). Although median zinc concentrations are expected to increase at most stations in the Rose-Anvil creek system relative to baseline conditions, they are predicted to be comparable to or less than those observed at X14 between 2008 and 2012, depending on the season (Table 7-15). Also, the predicted median concentrations are unlikely to cause acute lethality to fish (Table 7-14).

There is a very small potential for periodic lethal effects to fish in NFRC during winter based on predicted winter 95th percentile concentrations of up to 0.23 mg/L compared to baseline maxima of 0.13 mg/L (Appendix 7C, Attachment Tables A.10, A.11). Overall, the data indicate aquatic effects for the Normal scenario in surface waters around the FMC would generally be comparable to those currently observed at X14 (i.e., relatively minor) and aquatic toxicity would be unlikely outside of the local study area.

For the Adverse scenario, zinc concentrations are expected to temporarily exceed those associated with the Normal operating scenario, with concentrations of zinc up to those listed in Table 7-16. Average zinc concentrations of 0.2 mg/L or more, such as were observed in November 2013 (Table 7-16), are in the range for potential lethal effects on biota, including fish. However, a study tracking Arctic grayling around the FMC local and

regional study areas using radio telemetry showed two active grayling in the RCD on December 10 (EDI, 2013), where November concentrations averaged 0.34 mg/L (at X3A) (Table 7-16). As Appendix 7C described, the literature suggests concentrations of approximately 0.24 mg/L may be acutely lethal to Arctic grayling, but also shows that fish can acclimate to low-level zinc exposure levels so that their tolerance to subsequently elevated zinc exposure concentrations also increases.

Consistent with the AMP, the elevated zinc in the NFRC and downstream areas is being monitored closely while a remedial solution is developed and implemented. During the IW, under this type of scenario, there is increased potential for temporary toxicity to aquatic biota (approximately 6 to 8 months), possibly including toxicity to fish, until remediation can be implemented. Thereafter, concentrations are expected to return to those associated with the Normal operating scenario, with associated recovery of biological communities to conditions typically associated with normal operations.

7.3.4.7 Analysis of Potential Physical Effects on Fish and Fish Habitat

Fish habitat includes the physical structure of the areas inhabited by fish, such as stream and bank morphology; substrate and cover characteristics; and water quality, depth and elevation; as well as the aquatic plant and invertebrate communities that contribute to ecosystem function and represent a food source for fish. Potential chemical effects associated with the IW on fish and on the biological components of fish habitat were described above in Section 7.3.4.6. The IW's potential effects on physical aspects of fish habitat will be minimal, relating mainly to potential mobilization of particulates into surface waters. Such effects will be mitigated through BMPs for erosion control and sediment transport. Fish habitat may also be disrupted temporarily during the IW; for example, if a new road crossing is required to transport site investigation equipment (e.g., drill rigs) to appropriate locations. The effects on fish habitat will be mitigated by controlling particulate release during associated construction and by adhering to applicable sections of the federal *Fisheries Act.* No other aspects of the IW are expected to affect physical characteristics of fish habitat (e.g., diversions, channel realignment, flow alterations). Therefore, no residual effects are anticipated on physical fish habitat. Proposed monitoring will track the condition of physical and biological aspects of fish habitat during the IW (Appendix 5B, EMSRP).

7.3.4.8 Mitigation of Aquatic Effects

Beyond the activities proposed as part of the IW, no additional, standard mitigation practices are available that could be expected to lessen chemical loads from the FMC to surface waters during the IW. More permanent forms of mitigation will be undertaken as part of the FMRP, but planning, design, permitting, and procurement are required before these measures can be implemented. An objective of IW site investigations will be to identify opportunities for further mitigation or remediation that could be implemented as part of the long-term mine closure plan.

7.3.4.9 Significance of Aquatic Effects

Neither sulphate nor lead concentrations are expected to exceed water quality guidelines for the protection of aquatic life during the IW. Median concentrations of cadmium will be less than the hardness-adjusted water quality guidelines in all local and regional study areas, but the guidelines may sometimes be exceeded in localized stream reaches within the local study area (e.g., NFRC and in Rose Creek immediately downstream from the Faro Mine Area). However, the predicted concentrations are not expected to be toxic to fish and effects on other aquatic biota are expected to be minimal. Cobalt concentrations are expected to exceed the water quality guideline in Rose Creek at X14 and R4 in approximately 45 percent and 35 percent of months, particularly during the ice-free seasons. However, predicted concentrations are not expected to be toxic to fish and effects on other aquatic biota are expected to be minimal. Manganese concentrations are not predicted to change substantially from baseline conditions, except that they may decrease slightly in winter months and increase slightly in other months at Rose Creek stations at, and downstream from, X14. Overall, manganese concentrations are predicted to be greater than the hardness-adjusted guidelines in approximately 65 percent of months at X14 and in an increasingly lower percentage of months at stations farther downstream. The available data indicate that aquatic effects of manganese in surface waters around the FMC would be limited to the vicinity of X14 (i.e., within the LSA) and would likely be minor in magnitude.

DRAFT

During the 10-year IW period, it is predicted that, under Normal operating conditions, winter and summer/autumn zinc concentrations will exceed guidelines throughout the Rose Creek system downstream of NF1 to the mouth at Anvil Creek (R4). At these stations, probabilities of monthly guideline exceedance range from 60 percent to 80 percent but decline from 80 percent at X14 to 70 percent at the mouth of Rose Creek (R4). They further decline to 30 percent after the confluence with Anvil Creek (R5), and to 20 percent at the Anvil Creek mouth (A1). The water quality guideline for zinc is also expected to be exceeded in approximately 30 percent of months at V8, near the mouth of Vangorda Creek, but will not be exceeded at P4 in the Pelly River downstream of either Vangorda Creek or Anvil Creek. Despite these elevated zinc conditions, the available data indicate aquatic effects in surface waters around the FMC would be comparable to those currently observed at X14. This means concentrations would rarely exceed fish toxicity thresholds, effects to other aquatic biota would be minor (i.e., affecting only a few sensitive species), and the effects would be limited to the LSA.

There is potential for periodic, unpredictable, and unpreventable breakthroughs of contamination to surface waters from mine sources via new groundwater pathways, which is currently occurring in the NFRC. Under such conditions, increased toxicity may temporarily occur (approximately 6 to 8 months), possibly including toxicity to fish, until remediation can be implemented. Thereafter, concentrations are expected to return to those associated with the Normal operating scenario, with associated recovery of biological communities to conditions typically associated with Normal operations.

Predicted changes in water quality associated with the IW correspond with significance rankings of Low to Medium for all relevant chemical variables (sulphate, cadmium, cobalt, lead, manganese, and zinc) and all relevant effect attributes (magnitude, likelihood and duration, geographic extent, and reversibility) as defined in Table 7-12.

7.3.4.10 Monitoring of Aquatic Effects

The aquatic environment will be monitored to confirm predicted environmental performance and demonstrate compliance with regulatory requirements. Monitoring results will be presented in comprehensive reports that will assess conditions relative to predictions and provide recommendations for future actions allowing for adaptive management of the FMC. The proposed aquatic monitoring program for the IW is summarized in Appendix 7C (Section 3.6) with additional detail provided in Appendix 5B, the Environmental Monitoring, Surveillance and Reporting Plan.

7.3.5 Wildlife and Wildlife Habitat Effects Assessment

This section describes the results of the detailed analysis of the IW's potential effects on wildlife and wildlife habitat. As identified in Table 7-4, this effects assessment has identified a series of interactions between project activities and wildlife and wildlife habitat, including four major interactions (i.e., ranked as "2" in the interaction matrix). These interactions occur through effects pathways including contaminant transport and uptake, wildlife physical safety risks or disturbances, destruction of habitat and direct contaminant contact. Each of these effects pathways were considered in the context of all project activities to develop the interactions noted previously.

The following sections outline the methods and results of the effects assessment specific to wildlife and wildlife habitat in relation to the project, where the identified project interactions and pathways are described using a series of wildlife and wildlife habitat indicators. Each of these indicators has a set of ecological objectives specifically related to IW activities. An analysis of potential project effects and associated mitigation measures are presented, as well as a description of effect significance as described in Section 7.2.3.

7.3.5.1 Wildlife and Wildlife Habitat – Pathways of Effects

Pathways of effects are the linkages of mechanism through which project activities result in effects to a project VC. Pathways can be of a physical, chemical, environmental, or other nature, and form the cause-effect link through which effects are realized.

Effects on wildlife and wildlife habitats as a result of project activities are anticipated to occur via five main pathways (Table 7-17). Each identified pathway is subsequently described in terms of linkages to project activities and potential effects.

TABLE 7-17
Wildlife and Wildlife Habitat Pathways of Effects
Faro Mine Interim Works

Pathway	Potential Effects
Permanent or temporary destruction (loss) or alteration of habitat.	Habitat loss Nest disturbance Disruption of nesting
Metals uptake through feeding or exposure.	Sublethal health effects or mortality
Entrapment / drowning.	Mortality
Vehicle collisions with wildlife or equipment trauma.	Mortality
Sensory Disturbance (visual, olfactory, auditory).	Disturbance, disruption or avoidance

Habitat Destruction or Alteration

Site access, maintenance, and route development activities have the potential to destroy or alter wildlife habitats. This pathway may result from any activity that includes ground or vegetation disturbance, most often through the use of heavy equipment to remove vegetation, scarify land, clear access trails or move earth. These activities can reduce or remove the value of land as habitat for wildlife through physical disturbance, removal of vegetation or other cover, or the removal or alteration of nests, feeding/foraging areas or travel pathways. Habitat destruction or alteration can have direct and/or indirect adverse effects. For example, in the case of nesting, nest disturbance can have direct effects through the mortality of eggs or hatchlings in nests. Effects can also be indirect through habitat loss (less nesting habitat available for a particular species) or disruption of nesting (individuals are forced from nests or blocked from nesting in a particular area).

Metals Uptake

Tailings storage and water management activities related to site maintenance can result in pathways of metals uptake to wildlife. Tailings stored at the RCTA become mobile in the environment by wind transfer, creating fugitive dust that settles on and can increase the metal concentrations in vegetation and soils. Metals contaminated water is present in pits, ponds, seepage pathways, and other wet environments at the FMC, and can be taken up by vegetation in these areas. Once mobilized in the environment, the contaminant pathway is realized when wildlife species uptake contaminated sediment, soil, vegetation, animal/invertebrate tissue, or water. In addition, direct contact (e.g., skin exposure) with vegetation, soil, water, and tailings sediment may also be another pathway of uptake. Depending on factors such as the concentrations of chemicals, exposure duration, and uptake rates, sublethal or behavioural effects may also result from the accumulation of heavy metals in body systems.

Entrapment and Drowning

Entrapment and drowning were identified as pathways that have the potential to result from waste and water management activities that specifically include the storage of tailings material in the RCTA and the diversion of clean water around site facilities. The tailings materials in the RCTA cover a large area and are open to the environment. The physical nature of the stored materials may be variable across the storage facility area and may pose a risk to wildlife that walk across it, particularly where the materials are unconsolidated. The resulting direct effect can include entrapment of an individual that has sufficient mass (i.e., moose) to sink into tailings where it is unconsolidated. Similarly, the current clean water diversions may result in wildlife entrapment when wildlife attempt to cross them. For example, the Vangorda Creek Diversion includes a half-culvert flume that may restrict the ability for wildlife to escape. Entrapment in the diversion structures may result in injury from escape attempts or mortality from drowning. Furthermore, entrapment within a structure could increase an individual's vulnerability and potential risk of predation.

DRAFT

Vehicle and Equipment Collisions or Trauma

Vehicle and equipment collisions or trauma are pathways that were identified as having the potential to result from supporting activities involving vehicle and equipment use, including those relating to transporting fuel, materials, personnel and supplies, as well as snow and site clearing and general onsite traffic. These activities result in interactions between motorized traffic or equipment and wildlife that use the FMC. The resulting interaction can be a collision between vehicle and wildlife individuals and can have the direct effect of mortality. In the case where a collision does not result in direct mortality, physical trauma from the collision may hinder or reduce the individual's ability to survive (e.g., reduced motility or ability to feed) and may therefore indirectly result in mortality by increasing an individual's vulnerability and potential risk of predation.

Sensory Disturbance

Sensory disturbance is a pathway that was identified as having the potential to result from many of the activities and physical works proposed for the IW, including on-land construction, waste and water management, supporting and site investigation activities, ID spillway upgrades, and RCD modifications. Sensory disturbance can result from any activities that stimulate and disrupt the visual, olfactory, and auditory senses of wildlife, including machine operation, blasting or drilling, earthmoving, and vegetation clearing. Personnel, machines, and equipment (e.g., work crews, trucks, excavators, and drill rigs) create temporary noise (e.g., engine operation, blasting, or verbal communication) and also unnatural odours (e.g., exhaust fumes, crew food, and cigarette smoke). These disturbances may directly engage an avoidance or stress response in wildlife species, leading to the disruption of a migration route/movement trajectory or abandonment of activities and habitat related to breeding, nesting, resting, feeding, or shelter/cover. Indirect effects may include increased essential energy consumption burning fat stores necessary for winter months, the displacement from habitats near to project activities, cessation in breeding, nesting and feeding, and exposure and vulnerability to predators.

7.3.5.2 Wildlife Species and Wildlife Habitat – Indicators

Effects on wildlife and wildlife habitat can manifest themselves through a variety of pathways, and on a multitude of local species or species groups. Consequently, it is not feasible to assess the potential effects of the IW on wildlife and wildlife habitat for all species occurring within the area of influence of the FMC (LSA or RSA). To adequately describe potential effects applicable to a wide variety of species, six indicators of wildlife and wildlife habitat were chosen on which to conduct a detailed assessment of potential project effects. Indicator species were chosen based on their relative high local value or cultural significance, their effectiveness as key receptors for a particular project interaction, and specific habitat requirements that exemplified the potential interactions of many other species. Indicator habitats were chosen based on their importance to sustain a specific life function for a broad group of species, or on the importance of specific key habitats to support species or species groups (Table 7-18).

Together, these six indicators are considered to represent the identified effect pathways and the wildlife and wildlife habitats occurring in the vicinity of the FMC.

TABLE 7-18
Wildlife Species and Wildlife Habitat Indicators
Faro Mine Interim Works

Indicator	Rationale
Moose	Moose are an important species ecologically and socioeconomically, and are harvested in the FMC area. While they are abundant in the RSA and occur in the LSA, there are concerns over potential overharvest that may be developing in the area (Clarke et al., 2012).
Thinhorn sheep	Thinhorn sheep are an important species ecologically and socioeconomically in the FMC and YT. This species is sensitive to disturbances, particularly during their lambing season and during winter. A migration corridor connecting summer and winter habitats intersects with the FMC, and therefore sheep occur relatively regularly in the LSA. Sheep are a good indicator species to represent disturbance effects on other ungulate species.

TABLE 7-18
Wildlife Species and Wildlife Habitat Indicators
Faro Mine Interim Works

Indicator	Rationale
Grizzly bear	Grizzly bear are listed as a species of Special Concern under *SARA*, and are of ecological, cultural and socio-economic importance. Grizzly bear use a variety of specific habitats seasonally and are wide ranging. This species is a good indicator of ecosystem integrity, as well as an indicator of local wildlife-human interactions. Grizzly bear are a good indicator species to represent effects on other large-ranging carnivores and omnivores.
Avian nesting habitat	Passerines (small terrestrial migratory or non-migratory birds) are abundant within the FMC LSA, including several passerine SAR that may be present (olive-sided flycatcher, bank swallow and rusty blackbird). Passerines have relatively specialized nesting habitat requirements and are ubiquitous to nearly all habitats at the FMC due to the broad variety of species present. Accordingly, avian nesting habitat was chosen as an indicator for the effects of local habitat loss or disturbance.
Waterfowl	Waterfowl are known to use the pits and ponds at the FMC at least seasonally, including several species at risk (e.g. harlequin duck, horned grebe and trumpeter swan). Waterfowl using the pits and ponds have the potential for exposure to contaminant pathways through drinking of water or feeding, and therefore provide a representative indicator for wildlife that may use the pits and ponds of the FMC either regularly or occasionally.
Small Mammals	Several species of small mammals are ubiquitous to the FMC area and form a primary food source for other wildlife species. As small mammals generally have limited home ranges and forage on vegetative materials, they are good indicators of local conditions and form a potential link for environmental contaminants to enter the food chain and reach higher trophic levels.

Consideration of Species at Risk in Indicator Selection

SAR occurring in the LSA and RSA include caribou, wolverine, grizzly bear, olive-sided flycatcher, bank swallow and rusty blackbird (as identified in Appendix 6J). Not all SAR occurring or potentially occurring in the LSA or RSA were included as indicators; however, the habitat requirements and sensitivities of the selected indicator species are considered to adequately represent potential impacts to these SAR.

Caribou are listed under Schedule 1 of *SARA* as a species of special concern and do occur in the project area, although not frequently (as described in Appendix 6J). A total of 13 caribou observations have been recorded over a five-year period at the FMC (as compared to 263 observations of moose), and the LSA does not overlap with key habitats for caribou. Based on these data, effects on caribou are not predicted to result from the IW, and are believed to be adequately represented by moose (for caribou moving through the LSA area) or thinhorn sheep (for effects in alpine areas during the calving and post-calving areas).

Wolverine are listed as a species of Special Concern by COSEWIC, and are stable in YT. While wolverine do occur in the LSA, their presence is rare (two observations in five years at the FMC), likely due to very large home ranges and nomadic behaviours. Wolverine are sensitive to anthropogenic disturbances on habitat; however, effects on this species are considered to be adequately represented by grizzly bear for the purposes of this assessment.

Several avian SAR also have the potential to occur in the IW LSA area, including the olive-sided flycatcher (*SARA* Schedule 1 - threatened), the bank swallow (COSEWIC - threatened) and the rusty blackbird (*SARA* Schedule 1 - special concern). One potential nesting area for bank swallow was identified near the ID and CVD Pond; while olive-sided flycatcher and rusty blackbird have not been confirmed as occurring in the LSA. While not specifically identified as project indicators, effects on these avian SAR were considered to be adequately represented through the assessment of effects on avian nesting habitat.

7.3.5.3 Wildlife and Wildlife Habitat – Ecological Objectives

The following series of ecological objectives were developed for the IW to define acceptable thresholds or limits resulting from the identified pathways and project-related effects on wildlife and wildlife habitat. Ecological objectives will assist in determining the significance of effects and guide the development of project-specific mitigation measures in the FMC LSA.

Ecological objectives considered for the IW include those related to habitat use, habitat availability or acceptable loss, metals concentrations or rates of uptake, as well as acceptable rates of project-related wildlife mortality (categories that best define the potential project effects). Ecological objectives for the project are described for the chosen indicators in terms of these four broad categories, and are summarized according to indicator in Table 7-19.

TABLE 7-19
Wildlife Species and Wildlife Habitat Indicators
Faro Mine Interim Works

Indicator	Category	Specific Ecological Objective
Moose	Habitat Loss	No objective defined.
	Mortality	No onsite mortality of moose.
	Local Site Use	Maintain current frequency of site usage by moose. Maintain existing connectivity (travel corridors) amongst habitat areas.
	Metals Uptake	No increase in contaminant uptake related to LSA habitat use.
Thinhorn Sheep	Habitat Loss	No objective defined.
	Mortality	No onsite mortality of sheep.
	Local Site Use	Maintain connectivity between existing habitat patches and maintain corridors between seasonal habitat ranges. Avoid disturbance in the Wildlife Key Area that traverse the FMC during migratory period. Maintain current frequency and rate of site use by thinhorn sheep.
	Metals Uptake	No increase in contaminant update related to LSA habitat use.
Grizzly Bear	Habitat Loss	No objective defined.
	Mortality	Zero human-bear incidents on site and zero mortality on site due to human-bear incidents.
	Local Site Use	Maintain existing travel corridors or connectivity between existing habitat patches. Maintain current frequency of site use by grizzly bear.
	Metals Uptake	No objective defined.
Avian Nesting Habitat	Habitat Loss	Minimize losses of avian nesting habitat. No habitat loss during active nesting window for migratory and non-migratory birds.
	Mortality	No mortality of nesting birds, eggs, or hatchlings.
	Local Site Use	No objective defined.
	Metals Uptake	No objective defined.
Waterfowl	Habitat Loss	No objective defined.
	Mortality	No project-associated mortality of waterfowl
	Local Site Use	Net decrease, or no net increase in local site use by waterfowl during the project term.
	Metals Uptake	No increase in contaminant uptake related to LSA habitat use.
Small Mammals	Habitat Loss	Minimize losses of small mammal habitat within the LSA.
	Mortality	Minimize mortality to small mammals in LSA.
	Local Site Use	Limited disruption to site use and change in population size.
	Metals Uptake	No increase in contaminant uptake related to LSA or RSA habitat use.

DRAFT

Habitat Loss Objectives

There are no specific legislative guidelines or thresholds protecting the habitat of most wildlife habitat, including the habitat of wildlife that occur within FMC LSA. While critical habitat vital to the survival or recovery of wildlife species at risk is afforded legal protection, such habitats to not occur within the project area. Accordingly, no specific (area-based) threshold for habitat loss is applied to define habitat loss. Rather, the ecological objective defined for habitat loss aims to conserve habitat in the LSA. This is consistent with the overall ecological objective, to maintain the current rate of wildlife use, which from a habitat perspective, translates to minimizing habitat loss.

Mortality Objectives

For the purpose of the IW assessment, objectives for wildlife mortality are based on both legal requirements and more general ecological objectives.

An objective of zero mortality for nesting birds, eggs, or hatchlings was identified based on legislation in both the *Migratory Birds Convention Act* and the Yukon *Wildlife Act*. Under the former, it is illegal to disturb or destroy an egg or nest of a migratory bird without a permit. Under the latter, it is illegal to destroy, take, or possess any egg or nest of a bird that is wild by nature but that is not migratory (as defined by being subject to the *Migratory Birds Convention Act*). Accordingly, the ecological objective for the IW is to avoid any mortality of nesting migratory or non-migratory birds.

Moose, sheep, and grizzly bear are all regulated under the Yukon *Wildlife Act*, which states that it is only legal to kill these species by licensed hunters within season, in an area where hunting is permitted, and according to the terms detailed in the Yukon *Wildlife Act*. Killing of wildlife is also permitted under the Yukon *Wildlife Act* where there is an imminent threat of grievous bodily harm or irrecoverable and substantial damage to property and other practical means have been exhausted. Correspondingly, no hunting or intentional killing of wildlife will be tolerated by site personnel at the FMC during the 10-year period of the IW. The potential destruction of grizzly bear, black bear, or other wildlife that are threatening the safety of humans onsite will be deferred to as a last resort. Any other potential wildlife mortalities are anticipated to be associated with accidental interactions (e.g., vehicle collisions, entrapment, drowning). Accordingly, a zero mortality objective has been established for moose, sheep, and grizzly bear.

Local Site Use Objectives

The LSA and RSA provide suitable habitats for a variety of wildlife. The footprint of the FMC totals approximately 20 percent of the LSA, and includes land altered from a pre-disturbance condition in some way (i.e., pits, waste rock piles, roads or other infrastructure). These disturbed areas were cleared of vegetation during the mine development process. Although some natural revegetation has occurred since original disturbance, these areas are sparsely vegetated with pioneering species including grasses, herbs, shrubs, and aspen or balsam poplar. In addition, vegetation re-established on contaminated soils or water may have elevated metal concentrations, particularly on the periphery of the site ponds or waste rock piles.

The remaining 80 percent of the LSA surrounding the FMC footprint is composed of a variety of relatively natural habitats that are used by a variety of ungulates, birds, carnivores, small mammals and amphibians. Wildlife are present in the LSA, moving through the footprint area, and also throughout the RSA through larger undisturbed habitat patches or via corridors between smaller habitat patches (e.g., riparian corridors). The LSA is not considered to provide any limiting or key regional habitats, but does contribute to regional habitat both by supporting local species and by allowing regional connectivity.

Wildlife habitat use objectives at the FMC are not based on specific guidelines or legislation, but rather are defined qualitatively by considering the desired outcomes for local habitat use. For ungulate species such as moose or sheep, and carnivores such as grizzly bear, ensuring the LSA continues to function as part of the regional landscape is a desired outcome. Accordingly, the ecological objective for the IW is to maintain current rates of site usage (e.g., frequency of occurrence at the site) by terrestrial wildlife. Trends in local site usage by wildlife can

DRAFT

also be assessed semi-quantitatively, and is to be assessed through trends in incidental wildlife reporting which is completed as part of the site operations program.

Contrary to the general objective for wildlife use, for waterfowl species using pits or ponds at the FMC LSA that are contaminated there is a desire to reduce the degree of site use during the term of the IW. Risks associated with metals uptake is likely related to the degree of site usage (specifically feeding or stopover on pits and ponds, as described in further detail below), and therefore the objective for reducing site use during the temporal span of the IW is established to help curb metals uptake.

Metals Uptake Objectives

The storage of metals contaminated water and tailings at the FMC presents the potential for contaminant uptake by local wildlife. Concentrations of metals in wildlife tissues are influenced by numerous factors including, but not limited to, the following:

- Metals concentrations in ingested materials/prey (animals and plants)
- Chemical bioavailability (ability to be absorbed into tissues)
- Metabolic pathways and species-specific physiology
- Biotic and abiotic factors in the contaminated environments
- Volume of contaminated material ingested
- Feeding rates, or frequency and duration of exposure

It is not practical to monitor actual contaminant concentrations in most wildlife as lethal sampling techniques are required to harvest tissues needed for metals analysis. Lethal sampling techniques are not practical or accepted for larger wildlife (i.e., ungulates), waterfowl, or small mammals. Furthermore, wide-ranging wildlife such as waterfowl or ungulates would not be appropriate study species for monitoring tissue metals concentrations and contaminant uptake from a localized area such as the FMC. The diversity of habitats and conditions these far-ranging species encounter hinder the ability to correlate metal toxicity or loading back to a single (or localized) area. Accordingly, as it is not practicable to set an absolute objective for metal uptake, a qualitative objective of no net increase in metals uptake was established for the IW. The corresponding ecological objective for the contaminant uptake pathway of effects is therefore to maintain or reduce the frequency of contact between wildlife and contaminants, including: water, vegetation or other food sources, or sediment. These means are discussed further in Sections 7.3.5.4 and 7.3.5.5.

7.3.5.4 Wildlife and Wildlife Habitat – Analysis of Potential Effects

Table 7-20 identifies the various interactions between IW activities and wildlife and wildlife habitat VCs. Four significant (i.e., ranked as a "2") interactions between the IW activities and indicators of wildlife and wildlife habitat were identified. For each of these interactions, an analysis of potential effects is provided below which describes the specific pathways and scenarios whereby an effect may potentially occur, and describes the characteristics of each potential effect. This analysis of effects is organized according to indicator.

Moose

Moose may be affected by the IW activities identified in Table 7-4, specifically the diversion of clean water around site facilities as part of the waste and water management activities. These activities are identified as a major interaction (ranked as a "2"), where the potential interaction may result in an effect that is not mitigable through standard mitigations or BMPs.

The existing clean water diversions at the FMC consist of the RCD, FCD and VCD. Of these, the VCD poses a potential hazard to wildlife as it is composed of an 800 m open half-round steel pipe 2,400 mm in diameter, which is partially-buried (i.e., half-culvert). Alternate opportunities to safely cross this confined channel are on road crossings at the upstream and downstream extents of the diversion. It is anticipated that some wildlife species[1]

[1] Although it is possible that other species, including sheep and grizzly bears, may also access the VCD, it is assumed that each of these species are more agile and better climbers than moose and are likely better equipped to climb out of the channel. In addition, for the purposes of the effects assessment, the least capable climber and subsequently the species most vulnerable to entrapment was used here for simplicity. It is assumed that measures intended to minimize effects for moose will be equally or more effective for these other species.

may attempt to cross the channel along its length. Although an individual may be able to enter the channel, the steep and slippery side walls of the pipe provide little traction for a large hoofed animal, preventing easy exit leading to entrapment. The potential resulting effect may include injury to moose and potential mortality through exhaustion, drowning or predation if entrapped in the channel.

Any mortality of moose as a result of the project (in this case entrapment within the VCD) would not meet the ecological objective of zero-mortality identified for the project. Accordingly, measures and guidelines have been developed to mitigate the potential for this effect to occur and to ensure that there is no loss of life as a result of this interaction (Section 7.3.5.5).

Avian Nesting Habitat

IW activities have the potential to result in effects on avian nesting habitat. The only major interaction identified (which was ranked as a "2") may occur between avian nesting habitat and project activities, specifically related to the development of access routes for site investigations or borrow development (Table 7-20). Although some aspects of these works will be conducted on existing footprint areas, some site clearing and removal of vegetation will occur in previously undisturbed areas. Approximately 5 km of 4 m-wide route development requiring site clearing is planned over the 10-year project duration. Up to 10 km of line cutting for surface geophysics is also to be conducted (up to 1.5 m wide). These two activities may result in the clearing of up to 0.025 km^2 of vegetation, or roughly 0.0003 percent of the LSA area (81.5 km^2). Finally, various site works have the potential to result in ground disturbances within footprint areas. Not all effects can be mitigated through the use of BMPs, and are discussed here.

Naturally vegetated areas tend to provide the higher quality nesting habitat relative to disturbed areas. In the LSA, naturally vegetated areas include graminoid (i.e., grass), riparian shrub, boreal woodland (e.g., white spruce - willow, mixed coniferous-deciduous and pine), and subalpine (e.g., dwarf birch - subalpine fir) ecosystems (Appendix 6I). These ecosystems provide suitable nesting and foraging habitats for ground shrub and tree-nesting species. Mid-elevation northern coniferous forests ecosystems may provide suitable breeding habitat for the olive-sided flycatcher, although this species is not confirmed to occur in the FMC.

In addition to the high value of undisturbed areas onsite, previously disturbed sites can also contribute to available nesting habitat onsite. For example, a road cut silt and sand cliff near the ID and CVD Pond provides suitable habitat for bank nesters such as the bank swallow.

Equipment used to conduct site investigation activities could affect avian nesting habitat through two means. The first potential effect is direct mortality of individuals realized through nest disturbance whereby eggs or hatchlings in nests are mechanically destroyed. The second is indirect mortality, realized by the disruption of nesting behaviours such as brooding, whereby any sensory disturbance (e.g., visual, audible or olfactory) is anticipated to keep the avian parents away (e.g., abandonment) from their nest thereby reducing the viability of the eggs or hatchlings.

Federal and territorial legislation states that is it illegal to disturb or destroy active nests, eggs, or individuals of migratory and non-migratory avian species without a permit. Accordingly, the primary objective with respect to avian nesting habitat is preventing mortality, as defined in Section 7.3.5.3. Accordingly, measures and guidelines have been developed to mitigate the potential for this effect to occur and to ensure that there is no loss of life as a result of this interaction, and are discussed in Section 7.3.5.5.

Waterfowl

A variety of waterfowl species frequent the FMC and project-related activities will potentially negatively interact with waterfowl activity on-site. The only major interaction identified (which was ranked as a "2") for waterfowl is related to the storage of contaminated water in the ponds on the FMC. (Table 7-20).

Observations from the FMC show that waterfowl use pits and ponds in the FMC at least seasonally, and that waterfowl appear to be drinking water or attempting foraging while present (Appendix 6J). These waterfowl activities are concentrated within the man-made pits and ponds onsite that store metals contaminated waters, as well as in the altered habitats of the NFRC and RCD areas. Existing site data indicates that some pits and ponds

contain water, vegetation, and sediment that are elevated in metals, including aluminum, cadmium, arsenic, copper, iron, nickel, lead, titanium, uranium and zinc, sometime above recognized guideline levels (e.g., CCME Canadian Sediment Quality Guidelines for the Protection of Aquatic Life). The use of these habitats by waterfowl presents a potential pathway for metals uptake and subsequent accumulation within body tissues. The ingestion of these metals above the tolerance limits of waterfowl can influence physiology, morphology and reproductive success (Flint, 1997; Kalisinska, 2004; ELR, 2013a). The degree of habitat use by waterfowl at the FMC varies, and the overall volume of water or forage consumed by waterfowl and associated contaminant concentrations are not known. As a result, the degree of actual exposure cannot be determined, only the potential for exposure and/or effect.

Diving species like goldeneyes observed on the SPP, harlequins observed on the SPP and Grum SCP and shorebirds, such as the sandpiper observed on the Grum SCP, all filter sediment to glean benthic invertebrates. This filtration results in contact with elevated metals in water, invertebrates and sediment. Sediment samples collected from the SPP exceeded the CCME guidelines for sediment for cadmium, mercury, lead, arsenic and zinc. The Grum SCP sediment samples report elevated concentrations of cadmium, lead, arsenic, and zinc. While the bioavailability of these metals is not known, waterfowl are both in contact and ingesting sediment and potentially invertebrates with significantly elevated metal concentrations.

Dabbling species such as American wigeons forage on aquatic and riparian vegetation, and have been observed at the IP. Feeding on aquatic plant species can involve the inadvertent ingestion of contaminated sediment along with the metal-laden bulbs of the plants, adding to the concentration of metals ingested. Aquatic vegetation and suitable forage occurs at the CVD Pond, Grum SCP, SPP, and Grum Settling Pond. At these sites, vegetation and sediment were found to be elevated in metals. Specifically, copper, chromium, cadmium, mercury, lead, arsenic, and zinc concentrations were elevated at the CVD Pond. Cadmium, mercury, lead, arsenic, and zinc concentrations were elevated at the SPP. Arsenic, cadmium, lead, and zinc concentrations were elevated at the Grum SCP.

The duration of exposure and the volume of sediment, vegetation and water consumed will influence the rate of uptake of metals, and therefore the long-term effects of elevated metals on waterfowl health. For example, a review of literature resources suggests an observable effect on waterfowl health is possible in less than 10 days of chronic exposure to lead at concentrations equivalent to those present in some FMC ponds (Kalisinska, 2004; Flint, 1997; Cook, 1966). These reported timelines are of a single metal at an elevated concentration, rather than elevated concentrations of numerous metals from multiple sources. Further, the toxicity and availability of each of these metals are often strongly correlated with other water chemistry parameters, such as total hardness or pH (Scheuhammer, 1991; Babich, 1983).

The potential for synergistic or additive relationships must be considered when assessing the overall threat or potential for effect on migrating waterfowl. Synergistic interactions between cadmium and lead, and lead and iron, can influence waterfowl metabolism and result in deficiencies of other essential elements such as calcium, zinc and iron (Kalisinska, 2004; Scheuhammer, 1987).

The continued uptake of metals by waterfowl using the pits and ponds of the FMC would not meet the ecological objective of a decrease in metals update over the term of the IW. Accordingly, measures have been developed to mitigate the potential for this effect to occur, as discussed in Section 7.3.5.5.

Small Mammals

The LSA and RSA provide habitat for a variety of small mammal species, and IW activities have the potential to affect their health, abundance and diversity. Minor project interactions where potential effects are expected to be mitigated through BMPs (ranked as a “1”) as proposed in Table 7-20. The only project activity identified as having the potential to result in effects on small mammals not mitigated by standard best practices (ranked as “2”) is the storage of tailings in the RCTA. A description of the anticipated interaction and potential effects are provided in the following section.

The storage of tailings material in the RCTA generates fugitive dust which is in turn deposited on vegetation and soils in both the LSA and RSA, thereby increasing metal concentrations in vegetation in depositional areas.

Currently, vegetation in both the RSA and the LSA is reported to possess elevated metal concentrations which are confirmed to be a result of past project activities (C.E. Jones and Associates Ltd., 2003; GLL, 2006). Trends in lead deposition outside of the FMC footprint indicate that prevailing winds and water in the RCTA and Rose Creek transport contaminants to the west and northwest into the Anvil Creek basin and onwards north towards the Pelly River. Samples taken from specific areas within the FMC footprint were up to 450-times greater than reference sites for some metals. In addition, between 61 and 100 percent of lead detected in the LSA and 65 to 90 percent detected in Anvil Creek was a result of ore dust deposits (GLL, 2006). There is also the potential that fluvial and airborne transport of tailings material will continue, increasing the affected area over time. Within the FMC footprint area, vegetation has also been found to be elevated in lead, arsenic, zinc, mercury and cadmium (ELR, 2013b).

Vegetation (in particular seed-producing plants) provides a food source for small mammals, and may result in a contaminant pathway in small mammals that could continue through accumulation in higher level predators (GLL, 2006; Hunter, Johnson, and Thompson 1987; Johnson et al., 1978). Metals can also have effects directly on small mammals consuming metals. For example, lead or cadmium intake can be correlated with renal disorders and histopathological changes (Johnson, et al. 1978). Further, zinc can ameliorate the potential toxicity of elevated cadmium concentrations due to competing enzyme and metabolic processes (Johnson et al., 1978; Hunter, Johnson, and Thompson, 1987). The toxicity of these metals is largely dependent on the volume and contaminant concentrations of contaminated materials ingested over specific periods of time.

Metal concentrations in small mammal tissues collected as part of the 2005 terrestrial effects monitoring program did not show a significant correlation with mine activity (GLL, 2006); however, the sample size was insufficient to determine statistical significance. Therefore, the toxicity of metals at the concentrations reported in the LSA and RSA is difficult to determine without tissue samples from exposed animals correlated with metal concentrations in food resources.

The continued uptake of metals by small mammals in the LSA or RSA would not meet the ecological objective of a decrease in metals update over the term of the IW. Accordingly, measures have been developed to mitigate the potential for this effect to occur, as discussed in Section 7.3.5.5.

TABLE 7-20
Wildlife and Wildlife Habitat Interactions Summary by Indicator
Faro Mine Interim Works

	Project Activities/Physical Works	Wildlife and Wildlife Habitat Indicators: Moose	Thinhorn Sheep	Grizzly Bear	Waterfowl	Avian Nesting Habitat	Small Mammals and Habitat	Description of Interaction / Effects	Mitigation Measures
Waste and Water Management	Tailings Storage n the RCTA	1	0	0	1	0	2	• Deposition of fugitive dust from the RCTA has the potential to increase vegetation metal concentrations, creating a pathway of uptake and transfer up the food chain. • Direct contact with riparian vegetation and tailings sediment may create a local pathway of uptake. • Potential for entrapment and mortality in tailings by ungulates.	• Employment of tackifiers at the RCTA to control dust erosion. • Control of vegetation in the vicinity of tailings to reduce habitat value. • Additional mitigation measures to be implemented through site BMPs.
	Clean water diversion	2	1	1	0	0	0	• Potential for wildlife entrapment, injury, or mortality in VCD.	• Potential use of fencing to limit wildlife access to the VCD.
	Contaminated water storage in pit lakes and backfilled pits (Faro, Vangorda, Grum, and Zone II)	0	1	0	1	0	0	• Potential for uptake of metals contaminated water, leading to potential accumulation and sublethal effects.	• Mitigation measures to be implemented through site BMPs.
	Contaminated water storage in LCD Pond, ID Pond, CVD Pond, SPP, Moose Pond, Grum Settling Pond, Grum Pit SCP, Vangorda Water Treatment Pond, and all other ponds	1	1	0	2	0	1	• Potential for uptake of metals contaminated water, vegetation, sediment, or food sources, leading to accumulation and sublethal effects. • Direct contact with riparian vegetation and tailings sediment may create a local pathway of uptake.	• Control of vegetation in the riparian zone of ponds to discourage wildlife use and remove potential pathways. • Use of control mechanisms to limit waterfowl use (e.g., pyrotechnics or report shells. • Additional patrols during migration season to employ deterrents. • Additional mitigation measures to be implemented through site BMPs.
	Diversions and site drainage containment system maintenance (dams, spillways, dikes, berms, collection ponds)	0	0	0	0	1	1	• Potential minor localized loss of habitat, or mortality of species with low motility. • -Potential of avian nest disruption or destruction. • Avoidance of work areas by wildlife due to sensory disturbance (e.g. sound, visual, dust).	Mitigation measures to be implemented through site BMPs.
Site Investigation Activities	Boreholes/test pits	1	1	1	0	1	1	• Potential minor localized loss of habitat, or mortality of species with low motility. • -Potential of avian nest disruption or destruction. • Avoidance of work areas by wildlife due to sensory disturbance (e.g. sound, visual, dust).	Mitigation measures to be implemented through site BMPs.
	Monitoring equipment installation including wells, thermistors, flow measurement facility	1	1	1	0	1	1	• Potential minor localized loss of habitat, or mortality of species with low motility. • -Potential of avian nest disruption or destruction. • Avoidance of work areas by wildlife due to sensory disturbance (e.g. sound, visual, dust).	Mitigation measures to be implemented through site BMPs.
	Access route development (may include stream crossings)	1	1	1	0	2	1	• Potential minor localized loss of habitat, or mortality of species with low motility. • Potential of avian nest disruption or destruction. • Avoidance of work areas by wildlife due to sensory disturbance (e.g. sound, visual, dust)	• Areas of vegetation clearing to be limited, and timing of vegetation clearing to coordinated to minimize potential effects. • Additional mitigation measures to be implemented through site BMPs.
	Helicopter / aircraft use	0	1	0	0	0	0	• Potential for disturbance of wildlife from aircraft use. Potential for effects most pronounced during and post calving / lambing period or during winter.	Mitigation measures to be implemented through site BMPs.
DVIHU	Excavation of ID Spillway	0	0	0	0	1	1	• Potential minor localized loss of habitat, or mortality of species with low motility. • -Potential of avian nest disruption or destruction. • Avoidance of work areas by wildlife due to sensory disturbance (e.g. sound, visual, dust).	Mitigation measures to be implemented through site BMPs.
	Borrow material sourcing and transport	1	1	1	0	1	1	• Potential minor localized loss of habitat, or mortality of species with low motility. • -Potential of avian nest disruption or destruction. • Avoidance of work areas by wildlife due to sensory disturbance (e.g. sound, visual, dust).	Mitigation measures to be implemented through site BMPs.
	Removal of vegetation in RCD	0	0	0	0	1	1	• Potential minor localized loss of habitat, or mortality of species with low motility. • -Potential of avian nest disruption or destruction.	Mitigation measures to be implemented through site BMPs.

Wildlife and Wildlife Habitat Interactions Summary by Indicator
Faro Mine Interim Works

		Wildlife and Wildlife Habitat Indicators							
	Project Activities/Physical Works	Moose	Thinhorn Sheep	Grizzly Bear	Waterfowl	Avian Nesting Habitat	Small Mammals and Habitat	Description of Interaction / Effects	Mitigation Measures
								• Avoidance of work areas by wildlife due to sensory disturbance (e.g. sound, visual, dust).	
	Removal of bank sloughs in RCD	0	0	0	0	1	1	• Potential minor localized loss of habitat, or mortality of species with low motility. • -Potential of avian nest disruption or destruction. • Avoidance of work areas by wildlife due to sensory disturbance (e.g. sound, visual, dust).	Mitigation measures to be implemented through site BMPs.
	Repair of RCD Dike	0	0	0	0	1	1	• Potential minor localized loss of habitat, or mortality of species with low motility. • -Potential of avian nest disruption or destruction. • Avoidance of work areas by wildlife due to sensory disturbance (e.g. sound, visual, dust).	Mitigation measures to be implemented through site BMPs.
Accessory Activities	Transport fuel and materials	1	1	1	0	0	1	• Potential for injury or mortality due to wildlife vehicle collisions. • Potential Avoidance of habitat in travel corridors due to sensory disturbance (e.g. sound, visual, dust).	Mitigation measures to be implemented through site BMPs.
	Transport of personnel and supplies	1	1	1	0	0	1	• Potential for injury or mortality due to wildlife vehicle collisions. • Potential Avoidance of habitat in travel corridors due to sensory disturbance (e.g. sound, visual, dust).	Mitigation measures to be implemented through site BMPs.
	Waste management (disposal to landfills), include domestic waste	0	0	1	0	0	0	• Potential of wildlife attraction to waste sources resulting in conflict/risk to humans, and eventual mortality (wildlife destruction to mitigate risk).	Mitigation measures to be implemented through site BMPs.
	Snow clearing and stockpiling	0	1	0	0	0	0	• Potential for disruption of sheep migration pathways by snowbanks. May limit movement across road corridors or trap sheep on roadways, thereby increasing the risk of displacement along the roadway or vehicle collisions.	Mitigation measures to be implemented through site BMPs.
	Temporary camp	0	0	1	0	0	0	• Potential of wildlife attraction to waste sources resulting in conflict/risk to humans, and eventual mortality (wildlife destruction to mitigate risk).	Mitigation measures to be implemented through site BMPs.
	Sourcing and transport of borrow material	1	1	1	0	0	0	• Avoidance of work areas by wildlife due to sensory disturbance (e.g. sound, visual, dust).	Mitigation measures to be implemented through site BMPs.
	General project-related traffic	1	1	1	0	0	1	• Potential for injury or mortality due to wildlife vehicle collisions. • Potential avoidance of habitat in travel corridors due to sensory disturbance (e.g. sound, visual, dust).	Mitigation measures to be implemented through site BMPs.

DRAFT

7.3.5.5 Wildlife and Wildlife Habitat – Mitigation

Moose

Standard mitigation measures typically included in BMPs and environmental management guidelines are not anticipated to be adequate to prevent mortalities to moose that become entrapped in the VCD. Accordingly, the following additional mitigation measure is recommended: the use of fencing or wildlife deterrent mechanisms may be used to limit access to the VCD.

The installation of fencing may be used to deter wildlife from crossing from the VCD should wildlife mortality occur. Fencing could either be installed to exclude wildlife from the VCD, or to discourage crossings within the constructed diversion area. If installed, the interim installations should be monitored daily (at a minimum) to ensure that they are functioning effectively.

Avian Nesting Habitat

Several standard mitigations measures will be employed to limit effects on avian nesting habitat, including best management practices directed at preventing avian mortality during the bird nesting season, as regulated by the *Migratory Bird Convention Act* and the Yukon *Wildlife Act*. These will focus on scheduling construction activities to fall outside of the migratory bird nesting window, or pre-clearing of vegetation from construction areas during the non-nesting season. The following additional mitigation measures are recommended:

- Avian nest searches will be conducted within proposed clearing areas prior to commencing works if works must be completed during the bird nesting window; and,
- A survey of key footprint area nesting sites will be conducted, and any areas identified are to be marked and identified to reduce the risk of project conflicts.

Avian nest search would be conducted during the bird nesting window (June 1 to July 30) according to standard nest search protocols and would include three survey passes conducted by a crew of two biologists over a three-day period (i.e., one pass per day) to ensure adequate opportunity for nest detection. Surveys must be performed between the period of 04:30 and 09:30 when birds are most active. Active nests will be flagged using an appropriate buffer distance within which no clearing is to occur until after the close of the bird nesting window. Clearing activities must commence no more than 24 hours following the completion of the final survey pass to ensure no new nests are initiated after that time.

Similarly, any footprint areas in the vicinity of active works would be surveyed during the bird nesting window and between the hours of 04:30 and 09:30. Protective measures (e.g., area flagged and barricaded) should be implemented if evidence of active nesting is observed, in order to limit disturbance and prevent mechanical damage to the bank thereby preventing any mortality of brooding adults, eggs, nestlings or a fledglings.

Waterfowl

The primary objective of mitigation measures developed to minimize the potential and degree of contaminant pathways in waterfowl is to limit the accessibility and time spent on contaminated habitats in the FMC. Based on current data regarding waterfowl habitat use and behaviors at pits and ponds in the FMC, it is likely that the FMC is primarily used as a stop-over point during migration; therefore, reducing the availability or attractiveness of the habitats during that time will help to reduce waterfowl use and therefore the potential for contaminant exposure.

Employing the following mitigation measures either in combination or individually, will assist in reducing waterfowl use of pond and pit habitats in the FMC.

- Riparian vegetation around the perimeter of pond habitats will be managed to reduce vegetative cover which can provide nesting, loafing and foraging habitats for various species of waterfowl.
- Shore or bank restoration at the FMC will be limited to only that which is required to stabilize the features for erosion. If planting occurs, alternative ground covers such as unpalatable mulches or geotextile are to be used rather than vegetation.

DRAFT

- Pyrotechnics, air cannons, or report shells should be deployed by site staff during key migratory periods, particularly during peak migratory periods in April, May, August, and September to create an inhospitable environment and deter establishment or temporary stop-over.
- Other deterrents (e.g., BirdBalls or a Goosenator robot) will be deployed if necessary to assist in deterring waterfowl from landing, foraging, or breeding in the pits and ponds.
- Wildlife patrols will be conducted during key migratory periods to monitor the effectiveness of deterrents and supplement deterrent effectiveness, if required, with non-lethal shooting.

Riparian areas associated with many of the pond habitats, provide suitable foraging, nesting and stop-over habitats for both resident and migratory waterfowl species. Grasses and sedges provide attractive nesting habitat for many species of ducks, swans and other shorebird species. Taller shrub and treed riparian areas provide cover and protection for nesting and rearing of young. Many of the plant species recorded in these areas are suitable food for many waterfowl species. Removal or trimming of the riparian vegetation prior to the breeding and nesting seasons will reduce the suitability for nesting, encouraging waterfowl to seek habitats in less-disturbed areas outside of the FMC footprint.

For waterfowl that still stop at FMC pits or ponds, auditory disturbances such as air cannons or report shells deployed during key migratory periods and at inconsistent intervals can deter waterfowl from using (for example, nesting and foraging) any of the habitats in the FMC. These tools can be reinforced during seasonal wildlife patrols with non-lethal shooting.

Migrating waterfowl look for large bodies of open water for stop-over habitats, such as those provided by the three pits, the CVD Pond and IP. The steep walls of the pits provide shelter from high winds, and the large expanses of open water allow for suitable space for easy landing and takeoff by diving ducks and larger species such as swans and geese. To deter rafts of waterfowl, deploying BirdBalls will make the open water less visible to migrating birds and decreasing the available landing/takeoff area required. BirdBalls are hollow plastic balls that camouflage water surfaces, preventing birds from alighting on ponds. Alternatively, deploying a remote-controlled robot when rafts are observed, will encourage birds to seek alternative habitats. The Goosenator is a remote-controlled robot that acts as a scare-tactic discouraging waterfowl from remaining on ponds.

Small Mammals

The deposition of fugitive dust generated from the RCTA is identified to be a key potential contaminant pathway for small mammals. The implementation of the following mitigation measures will serve to reduce the deposition of contaminated dust and minimize the potential for contact leading to a toxicological pathway in small mammals.

- Vegetation will be managed in the areas immediately within the RCTA where vegetation metal concentrations are significantly elevated.
- Regular application of tackifiers will minimize the generation and subsequent deposition of fugitive dust on vegetation within the LSA and the RSA.

Consistent with the removal and management of riparian vegetation for waterfowl, the management of grasses and other seed-producing plants and the reduction of structural diversity in riparian areas adjacent to the RCTA will reduce the value of habitat for small mammals in the critical deposition areas. Without sufficient food resources and suitable habitat, the potential for a contaminant pathway can be reduced.

Regular application of tackifiers on tailings material, and the application of water on roads in close proximity to the mill and historic mine operations will reduce fugitive dust generation. The reduction of dust from the FMC footprint will reduce the subsequent contamination of soil, vegetation and waterways in the LSA and RSA, reducing the potential for transport away from the footprint. Over time, the reduction of additional or continued deposition of metals will result in decreases to metals contamination of surrounding areas.

DRAFT

TABLE 7-21
Wildlife and Wildlife Habitat Significance Assessment Criteria
Faro Mine Interim Works

Valued Components	Effects Assessment Indicator	Rationale for Selection	Measurements	Effect Attributes	Significance Ranking	Ranking Criteria
Wildlife	Moose	Moose are an important species ecologically and socioeconomically that are harvested in the FMC area. They are abundant in the RSA but there are local concerns over potential overharvest.	Rates of observations of moose in the FMC LSA (as recorded through site wildlife log), rates of occurrences of human interactions or mortality onsite.	Magnitude and Likelihood/Duration	Low	No reduction in the frequency of occurrence on site during the 10-year period. Zero road mortalities; No disruption to movements on FMC roads (including Main Access and Haul Roads). No detectable change in local/regional population density (based on 5-year trend analysis typically used by EY wildlife managers to assess population trends.
					Medium	Periodic movement disruption and infrequent road mortality (vehicle collisions). Less than a 50% reduction in the frequency of occurrence on site as observed through wildlife logs. No detectable change in local/regional population density (based on 5-year trend analysis typically used by EY wildlife managers to assess population trends).
					High	Frequent movement disruption and road mortality (vehicle collisions). Greater than a 50% reduction in the frequency of occurrence on site as observed through wildlife logs. Detectable change in local/regional population density (based on 5-year trend analysis typically used by EY wildlife managers to assess population trends).
				Geographic Extent	Low	Changes affect individual moose at the LSA level (i.e., Faro Mine, Vangorda/Grum Area, Haul Road, and Main Access Road).
					Medium	Changes affect moose at the GMS level, and effects apply to the GMSs that overlap with the FMC.
					High	Changes affect moose at the regional population level (RSA), and effects apply to the regional area surveyed by YG in 2011.
				Reversibility	Low	Not applicable as there is no change from baseline (i.e., there is no condition to reverse).
					Medium	Population effects are reversible; time to reverse is dependent on time required to develop and implement an adaptive management plan.
					High	Population effects are not reversible.
	Thinhorn Sheep	Thinhorn sheep are an important species both ecologically and socioeconomically. This species is susceptible to disturbances and sensitive during their lambing season. Sheep are a good indicator species to represent disturbance effects.	Rates of onsite mortality or occurrence onsite (as recorded through site wildlife log). Area or regional surveys of population size and structure.	Magnitude and Likelihood/Duration	Low	No reduction in the frequency of occurrence on site during the 10-year period. Zero road mortalities; No disruption to movements on FMC roads (including Main Access and Haul Roads).
					Medium	Only infrequent movement disruption and infrequent road mortality (fewer than one per five-year period). Less than a 50% reduction in the frequency of occurrence on site as observed through wildlife logs.
					High	Frequent of movement disruption and road mortality. Greater than a 50% reduction in the frequency of occurrence on site as observed through wildlife logs.
				Geographic Extent	Low	Changes affect individual sheep at the FMC level (i.e., Faro Mine, Vangorda/Grum Area, Haul Road, and Main Access Road).
					Medium	Changes affect sheep using mountain habitats adjacent to the FMC and effects apply to the mountain blocks adjacent to FMC.
					High	Changes affect sheep at the Faro region sheep population level, and effects apply to the regional area surveyed by YG in 2011 during the lambing surveys.
				Reversibility	Low	Not applicable as there is no change from baseline (i.e., there is no condition to reverse).
					Medium	Population effects are reversible; time to reverse is dependent on time required to develop and implement an adaptive management plan.
					High	Population effects are not reversible.
	Grizzly Bear	Grizzly bear are of ecological, cultural and socio-economic importance. This species is an indicator of ecosystem integrity, as well as an indicator of local wildlife human interactions.	Rates of observations of grizzly bear in the FMC LSA (as recorded through site wildlife log), and rates of occurrences of bear-related incidents at the FMC.	Magnitude and Likelihood/Duration	Low	No reduction in the frequency of occurrence on site during the 10-year period. Zero human-bear conflicts and zero road or human-conflict mortalities.
					Medium	Infrequent human-bear conflict and rare mortality due to conflict or road collision (fewer than one per 5-year period). Less than a 50% reduction in the frequency of occurrence on site as observed through wildlife logs.
					High	Frequent human-bear conflicts at the FMC resulting in problem bear mortalities, and/or frequent mortality due to road collisions. Greater than a 50% reduction in the frequency of occurrence on site as observed through wildlife logs.
				Geographic Extent	Low	Changes affect individual bear(s) at the FMC level (i.e., Faro Mine, Vangorda/Grum Area, Haul Road and Main Access Road).
					Medium	Changes affect bears at the GMS level, and effects apply to the GMSs that overlap with the FMC.
					High	Changes affect bears at the regional population level, and effects apply to the FMC RSA.
				Reversibility	Low	Not applicable as there is no change from baseline (i.e., there is no condition to reverse).
					Medium	Population effects are reversible; time to reverse is dependent on time required to develop and implement an AMP.
					High	Population effects are not reversible.

TABLE 7-21
Wildlife and Wildlife Habitat Significance Assessment Criteria
Faro Mine Interim Works

Valued Components	Effects Assessment Indicator	Rationale for Selection	Measurements	Effect Attributes	Significance Ranking	Ranking Criteria
	Avifauna (Nesting Habitat)	Passerines are abundant within the FMC LSA, including the potential for several species at risk. Passerines are ubiquitous to nearly all habitats at the FMC, and have relatively specialized nesting habitat requirements. Accordingly, avian nesting habitat was chosen as an indicator for local habitat loss or disturbance.	The level of compliance with site mitigations effective at limiting disturbance-related nesting disturbance or mortality.	Magnitude and Likelihood/Duration	Low	No alteration, disruption, or destruction of nesting habitat during the avian nesting season. No destruction or avian mortalities as work will be completed outside of nesting season, or nest surveys will be conducted prior to clearing activities to avoid disturbing or destroying active nests.
					Medium	Minor disruption to nesting avifauna or loss of habitat will occur due to vegetation clearing during the breeding bird season. Works will be completed outside of the nesting season, or nest surveys will be conducted prior to clearing activities to avoid disturbing or destroying active nests. Some minor habitat loss or disruption of nests will occur due to incomplete application of mitigations or unforeseen nests
					High	Habitat and disturbance effect of clearing activities could be of sufficient magnitude or duration to impact local avian populations.
				Geographic Extent	Low	Effects on avifauna and habitat will be local and isolated (i.e. site level).
					Medium	Effects on avifauna and habitat will be localized and more widespread (i.e. LSA level).
					High	Effects on avifauna and habitat will be regional and widespread (i.e. RSA level).
				Reversibility	Low	Habitat effect will be completely reversible.
					Medium	Habitat effect will be temporary but reversible within some length of time (e.g., alternate habitat are available, vegetation will recover over time).
					High	Habitat effect will be permanent.
	Avifauna (Waterfowl)	Waterfowl use of pits and ponds at the FMC, including several species at risk (e.g. harlequin duck, horned grebe and trumpeter swan). Waterfowl provide a good indicator for wildlife using the pits and ponds of the FMC.	Degree of metal uptake to waterfowl from water and/or food sources.	Magnitude and Likelihood/Duration	Low	Waterfowl use of pits and ponds is limited and temporary (i.e., stop-over only). Decreases, or no increases in metal uptake by waterfowl over the 10-year project period as indicated by a net reduction in waterfowl use of pits and ponds, and a reduction in available pathways.
					Medium	Waterfowl use of pits and ponds is limited and temporary, including stop-over and limited feeding. Slight to moderate increases in metal uptake by waterfowl over the 10-year project period.
					High	Increase in waterfowl use of pits and ponds, including seasonal resident waterfowl feeding locally. Significant increases in metal update by waterfowl over the 10-year project period.
				Geographic Extent	Low	Project effects will be limited to a specific site or area at the FMC (i.e., ID Pond).
					Medium	Project effects will be site-wide at the FMC.
					High	Project effects will be site-wide at the FMC, and some population scale effects may occur offsite.
				Reversibility	Low	Not applicable as there is no change from baseline (i.e., there is no condition to reverse).
					Medium	Projects effects will be short-term/temporary and largely reversible (e.g., avian individuals' visit will be brief and will recover following departure from FMC).
					High	Project effects are irreversible. Individual avian health will be compromised and will lead to reduced reproductive success and/or direct mortality.
	Small Mammals (Rodents)	Small mammals are ubiquitous to the FMC area and are a primary food source. As small mammals have a small home range and are eaten by a variety of animals, they forms a potential link for environmental contaminants to higher trophic levels.	Health of local small mammal populations and concentrations of heavy metals in tissue.	Magnitude and Likelihood/Duration	Low	No increase in tissue heavy metal concentrations over the 10-year project period. No measurable decrease in local small mammal population density in LSA.
					Medium	Minor increase in tissue heavy metal concentrations over the 10-year project period. Slight to moderate decrease in small mammal population density in LSA.
					High	Significant increase in tissue heavy metal concentrations over the 10-year project period. Significant decrease in small mammal population density in LSA.
				Geographic Extent	Low	Changes to affect small mammal populations local to FMC infrastructure only (i.e. project footprint area).
					Medium	Changes to affect small mammal populations within the FMC LSA.
					High	Changes to affect small mammal populations at a regional scale (RSA, or within zone of dust deposition from the FMC infrastructure).
				Reversibility	Low	Not applicable as there is no change from baseline (i.e., there is no condition to reverse).
					Medium	Population and physical effects are reversible over time once factors resulting in effect are removed.
					High	Population effects are not reversible.

DRAFT

7.3.5.6 Wildlife and Wildlife Habitat – Significance of Effects

A series of criteria were established based on which to evaluate the significance of project effects on wildlife. These criteria were developed in terms of magnitude and likelihood/duration, geographic extent, and reversibility. For each of the six identified wildlife and wildlife habitat indicators, specific ranking criteria were developed in terms of the ecological objectives defined above in Section 7.3.5.3. Table 7-21 provides these ranking criteria in terms of indicator-specific end points or changes. During the assessment process, the ranking criteria were reviewed for each indicator, and according to each project activity. Table 7-22 provides an overall summary of their residual effects for the major project interactions.

Moose

The IW effects on moose are expected to be limited to disturbance effects around roadways and infrastructure, as well as the potential for site-related mortality from vehicle collisions or entrapment in site infrastructure. Contaminant uptake from the site is expected to be minimal. Following the implementation of site mitigations, effects on moose are expected to be Low to Medium in magnitude and limited to the project duration (10 years). The geographic extent is expected to be Low (LSA area), with effects being fully reversible (Low to Medium). Overall, project effects on moose are expected to have a low significance.

Thinhorn Sheep

The IW effects on thinhorn sheep are expected to be limited to Minor interactions (ranked as "1") that involve minor sensory disturbance or avoidance, minor metals uptake, and potential mortality due to site activities. Following the implementation of project mitigations, effects on thinhorn sheep are expected to be low in magnitude and limited to the project duration (10 years). The geographic extent of effects is expected to be low (limited to the LSA area), with effects being fully reversible (Low to Medium). Overall, project effects on thinhorn sheep are expected to have a low significance.

Grizzly Bear

The IW effects on grizzly bear are expected to be limited to Minor interactions (ranked as "1") that involve potential mortality or changes in local site use due to sensory disturbance or habitat disruption. Following the implementation of project mitigations, effects on grizzly bear are expected to be Low to Medium in magnitude and limited to the project duration (10 years). The geographic extent of effects is expected to be Low (limited to the FMC and individual bears), with effects being of Low to Medium reversibility. Overall, project effects on grizzly bear are expected to have low significance.

Avian Nesting Habitat

The IW effects on avian nesting habitat are expected to be limited primarily to Minor interactions (ranked as "1") that involve minor losses of available nesting habitat on site or mortalities of nesting birds, eggs, or young. When assessed in the context of access development for the project, these effects were ranked more highly ("2") due to the extent of access trail development over the span of the project. Following the implementation of project mitigations, effects on avian nesting habitat and birds are expected to be Low to Medium in magnitude. Effects may continue beyond the project lifespan, but are reversible (as vegetation regrows). The geographic extent of effects is expected to be Low (site level). Overall, project effects on avian nesting habitat are expected to have low significance.

Waterfowl

The IW effects on waterfowl are expected to be limited to potential metals uptake related to usage of pit and pond habitats on site, with no associated habitat effects. Following the implementation of project mitigations, effects on avian nesting habitat and birds are expected to be Low to Medium in magnitude and limited to the lifespan of the project (10 years). The geographic extent of effects is expected to be Low to Medium in extent, with effects being of Low to Medium reversibility. Overall, project effects on waterfowl are expected to have low significance.

Small Mammals

The IW effects on small mammals are expected to primarily be limited to minor interactions (ranked as "1") that involve minor site disturbances, mortality, or losses of habitat. When assessed in the context of tailings storage for the project, effects of potential metals uptake were more highly ranked ("2") due to the potential for contaminant accumulation. Following the implementation of project mitigations, effects on small mammals are expected to be Low in magnitude and limited to the lifespan of the project or a short duration thereafter. The geographic extent of effects is expected to be Medium to High in extent, with the effects being of Low to Medium reversibility. Overall, project effects on small mammals are expected to have low overall significance.

7.3.5.7 Wildlife and Wildlife Habitat – Monitoring

Three techniques will be employed to monitor the effects of the project on wildlife and wildlife habitat: monitoring of site use by waterfowl, monitoring of general wildlife use within the FMC footprint area, and monitoring of small mammal contaminants levels in relation to the FMC.

Additional monitoring of site use by waterfowl is to be employed in years one through three of the project to determine whether mitigation measures focussed on reducing waterfowl presence at the FMC are effective. This monitoring will employ specific efforts to quantify the rate of site use.

The FMC incidental wildlife log program is to continue to be employed on site to monitor the degree of wildlife occurrence on site as measured through observations made by personnel on site.

A small mammal contaminants monitoring program is to be conducted in years five and ten of the project to determine whether the level of tissue contaminants in small mammals within the LSA is decreasing, stable, or increasing. This program will be in addition to a year zero program that is planned as part of a baseline study program.

These wildlife monitoring techniques are outlined in detail in Appendix 5E.

7.3.6 Socio-economic Effects Assessment

7.3.6.1 Introduction

This section describes the potential socio-economic effects that could result from the IW. The four IW components—site operations, site investigations, DVIHU and accessory activities (see Section 5.0, Project Description)—could each result in different socio-economic effects at different times and in different places.

The IWPP considers potential IW effects on a number of socio-economic values consistent with YESAA's definition of socio-economic effects, which includes "effects on economies, health, culture, traditions, lifestyles and heritage resources."(Government of Canada, 2003)

The socio-economic assessment team identified VCs and relevant indicators, as well as the geographic scope of potential effects, and the pathways the IW's effects may follow to affect the values. The assessment describes potential effects on the FMC, the Town of Faro, and the affected First Nations identified in the Yukon Devolution Transfer Agreement (YG, 2001).

DRAFT

TABLE 7-22
Wildlife and Wildlife Habitat Effects Summary, Significance, and Residual Effects for Major Project Interactions
Faro Mine Interim Works

Project Activities / Physical Works		Indicator	Description of Interaction / Effect	Recommended Mitigation Measures or Best Management Practices	Residual Effect	Significance of Residual Effect
Waste and Water Management	Storage of Tailings Material in the RCTA	Small Mammals and their Habitats	Uptake and transfer of heavy metals resulting from contact and ingestion of plant material contaminated by fugitive dust	Manage vegetation in the critical deposition areas to limit the feeding opportunities and overall habitat value in the areas immediately within the RCTA where vegetation metal concentrations are significantly elevated. Regular application of tackifiers will minimize the generation and subsequent deposition of fugitive dust on vegetation within the LSA and the RSA.	Zero mortalities No increase in tissue metal concentrations.	Low
	Diversion of clean water around site facilities	Moose	Direct mortalities due to entrapment in the VCD channel	Replace existing VCD channel using a wildlife friendly design. Install wildlife deterrent mechanisms until the existing structure can be replaced. Regularly monitor the VCD to ensure that no wildlife species are trapped within the steel pipe diversion structure prior to and during the installation of the wildlife deterrent mechanism.	Zero mortalities.	Low
	Storage of contaminated water in pits and ponds	Waterfowl	Direct contact with contaminated water Ingestion of contaminated water, sediment and vegetation	Manage riparian vegetation around the perimeter of pond habitats to reduce vegetative cover which provides nesting, loafing and foraging habitats for various species of waterfowl. Limit any shore or bank restoration to only that which is required to stabilize the features for erosion, and use alternative ground covers such as unpalatable mulches or geotextile rather than vegetation. Deploy pyrotechnics, air cannons or report shells during key migratory periods, particularly in April, May, August, and September when flocks will be traveling through the LSA, to create an inhospitable environment and deter establishment or temporary stop-over. Deploy BirdBalls or Goosenator robots to deter waterfowl from landing, foraging or breeding on the pits and ponds. Complete wildlife patrols during key migratory periods to monitor effectiveness of deterrents and supplement with non-lethal shooting to reinforce automated systems.	No increase in tissue metal concentrations.	Low
Site Investigation Activities	Access route development, including stream crossings	Avifauna	Direct effect of mortality of individuals through nest disturbance (mortality of eggs or hatchlings in nests) from mechanized removal of vegetation during clearing activities Indirect effect of disruption to nesting (individuals are forced from nests or blocked from nesting in a particular area), potentially leading to mortality of eggs or hatchlings in nests	Conduct avian nest searches within the proposed clearing area prior to commencing works if works must be done during the bird nesting window. Survey key footprint area nesting sites, and mark any identified areas to reduce the risk of project conflicts.	Zero mortalities.	Low

DRAFT

7.3.6.2 Geographic Scope

Based on the scope of activities proposed for the IW, the assessment team identified the following First Nations and communities for the socio-economic effects assessment:

- RRDC, primarily located in Ross River
- SFN, primarily located in Pelly Crossing
- LFN, primarily located in Watson Lake
- KDC
- Community of Faro (Town of Faro)

The assessment team collected and synthesized the available secondary data for these First Nations' and communities' VCs (refer to Appendix 6L for the baseline conditions). The Ross River Dena reside primarily in Ross River, where they maintain their offices of governance. The SFN is centred in Pelly Crossing. LFN members reside primarily in the community of Watson Lake. The KDC is a society formed to advance the interests of Kaska individuals in the five Kaska First Nations in British Columbia and Yukon. RRDC and LFN are the Kaska First Nations members of KDC that are centred in Yukon.

The assessment considered effects in three distinct study areas including:

- Site study area: the FMC site
- LSA that includes the FMC, Town of Faro, and Ross River
- RSA that includes the FMC, Faro, Ross River, Pelly Crossing, and Watson Lake

The socio-economic effects assessment identified pathways through which the IW could affect the VCs in each of the study areas and communities. The assessment team provided explanations for the pathways identified and then characterized the potential socio-economic effects related to each pathway. For the human health and safety VC, now major interactions were noted (Table 7-4). However, a qualitative assessment of effects was complete and is also presented in Section 7.3.6.10.

7.3.6.3 Socio-Economic Valued Components

As stated in Section 7.1.2, the assessment considered the following socio-economic VCs:

- Economy and employment
- Community stability and well-being
- Infrastructure and services
- Land use and access
- Culture and heritage
- Human health and safety

The assessment team identified indicators, which could be used to quantitatively or qualitatively measure each value. Table 7-23 describes the VCs, their indicators, and the rationale for their inclusion in the assessment.

TABLE 7-23
Socio-economic Valued Components and Indicators
Faro Mine Interim Works

Valued Component	Indicators	Rationale for Inclusion
Economy and Employment	Business development	The IW may stimulate local economies, and could increase employment and lead to skills development, training, and education in local communities. This value evaluates (1) the community's ability to adapt to economic growth, (2) the effects of increased disposable income, the distribution of costs/benefits among affected people (adverse effect/income equity), and (3) the effects on local and regional cost of living.
	Economic diversification	
	Employment opportunities and income	
	Education and training	

TABLE 7-23
Socio-economic Valued Components and Indicators
Faro Mine Interim Works

Valued Component	Indicators	Rationale for Inclusion
Community Stability and Well-being	Demographics	The influx of temporary workforce during each project component may influence community makeup, including demographics and mobility, such as effects of migration (in and out), changes in social and cultural makeups of communities, and influences on individual, family, and community health.
	Cultural well-being	
	Social cohesion	
Infrastructure and Services	Roads and traffic	The potential influx of temporary workforce may strain community infrastructure, housing, and emergency and health services. The IW construction and maintenance activities may increase traffic, which could in turn affect local road safety and cause wear to road infrastructure.
	Housing	
	Health services	
	Emergency services	
	Community infrastructure (water, sewer, garbage education, and education and recreation facilities)	
Land Use and Access	Traditional land use	The IW may affect how existing land users and First Nations traditionally access the FMC and surrounding areas (for hunting, trapping, and gathering). IW construction and maintenance activities might also affect access for commercial and recreation land users.
	Hunting and fishing (recreational and commercial)	
	Recreation	
	Tourism	
	Forestry	
Culture and Heritage	Traditional culture and use	The IW may affect known or unknown heritage resources when clearing previously undisturbed land within the FMC. The IW may indirectly affect traditional culture if land use and access is affected.
	Heritage resources	
	Culture (language, traditions)	

Along with the above socio-economic VCs, human health and safety is also considered a VC. The potential effects on both the community and worker health and safety are also discussed in this section.

7.3.6.4 Pathways of Effects

To understand which project activities could potentially interact with the socio-economic VCs and result in socio-economic effects, the assessment team developed an interaction matrix. Table 7-24 provides the results of this analysis for the socio-economic VCs. The interaction matrix classifies the activity/VC interactions according to the criteria described in Section 7.2.1.

For interactions identified as a “0,” the assessment team does not anticipate the IW will interact with the VC in a measurable way, and the IWPP does not further consider these interactions. For interactions identified as a “1”, suitable mitigation of the effects of the IW relies on the effective development and application of appropriate strategies such as BMPs. The Section 5 appendices provide mitigation and management plans that describe the BMPs and provide a framework for the administrative structure that will be established to assure the plans are followed. Table 7-5 identifies the specific mitigation and management plans for each of the activities that make up the IW. By applying these mitigation and management plans, the assessment team concluded that “1” interactions, when considered individually, will not cause significant adverse socio-economic effects.

For interactions identified as a "2", this assessment further investigated and characterized the socio-economic effect that could arise as a result of the interaction. Sections 7.3.6.5 through 7.3.6.8 present these assessments for each VC.

TABLE 7-24
Project-Valued Component Interactions
Faro Mine Interim Works

Project Activity or Physical Work	Economy and Employment	Community Stability and Well-being	Infrastructure and Services	Land Use and Access	Culture and Heritage
Site Operations					
Site operations workforce management; employment; contracts; and taxes	2	1	0	0	0
Tailings storage in the RCTA	0	1	0	0	0
Site Investigations					
Site investigation workforce management; employment; contracts; and taxes	2	1	0	0	0
Access route development (may include stream crossings)	0	0	0	2	1
Surface geophysics	0	0	0	2	1
DVIHU					
Construction workforce management; employment; contracts; and taxes	2	1	0	0	0
ID Spillway excavation	0	1	0	0	0
Ancillary Activities					
Waste management (disposal to landfills), including domestic waste	0	0	2	0	0
Site access control	0	0	0	2	0
Housing in Town of Faro	0	0	1	0	0
Potable water supply	0	0	2	0	0
Sewage treatment and discharge	0	0	2	0	0

Table 7-4 does not identify any "major" interactions for the Human Health and Safety VC, as the IW focuses on minimizing contaminants released from the site. However, because of concerns expressed by local communities and people a qualitative assessment of potential affects and mitigation measures is also included in this section.

7.3.6.5 Economy and Employment Effects Assessment

Economy and employment were identified as VCs because the economic activity generated as a result of IW may influence how income and capital is distributed through individuals, families, First Nations, businesses and communities in the RSA.

Indicators

The assessment uses indicators, or key characteristics, to measure expected changes in the VCs due to the IW. The assessment team has identified the following four indicators for the economy and employment VCs:

- **Business development:** A change in the number of businesses and associated employment in local economies.
- **Economic diversification:** The capture and distribution of supply and service opportunities in local economies.

- **Employment and income levels:** The capture and distribution of employment opportunities for skilled and unskilled labour.
- **Education and training:** The leveraging of training and skill development opportunities associated with project activities.

Study Area

The assessment team collected and synthesized baseline socio-economic information from available secondary data sources related to the economy and employment VC across the RSA.

Initially, the assessment considered potential IW effects on economy and employment for all study areas. As the IW will not affect every community in the same way, the assessment focused on those communities where potential pathways for IW effects were identified.

The co-proponents are committed to providing equal opportunities for affected First Nations to benefit from employment and economic opportunities associated with the FMC. This approach creates pathways for the IW to affect the economy and employment in each community. The FMC does not house full-time residents, businesses, or governments, so an assessment of potential effects on economy or employment was not conducted for the site study area. Table 7-25 summarizes which communities were assessed for effects on economy and employment.

TABLE 7-25
Study Areas for Socio-economic Effects Assessment – Economy and Employment
Faro Mine Interim Works

Value	FMC	Faro	Ross River	Pelly Crossing	Watson Lake
Economy and employment		✓	✓	✓	✓

Pathways of Effects

For each economic and employment indicator identified in Table 7-23, there will be a variety of potential interactions with the proposed activities. Table 7-26 summarizes the pathways for these interactions.

TABLE 7-26
Pathways for Effects for Economy and Employment
Faro Mine Interim Works

Project Component	Project Activity and Potential Interaction
Site Operations	Employment activities and purchase of supplies
Site Investigations	Employment activities and purchase of supplies
DVIHU	Employment activities, equipment operation, and purchase of supplies and materials

Analysis of Potential Effects

The IW is scheduled to take place over 10 years, with its four components requiring different types and amounts of labour, depending on the season and the year. The activities will also generate different economic inputs, depending on the season and the year. The assessment explores the potential effects of each IW activity on the economy and employment VCs.

Site Operations

Data on anticipated employment and labour income expenditures are available for site operations in 2014. These are expected to remain relatively consistent for the remainder of the project timeframe.

Figure 7-1 presents the estimated average number of site operations employees anticipated at the FMC in 2014, broken down by month and job type. The site operations are expected to require similar levels and types of employment for the remainder of the project. Site operations employment will be highly seasonal, staffing positions for 8 months a year. Each year, the average number of site operations employees will peak in July, at 52. The site operations position with the most staff will be that of WTP operator, peaking at 16 from July through to September. The majority of staff onsite between November and March (approximately 25 people) are included under the management and administration.

Non-local workforce for site operations will likely be housed in a mix of hotel/B&B accommodation and leased or rental housing in Faro. Consultation with Faro is occurring to assess the availability of possible rental units and other housing accommodation solutions to meet the anticipated accommodation needs. (Section 5.7.2)

Labour incomes (which include both salary and wage incomes) associated with site operations employment (excluding payroll burden) are expected to total about $2.1 million in 2014 (Table 7-27).

TABLE 7-27
2014 Site Operations – Labour Income by Job Type
Faro Mine Interim Works

Job Type	Labour Income ($)
Automotive and Light Duty Mechanic	22,642
Certified Electrician	127,965
Certified Journeyman (various)	45,936
Certified Millwright	99,760
Chemist	57,931
Environmental Coordinator	5,915
Environmental Technologist	56,430
Licensed Welder	96,773
Security / Safety Personnel	199,818
Skilled Labour / Equipment Operator	239,461
Student	108,688
Supervisor / Foreperson	210,834
Unskilled Labour	97,604
Water Treatment Plant Operator	720,852
Total Labour Income	**2,090,608**

Note: Labour Income include both salary and wage incomes and does not represent individual salaries

During each month of 2014, an estimated $76,472 will be spent on management fees for site operations. The total management fees for 2014 will be $917,668. Management fees cover positions such as the superintendent, site manager, and project managers. Monthly expenditures for site operations administration fees are estimated at $182,921, and the total administration fees for 2014 will be about $2,195,050. Administration fees cover all office staff at the FMC and accountants from the head office.

Site Investigations

Employment, labour income, and supplies, materials, and equipment expenditures for site investigations activities are expected to peak in 2014 due to a more extensive field program. The IW will require lower levels of labour and resources (about $2 million annually) for the rest of the project.

DRAFT

Spending associated with site investigations for the IW will amount to several million dollars in 2014. However, these activities may have limited effects on the local communities, as they will focus on geotechnical investigations and field surveys. The workforce for most site investigations is anticipated to combine non-local technical experts with Whitehorse-based and local support. The co-proponents emphasize the use of local available workforce when contracting this site work and the prime contractor for this work has developed a participation plan focused on AYFN and Yukoners (CH2M HILL, 2013d).

Figure 7-2 presents the estimated average number of employees for FMC site investigations in 2014, broken down by month and job type. Site investigations jobs will be highly seasonal, and the average number of employees will peak in July, at 41. The site investigations position with the most staff will be that of field engineer/scientist, peaking at 12 from June until October.

Labour incomes associated with site investigations employment (excluding payroll burden) are expected to total about $8.5 million in 2014 (Table 7-28). Annual IW site investigations are expected to continue through the remaining 9 years of the project, though they will only require about one-fifth of the 2014 resources.

TABLE 7-28
2014 Site Investigations – Labour Income by Job Type
Faro Mine Interim Works

Job Type	Labour Income ($)
Drillers	2,159,992
Environmental Pit Lake Sampling Staff	64,000
Equipment Manager	252,000
Field Engineers/Scientists	2,772,000
Health and Safety Manager	270,000
Operations Manager	342,000
Pump Testing Staff	290,000
Quality Manager	270,000
Site Field Manager	270,000
Staffing Manager	252,000
Surveyors	408,000
Task Manager	342,000
Test Pit Excavations Staff	228,000
Utility Locator Staff	60,000
Vegetation Survey Staff	313,832
Wildlife Survey Staff	171,204
Total Labour Income	8,465,028

Non-local technical staff are expected to make up the majority of the 2014 site investigations workforce. These staff will likely be housed in Faro and, if required, in a temporary camp in the old Pelly Camp area, located off the Grum Access Road. The site investigations' labour requirements are highly seasonal and most positions will only be required onsite during summer 2014. The site investigations' labour requirements are not expected to result in an inflow of permanent residents to Faro. As a result, the total value of labour incomes captured in the local economies of Faro, Ross River, Pelly Crossing, and Watson Lake is expected to be limited.

DRAFT

Expenditures on site investigation supplies are expected to total about $1.3 million in 2014. Table 7-29 outlines expenditures by supply type.

TABLE 7-29
2014 Site Investigations – Supply Expenditures by Type
Faro Mine Interim Works

Supply Type	Expenditures ($)
Air transport	216,000
Communications (e.g., phone)	30,000
Diesel/gasoline	24,000
Expediting/shipping	6,000
Janitorial supplies/subcontract	4,800
Office supplies	1,800
Per diem and lodging	784,080
Propane fuel	5,100
Rental equipment	3,000
Safety and training supplies	12,000
Shop supplies	1,200
Vehicle rental	180,000
Total Supply Expenditures	**1,267,980**

Down Valley Interim Hydraulic Upgrades

The DVIHU field construction activities are expected to be completed in summer 2016, with potential economic and employment effects expected to be largely experienced in that period. Data on employment, labour income, and supplies and equipment expenditures for DVIHU activities are provided in Tables 7-30, 7-31, and 7-32.

Figure 7-3 presents the labour requirements for the DVIHU in 2016; that is, the estimated average number of employees, broken down by month and job type. DVIHU jobs will be highly seasonal, with most employment occurring from April through September. The average number of DVIHU employees will peak in June at 26. The job type with the highest number of positions is Labour - General, reaching a peak of five for the 5-month period from May to September.

The non-local workforce for the DVIHU will likely be housed in Faro and, if required, in a temporary camp in the old Pelly Camp area, located off the Grum Access Road. However, the DVIHU labour requirements are highly seasonal and most positions will only be required onsite during 2016. The DVIHU labour requirements are not expected to result in an inflow of permanent residents to Faro.

Labour incomes associated with DVIHU activities employment (excluding payroll burden) are expected to total approximately $1.1 million in 2016 (Table 7-30). In addition, the DVIHU construction activities expect to generate about $948,000 in per diem to non-local staff in 2016.

DRAFT

TABLE 7-30
Faro Interim Works: 2016 DVIHU – Labour Income by Job Type

TPH = tonnes per hour

DRAFT

Ancillary Activities

The IWPP has identified a number of ancillary activities that are intended to support site operations, site investigations, and the DVIHU, including the following:

- Establishing a temporary camp for up to 20 people at the FMC, to house site investigation and construction crews
- Hauling and storing fuel
- Managing waste

A temporary camp would be constructed if the amount of local accommodation is exceeded by seasonal summer workforce in 2014 (site investigations) and 2016 (DVIHU). The purchasing of fuel is identified in the supply needs for the IW, and a pathway for waste management to affect the economy and employment VC has not been identified. As a result, the ancillary activities are not expected to result in material interactions with the economy and employment VC in the communities of Faro, Ross River, Pelly Crossing, or Watson Lake (Table 7-2).

Predicted Change from Baseline

Business Development

As previously mentioned, labour incomes from site operations and site investigations are expected to total $10.6 million in 2014 (excluding payroll burden). Site operations entails activities that are currently occurring on the FMC. As a result, there is little incremental potential for local businesses to supply contract labour above what is being provided already and the potential for local business development is predicted to be correspondingly small. Labour incomes for site investigations activities peak in 2014 and are focussed on technical job types that are unlikely to be economically maintained by local businesses. Ongoing site investigations at a decreased scale through 2023 could support very limited and targeted business development.

Labour incomes for DVIHU activities are estimated at about $1.1 million in 2016. Similar to site operations and site investigations, there is little potential that local businesses will supply contract labour and therefore, little potential for local business development. The Town of Faro and Ross River are closer to the FMC than the other communities and can be accessed via year-round roads, so they are expected to experience a greater potential for business development than other communities in the RSA. The DVIHU activities are expected to have limited benefits on business development. The short duration of the DVIHU activities does not provide incentive for long-term business development.

Economic Diversification

Expenditures on supplies for site investigation activities are expected to total about $1.3 million in 2014. As some categories of goods and services are available in local communities, there is some potential for the Town of Faro to capture supply and service retail opportunities (this potential also applies to Ross River, Pelly Crossing, and Watson Lake, to a lesser extent). The long-term housing of site operations workforce in Faro is expected to support limited community diversification or expansion into the provision of accommodations in that community. Expenditures on supplies and equipment for the DVIHU are expected to total about $3.2 million in 2016. As most of the supplies and equipment will be imported into the project area, limited potential for economic diversification is predicted. The DVIHU is expected to generate almost $1 million in per diem to the non-resident workforce in 2016, some of which is expected to stay within the LSA. The DVIHU will provide income to some local businesses and services in 2016, and could result in limited beneficial effects on economic diversification.

Employment and Income Levels

As previously mentioned, average monthly employment is expected to range between 36 and 52 employees for site operations from April until October 2014, with additional management and administrative staff year-round. Site investigations will require between 13 and 41 employees, also during the summer period. Average monthly employment is expected to range from 6 to 26 employees for the DVIHU (April 2016 to September 2016 field season).

In 2014, aggregate labour income is estimated at $2.1 million for site operations activities and $8.5 million for site investigations activities. Aggregate labour income for DVIHU is estimated to be $1.1 million in 2016.

While the IW will provide employment opportunities (and resulting labour incomes) for a range of job types, in most cases, these jobs will require specialized skill sets. As a result, the communities in the RSA are expected to capture a relatively small portion of the employment opportunities. The potential indirect beneficial effects of employment income on local businesses and services are discussed above under Business Development and Economic Diversification.

Education and Training

As noted, the IW will provide a range of employment opportunities. The 10-year duration of site operations activities provides incentive for local residents to commit to education or training programs to qualify for these jobs. The annual, seasonal employment opportunities for the site investigations and DVIHU are expected to be too short to encourage local residents to attend Yukon College to acquire equipment operator skill development and training, in order to take advantage of the employment opportunities.

The co-proponents and the assessment team can apply lessons learned related to local skill development and training opportunities for the IW to the full-scale FMRP, which is expected to begin in 2020.

Mitigation and Enhancements

The IW scope - site operations, site investigations, and the DVIHU and ancillary activities - is expected to have generally positive economic and employment effects over the study areas considered. The challenge for First Nations and communities of Faro, Ross River, Pelly Crossing, and Watson Lake will be to maximize the capture of as many of the IW-associated employment and economic benefits as possible. The job and expenditures types and amounts outlined previously in this section – and the corresponding incomes and expenditures – can be used as a starting point to develop a benefit-capture strategy.

YG, through its primary contractors at the FMC (CH2M HILL and TEES), is committed to contributing to maximizing local and Yukon socio-economic benefits in three participation areas; employment, contracting and subcontracting, and training and capacity building (CH2M HILL, 2013d). In 2014, this commitment will be demonstrated by activities such as visiting First Nations communities, participating in job fairs, coordinating training with Yukon College, hiring field staff for FMC Field Office, and awarding field support services to local vendors (CH2M HILL, 2013d).

Continued engagement will allow First Nations and communities to develop a more detailed understanding of the potential for capturing employment opportunities and associated incomes locally.

Significance of Effects

Overall, IW effects on the economic and employment VCs are generally positive and low magnitude. Significant adverse effects on economic and employment values are not predicted. Section 7.3.6.11provides further detail on the determination of significance.

7.3.6.6 Community Stability and Well-being Effects Assessment

Community stability and well-being was identified as a VC because an influx of temporary workforce as a result of IW may influence community makeup, including demographics and mobility. This effects assessment considered the effects of migration (in and out), changes to social and cultural makeup of communities, and influences on individual, family, and community health.

Indicators

The assessment uses indicators to measure expected changes in the VCs due to the IW. The assessment team has identified the following three indicators for changes in the community stability and well-being VC:

- **Community Demographics:** A change in the population of a community or in the distribution of genders, ages or ethnicity (e.g., aboriginal vs. non-aboriginal) of the residents in a community

- **Social Cohesion:** Changes to the length of time residents stay in a community (mobility status) and to family stability like marital status and family structure
- **Cultural Well-being:** A change in local crime rate or the AANDC community well-being index

Study Area

The assessment team collected and synthesized baseline socio-economic information from available secondary data sources related to the community stability and well-being VC across local and regional study areas.

Initially, the assessment considered potential IW effects on community stability and well-being for all study areas. As the IW will not affect every community in the same way, the assessment focused on those communities where potential pathways for IW effects were identified.

The IW proposes to accommodate non-local staff in the Town of Faro, with seasonal overflow in a temporary camp on the FMC. As a result, the assessment team identified a pathway for these workers to interact with communities in the LSA. Non-local IW workforce is not anticipated to reside in Watson Lake and a pathway to effects on the community stability and well-being of Watson Lake was not identified. In Pelly Crossing, community stability and well-being is considered as it relates to downstream and down-wind effects of contaminants on the local environment. The FMC does not contain a community, or any full-time residents, so the assessment of potential effects on community stability and well-being was not conducted for the site study area. Table 7-33 summarizes which communities were assessed for effects on community stability and well-being.

TABLE 7-33
Study Areas for Socio-economic Effects Assessment – Community Stability and Well-being
Faro Mine Interim Works

Value	FMC	Faro	Ross River	Pelly Crossing	Watson Lake
Community stability and well-being		✓	✓	✓	

Pathways of Effects

For each community stability and well-being indicator identified, there will be a variety of potential interactions with the proposed activities. Table 7-34 summarizes these potential interactions.

TABLE 7-34
Pathways of Effects for Community Stability and Well-being
Faro Mine Interim Works

Project Component	Project Activity and Potential Interaction
Site Operations	Site operations workforce management; employment; contracts and taxes – influx of workers into Faro and Ross River
	Storage of tailings in the RCTA; the perception of health effects from contaminants in dust and water
Site Investigations	Site investigations workforce management; employment; contracts and taxes – influx of workers into Faro and Ross River
DVIHU	Construction workforce management; employment; contracts and taxes - influx of workers into Faro and Ross River
	Excavation of Intermediate Dam spillway; upgrades to dam will increase security and safety of watershed

DRAFT

Analysis of Potential Effects

Site Operations

Site operations primarily consist of site care and maintenance activities that are already underway at the FMC. Interactions between these operations and the VC could include an influx of employees in the Town Faro (estimated to peak at 52 during July). The same interaction is possible to a lesser extent in Ross River. The relatively small number of any incremental Full-time Equivalent positions required to maintain, monitor, and repair the FMC are not expected to result in new IW staff or their families relocating to the Town of Faro or Ross River.

Site operations activities also include storing tailings in the RCTA. Hunters and harvesters active around the FMC have expressed concern regarding the dispersion of dust from this facility on local plants and on whether there would be a human health risk to eating plant matter affected by this dust or wildlife affected through bioaccumulation. The FMC operator adheres to a Dust Management Plan to address these issues; however, the perception of risks to human health can affect community well-being, such as a resulting fear of eating country foods (i.e., local berries and moose). Refer to Section 7.3.7 for a detailed discussion about risks to human health.

Site Investigations

The workforce for most site investigations will likely consist of non-local technical experts and local support. The co-proponents emphasize the importance of using the local workforce for this onsite work. Technical positions that cannot be filled locally because of a lack of specific skills will be filled by workers from outside the RSA.

The non-local workforce for the site investigations will likely be housed in a mix of hotel/B&B accommodation and leased or rental housing in Faro. Consultation with Faro is occurring to assess the availability of possible rental units and other housing accommodation solutions to the anticipated accommodation needs. Should additional capacity be required, a temporary camp may be constructed in the old Pelly Camp area, located off the Grum Access Road. It is unlikely that workers will permanently relocate to Faro or Ross River as a result of site investigations labour opportunities.

Down Valley Interim Hydraulic Upgrades

The RCTA includes dams and diversions constructed to retain tailings in the Rose Creek Valley. The DVIHU activities are all intended to reduce risks associated with extreme flood events. Increasing the robustness of this infrastructure is important to downstream water and aquatic resource users. These upgrade activities will likely increase the confidence of local and downstream water users that the site operators have decreased the risk of infrastructure failing during extreme events which could transport contaminants downstream.

The non-local construction workforce required for the DVIHU is anticipated to live in Faro during the 2016 construction season. The interactions between this workforce and the community could result in effects on community stability and well-being. The IW proposal for accommodating seasonal workforce in Faro and potentially in a temporary camp is presented above under Site Investigations.

Ancillary Activities

The assessment team did not identify any pathways for the ancillary activities described in the IW to the community stability and well-being characteristics of the communities in the RSA (Table 7-2). As a result this aspect of the assessment was discontinued.

Predicted Change from Baseline

Community Demographics

As Section 7.3.6.5 noted, the average monthly employment is expected to range from 36 to 52 employees for site operations from April until October 2014, with similar levels maintained for the remainder of the IW. Labour needs supporting the site operations represent the most important longer-term employment opportunities that could draw workers and their families to relocate to the LSA. However, staff are already in place conducting care and maintenance activities for the FMC. These positions are not expected to change substantially during site

operations. As a result, only minor, if any, increases in staff numbers are anticipated due to site operations and little or no corresponding changes are expected in community demographics.

It is expected that the number of employees for site investigations will range between 13 and 41 during the summer of 2014. Average monthly employment is expected to range between 6 and 26 employees for the DVIHU, from April to September 2016. One year of seasonal employment is not expected to encourage workers to relocate to communities in the LSA or RSA.

Given the predicted numbers of Full-time Equivalents for site operations, site investigations, and the DVIHU, the IW will likely not result in an influx of permanent residents into Faro or Ross River. Therefore, no changes are expected to the baseline demographics of residents in these communities.

Social Cohesion

The IW is not expected to result in a meaningful increase in the number of permanent or temporary residents into Faro or Ross River. Faro has experienced significant changes in population from over 2000 residents in the early 1980s to less than 400 currently. Population changes have been related to the level of mining activity at the FMC (Town of Faro, 2014). The IW are not predicted to change the baseline conditions in social cohesion.

Cultural Well-being

The IW will result in an influx of non-local workers using temporary accommodation in Faro. These workers will be housed in available accommodation, including the Studio Hotel and at least three B&Bs (Bears Den B&B, Far-O-Way Guest House, and the Valley B&B) and leased or rental housing (Section 5). Labour needs for site operations are expected to result in little or no increase in resident population. Labour for the site investigations and DVIHU will be seasonal and occur over a short duration in 2014 and 2016 respectively.

IW labour residing temporarily in Faro is not expected to result in an increase in crime rate over the LSA or a decrease in community well-being index. Worker behaviours that could potentially adversely affect community well-being will be managed through workforce guidelines.

As progress on the FMC remediation plans is demonstrated to the Town of Faro, Ross River, and Pelly Crossing communities, community wellness may be positively affected, relieving the longstanding burden of a large-scale, nearby contaminated site. Pelly Crossing is expected to perceive the DVIHU activities as important, because the upgrades will decrease the environmental risks associated with infrastructure failing during extreme events.

Mitigation Measures

The following list summarizes mitigation for addressing potential adverse effects on community well-being and stability.

- Dust Management Plan – A Dust Management Plan is currently in place for ongoing site activities. It is important for this plan to continue, to address community concerns over airborne contaminants. This will continue to promote positive effects on community well-being.
- Workforce Guidelines –The number of employees and the duration of their stay in the Town of Faro increases the potential for a community member to have a negative experience with a project employee. The co-proponents have appropriate expectations of employees for their behaviour (set forth in guidelines such as an employee code of conduct) at the FMC and in the Town of Faro. These expectations should continue to be upheld.
- Communications on Accommodation – The co-proponents have committed to engage the Town of Faro to develop options for workforce accommodation that meet the needs of the community and the IW.
- Temporary Camp –Additional labour is required for the 2014 site investigations and 2016 DVIHU programs. These staff may be accommodated in a temporary camp established at the FMC.

DRAFT

Significance of Effects

Faro, in particular, has experienced dramatic historic variability in resident populations and is expected to have some level of resilience to these changes. Overall, no significant effects are anticipated on community stability and well-being VC. The IW is expected to result in a decreased risk of downstream and downwind effects on the environment and a slight beneficial effect to the community stability and well-being VC. Section 7.3.6.10 provides more details about the significance of effects.

7.3.6.7 Infrastructure and Services Effects Assessment

The influx of the workforce associated with some components of the IW may strain infrastructure (e.g., sewage, water supply, and electricity) and services (e.g., health, education, social services, and emergency services) in the LSA. Increased traffic from IW-related construction and maintenance activities may affect local road safety and cause wear to road infrastructure. The effects assessment identified interactions between proposed project activities and community infrastructure and services in the LSA. It also identified potential effects on community infrastructure and services, and possible mitigation measures.

Indicators

The following infrastructure and services indicators were assessed for the IW:

- **Roads and Traffic -** Highway usage and maintenance (frequency and need)
- **Housing -** Local and regional housing price and availability
- **Health Services -** Local and regional health services and capacity
- **Emergency Services -** Local and regional emergency services and capacity
- **Community Infrastructure -** Community sewage, electricity capacity and maintenance, recreation services, child care, and support services

Study Area

The assessment team collected and synthesized baseline socio-economic information from available secondary data sources related to the infrastructure and services VC across local and regional study areas.

Initially, the assessment considered potential IW effects on infrastructure and services for all study areas. As the IW will not affect every community in the same way, the assessment focused on those communities where potential pathways for IW effects were identified.

The IW proposes to use infrastructure and services from the LSA (e.g., housing, nursing station, and airport in the Town of Faro). Pathways were not identified for the IW to interact with infrastructure and services of Watson Lake and Pelly Crossing so that portion of the assessment was discontinued. Public infrastructure and services on the FMC are limited to an access road between Faro and the FMC. Effects related to access management are considered in Section 7.3.6.8, so the assessment of potential effects on infrastructure and services was discontinued for the site study area. These conclusions are presented in Table 7-35.

TABLE 7-35
Study Areas for Socio-economic Effects Assessment – Infrastructure and Services
Faro Mine Interim Works

Value	FMC	Faro	Ross River	Pelly Crossing	Watson Lake
Infrastructure and services		✓	✓		

Pathways of Effects

Each identified infrastructure and services indicator could interact with proposed IW in a variety of ways. Table 7-36 summarizes the anticipated interactions and pathways of effects.

TABLE 7-36
Pathways of Effects for Infrastructure and Services
Faro Mine Interim Works

Project Component	Project Activity and Potential Interaction
Ancillary Activities	Waste management (disposal to landfills): The site may use Town of Faro facilities for disposal of domestic waste.
Ancillary Activities	Housing in Faro: the seasonal non-local workforce will likely be housed in a mix of hotel/B&B accommodation and leased or rental housing in Faro. A temporary camp on the FMC might be established.
Ancillary Activities	Sewage treatment and discharge: IW staff will require suitable wastewater treatment and discharge capacity associated with their accommodations in Faro.

Analysis of Potential Effects

Site Operations

Site operations include activities that are currently being undertaken as care and maintenance over the FMC. Site operations are anticipated to result in little or no increase in the number of employees residing in Faro. It is anticipated that there will be little change in baseline infrastructure and services demand due to the IW workforce, but existing demands from the workforce will continue for the duration of the IW.

Highway usage as a result of the site operations is also not expected to change from baseline conditions.

Site Investigations

Proposed site investigations during the IW will cost $8.5 million in labour in 2014, the majority of which will occur from April to September that year. Site investigations are anticipated to continue for the remainder of the project requiring less than $2 million dollars annually. Employees will be housed in temporary accommodation in the Town of Faro, unless peak demands in 2014 require the establishment of a temporary camp on the FMC.

Additional workforce will require local accommodation, potable water, wastewater disposal, and solid waste disposal, which could affect local infrastructure and services.

Down Valley Interim Hydraulic Upgrades

The proposed DVIHU are intended to reduce risks associated with extreme flood events. The DVIHU activities will result in between 6 and 26 additional employees onsite per month during the summer of 2016. The DVIHU workforce will be housed in temporary accommodation in Faro, unless peak demands in 2016 require the establishment of a temporary camp on the FMC.

The frequency of over-sized vehicle traffic is expected to increase slightly in the LSA during equipment mobilization and de-mobilization in support of the DVIHU construction.

Ancillary Activities

The following ancillary activities have been identified as part of the IW:

- Establishing a temporary 20-person camp at the FMC to house site investigation and construction crews
- Hauling and storing fuel
- Managing waste

A temporary 20-person camp will require potable water, wastewater disposal, and solid waste disposal, which could affect local infrastructure and services.

The equipment proposed to construct the DVIHU will require additional diesel fuel. The transport of this fuel is anticipated to increase the frequency of fuel trucks on LSA roads during the summer of 2016.

DRAFT

Predicted Change from Baseline

Roads and Traffic

Traffic related to IW site operations is expected to be similar to that generated by ongoing FMC care and maintenance activities. Site access for staff, equipment, and materials will continue over an aging road network, originally designed and built to support a much higher load (both vehicle weight and frequency) of heavy truck traffic from the FMC. As a result, traffic baseline conditions are not expected to change dramatically because of site operations.

The DVIHU construction in 2016 is expected to temporarily increase the frequency of over-sized vehicle traffic during equipment mobilization and de-mobilization. This effect is expected to occur on roads over the LSA, including the Robert Campbell Highway. If the DVIHU equipment moves to the site at a similar time, the disturbance to other road users could be higher, but for a shorter duration. If the equipment mobilizes over a broader timeframe, the additional traffic is less likely to be significantly different from baseline conditions. Heavier vehicles have the potential to increase the rate of road damage.

The site investigations and DVIHU are expected to require additional staff onsite during the summer months of 2016. It is expected that most employees will be housed onsite in a 20-person camp. Onsite lodging will greatly decrease vehicle travel that would otherwise be required to move these staff from accommodations (most likely in the Town of Faro) to the FMC. A limited to low increase in traffic is anticipated in the Town of Faro, and no increase in traffic is expected in Ross River.

Housing

The site investigations and DVIHU require accommodation for additional staff in the summers of 2014 and 2016 respectively. These seasonal staff will be housed in temporary accommodation in the Town of Faro.

During the IW, there are several periods when staffing levels may exceed the supply of rooms available in the Town of Faro. In addition, it is understood that there are competing demands for the available accommodations. Visitors and service providers who travel to the community, such as health care providers or non-FMC related construction workers (e.g., highways crews or forest fire crews), also require lodging. This competition for accommodation is highlighted by the same seasonal use requirements by the IW workforce as the seasonal use for tourism and non-FMC construction work. Therefore, the seasonal non-local workforce will likely be housed in a mix of hotel/B&B accommodation and leased or rental housing in the Town of Faro. Consultation with the Town of Faro is occurring to assess the availability of possible rental units and other housing accommodation solutions to the anticipated accommodation needs.

A temporary camp may be required in order to provide facilities for accommodation of workers for various components of the IW including construction activities and field investigation programs. If required, the proposed location for this temporary camp is the old Pelly Camp area, located off the Grum Access Road. Potable water supply for this temporary camp would be provided by a well located adjacent to the Grum Office Building.

These staff will only be active onsite seasonally, and are not expected to purchase houses. Little or no increase in demand on Town of Faro or Ross River housing is anticipated as a result of the proposed project.

Health Services and Emergency Services

Site operations are similar to ongoing care and maintenance activities and are not expected to increase the demand on health or emergency services in the Town of Faro. During DVIHU construction, increased personnel and use of heavy equipment could increase risks onsite. However, accident/emergency response is expected to effectively respond to an unlikely accident during construction activities by following these steps, as necessary: (1) accessing onsite First Aid, (2) escalating the response to the Faro Nursing Station, and (3) travelling via air medivac from Faro airport to Whitehorse or a southern hospital. During the IW, and in the event of an emergency, resources in Ross River are not anticipated to be accessed, so the IW are not expected to affect health and emergency services in Ross River.

DRAFT

Community Infrastructure

IW site operations staff numbers are expected to be similar to those conducting existing care and maintenance activities. Little or no change is expected in their use of community infrastructure in Faro or Ross River. Much of the community infrastructure in Faro is designed and built to support a residential population hundreds above the current 345 (YG, 2013). The population of the Town of Faro peaked in 1981 at just under 2,000 residents (Town of Faro, 2014).

The workforce to support the site investigations and DVIHU activities will temporarily be housed in Faro. If the entire workforce for both activities is housed in Faro, they would place an additional maximum 68-person demand on infrastructure designed and built for hundreds of more residents. For example, wastewater is treated in Faro through a multi-celled lagoon. This lagoon is operating well below capacity servicing the less than 400 residents in the town. If the lagoon reached capacity it would discharge to the Pelly River. The lagoon has not discharged since 1994 (YG, 2009). The total IW personnel would produce wastewater volumes well within the documented operating capacity of the Town of Faro wastewater infrastructure.

Should the temporary season accommodation needs of the site investigations in 2014 and the DVIHU in 2016 exceed the temporary housing capacity of the Town Faro, the IW proposes to establish a temporary camp on the FMC. Establishing and servicing this camp is expected to require onsite and Town of Faro infrastructure. The FMC has a septic tank and there is an existing septic system in place at the old Pelly Camp that has sufficient capacity to handle potential sewage flows generated by the temporary camp.

Potable water supply for this temporary camp would be provided by a well located adjacent to the Grum Office Building and would not affect Faro potable water supply infrastructure. Potable water would be required for the camp and to conduct the IW.

Non-organic solid waste from the proposed activities will be landfilled onsite and organic waste will be deposited in the Faro Solid Waste Facility. The landfill life was estimated in 2009 at 13+ years (YG, 2009). The limited amount of solid waste produced at the camp during the summer season and by the limited number of personnel (20 IW personnel versus 450 landfill users in 2009) would have a low or negligible effect on the Faro Solid Waste Facility.

Mitigation Measures

A temporary onsite camp for site investigations (in 2014) and for DVIHU (in 2016) personnel will mitigate the potential project effects on infrastructure and services. The proponent will follow a Traffic Management Plan and a Spill Contingency Plan as further mitigation measures.

Significance of Effects

The potential effects on infrastructure and services are related to short-term increases in personnel to complete the site investigations and DVIHU. The construction and use of an onsite camp decreases the magnitude of effects, which are already low in both magnitude and duration. Extending services to provide for the anticipated number of IW staff is well-within Faro's current infrastructure capacity. No significant adverse residual effects are expected on infrastructure and services. Section 7.3.6.10 provides further details about the significance of effects.

7.3.6.8 Land Use and Access Effects Assessment

The FMC covers a large area (25 square km^2 or 2,500 hectares) and includes a total of 70 million tonnes of tailings and approximately 376 million tonnes of waste rock (YG, 2011). Current land use activities on the site are primarily related to the ongoing maintenance and operations of existing facilities to manage and monitor the tailings and waste rock. However, other land use activities take place either on, or adjacent to, the FMC; these may be affected by the activities outlined in the IWPP. This section describes these activities as well as their interaction with the proposed activities, and assesses their potential effects on land use and access values.

Indicators

Key characteristics, or indicators, of changes to land use and access would be changes to the frequency of land users passing through the FMC, perceived changes to accessibility of parts of the FMC, or perceived changes to access through the FMC to other destinations. Site access is not anticipated to change. An Access Management Plan has been developed for the site and will be implemented as part of the IW.

The following key land use indicators were assessed for the IW:

- **Traditional Land Use –** This characteristic includes traditional land use activities currently conducted by First Nations people in the region. Specifically, it refers to the use of existing cabins, harvest areas (including berry picking), and medicinal/spiritual areas.
- **Hunting and Fishing –** This characteristic describes harvest location and numbers of key fish and wildlife species, broken down by harvesters (First Nation, resident, and non-resident hunters).
- **Recreation –** This characteristic identifies popular recreation areas and activities located within the FMC.
- **Tourism –** This characteristic includes a profile of local tourism operators or activities promoted within the region around the FMC.
- **Forestry –** This characteristic includes the current location and description of forestry activities in the FMC.

Study Area

The assessment team collected and synthesized baseline socio-economic information from available secondary data sources related to the land use and access VC across local and regional study areas.

Initially, the assessment considered potential IW effects on land use and access for all study areas. As the IW will not affect every area in the same way, the assessment focused on those study areas where potential pathways for IW effects were identified.

Land use and access is a value directly related to the footprint of the FMC. IW activities could interact with land use and access within the footprint, or in the immediate vicinity, of the FMC. Individuals from the Town of Faro and Ross River, closer communities with direct all-weather road links, are more likely to access and use the FMC. Nonetheless, the assessment team recognized that individuals from Watson Lake and Pelly Crossing could potentially access and use the areas over and around the FMC. As a result, all the communities in the RSA were carried through into the assessment. These conclusions are presented in Table 7-37.

TABLE 7-37
Study Areas for Socio-economic Effects Assessment – Land Use and Access
Faro Mine Interim Works

Value	FMC	Faro	Ross River	Pelly Crossing	Watson Lake
Land use and access	✓	✓	✓	✓	✓

Pathways of Effects

For each identified land use characteristic, a variety of potential interactions are anticipated with the proposed IW. Table 7-38 summarizes the anticipated interactions between these characteristics and the IW. Individuals from Faro and the RRDC are known to use parts of the FMC. Effects associated with the IW on health and food security are related to land use activities and are described in Section 7.3.7, Human Health and Safety Effects Assessment.

TABLE 7-38
Pathways of Effects for Traditional land Use and Access
Faro Mine Interim Works

Project Component	Project Activity and Potential Interaction
Site Investigations	Access Route Development: Short trails to re-position machinery will be required to access new borehole locations.
Site Investigations	Surface Geophysics: Trails (<1.5 m wide) up to an estimated total of 5 km of clearing will be created throughout the FMC.
Ancillary Activities	Site Access Control: A new reserve designation has been established for the FMC that will allow for more effective site access control, including enforcement for infractions. The Access Management Plan developed as part of the IW does not change the overall approach to site access management.

Analysis of Potential Effects

Site Operations

Site operations include FMC care and maintenance activities that are currently ongoing and considered baseline conditions. Land use activities are anticipated to continue to have minimal interaction. Dust control activities at the RCTA are expected to continue, and to mitigate community concerns related to food security for local harvesters (refer to Section 7.3.7 on human health and safety for more details). At present, site operations are likely not a major factor affecting specific land use activities.

Site Investigations

Site investigations include ongoing monitoring activities and remediation research. Some land use activities may be affected by cutting lines or clearing drilling areas. These activities may increase accessibility to parts of the FMC, depending on the location and type of clearing. However, it is anticipated that clearing for site investigations would generally not be suitable for non-IW related off-road traffic.

Down Valley Interim Hydraulic Upgrades

The DVIHU includes temporary construction activities associated with a secondary spillway and upgrades to the RCD. Given the location and timing of this construction, land users (mostly moose hunters) might have temporary difficulty accessing areas of Rose Creek, downstream from the FMC. The DVIHU is designed to decrease risk of infrastructure failure and so increase the sense of security for downstream and downwind fish and wildlife users.

Ancillary Activities

Ancillary activities are those related to more than one IW activity. Enforcing an Access Management Plan is the primary ancillary activity that could lead to socio-economic effects on the land use and access VC. The rules and conditions of access are not anticipated to change; however, more active enforcement could lead to the perception that they have.

Predicted Change from Baseline

Traditional Use

Construction and site investigation activities related to the IW may temporarily affect access to, and use of, traditionally used sites on the FMC. This includes access to a known cabin location and its associated infrastructure (Ecofor, 2013a). However, the use of these areas is not predicted to change from the baseline.

People, mostly hunters, use clearings and trails over the FMC to access the hinterland/wilderness area outside the FMC's footprint. Off-road vehicle drivers are the most frequent users of these trails and cleared areas. IW site investigations will require new trails to be cleared, to support a variety of drilling and sampling activities. The new trails could be used as additional access routes across the FMC. However, these trails will be relatively short, and most will end at drill sites or sampling locations. Generally, it is expected that the new trails will be less desirable for third-party users, and will deter off-road vehicle passage. These access trails are not expected to be used regularly, or to become permanent off-road vehicle trails.

The IW is not expected to in long-term or permanent changes to people's ability to visit or use sites within or around the FMC. The IW includes the implementation of an Access Management Plan for the FMC. This document intends to clarify understandings and perceptions about FMC access.

Harvest

The IW are expected to cause small-magnitude and temporary changes to the accessibility of localized hunting opportunities.

The DVIHU includes temporary construction activities that could interact with land users (mostly moose hunters) accessing areas around Rose Creek, downstream from the FMC. Though licensed moose harvesting can begin on August 1 in permitted Game Management Zones, most hunting activities take place after male moose enter the rut, generally after September 15 (YG, 2013). By September, construction-related traffic control will decrease, and

DRAFT

short-term access constraints are expected to be minimal. The IW are anticipated to have temporary, small-magnitude, and completely reversible effects on land use.

Local outfitters and trappers will continue to be able to access their concessions via the FMC.

Recreation

Frequency and location of recreational land use is not predicted to change from baseline conditions. People's ability to access recreation areas via the FMC will be maintained, and the proposed IW are not anticipated to affect adjacent recreation sites.

Tourism

Tourism is not predicted to change from baseline conditions. As with other land uses, access through the FMC will not change. The proposed IW are not anticipated to affect local or regional tourism activities.

Forestry

Forestry in the FMC is not predicted to change from baseline conditions. A new reserve status identified new land management authorities, who may need to review access to timber harvest areas within the reserve; however, this is not anticipated to be a major issue.

Mitigation Measures

The co-proponents will follow the Access Management Plan in order to consistently manage access across the FMC during the IW. RRDC will be contacted regarding potential overlap of IW activities and use of the known cabin and associated infrastructure.

Significance of Effects

The IW is not anticipated to directly adversely affect land use and access values. Potential effects on land use and access are related to access management activities at the FMC. This IWPP identifies an Access Management Plan, which will not change the way access is managed at the FMC. Enforcement activities may, however, be more active. Section 7.3.6.10 contains additional details about determining the significance of effects.

7.3.6.9 Culture and Heritage Effects Assessment

This section describes the results of the analysis of the IW's potential effects on culture and heritage values. The FMC is located within the traditional territories of the RRDC and the LFN. Land use activities related to cultural and heritage values have been documented in the pre-mining FMC area (Ecofor, 2013a).

Appendix 6K summarized the project area's cultural history. The FMC is located within the traditional territory of the RRDC and the LFN; both First Nations are part of the KDC and do not have settled land claims. Baseline conditions included routes through the FMC that were used to access harvesting locations, and limited third-party land use within the FMC footprint (please refer to Section 6.3.4, Land Use and Access) (Ecofor, 2013a). There is no year-round accommodation or settlement within the FMC footprint, and the closest communities are the Town of Faro (primarily non-First Nations residents) and Ross River (primarily Ross River Dena). Pelly Crossing, the home of SFN, is downstream from the FMC, along the Pelly River. Watson Lake, the home of LFN, is about 425 km southeast of the FMC along the Robert Campbell Highway.

Heritage Values

The Umbrella Final Agreement (Government of Canada, 1993) defines Heritage Resources as including Moveable Heritage Resources and Heritage Sites:

> *"Heritage Site means an area of land which contains Moveable Heritage Resources, or which is of value for aesthetic or cultural reasons…Moveable Heritage Resources means moveable non-documentary works or assemblies of works of people or of nature that are of scientific or cultural value for their archaeological, palaeontological, ethnological, prehistoric, historic or aesthetic features, including moveable structures and objects."*
>
> Government of Canada, 1993

Within the footprint of the FMC, historical mining activities have already substantially altered or destroyed heritage resources. Until 2013, there were no recorded heritage sites within or near the IW assessment areas, and no others recorded in the larger vicinity, primarily because little work had taken place to evaluate heritage values (Ecofor, 2013a). Fieldwork was undertaken to support a Heritage Resource Impact Assessment for the IW; this work identified sites containing lithic fragments and a known cabin location (and associated infrastructure) (Ecofor, 2013a). The fieldwork focused on areas that may be disturbed when developing sources of borrow materials for the IW. The sites located in the 2013 investigations may contain as-yet unidentified heritage resources.

Historical mining activities extremely modified much of the FMC. As a result, much of the area now represents limited cultural value. Heritage resources that would have been present in the mining-impacted areas would have been altered or destroyed. However, some activities outlined in this IWPP will take place in relatively undisturbed areas within the FMC, and could affect culture and heritage values.

Indicators

Indicators for cultural values include traditional First Nations' culture, such as language and traditions. The loss of First Nations' languages or culture would be considered an adverse effect of the IW.

Indicators for heritage values include heritage resources. The *Historic Resources Act* (YG, 2002) and Chapter 13 of the Umbrella Final Agreement (Government of Canada, 1993) aim to protect and preserve/conserve heritage resources. The IW could impact heritage resources by disturbing or destroying them, which would be considered an adverse effect.

Study Area

The assessment team collected and synthesized baseline socio-economic information from available secondary data sources related to the culture and heritage VC across local and regional study areas.

Heritage values are closely related to specific locations and landscapes so the assessment team concluded that the site study area was the most important study area for the assessment of potential IW effects on heritage resources.

The assessment team considered the secondary information sources available (e.g., Weinstein, 1992; Ecofor, 2013a) to link cultural values to the FMC and create pathways between the IW and First Nation/community-based study areas. Pathways were identified for Faro and Ross River, the communities in the LSA. Pathways were not clearly identified for Pelly Crossing and Watson Lake. The assessment team were confident that analyses for the LSA would be at least partly relevant for the RSA. As a result, the assessment of cultural effects on Pelly Crossing and Watson Lake was discontinued. Conclusions are presented in Table 7-39.

TABLE 7-39

Cultural and heritage values	✓	✓	✓		

Pathways of Effects

Table 7-39 summarizes several pathways through which the IW could affect cultural and heritage values. The pathways for these interactions are associated with accessing area for site investigations and then conducting those site investigations (e.g., surface geophysical investigations) and the perceived change in how access to the FMC will be controlled and enforced.

The proposed site investigations include surface geophysics and other information gathering (e.g., sampling). To facilitate these activities, some access trails will be cleared to install drilling and testing equipment. Narrower trails will also be cleared to lay geophysical cable. Areas for drill pads, operating equipment, and test pitting/re-

filling will be cleared. Clearing trails and areas could potentially disturb, destroy, or alter heritage resources within the clearing footprint.

Cultural values in an area can be related to how the area is used. Clearing the new access trails to facilitate the IW could increase access to areas within the FMC footprint. Implementing an Access Management Plan could lead to the perception that the rules for accessing the FMC have changed. Table 7-40 identifies these pathways between the IW and the culture and heritage VC. Section 7.3.6.7 discusses IW effects related to changes in land use and access.

TABLE 7-40
Pathways of Effects for Culture and Heritage
Faro Mine Interim Works

Project Component	Project Activity and Potential Interaction
Site Investigations	Access Route Development: The development of new access routes could disturb heritage sites.
Site Investigations	Surface geophysics**:** Clearing required for the surface geophysics work could disturb heritage sites.

Analysis of Potential Effects

Post-mining baseline conditions at the FMC include open pits, more than 300 million tonnes of waste rock, roads, tailings, and water conveyance infrastructure. These post-mining landscape features are dramatically different from the pre-mining landscape, and have altered the local aesthetics. The changed landscape and mining infrastructure is not suitable for traditional, pre-mining activities (Weinstein, 1992).

The lack of a year-round settlement and limited third-party land use within the FMC footprint (Ecofor, 2013a) suggests a baseline condition of extremely limited First Nations language on the FMC (both frequency and amount). As a result, the IW are anticipated to have a very low or negligible effect on First Nations language.

Where trails and areas must be cleared to support the site investigations, the IW could disturb, alter, or destroy heritage resources within the footprint of that clearing. To decrease the amount of new clearing, where possible, site investigation areas will be accessed via previously disturbed ground. The new access trails will branch off existing access trails and will be less than 1.5 m wide, where possible. Clearing will also be confined within the FMC footprint, where possible. During clearing, vegetation will be removed to permit personnel and equipment passage. Depending on conditions and passage requirements, the vegetation may not be cleared down to ground level (e.g., surface geophysics). Where there is minimal soil disturbance, activities will be less likely to disturb or destroy unidentified heritage resources. If site workers encounter a potential movable heritage resource while clearing, the Heritage Resources Management Plan (HRMP) for the FMC (Appendix 5H) will be activated to protect that potential resource from damage by the IW.

Mitigation

The most important tool for mitigating potential effects related to minor interactions between the IW and culture and heritage values is an HRMP (Appendix 5H). The HRMP is designed “to ensure the immediate and ongoing protection and management of heritage resources within their existing developments and planned work at Faro” (Ecofor, 2013b). The HRMP will do the following:

- Provide adaptive management actions and communication protocols to assist project staff, their contractors, and subcontractors in managing known, and as-yet unidentified, heritage resources within the FMC.
- Flag known heritage sites, educate onsite workers, and provide instructions if new potential resources are encountered. Where ground disturbance activities are scheduled but a Heritage Resource Impact Assessment did not take place, heritage staff must review the HRMP before activities begin.
- Set out a process to communicate and record new potential resources. The HRMP requires AAM, their contractors, and their subcontractors to inform the Heritage Resources Unit and relevant First Nations of

identified heritage resources, as well as of planned and accidental impacts to heritage resources. If a plan is in place to affect sites, individual heritage site mitigation plans will be developed and implemented.

By implementing the HRMP, the IW should not result in unmanaged effects on heritage resources and is not expected to have significant residual effects on cultural and heritage values. Regardless, the HRMP describes an adaptive management approach, in case heritage resources are identified during IW.

Significance of Effects

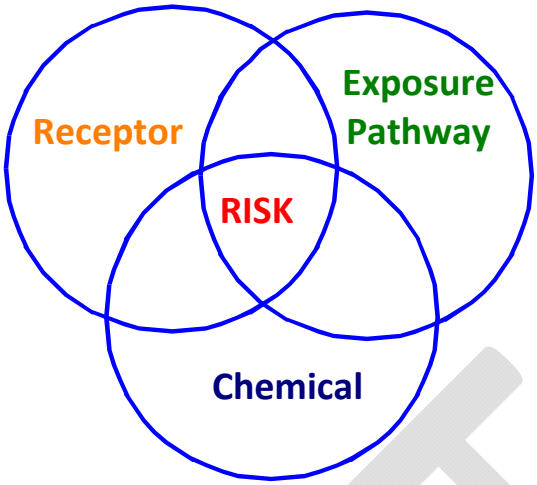
Clearing of access trails and areas for IW may adversely affect heritage resources. By locating these trails near existing disturbance, limiting trail length and width (footprint), and minimizing soil disturbance during clearing, it is unlikely that these activities will affect heritage resources significantly. Where potential sites are discovered during field work, the HRMP protocols will be triggered and guide efforts to preserve the uncovered resource.

The HRMP further decreases the likelihood of as-yet unidentified heritage resources being disturbed, altered, or destroyed. The geographic extent of these potential effects is low, as it is limited to the footprint of previously undisturbed areas in the FMC that must be cleared for the IW. The destruction of a movable heritage resource is considered irreversible and is important to both First Nations' and territorial governments. Overall, considering the provisions set forth by the HRMP and the low likelihood of interaction, the IW are unlikely to significantly adversely affect cultural and heritage values. Section 7.3.6.10 provides further detail on the significance of effects.

7.3.6.10 Human Health and Safety Effects Assessment

Table 7-4 does not identify any major interactions for the Human Health and Safety VC, in part because the IW focuses on minimizing contaminant release from the site. However, communities and local people frequently express concern about potential human health effects associated with contaminants from the FMC. In order to address this concern, this section describes a qualitative assessment of potential human health effects associated with proposed IW. It builds on the reported potential effects of the IW on air quality, water quality, fish, and wildlife.

Human health risks onsite because of the presence of chemicals in environmental media at the FMC are considered to be low or insignificant during the IW, understanding that occupational health and safety best practices are in place. Potential health risks to offsite individuals and communities are considered low or insignificant as a result of IW activities since the IW are understood to result in minimal effects on the presence of chemicals in the environment offsite.



Human Health Risk Effects Assessment

The potential for human health risks can be assessed by considering how the following three components interact:

- **Chemicals** present in the environment (e.g., soil, water, or air) at concentrations that may cause a health effect
- **Receptors,** which are people such as construction or remediation workers, nearby residents, or populations
- **Pathways of exposure** where chemicals from the environment can find their way to a receptor and into their body.

When all three components are present, risks are possible, and the potential risk can be evaluated. If one component is missing, there is no risk.

DRAFT

Where a potential risk is identified, the risk can be managed by affecting a change to any one of the three risk components.

In this assessment, potential effects identified on air quality, water quality, or wildlife from the IW activities will be examined qualitatively to determine the potential risk to likely human receptor groups. If there is a potential for significant risk, suggestions for risk management are provided.

Receptor Assumptions

Two groups of receptors have been identified for this assessment:

- Onsite workers at the FMC: For example, construction workers carrying out IW activities, maintenance and support-type workers, and other occupational workers including administrative or office workers. These types of workers are assumed to be onsite up to 50 hours per week, 50 weeks per year.
- Regional receptors: For example, members of the public working and living in nearby towns or communities or using the area for subsistence harvest or recreational purposes.

Exposure Route Assumptions

To represent a hazard, chemicals in environmental media (air, soil, dust, water, food derived from local wildlife) need to enter the body at concentrations that can cause a harmful effect. Chemicals can enter the body through any of three main routes:

- Through ingestion (eating) or for some things like dust (containing chemicals) incidental or accidental ingestion
- Through inhalation (breathing into the lungs)
- Through dermal contact and absorption of chemicals across the skin

For onsite receptors, administrative controls, engineering controls, and occupational health and safety requirements reduce or eliminate the opportunity for some of these exposure routes to be present. For example, use of dust control equipment (engineering control), eliminates inhalation of dust. Provision of hygiene facilities reduces or can eliminates potential dermal exposures.

Effects from each of the major disciplines (air quality, water quality, aquatic biota, and wildlife) are examined in the context of the potential for exposure pathways and routes of uptake to qualitatively assess the potential health risk for onsite and offsite human receptors.

Health Effects Assessment for Air Quality

The Air Quality Effects Report (Appendix 7A) identified the potential for localized air quality effects onsite only, in the immediate areas of IW activities. The assessment was considered to be conservative.

For human health considerations, inhalation of dust particulates (and possibly constituent metals in dust) is the primary pathway of exposure. In assessing predicted conditions onsite, the potential for human health effects arising from air quality effects are likely to be limited to occupational receptors in those localized areas. Through the use of dust control, engineering controls and the requirement to implement legislated occupational health and safety requirements for worker exposure, it anticipated that health effects from air quality issues will be mitigated and prevented by essentially removing the pathway of exposure.

The conservative air quality assessment predicted no effects for offsite or regional air quality. While members of the public frequently access areas near the proposed DVIHU construction works, access to that area will be managed during active construction. Therefore, no health effects are expected for offsite receptors from the inhalation pathway.

A minor, secondary pathway of exposure for human receptors is incidental ingestion of dust and dermal contact with dust deposited on surfaces. Based on Appendix 6E (Air Quality Baseline Report), dust generated is likely to settle quickly near the point of emission, limiting the contribution of metals to existing soils and surfaces. Considering that the local environment has elevated concentrations of minerals it is unlikely that dust deposition associated with the IW will have a significant effect on onsite concentrations in soil and on surfaces, and therefore unlikely to have a significant effect on human health. Furthermore, occupational health and safety requirements and the use of best practices (e.g., workers required to maintain hygiene, provided with sanitation / hand washing facilities, dust control on tailings) will reduce or eliminate this minor contribution to human receptors' exposure onsite. This secondary exposure pathway is expected to be negligible or absent for offsite human receptors.

The overall significance to human health effects arising from air quality effects associated with Faro IW is low.

Health Effects Assessment for Water Quality

For human health considerations, ingestion of surface water containing chemicals/parameters is the primary pathway of exposure. Surface water onsite that may be affected by the IW is not used for drinking water; therefore, the potential for onsite human exposure and human health effect arising from drinking surface water onsite is considered to be non-existent over the time period of the IW. Drinking water for workers and other human receptors is supplied from treated water sources. Similarly, surface water conditions onsite are not considered a potable source for nearby offsite communities. Offsite community water supplies are based groundwater wells and municipal treatment and distribution systems.

A minor pathway considered for onsite receptors is incidental or accidental direct contact exposure to surface water, where a very small amount of water is accidentally ingested (via hand-to-mouth contact) or skin contact with surface water occurs during a brief time period. Potential effects from this exposure is considered negligible because of either the very low probability of such an event or, in situations where dermal contact is more probable or expected to be frequent, onsite receptors are required to employ health and safety best practices to be protected from exposure using personal protective equipment such as gloves.

The proposed access management approach indicates that some recreational (hunting/hiking) or traditional users of the FMC area can collect water from two location that appears to be upgradient or upstream from areas that may be affected by the IW. The limited use of this water supply, if used at all, is unlikely to have a significant effect on health owing to limited and infrequent use. Best practice would be to communicate through access management that recreational or traditional users of the site should avoid the use of surface water on the site, and encourage the use of bottled water brought to site during such activities.

The overall significance to human health effects arising from water quality effects associated with Faro IW is low.

Health Effects Assessment for Fish Consumption

The Analysis of Aquatic Environment Effects (Appendix 7C) identified limited effect on water quality for the following chemicals/parameters in terms of effect on fish or fish habitat:

- Hardness (calculated using calcium and magnesium)
- Cadmium

- Cobalt
- Lead
- Manganese
- Sulphate
- Zinc

Recreational and traditional fishing uses are known to take place in the areas surrounding FMC. Fish consumption by members of the community represents a potential ingestion exposure pathway to metals in fish tissue. Thus two risk components (receptors and pathways) are likely present.

Based on Appendix 7C, metals (cadmium, cobalt, manganese, and zinc) with the greatest potential for effects in surface water, are not likely to present lasting effects, if any, to fish and other aquatic biota under the conditions of the IW in either the local or regional study areas. The assessment also indicates that locally relevant species (such as Chinook salmon and grayling) harvested during recreation or traditional fishing are not limited to the local or regional study areas. These species can travel large distances between seasonal habitats and the resulting tissue metal concentrations of fish may not relate to the water and habitat conditions where they are caught. Effects during the 10-year period of IW on fish are generally expected to be insignificant or low and limited to the local study area. Effects would be further reduced as relevant fish species are expected to have a larger habitat range diminishing the influence of local study area on fish metal tissue concentrations. Furthermore, metal uptake into various fish tissue is known to be variable with fish muscle (typically the edible portion) having the lowest uptake, and other tissues such as the gills and liver having higher uptake of metals.

Given the assessment that water quality during the IW will have a limited or low significant effect on fish, the habitat range of the fish (relevant for traditional uses) may be greater than any local affected area in the FMC, and tissue metal concentrations of the edible portions of fish are likely the lowest of impacted fish tissues, the overall significance to human health effects arising from consumption of fish impacted by Faro IW is low.

Health Effects Assessment for Game Consumption

The Wildlife and Wildlife Habitat Effects Assessment (Section 7.3.5) included consideration of birds, waterfowl, small mammals (e.g., voles), and large mammals (e.g., grizzly bear, moose, and thinhorn sheep). Of these, moose and possibly waterfowl are relevant from a traditional use, recreational hunting and harvesting, perspective. Moose and waterfowl can be exposed to metals in environmental media (e.g., soil and water) and vegetation affected by IW activities. Exposure can lead to uptake of metals into animal tissues. Subsequent consumption of game may expose people to tissue metal concentrations and potential health effects.

Based on Section 7.3.5, tissue metal concentrations in moose are unlikely to be affected by IW activities. The relatively large range of these animals minimizes the duration and frequency in the LSA where the potential for greater exposures to metals in environmental media and vegetation exists. As was the case with some of the relevant fish species, tissue concentrations in moose hunted and caught in the LSA or RSA may not reflect local conditions associated with the IW. Furthermore, best practice and management activities during IW that reduce the impact of metals on water and vegetation in the LSA will limit the potential for metal uptake by moose that make use of the site and region. Human health effects associated with the consumption of moose are expected to be insignificant as metal tissue concentrations are unlikely to be affected over the life of the IW.

Waterfowl are known to seasonally use some of the pits and ponds associated with FMC. Exposure to water and biota with metal concentrations could lead to metal uptake. Water quality management and reduction of impacts is part of the IW; it is therefore unlikely that IW activities would have a significant effect, if any, on tissue metal concentrations in waterfowl. Furthermore, Section 7.3.5 suggested additional management of the local areas that may be prone to seasonal use by waterfowl, such that these areas are less inviting or available to waterfowl. Overall, waterfowl would have less opportunity for contact with impacted environmental media and reduced contaminant exposure. Consumption of waterfowl caught in the RSA is unlikely to have significant effect on human health as a result of IW activities affecting waterfowl.

The significance of human health effects arising from consumption of game during the period of the IW is low.

Management of Worker Health and Safety

As described previously, onsite workers may have limited opportunity for exposure to dust and surface water. These pathways are mitigated through the implementation and adherence to health and safety plans, best management practices, and legislated requirements for worker hygiene. These practices protect human health.

A number of operational safety risks have been identified for the activities at the FMC during IW. Therefore, the use of legislated requirements and best practices are also key components for maintaining worker safety during the various IW activities. Worker health and safety protocols will be developed (or adopted) and implemented to support the various activities (such demolition, construction, or remediation) likely to occur during IW. Strict adherence to safety regulation, safety protocols and industry best practice (e.g., the use of task hazard analysis, implementation of programs for confined spaces, site access, site and building security, traffic control, waste management, or industrial hygiene) will be key to reducing exposures, controlling and/or eliminating worker safety risks.

Conclusion

The risk assessment paradigm (three components of risk) facilitates risk management by the identification of hazards (safety risk or chemical exposure risk) and the pathways of exposure to human receptors. Where possible, risks can be mitigated during the IW through reduction in hazards (e.g., reducing number of hazardous situations; reducing dust concentrations), and minimizing the frequency and duration of exposure (e.g., reducing consumption of water, wildlife, and fish). Continuing to monitoring air and water concentrations will support rapid response to a change in hazards.

7.3.6.11 Significance of Residual Socio-economic Effects

Table 7-41 details the rationale for the determination for the significance of the socio-economic effects, while. Table 7-42 rates the significance of residual socio-economic effects. With respect to human health and safety no major potential effects were identified.

TABLE 7-41
Characterization/Attributes of Residual Effects
Faro Mine Interim Works

Characterization/ Attribute	Description	Quantitative Measure or Definition of Qualitative Categories
Direction	The ultimate long-term trend of the socio-economic effect (positive or negative), relative to the baseline conditions.	▪ **Negative** (or Adverse) – VC would change for the worse. ▪ **Positive** (or Beneficial) – Change in VC would be an improvement. ▪ **Neutral** – No change in VC.
Socio-economic Context	Experience with previous projects, or socio-economic resiliency and ability to cope/adapt.	▪ **Low** – Community(s) has little or no experience with development, or is less resilient and has little capacity to adapt to change. ▪ **Moderate** – Community(s) has some experience with development, or is somewhat resilient and has some capacity to adapt to change ▪ **High**– Community(s) has considerable experience with development, or is resilient and able to adapt to change
Magnitude/Duration	The amount of change, relative to baseline conditions. The period of time required until the VC or indicator returns to its baseline condition, or until the effect can no longer be measured or otherwise perceived.	▪ **Low** – Effect occurs but may or may not be detectable; effect limited to <1 year ▪ **Moderate** – Effect occurs and is detectable; effect occurs >1 year and <10 years ▪ **High** – Effect represents a substantial change from baseline conditions; effect extends 10 to 25 years
Geographical Extent	The geographic area within which a socio-economic effect occurs.	▪ **LSA**– FMC, Town of Faro, Ross River ▪ **RSA** – FMC, Town of Faro, Ross River, Pelly Crossing, Watson Lake

TABLE 7-41
Characterization/Attributes of Residual Effects
Faro Mine Interim Works

Characterization/ Attribute	Description	Quantitative Measure or Definition of Qualitative Categories
Probability/Frequency	Professional judgement regarding the probability that an effect will occur, and how often.	**Probability** ▪ **Low –** Unlikely to occur ▪ **Moderate –**May occur ▪ **High –**Likely to occur **Frequency** ▪ **Low** - seldom or never ▪ **Moderate** – occasionally ▪ **High** – continuously

7.3.7 Effects of Extreme Events

To address the YESAA paragraph 42(1)(c) requirement to evaluate the effects of malfunctions and accidents, the IW environmental and socio-economic assessment relies on risk assessment approaches to characterize the potential effects of extreme events. Risk assessment is an effective tool for evaluating these potential effects because it considers both likelihood and consequences of potential failure events. Some risk events can only be managed by reducing the likelihood of the events, while other can be addressed through reducing both consequences and likelihood. Risk assessment provides a systematic approach for identifying appropriate management responses.

The environmental and socio-economic assessment considers two types of risk events: external factors (i.e., floods, earthquakes and forest fires), and malfunctions and accidents. Formal, annual risk assessments, as described in Appendix 5D, address operational and physical risks associated with FMC facilities and operations. For the IW, the assessment team supplemented the results of the annual risk assessment by specifically evaluating risks associated with proposed IW activities.

Based on the risk assessment results and risk management approaches described in this section, the IW are not expected to cause significant adverse environmental or socio-economic effects as a result of external factors, accidents, or malfunctions.

7.3.7.1 Effects of the External Events

As Section 7.1.6 stated, the FMC and the IW's abilities to withstand floods, earthquakes, and forest fires are important considerations in the assessment. These external factors present risks to the project that could result in adverse environmental or socio-economic outcomes. The following paragraphs describe risks associated with each of these types of events.

Floods

Important flood risks at the FMC are associated with the three main surface water diversions that convey clean water around the site: the RCD, the FCD, and the VCD. Failure of any of these diversions during flood events may lead to contamination of clean water by mine wastes, and possibly to release of contaminated water. The following appendices provide information related to evaluation of flood related risks at the FMC:

- Appendix 5D, C&M Risk Assessment Report, characterizes flood risks for facilities at the FMC.
- Appendix 5I, Down Valley Interim Hydraulic Upgrades Design, describes the current flood routing capacities for the RCD and the RCTA, and proposed upgrades to improve flood routing capacity.
- Appendix 6B, Hydraulic Characterization of Existing Facilities, describes the current hydraulic performance of flood routing facilities.
- Appendix 6C, Stability of Major Existing Facilities, describes the flood routing capacity for key facilities.
- Appendix 6F, Hydrology Baseline Report, provides flow estimates for floods of various return periods.

The RCD conveys fresh water around the RCTA. Hydraulic failure of the RCD could route water into the RCTA, resulting in risks for the ID. The RCD was designed and constructed to convey 140 m^3/sec, slightly more than the 120.2 m^3/sec estimate of the 1-in-500-year flood event (Appendix 6C). However, the current condition of the RCD is such that vegetative growth and other channel maintenance related issues have decreased this flow capacity (Appendix 5N). The RCD's existing configuration does not provide adequate capacity to convey the 1-in-50-year flood flow of 72.8 m^3/s before the flow overtops the overflow weir (Appendix 6C). The existing ID spillway capacity of 32 m^3/s is not sufficient to safely pass a moderate or major flood event without overtopping and potentially failing the ID, and releasing tailings to the downstream environment (Appendix 6C).

The annual operational risk assessment identified several flood-related risks for the RCD and RCTA (Appendix 5D). Table 7-43 lists these risks, alongside corresponding mitigation actions. Most importantly, the proposed DVIHU will increase capacity of both the RCD and the ID Spillway to 1-in-500-year peak flow, and will effectively manage flood risks for the RCTA during the IW.

The FCD conveys fresh water around the Faro Pit into the NFRC. Hydraulic failure of the FCD would route water into the Faro Pit, resulting in increased requirements for treatment of contaminated water. While the flood return period capacity of the existing FCD is unknown, it has performed suitably during the post-operational period. For geotechnical reasons, the FCD must be reconstructed at a new location during the FMRP. During the IW, the FCD's failure is unlikely to result in measureable environmental effects because the Faro Pit has enough capacity to store several months of Faro Creek inflows following a flood event. This would provide enough time for the FCD to be repaired before environmental effects took place. The annual risk assessment described in Appendix 5D identified flood risks associated with the FCD, as well as the following risk management measures:

- Ongoing monitoring and maintenance to maintain diversion capacity
- Management of Faro Pit water levels to maintain sufficient storage capacity for floods and failure events
- Retention of sufficient supplies to construct a piped diversion for Faro Creek on short notice after a failure event

The VCD conveys fresh water around the Vangorda Pit. For most of its components, their failures would result in water being routed into the Vangorda Pit. This would increase the requirements for water treatment, and possibly cause contaminated water to be released into Vangorda Creek. The existing VCD was designed and constructed to convey flows up to 10 m^3/s, the peak flow for a 1-in-100-year event. Over the last 10 years, the VCD has experienced floods, slope failures, and ice buildup that have compromised the diversion and resulted in significant maintenance requirements. Appendix 6B summarizes the existing condition of the VCD as follows:

- Existing flume structures require ongoing maintenance and repair to limit plugging of the diversion, erosion of roadway, and resulting discharge to Vangorda Pit
- Drop structures at roadways require ongoing maintenance to limit the risk of plugging and overtopping
- The VCD does not have capacity to convey peak flow in excess of 10 m^3/sec, which is the 1-in-100-year design peak flow event.
- Bank Slopes associated with the half-round CSP culvert component of the VCD are at risk of instability and slumping.
- Ice damage impacts the instability of the diversion structures.
- Pit wall instability threatens the VCD.

Faro Mine Interim Works

Risk	Risk Rating [a]	Risk Mitigation
A Probable Maximum Flood event exceeds the capacity of the ID spillway, leading to release of tailings and water to environment.	Moderately High	DVIHU will provide capacity for the ID to convey 1-in-500-year flood events. This provides suitable management for risk during IW, since the likelihood of larger floods is very small during a period of 10 years or less. Further upgrades to be completed as part of FMRP.
A 1-in-500-year to 1-in-1,000-year flood event exceeds the capacity of the ID spillway, leading to the breach of the ID, the release of contaminated water, and 10-20% of the total volume of tailings being released to the CVD Pond. The CVD Pond spillway releases contaminated water to the environment, but the tailings are contained in the CVD Pond.	Moderately High	DVIHU will provide capacity for the ID to convey 1-in-500-year flood events. This provides suitable management for risk during IW, since the likelihood of larger floods is very small during a period of 10 years or less. Further upgrades to be completed as part of FMRP. The CVD Pond Spillway has the capacity to convey approximately 300 m^3/sec, sufficient for the estimated flow during a 1-in-1,000-year event. The magnitude and duration of effects would be reduced because tailings would likely remain contained within the CVD Pond.
A flood event causes a breach of RCD dike, leading to a breach of the ID and the release of tailings and water.	Moderately High	DVIHU will reduce likelihood of a RCD dike breach, and provide additional capacity for ID to convey flood flows. This provides suitable management for risk during IW, since likelihood of larger floods is very small during a period of 10 years or less. Further upgrades to be completed as part of FMRP.
The catastrophic structural failure of the RCD during a 1-in-50 to 1-in-100-year event, causing the breach of the dike and the uncontrolled flow of RCD into the ID Pond for 1 month. The ID Pond spillway conveys majority of flow into CVD, where it short-circuits the pond and leads to the discharge of undiluted ID Pond overflow into the environment (elevated zinc/suspended solids).	Moderately High	DVIHU will reduce likelihood of a RCD dike breach. This provides suitable management for risk during IW, since the likelihood of larger floods is very small during a period of 10 years or less. Further upgrades to be completed as part of FMRP.
A flood event in the range of 1-in-50 to 1-in-100 year event overtops the RCD dike or fuse plug (no major structural failure), and leads to the flow of water into the ID Pond, with continued pumping capacity, out through ID Pond spillway/CVD and into receiving environment for 1 to 7 days. Mechanisms of debris flow, icing, and slope failure were also considered but have lower likelihoods.	Moderate	DVIHU will reduce the likelihood of RCD dike overtopping. This provides suitable management for risk during IW, since the likelihood of larger floods is very small during a period of 10 years or less. Further upgrades to be completed as part of FMRP. Ongoing maintenance of the diversion and pumping system, and effective management of water levels in the ID Pond will also reduce the likelihood and magnitude of contaminant releases.

[a] Refer to Appendix 5G for explanations about risk ratings.

DRAFT

The annual operational risk assessment identified several flood-related risks for the VCD (Appendix 6C). Table 7-44 lists these risks, alongside associated mitigation actions. The risk assessment did not identify specific flood-related risks for the VCD with ratings higher than Moderate. However, considering the VCD's limited hydraulic capacity and deteriorating condition, along with its limited storage capacity and very adverse water quality in Vangorda Pit, the combined risks for the VCD may warrant upgrading the facility before the FMRP is implemented. Design information to support evaluation of any upgrade is not currently available and will be addressed in future assessment and regulatory processes if needed.

The annual operational risk assessment and the specific risk assessment for the IW identified risks that flooding may overwhelm the capacity of water management systems for the Grum Dump, especially the pumping system at V-15, and the capacity of Moose Pond (Appendix 5D; Appendix 6K). Upgrades for the V-15 pumping system are planned to provide additional capacity during freshet and flood conditions.

Earthquakes

Risks associated with seismic events are an important consideration for waste- and water-retaining structures at the FMC, including the ID, Secondary Dam, CVD, LCD, and RCD dike. Each dams retains contaminated mine waste or water that would affect local aquatic ecosystems if the facilities failed. The RCD dike effectively separates clean water from the Rose Creek tailings. Appendix 6C - Stability of Major Existing Facilities describes the current status of FMC facilities, related to their expected seismic performances. Appendix 5D -Site Operations Risk Assessment characterizes seismic risks for facilities at the FMC.

Seismic analyses in Appendix 6C concluded that the ID, Secondary Dam and CVD would be stable for 1-in-500-year seismic events. These conditions effectively manage risks for the IW period, because the likelihood of seismic events larger than 1-in-500-year events is very small for the 10-year duration.

Appendix 5D identified Moderately High risks for RCD dike and LCD failures during seismic events. These risk ratings are related to the current lack of information about, or analyses of, the seismic stability of these facilities. Field investigations have been conducted and analyses are under way to develop a better understanding of seismic stability of the RCD dike. Both facilities need to undergo further seismic condition analyses. This need will be addressed by implementing recommendations that arise from the proposed 2014 Dam Safety Review, which will take place in accordance with the Dam Safety Guidelines (CDA, 2007), and ongoing annual dam safety inspections as described in Appendix 5B, Environmental Monitoring, Surveillance, and Reporting Plan. In the meantime, risks associated with seismic events at the LCD will be reduced by maintaining a low water level therein, at least 2 to 3 m below the spillway invert.

Forest Fires

Appendix 5D identified a Low risk associated with loss of access at the FMC for a period up to 14 days, resulting from forest fire. The assessment assumed that pumping and water treatment activities at the FMC would be curtailed during the forest fire event. Discontinuing water treatment presents no measurable risk to the environment because the pits have enough capacity to store contaminated water. Discontinuing pumping from SISs (e.g., S-Wells SIS) could lead to contaminant releases to the aquatic environment for short periods of time. The water quality and aquatic effects assessment considered events more severe than those associated with potential forest fire events and concluded that effects would not be significant.

DRAFT

TABLE 7-44
Flood Risks – Vangorda Creek Diversion
Faro Mine Interim Works

Risk	Risk Rating [a]	Risk Mitigation
A flood event greater than the capacity of the VCD allows water to flow into Vangorda Pit, which overflows, causing the release of contaminated water to Vangorda Creek.	Moderate	The VCD has capacity to convey peak flow from a 1-in-100-year event. Water level management in the Vangorda Pit provides capacity to store water if the VCD fails or is overtopped. At the average maintained water level (1,185 masl) there are approximately 4.8 Mm^3 of capacity to the final spill elevation of 1,130 masl. This provides 5.6 days of storage capacity at a peak 1-in-100-year flow of 10 m^3/sec.
A flood event greater than the capacity of the VCD allows water to flow into the Vangorda Pit, without overflowing.	Moderate	The VCD has capacity to convey peak flow from a 1-in-100-year event. Water level management in the Vangorda Pit provides capacity to store water if the VCD fails or is overtopped. At the average maintained water level (1,185 masl), there are approximately 4.8 Mm^3 of capacity to the final spill elevation of 1,130 masl. This provides 5.6 days of storage capacity at a peak 1-in-100-year flow of 10 m^3/sec.
An ice formation and flood event that causes damage to VCD flume.	Moderate	Ongoing monitoring and maintenance of the VCD, and effectively managing water levels in the Vangorda Pit, will also reduce the likelihood and magnitude of contaminant releases.

[a] See Appendix 5G for an explanation about risk ratings.

DRAFT

7.3.7.2 Effects of Malfunctions and Accidents

Appendix 5D and the evaluation of specific risks for the IW considered effects that could arise from a variety of potential failure modes and events:

- Engineering failures (e.g., structural failure of building)
- Human error (e.g., operator error, inspector error, mischief, or vandalism)
- Prediction errors (e.g., uncertainty in geochemical predictions, or underestimates of flood events)

As Appendix 5D described, the 2013 annual operational risk assessment did not identify any high environmental risks at the FMC. This outcome illustrates the success of ongoing risk management evaluations and responses at the FMC, where actions have been taken to reduce environmental risks. The risk assessment identified three environmental risks with moderately high ratings, indicating that mitigation plans should be developed and implemented. The following paragraphs describe scenarios with moderately high environmental risks, along with responses that will be implemented in the coming year.

- **A piping failure of the ID leads to release of contaminated water through the CVD Pond.** The status of the ID is addressed through ongoing monitoring programs, rendering the event unlikely.
- **Wind erosion from tailings causes contamination of surrounding land, affecting ecosystem health.** Revised protocols for undertaking dust control measures are needed to minimize wind erosion. These protocols have been developed as part of the IWPP and will be part of licence applications.
- **Contaminated water migrates below the CVD Pond, resulting in the escape of contaminated water to the environment.** The AMP includes monitoring and thresholds that will guide the timely design and implementation of groundwater collection systems. Existing pumping wells could be used for the immediate collection of affected water. A collection system is already being designed, and extensive aquifer testing has taken place to support that design.

The evaluation of specific risks for the IW identified several environmental risks that could arise during site investigation or DVIHU activities. Appendix 5E (Spill Contingency Plan) and Appendix 5A (Environmental Management Plan) address risks arising from transporting, transferring, and handling fuels or other hazardous materials. The Environmental Management Plan (Appendix 5A) addresses risks of contamination of clean water during drilling or aquifer testing activities. It also describes measures for preventing cross-contamination within aquifers during drilling, or preventing the release of contaminated water to surface water during drilling or aquifer testing. Risks associated with operational failures of pumping, piping, and water treatment systems will be addressed by Failure Modes Effects Analysis undertaken for specific pumping, conveyance, and treatment facilities, to identify appropriate mitigation strategies and critical spare parts lists. These Failure Modes Effects Analyses have been conducted for some facilities and will continue as part of ongoing operations.

The 2013 operational risk assessment identified two High human health and safety risks for the FMC. According the YG and AANDC risk management practices, appropriate mitigation responses must be developed and implemented immediately. The risks and responses that will be implemented in the coming year are described herein.

- **Faro pit wall failure occurs while personnel and equipment are working on the FCD.** This is a new risk identified in 2013, reflecting concern about heavy equipment operation along the FCD near the pit wall, and potential implications on physical stability. Stability under these circumstances will be further evaluated, and appropriate responses will be developed within the calendar year.
- **Worker breaks through the ice or falls into water, resulting in injury or death.** Operational procedures and training have been implemented for working on ice or water. However, working on ice/water is inherently hazardous and some risk remains.

Appendix 5D identified numerous moderately high human health and safety risks. Several of these are related to unauthorized access to onsite facilities by members of the public. Ongoing improvements to site and building security will reduce the likelihood of such events. The Mill Building is no longer used for water treatment, which

DRAFT

eliminates the need for site staff to access it on a daily basis and provides opportunities for more effective access control. Some additional moderately high risks are associated with use of the Mill Building. Reduced use of that facility will also reduce these risks. Finally, a new risk identifies potential worker health and safety effects associated with the daily operation of the proposed interim water treatment facility, in an area that may have high lead concentrations. Further investigation will identify the scope of the risk, and remedial measures may be required to address this risk.

The evaluation of specific risks for the IW identified several human health and safety risks that could arise during site investigation or DVIHU activities. These are primarily risks to worker safety and will be addressed via appropriate worker health and safety protocols.

Appendix 5D identified several cost risks for the FMC. While these risk events may cause additional costs for co-proponents, they are not expected to cause significant environmental or socio-economic effects.

7.3.7.3 Significance of Effects of Extreme Events

Based on the results of risk assessments, extreme events including floods, earthquakes, forest fires, and malfunctions and accidents are not expected to cause significant adverse environmental or socio-economic effects during the IW.

The facilities and operations at the FMC are sufficiently robust to effectively manage risks associated with floods, earthquakes, and forest fires during the IW period. Therefore, these events are not expected to cause significant adverse environmental or socio-economic effects. The proposed DVIHU will address higher risks associated with flood conveyance in the RCTA. Ongoing monitoring, maintenance, pit water management, and emergency preparedness planning will reduce risks associated with floods, earthquakes, and forest fires.

Appropriate actions will be taken to reduce and manage risks arising from malfunctions and accidents. Therefore, these events are not expected to cause significant adverse effects. The annual systematic operational risk assessment provides an effective tool to identify and track risks, and to develop appropriate responses.

7.3.8 Overall Significance of Effects

This section summarizes the major potential effects evaluated in the assessment for the IW, and describes the significance of those effects.

For air quality, the major potential effects arise from dust releases from the FMC, including metal-laden dust from mine wastes (e.g., tailings). The assessment evaluated the significance of the potential effects by comparing predicted concentrations of TSP, PM_{10}, $PM_{2.5}$ and metals against provincial and territorial air quality criteria (Appendix 7A).

For surface water quality, the major potential effects arise from contaminants of concern being released to receiving water. These releases could take place via controlled surface discharges (e.g., treated effluent from the Faro and Vangorda Water Treatment Systems), uncontrolled surface discharges (e.g., untreated runoff and seepage), and groundwater. The assessment evaluated the potential effects of sulphate, cadmium, cobalt, iron, lead, manganese, and zinc. These contaminants have exceeded water quality guidelines for the protection of aquatic life at surface water stations located around, and downstream from, the FMC. To evaluate the significance of potential effects, predicted contaminant concentrations for normal and adverse conditions were compared with water quality guidelines and aquatic toxicity thresholds (Appendix 7C).

For fish and fish habitat, the major potential effects arise from surface water contamination. The significance of these potential effects was addressed in conjunction with the effects on surface water quality. Predicted concentrations of contaminants of concern were compared with water quality criteria and aquatic toxicity thresholds (Appendix 7C).

For wildlife and wildlife habitat, the major potential effects arise from the permanent or temporary destruction or alteration of habitat, metals uptake through feeding or exposure, entrapment or drowning in site facilities, vehicle collisions or equipment-related trauma, or sensory disturbance (i.e., visual, olfactory, or auditory). To adequately describe these potential effects, which could apply to a wide variety of species, the assessment evaluated effects

of IW activities on six wildlife indicators: (1) moose, (2) thinhorn sheep, (3) grizzly bear, (4) avian nesting habitats, (5) waterfowl, and (6) small mammals. The evaluation compared the expected effects of the IW with ecological objectives for habitat loss, mortality, local site use, and metals uptake.

For economy and employment, the major potential effects arise from the increased employment and spending associated with the site investigations in 2014 and DVIHU construction in 2016. The assessment characterized the potential changes in business development, economic diversification, employment and income levels, and education and training.

For infrastructure and services, the major potential effects arise from the potential influx of workers for certain IW activities. The assessment characterized potential effects on roads and traffic, housing, health services, emergency services, and community infrastructure.

For land use and access, the IW may result in increased access to currently undisturbed areas and changes in access to the area by local users, resulting from changes in access management at the FMC. The assessment characterized potential effects on traditional land use, hunting and fishing, recreation, tourism, and forestry.

For community stability and well-being, major potential effects may arise from the potential influx of workers for certain IW activities. The assessment characterized potential effects on demographics, social cohesion and cultural well-being.

No major potential effect were identified for culture and heritage, or human health and safety. In addition, extreme events including floods, earthquakes, forest fires, and malfunctions and accidents are not expected to cause significant adverse environmental or socio-economic effects during the IW.

As Section 7.2.3 mentioned, the evaluation of the effects' significance considers the following factors:

- Direction
- Magnitude
- Likelihood
- Duration
- Geographic extent
- Probability/frequency
- Reversibility
- Socio-economic context

Table 7-45 summarizes the significance of the proposed IW's potential effects on the VCs for the above factors. The factors considered vary with the VC depending on its nature and measures used to rate significance. An overall significance rating for each VC is identified based on the evaluation. Because none of the ratings of overall significance are high, none of the potential effects exceed the threshold for significance defined in Section 7.2.3. Therefore, the co-proponents have concluded the IW will not cause significant adverse environmental or socio-economic effects.

January 2008

Faro Mine Closure
Fermeture de la mine Faro

Faro Mine Closure - History

1969 - The Faro Mine officially opened.

1998 - The mine's final owner was placed into receivership and all mining operations stopped.

2003 - The federal and Yukon governments acknowledged that the mine would not reopen. With the Ross River Dena Council (on behalf of the Kaska Nation) and Selkirk First Nation, they began working together to develop a closure and remediation plan for the Faro Mine Complex.

Closure planning over the years

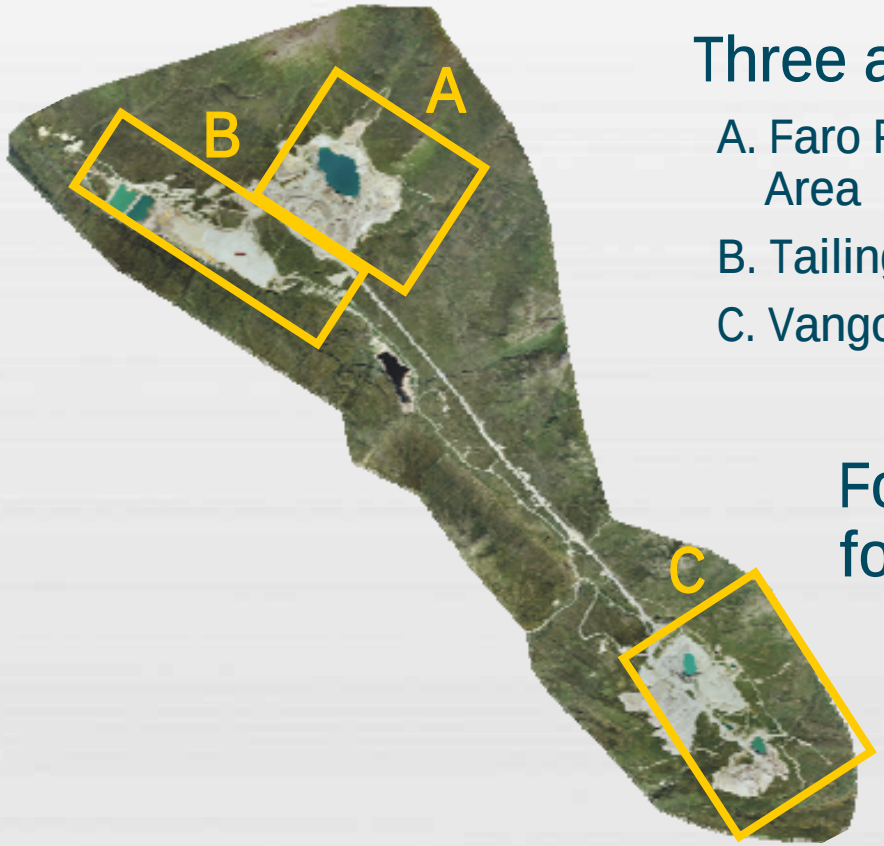
Many different plans have been proposed for addressing the environmental issues at the Faro Mine Complex:

1981 Tailings Abandonment Plan

1988 Curragh Resources Abandonment Submission

1991 Down Valley Tailings Abandonment Plan

1996 Integrated Comprehensive Abandonment Plan (ICAP)



Understanding the issues

To create a complete **final closure and remediation plan**, we gathered and studied information on a wide range of environmental issues.

- From 2002 to 2005 - conducted technical workshops with consultants, governments (federal, territorial, First Nation, municipal), regulatory agencies, and others.
- From 2003 to 2006 - completed over 90 technical studies.

2006 - Example Alternatives

From the studies and the workshop results, we created 12 “example alternatives”.

Three areas

A. Faro Pit and Waste Rock Area

B. Tailings Area

C. Vangorda/Grum Area

Four alternatives for each area

12 total

2007 – Further Narrowing the Options

During 2006 and 2007, the 12 example alternatives were subject to:

- Independent Peer Review
- Community input
- Further technical studies

This allowed us to refine and condense the

12 example alternatives

into

5 closure options

2007 - Closure Options

We now have 5 closure options.

Two areas

A. Faro Mine Area
(this combines the Faro Pit and Waste Rock with the Tailings Area)

B. Vangorda/Grum Area

3 options for the Faro Mine Area

2 options for the Vangorda/Grum Area

5 total

2007 – 5 Closure Options in Two Areas

Combined Faro Mine Area

Move All Tailings	+	Upgrade Faro Creek Diversion and Cover/Revegetate Faro Waste Rock
or		
Cover Tailings with Soil	+	Upgrade Faro Creek Diversion and Cover/Revegetate Faro Waste Rock
or		
Move Some Tailings and Cover Some Tailings with Soil	+	Upgrade Faro Creek Diversion and Cover/Revegetate Faro Waste Rock

= 3 Combined Options

Vangorda/Grum Mine Area

Move Vangorda Waste Rock into Vangorda Pit

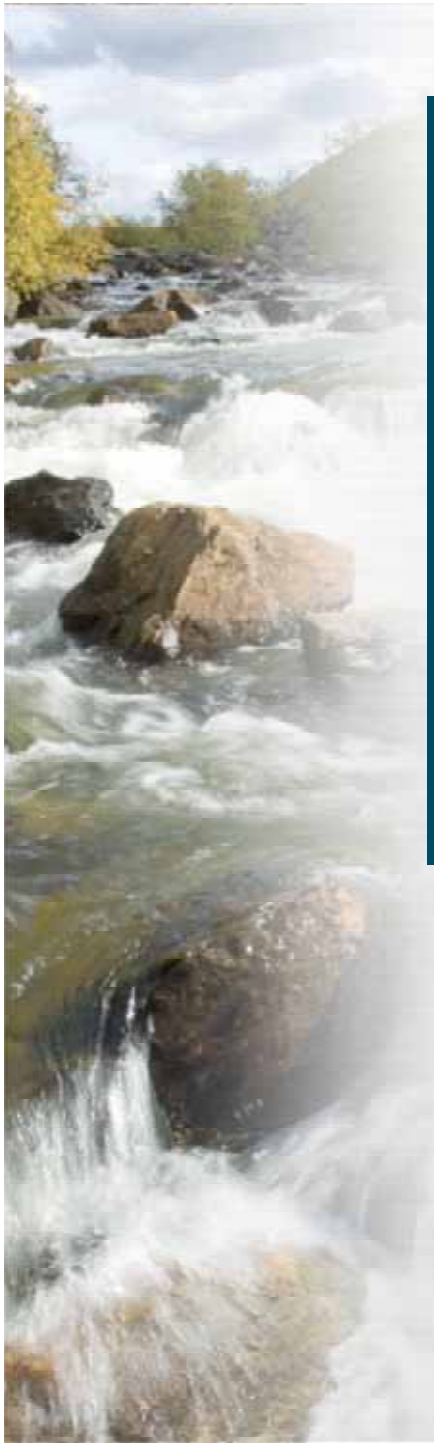
or

Cover Vangorda Waste Rock in Place

= 2 Options

Common Elements of the Options (1)

Any overall closure plan for the Faro Mine Complex will include some common things:



- Resloping and covering waste rock
- Revegetation of soil covers and other areas
- Diversion of clean water around the site
- Long-term collection and treatment of contaminated water
- Long-term management of water treatment sludge
- Long-term storage of water in pits
- Long-term maintenance of remaining site facilities (diversions, covers, water collection systems, water treatment systems, dams, etc.)
- Long-term monitoring of environmental conditions (water, animals, plants, climate, etc.)

Common Elements of the Options (2)

All of the closure options for the Faro Mine Complex are designed to do the following:

- Avoid unacceptable risks to public health and safety
- Avoid unacceptable risks to worker health and safety
- Meet appropriate environmental standards and guidelines, etc.

Combined Faro Mine Area Option 1

Upgrade Faro Creek diversion
Reslope, cover and revegetate Faro waste rock
Move all tailings

Estimated Jobs: 975 person years

Estimated Cost: $590 M

Combined Faro Mine Area Option 1:
Upgrade Faro Creek Diversion / Cover Faro Waste Rock

Closure Approach

What is involved?

- Build new diversion channel for Faro Creek
- Remove North Fork Rock Drain
- Build lined channel for North Fork Rose Creek
- Waste Rock
  - Reslope and cover with soil
  - Possibly move some waste rock to Faro Pit
- Revegetate covered waste rock
- Move tailings from Emergency Tailings Area to Faro Pit or Tailings Area.
- Collect and treat contaminated water from below waste rock, Zone 2 Pit and in Faro Pit (100s of years)
- Maintain covers and channels (100s of years)
- Monitor environmental conditions and adapt to changes

Estimated cost to build and maintain: $150M

Estimated employment: 230 person years

Each option is designed to meet technical and environmental standards.

An overall closure plan will be created by choosing one option for the Faro Mine Area and one for the Vangorda/Grum Area.

Before remediation (Now)

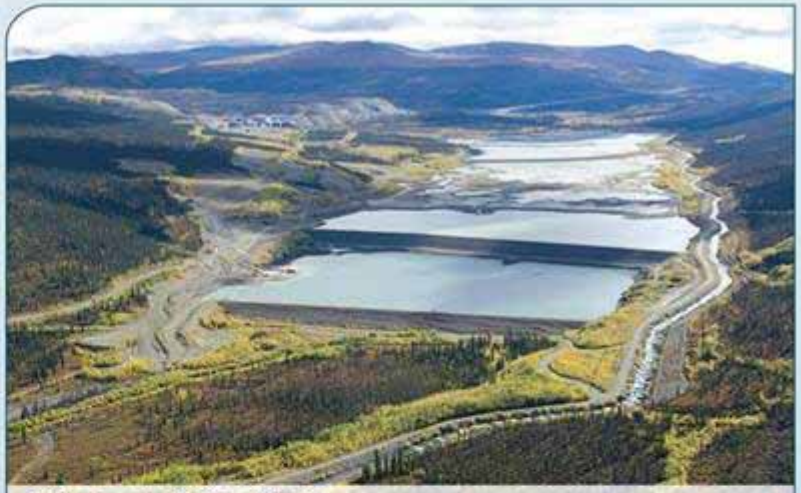
Image for illustration purposes only

After remediation (approximately 40 years time)

Combined Faro Mine Area Option 1:
Move all tailings

Move All Tailings to Faro Pit

What is involved?



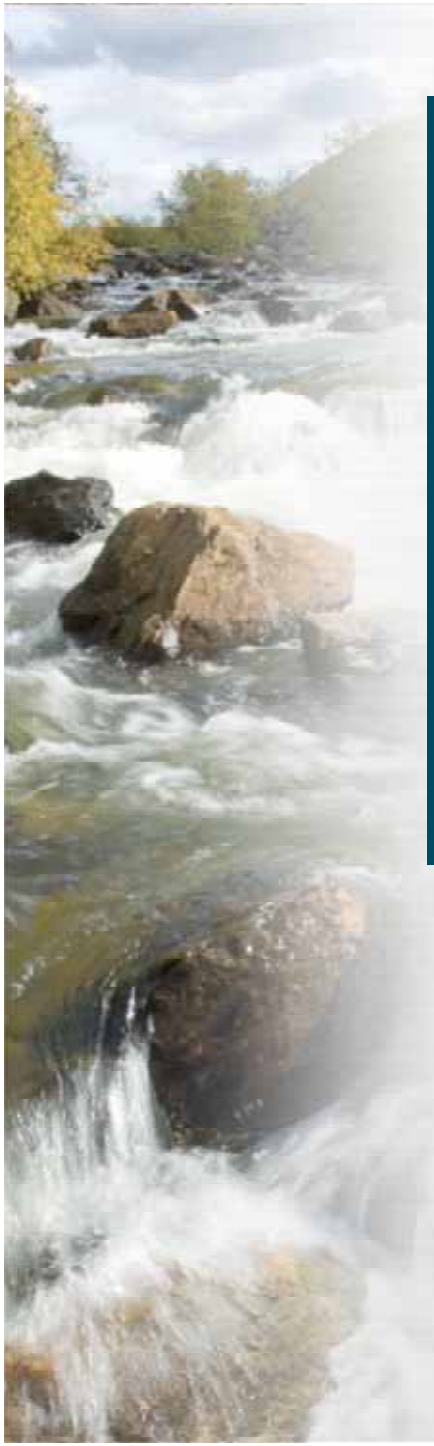
- Mix tailings with lime and water
- Pump tailings to Faro Pit
- Clean up remaining tailings with trucks and loaders
- Collect and treat contaminated water from under tailings (20 years?)
- Cut through dams and revegetate valley
- Construct channel for Rose Creek and put Rose Creek back in the valley when soil and water are clean
- May have to collect and treat contaminated water from mine area in Rose Creek Valley (100s of years)
- Monitor environmental conditions and adapt to changes

Estimated cost to build and maintain: $440M

Estimated employment: 745 person years

Each option is designed to meet technical and environmental standards.

An overall closure plan will be created by choosing one option for the Faro Mine Area and one for the Vangorda/Grum Area.



Before remediation (Now)

Image for illustration purposes only.

After remediation (approximately 40 years time)

Combined Faro Mine Area Option 2

Upgrade Faro Creek diversion
Reslope, cover and revegetate Faro waste rock
Cover tailings with soil

Estimated Jobs: 566 person years

Estimated Cost: $410 M

Combined Faro Mine Area Option 2:
Upgrade Faro Creek Diversion / Cover Faro Waste Rock

Closure Approach

What is involved?

- Build new diversion channel for Faro Creek
- Remove North Fork Rock Drain
- Build lined channel for North Fork Rose Creek
- Waste Rock
  - Reslope and cover with soil
  - Possibly move some waste rock to Faro Pit
- Revegetate covered waste rock
- Move tailings from Emergency Tailings Area to Faro Pit or Tailings Area.
- Collect and treat contaminated water from below waste rock, Zone 2 Pit and in Faro Pit (100s of years)
- Maintain covers and channels (100s of years)
- Monitor environmental conditions and adapt to changes

Estimated cost to build and maintain: $150M

Estimated employment: 230 person years

Each option is designed to meet technical and environmental standards.

An overall closure plan will be created by choosing one option for the Faro Mine Area and one for the Vangorda/Grum Area.

Before remediation (Now)

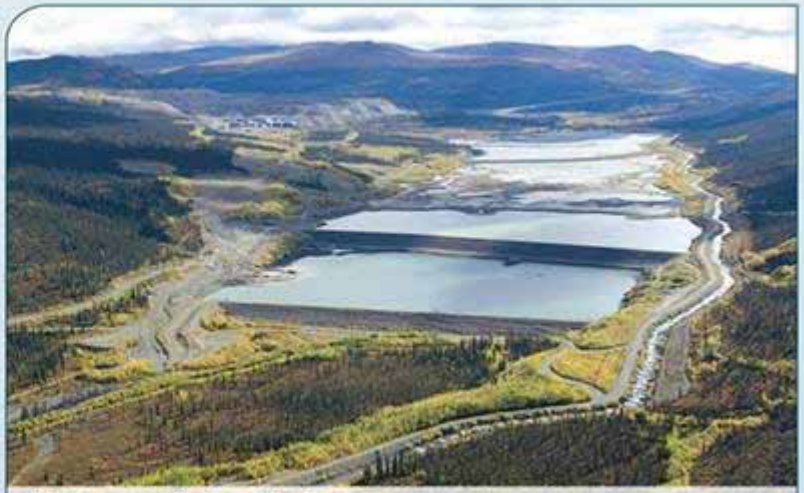
* Image for illustration purposes only.

After remediation (approximately 40 years time)

Combined Faro Mine Area Option 2:
Cover tailings with soil

Cover Tailings with Soil

What is involved?



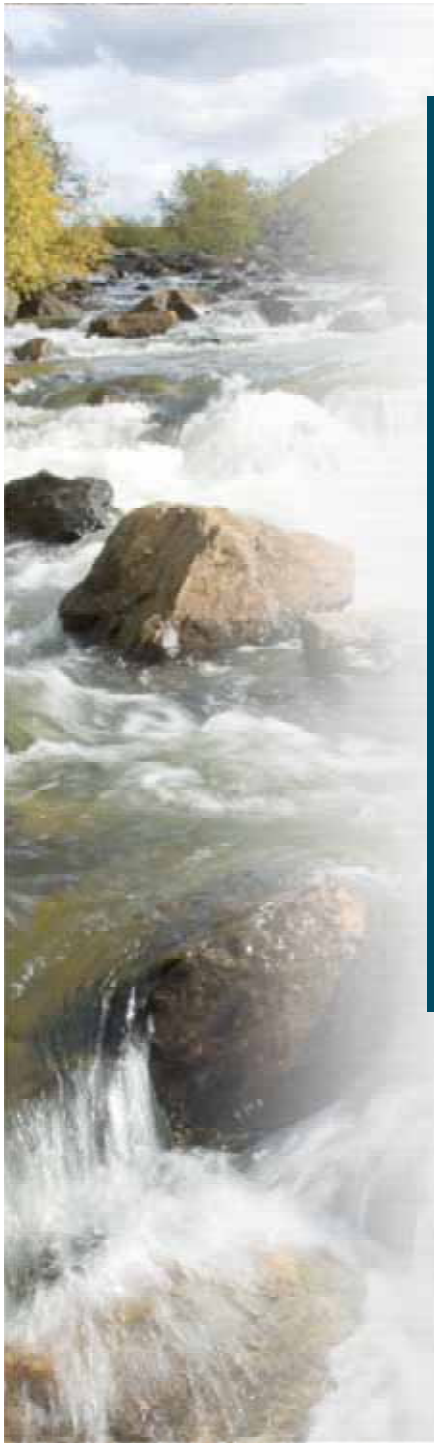
- Remove Cross-Valley Dam or change/upgrade it for emergency water storage
- Stabilize Second Dam
- Regrade tailings and cover with waste rock and soil
- Revegetate covered tailings and other areas
- Build/upgrade diversions, channels and spillways to deal with floods
- Collect and treat contaminated water from valley (100s of years)
- Maintain covers, channels and dams (100s of years)
- Monitor environmental conditions and adapt to changes

Estimated cost to build and maintain: $260M

Estimated employment: 336 person years

Each option is designed to meet technical and environmental standards.

An overall closure plan will be created by choosing one option for the Faro Mine Area and one for the Vangorda/Grum Area.



Before remediation (Now)

* Image for illustration purposes only

After remediation (approximately 40 years time)

Combined Faro Mine Area Option 3

Upgrade Faro Creek diversion
Reslope, cover and revegetate Faro waste rock
Move some tailings and cover some tailings with soil

Estimated Jobs: 782 person years

Estimated Cost: $490 M

Combined Faro Mine Area Option 3:
Upgrade Faro Creek Diversion / Cover Faro Waste Rock

Closure Approach

What is involved?

- Build new diversion channel for Faro Creek
- Remove North Fork Rock Drain
- Build lined channel for North Fork Rose Creek
- Waste Rock
  - Reslope and cover with soil
  - Possibly move some waste rock to Faro Pit
- Revegetate covered waste rock
- Move tailings from Emergency Tailings Area to Faro Pit or Tailings Area.
- Collect and treat contaminated water from below waste rock, Zone 2 Pit and in Faro Pit (100s of years)
- Maintain covers and channels (100s of years)
- Monitor environmental conditions and adapt to changes

Estimated cost to build and maintain: $150M

Estimated employment: 230 person years

Each option is designed to meet technical and environmental standards.

An overall closure plan will be created by choosing one option for the Faro Mine Area and one for the Vangorda/Grum Area.

Before remediation (Now)

Image for illustration purposes only.

After remediation (approximately 40 years time)

Combined Faro Mine Area Option 3:
Move some tailings and cover some tailings with soil

Move Some Tailings and Cover Some Tailings

What is involved?

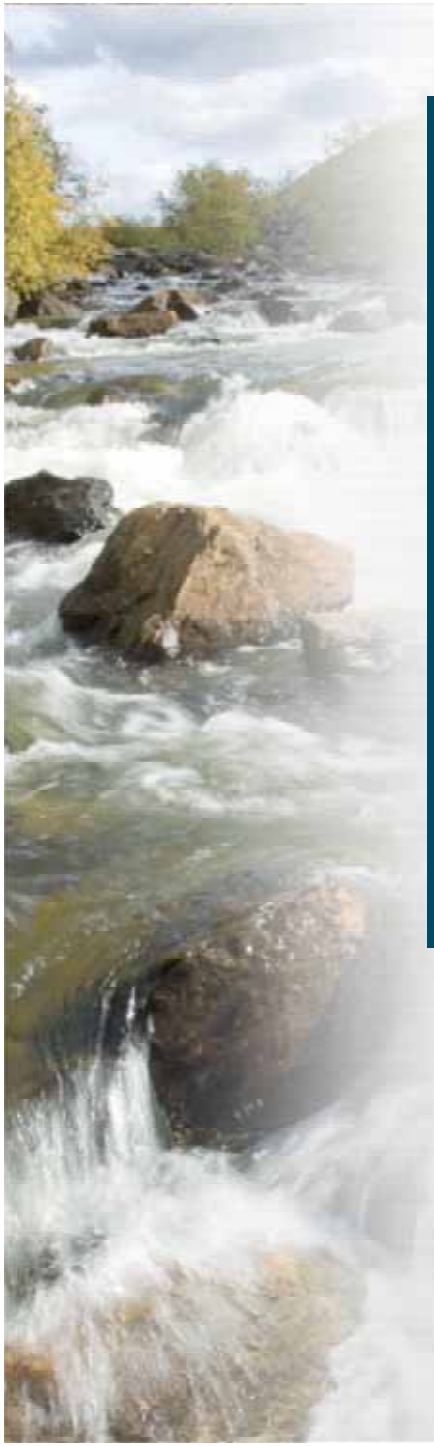
- Remove Cross-Valley Dam or change/upgrade it for emergency water storage
- Stabilize Second Dam
- Mix Intermediate Tailings with lime/water and pump to Faro Pit
- Clean up remaining Intermediate Tailings with trucks and loaders
- Regrade Original and Second Tailings and cover with waste rock and soil
- Revegetate covered tailings and valley area
- Upgrade diversion channel for upper part of Rose Creek
- Construct channel for lower part of Rose Creek and return the creek to the valley when soil and water are clean
- Collect and treat contaminated water (100s of years)
- Maintain covers, channels and dams (100s of years)
- Monitor environmental conditions and adapt to changes

Estimated cost to build and maintain: $340M

Estimated employment: 552 person years

Each option is designed to meet technical and environmental standards.

An overall closure plan will be created by choosing one option for the Faro Mine Area and one for the Vangorda/Grum Area.



Before remediation (Now)

* Image for illustration purposes only.

After remediation (approximately 40 years time)

Vangorda/Grum Area Option 1

Reslope, cover and revegetate Grum waste rock

Move Vangorda Waste Rock into Vangorda Pit

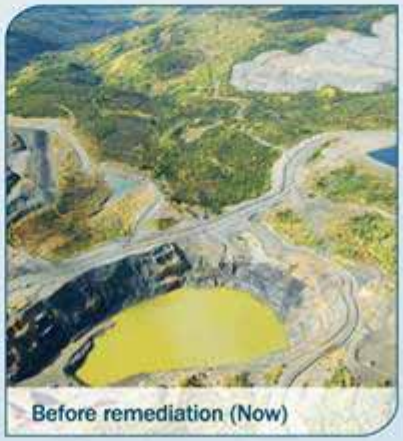
Estimated Jobs: 225 person years

Estimated Cost: $110 M

Vangorda/Grum Area Option 1

Move Vangorda Waste Rock into Vangorda Pit

What is involved?



- Mix Vangorda Waste rock with lime and place in Vangorda Pit
- Reslope Grum Waste Rock
- Cover Grum Waste Rock and relocated Vangorda Waste Rock with soil
- Revegetate covered waste rock and other areas
- Build new channel for Vangorda Creek – over filled pit
- Collect and treat contaminated water from Grum Waste Rock and Grum Pit (100s of years)
- Possibly collect and treat contaminated water from Vangorda Pit
- Maintain covers and channels (100s of years)
- Monitor environmental conditions and adapt to changes

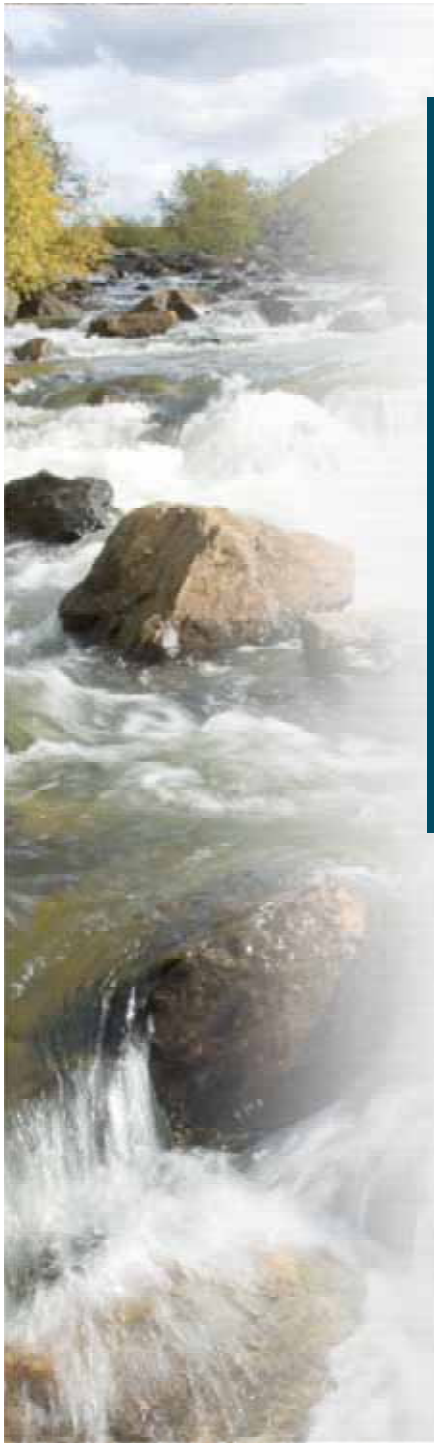
Estimated cost to build and maintain: $110M

Estimated employment: 225 person years

Each option is designed to meet technical and environmental standards.

An overall closure plan will be created by choosing one option for the Faro Mine Area and one for the Vangorda/Grum Area.

Before remediation (Now)



* Image for illustration purposes only.

After remediation (approx. 40 years)

Before remediation (Now)

* Image for illustration purposes only.

After remediation (approximately 40 years time)

Vangorda/Grum Area Option 2

Reslope, cover and revegetate Grum waste rock

Cover Vangorda waste rock in place

Estimated Jobs: 80 person years

Estimated Cost: $80 M

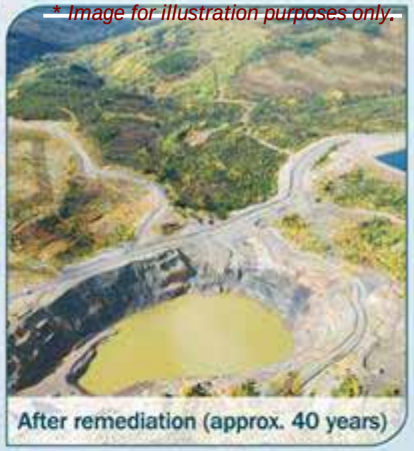
Vangorda/Grum Area Option 2

Cover Vangorda Waste Rock In-Place

What is involved?

- Reslope Vangorda and Grum Waste Rock and cover with soil
- Revegetate covered waste rock and other areas
- Build new diversion channel for Vangorda Creek
- Collect and treat contaminated water from Grum and Vangorda Waste Rock and Grum and Vangorda Pits (100s of years)
- Maintain channels and covers (100s of years)
- Monitor environmental conditions and adapt to changes

Estimated cost to build and maintain: $80M



Estimated employment: 80 person years

Each option is designed to meet technical and environmental standards.

An overall closure plan will be created by choosing one option for the Faro Mine Area and one for the Vangorda/Grum Area.

Before remediation (Now)

After remediation (approx. 40 years)

** Image for illustration purposes only.*

Before remediation (Now)

After remediation (approximately 40 years time)

** Image for illustration purposes only.*

So how do we get
from
5 options
to
a closure plan?

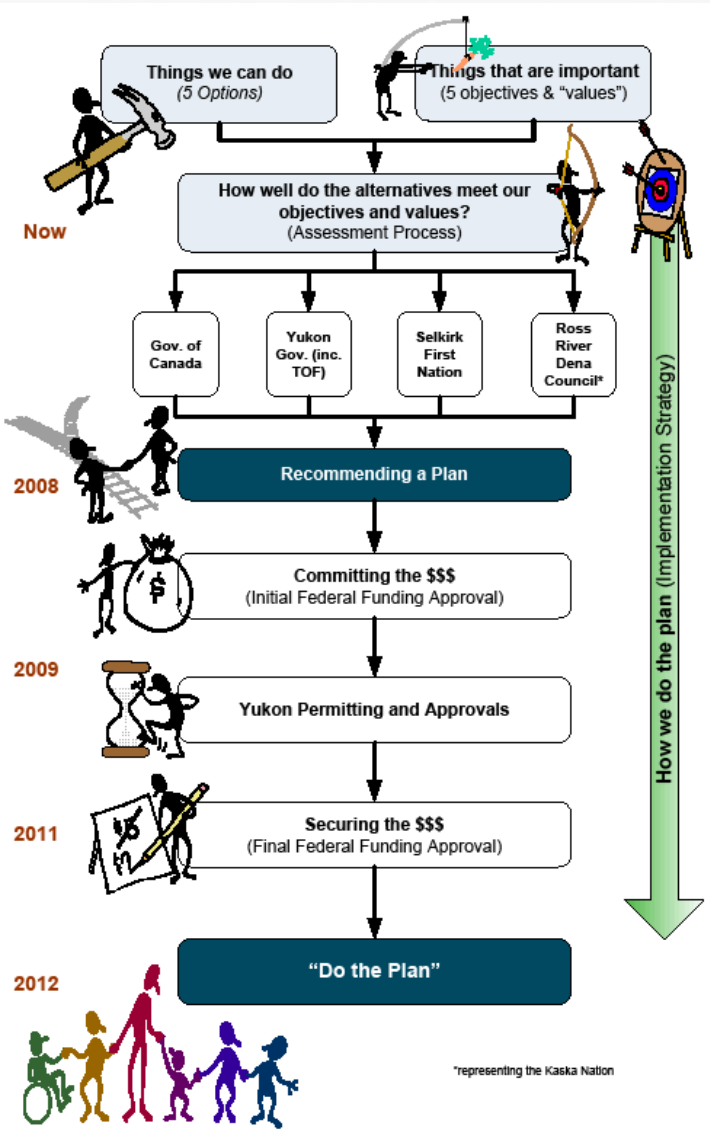
Closure Objectives

There are 5 things, or ***objectives***, we want a closure plan to achieve:

1. Protect human health & safety
2. Protect, and to the extent practicable, restore the environment including land, air, water, fish and wildlife
3. Return the mine site to an acceptable state of use that reflects pre-mining land use where practicable
4. Maximize local and Yukon socio-economic benefits
5. Manage long-term site risk in a cost effective manner

Final Closure Plan Options

A **final closure and remediation plan** will be created from:



ONE option for the Faro Mine Area

+

ONE option for the Vangorda/Grum Area

and will be designed to meet all of the stated closure objectives.

Next Steps: Roadmap to Remediation

- The communities and governments are now conducting their own assessment processes.
- Information from these processes will be used by the project Oversight Committee to arrive at a **final closure and remediation plan** to recommend to the federal government for initial funding approval.

Community Meeting with KDC & RRDC - Presentation and Maps, May 26, 2010

Faro Mine Closure
Fermeture de la mine Faro

Faro Project Management Team Update

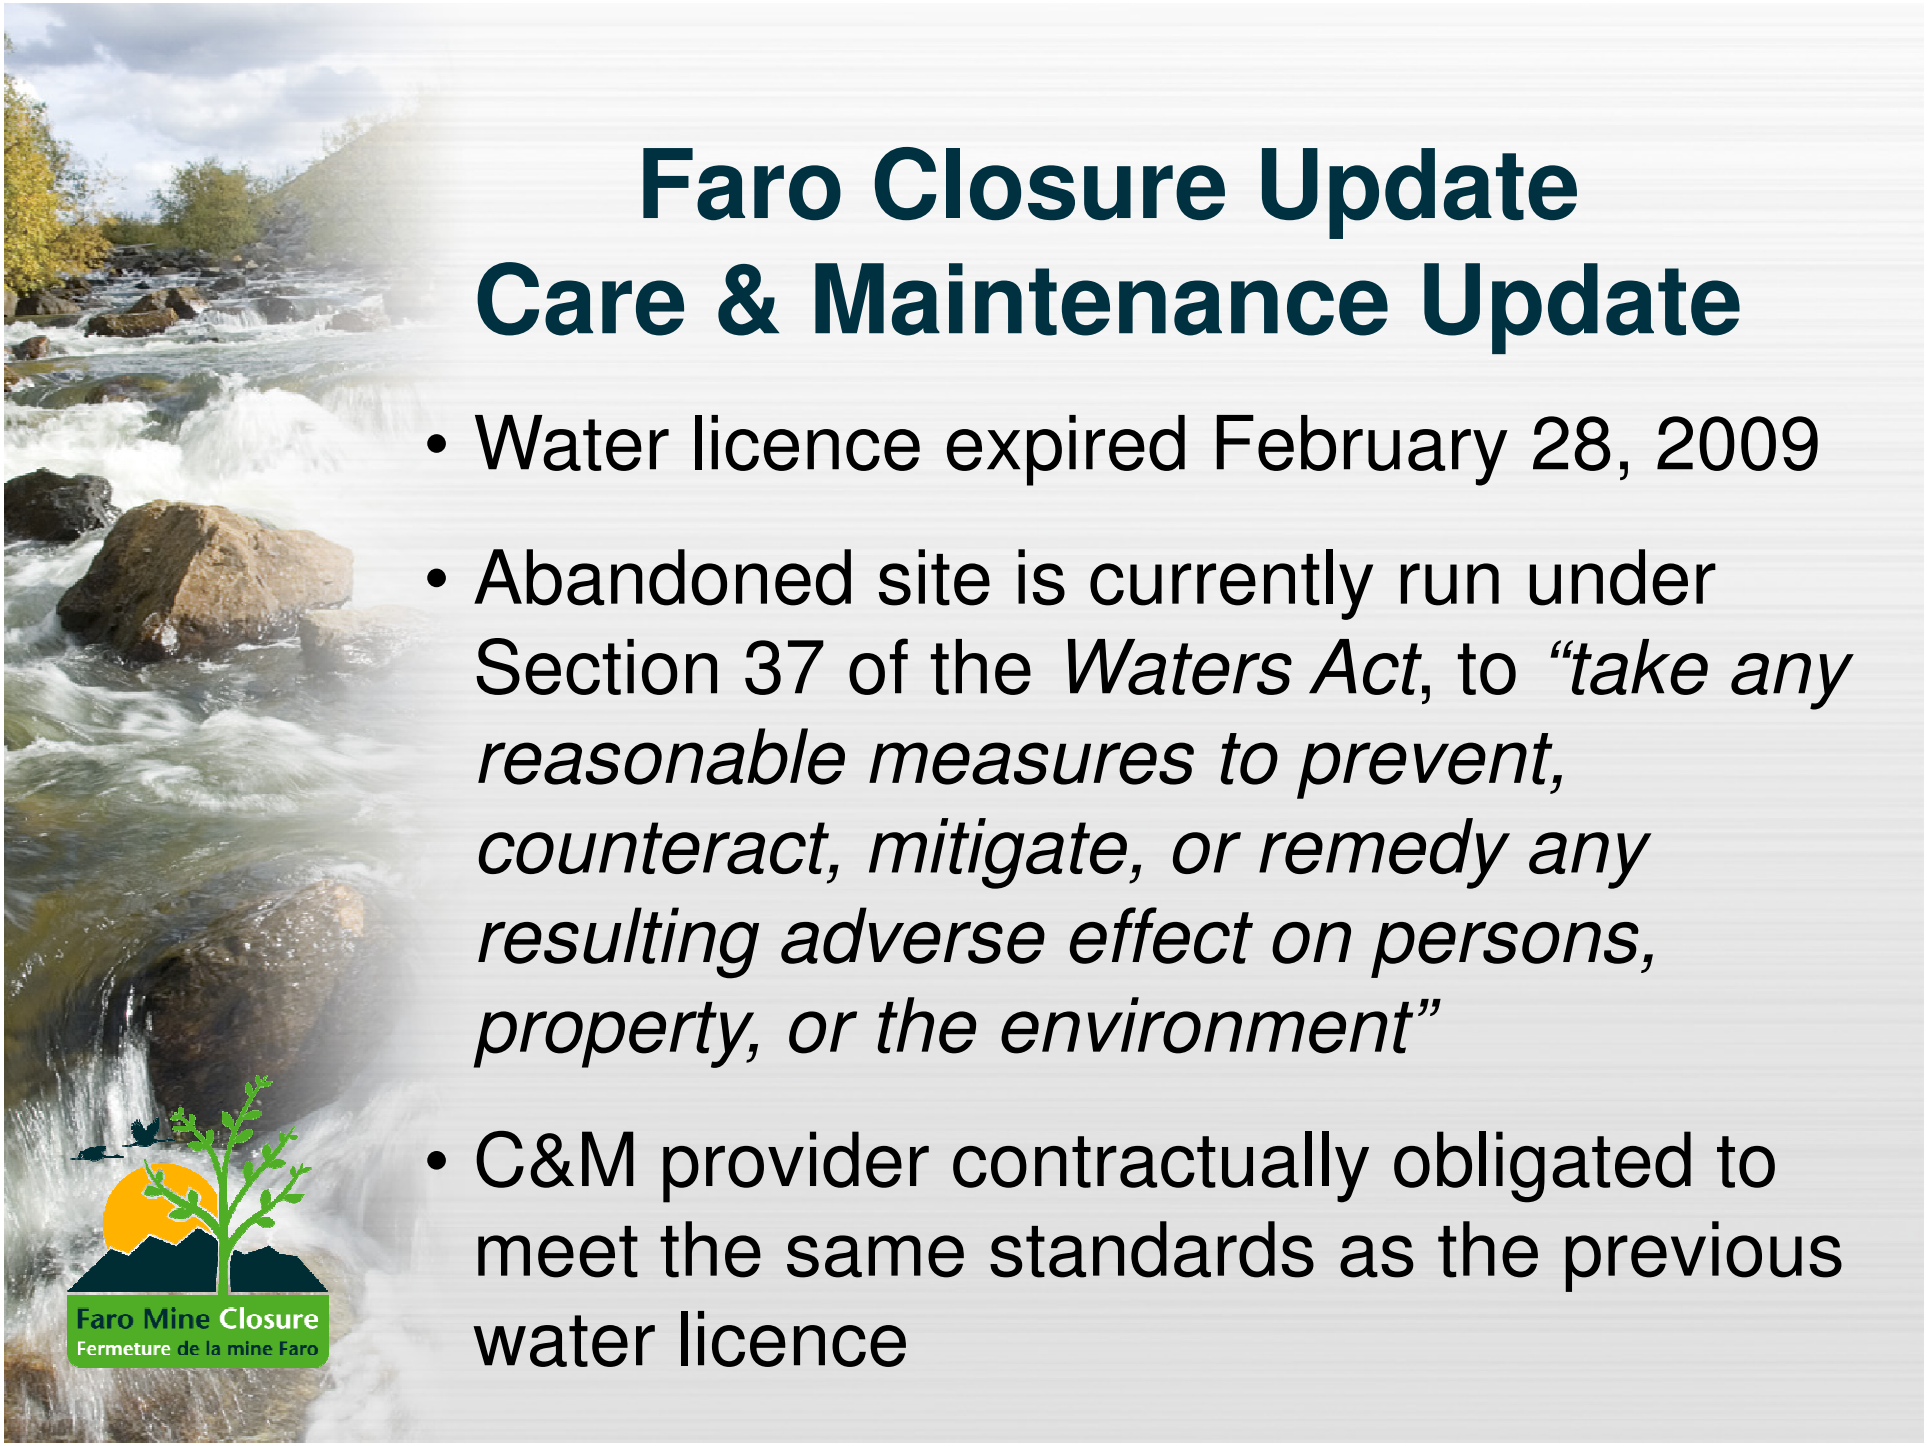
Kaska Nation Community Meeting
Information Update - May 2010

Faro Closure Update

- Care & Maintenance Update
- First Nation Participation Update
- Assessment and Regulatory Update

Faro Closure – Context Review

- Closure Plan (from consultation & selection of closure plan to YESAA & implementation)
- Transition from Deloitte & Touche to Yukon government
- Currently on site: care & maintenance



Faro Closure – Closure Planning

- Currently completing the project proposal
- Assessment Process Working Group involved in meetings to provide community input and feedback
- Governments in discussions regarding roles and responsibilities
- Submit project description to YESAA and regulatory processes

Faro Closure Update
Care & Maintenance Update

- Deloitte & Touche discharged from their duties as Interim Receiver as of February 28, 2009
- Denison Environmental Services was the successful bidder
- Contract signed with new care & maintenance contractor as of July 23, 2008

Faro Closure Update
Care & Maintenance Update

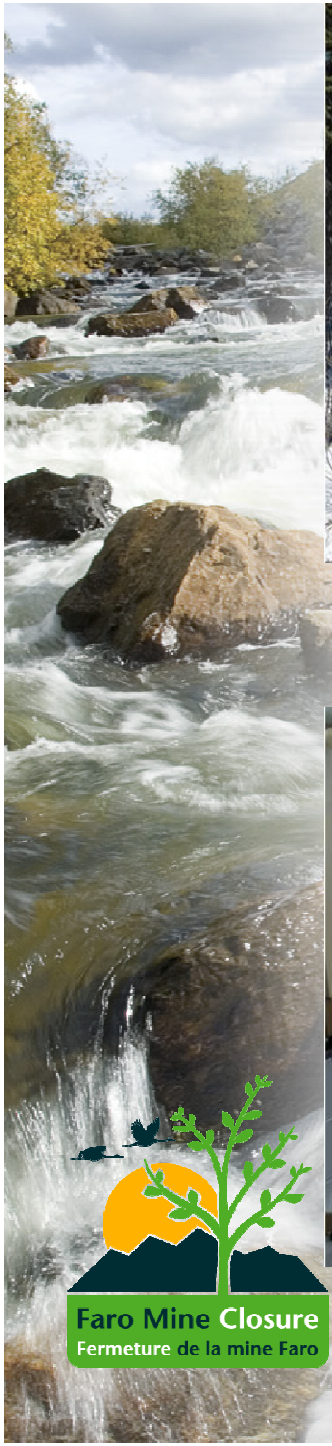
- Water licence expired February 28, 2009
- Abandoned site is currently run under Section 37 of the *Waters Act*, to *"take any reasonable measures to prevent, counteract, mitigate, or remedy any resulting adverse effect on persons, property, or the environment"*
- C&M provider contractually obligated to meet the same standards as the previous water licence

Faro Closure Update
Care & Maintenance Update

What's Care and Maintenance?

- Collection & treatment of contaminated water
- Maintenance of dams & diversions
- Protection of environment & human health & safety
- Early reclamation

Faro Closure Update
Care & Maintenance Update



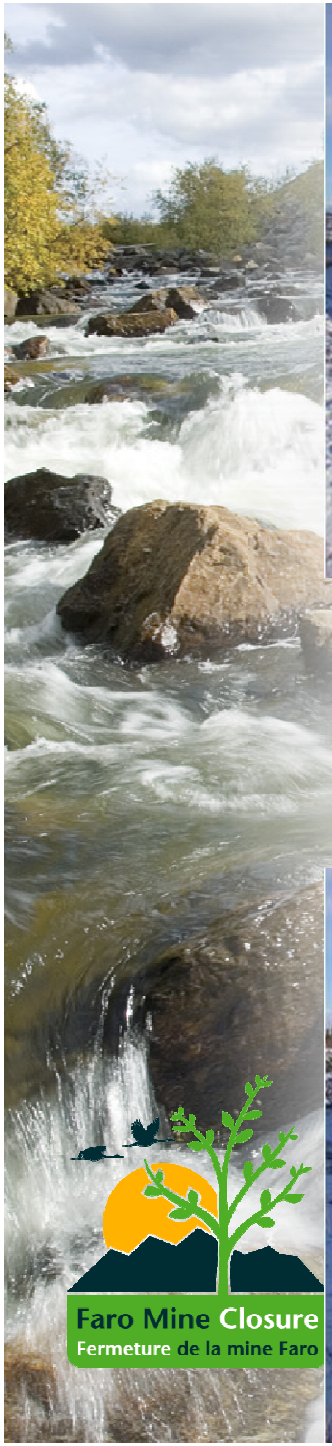
What does C&M look like at the site now?

- Water Treatment

Faro Mine Closure
Fermeture de la mine Faro

- Snow Survey

- Grum Climate Station



- Sample Analysis In New Lab

- CVP Sample Collection

Faro Mine Closure
Fermeture de la mine Faro

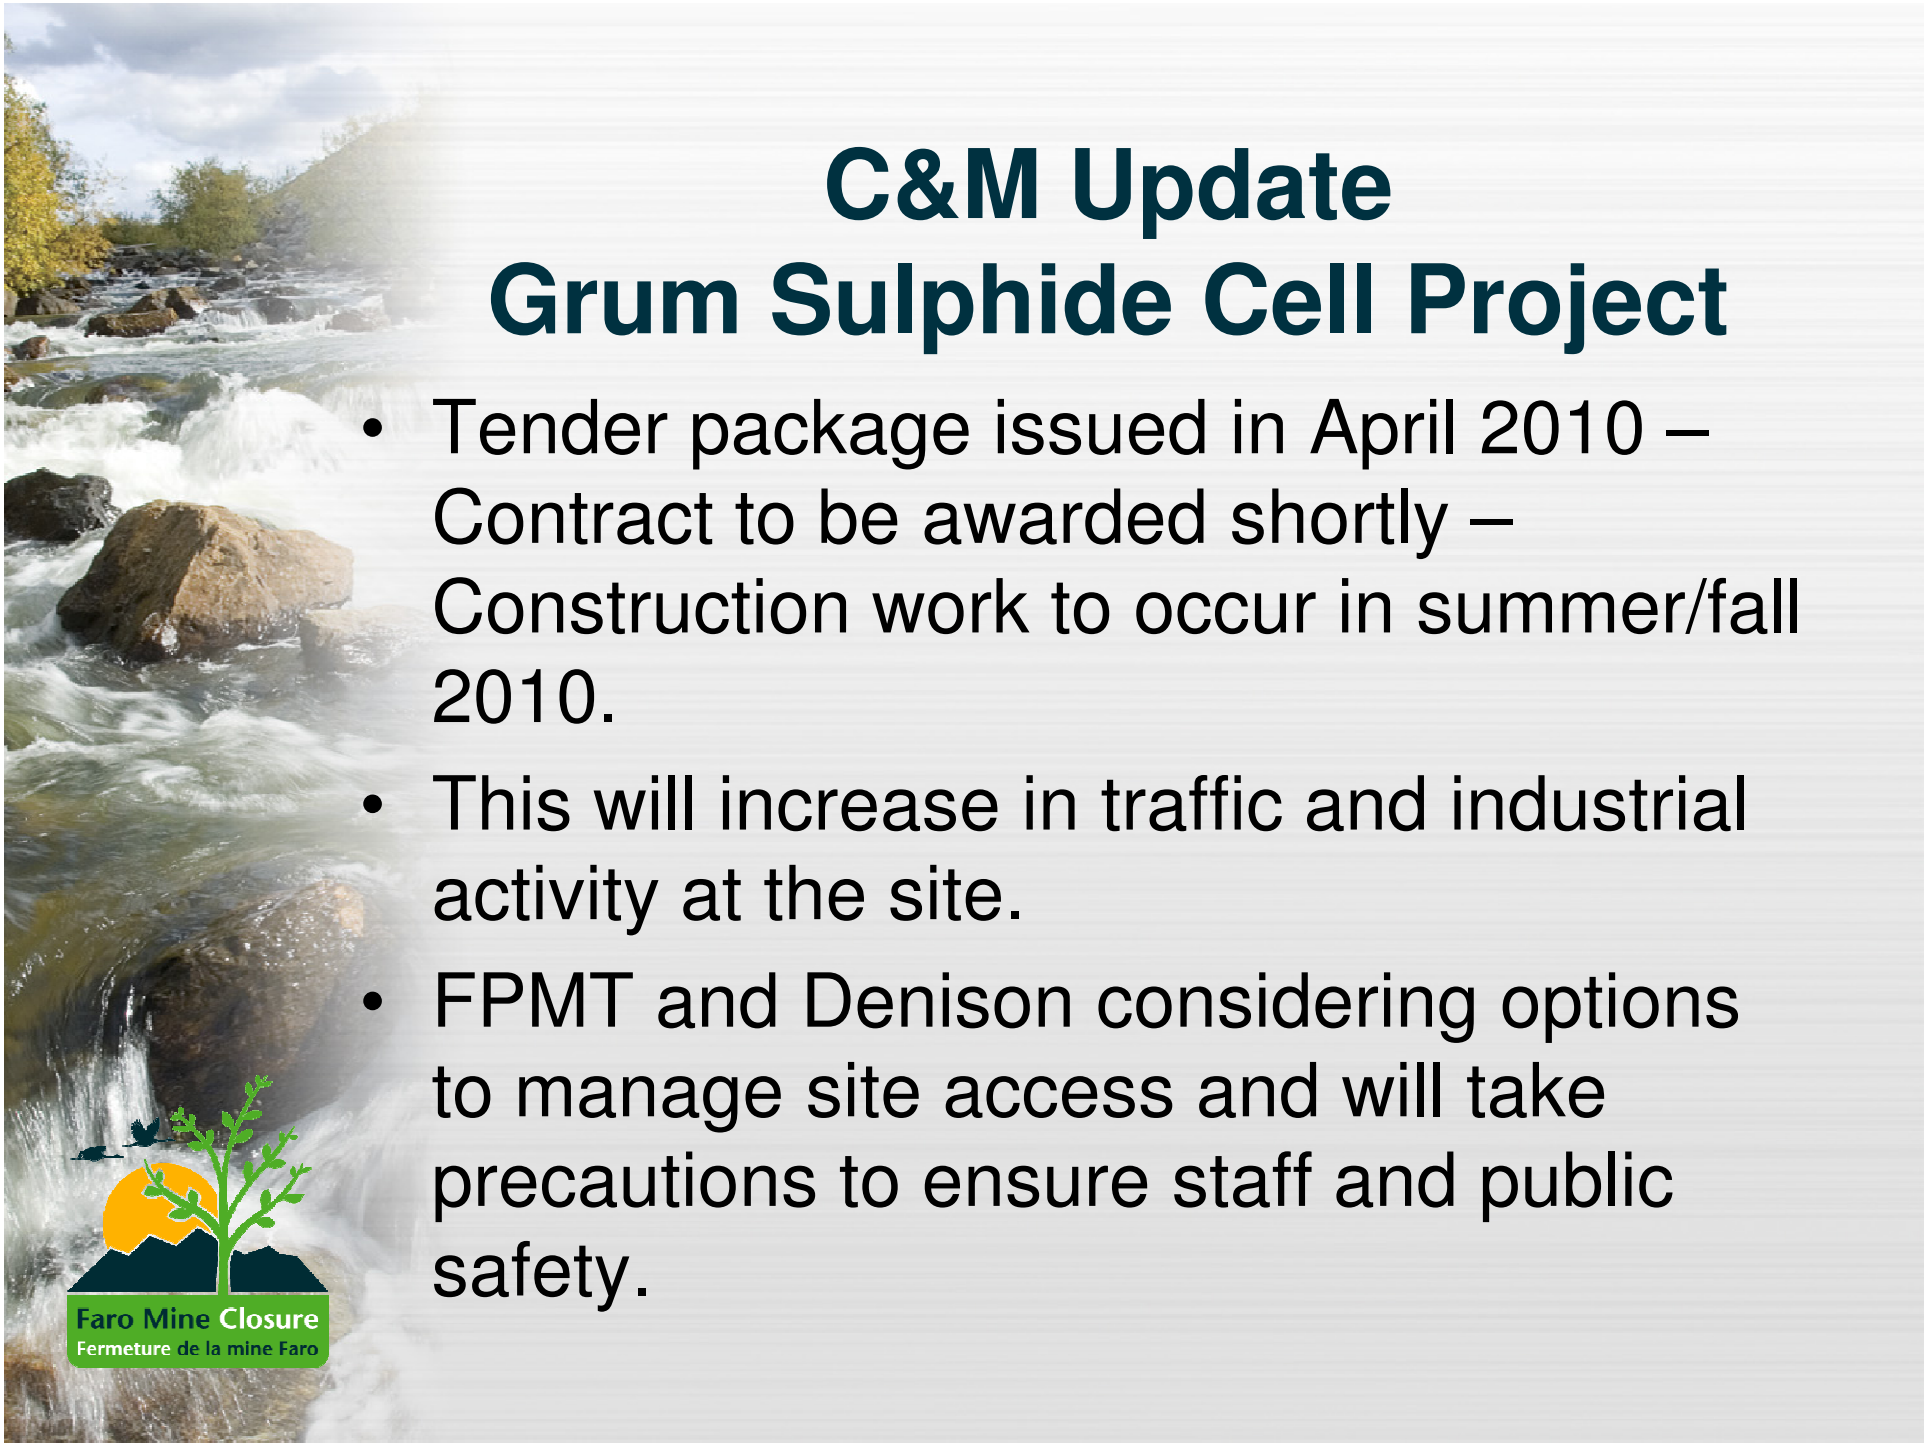
- Removing Sludge from Grum Clarification Pond

Faro Mine Closure
Fermeture de la mine Faro

Faro Closure Update
Care & Maintenance Update

- Early Remediation Projects

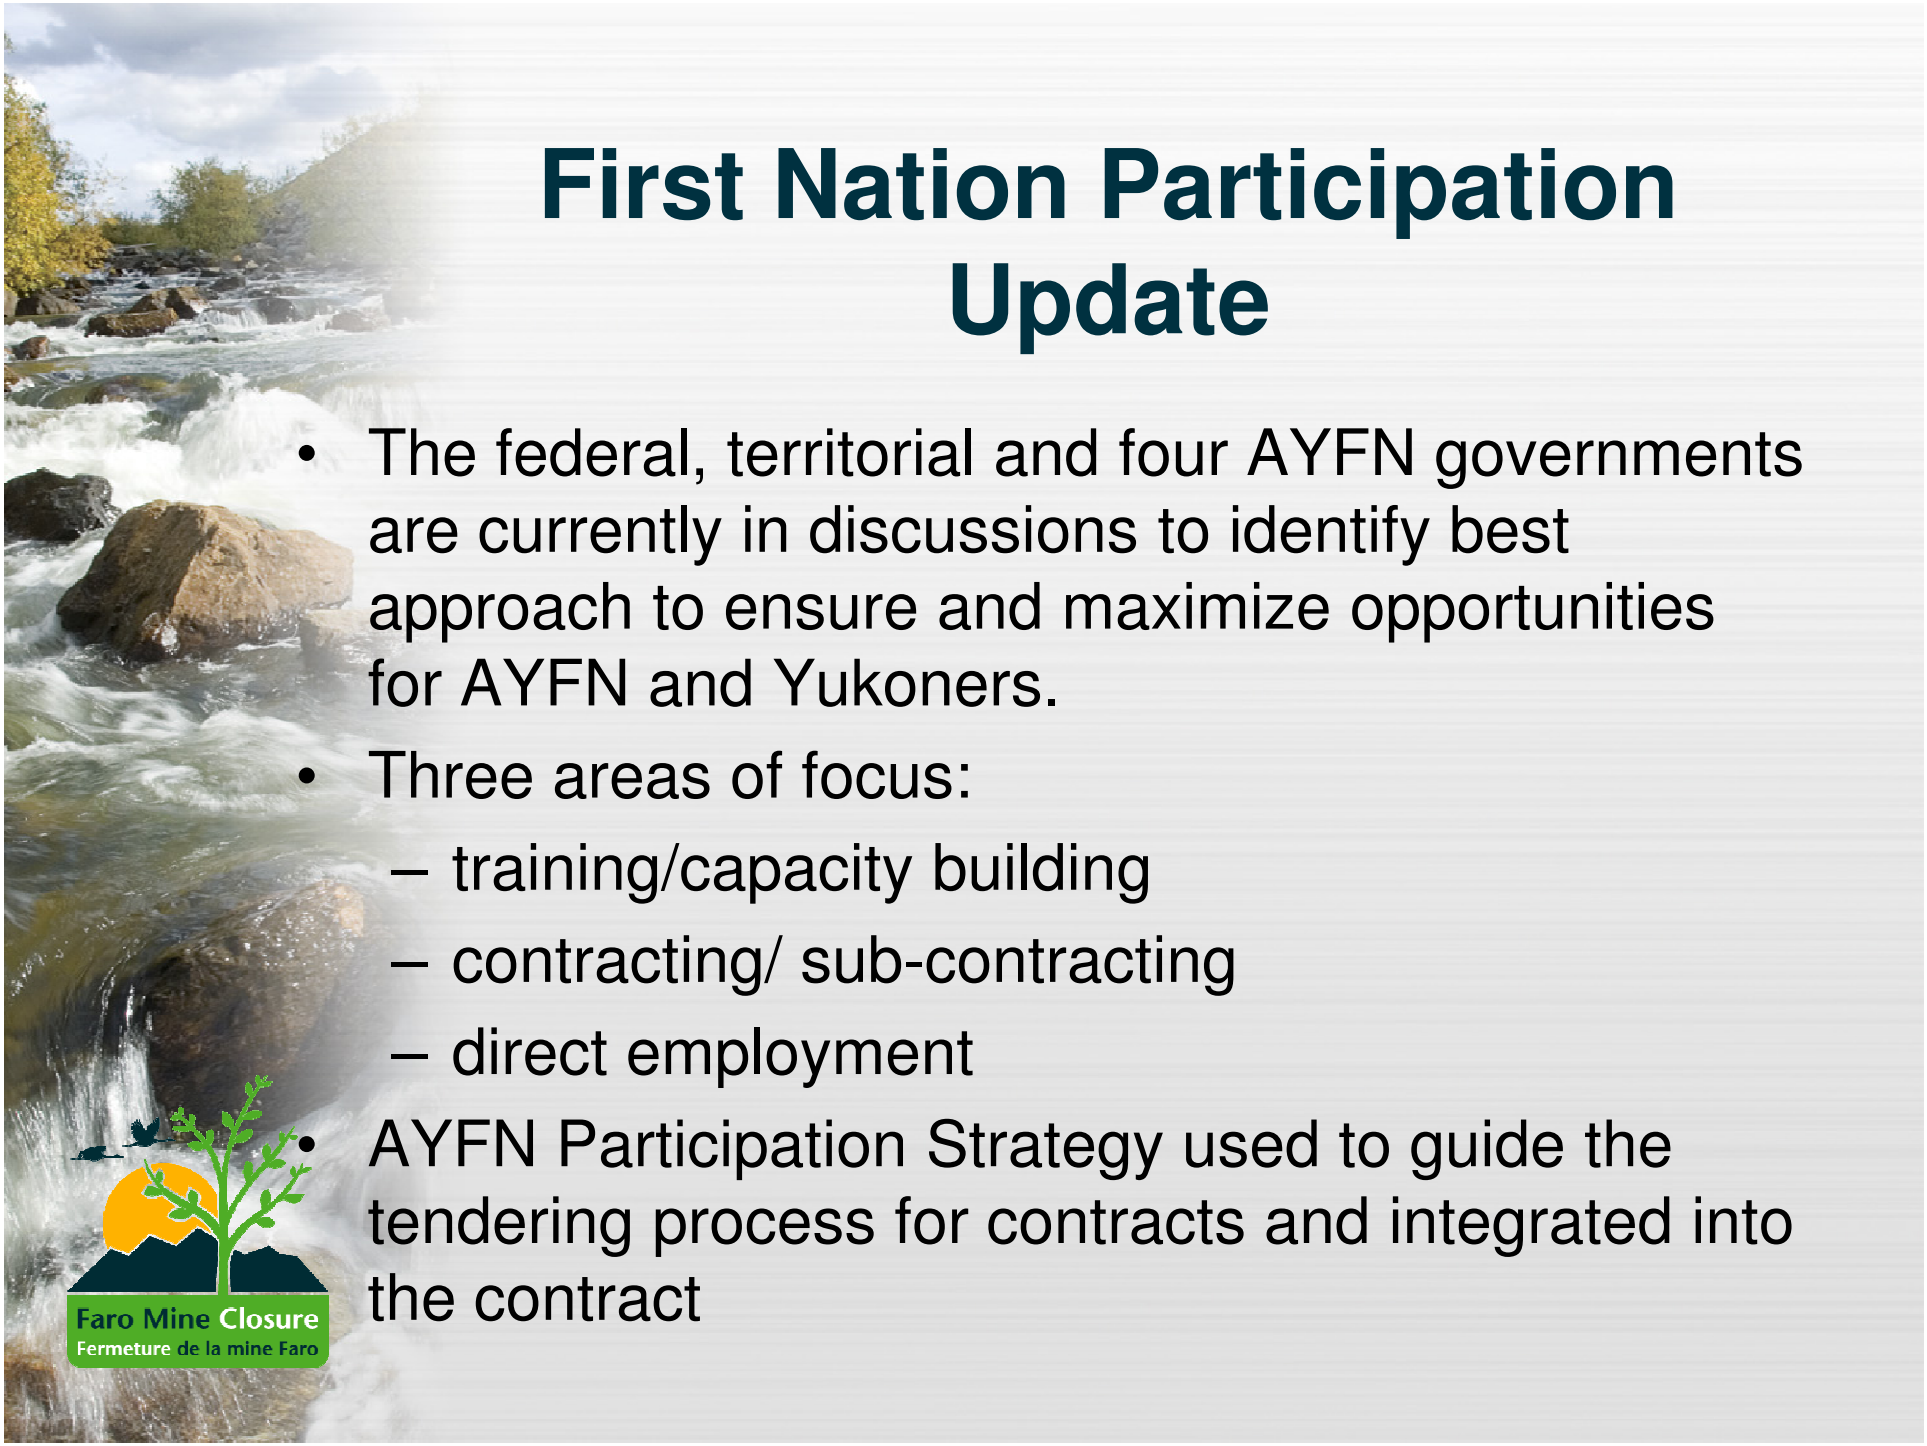
  –Grum Sulphide Cell



Faro Mine Closure
Fermeture de la mine Faro

C&M Update
Grum Sulphide Cell Project

- Early remediation project at Grum area of site.
- Some waste rock highly sulphidic and contributes to contamination.
- Project is to re-slope waste rock and install a cover to control contaminated seepage and then revegetate area.



Faro Mine Closure
Fermeture de la mine Faro

C&M Update
Grum Sulphide Cell Project

- Tender package issued in April 2010 – Contract to be awarded shortly – Construction work to occur in summer/fall 2010.
- This will increase in traffic and industrial activity at the site.
- FPMT and Denison considering options to manage site access and will take precautions to ensure staff and public safety.

Faro Mine Closure
Fermeture de la mine Faro

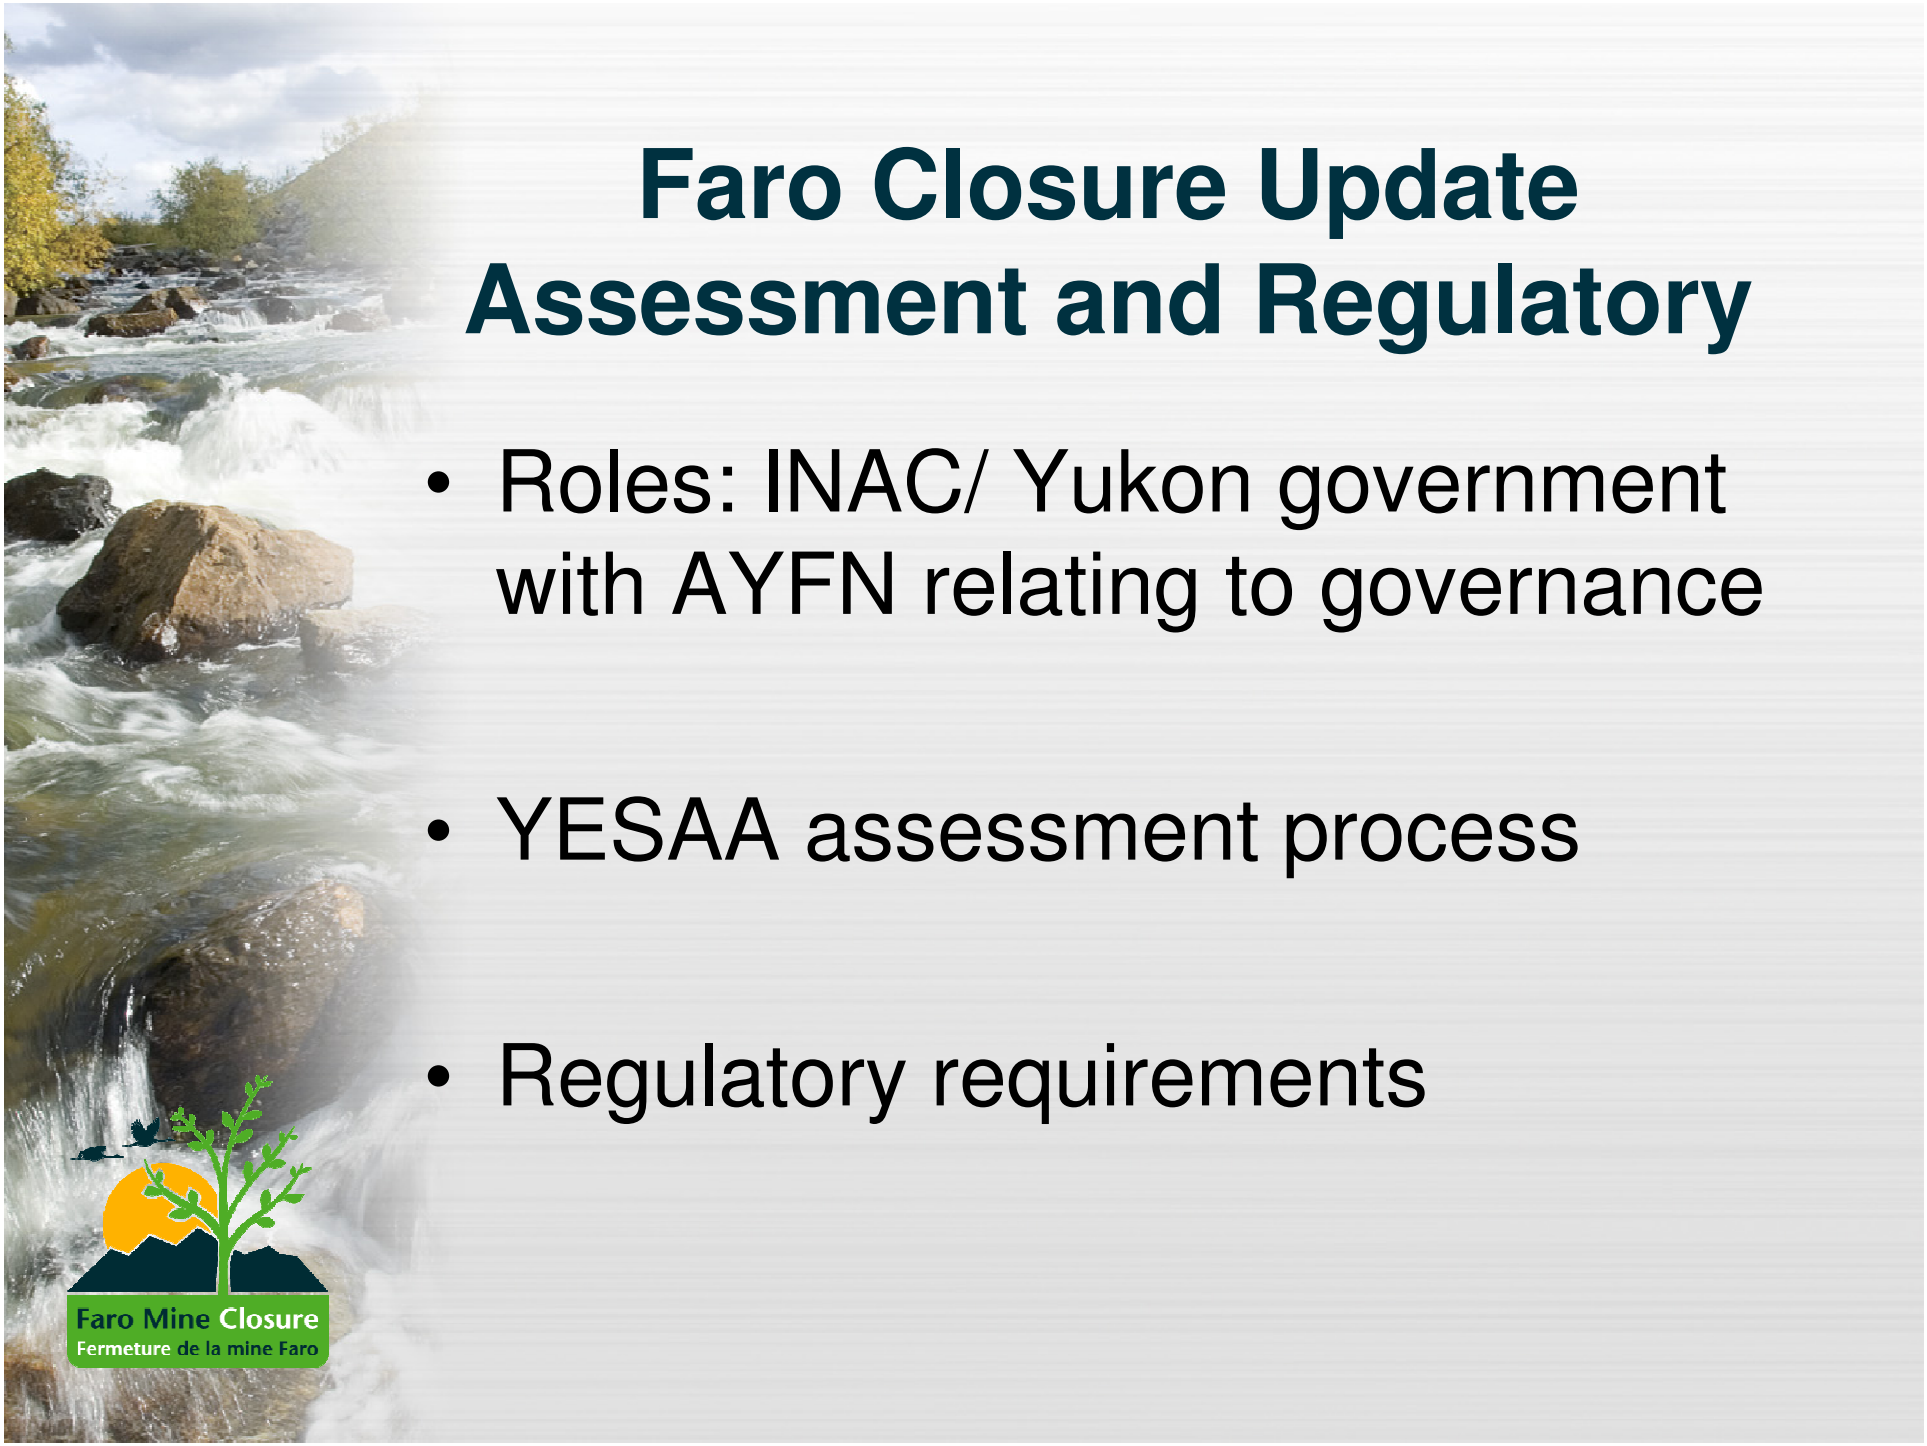
First Nation Participation Update

- The federal, territorial and four AYFN governments are currently in discussions to identify best approach to ensure and maximize opportunities for AYFN and Yukoners.
- Three areas of focus:
  - training/capacity building
  - contracting/ sub-contracting
  - direct employment
- AYFN Participation Strategy used to guide the tendering process for contracts and integrated into the contract

Faro Mine Closure
Fermeture de la mine Faro

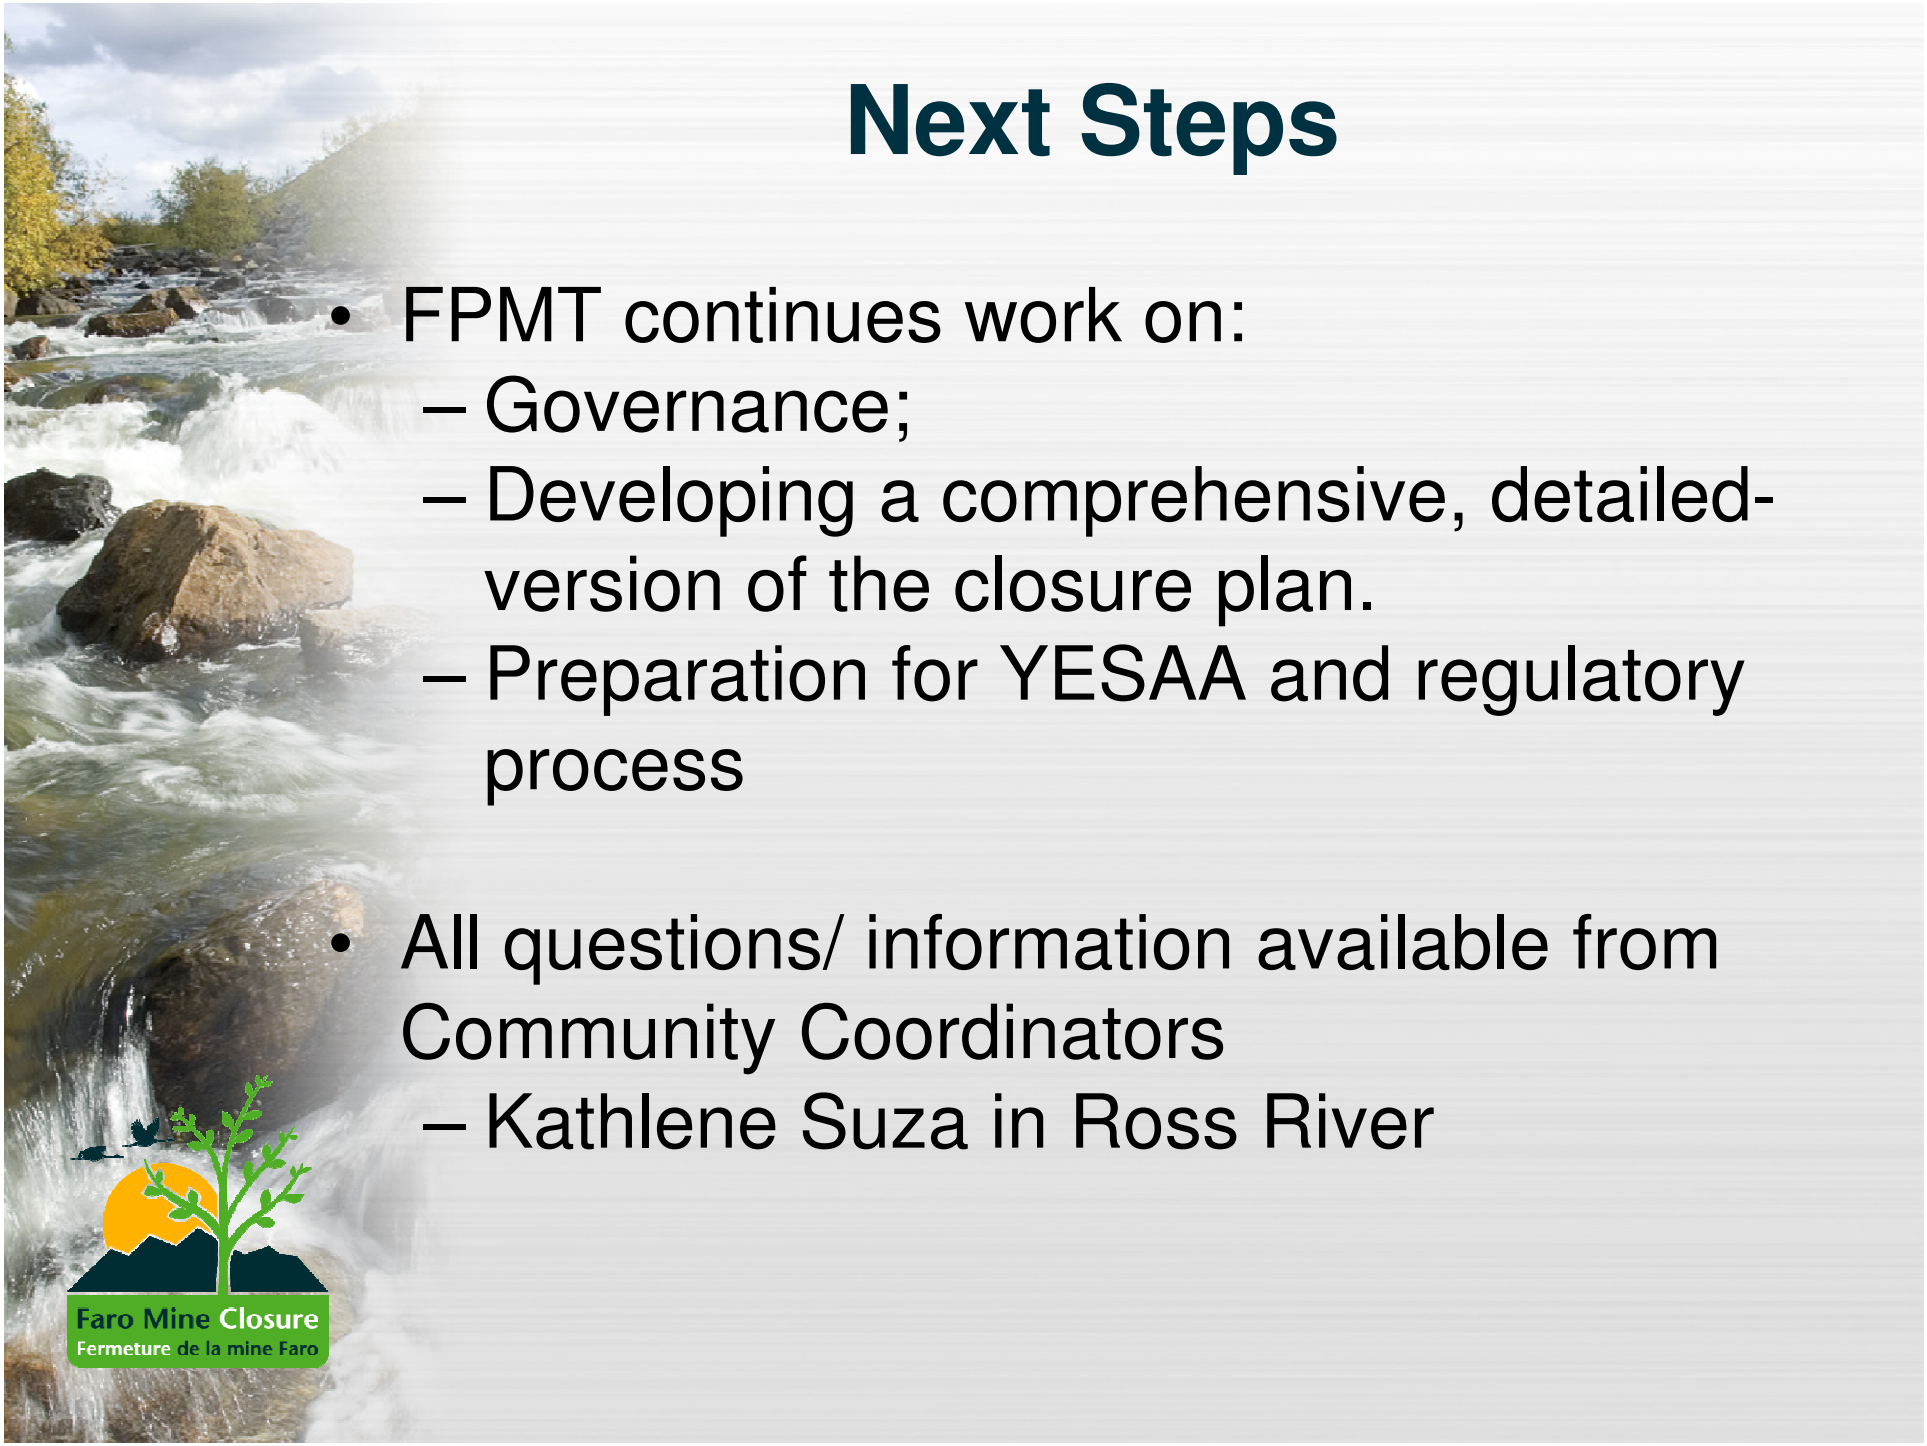
First Nation Participation C&M Update

- Faro Project Management Team, AYFN & Denison developed AYFN participation plan within the C&M contract.
- Employment and Training opportunities are being communicated through community coordinators.
- Currently meeting with community coordinators to plan for this coming year.



Faro Mine Closure
Fermeture de la mine Faro

First Nation Participation Early Remediation Update



- Continued implementation of the AYFN Participation Strategy for early remediation project contracts such as Grum Sulphide Cell.
- Guides how contractors develop AYFN participation plans within their contracts to provide opportunities to AYFN communities.
- Employment and Training opportunities are being communicated through community coordinators.

Faro Mine Closure
Fermeture de la mine Faro

Faro Closure Update Assessment and Regulatory

- Roles: INAC/ Yukon government with AYFN relating to governance
- YESAA assessment process
- Regulatory requirements

Next Steps

- FPMT continues work on:
  - Governance;
  - Developing a comprehensive, detailed-version of the closure plan.
  - Preparation for YESAA and regulatory process

- All questions/ information available from Community Coordinators
  - Kathlene Suza in Ross River

Construct West Valley Extension (102.2)

Regrade and Cover (106.1)

Consolidate with relocated LGO, Crusher SP, Oxide Fines(#1, 2, 3), and Medium Grade Ore Stockpile, Cover (Very low Infiltration, synthetic, or soil equivalent) and Revegetate (104.4)

Haul 681,000m³ of Waste to Tailings Pond for Trafficable Layer (202.1/2)

Faro Valley Dump

Construct Faro Creek Diversion (east valley) (102.1)

Regrade LGSP "A", Cover (Very low Infiltration, synthetic, or soil equivalent) and Revegetate (104.3)

Existing Faro Creek Diversion Channel to be decommissioned and revegetated

FARO PIT

Relocate Crusher SP, Oxide Fines(#1, 2, 3), LGO, and Medium Grade Ore to LGSP "C". Regrade and cover remaining area with rudimentary cover and revegetate (104.1/2).

Construct Safety Berm Around Faro Pit (101.2)

Regrade, Cover (Low Infiltration) and Revegetate (106.3/1/2/3)

LGO

Oxide Fines #3

Mt. Mungly (east)

Mt. Mungly (west)

Cover, Revegetate East Sulphide Cell Waste (106.2/1)

Regrade, Reslope, Cover and Revegetate Main and Intermediate Sulphide Cells (106.2/2)

Decontaminate and Demolish Buildings (108.2)

LGSP "A"

Oxide Fines #2

Southwest Pit Wall Dump

LGSP "C"

East Sulphide Cell

Crusher Stockpile

Medium Grade Ore Stockpile

Install Groundwater Wells, Piping, Heat Tracing for Zone II Pit Water Management (103.1)

Install Cutoff Wall to Capture Clean Flow of North Fork into Raised Channel (107.1B)

ETA Tailings

Oxide Fines #1 and Medium Grade Ore

Main Sulphide Cell

Zone II

Construct Sediment Basins and Run-off Control Ditches on Covers (106.4)

Relocate Contaminated Soil from Mill Site Area and Cover (Synthetic/Soil) (108.3/4)

Remove Tailings to Rose Creek Tailings Facility (105.1)

Intermediate Sulphide Cell

Construct Low Permeability Channel to Isolate North Fork from Groundwater (107.1)

Relocate Outwash Material to Intermediate Dump (107.2)

Install ETA Collection System. Pump to Faro Pit, if applicable (105.2)

Install Zone II outwash groundwater interception wells and trench. Pump to Faro Pit, if applicable (107.3).

Construct Sediment Basins and Run-off Control Ditches on Covers (106.4)

Regrade and Reslope Waste Rock Dumps (106.1B)

Place Cover on remaining Waste Rock and Revegetate (106.3/4/5)

Install S-wells Groundwater Collection System (107.5)

Haul Road - Remove Culverts, Scarify, Revegetate (108.1)

Develop and Decommission Faro Borrow Sources (108.5)

WTP

Sludge Pond

Construct Polishing Pond (205.2)

Construct New Water Treatment Plant and Sludge Pond (Final disposal in pit). Install Pipeline and Power Heat Supply Tracing System (101.1/3)

Legend

Construct Safety Berm Around Faro Pit (101.2)	Closure Activity (work item number, See Tables in Appendix B)
LGSP	Low Grade Ore Stock Pile
	Rudimentary Cover (vegetative soil cover) (1m of Loose Till)

C&M Community Meeting with LFN / Watson Lake - Poster and Presentation, November 29, 2011

Faro Mine Remediation Project

CARE AND MAINTENANCE COMMUNITY MEETING

EVERYONE IS WELCOME TO ATTEND A FARO MINE CARE AND MAINTENANCE MEETING

Date: Tuesday, November 29, 2011

Time: 1pm

Location: Watson Lake Community Center, Watson Lake

The presentation will cover activities that occurred during the fall season at the Faro Mine Complex.

This is an opportunity for you to discuss care & maintenance activities with representatives from Denison Environmental Services.

Refreshments will be provided.

Faro Mine Remediation Project
Projet d'assainissement de la mine Faro

Faro Mine Remediation Project

Activities Update

November 28, 2011

In 2011, the Faro Mine Remediation Project Team has been busy:

- Improving how we manage surface water runoff
- Collecting/updating information about how animals use the site
- Continuing planning for remediation (cleanup) of the site, including preparing for the YESAA process
- Securing a new contract for day-to-day site operations (new care & maintenance contract)
- Discussing how the 5 governments (Canada, Yukon, First Nations) will continue to work together now and in the future

How have we improved how we manage surface water runoff?

- Seeded the Grum Sulphide Cell with grass to reduce erosion of the soil (more planting next year)
- Constructed new ditches to divert runoff water safely to Vangorda Pit & away from the environment
- Built a large storage pond to safely store water
- Installed pump & pipeline to move excess water
- Lowered water levels in ponds/pits to give us more storage space for excess water in spring
- Planned for extra environmental monitoring

What information are we gathering about how animals use the site?

- YG Environment completed moose & sheep surveys throughout the territory this spring & summer & will share Faro-area results with the project team soon
- Bird & fish surveys were done this summer & fall on the Faro Mine Complex site to help us understand how they use the site & how the cleanup might affect them
- Similarly, a small mammal survey (looking at animals like hares, foxes, etc) will be done this winter

How are we planning for the remediation (cleanup) & the YESAA process ?

- Decided that Yukon and Canada will jointly lead the project through environmental & socioeconomic assessments (YESAA) & permits (Water Licence)
- Hired a Project Design Team – a company named CH2M HILL – to help with technical work
- Next steps: 1) finalize technical details of the overall plan, 2) identify how the cleanup project might effect the environment & people & 3) consult with communities as required by YESAA

Why are we writing a new contract for day-to-day site operations (C&M)?

- Contract was retendered this past summer because government must put out a new public tender for care & maintenance contract every 3 years or so
- This process is underway now – the present contract started in 2009 and ends in 2012, so YG needs to have a new contract in place soon
- Because one of our objectives is to ensure benefits for Affected Yukon First Nations & Yukoners, the new contract will have a Participation Plan for jobs, training & contracting opportunities (as it does now)

How will the 5 governments continue to work together?

- Chiefs continue to meet with government officials to discuss how their communities can benefit from & be involved in the project now and in the future – these discussions are ongoing
- Ideas now being worked on include a new land-based monitoring program to check on the health of the environment from the First Nations' viewpoint
- Do you have ideas about how you would like to see your community involved in the project? Please talk to your Chiefs & Community Coordinators

How will the 5 governments continue to work together now and in the future?

- New governance structure being developed for Faro Mine Remediation Project.
- FN Chiefs are meeting with government senior management and continue to discuss First Nation communities needs within the project.
- Working on identifying where First Nations can be involved in the project. Discussion ongoing.
- Ideas on how to be involved in project? Please talk to your Chiefs.

Introducing the First Nation Community Coordinators!

- The team meets weekly to work on improving opportunities for community residents & to help each other to keep you informed
- Have any questions on the project? Please see your community coordinators, they are here to help you!

Attachment 3A-4
C&M Community Meeting with SFN – Presentation, April 22, 2013

Faro Mine Remediation Project
Pelly Crossing Community Update

Kaori Torigai

April 22, 2013

Overview of Presentation

Project Update

- 2010 – 2012
  - Project Design Team
  - Completion of Grum Sulphide Cell Project
  - C&M Contractor
- Upcoming 2013 activities
  - Pelly Aquatics study planning
  - Infrastructure upgrades
  - Field Investigations

Activities in 2010

- AAM conducted a public tender process for a Project Design Team to complete a detailed design of the chosen remediation option.
- Grum Sulphide Cell Cover Project was publically tendered and largely completed by the fall.
  - Resloping
  - Placement of High Density Polythelene (HDPE) cover, similar to a type of plastic
  - Till/soil cover

Activities in 2010

GSC under construction in October 2010

GSC in summer 2011

Activities in 2011

- Awarded Project Design Team contract to CH2M Hill
  - International engineering firm with extensive experience in mine remediation
  - Develop detailed design for chosen closure option to submit to YESAA
- Grum Sulphide Cell completed
  - Final modifications and revegetation
- C&M contract publicly retendered as previous 3 year contract was coming to an end

Activities in 2012

- Project Design team conducted field studies
- Initial review of water treatment plant
- Development of a five year plan to guide project work
- Pelly River Aquatics study
  - Monitors water at approximately 20 locations as it leaves the site and makes its way to the Pelly River
  - Sampled the water in May, August and October
  - All samples in the receiving water environment downstream of the site met water quality standards.

C&M Activities for 2013

- Overall review of water treatment plant (WTP) for health and safety of employees
- Water treatment is on hold until review of WTP is complete
- Contaminated water from the Intermediate Pond will be pumped and stored in the Faro Pit
- Grum Pit water will be pumped to Vangorda Pit
- Implementing Vangorda sludge management system
- Tackifier used for tailings dust suppression

PDT Activities for 2013

- Field investigations for infrastructure projects
- Data collection for YESAA project proposal
- Advanced design for water treatment plant
- Preparation for required permitting for water treatment plant, hydraulic upgrades

Additional Activities for 2013

- AAM is working with Selkirk First Nations (SFN) Community Coordinator and SFN Technical Advisory Committee to involve SFN in the monitoring of the environment, including the Pelly River.

Faro Mine Remediation Project

Yukon Government

Canada

Attachment 3A-5
Meeting with YESAB – Agenda, October 7, 2011

Agenda

Faro Mine Closure/YESAB Meeting
October 7, 2011 9:00 – 10:00 a.m.

YESAB Office - Whitehorse

Meeting Purpose: Team and Project Introductory Meeting

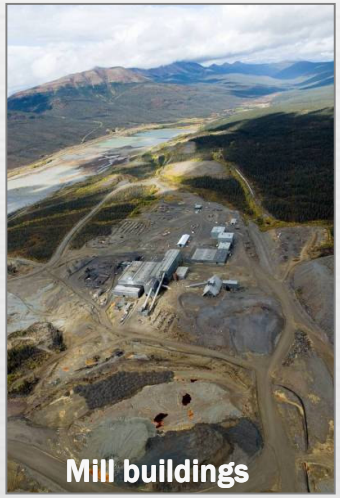
1. **Welcome and introductions**
2. **Faro Mine Closure Detailed Design Team introduction**
3. **Overview of proposed approach to development of Project Proposal**
4. **Project schedule**
5. **Next steps and short-term scheduling**

Attachment 3A-6
Meeting with YESAB - Agenda and Presentation, November 16, 2011

Agenda

Faro Mine Remediation Project/YESAB Meeting
November 16, 2011 10:30-12:00
Royal Bank Centre – 2nd Floor

Meeting Purpose: Project overview and discussion of consultation requirements



1. **Welcome and Introductions**
2. **Overview of Closure Options**
3. **Overview of Options Evaluation Process**
4. **Overview of Selected Closure Option**
5. **Consultation Requirements**
6. **Next Steps and Upcoming Meetings**

Faro Mine Project
Overview – *Alternatives, Evaluation and Selected Option*

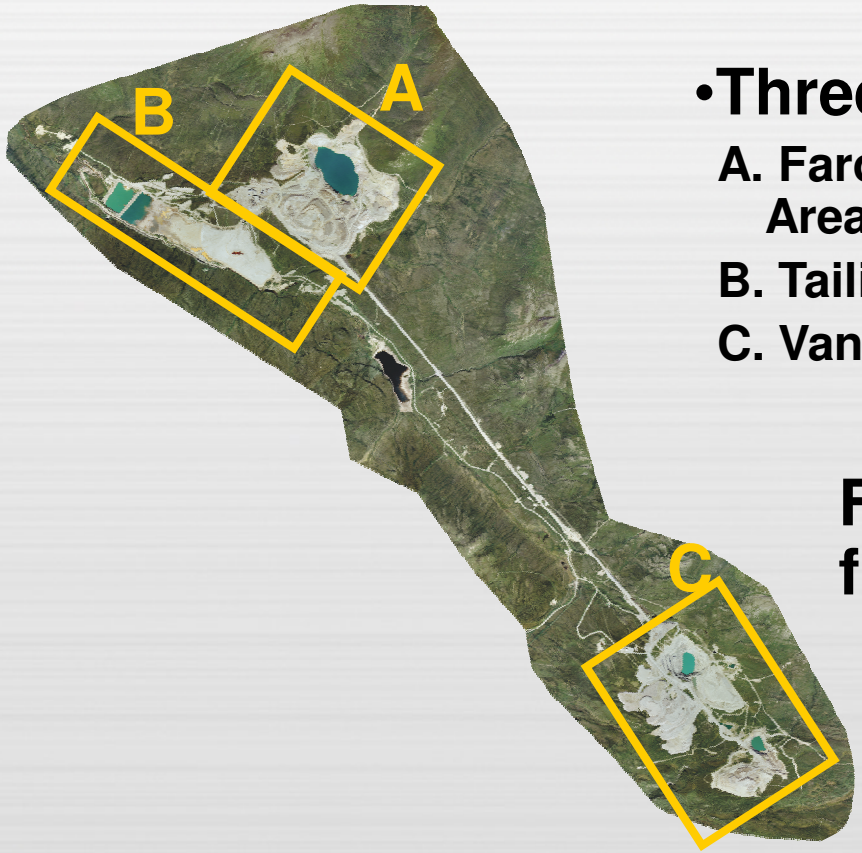
YESAB, November 16, 2011

Faro Mine Closure
Arriving at a Closure Plan

January 2008

Establishing The Objectives

1. **Protect Human Health and Safety**
2. **Protect, and to the extent practicable, restore the environment including land, air, water, fish and wildlife**
3. **Return the mine site to an acceptable state of use that reflects pre-mining land use where practicable**
4. **Maximize local and Yukon socio-economic benefits**
5. **Manage long-term site risk in a cost effective manner**



- **Workshops in communities.**
- **Interviews with elders (SFN) about concerns, expectations and objectives.**
- **Review and input from YG, SFN, RRDC, Town of Faro, INAC, DFO, EC. Specific information re: expectations.**
- **Overarching objectives approved by Oversight Committee**
- **Sub-objectives unique to each government.**

Understanding the issues

- To create a complete **final closure and remediation plan**, we gathered and studied information on a wide range of environmental issues.
  - From 2002 to 2005 - conducted technical workshops with consultants, governments (federal, territorial, First Nation, municipal), regulatory agencies, and others.
  - From 2003 to 2006 - completed over 90 technical studies.

2006 - Example Alternatives

From the studies and the workshop results, we created 12 “example alternatives”.

- **Three areas**
  - **A. Faro Pit and Waste Rock Area**
  - **B. Tailings Area**
  - **C. Vangorda/Grum Area**

Four alternatives for each area

<u>12 total</u>

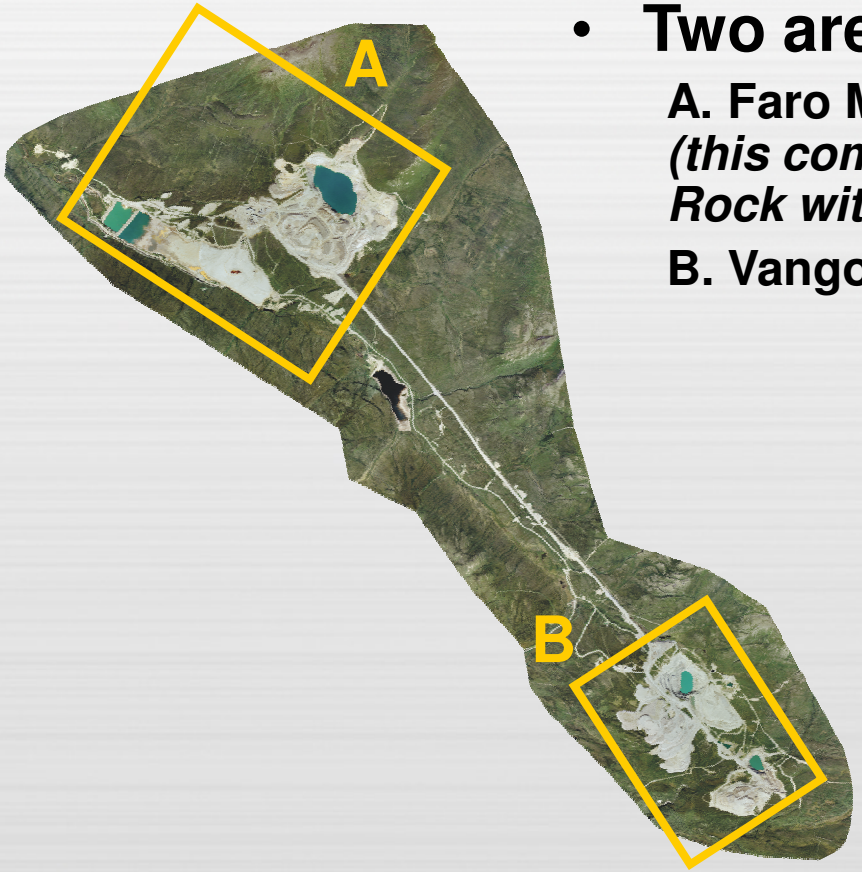
Component	Option	Description of Option	Under Current Consideration?	Rational for Current Exclusion	Options Reports
Faro Creek Diversion	Upgrade to East	Construct new, larger Faro Creek Diversion on east side of pit, connecting to the North Fork Rose Creek.	y	Note: Implementation of this option is delayed for FM3	Golder 2004
	Upgrade to West	Construct new, larger Faro Creek Diversion on west side of pit, connecting to North Wall Interceptor (also upgraded) and Rose Creek d/s of the tailings impoundment.	n	Higher cost than the upgrade to the east. Requires substantial upgrading of the North Wall Interceptor.	Golder 2004
	Tunnel to East	Construct tunnel to divert Faro Creek on the east side of the pit, connecting to North Fork Rose Creek.	n	High construction costs.	Golder 2004
	Reroute to Faro Pit	Reroute Faro Creek into the Faro Pit via a channel around and/or over the Faro Valley Dump. Energy dissipation may be required to minimize mixing of pit water.	n	Flow through pit option no longer considered feasible re: water quality concerns.	
	Retain as is	Retain and maintain the existing Faro Creek Diversion.	y	Existing diversion will not be stable in long-term. Capacity for large floods is not adequate, and pit wall regression will ultimately lead to failure.	

2007 – Further Narrowing the Options

During 2006 and 2007, the 12 example alternatives were subject to:

- Independent Peer Review
- Community input
- Further technical studies

This allowed us to refine and condense the



12 example alternatives

into

5 closure options

2007 - Closure Options

We now have 5 closure options.

- **Two areas**
  - **A. Faro Mine Area**
    (this combines the Faro Pit and Waste Rock with the Tailings Area)
  - **B. Vangorda/Grum Area**

3 options for the Faro Mine Area

2 options for the Vangorda/Grum Area

5 total

2007 – 5 Closure Options in Two Areas

Combined Faro Mine Area

•Move All Tailings	+	Upgrade Faro Creek Diversion and Cover/Revegetate Faro Waste Rock
or		
Cover Tailings with Soil	+	Upgrade Faro Creek Diversion and Cover/Revegetate Faro Waste Rock
or		
Move Some Tailings and Cover Some Tailings with Soil	+	Upgrade Faro Creek Diversion and Cover/Revegetate Faro Waste Rock

= 3 Combined Options

Vangorda/Grum Mine Area

Move Vangorda Waste Rock into Vangorda Pit

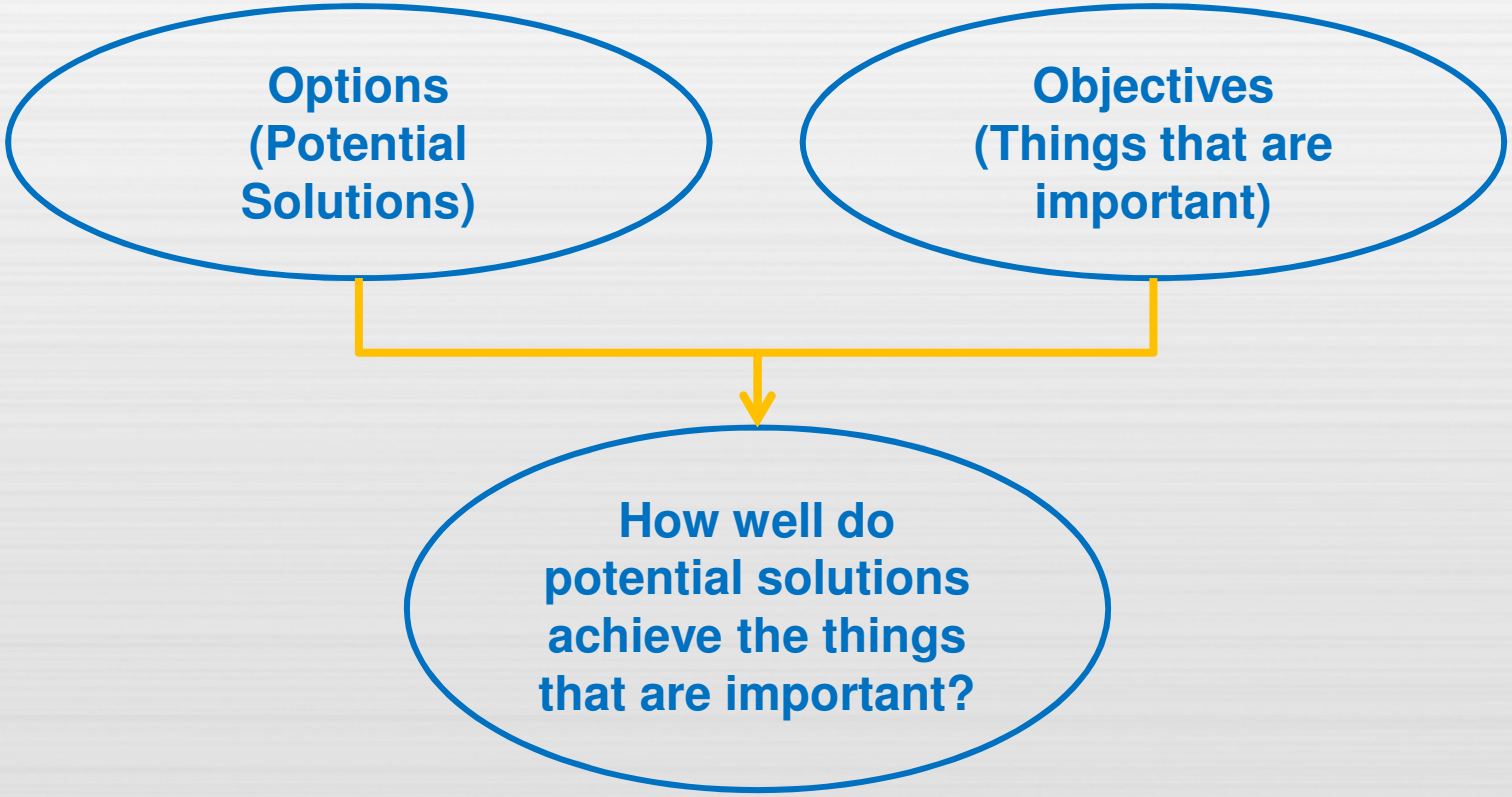
or

Cover Vangorda Waste Rock in Place

= 2 Options

Common Elements of the Options (1)

Any overall closure plan for the Faro Mine Complex will include some common things:



- Resloping and covering waste rock
- Revegetation of soil covers and other areas
- Diversion of clean water around the site
- Long-term collection and treatment of contaminated water
- Long-term management of water treatment sludge
- Long-term storage of water in pits
- Long-term maintenance of remaining site facilities (diversions, covers, water collection systems, water treatment systems, dams, etc.)
- Long-term monitoring of environmental conditions (water, animals, plants, climate, etc.)

Common Elements of the Options (2)

All of the closure options for the Faro Mine Complex are designed to do the following:

- Avoid unacceptable risks to public health and safety
- Avoid unacceptable risks to worker health and safety
- Meet appropriate environmental standards and guidelines, etc.

Options Evaluation Process (2007-2008)

Purposes of Options Evaluation Process

To provide Yukon, Federal and First Nations Governments with information needed to support well informed decisions about closure alternatives

- To compare remaining closure options with closure objectives (using a systematic methodology) – how well does each alternative perform against the objectives
- To identify discriminators and common elements between and among alternatives
- To document relevant assumptions, judgments, opinions and reasoning

One component - technical evaluation

- Systematic, rigorous and defensible process for evaluation alternatives
- Core Evaluation Team
- Multiple Variant Analysis
- Required clearly defined alternatives and objectives

Options Evaluation Team

Multiple Variant Analysis decision experts (experience with Nuclear Waste Management Organization)

- Lee Merkhofer
- Tony Hodge

Knowledgeable representatives bringing a range of perspectives for consideration/discussion

– Consultants
  - Randy Knapp, SENES
  - Daryl Hockley, SRK
  - Bill Slater, Bill Slater Environmental Consulting
– First Nation representatives and advisors
  - Ellie Marcotte, SFN
  - Kathlene Suza, RRDC
  - Dan Cornett, Access Consulting Group
  - Malcolm Foy, LGL Ltd.
– Yukon and federal government representatives
  - Stephen Mead, YG Assessment and Abandoned Mines
  - Mike Nahir, federal government, INAC

Objectives for Evaluation

Overarching Objectives

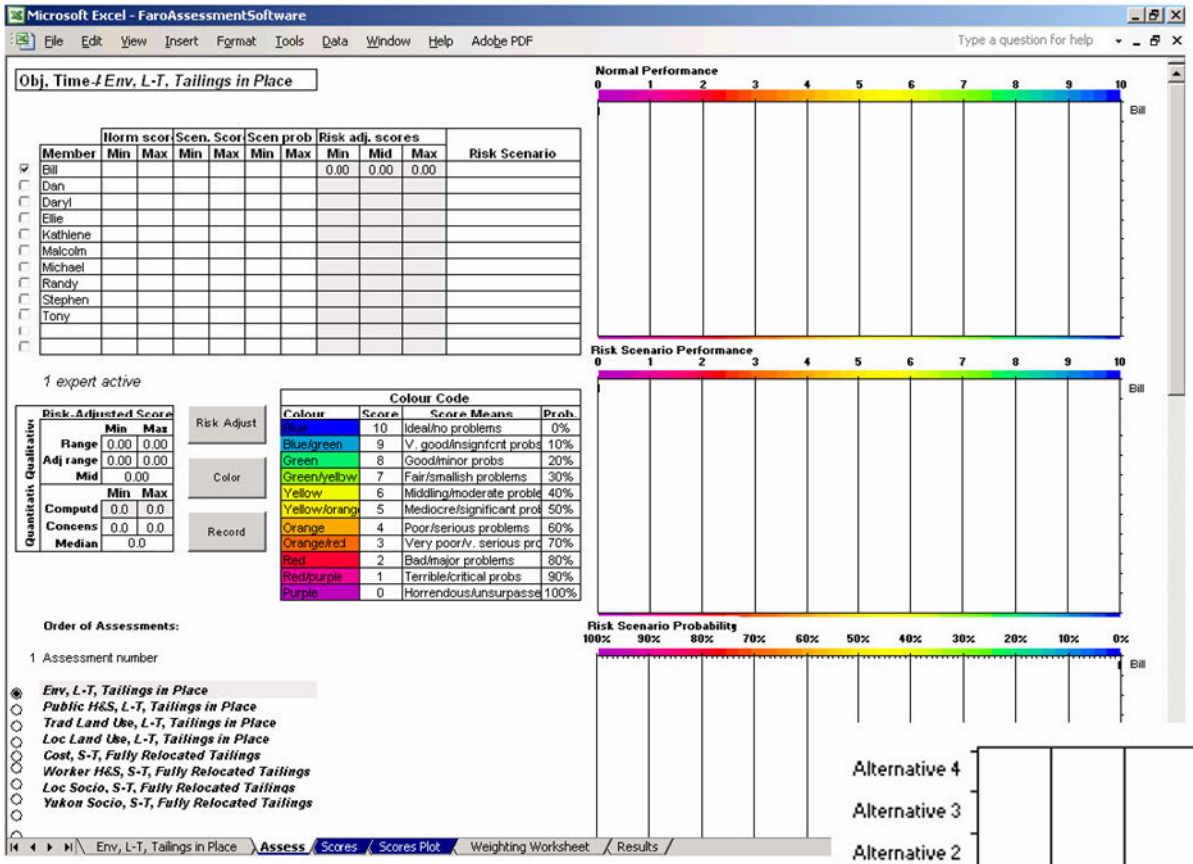
1. Protect Human Health and Safety
2. Protect, and to the extent practicable, restore the environment including land, air, water, fish and wildlife
3. Return the mine site to an acceptable state of use that reflects pre-mining land use where practicable
4. Maximize local and Yukon socio-economic benefits
5. Manage long-term site risk in a cost effective manner

Evaluation Objectives

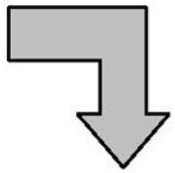
1. Maximize public health and safety
2. Maximize worker health and safety
3. Maximize restoration, protection and enhancement of the environment
4. Minimize restrictions on traditional land use
5. Minimize restrictions on local land use
6. Maximize local socio-economic benefits
7. Maximize Yukon socio-economic benefits
8. Minimize cost

Options Evaluation Process Key Steps

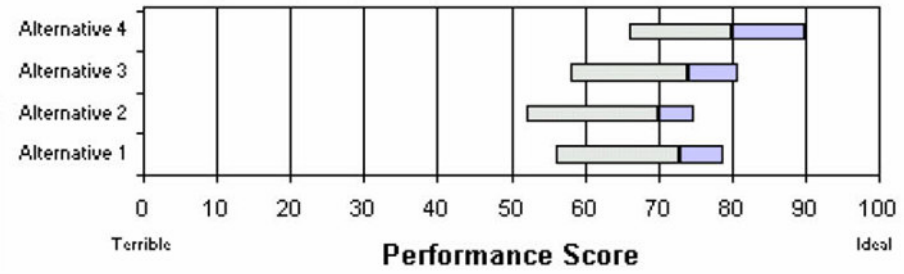
Step 1: Identify performance measures



Step 2: Develop scoring scales



Step 3: Compile background information to describe performance



Step 4: Individual evaluation of performance

Step 5: Group evaluation of performance

A spreadsheet will be used to facilitate the recording and analysis of scores

General Conclusions

- For many objectives, there is little distinction between the alternatives for normal operations
  - Greater differences during short-term
  - Normal operations very similar in long-term
- For some objectives, the performance under risk scenarios is a discriminator
- Institutional risk is an important consideration for all alternatives
- Cost is a discriminator

Additional Options Evaluation Inputs

- Multi-day community workshops in Ross River and Pelly Crossing, with community evaluation of options. These workshops were designed and facilitated by the First Nation coordinators and their technical advisors.

- Discussion of technical options evaluation results with a working group comprised of representatives from government and regulatory agencies.

- Review of the technical evaluation results by the Independent Peer Review Panel.

Selection of a Remediation Plan

- Late 2008 – First Nations, Federal and Territorial Governments came to a consensus and jointly selected the proposed remediation plan having considered results of technical evaluation, community evaluations and peer review.

- December 2008 – Letters of agreement from all parties confirming selection.

Faro Mine Remediation Project
Overview of Selected Option

Faro Mine Complex: Site Overview

Faro Mine Area

Components

Faro Pit

Waste Rock (250M tonnes)

Tailings (70M tonnes)

Four Dams

Mill Buildings

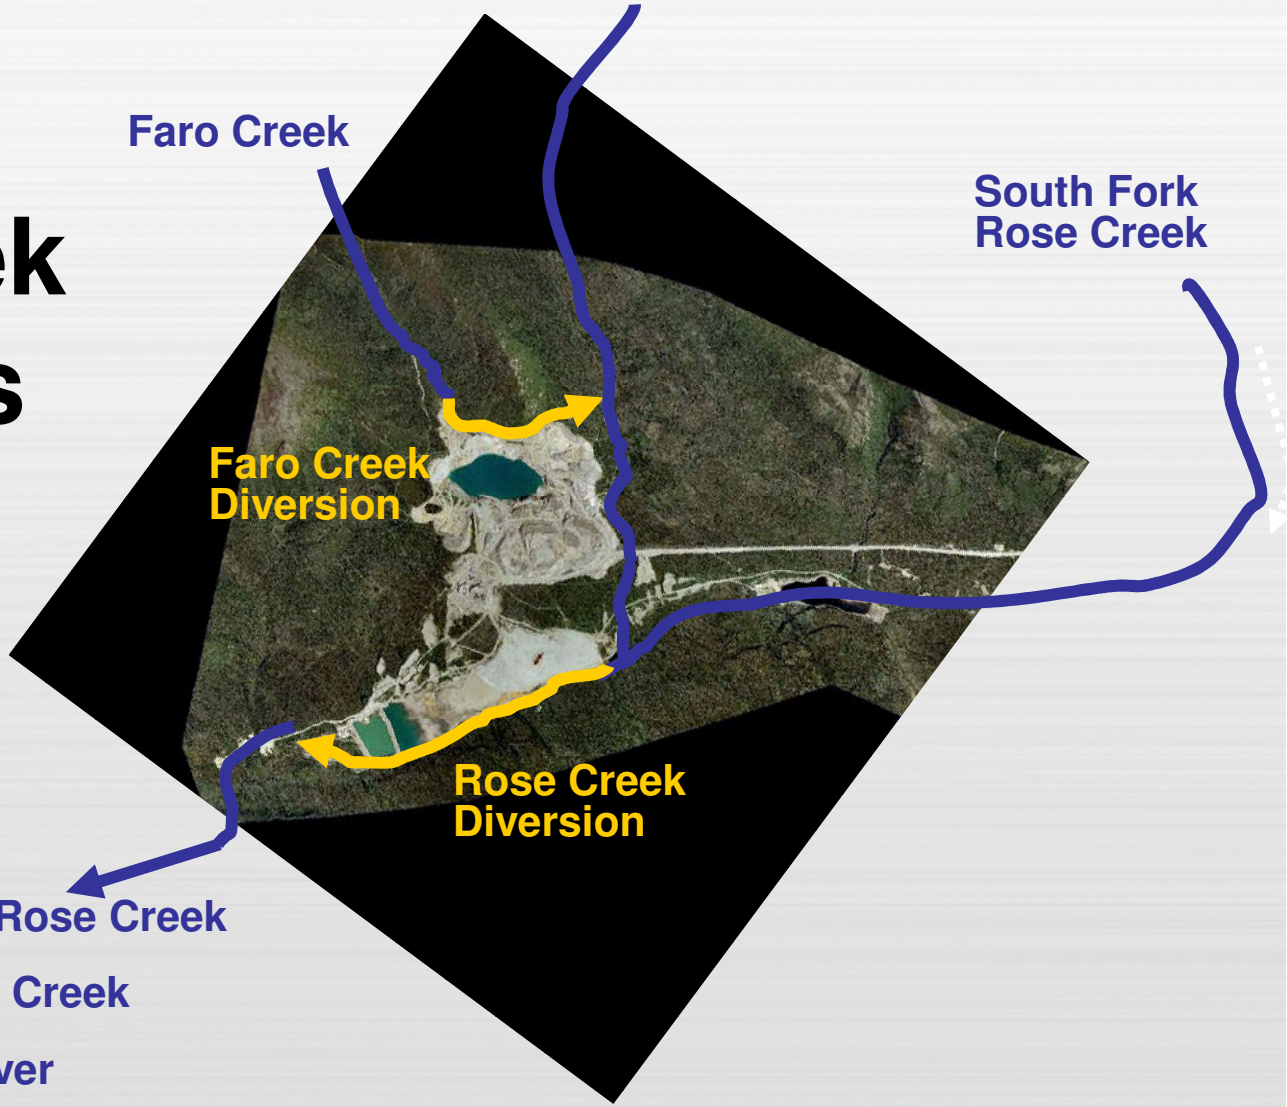
Faro and Rose Creek Diversions

13km Haul Road

Vangorda/Grum Area

Components

Vangorda & Grum Pits



Waste Rock (70M tonnes)

No tailings

Vangorda Creek Diversion

Faro Mine Area

Faro and Rose Creek Diversions

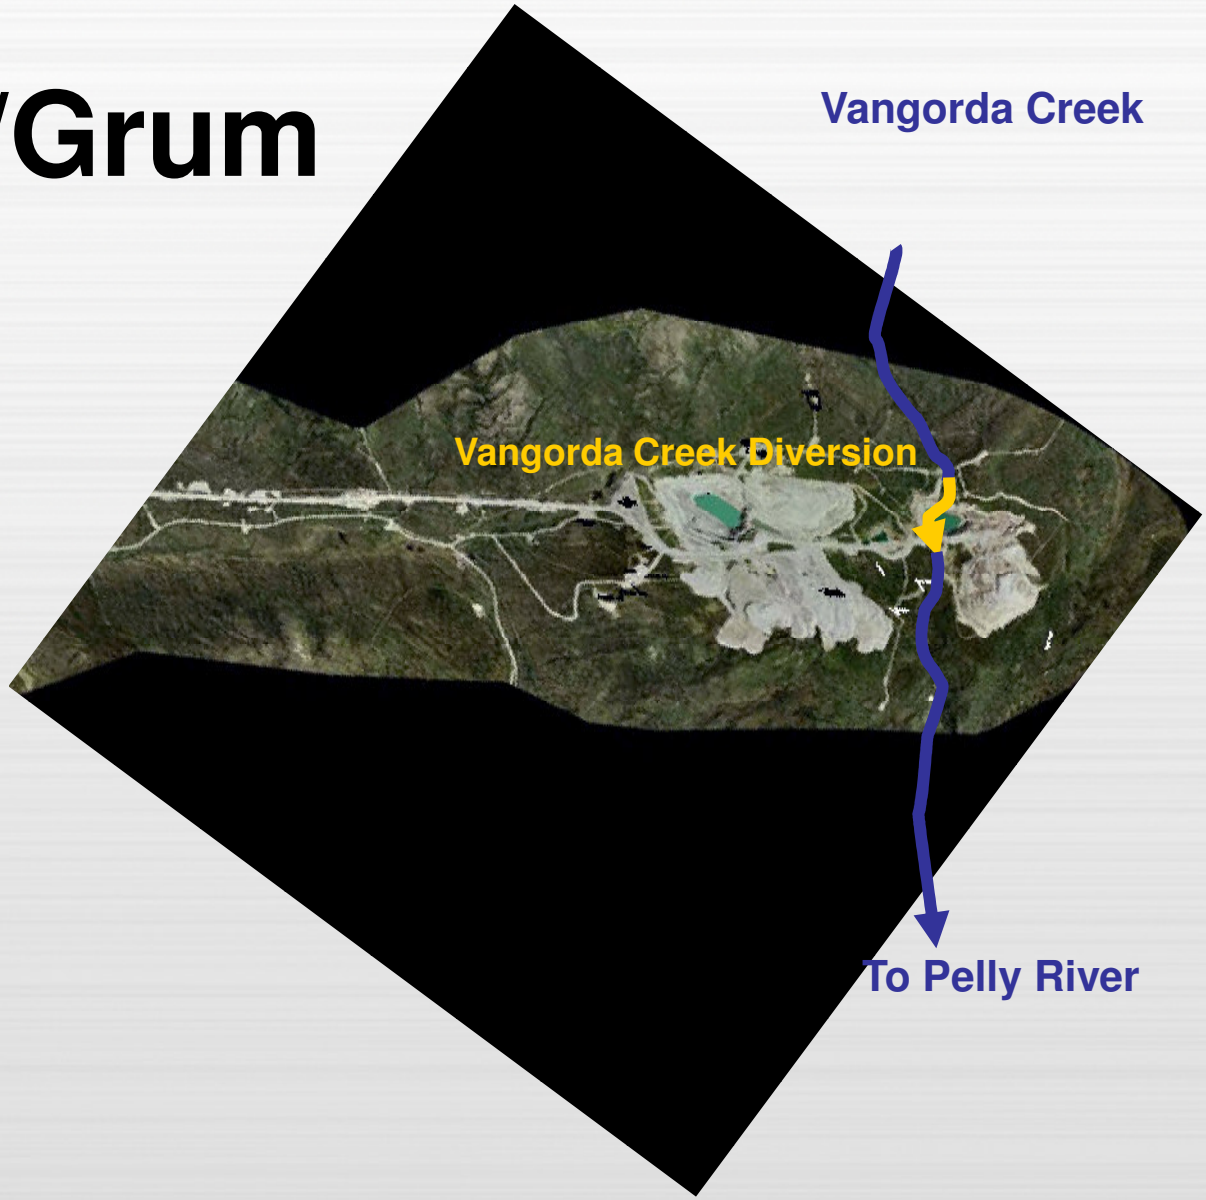
Plan for Faro Mine Area

Use Faro Pit to store contaminated water

Reslope, cover and revegetate waste rock

Remove mill buildings and revegetate

Improve tailings dams



Cover tailings with soil

Upgrade Rose Creek Diversion

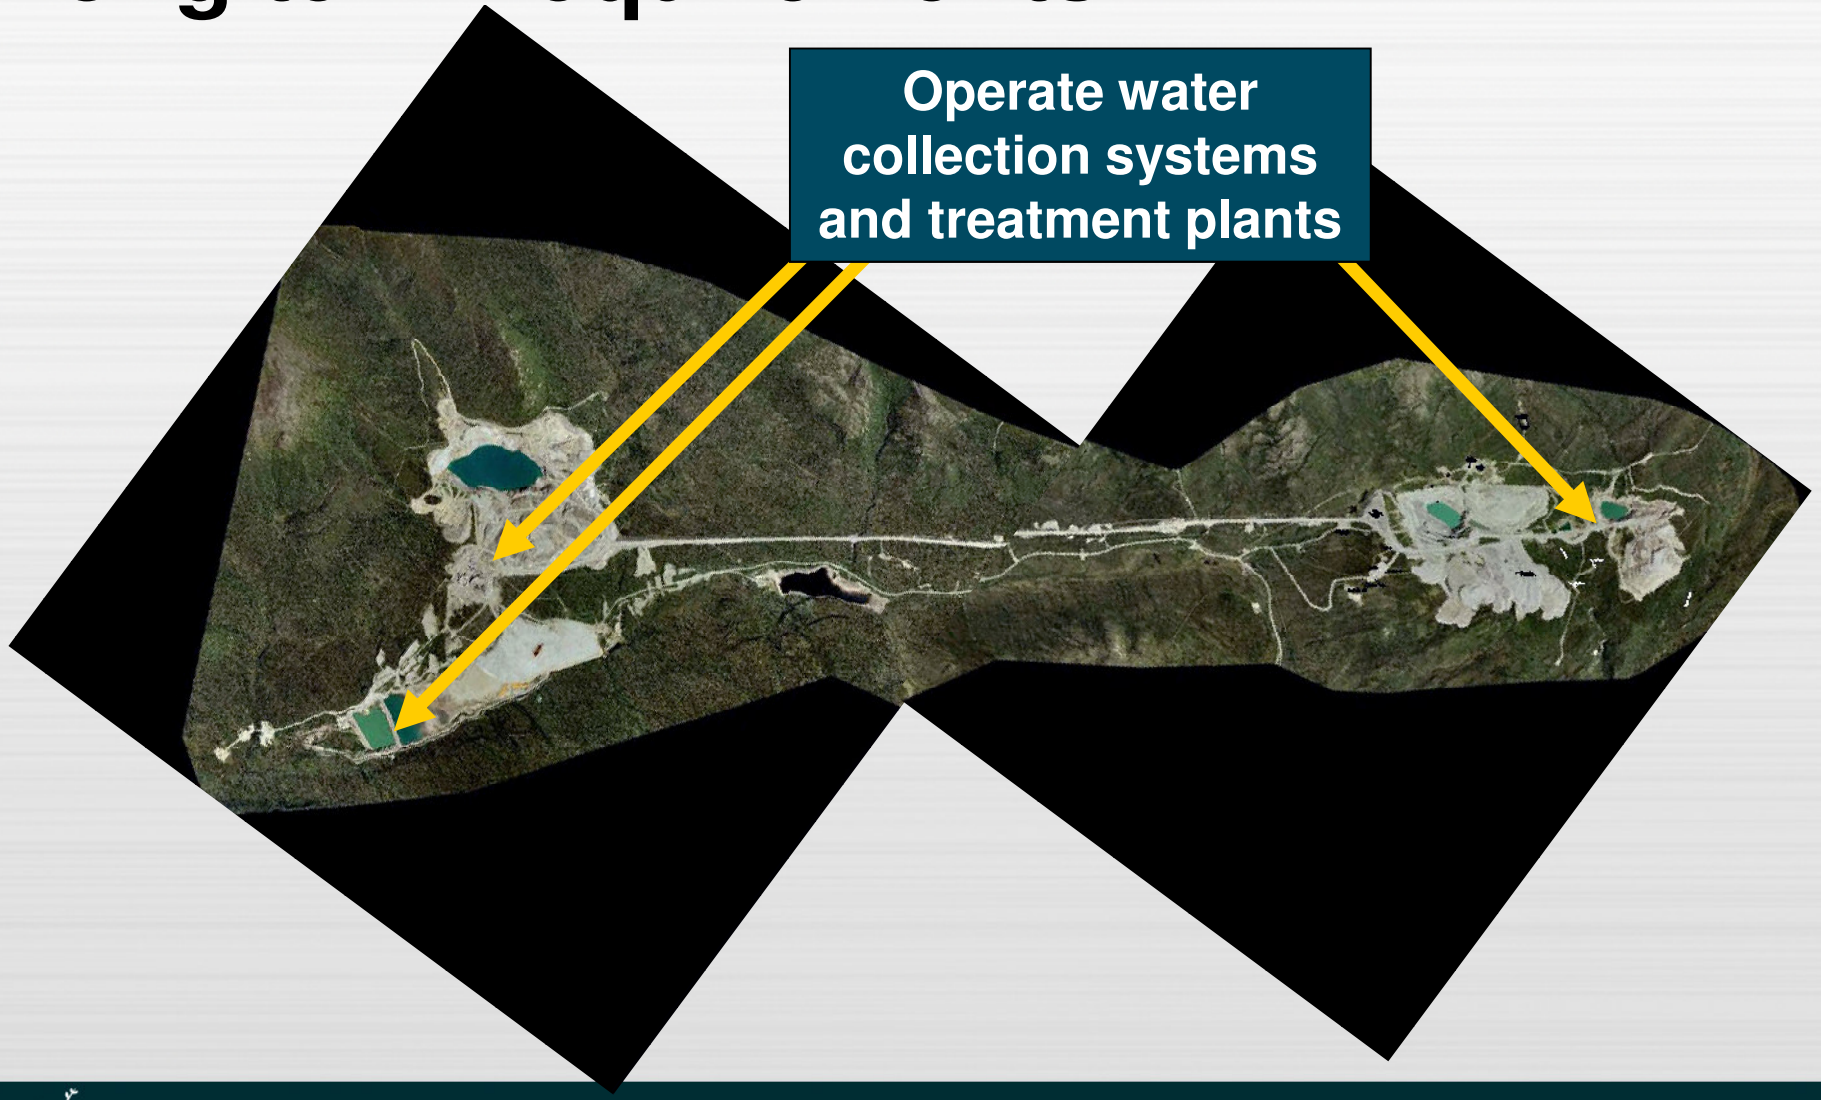
Upgrade Faro Creek Diversion & North Fork

Collect and treat all contaminated water

Vangorda/Grum Area

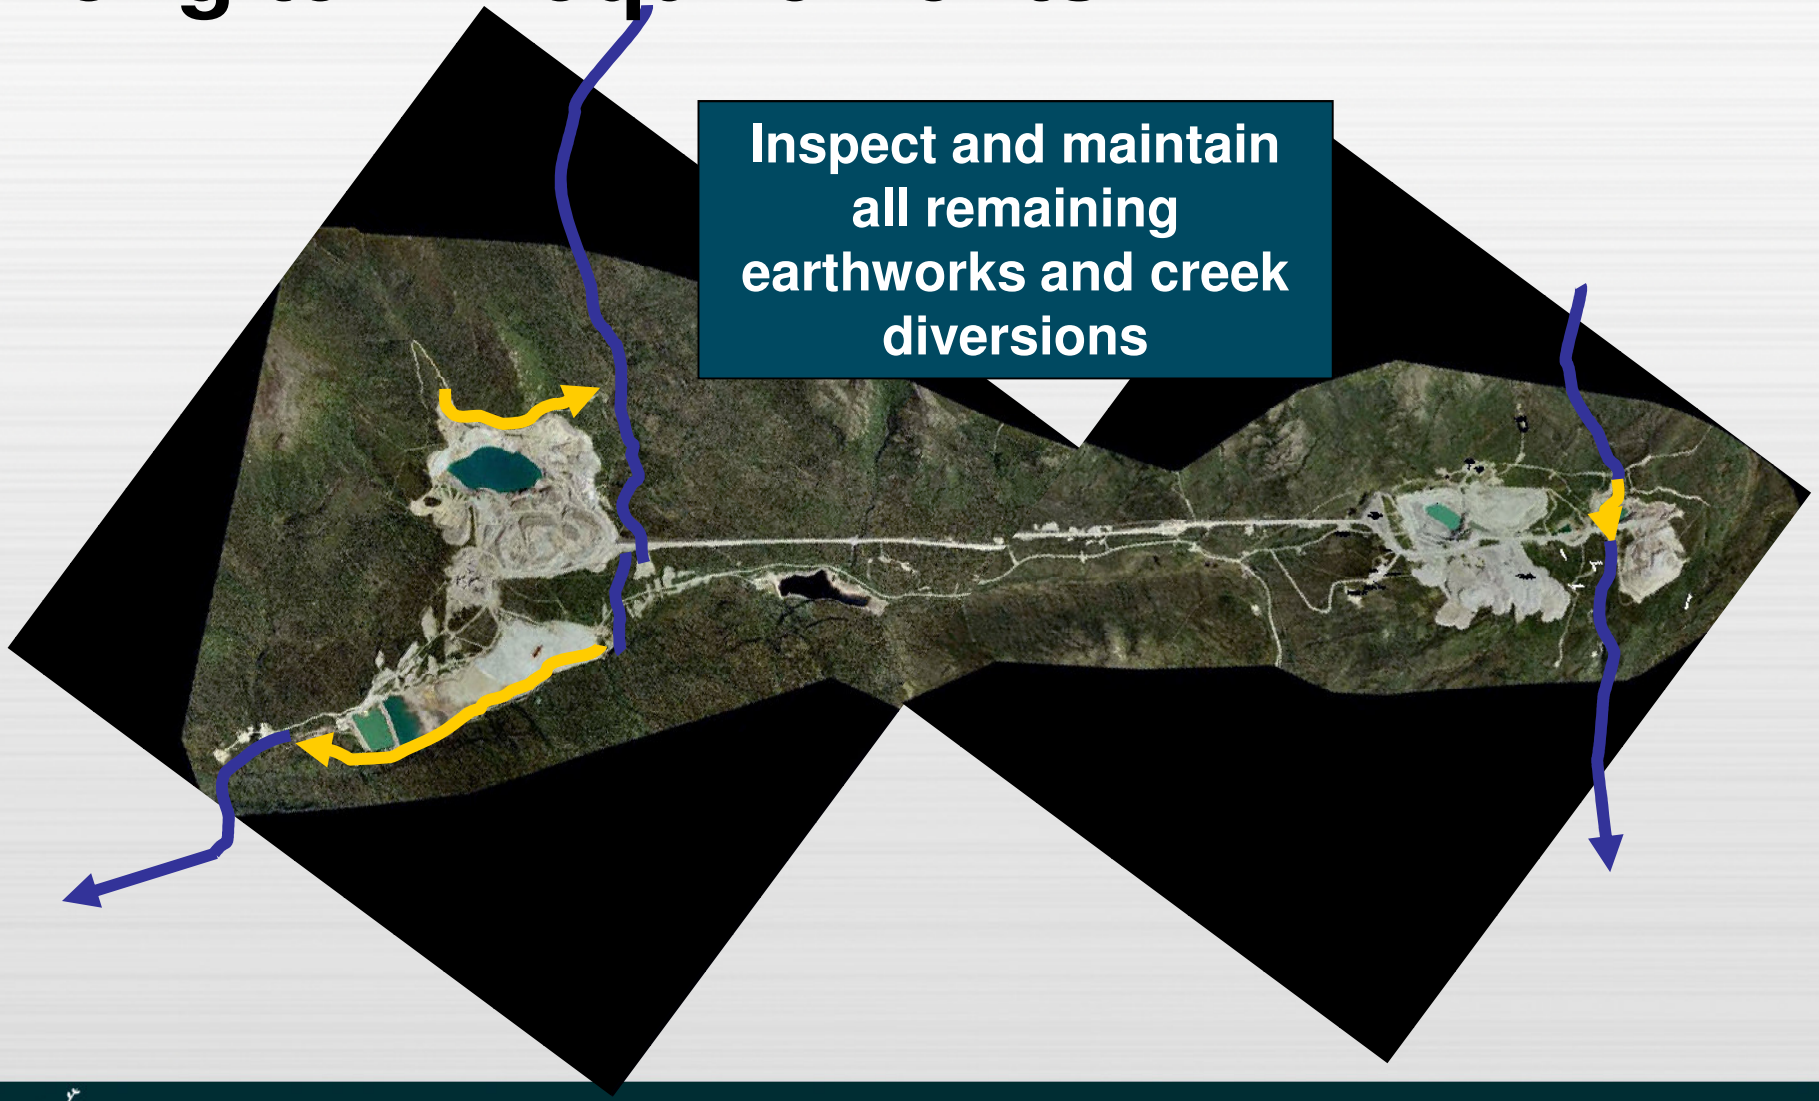
Plan for Vangorda/Grum Area

Vangorda Pit to store very contaminated water



Grum Pit for less contaminated water

Reslope, cover and revegetate all waste rock in place



Upgrade Vangorda Creek Diversion

Collect and treat all contaminated water

Attention: Steve Caram
Project Assessment Manager

Re: Faro Mine Remediation Project – Assessment of Interim Works

Assessment Scenario

The Faro Mine Remediation Project (FMRP) has been working towards design and planning of the overall remediation works for the site for a number of years. The project is anticipated to cost approximately $ 700- 900million with construction works lasting between 10 to 15 years. This project is currently scheduled to be submitted to the Executive Committee of the Yukon Environmental and Socio-economic Assessment Board (YESAB) in the 2016/17 fiscal year.

Over the next several years the Government of Yukon (YG), through Assessment and Abandoned Mines (AAM), and Aboriginal Affairs and Northern Development Canada (AANDC) will work to prepare the design and assessment documentation. However, over the past fiscal year AAM and AANDC have identified a number of items at the Faro Mine Site for which the risks associated with human health and safety and the environment have reached levels requiring a response in a shorter time frame. While these activities may fall within the scope of activities that could be undertaken in the interest of public welfare, health or safety or of protecting property or the environment, the governments are evaluating the implications of submitting a YESAA project proposal separate from that of the overall plan, and containing the items described in the section below.

Scope of Project Proposal for Interim Works

AAM intends to include the following items in its project proposal to YESAB:

- ***Land Lease***
  At this time, AAM and AANDC do not have tenure over the land upon which the site is located. The land lease would help to achieve a number of objectives including protection of health and safety. Also, as the design of the overall plan requires extensive site investigations, a lease would provide a mechanism for this type of work to be conducted in a more expedient manner,

due to a reduction in the number of permits and licenses required. AAM is currently in the process of gathering some information that would support this application. Activities proposed as part of the land use work include security measures, road and trail development, and clearing of small areas for drilling and testing.

- ***Water Treatment Plant Construction***
  The Water Treatment Plant, located in the mill area of the Faro Mine Site, requires prompt replacement. This plant, built in 2001 using components of the old Faro Mill had a design life of 5 years. Whilst a number of interim repairs/upgrades and improvements have been completed over the years, recent evaluation work has concluded that the risks to human health and the environment posed by the existing treatment facility have reached levels that necessitate replacement in the near term. Based on the state of the plant as well as its functionality, AAM would seek to move forward with the construction of a new 8100 gpm treatment plant in advance of the overall remediation work, recognizing that this plant would be used during remediation, but would likely undergo additional modification or expansion in the future, as contaminant sources change at the site.

- ***Care & Maintenance***
  The purpose of care and maintenance is to maintain the site to prevent adverse effects on persons, property, and the environment, and to counteract, mitigate, and remedy any adverse effects that may occur.

  At this time, this work largely consists of the following operations and maintenance activities:
  - Operations include operating, maintaining, repairing, monitoring and managing the following:
    - Fresh water conveyance systems
    - Contaminated water storage, conveyance, collection and treatment systems (including the existing treatment facilities)
    - Dams and diversions
    - Stationary and mobile equipment
    - Sludge storage facilities
    - Tailings storage facilities (including dust management)
    - Open pits
    - Waste rock piles and ore stockpiles
    - Implementation of the preventative maintenance plan
    - Provision of emergency response capability and responding to emergencies
  - Maintenance includes operating, maintaining, repairing, and providing for the following:
    - Security, health, and safety for the site
    - Site buildings and infrastructure
    - Electrical distribution systems
    - Purchase and manage use of electricity, fuels, and lubricants
    - Roads and culverts
    - Waste oil heating system

- Faro housing
- Permits and licences as required

The care and maintenance program includes an extensive monitoring program to evaluate environmental conditions and physical and chemical stability of the site. These monitoring programs support an adaptive management plan.

- ***Down Valley Interim Hydraulic Upgrades***

  The Down Valley Tailings Facility contains 55,000,000 tonnes of acid-generating tailings located in the original valley of Rose Creek. The Intermediate Dam spillway and the Rose Creek Diversion require upgrades in order to allow them to safely pass no less than a 1-in-500-year flood event (132 m^3/sec). This was their original constructed design specification, which, over time has reduced due to erosion, emergency response etc. Despite the Intermediate Dam being rated as a "Very High" to "Extreme" risk dam based on the Canadian Dam Association (CDA) Dam Safety Guidelines 2007 (CDA, 2007), the existing spillway (capacity of 32 m^3/sec) cannot safely pass a moderate or major flood event without potentially failing the dam. Intermediate Dam failure may cause an environmentally damaging discharge of metals-laden tailings to Rose Creek, Anvil Creek, and the Pelly River that would result in a significant or major loss of critical fish and wildlife habitat that would be impractical or impossible to restore. Failure of the Secondary Dam in 1975 within the Rose Creek Valley resulted in a loss of wildlife habitat, with little recovery evident more than 35 years later. Based on the current state of the Intermediate Dam and Rose Creek Diversion, AAM would seek to move forward with the required upgrades in advance of the overall remediation work. A final remediation plan would see this system upgraded again to meet PMF/MCE design criteria.

  The proposed down valley interim hydraulic upgrades consist of the following elements:

  - Increase the existing Intermediate Dam spillway capacity by increasing the depth of the existing spillway channel. Relocate existing piping and lime mix tank that have been placed within the ID spillway.
  - Increase the height of the Intermediate Dam embankment crest by installing a geomembrane layer to extend the core to the dam crest and by adding concrete traffic barriers.
  - Protect the Intermediate Dam spillway channel from erosion by installing gabion mattresses.
  - Increase the Rose Creek Diversion capacity to pass the 500-year storm event, by removing vegetation, repairing raveled slopes on the dike and cut slope, and by filling in low spots on the dike crest.

At this time, the governments have identified the need for completion of these activities in the near-term, and are considering schedule and other implications associated with a YESAA assessment. If the assessment can be conducted without incurring undue risks to health and safety, the environment, or

property, these interim measures would be described in a project proposal and submitted for assessment. Based on our current understanding of the scope, AAM would be in a position to submit this project proposal to YESAB during the winter of the 2013/14 fiscal year. For discussion purposes, AAM is requesting a meeting with YESAB to discuss the level of assessment that would be required for the interim works described above.

Sincerely,

Patricia Randell
Manager
Assessment & Type II

Meeting with Yukon Environment - Meeting Notes, January 19, 2012

Faro Mine Remediation - Meeting Notes

Topic: Wildlife Information Requirements : Faro Mine Remediation Project

Date: January 19, 2012

Attendees: Patricia Randell, YG-AAM; Bill Slater, CH2M Hill; Julia Ahlgren, YG- Env.; Matt Clark, YG-Env.

1. Update and meeting purpose

Patricia R. described meeting purpose – to discuss wildlife information requirements for a YESAA Project Proposal. Patricia R./Bill S. provided status update regarding remediation planning for Faro Mine Complex and described project context (i.e. existing disturbed site).

2. Caribou

Matt C. – 2009 survey conducted. Also, observations during 2011 moose survey. There is substantial use of Subzone 445 by caribou, especially in early winter. Caribou observed close to the site, but not on site. Note that caribou are very sensitive to disturbance and will not use areas with significant activity.

Patricia R. – plan to conduct habitat mapping as part of project planning and for inclusion within the Project Proposal.

Matt C. – given project context, it is important to understand what caribou are using and how do we mitigate activities. But, this does not appear to be an issue for activities within the existing footprint. For activities outside of existing footprint, need to confirm that these are not areas of use.

Conclusion: No further specific investigations required, but utilize existing survey information combined with incidental observations and habitat mapping – with potential mitigation requirements or potential further investigations if activities will occur in or near areas of known caribou utilization.

3. Moose

Matt C. – Surveys completed in 2011 for regional area. Consistent with survey scope from 2004. Smaller survey conducted specifically in Subzone 445 in 1997. Initial data from 2011 survey should be available by end of month. Initial overview report completed this spring. Final report completed fall 2012. 1997 survey showed highest density of moose recorded in Yukon, but trend since then has been negative. Also, low bull numbers, suggesting high hunting pressures

Matt C. – Further information requirements: may consider looking at late winter utilization by moose. It is possible that Rose Cr. elevation is higher than used regionally. Recommendation is to identify lowest parts of affected area and compare with regional data about late winter utilization. If elevations are consistent, late winter survey may be warranted.

Notes finalized on March 1, 2012

Conclusion: Follow two-step process. First step to compare elevations in Rose Creek/Project Area to elevations of regional winter use areas. If elevations are consistent, consider late winter survey. If not, no further field investigation required.

4. Sheep

Matt C. – Surveys completed in June and July 2011. June to identify lambing areas and July to evaluate composition of sheep in the area. 2011 numbers are down from 2004, but 2004 numbers were highest recorded. Overall, appears to be healthy population. Issue for project will be how the sheep use the site, as it is a known migration corridor. Need to not restrict or discourage movement through the site, while still protecting sheep from site risks (e.g. pit water quality). Current observations confirm that 1980s investigations of migration corridors are still relevant.

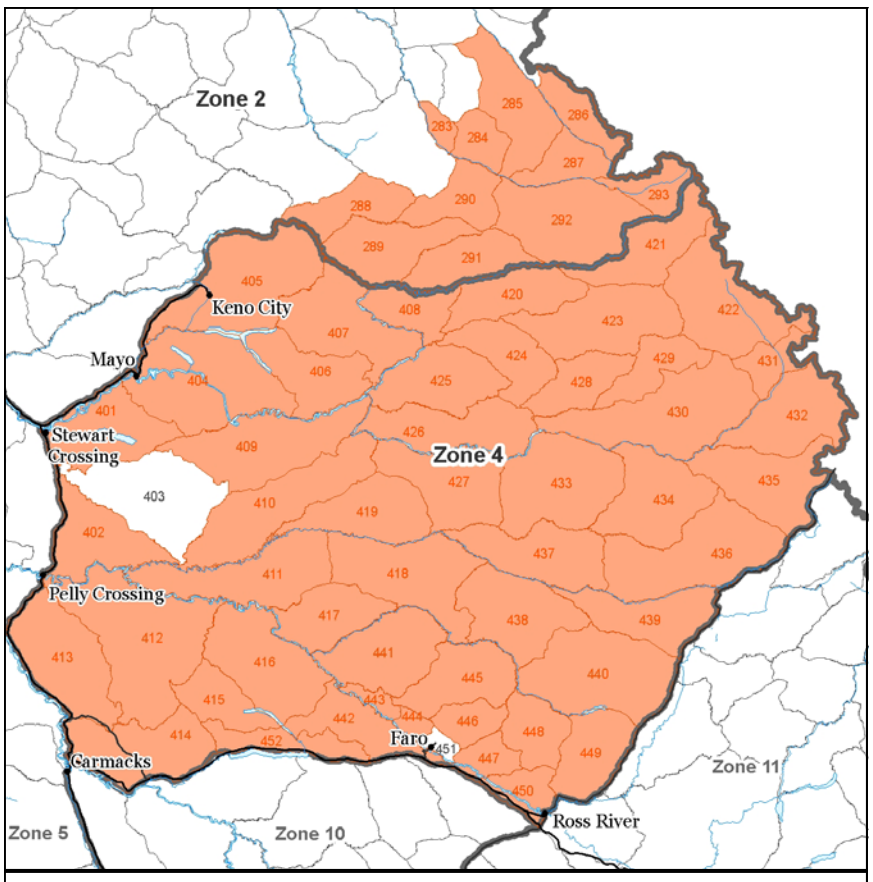
Conclusion: No further work is needed to investigate migration corridors. Using 1980s work, combined with current observations of sheep on the site and habitat mapping should be adequate. Documentation of current observations may be required, but should be available through site logs.

5. Grizzly Bear

Conclusion: Denning habitat may be important in the area and is currently unknown. Habitat mapping should be the focus of work to characterize potential utilization of the study area by grizzly bear, for denning as well as other activities. Remediation plan should avoid creating conditions for denning directly on current disturbed areas where there will be underlying contaminated materials (i.e. don't encourage denning on constructed covers). Matt C. to speak with Ramona Maraj and provide AAM with further feedback.

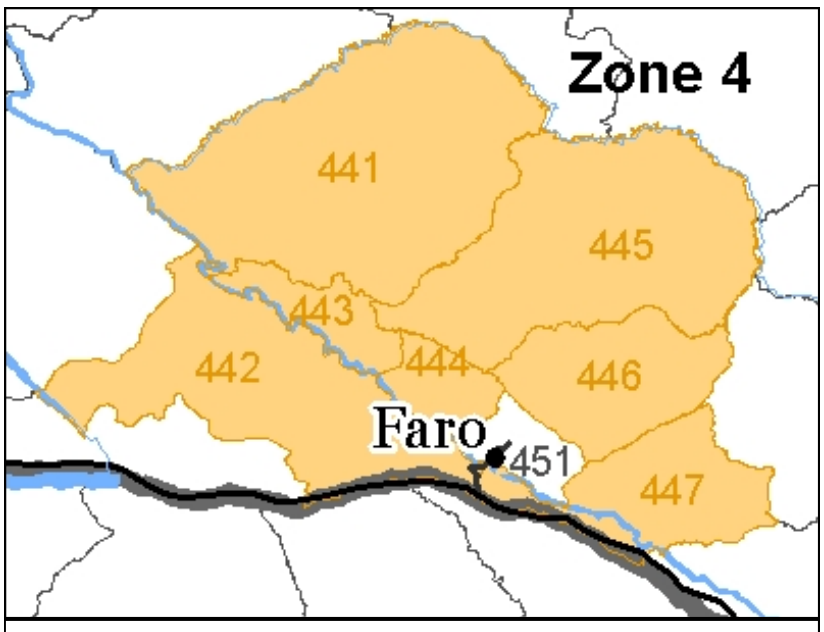
Attachment 3A-10
Poster for Hunted Wildlife Organ Collection Program - Poster

ATTENTION
Hunters near the Faro area



Yukon government needs your help in monitoring the health of wildlife in the Faro area.

Please donate samples of:



- kidney (whole)
- muscle
- liver
- incisor bar (front teeth)

From **caribou** hunted in Designated Game Management Zones 2-83 to 2-93 and all of Zone 4 (except for 4-03 and 4-51) or

From **moose and sheep** hunted in Designated Game Management Zones 4-41 to 4-47.

Caribou from Zones 2-83 to 2-93 and all of Zones 4 (except 4-03 and 4-51).

Moose or Sheep from Zones 4-41 to 4-47.

WHAT TO DO

- Please prepare liver and muscle samples to be the size and shape of a pound of butter.
- Put each sample in clean plastic bags.
- Freeze samples as soon as possible.
- Samples from different animals should be bagged separately.
- Please deliver the samples to any Environment Yukon—Game Branch Office before:

Monday, November 1, 2010

Thank you for your participation!

WIN A FREE CHARTER FLIGHT!

All hunters who bring in requested samples will be entered into a draw to win a free flight from Alpine Aviation. The flight can be used to fly the winner to their favourite spot next year. The draw will occur on **Tuesday, February 1, 2011**.

8 Occupational Health and Safety Plan 13

1 Background

1.1 Introduction

This environmental management plan (EMP) describes how environmental stewardship at the Faro Mine Complex is managed by the Yukon Government (GY). GY's role is to manage contractors who perform care and maintenance operations, or other physical works related to remediation.

An EMP is a site-specific plan developed to ensure that appropriate environmental management practices are followed during a project's construction and/or operation.

This EMP has been developed to ensure:

- Identification of current and potential human health and safety and environmental risks of the project or site;
- Risks associated with the project are properly managed (i.e. monitored and mitigated);
- Application of best management practice to the project or site; and
- Compliance with federal and territorial legislation.

To meet its environmental objectives, GY will employ a number management plans that include various mitigation measures and monitoring activities. This document provides summary descriptions of the purpose or content of each management plan.

1.2 Project Description

The Government of Yukon has been working towards design and planning of the overall Faro Mine Remediation Project (FMRP) for a number of years. While the FMRP is being prepared, YG will continue its activities on the FMC to protect, and minimize risks to human health and safety and the environment, as well as to support the development of the FMRP. These interim activities, collectively referred to as the Interim Works (IW), include the following tasks:

- Ongoing site operations;
- Site investigations in support of design and environmental characterization for the FMRP;
- The Down Valley Interim Hydraulic Upgrades (DVIHU) that comprise improvements in flood routing capacity for the Rose Creek Tailings Area (RCTA); and
- Ancillary activities associated with completing primary activities (e.g., accommodation for workers, utilization of borrow materials).

This EMP will apply to the IW activities which are further described in the sub-sections below.

1.2.1 Site Operations

The purpose of Site Operations is to maintain the site to prevent adverse effects on persons, property, and the environment, and to counteract, mitigate, and remedy any adverse effects that may occur.

This work largely consists of the following operations and maintenance activities:

- Operate, maintain, and repair the following components:
  - Fresh water systems;
  - Contaminated water systems;
  - Pumping systems;
  - Collection ditches;
  - Dams and diversions;
  - Contaminated water containment areas;
  - Contaminated water treatment systems;
  - Equipment;
  - Site buildings and infrastructure;
  - Electrical distribution systems; and
  - Roads and culverts.
- Perform sludge management.
- Perform tailings dust management.
- Implement the preventative maintenance plan.
- Provide emergency response capability and respond to emergencies.
- Provide security, health, and safety for the FMC.
- Purchase and manage use of electricity, fuels, and lubricants.
- Maintain all permits and licences as required.
- Implement an Affected Yukon First Nation and Yukoner Participation Plan.
- Provide site management and administration services.
- Comply with specified environmental standards.
- Conduct environmental and site monitoring.

The site operations program includes an extensive monitoring program to evaluate environmental conditions and physical and chemical stability of the site. These monitoring programs support an adaptive management plan.

1.2.2 Site Investigations

Development of the FMRP and design of remediation and closure elements requires extensive site investigation programs. These investigations will occur throughout the site and extend over the duration of the IW. Investigations will include the following types of activities:

- Drilling using various types of drilling equipment for the purposes of soil and rock sampling and also for the establishment of monitoring wells and installations.
- Conducting geotechnical investigation programs including test pitting, reconnaissance, drilling and sampling.
- Using water for a variety of programs including aquifer testing programs.

- Establishing, maintaining and operating various monitoring facilities including wells, flow measurement facilities, meteorological stations.
- Establishing, maintaining and operating test facilities to support reclamation research including cover trials and vegetation trials.
- Collecting vegetative material to support re-vegetation test programs.
- Conducting reconnaissance programs which may include use of helicopters.
- Utilizing heavy equipment to test remediation methods.
- Test pitting, drilling and sampling to support contaminated site assessment and the identification of borrow sources.
- Conducting heritage and archaeological assessment programs.
- Conducting water treatment test programs.
- Conducting field surveys and sampling programs for the physical and biological environment.
- Conducting geophysics and seismic refraction programs.
- Conducing surveying activities with associated line cutting and establishment of survey markers.

1.2.3 Down Valley Interim Hydraulic Upgrades

The DVIHU component of the IW is intended to address flood-related risks for the RCTA, thereby helping to reduce the likelihood of potential adverse effects on the environment. The DVIHU entails upgrading the hydraulic capacity of both the Intermediate Dam (ID) spillway and the Rose Creek Diversion (RCD) to provide capacity for the system to convey a 1-in-500-year flood event.

The DVIHUs have been designed as an option that can be completed in a timely and cost-effective way, thereby providing suitable risk management for the IW period prior to construction of the permanent flood routing facilities. The proposed works include:

- Increase the existing ID spillway capacity by increasing the depth of the existing spillway channel.
- Relocate existing piping and lime mix tank that have been placed within the ID spillway.
- Increase the height of the ID embankment crest by installing a geomembrane layer to extend the core to the dam crest and by addition of gabion mattresses.
- Protect the ID spillway channel from erosion by installing gabion mattresses.
- Increase the RCD capacity to pass the 1-in-500-year flood event, by removing vegetation, repairing raveled slopes on the dike and cut slope, and by filling in low spots on the dike crest.

The work is proposed for completion as soon as possible because the DVIHU are intended to provide temporary protection of the ID until implementation of the final closure plan.

2 Sediment and Erosion Control Plan

The Sediment and Erosion Control Plan (SECP) describes detailed measures to prevent sediment mobilization and erosion of exposed erodible materials. These measures are essential to minimize potential effects to the environment and ensure the stability of infrastructure. The SECP describes application of Best Management Practices (BMPs) and ensures compliance with relevant federal and territorial legislation (i.e. acts and regulations), permits and licences. Contractors will be required to develop plans in accordance with the SECP specific to the works/activities that they will be undertaking.

The SECP requires implementation of the following tasks prior to and during any activities that may expose erodible materials:

- Assessments of activities/works for their potential to cause the mobilization of sediments and erosion;
- Identification of mitigation measures for relevant activities/works and monitoring to ensure effectiveness (frequency dependent on risk and likelihood); and,
- Inspections to ensure the implementation of mitigation measures and compliance with relevant legislation, permits, licences and BMPs.

Standard mitigation measures identified in the SECP include:

- Minimize area of vegetation and soil disturbance;
- Minimize flow entering and flowing through work areas;
- Minimize the length of time that erodible materials are exposed;
- Minimize slopes of disturbed areas and material stockpiles;
- Avoid work during periods of high precipitation;
- Stabilize erodible materials as soon as practical through erosion control measures;
- Ensure the installation of erosion control measures before the commencement of works;
- Ensure that materials required for erosion control measures are available;
- Sediment barrier (e.g. straw bales, biofilter, brush barrier, pre-fabricated barrier) to capture and retain sediment;
- Geotextile sediment fence to reduce velocity and capture sediment; and,
- Sediment trap to pond water in order to allow sediment to precipitate.

3 Environmental Monitoring, Surveillance and Reporting Plan

The purpose of the Environmental Monitoring, Surveillance and Reporting Plan (EMSRP) is to track the effects of site activities so that potential environmental effects are identified before they become a problem. Environmental monitoring ensures environmental protection and compliance with legislation, permits and licences. It also confirms performance of BMPs. The EMSRP describes the monitoring activities that will be completed, as well as the practices and methodology to be employed by the teams responsible for conducting monitoring activities.

As identified in the EMSRP, monitoring effort depends on the sites, time of year, as well as the activities/works taking place. Annual monitoring programs are conducted at the Faro Mine, although additional monitoring will be conducted to verify the accuracy of predictions made in the IW Project Proposal effects assessment, the effectiveness of mitigation measures, and compliance with legislation, permits and licences. Additional monitoring effort will also be applied during the implementation of specific activities or works which have a higher risk and likelihood of affecting the environment. Should monitoring activities identify exceedences of prescribed thresholds, these will be brought to the attention of the relevant management personnel so that appropriate action may be taken (e.g. as specified in the adaptive management plan). The results of the data collected through the EMSRP, as well as the mitigation measures applied to address any exceedences, will be reported to the relevant regulatory agencies.

4 Emergency Response Plan

The emergency response plan (ERP) clearly defines what actions are required in response to the occurrence of high risk events (i.e. provides detailed guidance on how to respond to various emergency situations that could occur during normal operations).

The ERP identifies:

- What type of incident could occur;
- What general type of emergency response is required; and
- Any special response requirements.

The ERP provides an emergency telephone directory, roles of personnel responsible for the implementation of the ERP, a list of applicable legislation and standards, and an account of the different emergency scenarios and responses to these.

For each scenario, the ERP identifies the:

- The primary risks associated with the incident;
- How the incident may be identified and reported;
- Alarms or methods to alert persons of an emergency situation;
- The management response required;
- Any instructions specific to a scenario; and
- Contacts for specialist advice.

The ERP includes the following scenarios:

- Major Seismic Event/Earthquake;
- Open Pit Wall / Ramp Failure;
- Inrush into Open Pit;
- Animal Attack;
- White Out;
- Severe Electrical Storm;
- Severe Rain Storm/ Flood/ Freshet;
- Communicable Disease Outbreak: Human Epidemic;
- Vehicle Accident/ Incident;
- Heavy Equipment Break Through Ice;
- Dangerous Goods Truck Accident/ Incident;
- Light Vehicle Accident/ Incident;
- Heavy Vehicle Accident/ incident;
- Hazardous Substance Release;
- Water Treatment Plant Failure;
- Fire/ Explosion;

- Building Collapse;
- Working At Heights Accident/ Incident;
- Confined Space Accident/ Incident;
- Malicious Damage;
- Bomb Threat; and
- Armed Hold - Up/ Hostage Situation.

Specific plans, as described in the following sections, are appended to the ERP for emergency preparedness, these include:

- A Spill Contingency Plan (SCP); and
- Tailings and Water Management Structures Plans:
  - Emergency Response and Preparedness Plan (ERPP); and
  - Operations, Maintenance and Surveillance Manual (OMSM).

4.1 Spill Contingency Plan

The SCP provides a framework of responsibilities and response measures to be taken by staff and contractors when responding to spills. In the event of an accidental release of a deleterious substance, the implementation of the SCP will ensure that the necessary steps are taken to minimize the effects on human health and safety and the environment.

The SCP includes the following:

- Roles and responsibilities;
- Listing of products and activities which would require spill response (e.g., handling fuel and hazardous materials);
- Listing of spill response materials and equipment available on site;
- Training requirements;
- Spill containment procedures;
- Spill clean-up procedures;
- Notification and communication procedures;
- Reporting procedures (i.e. to applicable territorial and federal government agencies); and
- Listing of contacts.

4.2 Tailings and Water Management Structures Plans

The Faro Mine Complex is comprised of several tailings and water management structures. As per Canadian Dam Association Dam Safety Guidelines (2007), an Emergency Response and Preparedness Plan (ERPP) and an Operations, Maintenance and Surveillance Manual (OMSM) are required for retaining structures. Summaries of the contents of these documents are presented in the sections below.

4.2.1 Emergency Response and Preparedness Plan

The purpose of the ERPP is to provide a plan that includes mechanisms and processes for addressing potential failures of structures and equipment at the Faro Mine Complex. This ERPP describes the internal processes and procedures that would be undertaken in responding to a failure or potential failure at the site. Having an ERPP in place enables site personnel to be prepared in the event of an emergency. It also provides one component of a comprehensive facility management system for the tailings facility and associated structures. The goals of the ERPP are to firstly prevent the occurrences of emergencies and secondly reduce the impact of emergencies. In both cases the goal is to protect human health and safety, and the environment.

The ERPP includes the following components:

- Roles and responsibilities;
- Identification of a requirement for action (i.e. list of site conditions that necessitate an action under the ERPP);
- Plan activation, notification procedures and contacts; and
- Actions to prevent structure failure.

4.2.2 Operations, Maintenance and Surveillance Manual

This OMSM provides a documented framework for actions in order to ensure the safe operation, maintenance, and surveillance of water containment and conveyance facilities. The OMSM is a living document in that it regularly requires updating; information will be updated at a minimum of once per year, as well as at every change in critical personnel or contractors, and changes in procedures or conditions on-site.
As per the Canadian Dam Association Dam Safety Guidelines (2007), the OMSM includes:

- A site description;
- Operation information including roles and responsibilities, water management and flow control gauging and emergency systems;
- Maintenance information for all major facilities and infrastructure on site; and
- Surveillance information including inspections, instrumentation, response to unusual conditions, and documentation and follow-up.

The site operator is responsible for all on site operations including making immediate decisions required during an emergency, as well as ensuring all documentation is up to date and all procedures of the OMSM are followed. The OMSM specifies the operating procedures during normal, flood or drought, emergency, and unusual conditions.

Maintenance of site facilities is critical for safe and continuous operation as well as to ensure the integrity of the site components. The objectives of the maintenance program are to review and identify maintenance requirements, execute corrective measures, and repair all facility components as required.

The principal objective of the FMC physical structures surveillance program is to identify any conditions of concern (i.e. which could compromise the integrity of the structure) prior to them

becoming a problem. Early identification of those conditions allows issues to be addressed in a timely manner.

The program focuses on three areas of interest:

- Stability and deformation of embankments;
- Thermal conditions within the dams; and
- The quantity and quality of the water to be discharged.

5 Waste Management Plan

The Waste Management Plan (WMP) outlines the handling, containment, storage, transportation, recycling and disposal procedures specific to the different types of hazardous, solid, and special waste materials generated at the Faro Mine Complex (FMC). These procedures comply with current permits and licences as well as applicable territorial and federal legislation. Typical waste materials include:

- Domestic waste;
- Litter;
- Containers, drums, and barrels;
- Scrap metal;
- Tires;
- Treated timber;
- Waste oils and fluids;
- Waste chemicals; and
- Contaminated soils.

The WMP also identifies training requirements, waste characterization and sampling methods, as well as the forms required for documenting waste storage, inspection, transportation and disposal. Additionally, the WMP provides guidelines and practices to mitigate the effects of waste generation; for example:

- Materials will be used efficiently in order to minimize waste generation;
- When possible, materials that are less harmful to the environment will be used;
- Waste materials will be separated as recyclable and non-recyclable; and
- Waste will be handled in such a way to avoid attracting wildlife.

6 Wildlife and Habitat Management Plan

The Wildlife and Habitat Management Plan (WHMP) describes the management approaches and BMPs that are used to prevent and/or minimize adverse effects on wildlife and wildlife habitat, the monitoring and reporting procedures, and the roles and responsibilities of relevant positions. The WHMP provides considerations for all terrestrial, aquatic and riparian wildlife values.

The objectives of this WHMP include the following:

- Identify any activities that have the potential to result in adverse effects to wildlife and wildlife habitat, and describe those effects;
- Provide focused attention on risks to valued, rare and endangered species;
- Identify management approaches and BMPs to avoid and/or minimize potential adverse effects;
- Ensure effects are monitored and management strategies are adapted so as to ensure that mitigation measures are applied and are efficient;
- Ensure that management of wildlife and wildlife habitat are in compliance with territorial and federal legislation.

Examples of the mitigation measures found within the WHMP include:

- On-site communication of wildlife sightings to advise other personnel;
- Assess, delineate and avoid disturbance of habitats of ecological importance;
- Reduce footprint of works to the greatest extent possible;
- Implementation of speed limits to minimize dust and noise, and reduce collisions;
- Implementation of work that considers sensitive time periods (i.e. during the day and periods of the year) and sensitive areas (i.e. migratory routes);
- Remediate newly disturbed areas to the extent practicable (e.g. re-sloping and revegetation);
- Proper food waste disposal procedures (e.g. bear-resistant trash bins); and
- Prohibition against littering and feeding wildlife species.

7 Heritage Resources Management Plan

The Heritage Resources Management Plan (HRMP) assists in ensuring the immediate and ongoing identification, protection, and management of heritage resources at the FMC. This plan presents action items and communication protocols to assist with the orderly and successful management of heritage resources within the FMC.

The protection and management actions include:

- *Flagging and signage of known heritage sites to prevent impacts:*
  This will include making sure each known site is flagged with yellow flagging tape marked "No Work Zone". Signage will be added to each site with clear wording stating "No Disturbance Zone".
- *Creating, placing and reviewing heritage resources warning and information posters on site:*
  A poster will be created and put on display at Faro Mine Complex office reminding staff of the protected status of heritage resources; that known sites are marked (showing the type of flagging and signage used); and what to do in case of chance finds.
- *Heritage resources review of any future ground disturbances:*
  Any proposed ground disturbance activities, in areas that have not been the subject of heritage impact assessment, will be reviewed by heritage assessment staff prior to ground disturbance.
- *Flagging and signage of newly recorded heritage sites to prevent impacts:*
  Sites recorded in the future will be flagged and signed in the same manner as noted above.

The HRMP also provides two communication protocols:

- *Ground disturbing activities protocol:*
  This protocol will be used between equipment operators and the site manager to review areas of planned impacts compared to known heritage resources prior to heavy equipment use.

- *Chance finds protocol:*
  This protocol identifies the steps to take and the information to gather in the event that heritage resources are accidentally discovered during work activities.

The entire staff will be reminded of the protected status of heritage resources and instructed on what to do during each step in the management plan. If sites are planned to be impacted then individual site mitigation plans will be developed and implemented.

8 Occupational Health and Safety Plan

The objective of the Occupational Health and Safety Plan (OHSP) is to protect health and safety, manage risks, and promote safety awareness to all personnel and the public. The OHSP complies with the requirements identified in Yukon Occupational Health & Safety Act and Regulations and describes specific rules, practices, procedures and protocols to be followed by all personnel to mitigate health and safety hazards. The plan also includes all necessary forms, specific to the work being performed.

The OHSP communicates the following responsibilities:

- Work being performed must meet all legislated health and safety requirements;
- Supervisors have the responsibility to provide healthy and safe work conditions and ensure that all employees under their direction are appropriately trained;
- Employees have the responsibility to work safely and to report all unsafe or unhealthy conditions; and
- Contractors are responsible for ensuring they meet legislated health and safety requirements and that the rules, practices, procedures and protocols identified in the OHSP are adhered to.

The OHSP covers the following topics:

- Health and Safety Policy
- Hazard Assessment and Risk Control
- Safe Work Practices
- Safe Job Procedures
- Site Safety Rules
- Personal Protective Equipment
- Preventive Maintenance
- Training and Communication
- Inspections
- Incident Investigation & Reporting
- Emergency Preparedness
- Records and Statistics
- Occupational Health & Hygiene

SECTION 1

Introduction

The Environmental Monitoring, Surveillance, and Reporting Plan (EMSRP) defines the overarching monitoring objectives, monitoring design, and reporting to support the Faro Mine Interim Works (IW). The EMSRP outlines the monitoring for the IW to demonstrate the following:

- The project is executed as proposed and it performs as expected.
- Where performance differs from expectations that any adverse environmental effects are promptly identified and mitigated.
- The terms and conditions set out in the Yukon Environmental and Socio-economic Assessment Act (YESAA) Decision Document and any authorizations (e.g., Water Licence) are met.

The EMSRP outlines the anticipated environmental monitoring and reporting requirements for the Project related to aspects of water quality, meteorology, aquatic environment, wildlife and vegetation. The primary objectives of the environmental monitoring program are as follows:

1. Confirmation Monitoring – Confirmation monitoring is performed to define environmental conditions for comparison with future monitoring efforts. It is also used to describe natural conditions in areas not impacted by mine site operations.
2. Performance Monitoring – Performance monitoring is performed to evaluate the changes in environmental conditions resulting from actions or operations carried out as part of the IW. The monitoring data collected in these areas will support the evaluation of system effectiveness as well as support the design of potential improvements to system operations. Performance monitoring also includes, where applicable, compliance monitoring to determine whether the site operations are meeting conditions set out in the Water Licence.
3. Adaptive Management – adaptive management monitoring is performed to understand how environmental conditions in a particular area are changing, and whether a response is needed to address these changes to be protective of human health and the environment.

In addition, the EMSRP outlines the various components of the Geotechnical Monitoring Program that will be carried out to monitor the safety and integrity of the various physical structures on site including dams, diversions, and dikes.

This initial EMSRP will be updated to incorporate changes arising from of the terms of the YESAA Decision Document and terms and conditions that will be laid out in the Water Licence. The EMSRP is a “living document.” It will be regularly updated on the basis of management review, changes in site conditions, ongoing site investigations or other project related changes. Audits and management reviews of the EMSRP will be carried out annually in conjunction with preparation of the Annual Environmental Monitoring Report (AEMR), and throughout the year, if required. These reviews will provide a mechanism to assess the effectiveness of the various monitoring programs. Additionally, sampling programs may be modified based on evaluation of site wide data quality objectives, and by the specifications of a Quality Assurance Project Plan that is currently under development.

SECTION 2

Water Monitoring Program

2.1 Surface Water Monitoring Programs

Surface water has been extensively monitored at the Faro Mine Complex (FMC) for regulatory compliance, environmental monitoring, and closure planning purposes. Monitoring began during mine operations but has intensified since the cessation of mining activities in 1998. Surface water monitoring will continue to be a key component of the site environmental monitoring program to provide ongoing information for the following:

- Characterization of upstream/background surface water conditions
- Monitoring for changes in water quality and quantity on site that reflect the evolution of source areas within the mine complex
- Monitoring the downstream receiving environment, during the implementation of the project, to minimize impacts to the downstream receiving environment
- Providing for compliance monitoring as per the upcoming Water Licence for the IW
- Providing input to the site Adaptive Management Program (AMP)
- Providing for the ongoing collection of information that is required to support the closure planning process

2.1.1 Water Quality Program and Objectives

The primary objectives of the surface water quality monitoring program can be summarized as follows:

1. Confirmation Monitoring – Confirmation monitoring is performed to define baseline conditions for comparison with future monitoring efforts. It is also used to describe natural water quality conditions in areas not impacted by mine site operations. This type of monitoring will also be used to establish baseline conditions with respect to discharges from the site, specifically whether the discharge of impacted water from any portion of the site is currently resulting in degraded surface water quality.
2. Performance Monitoring – Performance monitoring is performed to evaluate the changes in surface water quality resulting from any action or operation affecting water quality and to confirm compliance with Water Licence effluent limits. This includes not only monitoring at locations internal to the FMC, but also locations in the receiving environment downstream of water management facilities such as the S-Wells Seepage Interception System (S-Well SIS) and the discharge from the Cross Valley Dam (CVD) Pond. The monitoring data collected in these areas will support the evaluation of the effectiveness of site water management systems as well as support the design of potential improvements to system operations.
3. Adaptive Management – Adaptive management monitoring is performed to understand how surface water quality conditions in a particular area are changing, and whether a management or mitigative response is needed to address these changes to be protective of human health and the environment.

The surface water quality monitoring program will consist of monitoring at stations that have been selected for characterization of site water quality based on the following criteria:

- Locations that would best represent conditions unaffected by mine-related disturbances, which are mostly located upstream of the site and provide information on background or reference water quality conditions – Reference
- Locations internal to the FMC that are used to monitor the water quality at key locations within the complex – Internal
- Locations that are used to monitor site discharges and sources of potential contaminant load to the receiving environment – Perimeter
- Locations that are used to monitor the conditions in receiving environment – Receiving

For implementation purposes, the FMC surface water quality monitoring program will continue to be carried out as two separate components: the Routine Water Quality Monitoring Program and the Pelly River Aquatic Monitoring Program. The surface water quality monitoring locations for both the Routine and Pelly Aquatics monitoring programs for the FMC are shown in Figure 5B-1, Figure 5B-2, and Figure 5B-3.

The Routine Water Quality Monitoring Program will be carried out by the contract site operator in accordance with the conditions of the care and maintenance contract. The Routine Water Quality Monitoring Program sample locations are listed in Table 5B-1 for the Faro Mine Area and Table 5B-2 for the Vangorda/Grum Area along with monitoring frequency. Water quality samples collected as part of the Routine Water Quality Monitoring Program will be analyzed for:

- Physical parameters including pH, specific conductance, total suspended solids, total dissolved solids and hardness;
- Anions and cations including ammonia-N, Nitrate-N, sulphate, chloride and alkalinity;
- Total organic carbon and dissolved organic carbon (field filtered) - except at internal stations; and
- Total metals and dissolved metals (field filtered).

At the time of sample collection field parameters will also be taken including pH, conductivity and temperature. In addition to the above water quality sample collection, quarterly toxicity testing, (96-hour LC50 acute toxicity) will be carried out at each of the site discharge locations: X5, X13, and V25BSP.

TABLE 5B-1
Faro Mine Area - Routine Water Quality Monitoring Locations
Faro Mine Interim Works

Station Name	Location Description	Frequency	Purpose
FAROCR	Outlet of Faro Creek Diversion (FCD)	M	Perimeter [a]
FCO	Old Faro Creek, Upstream of Faro Valley Waste Dump	3X	Internal [b]
GDHSECK	Lower Guardhouse Creek (LGC) at Intermediate Impoundment	3X	Internal
NF1	North Fork Rose Creek (NFRC) Site 1, Upstream of North Fork Rock Drain (NFRD)	M	Perimeter
NF2	NFRC Site 2, downstream of NFRD	M	Perimeter
R7	NFRC above FCD	M	Reference [c]
R8	NFRC, 100 metres (m) downstream of confluence with FCD	M	Receiving [d]
R9	NFRC, adjacent to Zone II waste rock dump (WRD)	M	Receiving
R10	NFRC, downstream of Zone II WRD and 100 m downstream of R9	M	Receiving
X2	NFRC, upstream of mine Access Road	M	Receiving

Faro Mine Area - Routine Water Quality Monitoring Locations
Faro Mine Interim Works

Station Name	Location Description	Frequency	Purpose
X22B	Faro Main Pit at Pumping Barge	M	Internal
	Emergency Tailings Area (ETA) combined collection from Pumping System	M	Internal
	ETA Bypass below Collection System	M	Internal
	ID Pond Pumping Barge	M	Internal

Legend

Frequency: SF = spring and fall; M = monthly; WD = weekly when discharging; WD/M = weekly when discharging/monthly otherwise; 3X = three times/year

[a] Perimeter stations are the interface between a mine source area and the external natural environment, where a contaminant may be released from the mine site to the environment.

[b] Internal stations are within the mine source area, and may receive contaminants released from the mine site.

[c] Reference stations are located upstream of the mine source area and reflect pre-mine water quality conditions.

[d] Receiving stations are located downstream of internal and perimeter stations and may receive contaminants released by the mine site.

TABLE 5B-2
Vangorda and Grum Area– Routine Water Quality Monitoring Locations
Faro Mine Interim Works

Station Name	Location Description	Frequency	Purpose
LCD	Little Creek Dam (LCD) Pond at Old Pumphouse	MO	Internal
V1	Vangorda Creek, upstream of Mine and Blind Creek Road	M	Reference
V2	Grum Creek, upstream of confluence Vangorda Creek, Main stem of Grum Creek below Tributary A	2M/M	Perimeter
V2A	Grum Creek, upstream of confluence with Moose Pond, adjacent to Tributary A, downgradient from V15	2M/M	Perimeter
V4	Shrimp Creek, upstream of Vangorda Creek confluence	M	Perimeter
V5	West Fork of Vangorda Creek at Gravel Pit	M	Receiving

V23	Grum Pit at Haul Road	Q	Internal
V24	Influent to Water Treatment Plant	WD	Internal
V25	Effluent from Vangorda WTP Sludge Pond	WD	Internal
V25BSP	Grum Interceptor Ditch below Sheep Pad Ponds	WD/M	Perimeter
V27	Vangorda Creek, just upstream of Shrimp Creek	M	

Legend

Frequency : 2M = twice monthly (May to October); M = monthly; Q = quarterly; WD = weekly when discharging; WD/M : weekly when discharging/monthly otherwise; MO = monthly during open water (May to October); 3X = three times/year

The Pelly River Aquatics Monitoring Program focuses solely on water quality in reference and receiving water locations including far-field locations in the Anvil/Rose Creek systems as well as the Pelly River. In addition, it includes locations that have been previously identified as potential sources of drinking and/or tea water by local First Nations. The majority of the monitoring locations in the Pelly River Aquatics Monitoring Program will continue to be sampled three times per year: spring, summer and fall, representing the three distinct flow conditions during the year (i.e., winter low flow, spring freshet and summer/fall). Exceptions include stations VW1, VW3, VGMAIN, V8, R4, R5, and A1, which will be sampled monthly. The program sample locations are listed in Table 5B-3.

TABLE 5B-3
Pelly Aquatic Monitoring Program - Water Quality Monitoring Locations
Faro Mine Interim Works

Station Name	Location Description	Frequency	Purpose
V8	Lower Vangorda Creek at the footbridge	M	Receiving
V17A	Creek from Grum Ore Transfer Pad	3X	Receiving
V20A	Dixon Creek upstream of mine workings	3X	Reference
VR	West Fork Vangorda Creek upstream of Haul Road	3X	Reference
VGMAIN	Main Fork Vangorda Creek downstream of mine but upstream of West Fork Vangorda Creek	M	Receiving
VW1	West Fork Vangorda downstream of landslide but upstream of VW2	M	Receiving
VW2	Tributary to West Fork Vangorda Creek which drains Grum west lobe	3X	Receiving
VW3	West Fork of Vangorda downstream of AEX Creek	M	Receiving
FC	Faro Creek above Diversion	3X	Reference

R4	Rose Creek upstream of confluence with Anvil Creek	M	Receiving
R5	Anvil Creek downstream of Rose Creek after full mixing	M	Receiving
R6	Anvil Creek upstream of Rose Creek	3X	Receiving
W10	Upper Guardhouse Creek upstream of Northwest WRD	3X	Reference
X14	Rose Creek downstream of the Rose Creek Diversion	3X	Receiving
NWID	Northwest Interceptor Ditch upstream of diversion point	3X	Receiving
USFR	SFRC upstream of Haul Road	3X	Reference
Grum Corner (GCULV)	SFRC downstream of Haul Road and upstream of mine Access Road	3X	Other
K8	Reservoir Creek upstream of Mine Access Road	3X	Other
A1	Anvil Creek near confluence with Pelly River	M	Receiving
P1	Pelly River upstream of Vangorda Creek	3X	Reference
P4	Pelly River downstream of Anvil Creek	3X	Receiving

Legend

Frequency: M = monthly; 3X = three times/year during winter low flow, spring freshet, and summer/fall

Water quality samples collected as part of the Pelly River Aquatics Monitoring Program and the Routine Water Quality Monitoring Program will be taken on the same day, or within the same few days. All sampling and analysis will be conducted in accordance with the current edition of “Standard Methods for the Examination of Water and

Waste Water" and all samples will be analyzed by the same external accredited laboratory for the same suite of parameters. Quality assurance/quality control (QA/QC) samples will be collected as specified in the site quality assurance project plan. This will include the use of field blanks, trip blanks, equipment blanks, duplicate samples and split samples.

2.1.2 Hydrology Monitoring Program and Objectives

The existing Hydrology Monitoring Program will be expanded during the IW period as current records of continuous flow monitoring data for many monitoring sites are limited and the dates of record are not consistent among the various sites. Upgrades of a number of the existing hydrometric stations, as well as the installation of several new stations are required.

The objectives of the expanded Hydrology Monitoring Program are to expand the ongoing flow monitoring network in order to support water balance and water quality modeling studies and to assist in planning of hydraulic facility upgrades, water management design, and fish habitat compensation planning.

2.1.2.1 Hydrology Monitoring Program

The Hydrology Monitoring Program during the IW period will focus on collecting continuous streamflow data in (1) the Rose Creek catchment, which contains the Faro Mine Area, and (2) the Vangorda Creek catchment, which contains the Vangorda/Grum Area. This will be achieved by maintaining a number of the automated hydrometric stations and establishing up to three new stations. The final number of existing stations that will be maintained and new stations to be installed will be selected to provide sufficient hydrological characterization of the FMC areas potentially impacted by the IW activities. All hydrometric stations will be established or upgraded in accordance with accepted standardized practices and procedures, as outlined by the British Columbia Resource and Inventory Standards Committee (RISC) (BC Ministry of the Environment, 2009).

At each installed station, water surface elevation and barometric pressure data will be measured at fifteen minute intervals by automatic dataloggers. Solinst Barologger and Levelogger series (Gold and Edge models) will be installed to ensure consistency among the existing and new stations and the hydrologist will calibrate dataloggers and equipment. Discharge measurements will be conducted during routine site visits as well as during special visits to cover hydrologic extremes (i.e., baseflow to high event flow). Discharge measurements at the hydrometric stations will be performed using the velocity-area method using instantaneous velocity meters. The hydrologist will perform discharge measurements in accordance with RISC standards to ensure high accuracy data collection. Rating curves correlating stage and discharge will be will be developed for all hydrometric stations based on these measurements.

During each site visit the hydrologist will perform the following tasks:

- Maintain flow monitoring stations and data collection equipment at least monthly to confirm that no damage has occurred to the equipment and that the site is free of obstructions or other factors that would negatively impact the collection of flow data.
- Download surface water elevation data from the dataloggers and verify performance of the dataloggers
- Perform discharge measurements
- Record gauge heights and perform bench mark surveys to verify staff gauge elevations and calibrate gauging instrumentation

Hydrology monitoring will occur at the frequencies summarized in Tables 5B-4 through 5B-6.

The existing hydrometric station locations in the Faro Mine Area – Rose Creek catchment are summarized in Table 5B-4 and shown on Figure 5B-2. The existing hydrometric station locations in the Vangorda/Grum Mine Area – Vangorda Creek catchment are summarized in Table 5B-5 and shown in Figure 5B-3. Potential new hydrometric station locations in the Faro Mine Area and in the Vangorda/Grum Mine Area are summarized in Table 5B-6 and shown on Figures 5B-2 and 3.

[a] Continuous: level logger with continuous water level elevation and routine spot-flow measurements. All other spot-flow measurements taken on the noted frequency.

2.1.2.2 Data Assessment and Reporting

Following site visits, the hydrologist will:

- QA/QC and post-process downloaded flow data and compile the data in Excel format.
- Extend the existing stage-discharge rating curve (if applicable depending on station configuration) for flows/stages that exceed maximum flow recorded at station to date.

In addition, a hydrology summary report, including updated stage-discharge curves and hydrographs, will be prepared for each station to be included in the AEMR.

2.1.3 Pit and Pond Water Levels Monitoring Program and Objectives

Monitoring of the pit and pond water levels plays an integral part of the water management at the FMC. As part of the Routine Monitoring Program, pit and pond water levels will continue to be measured at the following

locations as per the frequency listed in Table 5B-7: Faro Pit, Zone II Pit, ID Pond, CVP, Grum Pit, Vangorda Pit, LCD Pond, Moose Pond and the Grum Sulphide Cell (GSC) Pond.

TABLE 5B-7
Faro Mine Complex Pit and Pond Water Level Monitoring Table
Faro Mine Interim Works

Location	Frequency
Faro Pit	Continuous
Zone II Pit	Continuous
ID Pond	Continuous
CVD Pond	Monthly
Grum Pit	Monthly
Vangorda Pit	Continuous
LCD Pond	Continuous
Moose Pond	Twice/month
GSC Pond	After peak run-off events

2.1.4 Reporting

The results of the Routine Monitoring Programs will be summarized in the monthly site reports including water quality monitoring data, flow monitoring data and pit and pond water levels. A full detailed report of the surface water monitoring program will be included in the AEMR. Reporting for the Pelly River Aquatic Monitoring Program will consist of detailed field reports to be submitted following each sampling event that will include a full description of site conditions, water quality results, assessment and interpretation of the results.

2.2 Groundwater Monitoring Program

The purpose of the groundwater monitoring program for the FMC is to provide information for the following:

- Identify areas where impacted groundwater quality may represent a threat to surface water quality
- Monitor for changes in groundwater quality that reflect the evolution of source areas within the mine complex
- Improve understanding of the background groundwater quality in the vicinity of the FMC

2.2.1 Groundwater Monitoring Program Objectives

The primary objectives of the monitoring program include confirmation monitoring, performance monitoring, and adaptive management. Each of these objectives is described as follows:

- Confirmation Monitoring - Confirmation monitoring is performed to define baseline conditions for comparison with future monitoring efforts. It is also used to describe natural groundwater conditions in areas not impacted by mine site operations. This type of monitoring will also be used to establish baseline conditions with respect to surface water/groundwater interaction, specifically whether the discharge of impacted groundwater in any portion of the site is currently resulting in degraded surface water quality.
- Performance Monitoring - Performance monitoring is performed to evaluate the changes in groundwater quality resulting from the operation of any seepage interception system or other actions that may affect groundwater quality (such as surface water diversions or other mitigative measures). Currently at the FMC, the primary systems that will undergo performance monitoring are the ETA SIS and the S-Wells SIS. The operation of these systems has a direct impact on groundwater quality in the vicinity of the seepage interception systems and monitoring data collected in these areas will support the evaluation of system effectiveness as well as support the design of potential improvements to system operations.

- Adaptive Management - Adaptive management monitoring is performed to assess changes in groundwater conditions in a particular area, and whether a response is needed to address changes to be protective of human health or the environment. The process of adaptive management focuses on identifying potential sources of contamination that may evolve in the future as site conditions and contaminant transport change. At the FMC, this process generally involves the following:
  - Evaluation of evolving geochemical conditions within the waste rock dumps and ore piles
  - Forecasting the rate at which the neutralizing effect of the waste rock is degrading
  - Predicting if and when acid and metals generating reactions will become predominant

Once these chemical reactions become predominant, the mass flux from the source areas significantly increase, and the likelihood of increased areas of groundwater quality degradation downgradient of these sources greatly increases.

In adaptive management monitoring, the goal is to identify the likely pathways between these evolving contaminant sources and potential receptors, and collect groundwater monitoring data along these pathways to provide early warning of potential contaminant movement. In addition, the necessary data are collected to develop response strategies to effectively address the environmental threats.

2.2.2 Groundwater Monitoring Program

The proposed groundwater quality monitoring program consists of the routine monitoring of approximately 120 monitoring wells throughout the FMC (Figures 5B-4 and 5B-5). These monitoring wells are summarized in Table 5B-8. Also provided in Table 5B-8 is the general area where each of these wells are located and the recommended frequency for monitoring.

TABLE 5B-8
Faro Mine Complex Groundwater Quality Monitoring Wells
Faro Mine Interim Works

General Area	Approximate Number of Wells
CVD Area	12
ETA	8
Faro Rock Dumps	3
Grum Mine Area	9
ID	
Intermediate Impoundment	5
Mill Building Area	5
Original Impoundment	2
Second Impoundment	7
PumpHouse Pond	7
S-Wells	2
Toe Grum Dump	26
Toe North East Dump	3
Vangorda Mine Area	6
Zone II Outwash	13
Upper NFRC	10

All groundwater samples collected under this program will be analysed for the following parameters by an accredited external laboratory:

- Dissolved metals (field filtered)
- Unfiltered free cyanide
- Acidity
- Ferrous iron
- General chemistry parameters
  - Alkalinity (including calculated carbonate and bicarbonate) on samples with pH >4.5
  - Anions (sulphate, chloride, fluoride, nitrate, nitrite, and ortho-phosphate)
  - Ammonia-N
  - Dissolved organic carbon (DOC)
  - Total suspended solids (TSS)
  - Total dissolved solids (TDS)
- Field parameters
  - Time and date
  - Flow (sample pumping rate), purge volume, purge time
  - Water level depth (elevation)
  - Temperature, pH (temperature corrected), conductivity, dissolved oxygen (DO), oxygenation reduction potential (ORP), and turbidity using a YSI water quality meter and probe, calibrated daily

The proposed program was developed based on the current groundwater monitoring program at the FMC. As the remediation program proceeds, additional monitoring wells will be installed to fill critical data gaps that are identified. All new monitoring wells should be added to the groundwater monitoring program and sampled on a bi-annual basis for a 5-year period. These data are necessary to establish baseline groundwater quality conditions in the vicinity of each of the monitoring locations. After five years of data has been collected, the data set should be reviewed to determine whether the monitoring frequency should be modified for future monitoring activities.

2.3 Reporting

An annual groundwater monitoring report will be prepared and will present summarized observations, interpretation of analytical results and field data. This report will also include trend analysis, and associated conclusions and recommendations for the following year's sampling program. This report will be included as part of the AEMR.

SECTION 3

Seep Monitoring Program

A Seep Monitoring Program will be carried out at the FMC to continue the ongoing collection and data analysis of seeps from the Faro Mine Area, RCTA, and the Vangorda/Grum Area. Seep monitoring is critical to understanding the geochemical conditions at the FMC and it provides valuable data to measure changes in the geochemical conditions of the WRDs and tailings. This program will continue to include waste dump and pit seep monitoring, as well as seep monitoring in the RCTA and the ETA.

3.1 Seep Monitoring Program Objectives

The primary objectives of the Seep Monitoring Program are summarized as follows:

- To compare collected seep data with historical seep data and augment data gaps in the site seep data records
- To evaluate changes in the seepage chemistry which may indicate the evolution of source areas within the FMC with respect to acid rock drainage (ARD) and metal leaching (ML)
- To provide input to the site AMP
- To support ongoing assessment of geochemical characteristics (ARD/ML) of waste rock and tailings material
- To support ongoing development of the site-wide geochemical loading models in support of the closure planning process

3.2 Seep Monitoring Program

The Seep Monitoring Program covers the collection and data analysis of groundwater seepage (seeps) from the Faro Mine Area, RCTA, and Vangorda/Grum Area. Additional sampling including groundwater quality, geochemical testing of waste rock and tailings solids, soil, tailings pore water, and soil gas monitoring required to support development of the site-wide geochemical loading models for closure, will continue to be carried out under separate programs as part of the broader closure planning process.

Overall, the Seep Monitoring Program will consist of the following elements:

- Annual spring and fall seep monitoring within and around the waste dumps, pits, ETA, and RCTA, during which approximately 160 sites will be visited, observed, and measured for field parameters, if water is flowing. A subset of approximately 60 of these sites will be sampled for laboratory analysis. While conducting the seep surveys, sample collection for laboratory analysis will be added for any locations where field parameter measurements reveal significant changes in pH or conductivity compared to historical averages.
- New sampling stations will be established where water is observed flowing or can be inferred to have been flowing based on observations of moisture along flow paths or based on ponded water surfaces that were at the elevation of pond spill points.
- Fall sampling of boat accessible pit seeps where approximately 25 boat-access seeps will be visited. It is anticipated that field parameters and laboratory samples will be collected from approximately 10 locations.
- Routine monitoring as part of the Routine Monitoring program carried out by the contract site operator, of key sample locations around the site. These locations are monitored more frequently than the spring/fall seep program. Timing of the sampling of these sites by the site contractor during spring and fall will be tied to the broader Seep Monitoring Program to ensure consistency.

Foot-accessible seeps will be sampled twice per year, once during spring freshet and once in the late summer dry season. The spring seep sampling event will be performed after approximately 90 percent of the snow cover on the site has melted, and just prior to peak flow within the Pelly River. The fall seep sampling event will be conducted in September when the groundwater table is lower and ground conditions are thawed, in order to determine which seeps are flowing, compared to the snapshot provided during the spring event. While there are

no specific triggers for the exact timing of the fall sampling event in September, sampling should be conducted during low groundwater conditions as inferred from onsite monitoring well groundwater elevation data, and sampling should be timed during a dry period without excessive rain preceding or during sampling.

- Approximately 160 established foot accessible seep stations will be targeted for monitoring. These seep locations will be visited during the spring and fall sampling events, and field parameter measurements will be collected from every location found flowing. Observations of dry seeps and snow-covered locations will be recorded. Samples will be collected for laboratory analysis from a smaller subset of the seeps found flowing. A total of approximately 60 seeps are targeted for analytical sampling. An additional 20 bottle sets will be available during each sampling event to allow discretionary sampling of additional locations.
- Approximately 25 established boat-accessible pit seeps will be targeted for monitoring once per year in the fall, concurrent with the foot-accessible fall seep sampling event. Field parameter measurements and laboratory analysis samples will be collected from every location found flowing. Observations of dry seeps will be recorded.

The following is a list of field parameters that will be collected at each location:

- Time and date
- Seep flow rate
- Temperature, pH (temperature corrected), conductivity, DO, and ORP, using a YSI water quality meter and probe, calibrated daily
- Photographs of each site, capturing both general site appearance and close-up images of seepage flow paths
- Coordinates captured using a handheld global positioning system (GPS) unit
- Observations of precipitates, staining, or algae growth within seepage streams, and colour of water
- Observations of existing flagging marking the location
- Description of flowpath, including emergence point and downstream flow direction
- Observations of any other seepage sampling stations that lie along the same flowpath

Samples will be collected and sent for analysis at an accredited external laboratory for the following parameters:

- General chemistry parameters
  - Alkalinity (including calculated carbonate and bicarbonate) on samples with pH > 4.5
  - Anions (sulphate, chloride, fluoride, and nitrate and nitrite, ortho-phosphate)
  - Ammonia-N
  - DOC
  - TSS
  - TDS
- Dissolved metals (field filtered)
- Unfiltered free cyanide (only sampled for seeps flowing to receiving environment)
- Acidity
- Ferrous iron

Care will be taken during sampling to minimize sample turbidity and the collection of extraneous sediment and debris. Samples will be assigned a unique identification number, and QA/QC samples will be collected as specified in the site quality assurance project plan.

3.3 Reporting

An annual seepage monitoring report will be prepared and will present summarized observations, interpretation of analytical results and field data. This report will also include trend analysis, and associated conclusions and recommendations for the following year's sampling program. This report will be included as part of the AEMR.

SECTION 4

Meteorological Monitoring Program

Two onsite meteorological stations were established at the FMC on the Faro and Grum waste dump sites in December of 2003. The Faro Dump meteorological station is located close to the Main Dump, at an elevation of 1,200 metres above sea level. The Grum Dump meteorological station was located on the Grum Waste Dump before June 2010, at an elevation of 1,250 metres above sea level. To accommodate the GSC cover project, the station was moved on June 21, 2010, to a former gravel pit, located north of Grum overburden vegetation trials. When the Grum meteorological station was moved, efforts were made to verify that the station was installed at a similar location, elevation, and soil type to where it had been previously. Soil temperature, moisture, and heat flux sensors were reinstalled at the same depths as where they had been. The locations of the onsite meteorological stations are shown in Figure 5B-6.

4.1 Meteorological Monitoring Program Objectives

The objectives of the Meteorological Monitoring Program are to collect meteorological data required to support ongoing characterization of the meteorological conditions at the FMC, as well as to provide the required data to support the ongoing characterization of the hydrological environment and site water balance.

4.2 Meteorological Monitoring Program

The Faro Dump and Grum Waste Dump meteorological stations sensors measure the following climate parameters:

- Temperature
- Relative humidity
- Wind speed
- Wind direction
- Soil moisture
- Soil temperature (at two depths)
- Soil heat flux
- Net radiation
- Albedo
- Solar radiation (incoming)
- Snow depth
- Precipitation

Snow surveys will also be carried out at various locations around the site to provide valuable input to site water management.

Averages of sensor measurements taken every 5 seconds are logged on an hourly basis and meteorological station data are downloaded on a monthly basis. Maintenance of the meteorological stations will be carried out monthly to confirm that all instruments are functioning properly. Meteorological stations probes will be routinely calibrated as per manufacturers' specifications and non-functioning components will be replaced as required.

4.3 Reporting

Data collected from the meteorological stations will be used to report the monthly and annual climatic conditions observed at each station. Each month the downloaded data will undergo QA/QC, as well as post-processing, and will be summarized in the monthly site reports. A full report of the site meteorological data will be included in the AEMR.

SECTION 5

Geotechnical/Physical Monitoring Program

Regular monitoring of site earth structures is a critical component of the site operations activities during the IW. Inspections will continue to be carried out on most site earth structures which include, but are not limited to, the following structures:

- Faro Mine Area: CVD, ID, Secondary Dam, RCD, FCD, NWID, North Fork Rock Drain, K8 Rock Drain, and Faro Pit Slopes
- Vangorda/Grum Area: Vangorda Waste Dump (including seepage collection system), LCD, Vangorda Creek Diversion (VCD), Vangorda WTP Clarification Pond, Grum Overburden Dump and revegetation trials, Grum Settling Pond, V-15 Seepage Collection System and Moose Pond, Grum Interceptor Ditch, SPP, Vangorda Pit Slopes, Grum Pit Slopes, GSC Cover, and GSC Pond

5.1 Geotechnical/Physical Monitoring Program Objectives

The objectives of the Geotechnical/Physical Monitoring Program are to identify problems or potential problems with the earth structures on-site so that appropriate actions can be taken to address risks to human health and the environment.

5.2 Geotechnical/Physical Monitoring Program

The site Geotechnical/Physical Monitoring Program is divided into two main components: routine or operational inspections and formal geotechnical inspections/monitoring program. Routine or operational inspections are performed by site personnel and undertaken at least once a week. The formal geotechnical inspection/monitoring program, currently conducted annually by a qualified geotechnical engineer, will continue during the IW.

5.2.1 Operation Inspections

Routine operational inspections will be carried out to provide observations of site facilities. Weekly inspections will be carried out to provide observations of critical facilities to ensure that unusual or emergency events can be managed in a timely fashion. Monthly inspections will be performed in addition to weekly inspections and will entail more in-depth inspections of the earth dams and dykes as well as routine inspection of several other facilities not included in the weekly schedule. In addition, many of the facilities will undergo more frequent inspection particularly during spring freshet and during periods of active pumping, conveyance and treatment of water.

The routine environmental inspections will be typically performed and documented by the site environmental personnel. However, they may be performed and documented by any person working under the direction of the site manager who is reasonably knowledgeable regarding the environmental and geotechnical aspects of the site. Results of the inspections will be documented and where applicable any concerns noted and brought to the attention of the site manager.

Field-based site personnel will be trained to identify and document any potential hazards, damage or concerns. The site Operations, Maintenance, and Surveillance Manual (OMSM) will include detailed information and specific requirements and forms for these operational inspections. The results of the routine inspections will be documented in the monthly site reports and the AEMR.

Table 5B-9 and 5B-10 present a summary of the proposed weekly and monthly inspections for the Faro Mine Area. Tables 5B-11 and 5B-12 present a similar summary for the Vangorda/Grum Mine Area.

TABLE 5B-9
Faro Mine Area – Weekly Inspection Protocol
Faro Mine Interim Works

Facility	Monitoring Activity
CVD and CVD Pond	• Observe from the roads on the north and south and west (downstream) sides. • Is the pond water level acceptable? • Are the spillway and syphons functioning appropriately? • Does the dam appear stable (i.e., is there erosion, cracking, bulging, wet spots)? • Does seepage appear “normal” (three streams)?
ID and ID Pond	• Observe from the roads on the north and south sides. • Is the pond water level acceptable? • Are the spillway and syphons functioning appropriately? • Is the lime treatment system functioning appropriately? Any visible damage? • Does the dam appear stable (i.e., is there erosion, cracking, bulging, wet spots)?
Secondary Dam (Intermediate Dam access road)	• Observe road condition
RCD	• Drive length of channel including lower section and observe dike, backslope and bottom. • Is any cracking or sloughing visible along backslope? • Is any significant erosion or are any significant depressions apparent in the dike? • Is water channeling appropriately?
NWID	• Is any cracking or sloughing visible? • Is any significant erosion or are any significant depressions apparent? • Is water channeling appropriately?
West Valley Interceptor Ditch	• Is any cracking or sloughing visible? • Is any significant erosion or are any significant depressions apparent? • Is water channeling appropriately?
FCD	• Is any cracking or sloughing visible? • Is any significant erosion or are any significant depressions apparent? • Is water channeling appropriately?
North Fork Rock Drain	• Observe the rock drain from the edges of the Haul Road. • Is there any sloughing on the upstream and downstream faces? • Does the pond on the upstream side of the drain appear acceptable/normal?
K8 Rock Drain	• Observe the rock drain from the edges of the Haul Road. • Does the pond on the upstream side of the drain appear acceptable/normal? • Are flows passing normally? • Is there any accumulated sediment or debris?
Faro Pit Slope Instability Zones	• Observe the pit and pumping station from the pumping station. • Does the pit north east wall appear “normal”? • Does the inflow via the Faro Valley rock dump appear “normal”? • Is the pumping station functioning appropriately? • Is there any physical damage visible to the pumping barge or pipeline?
Faro and Zone II Pits	• Measure and record in-pit water levels.

TABLE 5B-10
Faro Mine Area – Monthly Inspection Protocol
Faro Mine Interim Works

Facility	Monitoring Activity
ID and CVD	• Perform detailed inspection of crests and toes by driving and/or walking each. • Note any significant cracking, erosion, sloughing, etc. • Record seepage flow estimates or weir staff gauge readings and pond levels. • Record any significant observations.
FCD	• Drive the length of the diversion at least as far upstream as the Faro Valley Waste Dump. • Is water flow channeling appropriately (i.e., flow over top of ice, ice jam)? • Is leakage from the channel excessive or visibly increased? • Are there visible indications of increased wall instability along the crest of the north east pit wall?

TABLE 5B-11
Vangorda/Grum Mine Area – Weekly Inspection Protocol
Faro Mine Interim Works

Facility	Monitoring Activity
Vangorda Waste Dump and Seepage Collection Systems	• Is any cracking or sloughing visible? • Is any significant erosion or are any significant depressions apparent? • Is water channeling appropriately?
LCD and Pond	• Drive the crest of the dam. • Is the pond level appropriate/ acceptable? • Does the dam appear stable (i.e., is there erosion, cracking, bulging, wet spots)? • Is there any visible damage to the pumphouse?
VCD	• Drive along the diversion flume. • Is the flume performing acceptably? • Is water channeling appropriately (i.e. flow over top of ice, ice jam)? • Are there signs of excessive or new damage or deformation to the flume or channel? • Are there signs of instability of the rock and soil slopes overlooking the flume?
Vangorda WTP and Clarification Pond Embankments	• Observe the Vangorda WTP Clarification Pond dike from the Blind Creek road and drive around the treatment plant. • Is the water level in the Clarification Pond acceptable? • Are the plant building and storage sheds secure? • Does the dike appear stable (i.e., is there erosion, cracking, bulging, wet spots)?
Grum Overburden Dump and Re-Vegetation Trials	• What is the condition of the sludge storage cell? • Is any significant erosion?
Grum Settling Pond	• Drive to and/or around the pond. • Is the water level acceptable? • Does the dike appear stable (i.e., is there erosion, cracking, bulging, wet spots)?
Moose Pond and V15 and Grum Creek Seepage Collection System	• Drive to the collection system and pond. • Is there any accumulated water? • Is inflow water channeling appropriately? • Are the pond water levels acceptable? • Is there any visible seepage coming out of the pond? • What is the condition of the pond wall? • Is there any ice or sediment build-up?

TABLE 5B-11
Vangorda/Grum Mine Area – Weekly Inspection Protocol
Faro Mine Interim Works

Facility	Monitoring Activity
Grum Interceptor Ditch	• Is any cracking or sloughing visible? • Is any significant erosion or are any significant depressions apparent? • Is water channeling appropriately?
SPP	• Observe the ponds from the haul road or drive onto the pond dikes. • Are the pond water levels acceptable? • Do the dikes appear stable (i.e., is there erosion, cracking, bulging, wet spots)? • Is the outflow channeling appropriately? (viewed from the road above the plunge pool) • Monitor erosion from Grum Overburden Dump
Grum Pit Wall Instability	• Observe the pit walls • Do the pit walls appear 'normal" or is there a notable change to their conditions?
Grum and Vangorda Pits	• Record estimates of water levels and other significant observations.

TABLE 5B-12
Vangorda/Grum Mine Site Area – Monthly Inspection Protocol
Faro Mine Interim Works

Facility	Monitoring Activity
Vangorda Waste Dump	• Drive to the toe of the dump. • Do the till berm and rock benches appear stable and secure?
Vangorda Creek Diversion	• Is the inlet to the culvert at the upstream end of the flume performing acceptably? • Is the outflow structure at the downstream end of the flume performing acceptably?
SPP, LCD and Pond, and Grum Settling Pond	• Estimate and record the pond water levels. • Inspect the crests and toes of the dam/dikes for signs of deterioration and document any seepage observed.
Grum Creek and Moose Pond	• Inspect the Moose Pond diversion. Is water channeling appropriately? • Is the Grum Creek road crossing functioning acceptably? • Is any water accumulating in the Moose Pond?

5.2.2 Formal Geotechnical Monitoring Program

An annual Geotechnical Monitoring Program will be carried out at the FMC that comprises the following components:

1. Two site visits by a professional engineer: (1) spring during freshet (geotechnical) and (2) fall (geotechnical and hydrotechnical) during low flow conditions, to examine and note site conditions. Observations and recommendations will be provided in a technical memo in the AEMR.
2. Monthly reporting (or as needed) to provide analysis of monitoring data collected by site staff with recommendations if issues noted.
3. Inspection of the following structures:
   - Faro Mine Area: CVD, ID, FCD, RCD, Faro Pit, and Zone II Pit.
   - Vangorda/Grum Area: Vangorda Waste Dump (including seepage collection system), LCD, VCD, SPP, Grum Creek and Moose Pond, Grum Settling Pond, and Vangorda and Grum Pits.

4. Preparation and submission of an Annual Geotechnical Inspection report in February of each year for submission to Government of Yukon.
5. Update of the Emergency Response Plan and OMSM for the various site structures as required.
6. Recommendations on frequency and sites to be incorporated into the geotechnical monitoring program.

In the Faro Mine Area, the following are the key components of the inspections program for each of the key facilities: CVD and Spillway, ID and Spillway, NWID, FCD, K8 and NFRD, RCD, RCD dike and back slope, and the toe of the slope along the RCD at pond elevation. The following specific items will be addressed, for each:

- CVD and Spillway
  - Inspect dam crest during the first visit (looking for longitudinal crack found in previous years) and inspect crest again during the fall visit (after crest has been re-graded in spring/summer to minimize surface water infiltration).
- ID and Spillway
  - Inspect and assess soil erosion conditions on the downstream slope of the ID during both visits. Provide recommendations for delineation of existing erosion and a program to monitor for potential change in slope conditions.
  - Measure sediment deposition over drainage measures on lower bench.
  - Inspect upstream slope for potential soil erosion of poorly armored shell material below rip rap surface and rip rap degradation (likely during fall visit when the water level of the pond is low). Check if wave or ice action is damaging dam and recommend corrective measures.
- NWID
  - Inspect sedimentation, ponding and gradients along entire length of channel. Toe erosion has been noted along the channel side slopes of the upper portion of the channel; assess and provide recommendations with regards to channel gradient.
  - Assess vegetation conditions in middle and lower portion of NVWID and provide recommendations.
- RCD
  - Inspect channel during peak flow conditions, noting performance after 2010 vegetation removal activities.
  - Note seepage from RCD to tailings impoundment area.
  - Reading of geotechnical instrumentation including, thermisters, piezometers, and slope indicators.
- Secondary Dam
  - Inspect the crest and side slopes of the Secondary Dam. The concentration will be on the areas adjacent to the NFRCD and the RCD.
- FCD
  - Inspect the condition of the diversion above the Faro Pit – particularly the overburden-bedrock interface - for identification of possible deteriorating performance or seepage from under the diversion that could undermine the Faro Pit wall and contribute to instabilities. Additionally, look for sloughing due to permafrost degradation. Exposed geotextile/bentomat liners in the diversion will be covered with rock armour. Any damaged geotextile/bentomat will be replaced prior to rock armour placement.
- Faro Pit Instability
  - Inspect the north and south instability zones to determine if significant recession or degradation of slope has occurred. This will include on-going monitoring of the instrumentation along the northeast Pit wall:

nine reference bars to monitoring pit wall regression and nine prisms to monitor pit wall movements. Provide recommendations for on-going monitoring and/or remediation.

In the Vangorda/Grum Area, inspections will cover the following: Vangorda WRD (including seepage collection system), LCD, VCD, Clarification Pond Embankments at the WTP, Grum Overburden Dump and revegetation trials, Grum Settling Pond, V-15 Seepage Collection System and Moose Pond, Grum Interceptor Ditch, Grum and Vangorda pit walls, and the SPP below the Grum Overburden Pile. The following specific items will be addressed, for each:

- Vangorda WRD
  - Inspect transverse drains, seepage collection channel, till starter dike, and rock pile, and note areas of sediment build-up in weirs and collection channel (particularly in upper reaches).
  - Inspect till starter dike for signs of instability, erosion gullies, subsidence, seepage, or salt deposition.
  - Inspect rock pile and note condition of old tension cracks.
- LCD
  - Inspect upstream and downstream slopes of the dam for erosion rill evolution.
  - Inspect downstream cracks at the end of the spillway outfall channel.
- VCD
  - Inspect freshet performance of channel during spring visit, noting any damage to the flume and cross braces as well as excessive seepage.
- Grum Pit Instability
  - Inspect the east wall slope instability zone of the Grum Pit to determine if recession or degradation of slope has occurred. Provide recommendations for ongoing monitoring and/or remediation.
  - Observe new cracks and ground deformation near reference rods.
- Moose Pond
  - Inspect the downstream slope of the retaining esker and ridge.

Generally, the engineer will make a visual assessment of the facilities; measurements and reading of instrumentation will not typically be carried out unless the engineer notes an unusual condition. Following the spring site visit, a *Summary of Recommendations Memo* will be prepared and reviewed with site staff so that recommendations on maintenance are conveyed immediately and directly to those responsible for the work.

5.2.2.1 Input, Review and Interpretation of Monitoring Data

The FMC has a number of instruments that are used to monitor the various structures at the site, including the following:

- 23 instruments in the ID, 14 of which are standpipes and 9 are pneumatic piezometers
- 15 instruments in the CVD, 10 of which are standpipes and 5 are pneumatic piezometers
- 13 instruments (pneumatic piezometers) in the RCD Dike monitoring the water levels and 8 slope indicators monitoring the stability of the area
- 6 piezometers in LCD measuring water level

Site staff will collect the required instrumentation readings for all instruments identified in the annual monitoring program. These instruments in the ID and CVD will be read three times a year, and those in the RCD Dike and LCD will be read bi-annually.

Monitoring data collected by site staff will include data from piezometer, thermistor, slope inclinometer, flow rate data, staff gauge, and pond water levels (CVP and ID Pond). All data will be provided to the engineer at the time of the site inspection and all subsequent data will be compiled by site personnel and then forwarded to the engineer. It is expected that the engineer will review data updates and provide commentary on any concerns that are noted. The engineer will provide a review of the frequency and sites involved in the geotechnical monitoring program and will make recommendations regarding revisions.

If required, the engineer will also update geotechnical stability analysis of the ID or other structures based on current conditions, including downstream slope and operating water levels.

5.2.2.2 Annual Geotechnical Performance Report

An Annual Geotechnical Performance Report will be prepared for inclusion into the AEMR. The annual inspection report will comprise the following information and be sealed by a professional engineer:

1. A written report detailing the inspection and interpretation of instrumentation data
2. Assembled instrumentation monitoring data and related plots
3. Recommendations regarding the monitoring season, including site inspections, surveys of structures, and monitoring of instrumentation

5.2.3 Third-party Dam Safety Reviews

According to the Canadian Dam Safety Guidelines (CDA, 2007), both the ID and the CVD will be due for their third-party safety review in 2014 because of their classification as “high” risk dams. This review will be carried out as part of the annual program in 2014. Future Dam Safety Reviews will be conducted in accordance with the frequency and guidance described in the Dam Safety Guidelines.

SECTION 6

Aquatic Environment Monitoring Program

The AEMP will be harmonized and integrated as much as possible with the Water Monitoring Program described in Section 2.1. Specifically the surface water quality and flow monitoring component of the AEMP will be covered by the Routine Monitoring Program and Pelly Aquatics Monitoring Program.

6.1 Aquatic Environment Monitoring Program Objectives

The objectives of the Aquatic Environment Monitoring Program are to assess the chemical and biological condition of the aquatic environments receiving mine drainage. The AEMP will integrate biological and chemical information for a weight of evidence approach. The following components of the FMC will be monitored:

- Surface water quality and flow
- Benthic invertebrate community monitoring
- Fish community and population assessment

6.2 Aquatic Environment Monitoring Program

6.2.1 Surface Water Quality and Flow

As part of the Pelly Aquatic Monitoring Program, water quality monitoring will be carried out at mine-exposed stations (V8, V17A, V20A, VGMAIN, VW1, VW2, VW3, R1, R4, R5, R6, W10, X14, NWID, A1, P1, and P4) as well as at five reference stations within the same drainages but upstream of mine influence (FC, R7, USFR, V1, and VR) and at two stations that have a history of drinking water use by First Nations (Grum Corner and K8). Aquatic Environment monitoring locations are shown in Figures 5B-1 to 5B-3. Additional stations may need to be added temporarily to the program on an as needed basis. Samples will be collected three times per year: spring, summer, and fall, representing the three distinct flow conditions during the year to capture representative high, low and mid-range concentrations (i.e., winter low flow, spring freshet, and summer/fall). Exceptions include stations VW1, VW3, VGMAIN, V8, R4, R5, and A1, which will be sampled monthly. Water samples will be collected and analyzed by an accredited external laboratory for the following:

- Physical parameters, including pH, specific conductance, TSS, TDS, and hardness;
- Anions and cations, including ammonia-N, Nitrate-N, sulphate, chloride and alkalinity
- Total and dissolved organic carbon (field filtered)
- Total and dissolved metals (field filtered)

At the time of sample collection field parameters (including pH, conductivity and temperature) will also be taken. Flows will be monitored at X2, X14 and V8, to allow for computation of loadings at these locations and tracking of potential changes in flow regimes over time. Flow measurements will be taken synoptic with chemical sampling to allow for accurate loadings estimates at those stations.

Should water quality monitoring indicate a substantial adverse change in surface water quality that might be associated with a change in toxicity to aquatic biota, samples of surface water will be collected from the affected areas for laboratory toxicity testing. The toxicity tests will include a variety of species representing different trophic levels and effects endpoints. Testing should be repeated if water quality continues to change, but would not need to be repeated if concentrations stabilize.

6.2.2 Benthic Invertebrate Communities

Benthic invertebrate communities will be assessed every three years at all of the water monitoring locations that are accessible to fish, starting in 2014. Community characteristics will be compared to those observed during the baseline period and to any other such surveys conducted at the site in the interim. Data will also be evaluated relative to an appropriate suite of synoptically sampled regional reference areas (i.e., having similar habitat characteristics) and will consider any changes in water quality that have been since the last cycle of study.

6.2.3 Fish

Routine monitoring of fish health and population characteristics and fish tissue metal concentrations is not recommended unless specific questions arise that necessitate fish sampling. This is because locally relevant species such as Chinook and grayling can move large distances between winter and summer habitats so the characteristics of individual fish may not reflect conditions in the areas in which they are captured. Also, population densities of these species, and slimy sculpin, are sufficiently low that it is very difficult to obtain sufficient sample sizes in any given area to support statistical comparisons of conditions among reference and mine-exposed areas. Also, lethal sampling should be avoided, if possible, to prevent population impacts that might be associated with the sampling program. There will be some fisheries related monitoring carried out in 2014 as part of the Site Investigations component of the IW and the results of these programs will be used to determine the need or frequency of subsequent programs.

6.3 Reporting

Each year following the benthic surveys, a monitoring report will be prepared summarizing the observations, interpretation of results and field data, including statistical comparison and assessment of changes, and associated conclusions and recommendations for the following year's sampling program. This report will be included as part of the AEMR for the year in which the program was completed.

SECTION 7

Wildlife Monitoring Program

The proposed Wildlife Monitoring Program continues and expands on the current site program that consists of the reporting of any incidental wildlife sightings that are reported to the site operator. This program is a more structured program that has been designed to meet the objectives outlined below, and will be integrated into the ongoing site investigations, inspections and operations programs. Given that the majority of the individuals contributing to the Wildlife Monitoring Program may not be specifically trained in biology or wildlife identification, a short "training" session will be provided to ensure consistency and clarity in the program execution. Resources for easy identification of bird type (duck, goose, swan, or gull), behaviours to watch for and basic information about animal tracks will be provided to carry out this program. In addition, field forms and direction will be provided to help simplify and add consistency to data collection.

7.1 Wildlife Monitoring Program Objectives

The objectives of the Wildlife Monitoring Program for the IW period are as follows:

- To monitor wildlife use of the FMC
- To identify where negative interactions with FMC components or IW activities may occur or are observed.
- To identify areas where seasonal or permanent wildlife presence/activity may negatively influence or hinder IW activities (beaver dams, bird nests etc.).
- To identify areas where seasonal or permanent wildlife presence/activity/health may be negatively affected by FMC activities.
- To assimilate the information which would allow for the development of updated mitigation measures in addition to those outlined in the associated Environmental Management Plan (EMP). This could include adjusting the timing, schedule, or method of tasks in order to protect or reduce-risk to wildlife, particularly during sensitive life stages such as during winter, during nesting, and while young are being reared.

7.2 Wildlife Monitoring Program

The wildlife monitoring program will consist of two main components:

1. Focused monitoring methods for avifauna
2. Incidental observation records for general wildlife

7.2.1 Focused Monitoring for Avifauna

A focused monitoring program for avifauna is proposed to collect site data which will allow site managers to determine whether mitigation measures aimed at reducing site usage by waterfowl are successful. This program is proposed to be performed in years one through three of the project, with an option for further monitoring if further adjustments to site mitigations are require. This program will focus on the period of highest site use by waterfowl (i.e., early May to mid-October), and will focus on pits, ponds and creek diversions where suitable waterfowl habitat has been identified. These areas include the following:

- Faro, Grum, and Vangorda Pits
- LCP
- Grum Settling Pond
- GSC Pond
- Moose Pond
- Grum Pit Slot Cut Pond
- SPP
- CVP

- ID Pond and any ponding on Original/Secondary and Intermediate Impoundment areas
- Rose Creek ponds including channel and diversion reach

At each location it is recommend that approximately 20 to 30 minutes be spent observing any avian activity. For each survey the following information will be recorded:

- Site name
- Time and duration of survey
- Weather during survey period (percent cloud cover, precipitation, temperature, wind (on the Beaufort Scale)
- Surveyor names
- UTM/location where survey took place
- For any bird activity/observations identified, the following will be recorded:
  - Bird type (duck, goose, swan, gull)
  - Behaviour/activity observed during survey time (e.g., diving, sleeping, or drinking)
  - Size of group
  - Age class (adult or duckling/gosling)
  - Any activity observed that suggests breeding or nesting within the FMC pits or ponds
  - The time during the survey the an observation was made (i.e., if the bird was already present at beginning of survey or arrived during the 20 minute period, or departed during the observation period)

The focused monitoring program is to be conducted by individuals trained in observational studies in avifauna to ensure accurate observations and recording. Site personnel and visitors will be encouraged to record similar information and details if and when incidental observations are made during their time on site.

7.2.2 Incidental Observation Record of General Wildlife

This program is intended to build on the current reporting of incidental wildlife sightings by site personnel for general sightings of wildlife at the FMC. The advantage of this component of the program is that it is carried out year-round, requires no additional resources, and consistently builds upon the current incidental data set for the FMC. This program of recording wildlife observations is to be conducted by site staff, contractors, and visitors on an ongoing basis throughout the year.

Throughout the year, personnel working at the site will be asked to report all observations of wildlife or wildlife signs while at the FMC (in footprint areas or at the site generally). These observations are relayed to the site operators (generally by radio), who will prompt personnel for the following information:

- Location
- Species or type of animal (e.g., grizzly or black bear if possible, or simply 'bear' if not identifiable)
- Group size
- Type of activity noted or interaction with personnel (e.g., feeding near pond, on road)

Personnel on site should be encouraged to provide the degree of detail that they are comfortable offering for an observation (i.e., to what degree they are comfortable with identification), and also should be encouraged to collect supporting information if possible, such as a photograph of the animal, tracks, or scat.

Care and maintenance site operators will maintain a log of the observations collected in a standard format database, which should include a set of fields to prompt complete collection of data for each event, including:

- Date and time
- Surveyors (personnel involved)
- Location
- Weather
- Details of the observation (as described above)

Each observation should be given a unique identifier, and any supporting data provided by personnel (e.g., photograph) will be stored by site operators with that identifier.

7.3 Reporting

Data collected from the Wildlife Monitoring Program will be summarized with monthly reporting of the following information:

- A summary of the incidental observations and supporting data
- Details of any specific monitoring efforts performed on site, such as waterfowl observations
- Identification of any potential for or realized human-wildlife conflict, and any mitigative measures carried out
- Photographs
- Raw data/record sheets

The information will also be summarized and included in the AEMR.

SECTION 8

Vegetation Monitoring Program

Vegetation patterns are determined by ecological interactions, physical and geochemical factors and are influenced by landscape position and topography, temperature, precipitation, substrate type and disturbance regime. Monitoring the relationships among plant community structure and composition and these environmental attributes is fundamental to understanding vegetation dynamics as well as the community changes that occur in response to IW activities, and any mitigation activities.

Changing conditions associated with IW activities could potentially impact vegetation around the FMC. The resulting changes in plant species composition, distribution and/or community interaction could subsequently affect ecosystem functions such as energy and nutrient exchange, carbon storage, biomass production and affect plant-animal interactions and habitat extent. The Vegetation Monitoring Program proposed for IW period is designed to complement existing information for the site while accomplishing the monitoring objectives outlined below.

8.1 Vegetation Monitoring Program Objectives

The vegetation monitoring program will have multiple objectives focused on characterization of vegetation communities and documenting trends in vegetation re-establishment on site:

- To monitor vegetation health and vigour in control and IW activity-adjacent areas of the FMC
- To identify where negative interactions with FMC components or IW activities may occur or are observed
- To identify areas where rare vegetation presence may negatively influence or hinder IW activities
- To identify areas where vegetation may be negatively affected by IW activities
- To monitor the project performance of re-growth for vegetation on the FMC (including revegetation plots)
- To assimilate the information and apply appropriate real-time mitigation measures in addition to those to be outlined in the associated EMP, such as changing timing/schedule/method of tasks to protect or reduce risk to vegetation

8.2 Vegetation Monitoring Program

The Vegetation Monitoring Program has been designed to sample vegetation over a temporal and spatial scale. The Vegetation Monitoring Program will commence July 2015 and be conducted within the months of July and August for the next 10 years. Specific sampling locations and permanent plots will be selected based on data collected from the 2014 vegetation and soil baseline study. For consistency and data comparability among data sets, the same methodology will be used for the duration of the Vegetation Monitoring Program. The Vegetation Monitoring Program will follow a standardized sampling methodology at each sampling location as outlined in the *Field Manual for Describing Terrestrial Ecosystems*, 2nd Edition (BC Ministry of Forests and Range and BC Ministry of Environment, 2010) and includes the following:

- Mapping: GPS mapping of each plot location and the permanent marker stake location
- Site characteristics: Photo taken for each of the main compass directions for each plot with description of slope, aspect, soil type, organic matter cover, evidence of water movement, erosion or sediment
- Species composition and percent cover for each species within each layer (canopy, shrub and ground) of the plot
- Species abundance for revegetation plots
- Health and vigour for each species within plot types (alive/dead, stress-level, evidence of browsing or insect damage)
- Rare plant identification

8.3 Reporting

Data collected from the Vegetation Monitoring Program will be summarized with annual reporting of the following information:

- Number of survey periods
- Survey dates and who completed the work
- Survey methods
- Survey results as per recorded data described above
- Discussion of results including any mitigative measures carried out
- Photographs
- Raw data/record sheets

It is recommended that a geodatabase be set up to maintain a georeferenced set of data for each monitoring plot. A report based on field notes, field data, and monitoring results will be produced for inclusion in the AEMR for the year in which the monitoring program was completed.

SECTION 1

Introduction

The Government of Yukon Assessment and Abandoned Mines and the Government of Canada, as represented by the Government of Yukon and Aboriginal Affairs and Northern Development Canada are continuing work to prepare a final remediation plan, the Faro Mine Remediation Plan (FMRP), for the Faro Mine Complex (FMC). In the meantime, Government of Yukon and Aboriginal Affairs and Northern Development Canada will continue to undertake activities to protect, and minimize risks to, human health and safety and the environment and support the development of the FMRP. These interim activities, collectively referred to as the Interim Works (IW), are the subject of this Project Proposal and include:

- Ongoing site operations
- Site investigations in support of design and environmental characterization for the FMRP
- The Down Valley Interim Hydraulic Upgrades, which comprise improvements in flood routing capacity for the Rose Creek Tailings Area (RCTA) to reduce risks to human health and safety for the environment
- Ancillary activities associated with completion of these activities

The IW is fundamentally a continuation of activities that have been conducted at the FMC since mine operations ceased in 1998. These activities will continue until implementation of the FMRP, addressing the following two main purposes:

1. To control and reduce the effects of the existing FMC on human health and safety, and the environment
2. To compile sufficient site and environmental information to support design, assessment, and permitting for the FMRP

As part of the IW, ongoing site operations and the Down Valley Interim Hydraulic Upgrades are intended to achieve the first purpose by managing clean and contaminated water; maintaining, repairing and monitoring mine facilities and structures; implementing site security measures; monitoring site and environmental conditions; and, responding to changes in accordance with an Adaptive Management Plan (AMP) and risk assessment. Site investigation activities that are part of the IW are intended to achieve the second purpose.

In addition to water and site facilities that will receive active management as part of the IW, there are waters and facilities at the FMC that are recognized as representing potential environmental risks, which at this time do not require immediate intervention. Long-term management of these components will be addressed in the FMRP. For example, geochemical conditions at the site are deteriorating, leading to increased contaminant mobilization. Source control measures (e.g., covers) that will be part of the FMRP will reduce mobilization and transport of contaminants. The design, permitting, and procurement for the FMRP will take several years, during which the IW are intended to manage effects and risks at the FMC while recognizing that the overarching objectives will be most effectively fulfilled by the FMRP. In the interim, as part of the IW, a short-term management strategy is required to monitor the potential degradation of conditions to the point where active intervention might be required before the implementation of the FMRP and to provide a framework so that appropriate management actions are implemented for ongoing protection of the environment.

An AMP is a management tool that provides a framework for implementing this short-term management strategy. This document provides the conceptual framework of the IW AMP. This framework builds on the current FMC AMP (Gartner Lee Limited, 2004). The final IW AMP will be developed and finalized as part of the Water Licencing process, which will include the definition of the specific thresholds or triggers for each AMP event.

SECTION 2

Approach to the Adaptive Management Plan

2.1 Objectives for the AMP

The AMP is a management tool that provides a consistent and predictable framework for responding to unforeseen environmental conditions that might result from the degradation of mine-related facilities and waters. The AMP provides the site operator with a pre-planned framework within which decisions can be quickly and efficiently made and provides regulators with the security of a consistent and predictable approach to unforeseen events.

The AMP takes the Precautionary Principle Approach: it provides a mechanism to identify potential environmental risks as they emerge and provides for a management response before an environmental impact occurs.

To be effective, the AMP must be linked to a monitoring program that is designed to provide an indication of when management intervention is necessary. This assures that the necessary data for the assessment of environmental conditions is being collected for evaluation against predetermined "triggers" or "thresholds."

Since the specific environmental conditions that may be encountered are, by definition, unknown, the AMP should not provide detailed description of specific management responses. The AMP, rather, should provide general descriptions of a range of possible responses that may be adapted or otherwise used to guide the design of an appropriate response that best suits the needs of the specific environmental conditions that are encountered. This approach is inherent to the fundamental purpose of the AMP.

Areas where there is uncertainty about site conditions, or where possible future conditions could lead to unacceptable environmental effects, have been identified, and the AMP provides a strong adaptive management approach that will be used to monitor, detect, and respond to changing conditions. Such an approach includes the following key components:

- Proactive monitoring to detect changing conditions in areas of expected uncertainty within a timeframe that allows for effective response.
- Clear and defensible triggers that will assure timely implementation of effective responses.
- Appropriate measures that can be undertaken to address unacceptable conditions and performance.

For the IW, there are three broad types of uncertainty that will be addressed through the AMP:

- When implementation of specific management responses will be required. For example, interception and collection of seepage water from the Zone II Outwash area is not required until water quality in the vicinity begins to show signs of deterioration. The timing of when this might occur is not known.
- Where implementation of specific management responses will be required. Depending on groundwater and seepage pathways, it is unclear where potential future contaminant sources could emerge.
- How the implemented measures/mitigations have performed. For example, the S-Wells Seepage Interception System (SIS) is currently intercepting contaminated water from the area immediately downgradient of the Intermediate Dump. Depending on downstream water quality, this system may not be performing adequately to assure the ongoing protection of North Fork Rose Creek (NFRC).

2.2 AMP Events

There are eight discrete events that comprise the AMP framework for the IW. These events represent anticipated environmental conditions that may decline to the point that may require a management response during the 10-year period of the IW. These events specifically focus on areas where deteriorating water quality conditions may affect receiving environments. If required, additional events will be developed as part of the final AMP to incorporate issues/concerns raised during the Environmental Assessment process.

The following eight events are included in the AMP framework:

1. Degraded Groundwater Quality in the Rose Creek Alluvial Aquifer (RCAA).
2. Degraded Water Quality in NFRC below S-Wells SIS.
3. Degraded Water Quality in NFRC below North Fork Rock Drain (NFRD).
4. Degraded Water Quality in NFRC above NFRD.
5. Degraded Water Quality in seepage from the Faro Northwest Waste Dumps.
6. Degraded Water Quality in Rose Creek, downstream of FMC facilities.
7. Degraded Water Quality below the Grum/V15 Collection System.
8. Degraded Water Quality in Vangorda Creek, downstream of FMC facilities.

The conceptual AMPs for each of these proposed events are described individually in subsequent sections.

2.3 Common Elements

To maintain consistency within the AMP framework, each of the AMP events is described according to common elements. These common elements provide a structure that will ensure that a consistent approach is followed for each event and that the AMP will be proactive in detecting changes and implementing appropriate responses before any unacceptable environment effects occurring. The following common elements form part of each specific AMP event.

- Event – This element describes the specific event that is addressed by the AMP.
- Possible Environmental Consequence – This element describes the environmental consequences that could arise if the event was allowed to proceed without appropriate response.
- Narrative Response Trigger – This is a narrative description of the trigger for the AMP event and leads to the development of the specific indicators and thresholds. In general, the narrative response trigger states that monitoring indicates that a specific type of unacceptable condition is occurring.
- Specific Indicators – This element describes the environmental parameters to be monitored and assessed as part of the AMP. These indicators will be selected to provide early detection of relevant changes in environmental conditions or system performance. They should be representative of the issue being monitored and assessed, easily measured, and reproducible.
- Thresholds – This element defines conditions, in terms of specific indicators, that would lead to actions being taken. They may be a series of staged thresholds or multiple thresholds for an individual AMP event. The specific thresholds for each AMP event will be defined in the final IW AMP, which will developed and finalized as part of the Water Licencing process.
- Monitoring Requirements – This element describes the monitoring that will be carried out to support implementation of the AMP. Parameters and general locations for sampling are discussed as part of the AMP framework. The proposed trigger locations for the AMP are presented in Figures 5B-1 to 5B-5 in Appendix 5B. Specific monitoring requirements will be defined as part of the final IW AMP. Physical inspections and visual monitoring can also form part of the monitoring requirements. Monitoring requirements may change at various stages of the AMP.
- Evaluation of Monitoring Results – This element describes the methods and frequencies that will be used to evaluate the monitoring data and determine whether specific thresholds have been reached or exceeded.
- Approach to Development of Response/Mitigation/Intervention – This element describes the overall approach to responses to be implemented if thresholds have been reached or exceeded. In most cases, the responses will include a range of actions that may be taken to address the events. The selection of the appropriate responses would depend on changed site conditions or system performance.

The sequence of AMP elements is presented in Figure 5C-1, which illustrates how the AMP will be applied to individual AMP events.

Within the context of implementing the AMPs, there will be an ongoing need to understand the validity of monitoring results and confirm the circumstances of threshold or trigger activation. This validation and confirmation process will be conducted in a timely manner and is necessary to verify that response actions are applied in the appropriate circumstances. For each AMP element, if monitoring identifies conditions that are approaching or meeting triggers or thresholds, a stepped response will be implemented for validation and confirmation. Although presented in a sequential order, some steps may occur concurrently or may be eliminated, depending on the individual circumstances of the trigger activation. In all cases, the approach to responses will be such that it expedites the process of responding to the trigger activation.

The initial response to the trigger will be the verification of the monitoring information. This will involve a comprehensive analysis of the laboratory results. The water quality at the trigger locations may then require re-sampling if warranted (i.e., quality assurance/quality control data or field notes indicates sampling issues/errors).

The second step will be a comprehensive analysis of the other related monitoring results from the locations including the monitoring data collected for this AMP and other relevant monitoring data, possibly including results collected for other associated AMP events. The goal of this analysis is to provide for a preliminary identification of the cause of the trigger activation.

The third step will be an analysis of the timing and potential consequences of trigger activation on the receiving environment. The results of this analysis will be used as a basis for the development of an appropriate response plan to prevent or mitigate any identified or predicted impacts and to highlight any required modifications to the monitoring program. Modelling may also be used to assess the effectiveness and impact of various mitigative options.

Following this analysis, the next step may be to increase monitoring intensity (parameters, locations, and frequency) to verify and understand the cause/source of the trigger activation.

2.4 Annual Review and Reporting

An annual review will be completed that assesses the adequacy and appropriateness of the elements of each event such as trigger locations, specific indicators and thresholds, and monitoring requirements. Updates, amendments, or other changes to the AMP will be recommended as part of the annual review.

Each AMP Event includes a management review of the relevant data. The results of these reviews will be reported, where a trigger occurs, monthly. The results of these reviews will also be summarized in the Annual Environmental Report.

SECTION 3

AMP Event 1, Degraded Groundwater Quality in the Rose Creek Alluvial Aquifer

3.1 Description

Groundwater in the RCAA is affected by seepage released from the Faro Waste Dumps via the former Faro Creek drainage and by contaminants released from the pore water of the surface tailings impoundments. This groundwater has the potential to become contaminated to the degree where discharge from the aquifer to Rose Creek may result in sustained adverse effects on the Rose Creek aquatic receiving environment. The groundwater quality in the RCAA is measured at various locations within the RCTA and downstream from the RCTA. Within the RCTA, groundwater quality is measured using multi-level wells with sample points in the tailings, near the tailings/aquifer interface and deep within the aquifer.

The environmental consequences of degraded water quality in the RCAA include the potential exposure of aquatic resources, terrestrial resources, and human resource users to increased levels of contaminants in Rose Creek, Anvil Creek, and the Pelly River.

Since the degradation of groundwater quality is anticipated to occur progressively from the source area (tailings) in a downgradient direction, the AMP for monitoring and addressing degrading water quality in the RCAA consists of three components to provide for early detection of emerging trends. The first component will focus on identifying the migration of contaminants of concern from the tailings into the aquifer. The second component will focus groundwater quality in the aquifer under the tailings upstream from the Intermediate Dam (ID), and the third will focus on groundwater quality downgradient of the Cross Valley Dam (CVD).

3.2 Narrative Triggers

Component 1 – Monitoring of the contaminant fronts in the tailings and underlying soils indicates that the zinc front has arrived at the tailings/aquifer interface. Monitoring locations in this stage will be selected to show early arrival/advanced fronts.

Component 2 – Monitoring of indicator parameters indicates that the water quality in the RCAA is degrading and there is an increasing trend in contaminant concentrations in the aquifer at target locations upstream from the ID.

Component 3 – Monitoring of indicator parameters indicates that the water quality in the RCAA is degrading and there is an increasing trend in concentrations of indicator parameters in the aquifer at target locations downstream from the CVD.

3.3 Specific Indicators and Thresholds

The following are specific indicators for the three components of the RCAA AMP:

Component 1 – Acidity, sulphate, alkalinity, pH, conductivity, dissolved iron, dissolved magnesium, and dissolved zinc concentrations in and below the tailings in the northern portion of the upper RCAA where the acid and zinc fronts are most likely to be further advanced.

Component 2 and Component 3 – Acidity, sulphate, alkalinity, pH, conductivity, dissolved iron, dissolved magnesium, and dissolved zinc concentrations will be monitored to support this AMP.

The selection of these parameters for use provides a comprehensive suite of indicators of the site conditions, allowing early detection of changes and effective tracking of changes over time.

The following are thresholds or triggers for the three components of the RCAA AMP, which will initiate an action for the specific indicators:

Component 1 - A statistically significant increasing trend in acidity, sulphate, conductivity, dissolved iron, dissolved magnesium, or dissolved zinc concentrations or a statistically significant decreasing trend in pH and alkalinity at the base of the tailings and immediately below the base of the tailings in the RCAA, at selected multi-level monitoring wells.

Component 2 – Either of the following two thresholds or triggers will initiate the AMP for Component 2 for water quality in the RCAA at target locations upstream from the ID:

- A statistically significant increasing trend in acidity, sulphate, conductivity, dissolved iron, dissolved magnesium, or dissolved zinc concentrations or a statistically significant decreasing trend in pH and alkalinity in the aquifer
- Acidity, sulphate, conductivity, dissolved iron, dissolved magnesium, or dissolved zinc concentrations increase to a predefined threshold value or pH and alkalinity decrease to a percentage of a predefined threshold value

Component 3 – Either of the following two thresholds or triggers will initiate the AMP for Component 3 for water quality in the aquifer at target locations downstream from the CVD:

- A statistically significant increasing trend in acidity, sulphate, conductivity, dissolved iron, dissolved magnesium, or dissolved zinc concentrations or a statistically significant decreasing trend in pH and alkalinity in the aquifer
- Acidity, sulphate, conductivity, dissolved iron, dissolved magnesium, or dissolved zinc concentrations increase to a predefined threshold value or pH and alkalinity decrease to a percentage of a predefined threshold value

3.4 Monitoring Requirements

Component 1 – Acidity, sulphate, alkalinity, pH, conductivity, dissolved iron, dissolved magnesium, and dissolved zinc concentrations in multi-level wells that include sample points in the tailings, near the tailings/aquifer interface, and below in the aquifer. The specific locations of these wells will be chosen to cover the spatial and temporal variability in the movement of the fronts (i.e., coarse and fine tailings, timing of placement, or proximity to downstream extent of tailings). The frequency of monitoring will be determined based on the site-specific characteristics of the sample locations and will range from annual to quarterly.

Component 2 – Acidity, sulphate, alkalinity, pH, conductivity; dissolved iron, dissolved magnesium, and dissolved zinc concentrations in wells that include sample points in the aquifer upstream from the ID. The specific locations of these wells will be chosen to cover both spatial and temporal variability in the movement of contaminants in the aquifer. The frequency of monitoring will be determined based on the site-specific characteristics of the sample locations and will range from annual to quarterly.

Component 3 – Acidity, sulphate, alkalinity, pH, conductivity; dissolved iron, dissolved magnesium, and dissolved zinc concentrations in wells that include sample points in the aquifer downstream from the CVD. The specific locations of these wells will be chosen to cover both spatial and temporal variability in the movement of contaminants in the aquifer. The frequency of monitoring will be determined based on the site-specific characteristics of the sample locations and will range from annual to quarterly.

In addition to the indicator parameters, other secondary parameters will also be monitored to track changes associated with the aquifer. These include, but are not limited to, dissolved manganese; dissolved calcium; and other dissolved trace metals such as copper, cadmium, arsenic, selenium, and thallium. Additional monitoring information that may be required for analysis should the AMP triggers be activated include water quality data and water level data from other monitoring well locations associated with the RCTA. In addition, surface water quality monitoring stations associated with the RCTA may also be relevant if a trigger is activated.

3.5 Evaluation of Monitoring Results

The management review of the relevant groundwater quality data will be carried out within 1 month of receiving the laboratory analysis report to compare monitoring data for thresholds and identify immediate timing concerns

and data issues. A more comprehensive review will be carried out as part of the annual review, including detailed data and trend evaluation.

3.6 Approach to Responses

Verification and confirmation of the trigger activation will be conducted as described in Section 2.3. Groundwater modelling may be used to support the analysis and indication of the contaminant transport pathways and the rate and development of contaminant loading to the receiving environment. This information will be used to assess the potential effects on the receiving environment and may also be used to assess the effectiveness of various mitigative options.

A response plan will subsequently be designed with the intent of mitigating the predicted adverse effects. This plan might include either of the following:

- Mitigation of the source area(s)
- Installation of an appropriate collection system to intercept the portions of aquifer flow to prevent adverse effects in Rose Creek

SECTION 4

AMP Event 2, Degraded Water Quality in North Fork Rose Creek below S-Wells SIS

4.1 Description

Water quality in NFRC below the S-Wells area has been affected by rock dump seepage and contaminated groundwater from the Main/Intermediate Waste Dumps. From 2006 to 2008, AMP triggers established as part of the current FMC AMP were repeatedly activated with statistically significant increasing concentrations of zinc and sulphate exceeding the established thresholds in NFRC as measured at X2. In response to the continued trigger activation at X2, a detailed assessment and investigation was carried out in 2008 in the S-Wells area. Results of these groundwater and surface water quality investigations indicated high levels of contaminants near NFRC, with a component of the contaminated groundwater discharging into the creek. Increasing trends in contaminant levels were also evident within the creek, particularly in the winter low-flow period. The likely source of the contaminant loading to the S-Wells area was identified as the Main and Intermediate Waste Dumps.

The S-Wells SIS is a first-phase groundwater interception system installed in winter 2009 in the S-Wells area. With the SIS, contaminated water is intercepted, collected, and pumped to the Faro Pit year-round. This system was upgraded in the autumn of 2009, and in 2010 several design modifications were implemented to address specific issues, including the installation of a second, larger pipeline to accommodate freshet flows. Water that is not captured by the S-wells SIS continues down the flowpath toward NFRC.

This AMP element is intended to identify if the performance of the S-Wells SIS is meeting its intended objective of minimizing the discharge of contaminated water to protect NRFC and to identify other potential sources of contaminant loading to NFRC. The water quality in NFRC downstream of the S-Wells SIS is measured monthly at Station X2, along with flow.

The environmental consequence of degraded water quality in NFRC is the potential exposure of aquatic resources, terrestrial resources, and human users of these resources to increased levels of contaminants in NFRC, Rose Creek Diversion, and, possibly, further downstream in Rose Creek, Anvil Creek, and the Pelly River. Zinc is currently the primary contaminant of concern, and zinc and sulphate are currently the primary indicators of acid rock drainage (ARD) in NFRC.

4.2 Narrative Trigger

Monitoring of surface water downgradient of the S-Wells SIS in NFRC indicates that water quality is starting to degrade or change and contaminants are advancing towards receiving environments. Monitoring locations and indicators will be selected, where appropriate, for early detection.

4.3 Specific Indicators and Thresholds

The specific indicators that should be measured in NFRC at X2 to provide the information necessary to support this AMP are:

- Total and dissolved zinc
- Sulphate

The following are thresholds or triggers for the S-Wells SIS AMP that will initiate an action for any of the specific indicators:

- A statistically significant increasing trend in zinc or sulphate concentrations at X2; or
- Increase in zinc or sulphate concentrations to a predefined threshold value

The specific threshold values will be defined to be “proactive” and “protective” and provide sufficient advance warning of changes in the receiving environment. Where warranted, this may include the development of seasonal thresholds: open-water and under-ice conditions.

4.4 Monitoring Requirements

The monitoring information required is monthly total zinc, dissolved zinc, and sulphate concentrations measured at X2. Additional monitoring information that is required for analysis, should the AMP triggers be activated, includes surface, groundwater, and seepage water quality and flow data from locations upgradient of X2. Both water quality and flow data are essential as they enable not only the analysis of contaminant concentrations, but loadings as well. In addition, information regarding the performance of the S-Wells SIS will be used for analysis, including pumping volumes, water quality of water transferred to Faro Pit, water levels in collection sump and wells, and visual presence of seepage bypassing the system as noted in routine visual inspections.

4.5 Evaluation

The management review of the relevant water quality data will be carried out monthly upon receiving the laboratory analysis report to compare monitoring data for thresholds and identify immediate timing concerns and data issues. As part of the monthly assessment, a comprehensive review will be carried out, including detailed data and trend evaluation.

4.6 Approach to Responses

Verification and confirmation of the trigger activation will be conducted as described in Section 2.3. This may include more intensive and focused monitoring and evaluation of potential pathways and effects. A response plan will subsequently be designed based on the trigger analysis with the intent of mitigating potential adverse effects in NFRC. This plan, where appropriate, may include both short-term and long- term mitigation measures.

If the source of contamination is identified to be because of seepage bypassing the SIS, then a short-term mitigation measure may be implemented while a longer-term mitigation plan is prepared. This might include pumping, berming, ditching, or other means to prevent receiving water quality from being further degraded in the short-term. If the source of contamination is identified to be because of a contaminant load resulting from sources other than seepage bypassing the SIS, then similarly a short-term mitigation may be implemented.

A longer-term mitigation would then be implemented to provide security until the implementation of the FMRP. This could include the design and implementation of appropriate collection system modifications to the SIS or design and implementation of additional interception and collection systems.

SECTION 5

AMP Event 3, Degraded Water Quality in North Fork Rose Creek below North Fork Rock Drain

In the autumn of 2013, a new sourceload to NFRC developed in the area of NFRD, which resulted in zinc concentrations in NFRC (NF2, X2) and at X14 above concentrations previously measured at these locations. The issue was originally identified through routine monitoring of water quality in Rose Creek at X14, and comparison was made with thresholds and targets laid out in the current FMC AMP and site water management protocols. Consistent with the current FMC AMP (Gartner Lee Limited, 2004), a detailed monitoring program and investigation was implemented to delineate the source of this new load. Based on the results of that program, the source of the increased zinc loading to NFRC is believed to be seepage from the Intermediate Dump Sulphide Cell. The increased loading associated with this source is most likely because of "break through" of a natural seep, possibly because of depletion of attenuation along the flow path, in a drainage channel beneath NFRD (Government of Yukon, 2013). According to the current FMC AMP, a response plan has been developed and is currently being implemented to locate and intercept this source. The development of AMP Event 3, Degraded Water Quality in NFRC as part of the IW AMP framework, is pending completion of the ongoing investigation and response plan implementation.

SECTION 6

AMP Event 4, Degraded Water Quality in North Fork Rose Creek above North Fork Rock Drain

6.1 Description

Water quality in NFRC upstream from NFRD could be affected by contaminated groundwater and seepage from waste dumps (Intermediate, Northeast, and Zone II Waste Dumps), seepage or overflow from the Zone II Pit, and seepage from the Zone II Outwash area. Seepage water from the Northeast Waste Dumps and from the former Zone II Pit (i.e., water that is not captured by the Zone II pumping well) contributes to NFRC, upstream from NFRD. In addition, seepage water in the waste dumps adjacent to the Zone II Pit catchment that is not captured by the well continues along a flowpath toward the Zone II Outwash area and NFRC. Groundwater quality associated with the Zone II Outwash area indicates that groundwater flowing towards NFRC is impacted with elevated concentrations of sulphate and zinc (CH2M HILL, 2014a) and support the need for continued monitoring and assessment of water quality trends in this area.

Surface water quality in NFRC upstream from NFRD is routinely monitored at several locations along the reach adjacent to the Northeast Waste Dumps and the Zone II Outwash area: R9, R10, and NF1. In addition, seepage and groundwater quality in the area is also monitored as part of the site monitoring program (CH2M HILL, 2014b).

6.2 Narrative Trigger

Monitoring of indicator parameters denotes that the water quality in NFRC is degrading with increasing concentrations of indicator parameters, and there is an increasing trend in concentrations at target seep and groundwater monitoring locations downgradient of the Zone II Outwash area and/or the Northeast Waste Dumps.

6.3 Specific Indicators and Thresholds

For seep and groundwater monitoring locations, the following are specific indicators that will be measured to provide the information necessary to support this AMP:

- Acidity, alkalinity, pH, and conductivity
- Dissolved iron, dissolved magnesium and dissolved zinc
- Sulphate

The specific indicators were selected to be proactive and provide advance warning of changes in seepage and groundwater quality; initially there will be an increase in magnesium and sulphate, followed by an increase in zinc.

The following are specific indicators for surface water quality monitoring locations:

- Total and dissolved zinc
- Sulphate

The following are thresholds or triggers for seepage and groundwater quality that will initiate an action for the specific indicators:

- A statistically significant increasing trend in acidity, sulphate, conductivity, dissolved iron, dissolved magnesium, or dissolved zinc concentrations or a statistically significant decreasing trend in pH and alkalinity in the aquifer; or
- Acidity, sulphate, conductivity, dissolved iron, dissolved magnesium, or dissolved zinc concentrations increase to a predefined threshold value or pH and alkalinity decrease to a percentage of a predefined threshold value.

The following are thresholds or triggers for surface water quality that will initiate an action for the specific indicators:

- A statistically significant increasing trend in zinc or sulphate concentrations at target seep locations; or
- Increase in zinc or sulphate concentrations to a predefined threshold value.

The specific threshold values, similarly, will be defined to be proactive and protective and will provide sufficient advance warning of changes in the receiving environment. Where warranted, this may include the development of seasonal thresholds: open-water and under-ice conditions.

6.4 Monitoring Requirements

The monitoring information required is dissolved magnesium, dissolved zinc, and sulphate in seeps and groundwater wells associated with the Zone II Waste Dumps, Northeast Waste Dumps, Zone II Outwash area, and Intermediate Dump. Monitoring locations will be selected to evaluate areas where there are known or anticipated pathways for ARD products and to provide for adequate characterization of the water quality associated with seepage from these areas. Frequency of monitoring will be determined based on the site-specific characteristics of the sample locations.

The monitoring information required for the surface water component is monthly total zinc, dissolved zinc, and sulphate concentrations measured at R9, R10, and NF1. Additional monitoring information that is required for analysis, should the AMP triggers be activated, includes other surface, groundwater, and seepage water quality and flow data from locations upgradient from NFRD. Both water quality and flow data is essential, as they enable not only the analysis of contaminant concentrations, but loadings as well.

6.5 Evaluation

A management review of the relevant surface water quality data will be carried out monthly upon receiving the laboratory analysis report to compare monitoring data for thresholds and identify immediate timing concerns and data issues. As part of the monthly assessment, a comprehensive review will be carried out, including detailed data and trend evaluation.

A management review of the relevant seepage and groundwater quality data will be carried out within 1 month of receiving the laboratory analysis report to compare monitoring data for thresholds and identify immediate timing concerns and data issues. A more comprehensive review will be carried out as part of the annual review, including detailed data and trend evaluation.

6.6 Approach to Responses

Verification and confirmation of the trigger activation will be conducted as described in Section 2.3. This may include more intensive and focussed monitoring and evaluation of potential pathways and effects. A response plan will subsequently be designed based on the trigger analysis with the intent of mitigating potential adverse effects in NFRC. This plan, where appropriate, may include both short-term and long-term mitigation measures.

If the source of contamination is identified to be runoff or seepage from all or a portion of the FMC facilities, then a short-term mitigation measure may be implemented to control migration of contaminants at the source while a longer-term mitigation plan is prepared. This might include pumping, berming, ditching, or other means to prevent receiving water quality from being further degraded in the short term. A longer-term mitigation system would then be designed and in such a way as to provide security until the implementation of the FMRP. If the source of the contamination is identified to be groundwater flow that is too deep for interception by surface ditching, then a groundwater interception plan, or another long-term remedial measure, may be designed and implemented.

SECTION 7

AMP Event 5, Degraded Water Quality in Seepage from the Faro Northwest Waste Dumps

7.1 Description

The Faro Northwest Waste Dumps are located primarily in the Guardhouse Creek watershed. There are two main contributors of flow in the Guardhouse Creek area: Upper Guardhouse Creek (UGC) and Lower Guardhouse Creek (LGC). UGC flows adjacent to the Faro Northwest Waste Dumps (along the westernmost edge) and may partially flow under the Northwest Waste Dumps. UGC ultimately flows to the CVD area, bypassing collection systems, and into Rose Creek (upstream of X14). UGC flows through mainly unimpacted terrain, with the exception of several seeps originating from the Northwest Waste Dumps. Monitoring of these seeps indicate that water quality is being affected by the Northwest Waste Dumps (CH2M HILL, 2014a).

LGC originates from waste dump seeps with mine-influenced water quality that flow into a ditch across from the Warehouse Building and from this ditch to the ID Pond, where the water is captured for treatment. Concentrations of sulphate and zinc in LGC have been increasing steadily. Seepage water emanating from the south toe of the Northwest Waste Dumps (Northwest Lower Waste Dump), contributes to X23 and to LGC. Although the seepage from the Northwest Lower Waste Dump remains internal to the FMC water management system, this seepage is impacted, with trends of decreasing alkalinity and increasing sulphate and zinc (CH2M HILL 2014a), and may be representative of the geochemical conditions in the Northwest Waste Dumps as a whole. Increasing constituent concentrations from these seeps indicate the possibility of future water quality effects associated with seepage from the Northwest Waste Dumps to UGC, and support the need for the proactive monitoring and assessment of seepage associated with the Northwest Waste Dumps.

7.2 Narrative Trigger

Monitoring of indicator parameters indicates that water quality in seeps associated with the Northwest Waste Dumps is degrading and there is an increasing trend in concentrations at target seep locations associated with the Northwest Waste Dumps. Monitoring locations will be selected for early detection and indication of ARD products migrating towards aquatic receptors.

7.3 Specific Indicators and Thresholds

The following are specific indicators that should be measured to provide the information necessary to support this AMP:

- Acidity, alkalinity, pH, and conductivity
- Dissolved iron, dissolved magnesium, and dissolved zinc
- Sulphate

The specific indicators were selected to be proactive and provide advance warning of changes in seepage water quality; initially there will be an increase in magnesium and sulphate, followed by an increase in zinc and decrease in alkalinity.

The following are thresholds or triggers for the Northwest Waste Dumps AMP that will initiate an action for the specific indicators:

- A statistically significant increasing trend in acidity, sulphate, conductivity, dissolved iron, dissolved magnesium, or dissolved zinc concentrations or a statistically significant decreasing trend in pH and alkalinity in the aquifer; or
- Acidity, sulphate, conductivity, dissolved iron, dissolved magnesium, or dissolved zinc concentrations increase to a predefined threshold value or pH and alkalinity decrease to a percentage of a predefined threshold value.

The specific threshold values, similarly, will be defined to be proactive and protective and provide sufficient advance warning of changes in the receiving environment.

7.4 Monitoring Requirements

Dissolved magnesium, dissolved zinc, and sulphate will be monitored in seeps downgradient from the Northwest Waste Dumps. Monitoring locations will be selected to evaluate areas where there are known or anticipated pathways for ARD products and to provide for adequate characterization of water quality associated with seepage from the Northwest Waste Dumps. Frequency of monitoring will be determined based on the site-specific characteristics of the sample locations.

Additional monitoring information that may be required for analysis, should the AMP triggers be activated, includes water quality data and water flow data from other monitoring locations downgradient from the Northwest Waste Dumps. This includes monitoring locations in UGC and LGC. Currently there are no groundwater monitoring wells in the area of the Northwest Waste Dumps, but groundwater monitoring well installations are planned for the summer of 2014. Once established, these wells will be included in the monitoring requirements for Northwest Waste Dumps AMP.

7.5 Evaluation

The management review of the relevant water quality data will be carried out within 1 month of receiving the laboratory analysis report to compare monitoring data for thresholds and identify immediate timing concerns and data issues. A more comprehensive review will be carried out as part of the annual review, including detailed data and trend evaluation.

7.6 Approach to Responses

Verification and confirmation of the trigger activation will be conducted as described in Section 2.3. Once trigger activation is confirmed, the specific responses will include the development and implementation of a program to monitor and investigate contaminant transport pathways to support a comprehensive understanding of concentrations, loadings, trends, travel times, and potential impacts to the receiving environment. This information will be used to determine the need for mitigative action.

SECTION 8

AMP Event 6, Degraded Water Quality in Rose Creek Downstream of Mine Site Facilities

8.1 Description

Water quality in Rose Creek downstream of the FMC facilities could be negatively affected by surface and groundwater inflows from FMC facilities, waste dumps, the RCTA, and existing water treatment plant discharges. The water quality in Rose Creek immediately downstream of the FMC is measured at Station X14. Water quality in Rose Creek is also measured farther downstream at the confluence with Anvil Creek (R4).

The potential environmental consequence of degraded water quality in Rose Creek is exposure of the aquatic resources to increased levels of contaminants, which may lead to an overall degradation in the downstream aquatic receiving environment. Zinc is currently the primary contaminant of concern in the receiving environment, and zinc and sulphate are currently key indicators for assessing changes in Rose Creek water quality. However, the consideration of degraded water quality should also include other metals that could originate from the FMC.

8.2 Narrative Trigger

Monitoring of surface water quality in Rose Creek downstream from the FMC indicates that the downstream water quality is starting to degrade or change and ARD products are advancing towards receiving environments. Monitoring locations and indicators will be selected for early detection.

8.3 Specific Indicators and Thresholds

The following are specific indicators that will be measured in Rose Creek at X14 to provide the information necessary to support this AMP:

- Total and dissolved zinc
- Sulphate

The following are thresholds or triggers for the Rose Creek AMP that will initiate an action for the specific indicators:

- A statistically significant increasing trend in zinc or sulphate concentrations at X14; or
- Increased zinc or sulphate concentrations to a predefined threshold value.

The specific threshold values will be defined to be proactive and protective and provide sufficient advance warning of changes in the receiving environment.

8.4 Monitoring Requirements

The monitoring information that is required monthly (or weekly when discharging) includes total zinc, dissolved zinc, and sulphate concentrations measured at X14. Additional monitoring information that is required for analysis, should the AMP triggers be activated, includes surface water, groundwater, and CVD seepage (Weir 3, X11, X12, and X13) water quality and flow data from locations upstream of X14. Both water quality and flow data are essential as they enable not only the analysis of contaminant concentrations, but the amount of loadings as well. The monitoring locations required are surface water quality stations located upstream in Rose Creek (Rose Creek Diversion, NFRC, and South Fork Rose Creek),UGC, surface seepage from the CVD, effluent flow from the CVD Pond, and surface flow and seepage from other FMC facilities. Groundwater quality beneath and downgradient from the RCTA, monitored as part of the Routine Monitoring Program and the RCAA AMP, will also provide important information should the Rose Creek AMP be activated.

8.5 Evaluation

The management review of the relevant water quality data (X14) will be carried out monthly upon receiving the laboratory analysis report to compare monitoring data for thresholds and identify immediate timing concerns and data issues. As part of the monthly assessment, a comprehensive review will be carried out, including detailed data and trend evaluation.

8.6 Approach to Responses

Verification and confirmation of the trigger activation will be conducted as described in Section 2.3. This may include more intensive and focussed monitoring and evaluation of potential pathways and effects. A response plan will subsequently be designed based on the trigger analysis, with the intent of mitigating potential adverse effects in Rose Creek. This plan, where appropriate, may include both short-term and long-term mitigation measures.

If the source of contamination is identified to be runoff or seepage from all or a portion of the mine facilities, then a short-term mitigation measure may be implemented to control migration of contaminants at the source while a longer-term mitigation plan is prepared. This might include pumping, berming, ditching, or other means to prevent receiving water quality from being further degraded in the short term. A longer-term mitigation system would then be designed and in such a way as to provide security until the implementation of the FMRP. If the source of the contamination is identified as groundwater flow that is too deep for interception by surface ditching, then a groundwater interception plan, or another long-term remedial measure, may be designed.

SECTION 9

AMP Event 7, Degraded Water Quality below the V15 and Grum Creek Pumping System

9.1 Description

Seepage from the Grum Waste Dump surfaces at the base of the waste rock pile on the southeastern side, just upgradient from V15 and Grum Creek. In 2006, increasing concentrations of zinc were observed at the V15 seep sampling location that corresponded to elevated concentrations of zinc in the lower portion of Grum Creek draining into Vangorda Creek (Station V2). In 2007, a seepage collection ditch was installed to convey seepage from V15 into an existing ditch routing upper Grum Creek water to Moose Pond, away from lower Grum Creek. In 2011, in response to continued increasing contaminant levels at V15 and the potential effects to the receiving environment, a collection sump and pumping system were installed: V15 and Grum Creek Pumping System. The pumping system at V15, located east of the Grum Waste Dump, consists of an insulated and heat-traced, 76-millimetre high-density polyethylene pipeline, a power supply, and pump (Denison Environmental Services, 2011). The system can redirect seepage from the Grum Waste Dump (V15, upper Grum Creek, or both) to the Vangorda Pit. When the system is not operated, discharge flows to Moose Pond. Currently the system is operated during peak freshet and storm event flows only, with Moose Pond receiving “normal” flows (Tracey Parkin, Personal Communication, 2013). Water in Moose Pond infiltrates through the ground, ultimately discharging into Vangorda Creek. During peak flow events, if the pumping system is not operating or not capable of handling the entire volume, there is the potential for discharge of contaminated, sediment-laden water directly to Vangorda Creek.

This AMP element is intended to identify if the performance of the V15 and Grum Creek Pumping System, including the use of Moose Pond and associated infiltration through the ground, is meeting its intended objective of minimizing the discharge of contaminated water and sediment to protect Vangorda Creek.

Surface water quality in the area is routinely monitored at V15, Moose Pond (V2A), and lower Grum Creek (V2). Seepage and groundwater quality is measured downgradient of Moose Pond at Moose Seep and Moose Well. The water level in Moose Pond is also routinely measured.

9.2 Narrative Trigger

Monitoring of surface water, groundwater, and seepage water quality at target locations downgradient from the Grum/V15 collection system or Moose Pond indicates that water quality downgradient is starting to degrade or change and contaminants are advancing towards receiving environments. Monitoring locations and indicators will be selected, where appropriate, for early detection.

9.3 Specific Indicators and Thresholds

The following are specific indicators that will be measured to provide the information necessary to support this AMP:

- Total (surface water samples only) and dissolved zinc
- Total suspended solids (surface water samples only)
- Sulphate

The following are thresholds or triggers for the Grum/V15 AMP that will initiate an action for the specific indicators:

- A statistically significant increasing trend in zinc or sulphate concentrations at trigger locations; or
- Increase in total suspended solids, zinc, or sulphate concentrations to a predefined threshold value.

The specific threshold values will be defined to be proactive and protective and provide sufficient advance warning of changes in the receiving environment. Target monitoring locations will include, but not be limited to, V2, Moose Pond (V2A), Moose Well, and Moose Seep.

9.4 Monitoring Requirements

Total zinc (surface water only), dissolved zinc, total suspended solids (surface water only), and sulphate at key locations downgradient of the Grum/V15 collections system including V2, Moose Pond (V2A), Moose Well, and Moose Seep. The specific locations will be chosen to cover both spatial and temporal variability in the movement of contaminants towards Vangorda Creek. The frequency of monitoring will be determined based on the site-specific characteristics of the sample locations and will range from annual to bi-weekly. Additional monitoring information that is required for analysis, should the AMP triggers be activated, includes surface and seepage water quality and flow data from locations upstream of the collection system including V15 and Grum Creek upstream of the collection system (GC Weir). Both water quality and flow data are essential, as they enable not only the analysis of contaminant concentrations, but loadings as well.

9.5 Evaluation

The management review of the relevant water quality data will be carried out monthly upon receiving the laboratory analysis report to compare monitoring data for thresholds and identify immediate timing concerns and data issues. As part of the monthly assessment, a comprehensive review will be carried out including detailed data and trend evaluation.

9.6 Approach to Responses

Verification and confirmation of the trigger activation will be conducted as described in Section 2.3. This may include more intensive and focussed monitoring and evaluation of potential pathways and effects. A response plan will subsequently be designed based on the trigger analysis, with the intent of mitigating potential adverse effects in Vangorda Creek. This plan, where appropriate, may include both short-term and long-term mitigation measures.

If the source of contamination is identified to be because of excessive flows during peak flow events resulting in bypassing of the collection system, then a short-term mitigation measure may be implemented while a longer-term mitigation plan is prepared. This might include pumping, berming, ditching, or other means to prevent receiving water quality from being further degraded in the short term. If the source of contamination is identified to be because of the contaminant load resulting from the exfiltration from Moose Pond to Vangorda Creek, then similarly a short-term mitigation may be implemented, including extending the operational period of the collection system.

A longer-term mitigation would then be implemented to provide security until the implementation of the FMRP. This could include the design and implementation of appropriate collection system modifications.

SECTION 10

AMP Event 8, Degraded Water Quality in Vangorda Creek Downstream of Mine Facilities

10.1 Description

Water quality in Vangorda Creek downstream from the FMC facilities could be negatively affected by surface and groundwater inflows from FMC facilities, waste dumps, and water treatment plant discharges. The water quality in Vangorda Creek downstream from the FMC is measured at Station V8 at the foot bridge in the Town of Faro. Water quality in Vangorda Creek is also routinely measured farther upstream in the main arm at V27 and in the west arm at V5.

The potential environmental consequence of degraded water quality in Vangorda Creek is exposure of the aquatic resources to increased levels of contaminants, which may lead to an overall degradation in the downstream aquatic receiving environment. Zinc is currently the primary contaminant of concern in the receiving environment, and zinc and sulphate are currently key indicators for assessing changes in Vangorda Creek water quality. However, the consideration of degraded water quality should also include other metals that could originate from the FMC.

10.2 Narrative Trigger

Monitoring of surface water quality in Vangorda Creek downstream of the FMC indicates that the downstream water quality is starting to degrade or change and ARD products are advancing towards receiving environments. Monitoring locations and indicators will be selected for early detection.

10.3 Specific Indicators and Thresholds

The following are specific indicators that should be measured in Vangorda Creek at V8 to provide the information necessary to support this AMP:

- Total and dissolved zinc
- Sulphate

The following are thresholds or triggers for the Vangorda Creek AMP that will initiate an action for the specific indicators:

- A statistically significant increasing trend in zinc or sulphate concentrations at V8; or
- Increased zinc or sulphate concentrations at V8 to a predefined threshold.

The specific threshold values will be defined to be proactive and protective and provide sufficient advance warning of changes in the receiving environment.

10.4 Monitoring Requirements

The monitoring information that is required monthly (or weekly when discharging) is total zinc, dissolved zinc, and sulphate concentrations measured in Vangorda Creek at V8. Additional monitoring information that is required for analysis should the AMP triggers be activated includes surface, groundwater, and seepage water quality and flow data from locations upstream from V8. Both water quality and flow data are essential as they enable not only the analysis of contaminant concentrations, but loadings as well. The monitoring locations required are surface water quality stations located upstream in the Vangorda Creek drainage, site discharges from V25BSP, and surface runoff and seepage from FMC-related facilities in the drainage. Groundwater quality at the Vangorda /Grum Area monitored as part of the Routine Monitoring Program and the Grum V15 AMP will also provide important information should the Vangorda Creek AMP be activated.

10.5 Evaluation

A management review of the relevant water quality data in Vangorda Creek at V8 will be carried out monthly upon receiving the laboratory analysis report to compare monitoring data for thresholds and identify immediate timing concerns and data issues. As part of the monthly assessment, a comprehensive review will be carried out, including detailed data and trend evaluation.

10.6 Approach to Responses

Verification and confirmation of the trigger activation will be conducted as described in Section 2.3. This may include more intensive and focused monitoring and evaluation of potential pathways and effects. A response plan will subsequently be designed based on the trigger analysis, with the intent of mitigating potential adverse effects in Vangorda Creek. This plan, where appropriate, may include both short-term and long-term mitigation measures.

If the source of contamination is identified to be runoff or seepage from all or a portion of the FMC facilities, then a short-term mitigation measure may be implemented to control migration of contaminants at the source while a longer-term mitigation plan is prepared. This might include pumping, berming, ditching, or other means to prevent receiving water quality from being further degraded in the short term. A longer-term mitigation system would then be designed and in such a way as to provide security until the implementation of the FMRP. If the source of the contamination is identified to be groundwater flow that is too deep for interception by surface ditching, then a groundwater interception plan, or another long term remedial measure, may be designed.

SECTION 1

Introduction

The Government of Canada, as represented by the Government of Yukon (YG) and Aboriginal Affairs and Northern Development Canada (AANDC), conduct annual qualitative risk assessments to identify and characterize physical and operational risks at the Faro Mine Complex (FMC). In accordance with the *Federal Contaminated Sites Action Plan, Decision Making Framework* (Government of Canada, 2013) and the *Contaminated Sites Management Policy* (AANDC, 2002), risk characterization and management play important roles in decision-making and prioritization for activities at contaminated sites managed under the Federal Contaminated Sites Action Plan. The results of the annual qualitative risk assessments guide work planning for site operations. This report describes the risk assessment process used by YG and AANDC, summarizes the results of the 2013 operational risk assessment, and describes how the results will be used to guide activities undertaken during the Interim Works (IW). These risk assessments are qualitative, and are intended to characterize physical hazards at the FMC, especially related to the effects potential failure modes could have on the environment, costs, and human health, and safety.

Additional risk assessment tools provide information and analysis to support remediation planning at the FMC. For example, combinations of qualitative assessments of physical hazards, as described in this report, and quantitative assessments of ecological and human health risks, are used to support decision-making for the Faro Mine Remediation Project. This report does not provide the results of quantitative risk assessments.

YG and AANDC track ongoing risk evaluations and responses in a comprehensive database that records changes in risks over time, as well as mitigation responses. This document summarizes results for 2013, but it does not provide details about underlying assumptions or how the risks have evolved.

SECTION 2

Operational Risk Assessment Methods

Annual operational risk assessments for the FMC follow an approach developed by AANDC. The qualitative risk assessment approach is a form of Failure Modes Effects Analysis (FMEA) that AANDC applies at sites it manages under the Federal Contaminated Sites Action Plan. The FMEA is a systematic and comprehensive account of potential events and scenarios (failure modes) that could result in adverse consequences to the environment and to human health and safety. The methodology requires a qualitative characterization of the consequences of failure and the likelihood of failure for specific failure modes. Applying this systematic and consistent approach to risk assessments provides a framework for informed decision-making about priorities for site activities and risk mitigation actions in accordance with the objectives of AANDC's *Contaminated Sites Management Policy "*to provide a scientifically valid, risk management based framework for setting priorities, planning, implementing and reporting on the management of contaminated sites" (AANDC, 2002).

Deloitte and Touche Inc. initiated the FMEA for the FMC in 2002, establishing a baseline for future risk assessments. As part of ongoing operations, YG and AANDC convene an annual operational risk assessment workshop to update the FMEA, taking into consideration current site conditions, mitigative activities that have taken place, monitoring results, and improved understanding of site processes. These workshops bring together teams of experts (i.e., site owners, site managers, site operators, remediation plan designers, engineers, environmental experts, and site technicians) to conduct a joint site inspection, combined with a systematic re-evaluation of previously identified risks and a characterization of newly identified risks. These operational risk assessments focus on events and consequences that may affect the environment, cost, or human health and safety. AANDC and YG use other forums to address other types of consequences like legal requirements and community relations.

The annual FMEAs consider each FMC component (e.g., Rose Creek Diversion [RCD] and the water treatment system) and characterize risks for each component using the following steps:

1. **Identify potential failure modes.** These could be natural causes (e.g., earthquake, flood), engineering failures (e.g., structural failure of building), human error (e.g., operator error, inspector error, mischief, or vandalism), or prediction errors (e.g., uncertainty in geochemical predictions, or underestimates of flood events).
2. **Describe failure modes and consequences arising from failure modes.** For these assessments, the failure consequences focus on effects on the environment, cost, or human health and safety (both site workers and the public). For example, a flood causing a dam failure would often have environmental consequences and also cost consequences associated with cleanup and repair. On the other hand, deteriorating water quality at a seepage collection system may only have cost consequences because of increased cost for water treatment.
3. **Characterize consequences of failures.** Table 5D-1 describes the "Consequence Categories" applied for the FMC, providing specific consequence descriptors for each consequence type (e.g., an event that leads to a cost increase of $500,000 to $2,500,000 has a "moderate" cost consequence). Consequences can be very low, minor, moderate, major, or critical.
4. **Characterize likelihood of failure modes.** Table 5D-2 describes the "Likelihood Categories" applied for the FMC, providing specific likelihood descriptors for each likelihood category (e.g., a scenario that would be expected to occur approximately once every 30 years would be assigned a likelihood of "possible"). Characterizing likelihood requires carefully considering the entire failure mode scenario, not just a specific part of the failure event. For example, a flood that overtops the FCD has a specific likelihood, while a flood that overtops the FCD and leads to the Faro Pit being filled and overtopped has a much smaller likelihood.
5. **Characterize the risk rating.** Table 5D-3 illustrates the risk matrix used to assign an overall risk rating for each failure mode. The risk rating is a combination of likelihood and consequence with ratings of low, moderate, moderately high, high and very high. AANDC and YG's site activities and responses to risks are defined by the risk ratings where "low" risks require ongoing tracking and re-evaluation, while "very high" risks require development and implementation of immediate responses.

6. **Identify risk mitigation measures.** For risks ranging from “moderate” to “very high,” the final step in the annual FMEA is to describe appropriate mitigation that could be applied to reduce or eliminate the risk. The identified actions support the development of work plans for the upcoming year.

AANDC and YG use a comprehensive risk database to track all identified FMC risks over time. The system allows site managers to monitor ongoing risk trends, keeping track of risks that are increasing over time and risks that have been addressed or reduced by mitigative activities.

AANDC and YG intend to continue applying an FMEA approach for identifying and characterizing environmental, cost, and human health and safety risks at the FMC during the period of the proposed IW. The results of monitoring programs and of condition evaluations (in accordance with the Adaptive Management Plan) will be important inputs for these ongoing risk assessment updates. These inputs will provide evidence about changing conditions and problematic trends at the FMC.

When considering the results of the annual operational risk assessments for the FMC, it is important to recognize that the risk characterizations assume continued active site operations. While the assessments consider failure modes that include operator error, they do not consider failure modes involving the complete discontinuation of site operations. This is a reasonable assumption for operational risk assessments that are used to identify and prioritize remedial actions while overall remediation planning and implementation continues at the FMC. The annual operational risk assessments assume the Faro Mine Remediation Project will be implemented in the foreseeable future, and will address long-term risks. As such, the likelihoods of failure events are characterized on the basis of current conditions. The need to mitigate risks during the IW considers the likelihood of failure during that period only. For example, the current risks associated with flood conveyance for the Rose Creek Tailings Area led to conclusions that the Down Valley Interim Hydraulic Upgrades are necessary to sufficiently reduce likelihood of failure during the period of approximately 8 to 10 years before final improvements can be completed. Risk assessments to support development of the permanent remediation plan consider the likelihoods of failure over much longer periods of time, but are not addressed in this report, as they are relevant to the Faro Mine Remediation Plan.

TABLE 5D-1
Consequence Categories
Faro Mine Interim Works

Consequence Categories	Very Low	Minor	Moderate	Major	Critical
1. Environmental Impact	No impact	Minor localized or short-term impacts	Significant impact on valued ecosystem component	Significant impact on valued ecosystem component and medium-term impairment of ecosystem function	Serious long-term impairment of ecosystem function
2. Consequence Costs	< $100,000	$100,000 - $500,000	$ 500,000 - $2.5 Million	$2.5-$10 Million	>$10 Million
3. Human Health and Safety	Low-level, short-term subjective symptoms; no measurable physical effect; no medical treatment	Objective but reversible disability/impairment and /or medical treatment/injuries requiring hospitalization	Moderate irreversible disability or impairment to one or more people	Single fatality and /or severe irreversible disability or impairment to one or more people	Multiple fatalities

TABLE 5D-2
Likelihood Categories
Faro Mine Interim Works

Assigned Likelihood	Descriptive	Health Events Only	Frequency of Occurrence for Other Events
Almost Certain	Happens often	1 case / 100 person-years	High frequency (more than once every 5 years)
Likely	Could easily happen	1 case / 1,000 person-years	Event does occur, has a history, once every 15 years
Possible	Could happen and has happened elsewhere	1 case / 10,000 person-years	Occurs once every 30 years
Unlikely	Hasn't happened yet but could	1 case / 100,000 person-years	Occurs once every 100 years
Very Unlikely	Conceivable, but only in extreme circumstances	1 case / 1,000,000 person-years	Occurs once every 1000 years

TABLE 5D-3
Risk Assessment Matrix
Faro Mine Interim Works

Likelihood	Consequence Severity				
	Low	Minor	Moderate	Major	Critical
Almost Certain	Moderate	Moderately High	High	Very High	Very High
Likely	Moderate	Moderate	Moderately High	High	Very High
Possible	Low	Moderate	Moderately High	High	High
Unlikely	Low	Low	Moderate	Moderately High	Moderately High
Very Unlikely	Low	Low	Low	Moderate	Moderately High

SECTION 3

2013 Risk Assessment Results

YG and AANDC convened the annual operational risk assessment workshop from October 22 to 24, 2013, in the Town of Faro. The goal was to identify and characterize current physical and operational risks at the FMC. Workshop participants provided a broad range of management, engineering, regulatory, and operational expertise and included representatives of YG, AANDC, the site operations contractor, the design and regulatory contractor, and the Independent Engineer. The workshop included a site inspection, followed by a detailed discussion and characterization of risks for each key mine component.

Tables 5D-4, 5D-5, and 5D-6 summarize the most significant environmental, cost, and human health and safety risks, respectively. The risks identified in these tables are the highest risk rating associated with each specific failure mode. Many of the risk scenarios would have consequences in more than one category, and these are all tracked in the risk database. However, for the summaries in this report, only the category(ies) with the highest rating appear in the tables. Also, the tables do not provide information about the analysis and assumptions that underlie the determination of the likelihood and consequence categories.

For example, Risk 1.3 identified in Table 5D-5 (1-in-500 to 1-in-1000-year return period flood, causing a breach of the Intermediate Dam [ID] with release of contaminated water through the Cross Valley Dam Pond [CVD Pond] but not a failure of the Cross Valley Dam [CVD] or release of tailings to the environment) has a clear environmental consequence in addition to a cost consequence. The event would contaminate downstream receiving environments, and would lead to cleanup and repair costs. The details recorded in the database describe analyses confirming the CVD spillway could convey a 1:500-year event; therefore, likelihood of tailings release is reduced, and the event sequence is a reasonable scenario. The release of contaminated water to the receiving environment, as described in the scenario, would cause adverse effects but they would likely be reversible, especially since they would occur during a period of extremely high flow with substantial dilution. This would result in, at most, a consequence category of “major” for environmental risk, “significant impact on valued ecosystem component and medium-term impairment of ecosystem function.” The cost to repair facilities would probably exceed $10,000,000, resulting in a consequence category of “critical” for cost risk. As a result, the summary tables only identify this risk in the cost category. This summary approach provides a valuable perspective because it is the highest risk rating for each event that defines the priorities for mitigative actions and annual work planning.

The following sections summarize environmental, cost, and human health and safety risks from the 2013 operational risk assessment.

3.1 2013 Environmental Risks

The 2013 operational risk assessment did not identify “high” or “very high” environmental risks for the FMC. This outcome illustrates the success of ongoing risk management evaluations and responses at the FMC, where actions have been taken to reduce environmental risks falling in these categories. Three environmental risks have ratings of “moderately high,” indicating that mitigation plans should be developed and implemented. The scenarios with “moderately high” environmental risks are described below along with responses that will be undertaken in the coming year.

- **A piping failure of the ID leads to release of contaminated water through the CVD Pond.** The status of the ID is addressed through ongoing monitoring programs, rendering the event unlikely.
- **Wind erosion from tailings causes contamination of surrounding land, affecting ecosystem health.** Dust control protocols should be revised to minimize wind erosion. These protocols have been developed as part of the IW Project Proposal and will be part of licence applications.
- **Contaminated water migrates below the CVD Pond, resulting in escape of contaminated water to environment.** The Adaptive Management Plan includes monitoring and thresholds that will guide the timely design and implementation of groundwater collection systems. Existing pumping wells could be used to

collect the affected water immediately. A collection system is currently being designed, and extensive aquifer testing has been completed to support this design.

3.2 2013 Cost Risks

The 2013 operational risk assessment identified three "high" cost risks for the FMC. These risks require appropriate mitigation responses to be developed and implemented immediately. The following paragraphs describe the "high" cost risks, alongside proposed responses that will be undertaken in the coming year.

- **The failure of the pit wall below the FCD, causingFaro Creek to flow into the pit for approximately 8 weeks.** This event would incur substantial additional costs to treat water and to repair the FCD. While the costs of repair cannot be addressed without constructing a new diversion (part of the Faro Mine Remediation Project), the treatment costs can be reduced by having pipe and pumps onsite to establish a temporary diversion quickly.
- **Poor water quality in the CVD Pond prevents discharge, requiring a change in water management strategy because storage and discharge through the CVD Pond is no longer functional.** Water quality changes in the CVD Pond in 2013 demonstrated this is a substantial risk, and it required the implementation of temporary filtration at the CVD Pond. Continuation of this approach, as well as other more cost-effective measures to address water quality concerns are under investigation.
- **Contaminated water migrates below the CVP, resulting in the escape of contaminated water to the environment.** Additional costs would arise because of requirements to implement groundwater collection and treatment. The Adaptive Management Plan includes monitoring and thresholds that will guide timely design and implementation of groundwater collection systems. A system is currently being designed, and extensive aquifer testing has been completed to support this design.

The 2013 operational risk assessment identified numerous "moderately high" cost risks. Many of these are associated with conveyance of extreme flood events through the Rose Creek Tailings Area, either in the RCD or through the ID spillway, or both. The Down Valley Interim Hydraulic Upgrades, proposed as part of the IW, focus on addressing these risks. Another series of "moderately high" cost risks are associated with potential changes in seepage collection requirements from waste rock dumps. The Adaptive Management Plan addresses seepage at these locations via monitoring and response thresholds. The effective implementation of this adaptive management approach led to the construction of the S-Wells seepage interception system that has provided protection of aquatic values in the North Fork Rose Creek since 2009. Similar responses will be implemented at other locations, as needed.

3.3 2013 Human Health and Safety Risks

The 2013 operational risk assessment identified two "high" human health and safety risks for the FMC. These risks require appropriate mitigation to be developed and implemented immediately. They are described herein, alongside mitigative actions that will be undertaken in the coming year.

- **Faro Pit wall failure occurs while personnel and equipment are working on the FCD.** This is a new risk identified in 2013, reflecting concern about heavy equipment operation along the FCD near the pit wall and potential implications on physical stability. Stability under these circumstances will be evaluated further, and appropriate responses developed.
- **Worker breaks through the ice and/or falls into water, resulting in injury or death.** Operational procedures and training have been implemented for working on ice or water. However, working on ice and water is inherently hazardous and some risk remains.

The 2013 operational risk assessment identified numerous "moderately high" human health and safety risks. Several of these are related to unauthorized access to onsite facilities by members of the public. Ongoing improvements to site and building security will reduce the likelihood of such events. The fact that the Mill Building is no longer in use for water treatment also eliminates the need for daily access by site staff and equipment,

providing opportunities for more effective access control. Some additional “moderately high” risks are associated with other uses of the Mill Building. Reduced overall use of that facility will reduce these risks. Finally, a new risk identifies potential worker health and safety effects associated with the daily operation of the proposed interim water treatment system in an area that may have high lead concentrations. Further investigation will identify the scope of the risk, and remedial measures may be required to address this risk.

TABLE 5D-4

2013 Characterization of Environmental Risks (Excluding "Low" Risks)

Faro Mine Interim Works

Likelihood	Consequence Severity					Risk Events
	Low	Minor	Moderate	Major	Critical	
Almost Certain						**1.4** Piping Failure of ID causing release of water/tailings to CVD Pond, with possible release of water from CVD Pond to environment. **8.4** Failure of CVD because of pit wall collapse, resulting in Vangorda Creek flowing into Vangorda Pit, filling and overflowing the pit, followed by the eventual discharge of contaminated water only to Vangorda Creek channel. **16.1** Extreme wind leads to erosion of tailings and offsite contamination, which affects health of local environment (humans, vegetation, wildlife). **28.4** Contaminated water migrating below CVD Pond results in escape of contaminated water to environment. **26.2** Seepage through Secondary Dam causes contamination in RCD, which leads to water quality issue. **33.1** Any delay to the interim water treatment system so that it is not operational for 2014 results in filling the Faro Pit beyond 1153 metres above sea level or increased inflows to Zone II. **36.1** Water level in ID Pond is higher than can be managed by current pumping system results in release of contaminated water into the receiving water environment through the CVD Pond. **14.6** Continued seepage through Grum Waste Dump discharging into Moose Pond leads to exfiltration to Vangorda Creek at unacceptable levels. **14.7** Catastrophic failure of Moose Pond leads to contamination of Vangorda Creek because of failure to divert additional flows.
Likely		33.1	16.1			
Possible		26.2, 36.1, 14.7	28.4			
Unlikely			8.4, 14.6	1.4		
Very Unlikely						

Note:
ID Pond = Intermediate Dam Pond

TABLE 5D-5

2013 Characterization of Cost Risks (Excluding "Low" and "Moderate" Risks)

Faro Mine Interim Works

Likelihood	Consequence Severity					Risk Events
	Low	Minor	Moderate	Major	Critical	
Almost Certain			**28.1**			**7.1** Failure of pit wall below FCD leads to Faro Creek flowing into the Faro Pit for approximately 8 weeks. **28.1** CVD Pond poor water quality prevents discharge through the CVD Pond and requires change to water management strategy, resulting in inability to store/release treated water in CVD Pond. **28.4** Contaminated water migrates below CVP results in escape of contaminated water to environment. **1.1** Earthquake induced liquefaction leads to failure of both ID and the CVD and a release of contaminated water and up to 10-20% of volume of tailings. Note: ID meets Maximum Credible Earthquake. **1.2** Probable Maximum Flood event exceeds the capacity of the ID spillway, leading to release of tailings and water to environment. **1.3** A 500- to 1,000-year return period flood event exceeds the capacity of the ID spillway, breach of the ID, release of contaminated water and 10-20% of the total volume of tailings to the CVD Pond. The CVD Pond spillway releases contaminated water to the environment, but the tailings are contained in the CVD Pond. **2.1** Seismic event results in a breach of the CVD and release of treated water and sludge. **4.1** Failure of Little Creek Dam and release of contaminated water in to Vangorda Creek. **6.1** Slope failure of the RCD resulting in outflow to ID Pond and exceedance of ID spillway capacity, overtopping and failure of ID with release of contaminated water and 10-20% of the total volume of tailings to the CVD Pond. The CVD Pond spillway releases contaminated water to the environment, but the tailings are contained in the CVD Pond. **6.2** Ice formation over extended length of time in RCD, overtopping into ID Pond, failure of ID, release of contaminated water and 10-20% of the total volume of tailings to the CVD Pond. The CVD Pond spillway releases contaminated water to the environment, but the tailings are contained in the CVD Pond. **6.3** Debris flow originating in the tributaries to the west of RCD blocks the channel, filling, overtopping, and failure of the ID with a release of contaminated water and 10-20% of the total volume of tailings to the CVD Pond. The CVD Pond spillway releases contaminated water to the environment, but the tailings are contained in the CVD Pond. **6.4** Seismic induced failure of the RCD over a 50- to 100-metre portion of channel, discharge (low volume – low velocity) into the ID Pond. Water with elevated concentrations of zinc (minimal suspended solids) fills the ID Pond, flows out via ID Pond Spillway, into and out of the CVD and into the receiving environment. **8.4** Failure of VCD because of pit wall collapse resulting in Vangorda Creek flowing into Vangorda Pit, filling and overflowing the pit, followed by the eventual discharge of contaminated water only to Vangorda Creek channel. **8.5** Collapse or failure of VCD Drop Structure, total blockage, overflowing road access and into the Vangorda Pit (not including peak flows, which is included in failure of VCD event). Environmental impact because of erosion of road and sediments entering the receiving environment. **30.1** Flood event causes a breach of RCD and leads to a breach of ID and release of tailings and water. **30.3** Catastrophic structural failure of the RCD during a 1:50 to 1:100 return event caused by overtopping/ erosion of fuse plug and/or high seepage stresses in dike, breach of dike, or uncontrolled flow of RCD into the ID Pond for a period of 1 month. ID Pond spillway conveys majority of flow into CVD, short circuits the CVP, and leads to discharge of undiluted IP overflow into the environment. **12.2** Monitoring shows need to collect and treat additional contaminated water from Faro Rock Dumps. **13.4** Monitoring shows need to collect and treat additional contaminated water from Vangorda Waste Dump. **14.2** Monitoring shows need to collect and treat additional contaminated water from Grum Waste Dump. **15.1** Monitoring shows need to collect and treat additional contaminated water from Grum Ore Transfer Pad.
Likely			**8.5, 12.2**			
Possible			**4.1, 6.4, 30.3, 13.4, 14.2, 15.1**	**7.1, 28.4**		
Unlikely				**2.1**	**1.3, 6.1, 6.3, 8.4, 30.1**	
Very Unlikely					**1.1, 1.2, 6.2**	

Note:
VCD = Vangorda Creek Diversion

TABLE 5D-6

2013 Characterization of Human Health and Safety Risks (Excluding "Low" Risks)

Faro Mine Interim Works

Likelihood	Consequence Severity					Risk Events
	Low	Minor	Moderate	Major	Critical	**7.3** Faro Pit wall failure occurs while personnel and equipment are working on the FCD.
						34.1 Worker breaks through the ice and/or falls into water, resulting in injury or death.
						22.1 Structural failures of Mill Building or component, or by impact of existing condition, causes injury or death to site staff or contractors.
Almost Certain						**22.2** Unauthorized access to Crusher and Coarse Ore buildings by public leads to serious injury or fatality.
						22.3 Unauthorized access to utilized buildings by public results in serious injury or fatality.
						22.4 Unauthorized access/entry to Mill Buildings by public leads to serious injury/fatality.
Likely			**33.2**			**19.2** Worker fatality results from condition/operation of the electrical distribution system.
						19.3 Fatality of public caused by unauthorized access and interaction with power distribution system, most likely because of theft of copper.
Possible				**34.1**	**7.3**	**33.2** Possible contaminants (lead dust, zinc, coal) in the proposed location for replacement water treatment plant causes health and safety issues.
						9.1 Unauthorized access to Faro Pit wall leads to injury or fatality (Fall Hazard).
Unlikely				**22.1, 22.2, 22.3, 22.4, 19.2, 19.3, 9.1, 9.3, 10.2, 11.2**		**9.3** Rockfall near Faro Pit walls causes injury or death.
						10.2 Unauthorized access to Vangorda Pit wall leads to injury or fatality (fall hazard).
						11.2 Unauthorized access to Grum Pit wall leads to injury or fatality (fall hazard).
Very Unlikely						

SECTION 4

Application of Risk Assessment Findings to Faro Mine Interim Works

The YG convenes risk assessment workshops annually in the autumn, and maintains a database that tracks the identification, evolution, and mitigation of risks over time. The results of the yearly risk assessments guide annual work planning for the FMC, justifying annual budgets. Risk assessments provide rationale for annual work plan budgets associated with site operations (e.g., monitoring requirements and changes in water management approaches), site investigations to address evolving areas of concern (e.g., drilling programs in areas of evolving groundwater conditions), mitigation measures to address risks (e.g .replacement or re-alignment of piping), or equipment replacement (e.g. water treatment equipment or heavy mobile equipment). In this context, risk assessment will continue to be one of the planning tools used throughout the IW to annually identify site actions and activities, and prioritize spending.

1 Introduction

The Spill Contingency Plan provides a framework of responsibilities and response measures to be taken by staff and contractors when responding to spills. In the event of an accidental release of a deleterious substance, the implementation of the Spill Contingency Plan will ensure that the necessary steps are taken to minimize the effects on human health and safety and the environment.

Under the Yukon *Environment Act*, a spill is defined as follows:

"spill" means a release of a substance (a) into the natural environment; (b) from or out of a structure, vehicle, or other container; and (c) that is abnormal in quantity or quality in light of all the circumstances of the release; or (d) in excess of an amount specified in the regulations.
"substance" means a hazardous substance, pesticide, contaminant, or special waste.

1.1 Regulatory Requirements

The regulatory requirements in the Yukon, as it relates to spills, are stipulated under *Part 11 – Spills* and under the *Spills Regulations* of the Yukon *Environment Act* (see Appendix A and Appendix B).

Spills Regulations

The Yukon *Spill Regulations* were developed pursuant to Section 147 of the Yukon *Environment Act* and came into force January 1, 1997. The regulations establish thresholds of various substances which, if quantities spilled are in excess of those amounts, constitute a spill under the Act.

The territorial regulations further require the reporting to the Yukon Spills Report Centre when such an event occurs. A report to the Yukon Spills Report Centre also constitutes a report to Environment Canada so only a single call is required. See Section 4.1 for further details.

With respect to the Faro Mine Complex (FMC), the most common substances which could result in a potentially reportable spill are presented in Table 1.1 (below).

Table 1.1: Reportable Substances Commonly Found at Site

Common Name	Classification	Reportable Threshold
Propane	Flammable Gas (Division 1 of Class 2)	Any amount of gas from a container larger than 100 L, or where the spill results from equipment failure, error or deliberate action or inaction
Gasoline, Diesel Fuel, Heating Fuel, Bulk Oil, Waste Oil	Flammable Liquids (Class 3)	200 L
Lime Solids or Lime Slurry	Class 8	5 kg or 5 L
Sodium Hypochlorite	Class 8	5 kg or 5 L
Contaminated Water	Class 8	Any amount of water containing concentrations of zinc, lead, total suspended solids or other materials in excess of allowable releasable concentrations. Any release of mine waters from a non-approved release point.

Contaminated Site Regulations

In the event of a spill, all remediation activities must be conducted in accordance with the *Contaminated Site Regulations* of the Yukon *Environment Act*. The *Contaminated Site Regulations* establishes cleanup standards, processes for identifying and investigating contaminated sites, and permits for managing contaminated material within the Yukon. See Appendix C for a guide to *Contaminated Site Regulations*.

Storage Tank Regulations

The Yukon *Storage Tank Regulations* were developed pursuant to Section 146 of the Yukon *Environment Act*. Section 5 of the regulations specifies above ground storage tank capacities that require a permit (i.e. petroleum product tank [4,000 L] and hazardous material tank [2,000 L]) and Section 8 specifies the requirement of a permit to remove, abandon or decommission tanks of these sizes. Section 11 specifies the inventory records that need to be maintained and the reporting requirements in the event of any discrepancies as stipulated in that section. See Appendix D for this regulatory document.

Transportation of Dangerous Goods Regulations

The *Transportation of Dangerous Goods Regulations* pursuant to *Transportation of Dangerous Goods Act* identifies the classification of various substances and outlines the federal restrictions with respect to the packaging, handling, placarding and transport of those substances.

2 Spill Preparedness and Prevention

2.1 Training

Spill prevention and response is included in the site worker orientation and reiterated at safety meetings during the treatment season. Employees participating in or authorizing program activities involving spill prevention, containment or counter measures shall receive training such that they acquire the competence, knowledge (including regulatory requirements) and skill necessary for the safe and comprehensive performance of the duties assigned. Mock spills are utilized from time to time to provide some practical experience.

Refresher training is conducted periodically according to legal requirements or at appropriate intervals, or at least once every year. A job-specific overview of the program shall be included in the standard training for new and transferred employees.

The site operator will regularly reminds its employees of the importance of taking preventative actions to avoid spills, immediate reporting in the event of a spill and the need for quick response.

2.2 Management and Procedures

2.2.1 Petroleum Products

Petroleum products are effectively managed and losses due to spills or leaks are avoided through the following inspection activities:

1. Fuel tanks are manually dipped before and after fuel delivery. After adding product to the tank, a site operations representative will inspect the site to verify valves are properly shut off and any small leaks or spills during filling have been appropriately cleaned up.

2. Storage area inspections are conducted daily by site operations personnel and during the tank measurements, to detect any abnormal situations and determine the need to pump water from the secondary containment of the storage tanks.

3. During winter periods, inspection of the fuel storage areas is included on the weekend on-call checklist.

4. On a quarterly basis, secondary containment of double walled tanks are inspected to determine if any leakage into the secondary containment area has occurred. This is included on the routine quarterly checklist.

Fuelling of heavy equipment by the site fuel truck is conducted well away from freshwater systems (minimum 30 meters) such that any potential spills can be isolated and cleaned up well before it enters freshwater. This principle is re-enforced with operating personnel through mechanisms such as Tool Box meetings. Special measures are taken for stationary equipment operating close to water to contain spills and facilitate immediate and effective clean up in the event of a loss of fuel (e.g. location must provide some protection to ensure a potential spill will not report directly to a waterbody). An inventory of spill response materials is maintained to effectively deal with fuel spills up to 1,000 litres.

2.2.2 Contaminated Water

The potential for contaminated water escaping to freshwater systems constitutes a spill risk at the FMC as the site is comprised of several water management structures. Over the years a number of actions have been undertaken at the site to prevent and reduce the likelihood of a spill. Some examples of these include:

- The pipeline from Vangorda Pit to the Vangorda Water Treatment Plant was placed within a secondary flow control ditch which would route a potential loss of water back to the pit.
- A pressure sensitive safety shutoff, which would terminate the pumping in the event of a line break, was installed S wells pumping system.
- A containment ditch, draining back to the dam, was constructed from the point where the Little Creek Dam Dewatering pipeline rises above the crest of the Dam to the point where it joins the Vangorda Haul Road.

As per Canadian Dam Association Dam Safety Guidelines (2007), an Emergency Response and Preparedness Plan (ERPP) and an Operations, Maintenance and Surveillance Manual (OMSM) are required for retaining structures. These documents provide detailed descriptions of measures taken at site to prevent and respond to emergencies at the site. A brief description of the ERPP and OMSM is provided below, although for further information these documents should be referred to.

Emergency Response and Preparedness Plan

The purpose of the ERPP is to provide a plan that includes mechanisms and processes for addressing potential failures of structures and equipment at the Faro Mine Complex. This ERPP describes the internal processes and procedures of a response to a failure or potential failure at the site. Having an ERPP in place enables site personnel to be prepared in the event of an emergency. It also provides one component of a comprehensive facility management system for the tailings facility and associated structures. The goals of the ERPP are to firstly prevent the occurrences of emergencies and secondly to reduce the impact of emergencies. In both cases the goal is to protect human health and safety, and the environment.

Operations, Maintenance and Surveillance Manual

This OMSM provides a documented framework for actions in order to ensure the safe operation, maintenance, and surveillance of the facility. The OMSM is a live document in that it will regularly requires updating; information is updated at a minimum of once per year, as well as at every change in critical personnel or contractors, and changes in procedures or conditions on-site.

3 Spill Response

3.1 Spill Response Procedure

Upon discovery of a spill, all personnel will take immediate action to notify others on site and, when appropriate, control and remediate the spill. Below are the general steps that will be followed in the event of a spill. Refer to Figure 1 for further detail on the process of responding to a spill as well as the roles and responsibilities of each party.

Identification

1. Identify hazards, secure the area (i.e. extinguish fire or spark) and restrict access if necessary.

    a. Refer to Appendix E spill response measures should the spilled substance be Sodium Hypochlorite.

2. Contact Site Security; inform them of situation and request medical or fire assistance if necessary. This initiates the communication procedures as identified in Figure 1.

3. Identify the spilled material and if it is safe to approach.

Response

4. Stop or minimize product flow, if safe to do so.

5. Assess the severity of the spill and personal protective equipment (PPE) needs; if necessary refer to the MSDS for information appropriate handling requirements.

Containment

6. Initiate product containment. Contain spill by:

    a. Damming or diverting the spilled material;

    b. Preventing wind dispersion or erosion by water; and/or

    c. Apply absorbent materials (in spill kit).

7. Site Manager verifies provisions for personal safety, stoppage of product flow, and containment.

Remediation

8. Notify site environmental coordinator to collect samples required. A spill sampling kit is available at the Faro Guardhouse (with Security); Appendix E identifies the contents of the kit and the sampling procedures. To assess the impact of the spill:

    a. If spill in water, water samples should be taken during the spill and throughout the remediation process (refer to Appendix F for sampling instructions); and

b. If spill on land, take soil samples following remediation of the spill site (refer to Appendix
F for sampling instructions).

9. Develop a remediation plan to restore the site, to the extent possible, to the same condition that it was in before the spill, in accordance with the *Contaminated Sites Regulation* (see Appendix C and refer to complete *Contaminated Sites Regulation*). Steps that may be included in the remediation plan include:

    a. Site assessment to identify the areas, depths and concentrations of contaminants on the site.

    b. Selecting a restoration strategy (e.g. ex-situ or in-situ remediation).

    c. Applying for and receiving necessary permits (e.g. Relocation Permit, Land Treatment Facility Permit).

    d. Confirmatory Sampling to show that all contaminants have been removed or remediated.

10. Implement remediation plan as approved by the Project Manager and/or Site Manager.

Report

11. The Mine Manager reports the spill as soon as possible to the Yukon Spill Report Line, at **867-667-7244** (i.e. should the volume meet or exceed reporting thresholds found in the Yukon *Spill Regulations* (Appendix B)). Be prepared to provide the following information:

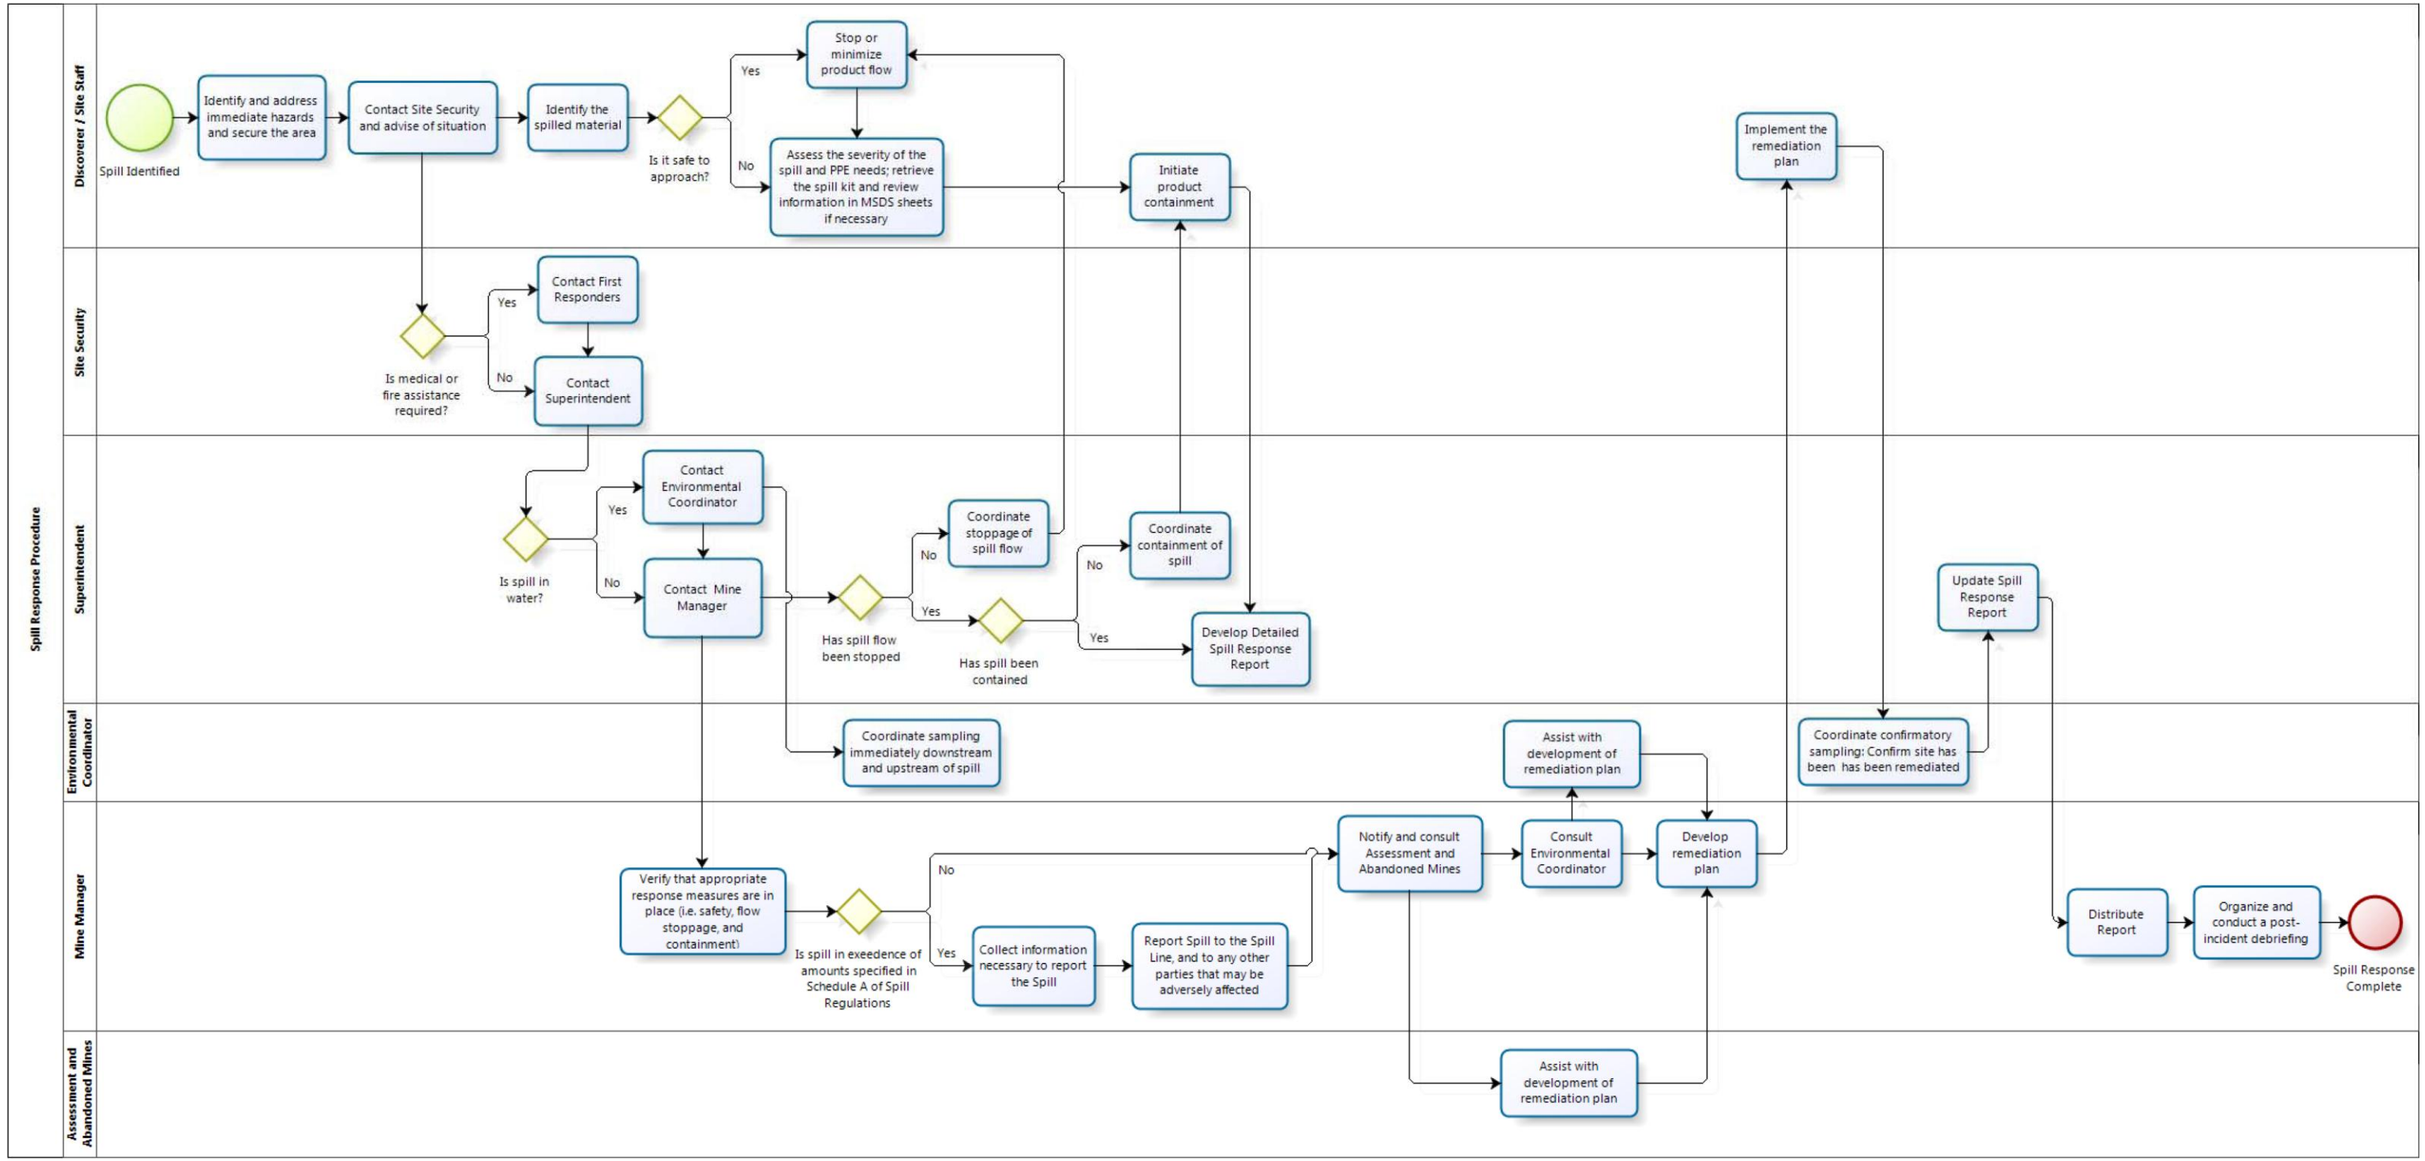
    a. The location and time of the spill;

    b. The circumstances leading up to the spill;

    c. The type and quantity of material spilled;

    d. The details of any action taken at the spill site; and

    e. A description of the environment at the location of the spill (e.g. terrain, watercourses, etc.)



12. Notify as soon as possible other parties or members of the public who may be adversely affected by the spill.

13. Develop a detailed Spill Response Report including but not limited to the information indicated above and other relevant details and explanations. See Spill Report Form in Appendix G for further detail.

Debrief

14. Organize and conduct a post-incident debriefing and implement any required procedural changes.

Figure 1: Spill Response Procedure Flow Diagram

3.2 Spill Kits and Material Safety Data Sheets

Material Safety Data Sheets (MSDS) contain detailed information about a specific product, including the risks of exposure, methods of storage and disposal, protective measures for exposed workers and emergency first aid procedures. Current MSDS must be maintained and accessible to all employees. The MSDS must be current (within 3 years) on all products in the workplace. The MSDS sheets for hazardous materials present at the FMC are provided in Appendix H. This Spill Contingency Plan (along with the appendices) is included in all spill kits and is available in the FMC guardhouse.

Spill response materials and supplies to effectively deal with spills are available at the following locations on site:

- Diesel Fuel Station
- Gas Fuel Station
- Guardhouse Lab

The spill kits at those locations contain response materials specific to the hazardous materials located in those areas. The Warehouse contains a larger quantity and variety of spill response materials. Refer to Appendix I for an inventory of spill response materials and supplies at the FMC.

Appendices

Appendix A – Environment Act - Part 11: Spills

PART 11

SPILLS

Definition

132 In this Part,

"spill" means a release of a substance

(a) into the natural environment;

(b) from or out of a structure, vehicle, or other container; and

(c) that is abnormal in quantity or quality in light of all the circumstances of the release; or

(d) in excess of an amount specified in the regulations. *« déversement »*

"substance" means a hazardous substance, pesticide, contaminant, or special waste. *« substance » S.Y. 1991, c.5, s.132.*

Report of spill

133 A person in control of a substance at the time of a spill or who causes a spill shall report the spill, as soon as possible under the circumstances, to an environmental protection officer and shall make a reasonable effort to notify the owner or person in charge of the spilled substance and any members of the public who may be adversely affected by the spill. *S.Y. 1991, c.5, s.133.*

Contents of report

134 The person who is required to report pursuant to section 133 shall report in person or by telephone, and shall, if they have knowledge of the information or can readily obtain it, provide the following information

(a) the location and time of the spill;

(b) a description of the circumstances leading up to the spill;

(c) the type and quantity of the material or

PARTIE 11

DÉVERSEMENTS

Définition

132 Les définitions suivantes s'appliquent à la présente partie.

« déversement » Rejet dans l'environnement naturel d'une substance dont l'évacuation hors d'un ouvrage, véhicule ou autre contenant présente des caractéristiques quantitatives ou qualitatives anormales, compte tenu des circonstances s'y rapportant, ou se fait en quantité excédant les maximums réglementaires. *"spill"*

« substance » Substance dangereuse, pesticide, polluant ou déchets spéciaux. "*substance*" *L.Y. 1991, ch. 5, art. 132*

Signalement des déversements

133 Quiconque a le contrôle d'une substance au moment de son déversement ou en cause le déversement est tenu de le signaler dans les meilleurs délais possible, à un agent de protection de l'environnement et de s'efforcer raisonnablement de le notifier au propriétaire ou au responsable de la substance déversée et à toute personne à qui le déversement pourrait causer un préjudice. *L.Y. 1991, ch. 5, art. 133*

Teneur du rapport

134 La personne visée à l'article 133 signale l'incident, en personne ou par téléphone, et mentionne les renseignements suivants, lorsqu'elle les détient ou peut les obtenir sans difficulté :

a) le lieu et le moment du déversement;

b) les circonstances s'y rapportant;

c) le type et la quantité de la matière ou de la

substance which has spilled;

(d) the details of any action taken at the site of the spill;

(e) a description of the location of the spill and the immediately surrounding area; and

(f) any additional information in respect of the spill that the Minister, environmental protection officer, or person designated by the regulations requires. *S.Y. 1991, c.5, s.134.*

Duty to mitigate

135 If a spill occurs, the person who owns or has possession, charge, or control of the spilled substance at the time of the spill shall, when they have knowledge of the spill,

(a) take all reasonable measures

(i) to confine, repair, and remedy the effects of the spill; and

(ii) to remove the substance spilled in such a manner as to reduce or mitigate any danger to human life, health, and the natural environment; and

(b) restore or rehabilitate the natural environment to a condition reasonably equivalent to the condition that existed immediately before the spill occurred. *S.Y. 1991, c.5, s.135.*

Environmental protection orders relating to spills

136 If there has been a spill, the Minister or an environmental protection officer may issue an environmental protection order to the person who owns or who had possession, charge, or control of the spilled substance at the time it was spilled ordering that person to take any measures that the Minister or the environmental protection officer considers necessary to protect, restore, or rehabilitate the natural environment, including any or all of the

substance déversée;

d) le détail des mesures correctives prises sur place;

e) une description du lieu où s'est produit le déversement et des environs immédiats;

f) toute autre donnée exigée par le ministre, l'agent de protection de l'environnement ou la personne désignée par règlement. *L.Y. 1991, ch. 5, art. 134*

Obligation d'atténuer les effets

135 Quiconque est propriétaire, a possession, ou a la responsabilité ou le contrôle de la substance déversée en question au moment de son déversement est tenu, lorsqu'il a connaissance du déversement :

a) de prendre toutes les mesures appropriées pour :

(i) limiter, réparer et corriger les conséquences du déversement,

(ii) récupérer la substance déversée de manière à réduire ou à atténuer le danger pour la vie ou la santé humaine et l'environnement naturel;

b) de restaurer l'environnement naturel ou de le remettre dans un état raisonnablement comparable à celui dans lequel il était immédiatement avant le déversement. *L.Y. 1991, ch. 5, art. 135*

Ordonnances de protection de l'environnement concernant les déversements

136 En cas de déversement, le ministre ou un agent de protection de l'environnement peut prendre une ordonnance de protection de l'environnement enjoignant à la personne qui est propriétaire, a possession ou a la responsabilité ou le contrôle de la substance déversée au moment de son déversement de prendre toutes les mesures qu'il juge nécessaires pour protéger et restaurer l'environnement

following measures

(a) to investigate the spill;

(b) to minimize or remedy the effects of the spill;

(c) to restore the area affected by the spill to a condition reasonably equivalent to the condition that existed immediately before the spill occurred;

(d) to measure the rate of release or the ambient concentration of the substance spilled;

(e) to install, repair, or alter any equipment or thing designed to control or eliminate the release of the substance spilled;

(f) to monitor, measure, contain, remove, store, destroy, or otherwise dispose of the substance spilled, or to lessen or prevent further spills of or control the rate of release of the substance spilled; and

(g) to report on any matter ordered to be done in accordance with directions set out in the order. *S.Y. 1991, c.5, s.136.*

Failure to mitigate

137 If any person fails to take the measures required under paragraph 135(a), and an environmental protection officer is of the opinion that danger to human life or health or to the natural environment is occurring or may occur, an environmental protection officer may take the measures, described under paragraph 135(a), cause them to be taken or direct any person referred to in section 135 to take them. *S.Y. 1991, c.5, s.137.*

Inconsistency with another act

138 Any direction of an environmental protection officer under section 137 that is inconsistent with any other enactment is void to the extent of the inconsistency. *S.Y. 1991, c.5, s.138.*

naturel ou le remettre en état, notamment :

a) faire enquête sur le déversement;

b) limiter le plus possible ou corriger les conséquences du déversement;

c) remettre la zone touchée dans un état raisonnablement comparable à celui dans lequel elle était immédiatement avant le déversement;

d) mesurer le taux de rejet ou la concentration de la substance déversée dans le milieu ambiant;

e) installer, réparer ou modifier tout matériel ou dispositif destiné à contrôler ou à empêcher le rejet de la substance déversée;

f) surveiller, mesurer, contenir, enlever, entreposer, détruire ou, de quelque autre façon, éliminer la substance déversée, diminuer ou empêcher tout autre déversement ou contrôler le taux de rejet de la substance en question;

g) signaler tout autre aspect visé par l'ordonnance. *L.Y. 1991, ch. 5, art. 136*

Manquement à atténuer les conséquences

137 Si le destinataire de l'ordonnance prévue à l'article 135 ne prend pas les mesures exigées à l'alinéa 135a), l'agent de protection de l'environnement peut les prendre lui-même, les faire prendre ou ordonner au destinataire de les prendre, s'il estime que l'omission compromet ou risque de compromettre la vie ou la santé humaine. *L.Y. 1991, ch. 5, art. 137*

Incompatibilité avec une autre loi

138 Les dispositions d'un autre texte l'emportent sur les directives incompatibles données par l'agent de protection de l'environnement en vertu de l'article 137. *L.Y. 1991, ch. 5, art. 138*

Right of access

139(1) When it is necessary to prevent serious imminent harm to a person or the natural environment, an environmental protection officer authorized or other person directed to take any measures under section 137 may subject to section 152 enter and have access to any place or property and may do any reasonable things necessary in the circumstances.

(2) Subject to subsection (3) a person who provides assistance or advice in taking the measures required by sections 135, 136 or 137, is not personally liable in respect of anything done or omitted in good faith in the course of providing the assistance or advice.

(3) Subsection (2) does not exempt from liability a person described in subsection 133. *S.Y. 1991, c.5, s.139.*

Droit d'accès

139(1) L'agent de protection de l'environnement autorisé ou la personne visée à l'article 137 peuvent, sous réserve de l'article 152, pénétrer dans tout lieu ou bien et prendre les mesures nécessaires pour empêcher qu'un grave préjudice imminent ne soit causé à une personne ou à l'environnement naturel.

(2) Sous réserve du paragraphe (3), n'encourt aucune responsabilité personnelle pour les actes ou omissions qu'elle commet de bonne foi à cette occasion, la personne qui fournit aide et conseils pour l'intervention visée aux articles 135, 136 ou 137.

(3) Le paragraphe (2) n'exonère pas de sa responsabilité la personne visée à l'article 133. *L.Y. 1991, ch. 5, art. 139*

PART 12

REGULATIONS

Regulations concerning Parts 1, 2, 4, 5 and 15

140 The Commissioner in Executive Council may make regulations relating to Parts 1, 2, 4, 5 and 15 respecting any matter which the Commissioner in Executive Council considers necessary to carry the purposes and provisions of Parts 1, 2, 4, 5, and 15 into effect. *S.Y. 1991, c.5, s.140.*

Regulations concerning Part 3

141 The Commissioner in Executive Council may make regulations relating to Part 3 including regulations

(a) prescribing the establishment of work place environmental committees and their composition, function, powers, procedures, and related matters;

(b) respecting regulatory, economic, or other incentives to encourage conservation of the natural environment and to promote

PARTIE 12

RÈGLEMENTS

Règlements d'application des parties 1, 2, 4, 5 et 15

140 Le commissaire en conseil exécutif peut, par règlement, prendre les mesures qu'il juge nécessaires pour l'application des parties 1, 2, 4, 5 et 15. *L.Y. 1991, ch. 5, art. 140*

Règlements d'application de la partie 3

141 Le commissaire en conseil exécutif peut, par règlement pris en application de la partie 3 :

a) régir l'établissement de comités de l'environnement en milieu de travail et fixer leur composition, leur mission, leur règlement interne et autres questions connexes;

b) instituer des mesures d'encouragement réglementaires, économiques ou autres pour la conservation de l'environnement naturel

Appendix B – Environment Act - Spills Regulations

ENVIRONMENT ACT

Pursuant to section 147 of the *Environment Act*, the Commissioner in Executive Council orders as follows:

1. The annexed Spills Regulations are established.

2. The annexed Regulations shall come into force with effect from the 1st day of January, 1997.

Dated at Whitehorse, in the Yukon Territory, this 16th day of December, 1996.

_____
Commissioner of the Yukon

LOI SUR L'ENVIRONNEMENT

Le Commissaire en conseil exécutif, conformément à l'article 147 de la *Loi sur l'environnement*, décrète ce qui suit :

1. Le Règlement sur les déversements ci-joint est établi.

2. Ce même règlement entre en vigueur le 1er janvier 1997.

Fait à Whitehorse, dans le territoire du Yukon, ce 16 décembre 1996.

_____
Commissaire du Yukon

SPILLS REGULATIONS

Definitions

1. In these regulations,

"Act" means the *Environment Act*; *«loi»*

"Federal Regulations" means the Transportation of Dangerous Goods Regulations (Canada) SOR/85/77 of January 18, 1985, as amended from time to time; *«règlement fédéral»*

"government officials" means federal, territorial or municipal government representatives responsible for responding to spill reports to the Yukon Spills Report Centre. *«fonctionnaires du gouvernement»*

Application

2.(1) These regulations do not apply to a release of gas without flaring where authorized by a licence issued under the *Yukon Oil and Gas Act.*

(2) These Regulations do not apply to ozone depleting substances listed in Schedule A of the Ozone Depleting Substances Regulations.

Spill thresholds

3. A spill in excess of the amounts specified in Schedule A is a spill under the Act.

Spill reporting

4. For the purposes of section 133 of the Act, a report to the Yukon Spills Report Centre will be considered a report to an environmental protection officer.

RÈGLEMENT SUR LES DÉVERSEMENTS

Définitions

1. Les définitions suivantes s'appliquent au présent règlement :

«fonctionnaires du gouvernement» Les représentants des gouvernements fédéral, provinciaux ou municipaux, responsables d'intervenir suite à un avis de déversement auprès du «Yukon Spills Report Centre»; *"government officials"*

«loi» S'entend de la *Loi sur l'environnement*; *"Act"*

«règlement fédéral» S'entend du Règlement sur le transport des marchandises dangereuses (Canada), DORS/85-77, du 18 janvier 1985, ainsi que ses modifications. *"Federal Regulations"*

Application

2.(1) Le présent règlement ne s'applique pas à un rejet de gaz sans torchage lorsqu'il est autorisé en vertu d'un permis émis conformément à la *Loi du Yukon sur le pétrole et le gaz*.

(2) Le présent règlement ne s'applique pas aux substances appauvrissant la couche d'ozone apparaissant à l'annexe A du Règlement sur les substances appauvrissant la couche d'ozone.

Seuils limites

3. Un déversement qui excède les quantitées indiquées à l'annexe A est assimilé à un déversement en vertu de la Loi.

Rapport de déversement

4. Aux fins de l'article 133 de la Loi, un rapport de déversement au «Yukon Spills Report Centre» est assimilé à un rapport fait à un agent de protection de l'environnement.

SCHEDULE A

ITEM	COLUMN 1 - SUBSTANCE SPILLED	COLUMN 2 - SPECIFIED AMOUNT
1.	Explosives of Class 1 as defined in section 3.9 of the Federal Regulations	any amount
2.	Flammable gases, of Division 1 of Class 2 as defined in section 3.11(a) of the Federal Regulations	Any amount of gas from a container larger than 100L, or where the spill results from equipment failure, error or deliberate action or inaction
3.	Non-flammable gases of Division 2 of Class 2 as defined in section 3.11(d) of the Federal Regulations	Any amount of gas from a container larger than 100L, or where the spill results from equipment failure, error or deliberate action or inaction
4.	Poisonous gases of Division 3 of Class 2 as defined in section 3.11(b) of the Federal Regulations	any amount
5.	Corrosive gases of Division 4 of Class 2 as defined in section 3.11(c) of the Federal Regulations	any amount
6.	Flammable liquids of Class 3 as defined in section 3.12 of the Federal Regulations	200 L
7.	Flammable solids of Class 4 as defined in section 3.15 of the Federal Regulations	25 kg
8.	Products or substances that are oxidizing substances of Division 1 of Class 5 as defined in sections 3.17(a) and 3.18(a) of the Federal Regulations	50 kg or 50 L
9.	Products or substances that are organic compounds that contain the bivalent "-0-0-" structure of Division 2 of Class 5 as defined in sections 3.17(b) and 3.18(b) of the Federal Regulations	1 kg or 1 L
10.	Products or substances that are poisons of Division 1 of Class 6 as defined in sections 3.19(a) to (e) and 3.20(a) of the Federal Regulations	5 kg or 5 L
11.	Organisms that are infectious or that are reasonably believed to be infectious and the toxins of these organisms as defined in sections 3.19(f) and 3.20(b) of the Federal Regulations	any amount
12.	Radioactive materials of Class 7 as defined by section 3.24 of the Federal Regulations	any discharge or a radiation level exceeding 10 mSv/h at the package surface and 200 mSv/h at 1 m from the package surface
13.	Products or substances of Class 8 as defined by section 3.24 of the Federal Regulations	5 kg or 5 L

ITEM	COLUMN 1 - SUBSTANCE SPILLED	COLUMN 2 - SPECIFIED AMOUNT
14.	Miscellaneous products or substances of Division 1 of Class 9 as defined by sections 3.27(1) and 2(a) of the Federal Regulations	50 kg or 50 L
15.	Miscellaneous products or substances of Division 2 of Class 9 as defined in section 3.27(1) and 2(b) of the Federal Regulations	1 kg or 1 L
16.	Miscellaneous products or substances of Division 3 of Class 9 as defined in section 3.27(1) and 2(c) of the Federal Regulations	5 kg or 5 L
17.	Special waste as defined in section 1 of the Special Waste Regulations	amounts specified in s. 3(1)(b) of Special Waste Regulations
18.	A pesticide as defined in section 2 of the *Environment Act*, but not including those pesticides and fertilizers listed in Schedule 4 of the Pesticide Regulations	5 kg or 5L
19.	Pesticides and fertilizers listed in Schedule 4 of the Pesticide Regulations	any amount

ANNEXE A

ITEM	1ière COLONNE - SUBSTANCE DÉVERSÉE	2ième COLONNE - QUANTITÉ DÉTERMINÉE
1.	Explosifs de classe 1, tels que décrits à l'article 3.9 du règlement fédéral	Toute quantité
2.	Gaz inflammables de la division 1, classe 2, tels que décrits à l'alinéa 3.11 a) du règlement fédéral	Toute quantité de gaz à l'intérieur d'un récipient pouvant contenir plus de 100 litres, ou lorsque le déversement est le résultat d'une défectuosité de l'équipement, d'une erreur ou d'un acte ou d'une omission délibéré
3.	Gaz ininflammables de la division 2, classe 2, tels que décrits au règlement fédéral	Toute quantité de gaz à l'intérieur d'un récipient pouvant contenir plus de 100 litres, ou lorsque le déversement est le résultat d'une défectuosité de l'équipement, d'une erreur ou d'un acte ou d'une omission délibéré
4.	Gaz toxiques de la division 3, classe 2, tels que décrits à l'alinéa 3.11 b) du règlement fédéral.	Toute quantité
5.	Gaz corrosifs de la division 4, classe 2, tels que décrits au règlement fédéral	Toute quantité
6.	Liquides inflammables de la classe 3, tels que décrits à l'article 3.12 du règlement fédéral.	200 L
7.	Solides inflammables de la classe 4, tels que décrits à l'article 3.15 du règlement fédéral	25 kg
8.	Produits ou substances qui sont des matières comburantes de la division 1, classe 5, tels que décrits aux alinéas 3.17 a) et 3.18 a) du règlement fédéral	50 kg ou 50 L
9.	Des produits ou des substances qui sont des composés organiques qui contiennent la structure bivalente «-0-0-», de la division 2, classe 5, tels que décrits aux alinéas 3.17 b) et 3.18 b) du règlement fédéral	1 kg ou 1 L
10.	Produits ou substances toxiques de la division 1, classe 6, tels que décrits aux alinéas 3.19 a) à e) et 3.20 a) du règlement fédéral	5 kg ou 5 L
11.	Organismes infectieux ou dont il est raisonnable de croire qu'ils sont infectieux ainsi que leurs toxines, tels que décrits aux alinéas 3.19 f) et 3.20 b) du règlement fédéral	Toute quantité

ITEM	1ière COLONNE - SUBSTANCE DÉVERSÉE	2ième COLONNE - QUANTITÉ DÉTERMINÉE
12.	Matières radioactives, de la classe 7, telles que décrites à l'article 3.24 du règlement fédéral	Toute quantité d'un rejet ou de l'intensité de rayonnement radioactif supérieur à 10 millisievert par heure à la surface du colis et de 200 miilisievert par heure à 1 m de la surface du colis
13.	Produits ou substances de la classe 8, tels que décrits à l'article 3.24 du règlement fédéral	5 kg ou 5 L
14.	Matières ou produits divers de la division 1, classe 9, tels que décrits au paragraphe 3.27(1) et à l'alinéa 2 a) du règlement fédéral	50 kg ou 50 L
15.	Matières ou produits divers de la division 2, classe 9, tels que décrits au paragraphe 3.27(1) et à l'alinéa 2 b) du règlement fédéral	5 kg ou 5 L
16.	Matières ou produits divers de la division 3, classe 9, tels que décrits au paragraphe 3.27(1) et à l'alinéa 2 c) du règlement fédéral	5 kg ou 5 L
17.	Déchets spéciaux, tels que décrits à l'article 1 du Règlement sur les déchets spéciaux.	Quantité déterminée à l'alinéa 3(1) b) du Règlement sur les déchets spéciaux
18.	Un pesticide tel que décrit à l'article 2 de la *Loi sur l'environnement*, à l'exception des pesticides et des engrais chimiques énumérés à l'annexe 4 du Règlement sur les pesticides.	5 kg ou 5L
19.	Les pesticides et les engrais chimiques énumérés à l'annexe 4 du Règlement sur les pesticides.	Toute quantité

Appendix C – Guide to the Contaminated Sites Regulation

Environmental Programs

Contaminated Sites Regulation

Guide to the Contaminated Sites Regulation

The Contaminated Site Regulation establishes cleanup standards, processes for identifying and investigating contaminated sites, and permits for managing contaminated material within Yukon. This fact sheet gives a brief overview of some aspects of the regulation. To view the regulation and access other resources, visit our website at http://environmentyukon.gov.yk.ca/contaminatedsites.

Site Assessment Processes

A two step process is normally used to determine whether contamination exists at a site:

1. During a **Site Investigation** (or "Phase I Assessment"), information about the site – such as past and current activities, spills and material handling practices – is compiled. A list is then developed of possible contaminants that may be found on the site and areas where they might be located.

2. If potential areas of contamination are identified, a **Site Assessment** (or "Phase II Assessment") may be carried out. This involves sampling the soil or water in those areas and analyzing the samples for the possible contaminants identified in the Site Investigation. The goal of a Site Assessment is to identify the areas, depths and concentrations of contaminants on the site.

The Contaminated Sites Regulation contains soil and water standards that set out allowable levels of contaminants based on the risks they pose to human and environmental health. If concentrations of contaminants at a site exceed any of these standards, the site is considered a contaminated site.

If you have prepared or received a Site Investigation or Site Assessment report, you can submit it to Environment Yukon for review. We will evaluate the report and tell you if the work was conducted properly, and whether we agree with the report's recommendations.

Cleaning Up Contaminated Sites

Once a site is determined to be contaminated, the contaminants should be removed or contained to reduce the risk to human health and the environment. This process is called remediation or restoration.

A **Plan of Restoration** (or "Remedial Action Plan") is often developed to establish how contamination at a site will be cleaned up. The process of preparing this plan provides an opportunity to determine what cleanup standards are most appropriate and which method should be used to remediate the site.

May 2010

Yukon Environment

Selecting Restoration Standards

Most sites are simply remediated until they meet the **numerical standards** listed in the Contaminated Sites Regulation. For typical sites, this approach is simple, fast, and relatively inexpensive.
For some sites, however, it may not be practical to meet the standards established for typical sites. In such cases, there are a few other options.

1. **Site-specific numerical standards** can be developed by adjusting the generic standards to fit site-specific conditions.

2. In some cases, such as where soil has naturally high concentrations of heavy metals, the site can be cleaned up to meet the natural **background concentrations** of contaminants.

3. When the existing models can't sufficiently address the complexity of the site, **risk assessment** can be used to determine what actual hazards are created by the contamination, and what actions can be taken to reduce those hazards to acceptable levels.

Selecting a Restoration Strategy

Once the appropriate standards have been chosen, a strategy must be selected to clean up the site so that it meets those standards. Remedial strategies generally fall into one of three categories: ex-situ remediation, in-situ remediation, and risk management.

1. **Ex-situ remediation** refers to the removal of contaminants from the site so that they can be treated or disposed of at a facility designed for that purpose. The most common type of ex-situ treatment is removing contaminated soil to a land treatment facility, where it is contained and treated by encouraging bacteria in the soil to break down the contaminants.

2. **In-situ remediation** means treating contaminated soil or water without removing it from the environment. This option is often selected when removing all of the contaminated material would be unreasonably expensive or impractical. It often takes longer than ex-situ treatment, but can be more efficient for certain types of sites.

3. **Risk management** is a method of reducing the risk to human and environmental receptors without removing the contaminants. This may be done by constructing a barrier to stop the spread of contaminants, installing a ventilation system to remove harmful vapours, placing restrictions on land use to prevent exposure to the most sensitive receptors, or a variety of other approaches.

Confirmatory Sampling and Reporting

When remediation is complete, confirmatory sampling must be conducted to show that all contaminants have been removed or remediated. Depending on the nature of the site and the contamination, follow-up monitoring may also be required.

Once your site has been remediated, be sure to submit a final report to Environment Yukon so that the public registry of contaminated sites can be updated to show that your site is no longer contaminated.

Public Registry of Contaminated Sites

Environment Yukon maintains information on reported contaminated sites and spills in the Yukon. Contact the Environmental Programs Branch for information on a specific site.

Reporting Contaminated Sites

The Contaminated Sites Regulation does not require landowners to advise Environment Yukon if they find historical contamination, but many people choose to do so. Once you have reported the contamination, Environment Yukon can provide advice on how to deal with it appropriately, including site assessment procedures and disposal options. Also, many real estate transactions, financing institutions, and insurance companies now require confirmation that properties have been cleaned up to the appropriate standards.

The Environmental Programs Branch can assist landowners, vendors and purchasers in reviewing reports of contamination or cleanup and determining how the CSR applies to the site.

If you would like to report a suspected contaminated site, please contact your local Conservation Officer or the Environmental Programs Branch.

Permits and Protocols

Under the Contaminated Sites Regulation, permits are required to do any of the following:

- A **Relocation Permit** is required to move contaminated material from one site to another.
- A **Land Treatment Facility Permit** is required to construct or operate a facility to treat contaminated materials.
- A **Risk-based Restoration Permit** is required to implement the site-specific cleanup standards developed through the risk assessment process.

To apply for a permit, please download the appropriate application form from our website, and submit it to the Environmental Programs Branch for processing.

Even when a permit is not required, all work related to contaminated sites in the Yukon must adhere to the protocols adopted by Environment Yukon under the authority of the Contaminated Sites Regulation. For more information on these protocols and how they apply to your site, contact the Environmental Programs Branch or visit our website.

Appendix D – Storage Tank Regulations

ENVIRONMENT ACT

Pursuant to section 146 of the *Environment Act*, the Commissioner in Executive Council orders as follows:

1. The annexed Storage Tank Regulations are established.

2. The annexed Regulations shall come into force with effect from the 1st day of January, 1997.

Dated at Whitehorse, in the Yukon Territory, this 16th day of December, 1995.

_____
Commissioner of the Yukon

LOI SUR L'ENVIRONNEMENT

Le Commissaire en conseil exécutif, conformément à l'article 146 de la *Loi sur l'environnement*, décrète ce qui suit :

1. Le Règlement sur les réservoirs de stockage ci-joint est établi.

2. Ce même règlement entre en vigueur le 1er janvier 1997.

Fait à Whitehorse, dans le territoire du Yukon, ce 16 décembre 1996.

_____
Commissaire du Yukon

STORAGE TANK REGULATIONS

Interpretation

1. In these regulations,

"aboveground storage tank" means a storage tank with more than 90% of the storage tank volume above surface grade and that operates at atmospheric pressure plus or minus 10 kPa; *«réservoir de stockage hors sol»*

"aboveground storage tank system" means one or more aboveground storage tanks with any connecting piping, both aboveground or underground, and including pumps on product transfer apparatus, dyking, overfill protection equipment and associated spill containment and collection apparatus; *«système de stockage hors sol»*

"Act" means the *Environment Act*; *«loi»*

"alter" means to enlarge, reduce, upgrade or remove a storage tank system, change the configuration of the piping, tanks, dyking of a storage tank system or replace any tank, but does not include carrying out minor maintenance activities or replacements that do not affect the integrity of the system; *«modifier»*

"Code of Practice for Aboveground Storage Tanks" means the Environmental Code of Practice for Aboveground Storage Tank Systems Containing Petroleum Products (CCME-EPC-LST-71E), published in August 1994, by Canadian Council of Ministers of the Environment, as amended from time to time; *«Code de recommandations applicable aux réservoirs de stockage hors sol»*

"Code of Practice for Underground Storage Tanks" means the Environmental Code of Practice for Underground Storage Tank Systems Containing Petroleum Products and Allied Petroleum Products (CCME-EPC-LST-61E), published in March, 1993 by the Canadian Council of Ministers of the Environment, as amended from time to time; *«Code de recommandations applicable aux réservoirs de stockage souterrains»*

"comfort heating systems" means heating systems with storage tank systems for petroleum products having a capacity of 4,000 litres or less used to supply heat to buildings; *«systèmes de chauffage des locaux»*

RÈGLEMENT SUR LES RÉSERVOIRS DE STOCKAGE

Définitions

1. Les définitions qui suivent s'appliquent au présent règlement :

«carburant moteur» Tout produit pétrolier utilisé afin de propulser un véhicule, un aéronef ou un vaisseau; *"motive fuel"*

«Code de recommandations applicable aux réservoirs de stockage hors sol» S'entend du Code de recommandations techniques pour la protection de l'environnement applicable aux systèmes de stockage hors sol de produits pétroliers (CCME-EPC-LST-71E) et ses modifications, publié au mois d'août 1994 par le Conseil canadien des ministres de l'environnement; *"Code of Practice for Aboveground Storage Tanks"*

«Code de recommandations applicable aux réservoirs de stockage souterrains» S'entend du Code de recommandations techniques pour la protection de l'environnement applicable aux systèmes de stockage souterrains de produits pétroliers et de produits apparentés (CCME-EPC-LST-61E) et ses modifications, publié au mois de mars 1994 par le Conseil canadien des ministres de l'environnement; *"Code of Practice for Underground Storage Tanks"*

«Code national de prévention des incendies» Code national de prévention des incendies du Canada, 1995, publié par la Commission canadienne des codes du bâtiment et de prévention des incendies, Conseil national de recherche, et ses modifications; *"National Fire Code"*

«construire» Bâtir, poser, assembler, positionner, raccorder ou brancher; *"construct"*

«huile de chauffage» Tout produit pétrolier utilisé pour le chauffage de locaux, comprenant, entre autres, le pétrole de chauffage ou le mazout domestique; *"heating fuel"*

«loi» La *Loi sur l'environnement*; *"Act"*

«modifier» Signifie agrandir, réduire, améliorer ou enlever un système de stockage, changer la configuration de la tuyauterie, des réservoirs, de l'endiguement d'un système de stockage ou remplacer tout réservoir, à l'exclusion de la mise en oeuvre

"construct" means to build, install, assemble, position or connect; *«construire»*

"heating fuel" means any petroleum product used for comfort heating, including stove oil or furnace oil; *«huile de chauffage»*

"motive fuel" means any petroleum product used to power a vehicle, aircraft or vessel; *«carburant moteur»*

"National Fire Code" means the National Fire Code of Canada, 1995, issued by the Canadian Commission on Building and Fire Codes, National Research Council, as amended from time to time; *«Code national de prévention des incendies»*

"petroleum product" means a single product or mixture of at least 70% hydrocarbons refined from crude oil, with or without additives, that is used or could be used as a fuel, lubricant or power transmitter and without restricting the foregoing, includes gasoline, diesel fuel, aviation fuel, kerosene, naphtha, lubricating oil, fuel oil and engine oil, but excludes propane, paint and solvents; *«produit pétrolier»*

"piping" means all pipes, fittings and valves necessary for the safe handling and storage of a petroleum product or hazardous substance; *«tuyauterie»*

"storage tank" means a closed container with a capacity of more than 230 litres that is designed to be installed in a fixed location, and includes either an aboveground storage tank or an underground storage tank; *«réservoir de stockage»*

"storage tank system" means one or more storage tanks together with all underground or aboveground connections, piping, pumps and dispensers; *«système de stockage»*

"underground storage tank" means a storage tank with 10% or more of the storage tank volume covered with material such as earth, backfill or concrete; *«réservoir de stockage souterrain»*

"underground storage tank system" means one or more underground storage tanks with all underground or aboveground connections, piping, pumps and dispensers. *«système de stockage souterrain»*

d'activités mineures d'entretien ou de remplacement, ne modifiant pas l'intégrité du système; *"alter"*

«produit pétrolier» Un produit unique ou un mélange contenant au moins 70% d'hydrocarbures, raffiné à partir de pétrole brut, avec ou sans additifs, utilisé ou qui pourrait l'être à titre de carburant, de lubrifiant ou d'émetteur de puissance et, notamment, comme essence, carburant diesel ou d'aviation, kérosène, naphte, huile lubrifiante, mazout, huile pour moteur, à l'exclusion du propane, de la peinture et des solvants; *"petroleum product"*

«réservoir de stockage» Un contenant fermé d'une capacité supérieure à 230 litres, conçu pour être installé à un emplacement fixe, et comprend aussi bien un réservoir hors sol que souterrain; *"storage tank"*

«réservoir de stockage hors sol» Un réservoir de stockage dont plus de 10% de son volume est au-dessus du niveau de la surface et qui fonctionne à une pression atmosphérique de plus ou moins 10 kPa; *"aboveground storage tank"*

«réservoir de stockage souterrain» Un réservoir de stockage dont au moins 10% de son volume est recouvert de matériaux, tels que de la terre, du remblai ou du béton; *"underground storage tank"*

«systèmes de chauffage des locaux» Systèmes de chauffage comprenant des réservoirs de stockage pour les produits pétroliers dont la capacité est de moins de 4 000 litres, utilisés pour fournir du chauffage à des locaux; *"comfort heating systems"*

«système de stockage» Un ou plusieurs réservoirs de stockage, incluant les pièces de jonction, la tuyauterie, les pompes et les distributeurs, aussi bien hors sol que souterrains; *"storage tank system"*

«système de stockage hors sol» Un ou plusieurs réservoirs de stockage hors sol, incluant la tuyauterie de raccordement, aussi bien hors sol que souterraine, y compris les pompes faisant partie des appareils pour le transversement des produits, les endiguements, les dispositifs de protection contre les débordements, et tout autre appareil relié à la retenue et à la collecte des déversements; *"aboveground storage tank system"*

«système de stockage souterrain» Un ou plusieurs réservoirs de stockage souterrains, incluant les pièces

de jonction, la tuyauterie, les pompes et les distributeurs, aussi bien hors sol que souterrains; *"underground storage tank system"*

«tuyauterie» Comprend les tuyaux, les raccords et les soupapes nécessaires pour le maniement sécuritaire et le stockage d'un produit pétrolier ou d'une substance dangereuse. *"piping"*

Application

2.(1) These regulations apply to new storage tank systems and to storage tank systems that are to be altered.

(2) These regulations do not apply to storage tanks used to supply comfort heating systems.

(3) These regulations do not apply to storage tanks used for storing crude oil.

Application

2.(1) Le présent règlement s'applique aux nouveaux systèmes de stockage ainsi qu'à ceux qui sont modifiés.

(2) Le présent règlement ne s'applique pas aux réservoirs de stockage utilisés dans les systèmes de chauffage des locaux.

(3) Le présent règlement ne s'applique pas aux réservoirs de stockage utilisés pour emmagasiner le pétrole brut.

Hazardous Substances

3. For the purposes of section 118 of the Act, a hazardous substance has the same meaning as a dangerous good in the *Dangerous Goods Transportation Act* (Yukon).

Substances dangereuses

3. Pour les fins de l'article 118 de la Loi, une substance dangereuse a la même signification qu'une marchandise dangereuse en vertu de la *Loi sur le transport des marchandises dangereuses* (Yukon).

Petroleum Products in Underground Storage Tanks

4. No person shall alter, construct, cause to construct or operate an underground storage tank system for petroleum products, except as authorized by a permit issued under these regulations.

Produits pétroliers dans des réservoirs de stockage souterrains

4. Nul ne doit modifier, construire, faire en sorte que soit construit ou exploiter un système de stockage souterrain pour des produits pétroliers, à moins d'obtenir un permis en vertu du présent règlement.

Petroleum Products in Aboveground Storage Tanks

5. No person shall alter, construct, cause to construct or operate an aboveground storage tank system for petroleum products having a capacity greater than 4,000 litres, except as authorized by a permit issued under these regulations.

Produits pétroliers dans des réservoirs de stockage hors sol

5. Nul ne doit modifier, construire, faire en sorte que soit construit ou exploiter un système de stockage hors sol pour des produits pétroliers, ayant une capacité de plus de 4 000 litres, à moins d'obtenir un permis en vertu du présent règlement.

Hazardous Substances in Underground Storage Tanks

6. No person shall alter, construct or cause to construct an underground storage tank system for hazardous substances other than petroleum products.

Substances dangereuses dans des réservoirs de stockage souterrains

6. Nul ne doit modifier, construire ou faire en sorte que soit construit un système de stockage souterrain pour des substances dangereuses, autres que des produits pétroliers.

Hazardous Substances in Aboveground Storage Tanks

7.(1) This section applies to aboveground storage tank systems for hazardous substances other than petroleum products having a capacity of 2,000 litres or greater.

(2) No person shall alter, construct, cause to construct or operate an aboveground storage tank system described in subsection (1), except as authorized by a permit issued under these regulations.

Removal of Storage Tank Systems

8.(1) When a storage tank system has no further use or has been out of service for one year, the storage tank system shall be removed, unless decommissioning or abandonment in place is authorized by the Minister.

(2) No person shall remove, decommission or abandon a storage tank system, except as authorized by a permit issued under these regulations.

Public Register

9.(1) The Minister shall establish a register for the purpose of recording the names of persons who have applied for and received a permit under these regulations.

(2) The Minister shall provide public access during normal office hours to the public register established pursuant to subsection (1).

Permits

10.(1) A person applying for a permit or a renewal of a permit under these regulations shall make the application in a form provided by the Minister, and submit the information specified by the Minister, including without limitation,

(a) identification of the applicant;

(b) identification of the owner and operator of the storage tank, if different than the person identified in (a);

(c) any plans related to the activity to be undertaken, including storage tank system design plans, safety and inspection plans and closure and reclamation plans;

(d) identification of on-site and adjacent groundwater and surface water sources; and

Substances dangereuses dans des réservoirs de stockage hors sol

7.(1) Le présent article ne s'applique qu'aux réservoirs de stockage hors sol pour des substances dangereuses, autres que des produits pétroliers, ayant une capacité de 2 000 litres ou plus.

(2) Nul ne doit modifier, construire, faire en sorte que soit construit ou exploiter un système de stockage hors sol, tel que décrit au paragraphe (1), à moins d'obtenir un permis en vertu du présent règlement.

Enlèvement d'un système de stockage

8.(1) Lorsqu'un système de stockage ne sert plus ou est hors service pour une période d'un an, il doit être enlevé, à moins que sa désaffection ou son abandon sur place soit autorisé par le ministre.

(2) Nul ne doit enlever, mettre hors service ou abandonner un système de stockage, à moins d'y être autorisé par un permis émis en vertu du présent règlement.

Registre public

9.(1) Le ministre doit constituer un registre public dans le but d'y inscrire le nom des personnes à qui un permis a été émis en vertu du présent règlement.

(2) Le ministre doit s'assurer que le public puisse avoir accès au registre public constitué en vertu du paragraphe (1) et ce, pendant les heures normales de bureau.

Permis

10.(1) En vertu du présent règlement, une personne qui soumet une demande de permis ou une demande pour le renouvellement de ce dernier doit le faire en utilisant un formulaire prévu par le ministre et y inclure les renseignements demandés, entre autres :

a) l'identité du demandeur;

b) l'identité du propriétaire ainsi que de l'exploitant du réservoir de stockage, si leur identité diffère de celle mentionnée à l'alinéa a);

c) tout projet relié à l'activité à être entreprise, y compris la conception des plans pour un système de stockage, la sécurité, l'inspection, la fermeture et la remise en état;

d) l'identification des nappes d'eau souterraines et de surface, à l'emplacement et dans son voisinage

(e) the proposed dates and timing of work to be undertaken in relation to the permitted activity.

(2) The Minister may issue a permit to the applicant subject to any terms and conditions that the Minister considers appropriate, or may refuse to issue a permit to the applicant.

(3) In issuing a permit under these regulations, the Minister shall consider the Code of Practice for Aboveground Storage Tanks, the Code of Practice for Underground Storage Tanks, and the National Fire Code.

(4) A permit may be issued for a period of up to three years.

(5) The Minister may renew a permit subject to any terms and conditions that the Minister considers appropriate or may refuse to renew a permit.

(6) An environmental protection officer may from time to time conduct an inspection of a site for which a permit issued under these regulations applies to determine whether any of the activities at the site contravene a term or condition of the permit.

(7) It is a condition of every permit to operate a storage tank system that a permittee shall provide notice to the Minister, in writing and as soon as is reasonably practicable, of any significant changes of circumstances involving a permitted storage tank system, including without limitation,

(a) plans to close or remove a storage tank or storage tank system, or

(b) the ownership of the storage tank or storage tank system.

Motive Fuel Records

11.(1) The operator of an underground storage tank system for motive fuel shall maintain and reconcile inventory records each day that motive fuel is added or removed from the storage tank, and shall maintain monthly summaries for each month or part thereof that the storage tank system is operated.

immédiat;

e) les dates prévues ainsi que l'échéancier des travaux à être entrepris, reliés à l'activité permise.

2) Le ministre peut émettre ou non un permis au demandeur, sous réserve des conditions qu'il juge pertinentes.

(3) Lorsqu'il émet un permis en vertu du présent règlement, le ministre doit tenir compte du Code de recommandations applicable aux réservoirs de stockage hors sol, du Code de recommandations applicable aux réservoirs de stockage souterrains, et du Code national de prévention des incendies.

(4) Un permis peut être émis pour une période pouvant aller jusqu'à trois ans.

(5) Le ministre peut renouveler ou non un permis, sous réserve des conditions qu'il juge pertinentes.

(6) Un agent de protection de l'environnement peut, selon les besoins, entreprendre une inspection d'un emplacement pour lequel un permis a été émis en vertu du présent règlement afin de déterminer si l'une des activités entreprises sur cet emplacement enfreint une condition du permis.

(7) Tout titulaire d'un permis permettant d'assurer l'exploitation d'un système de stockage doit, dès que possible, en vertu d'une condition du permis, aviser le ministre par écrit de tout changement important relié au système de stockage, y compris, entre autres :

a) tout projet de fermer ou d'enlever un réservoir de stockage ou un système de stockage;

b) un changement au niveau de la propriété d'un réservoir de stockage ou d'un système de stockage.

Fichiers pour les carburants moteurs

11.(1) L'exploitant d'un système de stockage souterrain pour les carburants moteurs doit tenir à jour et faire concorder les fichiers de stocks pour chaque jour que du carburant moteur est ajouté ou enlevé du réservoir de stockage, et doit également tenir à jour un sommaire mensuel pour chaque mois ou partie de mois au cours duquel le système de stockage est en exploitation.

(2) For the purposes of subsection (1), the operator shall obtain measurements of motive fuel levels and water levels as a part of reconciling inventory records.

(3) Where the inventory records referred to in subsection (1) indicate,

(a) 18 losses in 30 days;

(b) 5 consecutive losses; or

(c) a cumulative gain or loss greater than 0.5% monthly tank throughput or 2.5% of tank capacity

the operator shall immediately report the discrepancy to an environmental protection officer.

(4) The operator of an aboveground storage tank system for motive fuel having a capacity greater than 4,000 litres shall maintain and reconcile inventory records each time motive fuel is added to the storage tank, and shall maintain monthly summaries for each month or part thereof that the storage tank system is in operation.

(5) Where the inventory records referred to in subsection (4) indicate,

(a) a 1.0% shortage of monthly tank throughput or tank capacity, whichever is greater;

(b) 4 consecutive shortages of 50 litres or more; or

(c) consecutive losses totalling 200 litres or more,

the operator shall immediately report the discrepancy to an environmental protection officer.

Heating fuel Records

12.(1) The operator of a storage tank system for heating fuel with a capacity greater than 4000 litres, shall maintain and reconcile inventory records each time heating fuel is added to the storage tank and maintain monthly summaries for each month or part thereof that the storage tank system is operated.

(2) Where the inventory records referred to in subsection (1) indicate,

(2) Pour les fins du paragraphe (1), l'exploitant doit obtenir les lectures du niveau d'eau et de carburant moteur afin de compléter les fichiers de rapprochement des stocks.

(3) L'exploitant doit, dès que possible, faire rapport à un agent de protection de l'environnement de toute anomalie lorsque les fichiers de stocks mentionnés au paragraphe (1) indiquent :

a) 18 pertes en 30 jours;

b) 5 pertes consécutives;

c) une perte ou un gain cumulatif représentant plus de 0,5% du débit mensuel du réservoir ou 2,5% de la capacité de ce dernier.

(4) L'exploitant d'un système de stockage hors sol pour les carburants moteurs, dont la capacité est de plus de 4 000 litres, doit tenir à jour et faire concorder les fichiers de stocks chaque fois que du carburant moteur est ajouté au réservoir de stockage, et doit également tenir à jour un sommaire mensuel pour chaque mois ou partie de mois au cours duquel le système de stockage est en exploitation.

(5) L'exploitant doit, dès que possible, faire rapport à un agent de protection de l'environnement de toute anomalie lorsque les fichiers de stocks mentionnés au paragraphe (4) indiquent :

a) un déficit de 1,0% du débit mensuel du réservoir ou de la capacité de ce dernier, selon le plus élevé des deux;

b) 4 déficits consécutifs de 50 litres ou plus;

c) des pertes consécutives totalisant 200 litres ou plus.

Fichiers de l'huile de chauffage

12.(1) L'exploitant d'un système de stockage pour l'huile de chauffage dont la capacité est de plus de 4 000 litres doit tenir à jour et faire concorder les fichiers de stocks chaque fois que de l'huile de chauffage est ajoutée au réservoir de stockage, et doit également tenir à jour un sommaire mensuel pour chaque mois ou partie de mois au cours duquel le système de stockage est en exploitation.

(2) L'exploitant doit, dès que possible, faire rapport à un agent de protection de l'environnement de toute anomalie lorsque les fichiers de stocks mentionnés au

(a) 4 consecutive shortages of 50 litres or more; or

(b) consecutive losses totalling 200 litres or more

the operator shall immediately report the discrepancy to an environmental protection officer.

Continuous Leakage Detection

13. Sections 11 and 12 do not apply where the Minister has approved in a permit the installation and operation of a continuous leakage detection device in a storage tank system.

Maintenance of Records

14.(1) The operator shall maintain inventory records and monthly summaries collected pursuant to sections 11 and 12 on forms approved by the Minister.

(2) The operator shall retain inventory records and monthly summaries collected pursuant to section 11 and 12 at the site of the storage tank system or at a location specified in a permit for a minimum of two years and shall make them available for inspection upon the request of an environmental protection officer.

Leak Test

15. If any storage tank system fails a leak test, the operator shall immediately report the results of the test to an environmental protection officer.

Fees

16.(1) A person applying for a permit, or an amendment or renewal to a permit shall submit the fee prescribed in Schedule A to the Minister with the application for the permit.

(2) A fee is not refundable.

(3) The Minister may waive fees if the Minister considers it appropriate in the circumstances.

paragraphe (1) indiquent :

a) 4 déficits consécutifs de 50 litres ou plus;

b) des pertes consécutives qui totalisent 200 litres ou plus.

Mécanisme permanent de détection des fuites

13. Les articles 11 et 12 ne s'appliquent pas lorsque le ministre a donné son approbation, dans un permis, pour l'installation et l'exploitation d'un mécanisme permanent de détection des fuites dans un système de stockage.

Mise à jour des fichiers

14.(1) L'exploitant doit tenir à jour les fichiers de stocks ainsi que les sommaires mensuels recueillis conformément aux articles 11 et 12, sur des formulaires approuvés par le ministre.

(2) L'exploitant doit conserver les fichiers de stocks ainsi que les sommaires mensuels recueillis conformément aux articles 11 et 12 à l'emplacement du système de stockage ou dans un lieu mentionné dans un permis et ce, pour une période de deux ans. Il doit les rendre disponibles pour examen suite à la demande d'un agent de protection de l'environnement.

Épreuve d'étanchéité

15. Un exploitant doit dès que possible aviser un agent de protection de l'environnement lorsqu'un fuite est détectée à partir d'un système de stockage, suite à une épreuve d'étanchéité.

Frais

16.(1) La personne qui soumet une demande de permis, ou une demande de modification ou de renouvellement de ce dernier, doit joindre à cette demande, à l'intention du ministre, les frais indiqués à l'annexe A.

(2) Les frais ne sont pas remboursables.

(3) Le ministre peut renoncer aux frais, s'il le juge à propos, compte tenu des circonstances.

SCHEDULE A - PERMIT FEES

ITEM	DESCRIPTION	FEE
1.	Construct, alter or operate storage tank system	
(a)	**underground storage tanks**	
	tanks up to 5,000 litres	$100.00
	tanks 5,001 litres to 20,000 litres	$5.00/ additional 1,000 litres
	tanks 20,001 litres and greater	$2.00/ additional 1,000 litres
(b)	**aboveground storage tanks**	
	tanks up to 10,000 litres	$25.00
	tanks 10,001 litres to 100,000 litres	$1.00/ additional 1,000 litres
	tanks 100,001 to 500,000 litres	$0.50/ additional 1,000 litres
	tanks 500,001 litres and greater	$0.20/ additional 1,000 litres
2.	Closure, decommissioning or a bandonment in place of storage tank system	Free
3.	Amendments of renewals	Free

ANNEXE A - FRAIS DE PERMIS

NUMÉRO	DESCRIPTION	FRAIS
1.	Construction, modification ou exploitation d'un système de stockage	
a)	**réservoirs de stockage souterrain**	
	réservoirs jusqu'à 5 000 litres	100 $
	réservoirs de 5 001 litres à 20 000 litres	5$ par 1 000 litres additionnels
	réservoirs de 20 001 litres ou plus	2 $ par 1 000 litres additionnels
b)	**réservoir de stockage hors sol**	
	réservoirs jusqu'à 10 000 litres	25 $
	réservoirs de 10 001 à 100 000 litres	1 $ par 1 000 litres additionnels
	réservoirs de 100 001 à 500 000 litres	0,50 $ par 1 000 litres additionnels
	réservoirs de 500 001 litres ou plus	0,20 $ par 1 000 litres additionnels
2.	Fermeture, désaffection ou abandon sur place d'un système de stockage	Aucun
3.	Révisions ou renouvellements	Aucun

Appendix E – Spill Response for Sodium Hypochlorite

Spills Response : Sodium Hypochlorite

Faro Mine Complex Guardhouse and area water supply chlorine source for water treatment: Advance 12-A, a 12% solution of sodium hypochlorite

Sodium Hypochlorite (Industrial Bleach)

WHMIS Classification:

Class C, Oxidizing Material

Class D, Div. 2, Toxic Liquid, Skin Sensitizer

Class E, Corrosive Liquids

TDG Classification:

Hypochloride Solutions

UN 1791, Class 8, Packing Group III - Corrosive

Not considered flammable. Polymerization will not occur.

Storage:

- Store upright in a cool, dry, well ventilated area away from incompatible materials;
- Keep container tightly closed when not in use;
- Wash hands thoroughly after handling container;
- Do not cut, grind, weld or drill in, on or near the container;
- Keep away from sources of heat and open flame;
- Empty containers can have residues, gases and mists and are subject to precautionary procedures as well;

Thermal stability:

- Product decomposes thermally above 40°C. Hazardous and toxic decomposition products may include chlorine gas, oxygen and sodium chlorate. Unvented containers will build up internal pressure and may rupture causing a product leak.

Incompatible Substances to Sodium Hypochlorite

All acids, ammonium salts and aqueous ammonium hydroxide solutions, metals, oxidizers, nitrogen compounds, and methanol.

Advance 12A Sodium Hypochlorite Spill Response Plan:

1) Ensure all persons have the required personal protective equipment prior to assessing incident.
2) Assess incident and size of spill;
3) Contact appropriate personel as per company policy
4) Respond with appropriate action plan;
5) Complete and submit incident report.

Spill Response:

Assess size of spill and respond accordingly.

Small Spills – Under 5 kg

- Keep all unauthorized personnel away from the area (50-100 m in all directions).
- Do not touch damaged containers or spilled material unless wearing impermeable protective clothing;
- Attempt to catch or prevent spilled material from contacting surface;
- Cover with DRY san, or other non-combustible material followed with plastic sheet to minimize spreading or contact with rain;
- Use clean tools, preferably non-metallic, to collect materials and place into loosely covered plastic containers for later disposal.

Large Spills – Over 5 kg

- Eliminate all ignition sources;
- Keep all unauthorized personnel away from the area (160 to 330 m in all directions);
- Do not touch damaged containers or spilled material unless wearing impermeable protective clothing;
- Stop leak if you can do it without risk;
- Confine spill to smallest possible area, prevent entry into waterways, sewers, etc.
- Use water spray to reduce vapours or divert cloud drift. Avoid allowing water runoff to contact material.
- Neutralise spilled product with sodium thiosulphate:
    - For spills where product is visible, sodium thiosulphate can be used undiluted.
    - For spills that have been saturated into the surface, sodium thiosulphate should be diluted using potable water.
    - In all cases – ADD SLOWLY, starting at the perimeter of the spill.
        - Adding sodium thiosulphate neutralises the available chlorine content while reducing the pH to about pH 4. Check with a pH meter or test strip. In all cases, depending on the strength of Sodium Hypochlorite, chlorine gas is a dangerous by-product of this reaction procedure.
        - Increase the pH of the contained spill to about pH 7 by slowly adding soda ash. Check pH frequently.

        - The spill should be neutral, with a pH of 7. Check with the appropriate local, provincial or federal agencies for proper and correct disposal methods for this product. If available, use a field test kit to check for levels of residual chlorine in the treated waste water.
    - Ensure proper protective clothing and equipment is worn when handling the sodium thiosulphate.
        - Small spills: Sodium thiosulphate can be dispersed by hand, plastic shovel, or broom.
        - Large spills: if the product has been dyked and contained a circulation pump can be used to move the product to spread the sodium thiosulphate through the contained area.
    - Theoretical amount of sodium thiosulphate required to completely neutralize sodium hypochlorite:

Concentration of Sodium Hypochlorite Bleach Solution	Litres of Sodium Hypochlorite Bleach Solution	Kg of Sodium Hypochlorite Bleach Solution	Kg Sodium Thiosulphate required to completely neutralise chlorine (theoretical)
12%	0.86	1	0.21
12%	1	1.165	0.24
12%	10	11.65	2.41
12%	20	23.23	4.82

- Transfer remaining product from damaged container into approved containers.

Appendix F – Sampling Instructions

SAMPLING INSTRUCTIONS

The following sampling containers are enclosed.

Remember to fill out label on container with a water proof pen – the most important areas are:

Sample ID

Date sample collected

Required Analysis.

General Water Analysis:

- Inorganic/Dissolved Metals – Fill 2 litre plastic bottle
- Total Metals – Fill 250 ml AW (Acid Washed) bottle – add one vial of Nitric Acid.
- Cyanide: Fill 1 litre plastic bottle – Sodium Hydroxide pellets (NaOH) in bottle.

Hydrocarbon Water Analysis:

- Diesel fuel/oil analysis – Fill 1 litre amber glass bottle, ensure Aluminum foil is still in bottle cap
- Gasoline – Fill two 40 ml clear glass vials (HCL Preservative), there must be no headspace in the vial. Use 150 ml glass beaker to collect water and then pour into the glass vial
- Glycol – Fill 125 ml amber glass bottle.

Hydrocarbon Soil Analysis:

- Fill two 125 ml pre-cleaned glass jars – Jars also have a piece Teflon in the lid. All hydrocarbon analysis can be performed from the sample in the two jars.

Samples must be kept cool prior to and when transporting the off-site laboratory for analysis. Samples will be flagged at the laboratory if the temperature is greater than 10 degrees Celsius. This is especially important for Hydrocarbon type samples

Appendix G – Spill Report Form

SPILL REPORT FORM

1. **IDENTIFICATION**

Date of Incident: Date: _____ Time: _____
Date of Discovery: Date: _____ Time: _____
Name of Product: (Attach copy of MSDS) _____
_____
Location of Incident: (Attach Sketch, if helpful) _____
_____
Type of Spill: (Check one)

1. Point Spill: _____ Approx. Area affected: _____ sq. ft/sq. m.

2. Linear Spill: _____ Length of area affected: _____ ft./m.

Volume of Spill: _____ (Estimate volume and identify units, i.e. Imperial gallons, litres, etc.)

Estimated rate of release: _____

Concentration: _____

Expressed in estimated % strength – 100% is not diluted.

2. **DETAILS OF DISCOVERY**

(Prepare, in point form, a chronological sequence of events leading up to the spill or its discovery. Include name, job titles of individuals complete with dates and times with each point)

A. _____
_____
_____

B. _____
_____
_____

C. _____
_____
_____

D. _____
_____
_____

E. _____
_____
_____

3. RISK ASSESSMENT

A) Was MSDS consulted? Yes: _____ No: _____

B) Personal Protective Equipment Required:

_____
_____
_____

Is Employee Safety at Risk? Yes: _____ No: _____

C) Can Material enter a Water Course? Yes: _____ No: _____

D) Is Spill Easily Contained? Yes: _____ No: _____

CHECK ONE:

Spill is considered high-risk immediate action required _____

Call Emergency Response Team for initial response.

OR

Spill is considered low risk, no imminent danger: _____

Proceed with clean-up.

4. ACTION TAKEN UPON DISCOVERY

A) Initial Containment: Date: _____ Time: _____

Describe Methods:

_____
_____
_____

Final Containment: Date: _____Time: _____
Describe methods, if different than above:
_____
_____
_____
Samples taken for analysis: Yes ___ No ___ Date _____ Time _____

5. **DISPOSAL**

Temporary Storage: Date: _____ Time: _____
_____
_____
Final Storage: Date: _____ Time: _____
_____
_____
Ultimate Disposal: Date: _____ Time: _____
_____
_____

6. **REPORTING**

Did the spill quantity exceed the spill reporting threshold as per the Yukon Spill Regulations? (copy attached): Yes _____ No _____
If the spill was of contaminated water, is there a potential that contaminant levels may exceed release criteria?: Yes _____ No _____
If the spill material entered a waterbody, did it occur to an unauthorized release point? (only the Cross Valley Dam, the Sheep Pad Outflow and the Moose Pond Outflow are authorized discharge points): Yes _____ No _____
If answers to any of the above questions is yes, the event is a reportable spill. The Site Manager or his designate must report to the Yukon Spill Report Centre at (867) 667-7244.
Was the spill reported to the above number? Yes _____ No _____
The Site Manager should discuss the incident with the Faro Mine Closure Office to determine if it should also be reported to local and First Nations stakeholders.

7. **RECOMMENDED ACTION**

Short Term: (To solve immediate problem) _____
_____
_____
Long Term: (To prevent a recurrence) _____
_____
_____

8. PERSONS INVOLVED

Name	Position	Organization (AR, other)

9. REPORT CIRCULATION: (In Order – Please Sign)

Shift Supervisor: Date: _____ Time: _____
Comments: _____
_____
_____

Site Superintendent: Date: _____Time: _____
Comments: _____
_____
_____

Site Manager: Date: _____ Time: _____
Comments: _____
_____
_____

Appendix H – FMC Material Safety Data Sheets

Safety Data Sheet

Material Name: Fuel Oil No. 2

SDS No. 0088
US GHS

Synonyms: #2 Heating Oil; 2 Oil; Off-road Diesel Fuel

* * * Section 1 - Product and Company Identification * * *

Manufacturer Information

Hess Corporation
1 Hess Plaza
Woodbridge, NJ 07095-0961

Phone: 732-750-6000 Corporate EHS
Emergency # 800-424-9300 CHEMTREC
www.hess.com (Environment, Health, Safety Internet Website)

* * * Section 2 - Hazards Identification * * *

GHS Classification:

Flammable Liquids - Category 3
Acute Toxicity, Inhalation - Category 4
Skin Corrosion/Irritation – Category 2
Eye Damage/Irritation – Category 2B
Carcinogenicity - Category 2
Specific Target Organ Toxicity (Single Exposure) – Category 3 (respiratory irritation, narcosis)
Aspiration Hazard – Category 1
Hazardous to the Aquatic Environment, Acute Hazard – Category 3

GHS LABEL ELEMENTS

Symbol(s)

Signal Word

DANGER

Hazard Statements

Flammable liquid and vapor.
Harmful if inhaled.
Causes skin irritation.
Causes eye irritation.
Suspected of causing cancer.
Suspected of causing genetic defects.
May cause respiratory irritation.
May cause drowsiness or dizziness.
May be fatal if swallowed and enters airways.
Harmful to aquatic life.

Precautionary Statements

Prevention

Keep away from heat/sparks/open flames/hot surfaces. No smoking

Keep container tightly closed.
Ground/bond container and receiving equipment.
Use explosion-proof electrical/ventilating/lighting/equipment.
Use only non-sparking tools.
Take precautionary measures against static discharge.
Wear protective gloves/protective clothing/eye protection/face protection.
Avoid breathing fume/mist/vapors/spray.
Use only outdoors or in a well-ventilated area.
Wash hands and forearms thoroughly after handling.
Obtain special instructions before use.
Do not handle until all safety precautions have been read and understood.
Avoid release to the environment.

Response
In case of fire: Use water spray, fog or foam.
If on skin (or hair): Wash with plenty of soap and water. Take off immediately all contaminated clothing and wash it before reuse. If skin irritation occurs, get medical advice/attention.
If inhaled: Remove person to fresh air and keep comfortable for breathing. Call a poison center or doctor if you feel unwell.
If in eyes: Rinse cautiously with water for several minutes. Remove contact lenses, if present and easy to do. Continue rinsing. If eye irritation persists: Get medical advice/attention.
If exposed or concerned: Get medical advice/attention.
If swallowed: Immediately all a poison center or doctor/physician if you feel unwell. Do NOT induce vomiting.

Storage
Store in a well-ventilated place.
Keep cool. Store locked up.
Keep container tightly closed.

Disposal
Dispose of contents/container in accordance with local/regional/national/international regulations.

* * * Section 3 - Composition / Information on Ingredients * * *

CAS #	Component	Percent
68476-30-2	Fuel oil No. 2	100
91-20-3	Naphthalene	<0.1

A complex combination of hydrocarbons with carbon numbers in the range C9 and higher produced from the distillation of petroleum crude oil.

* * * Section 4 - First Aid Measures * * *

First Aid: Eyes

In case of contact with eyes, immediately flush with clean, low-pressure water for at least 15 min. Hold eyelids open to ensure adequate flushing. Seek medical attention.

First Aid: Skin

Remove contaminated clothing. Wash contaminated areas thoroughly with soap and water or with waterless hand cleanser. Obtain medical attention if irritation or redness develops.

First Aid: Ingestion

DO NOT INDUCE VOMITING. Do not give liquids. Obtain immediate medical attention. If spontaneous vomiting occurs, lean victim forward to reduce the risk of aspiration. Monitor for breathing difficulties. Small amounts of material which enter the mouth should be rinsed out until the taste is dissipated.

First Aid: Inhalation

Remove person to fresh air. If person is not breathing, provide artificial respiration. If necessary, provide additional oxygen once breathing is restored if trained to do so. Seek medical attention immediately.

* * * Section 5 - Fire Fighting Measures * * *

General Fire Hazards

See Section 9 for Flammability Properties.

Vapors may be ignited rapidly when exposed to heat, spark, open flame or other source of ignition. When mixed with air and exposed to an ignition source, flammable vapors can burn in the open or explode in confined spaces. Being heavier than air, vapors may travel long distances to an ignition source and flash back. Runoff to sewer may cause fire or explosion hazard.

Hazardous Combustion Products

Carbon monoxide, carbon dioxide and non-combusted hydrocarbons (smoke).

Extinguishing Media

SMALL FIRES: Any extinguisher suitable for Class B fires, dry chemical, CO2, water spray, fire fighting foam, or gaseous extinguishing agent.

LARGE FIRES: Water spray, fog or fire fighting foam. Water may be ineffective for fighting the fire, but may be used to cool fire-exposed containers.

Unsuitable Extinguishing Media

None

Fire Fighting Equipment/Instructions

Small fires in the incipient (beginning) stage may typically be extinguished using handheld portable fire extinguishers and other fire fighting equipment. Firefighting activities that may result in potential exposure to high heat, smoke or toxic by-products of combustion should require NIOSH/MSHA- approved pressure-demand self-contained breathing apparatus with full facepiece and full protective clothing. Isolate area around container involved in fire. Cool tanks, shells, and containers exposed to fire and excessive heat with water. For massive fires the use of unmanned hose holders or monitor nozzles may be advantageous to further minimize personnel exposure. Major fires may require withdrawal, allowing the tank to burn. Large storage tank fires typically require specially trained personnel and equipment to extinguish the fire, often including the need for properly applied fire fighting foam.

* * * Section 6 - Accidental Release Measures * * *

Recovery and Neutralization

Carefully contain and stop the source of the spill, if safe to do so.

Materials and Methods for Clean-Up

Take up with sand or other oil absorbing materials. Carefully shovel, scoop or sweep up into a waste container for reclamation or disposal.

Emergency Measures

Evacuate nonessential personnel and remove or secure all ignition sources. Consider wind direction; stay upwind and uphill, if possible. Evaluate the direction of product travel, diking, sewers, etc. to confirm spill areas. Spills may infiltrate subsurface soil and groundwater; professional assistance may be necessary to determine the extent of subsurface impact.

Personal Precautions and Protective Equipment

Response and clean-up crews must be properly trained and must utilize proper protective equipment (see Section 8).

Environmental Precautions

Protect bodies of water by diking, absorbents, or absorbent boom, if possible. Do not flush down sewer or drainage systems, unless system is designed and permitted to handle such material. The use of fire fighting foam may be useful in certain situations to reduce vapors. The proper use of water spray may effectively disperse product vapors or the liquid itself, preventing contact with ignition sources or areas/equipment that require protection.

Prevention of Secondary Hazards

None

* * * Section 7 - Handling and Storage * * *

Handling Procedures

Handle as a combustible liquid. Keep away from heat, sparks, excessive temperatures and open flame! No smoking or open flame in storage, use or handling areas. Bond and ground containers during product transfer to reduce the possibility of static-initiated fire or explosion.

Special slow load procedures for "switch loading" must be followed to avoid the static ignition hazard that can exist when this product is loaded into tanks previously containing low flash point products (such as gasoline) - see API Publication 2003, "Protection Against Ignitions Arising Out Of Static, Lightning and Stray Currents."

Storage Procedures

Keep containers closed and clearly labeled. Use approved vented storage containers. Empty product containers or vessels may contain explosive vapors. Do not pressurize, cut, heat, weld or expose such containers to sources of ignition.

Store in a well-ventilated area. This storage area should comply with NFPA 30 "Flammable and Combustible Liquid Code". Avoid storage near incompatible materials. The cleaning of tanks previously containing this product should follow API Recommended Practice (RP) 2013 "Cleaning Mobile Tanks In Flammable and Combustible Liquid Service" and API RP 2015 "Cleaning Petroleum Storage Tanks."

Incompatibilities

Keep away from strong oxidizers; Fluorel ®

* * * Section 8 - Exposure Controls / Personal Protection * * *

Component Exposure Limits

Fuel oil No. 2 (68476-30-2)

ACGIH: 0.2 mg/m3 TWA (inhalable fraction and vapor, as total hydrocarbons, listed under Diesel fuel)
Skin - potential significant contribution to overall exposure by the cutaneous route (listed under Diesel fuel)

Naphthalene (91-20-3)

ACGIH: 10 ppm TWA
15 ppm STEL
Skin - potential significant contribution to overall exposure by the cutaneous route
OSHA: 10 ppm TWA; 50 mg/m3 TWA
NIOSH: 10 ppm TWA; 50 mg/m3 TWA
15 ppm STEL; 75 mg/m3 STEL

Engineering Measures

Use adequate ventilation to keep vapor concentrations of this product below occupational exposure and flammability limits, particularly in confined spaces.

Personal Protective Equipment: Respiratory

A NIOSH/MSHA-approved air-purifying respirator with organic vapor cartridges or canister may be permissible under certain circumstances where airborne concentrations are or may be expected to exceed exposure limits or for odor or irritation. Protection provided by air-purifying respirators is limited.

Use a positive pressure, air-supplied respirator if there is a potential for uncontrolled release, exposure levels are not known, in oxygen-deficient atmospheres, or any other circumstance where an air-purifying respirator may not provide adequate protection.

Personal Protective Equipment: Hands

Gloves constructed of nitrile, neoprene, or PVC are recommended.

Personal Protective Equipment: Eyes

Safety glasses or goggles are recommended where there is a possibility of splashing or spraying.

Personal Protective Equipment: Skin and Body

Chemical protective clothing such as of E.I. DuPont TyChem®, Saranex® or equivalent recommended based on degree of exposure. Note: The resistance of specific material may vary from product to product as well as with degree of exposure. Consult manufacturer specifications for further information.

* * * Section 9 - Physical & Chemical Properties * * *

Appearance:	Red or reddish/orange colored (dyed)	**Odor:**	Mild, petroleum distillate odor
Physical State:	Liquid	**pH:**	ND
Vapor Pressure:	0.009 psia @ 70 °F (21 °C)	**Vapor Density:**	>1.0
Boiling Point:	340 to 700 °F (171 to 371 °C)	**Melting Point:**	ND
Solubility (H2O):	Negligible	**Specific Gravity:**	AP 0.823-0871
Evaporation Rate:	Slow; varies with conditions	**VOC:**	ND
Octanol/H2O Coeff.:	ND	**Flash Point:**	100 °F (38 °C) minimum
Flash Point Method:	PMCC	**Upper Flammability Limit (UFL):**	7.5
Lower Flammability Limit (LFL):	0.6	**Burning Rate:**	ND
Auto Ignition:	494°F (257°C)		

* * * Section 10 - Chemical Stability & Reactivity Information * * *

Chemical Stability

This is a stable material.

Hazardous Reaction Potential

Will not occur.

Conditions to Avoid

Avoid high temperatures, open flames, sparks, welding, smoking and other ignition sources.

Incompatible Products

Keep away from strong oxidizers; Fluorel ®

Hazardous Decomposition Products

Carbon monoxide, carbon dioxide and non-combusted hydrocarbons (smoke).

* * * Section 11 - Toxicological Information * * *

Acute Toxicity

A: General Product Information

Harmful if swallowed.

B: Component Analysis - LD50/LC50

Fuel oil No. 2 (68476-30-2)

Oral LD50 Rat 12 g/kg; Dermal LD50 Rabbit 4720 µL/kg; Dermal LD50 Rabbit >2000 mg/kg; Inhalation LC50 Rat 4.6 mg/L 4 h

Naphthalene (91-20-3)

Inhalation LC50 Rat >340 mg/m3 1 h; Oral LD50 Rat 490 mg/kg; Dermal LD50 Rat >2500 mg/kg; Dermal LD50 Rabbit >20 g/kg

Product Mixture

Oral LD50 Rat 14.5 ml/kg; Dermal LD50 Rabbit >5 mL/kg; Guinea Pig Sensitization: negative; Primary dermal irritation: moderately irritating (Draize mean irritation score - 3.98 rabbits); Draize eye irritation: mildly irritating (Draize score, 48 hours, unwashed - 2.0 rabbits)

Potential Health Effects: Skin Corrosion Property/Stimulativeness

Practically non-toxic if absorbed following acute (single) exposure. May cause skin irritation with prolonged or repeated contact. Liquid may be absorbed through the skin in toxic amounts if large areas of skin are repeatedly exposed.

Potential Health Effects: Eye Critical Damage/ Stimulativeness

Contact with eyes may cause mild irritation.

Potential Health Effects: Ingestion

Ingestion may cause gastrointestinal disturbances, including irritation, nausea, vomiting and diarrhea, and central nervous system (brain) effects similar to alcohol intoxication. In severe cases, tremors, convulsions, loss of consciousness, coma, respiratory arrest, and death may occur.

Potential Health Effects: Inhalation

Excessive exposure may cause irritations to the nose, throat, lungs and respiratory tract. Central nervous system (brain) effects may include headache, dizziness, loss of balance and coordination, unconsciousness, coma, respiratory failure, and death.

WARNING: the burning of any hydrocarbon as a fuel in an area without adequate ventilation may result in hazardous levels of combustion products, including carbon monoxide, and inadequate oxygen levels, which may cause unconsciousness, suffocation, and death.

Respiratory Organs Sensitization/Skin Sensitization

This product is not reported to have any skin sensitization effects.

Generative Cell Mutagenicity

This product is not reported to have any mutagenic effects. Material of similar composition has been positive in a mutagenicity study.

Carcinogenicity

A: General Product Information

Suspected of causing cancer.

Dermal carcinogenicity: positive - mice
Studies have shown that similar products produce skin tumors in laboratory animals following repeated applications without washing or removal. The significance of this finding to human exposure has not been determined. Other studies with active skin carcinogens have shown that washing the animal's skin with soap and water between applications reduced tumor formation.

This product is similar to Diesel Fuel. IARC classifies whole diesel fuel exhaust particulates as probably carcinogenic to humans (Group 2A) and NIOSH regards it as a potential cause of occupational lung cancer based on animal studies and limited evidence in humans.

B: Component Carcinogenicity

Fuel oil No. 2 (68476-30-2)

ACGIH: A3 - Confirmed Animal Carcinogen with Unknown Relevance to Humans (listed under Diesel fuel)

Naphthalene (91-20-3)

ACGIH: A4 - Not Classifiable as a Human Carcinogen
NTP: Reasonably Anticipated To Be A Human Carcinogen (Possible Select Carcinogen)
IARC: Monograph 82 [2002] (Group 2B (possibly carcinogenic to humans))

Reproductive Toxicity

This product is not reported to have any reproductive toxicity effects.

Specified Target Organ General Toxicity: Single Exposure

This product is not reported to have any specific target organ general toxicity single exposure effects.

Specified Target Organ General Toxicity: Repeated Exposure

This product is not reported to have any specific target organ general toxicity repeat exposure effects.

Aspiration Respiratory Organs Hazard

The major health threat of ingestion occurs from the danger of aspiration (breathing) of liquid drops into the lungs, particularly from vomiting. Aspiration may result in chemical pneumonia (fluid in the lungs), severe lung damage, respiratory failure and even death.

* * * Section 12 - Ecological Information * * *

Ecotoxicity

A: General Product Information

Very toxic to aquatic life with long lasting effects. Keep out of sewers, drainage areas and waterways. Report spills and releases, as applicable, under Federal and State regulations.

B: Component Analysis - Ecotoxicity - Aquatic Toxicity

Fuel oil No. 2 (68476-30-2)

Section 2: HAZARDS IDENTIFICATION

EMERGENCY OVERVIEW
DANGER

EXTREMELY FLAMMABLE LIQUID AND VAPOR - VAPOR MAY CAUSE FLASH FIRE. HARMFUL OR FATAL IF SWALLOWED. CAN ENTER LUNGS AND CAUSE DAMAGE. CANCER HAZARD – CAN CAUSE CANCER. IRRITATING TO EYES AND SKIN.

Colour: Colourless or dyed red or purple.
Physical State: Liquid.
Odour: Petroleum.

WHMIS	Personal Protection Equipment	TDG (Ground)
		

Potential Health Effects: See Section 11 for more information.

Likely Routes of Exposure: Eye contact. Skin contact. Inhalation. Ingestion. Skin absorption.

Eye: Irritating to eyes. Signs/symptoms may include redness, swelling, pain, tearing, and blurred or hazy vision. Product vapours are moderately irritating to the eyes with effects beginning near 200-500 ppm.

Skin: Irritating to skin. Signs/symptoms may include localized redness, swelling, and itching.

Ingestion: Harmful or fatal: may cause lung damage if swallowed. Swallowing the liquid may cause aspiration into the lungs with the risk of chemical pneumonitis. May cause gastrointestinal irritation. Signs/symptoms may include abdominal pain, stomach upset, nausea, vomiting and diarrhea.

Inhalation: May cause respiratory tract irritation. Signs/symptoms may include cough, sneezing, nasal discharge, headache, hoarseness, and nose and throat pain. May cause headache, dizziness, confusion, loss of appetite and loss of consciousness. At concentrations near

1000 ppm, central nervous system effects such as headache, blurred vision, dizziness, and loss of coordination may occur. Exposure to vapour concentrations exceeding 5000 ppm may result in loss of consciousness, coma and death.

Chronic Effects: See Section 11 for more information.

Medical Conditions Aggravated By Exposure: Not available.

Target Organs: Skin. Eyes. Gastrointestinal tract. Respiratory system. Blood. Cardiovascular system. Bone marrow. Spleen. Liver. Kidneys. Nervous system. Thymus.

Potential Environmental Effects: See Section 12 for more information.

This material is considered hazardous by the OSHA Hazard Communication Standard, (29 CFR 1910.1200).

Section 3: COMPOSITION / INFORMATION ON INGREDIENTS

Component	CAS No.	Wt. %
Gasoline	86290-81-5	60 - 100

Section 4: FIRST AID MEASURES

Eye Contact: Flush eyes with plenty of water for at least 15 minutes. If signs/symptoms persist, get medical attention.

Skin Contact: Wash skin with soap and water for at least 15 minutes while removing contaminated clothing and shoes. If signs/symptoms develop, get medical attention.

Ingestion: Do NOT induce vomiting unless directed to do so by medical personnel. Never give anything by mouth to an unconscious person. Get medical attention immediately.

Inhalation: Remove person to fresh air. If breathing has stopped apply artificial respiration. If signs/symptoms develop, get medical attention.

General Advice: In case of accident or if you feel unwell, seek medical advice immediately (show the label or MSDS where possible).

Note to Physicians: Symptoms may not appear immediately.

Section 5: FIRE FIGHTING MEASURES

Flammability: Flammable liquid by WHMIS criteria. Flammable liquid by OSHA criteria. Released vapours may form flammable/explosive mixtures at or above the flash point. Vapours may travel considerable distances to ignition sources and cause a flash fire. Cool containing vessels with water jet in order to prevent pressure build-up, auto-ignition or explosion.

Means of Extinction
Suitable Extinguishing Media: Dry chemical, foam, or carbon dioxide.
Unsuitable Extinguishing Media: Water may not be an effective medium to extinguish fire.

Products of Combustion: Oxides of carbon.

Protection of Firefighters: Keep upwind of fire. Wear full fire fighting turn-out gear (full Bunker gear) and respiratory protection (SCBA).

Explosion Data
Sensitivity to Mechanical Impact: This material is not sensitive to mechanical impact.
Sensitivity to Static Discharge: This material is sensitive to static discharge at temperatures above the flash point.

Section 6: ACCIDENTAL RELEASE MEASURES

Personal Precautions: Evacuate all unnecessary personnel. Stay upwind. Eliminate all ignition sources. Use personal protection recommended in Section 8. Isolate the hazard area and deny entry to unnecessary and unprotected personnel.

Environmental Precautions: Keep out of drains, sewers, ditches, and waterways.

Methods for Containment: Stop leak if without risk. Contain spill and absorb with inert absorbent. Large pools may be covered with foam to prevent vapour evolution. Do not flush to sewer or allow to enter waterways.

Methods for Clean-Up: Absorb or cover with dry earth, sand or other non-combustible material and transfer to containers. Use clean non-sparking tools to collect absorbed material. Large spills should be removed with explosion proof vacuum equipment.

Other Information: Dispose of in accordance with all federal, provincial and local regulations. Comply with federal, provincial, and local requirements for spill and/or release notification.

Section 7: HANDLING AND STORAGE

Handling:
Do not swallow. Do not get in eyes, or on skin. All equipment used when handling the product must be grounded. Handle and open container with care. When using do not eat or drink. Wash hands before eating, drinking, or smoking. See Section 8 for information on Personal Protective Equipment.

Storage:
Store in cool, dry, well-ventilated area away from incompatible materials, heat, and sources of ignition. All storage containers and pumping equipment should be grounded. Keep out of the reach of children.

Section 8: EXPOSURE CONTROLS / PERSONAL PROTECTION

Exposure Guidelines
Component

Gasoline
(86290-81-5) **ACGIH:** 300 ppm (TWA); 500 ppm (STEL); A3 (1990)
(86290-81-5) **OSHA:** 300 ppm (TWA); 500 ppm (STEL) [Vacated]; For Gasoline

Naphtha (petroleum), catalytic reformed
(68955-35-1) **ACGIH:** 100 ppm (TWA); (1980); For Stoddard solvent
(68955-35-1) **OSHA:** 100 ppm (TWA), 400 mg/m³ (TWA); For Naphtha.

Naphtha (petroleum), light catalytic cracked
(64741-55-5) **ACGIH:** 100 ppm (TWA); (1980); For Stoddard solvent
(64741-55-5) **OSHA:** 100 ppm (TWA), 400 mg/m³ (TWA); For Naphtha.

Naphtha (petroleum), isomerization

(64741-70-4) **ACGIH:** 100 ppm (TWA); (1980); For Stoddard solvent

(64741-70-4) **OSHA:** 100 ppm (TWA), 400 mg/m³ (TWA); For Naphtha.

Hydrocarbons, C1-4, debutanizer fraction

(68527-19-5) **ACGIH:** No TLV established.

(68527-19-5) **OSHA:** No PEL established.

Benzene

(71-43-2) **ACGIH:** 0.5 ppm (TWA); 2.5 ppm (STEL); Skin; A1; BEI (1996)

(71-43-2) **OSHA:** 1 ppm (TWA); 5 ppm (STEL);

Xylenes

(1330-20-7) **ACGIH:** 100 ppm (TWA); 150 ppm (STEL); A4; BEI (1992)
(1330-20-7) **OSHA:** 100 ppm (TWA), 435 mg/m³ (TWA);
150 ppm (STEL) [Vacated]

PEL: Permissible Exposure Limit
TLV: Threshold Limit Value
TWA: Time-Weighted Average
STEL: Short-Term Exposure Limit
C: Ceiling

Engineering Controls:	Use ventilation adequate to keep exposures (airborne levels of dust, fume, vapour, gas, etc.) below recommended exposure limits. Use explosion-proof ventilation equipment.
Personal Protective Equipment	
Eye/Face Protection:	Wear safety glasses. Ensure that eyewash stations are close to the workstation location.
Hand Protection:	Wear impervious gloves. Neoprene or nitrile material is suggested. Consult manufacturer specifications for further information.
Skin and Body Protection:	Wear suitable protective clothing. Flame resistant clothing such as Nomex ® is recommended in areas where material is stored or handled.
Respiratory Protection:	If engineering controls and ventilation are not sufficient to control exposure to below the allowable limits then an appropriate NIOSH/MSHA approved air-purifying respirator or self-contained breathing apparatus (SCBA) should be used. Supplied air breathing apparatus must be used when oxygen concentrations are low or if airborne concentrations exceed the limits of the air-purifying respirators.
General Hygiene Considerations:	Handle according to established industrial hygiene and safety practices.

Section 9: PHYSICAL AND CHEMICAL PROPERTIES

Appearance:	Colourless or dyed red or purple liquid.
Colour:	Colourless or dyed red or purple.
Odour:	Petroleum.
Odour Threshold:	0.12 - 0.15 ppm recognition. 0.06 - 0.08 ppm threshold.
Physical State:	Liquid.
pH:	Not available.
Viscosity:	Not available.
Melting Point:	Not available.
Boiling Point:	30 to 215 °C
Flash Point:	-50 °C (TCC)
Evaporation Rate:	Not available.
Lower Flammability Limit:	1.3 %
Upper Flammability Limit:	7.1 %
Vapor Pressure:	Not available.
Vapor Density:	Not available.
Specific Gravity:	0.7 (Water = 1)
Density:	Not available.
Solubility in Water:	Insoluble.
Coefficient of Water/Oil Distribution:	Not available.
Auto-ignition Temperature:	257 °C
Percent Volatile, wt. %:	Not available.
VOC content, wt. %:	Not available.

Section 10: STABILITY AND REACTIVITY

Stability:	Stable under normal storage conditions.
Conditions of Reactivity:	Contact with incompatible materials. Sources of ignition.
Incompatible Materials:	Strong acids. Strong oxidizers. Chlorine.
Hazardous Decomposition Products:	Not available.
Possibility of Hazardous Reactions:	None known.

Section 11: TOXICOLOGICAL INFORMATION

EFFECTS OF ACUTE EXPOSURE

Component Toxicity

Component	CAS No.	LD_{50} oral	LD_{50} dermal	LC_{50}
Gasoline	86290-81-5	60 mL/kg, (mouse)	Not available.	Not available.
Naphtha (petroleum), catalytic reformed	68955-35-1	5400 mg/kg, (rat)	Not available.	Not available.
Naphtha (petroleum), light catalytic cracked	64741-55-5	Not available.	Not available.	Not available.
Naphtha (petroleum), isomerization	64741-70-4	Not available.	Not available.	Not available.
Hydrocarbons, C1-4, debutanizer fraction	68527-19-5	Not available.	Not available.	Not available.
Benzene	71-43-2	930 mg/kg, (rat)	>9400 µl/kg, (rabbit)	10000 ppm, (rat), 7H
Xylenes	1330-20-7	>1700 mg/kg, (rat)	4300 mg/kg, (rabbit)	5000 ppm, (rat), 4H

Eye: Irritating to eyes. Signs/symptoms may include redness, swelling, pain, tearing, and blurred or hazy vision. Product vapours are moderately irritating to the eyes with effects beginning near 200-500 ppm.

Skin: Irritating to skin. Signs/symptoms may include localized redness, swelling, and itching.

Ingestion: Harmful or fatal: may cause lung damage if swallowed. Swallowing the liquid may cause aspiration into the lungs with the risk of chemical pneumonitis. May cause gastrointestinal irritation. Signs/symptoms may include abdominal pain, stomach upset, nausea, vomiting and diarrhea.

Inhalation: May cause respiratory tract irritation. Signs/symptoms may include cough, sneezing, nasal discharge, headache, hoarseness, and nose and throat pain. May cause headache, dizziness, confusion, loss of appetite and loss of consciousness. At concentrations near 1000 ppm, central nervous system effects such as headache, blurred vision, dizziness, and loss of coordination may occur. Exposure to vapour concentrations exceeding 5000 ppm may result in loss of consciousness, coma and death.

Skin Sensitization: Not hazardous by OSHA/WHMIS criteria.

Respiratory Sensitization: Not hazardous by OSHA/WHMIS criteria.

EFFECTS OF CHRONIC EXPOSURE

Target Organs: Skin. Eyes. Gastrointestinal tract. Respiratory system. Blood. Cardiovascular system. Bone marrow. Spleen. Liver. Kidneys. Nervous system. Thymus.

Chronic Effects: Hazardous by OSHA/WHMIS criteria. Prolonged or repeated contact may dry skin and cause irritation. Long term inhalation of Benzene or Xylene vapours can result in bone marrow abnormalities with damage to blood forming tissues and may cause anemia and other blood cell abnormalities. Immunodepressive effects have also been reported. Repeated exposure of the eyes to high concentrations of Xylenes vapour may cause reversible eye damage.

Carcinogenicity: Hazardous by OSHA/WHMIS criteria. May cause cancer. Long-term exposure to Gasoline vapors has caused cancer in laboratory animals. Chronic exposure to benzene has been associated with an increased incidence of leukemia and multiple myeloma (tumour composed of cells of the type normally found in the bone marrow).

Component Carcinogenicity

Component	ACGIH	IARC	NTP	OSHA	Prop 65
Gasoline	A3	Group 2B	Not listed.	OSHA Carcinogen.	Listed.
Naphtha (petroleum), catalytic reformed	Not listed.	Not listed.	Not listed.	Not listed.	Not listed.
Naphtha (petroleum), light catalytic cracked	Not listed.	Not listed.	Not listed.	Not listed.	Not listed.
Naphtha (petroleum), isomerization	Not listed.	Not listed.	Not listed.	Not listed.	Not listed.

Benzene	A1	Group 1	List 1	OSHA Carcinogen.	Listed.
Xylenes	A4	Group 3	Not listed.	Not listed.	Not listed.

Mutagenicity: Hazardous by OSHA/WHMIS criteria. May cause heritable genetic damage.

Reproductive Effects: Not hazardous by OSHA/WHMIS criteria.

Developmental Effects

Teratogenicity: Not hazardous by OSHA/WHMIS criteria.

Embryotoxicity: Benzene and Xylene have caused adverse fetal effects in laboratory animals.

Toxicologically Synergistic Materials: Not available.

Section 12: ECOLOGICAL INFORMATION

Ecotoxicity: Not available.

Persistence / Degradability: Not available.

Bioaccumulation / Accumulation: Not available.

Mobility in Environment: Not available.

Section 13: DISPOSAL CONSIDERATIONS

Disposal Instructions: Disposal should be in accordance with applicable regional, national and local laws and regulations. Local regulations may be more stringent than regional or national requirements.

Section 14: TRANSPORTATION INFORMATION

Section 15: REGULATORY INFORMATION

Chemical Inventories

US (TSCA)
The components of this product are in compliance with the chemical notification requirements of TSCA.

Canada (DSL)
The components of this product are in compliance with the chemical notification requirements of the NSN Regulations under CEPA, 1999.

Federal Regulations

Canada
This product has been classified in accordance with the hazard criteria of the Controlled Products Regulations and the MSDS contains all the information required by the Controlled Products Regulations.

WHMIS Classification:
Class B2 - Flammable Liquids.
Class D2A - Carcinogenicity.
Class D2A - Mutagenicity.
Class D2A - Chronic toxic effects.
Class D2B - Skin irritant.
Class D2B - Eye irritant.

Hazard Symbols:

United States
This MSDS has been prepared to meet the U.S. OSHA Hazard Communication Standard, 29 CFR 1910.1200.

Material Safety Data Sheet

FIR No.: 175527 **Level:** 2
Version Number: CA-EN-8 **Release Date:** 2011-07-13

1. Product and Company Identification

Product Name: SAE 75W-90 API GL-4 Gear Oil
Product Code: See Attachment
Application: Gear oil
Supplier: Ford Motor Company of Canada
Oakville, Ontario L6J 5E4
1-800-392-3673
Emergency Telephone: Poison Control Center: 1-800-959-3673
CHEMTREC: U.S. and Canada: 1-800-424-9300
CHEMTREC: International: 1-703-527-3887

2. Composition/Information on Ingredients

This chemical product is a preparation.

Chemical Name	CAS Number	Percent Concentration	Hazard Classification
PETROLEUM DISTILLATES HYDROTREATED HEAVY PARAFFINIC	64742-54-7	40-70	HAZCOM RSMS_P_SOM RSMS_D_ALL DSL LISTED
PETROLEUM DISTILLATES, HYDROTREATED HEAVY NAPHTHENIC	64742-52-5	10-30	RSMS_P_SOM RSMS_D_ALL HAZCOM DSL LISTED
PETROLEUM DISTILLATES, HYDROTREATED LIGHT PARAFFINIC	64742-55-8	3-7	DSL LISTED RSMS_P_SOM HAZCOM RSMS_D_ALL

3. Hazards Identification

Health:

Exposure to oil mist/fume/vapor may cause respiratory tract irritation.
Inhalation of mist and vapors may irritate the nose, throat, and lungs.
Ingestion may cause slight stomach irritation and discomfort.
This product is not expected to cause eye irritation under normal conditions of use. Symptoms of slight eye irritation may result when direct contact occurs, or when exposed to high mist levels in poorly ventilated areas.
No skin irritation can be expected from single short-term exposure to this product. Prolonged or repeated contact may produce some irritation.

4. First-Aid Measures

Inhalation:
If inhalation of gas/fume/vapor/dust/mist from the material is excessive (air concentration is greater than the TLV or health effects are noticed), immediatly remove the affected person(s) to fresh air.
If irritation persists, get medical attention.

Skin Contact:
Immediately take off all contaminated clothing.
Wash skin with soap and water.
If irritation persists, get medical attention.

Eye Contact:
In case of contact with eyes, rinse immediately with plenty of water for at least 15 minutes and seek medical attention.
If irritation persists, get medical attention.

Ingestion:
If the material is swallowed, get immediate medical attention or advice -- Do not induce vomiting.

5. Fire-Fighting Measures

Extinguishing Media:
EXTINGUISHER INFORMATION: Dry chemical, foam, carbon dioxide, water fog.

Specific Methods:
Use water to cool fire-exposed containers, structures, and to protect personnel.
Water may be an ineffective extinguishing medium.

Specific Hazards:
Empty containers may retain product residue including Flammable or Explosive vapors. Do not cut, drill, grind, or weld near full, partially full, or empty product containers.
Irritating and/or toxic fumes and gases may be emitted upon the product's decomposition.
Upon decomposition, this product emits carbon monoxide, carbon dioxide and/or low molecular weight hydrocarbons.

Protection of Firefighters:
Fire fighters should be equipped with NIOSH-approved, self-contained breathing apparatus (SCBA) and full protective clothing.

6. Accidental Release Measures

Personal Precautions:
Avoid inhalation of vapors and contact with skin and eyes.
In case of spills, beware of slippery floors and surfaces.
Wear appropriate protective equipment and clothing during clean-up.

Environmental Precautions:
Do not allow the spilled product to enter public drainage system or open water courses.
WATER SPILL: Remove from surface by skimming or with suitable absorbents. If allowed by local authorities and environmental agencies, sinking and/or suitable dispersants may be used in confined waters.

Methods for Cleaning Up: Contain the discharged material.
Absorb the spilled material with an inert absorbent (nonflammable) material.
In case of large spills, follow all facility Emergency Response Procedures.

7. Handling and Storage

Handling:

Technical Measures: Avoid the generation of oil mists.

Precautions and Advice for Safe Handling: Elevated temperature or mechanical action may form vapors, mist, or fumes which may be irritating to the eyes, nose, throat, and lungs.
Avoid breathing vapors or mist.
Keep the container closed when not in use.

Storage: **Technical Measures:** No special precautions.

Storage Conditions: Keep the container tightly closed and in a cool, well-ventilated place.
Store this product away from strong oxidizing agents.

8. Exposure Controls/Personal Protection

Engineering Measures: Use adequate mechanical ventilation (general and/or local exhaust) ventilation to maintain exposure below PEL(s) and/or TLV(s).

Control Parameters: If oil mist is generated, observe the OSHA exposure limit of 5 mg/m3.
Ford Motor Company recommends an exposure limit of 1.0 mg/m3.

Personal Protective Equipment:

Respiratory Protection: If engineering controls do not maintain airborne concentrations to a level which is adequate to protect worker health, an approved respirator must be worn. Respirator selection, use and maintenance should be in accordance with the requirements of OSHA Respiratory Protection Standard 29 CFR 1910.134 and/or Canadian Standard CSA Z94.4.

Hand Protection: Use of impervious gloves is recommended, such as neoprene.
The use of nitrile-latex gloves is recommended.
The use of polyvinyl chloride gloves is recommended.

Eye Protection: Wear safety glasses with side shields.
Wear chemical goggles; face shield (if splashing is possible).

Skin and Body Protection: Remove contaminated clothing and wash before reuse.

FIR No.:	175527	**Level:**	2
Version Number:	CA-EN-8	**Release Date:**	2011-07-13

Hygiene Measures: Wash thoroughly after handling.
When using this material, do not eat, drink or smoke.

9. Physical and Chemical Properties

Specific Gravity: 0.88-0.89 H2O=1 @20-25°C

Physical State: LIQUID

Form: OIL

Odor: HYDROCARBON

Color: BRIGHT AND CLEAR

pH: NA N.AP

Temperature Range During which Changes in Physical State Occur:

Boiling Point: >280 °C

Flash Point: 177 °C COC

Auto-ignition Temperature: >320 °C

Explosion Properties:

UEL: N.AV

LEL: N.AV

Vapor Pressure: <0.5@20°C Pa

Vapor Density: >1 (AIR=1)

Solubility: NEGLIGIBLE IN WATER

Viscosity: > 40 mm2/s @40°C

Evaporation Rate: N.AV

10. Stability and Reactivity

Stability: This is a stable material.

Conditions and Materials to Avoid: This product may react with strong oxidizing agents (bleach--sodium hypochlorite, calcium hypochlorite, hydrogen peroxide, permanganate, nitric acid, concentrated OXYGEN, perchlorates).

Hazardous Decomposition Products: Carbon monoxide, carbon dioxide, and other low molecular weight hydrocarbons.
Irritating and/or toxic gases may be emitted upon the product's decomposition.

FIR No.:	175527	**Level:**	2
Version Number:	CA-EN-8	**Release Date:**	2011-07-13

11. Toxicological Information

Chronic (Long Term) Toxicity:

Base oil severely refined: Not carcinogenic in animal studies.
Representative material passes IP-346, Modified Ames test, and/or other screening tests.
Continuous long term contact with used motor oil has caused skin cancer in animal tests.

12. Ecological Information

No specific aquatic data available for this product.

13. Disposal Considerations

Waste from Residues:

Dispose of waste material according to Local, State, Federal, and Provincial Environmental Regulation.

Contaminated Packaging:

No consideration given when disposed of according to local, state, and Federal regulations.

Material Safety Data Sheet

FIR No.:	175527	**Level:**	2
Version Number:	CA-EN-8	**Release Date:**	2011-07-13

14. Transport Information

U.S. Department of Transportation (DOT) 49 - CFR 172.101
This product is not regulated as a dangerous good.

Canadian Transportation of Dangerous Goods (T.D.G.) - TDGR Schedule II
This product is not regulated as a dangerous good.

Secretary of Communication and Transportation (SCT) - NOM-002-SCT2/1994 (Mexico)
This product is not regulated as a dangerous good.

International and Domestic Air Transportation - ICAO & IATA Section 4.2
This product is not regulated as a dangerous good.

International Water Transportation - IMDG Code Amendment 31-02
This product is not regulated as a dangerous good.

15. Regulatory Information

This product has been classified in accordance with the hazard criteria of the Controlled Products Regulations and the MSDS contains all the information required by the Controlled Products Regulations.
Don't pollute. Conserve resources. Return used oil to collection centers.
Material contains a chemical which is a Ford Motor Company Material of Concern. Use and release of this material should be minimized to the greatest extent possible.
Not a controlled product.

16. Other Information

Key/Legend: N.AP = Not applicable; N.AV = Not available; ND = Not determined or No data; TLV = Threshold limit value; TWA = Time-weighted average; STEL = Short-term exposure limit; C = Ceiling limit

The following sections contain revisions OR NEW statements.	2 15 16 4 8
Preparation Information:	The chemical identification and properties for this material were provided by the manufacturer. For Canadian locations, a manufacture's MSDS is available upon request. Health and safety information has been evaluated by the Occupational and Environmental Health Sciences Department, Ford Motor Company, Diagnostic Service Center II, 1800 Fairlane Drive, Allen Park, MI 48101, USA.

2. Hazards Identification

Emergency overview

DANGER

Corrosive. Causes severe skin and eye burns. Causes digestive tract burns. Mist or vapor extremely irritating to eyes and respiratory tract. Reacts with water.

OSHA regulatory status

This product is considered hazardous under 29 CFR 1910.1200 (Hazard Communication).

Potential health effects

Routes of exposure	Ingestion. Inhalation. Skin contact. Eye contact.
Eyes	Corrosive. Causes severe eye burns. Dust or splashes from the mixture may cause permanent eye damage.
Skin	Corrosive. Causes severe skin burns.
Inhalation	Corrosive. May cause damage to mucous membranes in nose, throat, lungs and bronchial system.
Ingestion	Corrosive. Ingestion may produce burns to the lips, oral cavity, upper airway, esophagus and possibly the digestive tract.

Target organs

Eyes. Skin. Respiratory system.

Chronic effects

Corrosive. Prolonged contact causes serious tissue damage.

Potential environmental effects

The product may affect the acidity (pH-factor) in water with risk of harmful effects to aquatic organisms.

3. Composition / Information on Ingredients

Components	CAS #	Percent
CALCIUM OXIDE	1305-78-8	90 - 100

4. First Aid Measures

First aid procedures

Eye contact

Immediately flush with plenty of water for at least 15 minutes. If easy to do, remove contact lenses. Call a physician or poison control center immediately. In case of irritation from airborne exposure, move to fresh air. Get medical attention immediately.

Skin contact	Immediately flush with plenty of water for at least 15 minutes while removing contaminated clothing and shoes. Call a physician or poison control center immediately. Wash clothing separately before reuse. Destroy or thoroughly clean contaminated shoes.
Inhalation	Move to fresh air. If breathing stops, provide artificial respiration. If breathing is difficult, give oxygen. Call a physician or poison control center immediately.
Ingestion	Call a physician or poison control center immediately. Do not induce vomiting. If vomiting occurs, the head should be kept low so that stomach vomit doesn't enter the lungs.
Notes to physician	Keep victim under observation. Treat symptomatically.
General advice	In the case of accident or if you feel unwell, seek medical advice immediately (show the label where possible). Show this safety data sheet to the doctor in attendance. Ensure that medical personnel are aware of the material(s) involved, and take precautions to protect themselves.

5. Fire Fighting Measures

Flammable properties	The product is not flammable. No unusual fire or explosion hazards noted.
Extinguishing media	
Suitable extinguishing media	Carbon dioxide (CO2). Dry chemical powder. Foam.
Unsuitable extinguishing media	The product reacts with water and will generate heat.
Protection of firefighters	
Protective equipment and precautions for firefighters	Use water spray to cool unopened containers. Self-contained breathing apparatus and full protective clothing must be worn in case of fire. Cool containers exposed to flames with water until well after the fire is out.
Special protective equipment for fire-fighters	Wear full protective clothing, including helmet, self-contained positive pressure or pressure demand breathing apparatus, protective clothing and face mask. Wear self-contained breathing apparatus with a full facepiece operated in the positive pressure demand mode when fighting fires.
Specific methods	In the event of fire and/or explosion do not breathe fumes.

6. Accidental Release Measures

Personal precautions	Wear appropriate protective equipment and clothing during clean-up. Keep upwind. Keep out of low areas. Ventilate closed spaces before entering them.
Environmental precautions	Prevent further leakage or spillage if safe to do so. Avoid discharge into drains, water courses or onto the ground.
Methods for cleaning up	Avoid dust formation. Large Spills: Sweep up or vacuum up spillage and collect in suitable container for disposal. Small Spills: Sweep up and place in a clearly labeled container for chemical waste. Clean surface thoroughly to remove residual contamination. Never return spills in original containers for re-use. DO NOT GET WATER on spilled material or inside containers. Collect in a non-combustible container for prompt disposal. Clean up in accordance with all applicable regulations.

7. Handling and Storage

Handling	Do not get in eyes, on skin, on clothing. Do not taste or swallow. Wash thoroughly after handling. Do not eat, drink or smoke when using the product. Considerable heat is generated when water or acid is added, therefore when making solutions always add the caustic to the water or acid with constant stirring.
Storage	Keep tightly closed in a dry, cool and well-ventilated place.

8. Exposure Controls / Personal Protection

ACGIH

Material	Type	Value
CALCIUM OXIDE (1305-78-8)	TWA	2.0000 mg/m3

Occupational exposure limits

U.S. - OSHA

Material	Type	Value
CALCIUM OXIDE (1305-78-8)	PEL	5.0000 mg/m3

Engineering controls Good general ventilation (typically 10 air changes per hour) should be used. Ventilation rates should be matched to conditions. If applicable, use process enclosures, local exhaust ventilation, or other engineering controls to maintain airborne levels below recommended exposure limits. If exposure limits have not been established, maintain airborne levels to an acceptable level.

Personal protective equipment

Eye / face protection Wear safety glasses with side shields (or goggles) and a face shield.

Skin protection Wear appropriate chemical resistant clothing. Wear appropriate chemical resistant gloves.

Respiratory protection If engineering controls do not maintain airborne concentrations below recommended exposure limits (where applicable) or to an acceptable level (in countries where exposure limits have not been established), an approved respirator must be worn. Respirator type: High-efficiency particulate respirator with full facepiece.

General hygeine considerations Provide eyewash station and safety shower. Always observe good personal hygiene measures, such as washing after handling the material and before eating, drinking, and/or smoking. Routinely wash work clothing and protective equipment to remove contaminants.

General Wear chemical protective equipment that is specifically recommended by the manufacturer. Launder contaminated clothing before reuse.

9. Physical & Chemical Properties

Appearance	Granular.
Color	White to yellow.
Odor	Not available.
Odor threshold	Not available.
Physical state	Solid.
Form	Powder.
pH	12.8 (Saturated solution)
Melting point	4661.6 °F (2572 °C)
Freezing point	4661.6 °F (2572 °C)
Boiling point	5162 °F (2850 °C)
Flash point	Not available.
Evaporation rate	Not available.
Flammability limits in air, upper, % by volume	Not available.
Flammability limits in air, lower, % by volume	Not available.
Specific gravity	3.37
Relative density	Not available.
Partition coefficient (n-octanol/water)	Not available
Auto-ignition temperature	Not available.
Molecular weight	56.08 g/mol

Molecular formula	Ca-O

10. Chemical Stability & Reactivity Information

Chemical stability	Material is stable under normal conditions. Material reacts with water.
Conditions to avoid	Exposure to moisture. Reacts violently with strong acids.
Incompatible materials	Moisture. Oxidizing agents. Acids. Halogens. Alcohols.
Hazardous decomposition products	Oxides of calcium.
Possibility of hazardous reactions	Hazardous polymerization does not occur.

11. Toxicological Information

Sensitization	Not a skin sensitizer.
Local effects	Causes severe burns.
Chronic effects	Corrosive. Prolonged contact causes serious tissue damage.
Carcinogenicity	This product is not considered to be a carcinogen by IARC, ACGIH, NTP, or OSHA.
Skin corrosion/irritation	Corrosive to skin and eyes.
Epidemiology	No epidemiological data is available for this product.
Mutagenicity	No data available to indicate product or any components present at greater than 0.1% are mutagenic or genotoxic.
Neurological effects	No data available for this product.
Reproductive effects	Contains no ingredient listed as toxic to reproduction
Teratogenicity	No data available to indicate product or any components present at greater than 0.1% may cause birth defects.
Symptoms and target organs	Corrosive effects.
Further information	Danger of very serious irreversible effects. Symptoms may be delayed.

12. Ecological Information

Ecotoxicity	The product may affect the acidity (pH-factor) in water with risk of harmful effects to aquatic organisms.
Persistence and degradability	Not available.
Partition coefficient (n-octanol/water)	Not available

13. Disposal Considerations

Disposal instructions	Dispose of this material and its container to hazardous or special waste collection point. Incinerate the material under controlled conditions in an approved incinerator. All wastes must be handled in accordance with local, state and federal regulations.
Contaminated packaging	Since emptied containers retain product residue, follow label warnings even after container is emptied. Offer rinsed packaging material to local recycling facilities.

14. Transport Information

DOT

Basic shipping requirements:

UN number	UN1910
Proper shipping name	Calcium oxide
Hazard class	8
Packing group	III

15. Regulatory Information

US federal regulations

This product is a "Hazardous Chemical" as defined by the OSHA Hazard Communication Standard, 29 CFR 1910.1200.
All components are on the U.S. EPA TSCA Inventory List.

CERCLA/SARA Hazardous Substances - Not applicable.

CERCLA (Superfund) reportable quantity

None

Superfund Amendments and Reauthorization Act of 1986 (SARA)

Hazard categories	Immediate Hazard - Yes Delayed Hazard - No Fire Hazard - No Pressure Hazard - No Reactivity Hazard - No
Section 311 hazardous chemical	Yes
Food and Drug Administration (FDA)	Total food additive Direct food additive GRAS food additive

Inventory status

Country(s) or region	Inventory name	On inventory (yes/no)*
Australia	Australian Inventory of Chemical Substances (AICS)	Yes
Canada	Domestic Substances List (DSL)	Yes
Canada	Non-Domestic Substances List (NDSL)	No
China	Inventory of Existing Chemical Substances in China (IECSC)	Yes
Europe	European Inventory of Existing Commercial Chemical Substances (EINECS)	Yes
Europe	European List of Notified Chemical Substances (ELINCS)	No
Japan	Inventory of Existing and New Chemical Substances (ENCS)	Yes
Korea	Existing Chemicals List (ECL)	Yes
New Zealand	New Zealand Inventory	Yes
Philippines	Philippine Inventory of Chemicals and Chemical Substances (PICCS)	Yes
United States & Puerto Rico	Toxic Substances Control Act (TSCA) Inventory	Yes

*A "Yes" indicates that all components of this product comply with the inventory requirements administered by the governing country(s)

State regulations This product does not contain a chemical known to the State of California to cause cancer, birth defects or other reproductive harm.

US - Pennsylvania RTK - Hazardous Substances: Listed substance

CALCIUM OXIDE (CAS 1305-78-8) Listed.

Saf-T-Data

Health: 2 - Moderate
Flammability: 0 - None
Reactivity: 2 - Moderate
Contact: 3 - Severe (Corrosive)
Lab Protective Equip: D - GOGGLES & SHIELD; LAB COAT & APRON; VENT HOOD; PROPER GLOVES
Storage Color Code: W - White (Corrosive)

16. Labeling Info

Label Hazard Warning

DANGER

Corrosive. Causes severe skin and eye burns. Causes digestive tract burns. Mist or vapor extremely irritating to eyes and respiratory tract. Material reacts with water.

Label Precautions Use only with adequate ventilation. Do not get in eyes, on skin, or on clothing. Do not breathe dust. Do not taste or swallow. Wash thoroughly after handling.

Label First Aid Immediately flush eyes with plenty of water for at least 15 minutes. Immediately flush skin with plenty of water. If gas/fume/vapor/dust/mist from the material is inhaled, remove the affected person immediately to fresh air. Get medical attention immediately. IF SWALLOWED: Immediately call a POISON CENTER or doctor/physician. Do not induce vomiting without advice from poison control center. If vomiting occurs, keep head low so that stomach content doesn't get into the lungs. Do not use mouth-to-mouth method if victim ingested the substance.

17. Other Information

NFPA ratings

Health: 3
Flammability: 0
Instability: 1
Special hazards: W

Disclaimer

THE INFORMATION PRESENTED IN THIS MATERIAL SAFETY DATA SHEET (MSDS/SDS) WAS PREPARED BY TECHNICAL PERSONNEL BASED ON DATA THAT THEY BELIEVE IN THEIR GOOD FAITH JUDGMENT IS ACCURATE. HOWEVER, THE INFORMATION PROVIDED HEREIN IS PROVIDED “AS IS,” AND AVANTOR PERFORMANCE MATERIALS MAKES AND GIVES NO REPRESENTATIONS OR WARRANTIES WHATSOEVER, AND EXPRESSLY DISCLAIMS ALL WARRANTIES REGARDING SUCH INFORMATION AND THE PRODUCT TO WHICH IT RELATES, WHETHER EXPRESS, IMPLIED, OR STATUTORY, INCLUDING WITHOUT LIMITATION, WARRANTIES OF ACCURACY, COMPLETENESS, MERCHANTABILITY, NON-INFRINGEMENT, PERFORMANCE, SAFETY, SUITABILITY, STABILITY, AND FITNESS FOR A PARTICULAR PURPOSE, AND ANY WARRANTIES ARISING FROM COURSE OF DEALING, COURSE OF PERFORMANCE, OR USAGE OF TRADE. Safety Data Sheet

1. PRODUCT INDENTIFICATION

Name **Diethylene Glycol**
Synonyms **dihydroxydiethyl ether; 2,2-oxydiethanol; 2-hydroxyethyl ether**
CAS# **111-46-6**
Europe EC# **203-872-2**
Product Uses **mfg of resins & polyols; antifreeze, dehydrating agent, component of inks, etc**

2. HAZARDS

Quick Guide: will burn in fire; toxic substances form in fire; may ignite on hot surface; toxic on ingestion

Canada – WHMIS **D 1B**
Key: ***B 2*** *– Flash Point <38°C,* ***B 3*** *– Flash Point >38°C & <93°C*
D 1 *– Immediately Toxic,* ***D 2*** *– Chronic Toxicity*
C *– Oxidising Substance,* ***E*** *– Corrosive,* ***F*** *– Reactive Substance*

U.S.A. – HMIS **Health – 2, Fire – 1, Reactivity – 0**
Key: ***0****=minimal,* ***1****=slight,* ***2****=moderate,* ***3****=serious,* ***4****=severe*

3. COMPOSITION

	%	TWAEV / TLV mg/m^3	LD_{50} (mg/kg) ORAL	LD_{50} (mg/kg) SKIN	LC_{50} ppm INHALATION
2-hydroxyethyl ether	100%	not listed	2300	11,890	1070

4. FIRST AID

SKIN: Wash with water. Remove contaminated clothing and do not reuse until laundered.
EYES: Wash eyes with plenty of water, holding eyelids open. Seek medical assistance promptly if there is irritation.
INHALATION: Remove from contaminated area promptly. ***CAUTION: Rescuer must not endanger himself!*** If breathing stops, administer artificial respiration and seek medical aid promptly.
INGESTION: Give plenty of water to dilute product. Do not induce vomiting (NOTE below). Keep victim quiet. If vomiting occurs, lower victim's head below hips to prevent inhalation of vomited material. Seek medical help promptly.

Inadvertent inhalation of vomited material may seriously damage the lungs. The danger of this is greater than the risk of poisoning through absorption of this relatively low-toxicity substance. The stomach should only be emptied under medical supervision, and after the installation of an airway to protect the lungs.

5. FIRE FIGHTING & FLAMMABILITY

Flash Point	124°C / 255°F (closed cup)
Autoignition Temperature	224°C / 435°F
Flammable Limits	1.6% – 10.8%
Combustion Products	carbon monoxide, nitrogen oxides, smoke, part oxidised hydrocarbon fragments, including (irritating) formaldehyde
Fire Fighting Precautions	foam, dry chemical, water fog, water spray – water jet spreads flames; firefighters must wear SCBA
Static Charge Accumulation	cannot accumulate a static charge

Please ensure that this MSDS is given to, and explained to people using this product.

6. ACCIDENTAL RELEASE MEASURES

Leak Precaution	dyke to control spillage and prevent environmental contamination
Handling Spill	ventilate contaminated area; recover free liquid with suitable pumps; absorb residue on an inert sorbent, sweep, shovel & store in closed containers for recycling or disposal

7. HANDLING & STORAGE

Diethylene glycol absorbs moisture from the air. Store in a dry environment, away from sources of open flame, oxidising agents and substances listed in Part 10.

This product may react with oxygen in the air to form explosive or flammable peroxides. Ensure that containers are full and tightly sealed. If prolonged storage of a part container is anticipated, flush headspace with dry nitrogen gas prior to sealing. Always ensure that containers, whether empty or full, or part full, are tightly sealed unless in use.

Avoid breathing product mist. Use with adequate ventilation. Never cut, drill, weld or grind on or near this container. Avoid contact with skin and wash work clothes frequently. An eye bath and safety shower must be available near the workplace.

Sweet taste makes glycols attractive to pets and children. Keep away from children and clean spills promptly.

8. EXPOSURE CONTROL & PERSONAL PROTECTION

Ontario TWAEV	not listed – *AIHA WEEL is 10 mg/m^3 / 2.3ppm*
ACGIH TLV	not listed
OSHA PEL	not listed
Ventilation	not required; if visible mist is generated, install mechanical ventilation at source
Hands	no special protective gloves required; nitrile or butyl gloves are resistant to diethylene glycol
Eyes	safety glasses with side shields – *always protect the eyes*
Clothing	no special protective clothing required

9. PHYSICAL PROPERTIES

Odour & Appearance	clear, colourless, odourless, viscous, hygroscopic liquid with a sweet taste
Odour Threshold	not known – odourless
Vapour Pressure	0.0057mmHg / 0.00076kPa (25^{o}C / 77^{o}F)
Evaporation Rate (*Butyl Acetate = 1*)	0.001 – *not considered volatile*
Vapour Density (air = 1)	3.7
Boiling Range	246^{o}C / 475^{o}F
Melting Point	-10.5^{o}C / 13^{o}F – *supercools to well below this temperature*
Specific Gravity	1.118 (20/20^{o}C)
Water Solubility	complete
Also soluble in	alcohols, ketones, ethers, esters; limited solubility in hydrocarbons
Viscosity	38centipoise (20^{o}C / 68^{o}F)
pH	none – (*does not liberate hydrogen ions when dissolved*)
Conversion Factor	1ppm = 4.3mg/m^3
Molecular Weight	106grams per mole

10. REACTIVITY

Dangerously Reactive With	strong oxidising agents & hypochlorites; reacts with powdered metals: aluminium, zinc, or alkali metals: sodium, potassium, lithium, or their hydrides releases hydrogen & creates alkali; reacts with boron trichloride & aluminium chloride to produce hydrogen chloride gas
Also Reactive With	epoxides, strong acids & acid anhydrides, carbon disulphide, halogens & isocyanates
Stability	stable; will not polymerize
Decomposes in Presence of	air to form peroxides which may explode; oxidation is faster in the presence of acid & if heated
Decomposition Products	none apart from Hazardous Combustion Products
Sensitive to Mechanical Impact	no

Please ensure that this MSDS is given to, and explained to people using this product.

11. TOXICITY

Effects, Acute Exposure

Skin Contact	little to no effect
Skin Absorption	slight; no toxic effects by this route
Eye Contact	may be slightly irritating
Inhalation	little to no effect; low vapour pressure makes vapour formation unlikely; diethylene glycol is used to create theatrical mist with no reported consequences
Ingestion*	ingestion in amounts similar to those producing intoxication with alcohol cause similar effects; headache, dizziness, drowsiness; *not a route of occupational exposure*

Effects, Chronic Exposure

General	experimental long-term ingestion has produced renal stones & liver damage in rodents
Sensitising	not a sensitiser in humans or animals
Carcinogen/Tumorigen	not considered a tumorigen or a carcinogen in humans or animals
Reproductive Effect	no known effect in humans or animals
Mutagen	no known effect on humans or animals
Synergistic With	consumption of ethyl alcohol
LD_{50} (oral)*	2300 & 28,100mg/kg (mouse), 3300 & 3400mg/kg (cat), 4400 – 44,000mg/kg (rabbit),
(*Note very broad range of oral LD_{50}*)	7800 – 30,000mg/kg (rat), 8000-9900mg/kg (dog), 7800 – 13,200mg/kg (guinea pig)
LD_{50} (skin)	11,890 & 13,300mg/kg (rabbit)
LC_{50} (inhalation)	above 1070ppm (rat)

**** NOTE on oral toxicity:*** *Diethylene glycol is more toxic in humans than to the laboratory animals used in testing (above). Obviously, LD_{50} testing cannot be carried out on humans. In 1937, 105 people (34 children, 71 adults) died after ingesting an elixir containing 72% diethylene glycol, 8% sulfanilamide & 20% flavours, saccharin, caramel, plus 10% water for 6-13 days. More recently, half of a group of male prisoners, who had ingested diethylene glycol for 2 years (as a cleaning solution), were found to be suffering some neurological abnormalities. However, ingestion is not an expected route of entry for this industrial substance.*

12. ECOLOGICAL INFORMATION

Bioaccumulation	highly water soluble; cannot bioaccumulate
Biodegradation	biodegrades readily in the presence of oxygen; a wide range of degradation rates are seen: 30% to 70% in 20 – 30 days; also, over 90% after 28 days
Abiotic Degradation	reacts with atmospheric hydroxyl radicals; estimated ½-life in air is 6 to 12 hours
Mobility in soil, water	water soluble; moves readily in soil & water
Aquatic Toxicity	
LC_{50} (Fish, 96hr)	>32,000mg/kg (Gambusia affinis), >10,000mg/kg (Leuciscus idus, 48hr), >5000mg/kg (Carassius auratus, 24hr),
LC_{50} (Crustacea, 24hr)	>10,000mg/kg (Artemia salina), >10,000mg/kg (Daphnia magna)
NOEC (Algae)	800mg/litre (Anacystis aeruginosa)
EC_0 (Algae)	1700mg/litre (Microcystis aeruginosa) – *this is an EC_0, not an EC_{50} – no effect at this dose*
EC_{50} (Bacteria)	29,228mg/litre (Photobacterium phosphoreum, 15min), 40,000mg/litre (mixed bacterial culture)
NOEC (Bacteria)	4000mg/litre (Chilomonas paramaecium), 8000mg/litre (Pseudomonas putida)

13. DISPOSAL

Waste Disposal	**do not flush to sewer**, recycle solvent if possible, local regulations may permit disposal in sanitary landfill, may be incinerated in approved facility after mixing with a flammable waste
Containers	**Drums** should be reused. Recondition and pressure test by a licensed reconditioner prior to re-use. **Pails** must be vented and thoroughly dried prior to crushing and recycling. **IBCs** (intermediate bulk containers): polyethylene bottle must be pressure tested & recertified at 30 months. Replace at 60 months (5yrs). Steel containers must be inspected, pressure tested & recertified every 5 years. ***Never cut, drill, weld or grind on or near this container, even if empty***

Please ensure that this MSDS is given to, and explained to people using this product.

14. TRANSPORT CLASSIFICATION

Canada TDG	**PIN**	**UN - not regulated for transport**
AND	**Shipping Name**	**not regulated for transport**
U.S.A. 49 CFR	**Class & Packing Group**	**not regulated for transport**
Marine Pollutant		not a marine pollutant
ERAP Required		**NO**

EMERGENCY INFORMATION

Canada	**Call CANUTEC (collect)**	**(613) 996-6666**
U.S.A.	**Call CHEMTREC**	**(800) 424-9300**

15. REGULATIONS

Canada DSL	**on inventory**
U.S.A. TSCA	**on inventory**
Europe EINECS	**on inventory**
Europe Classification	**Harmful** 
Europe Risk Phrases	**R: 22 –** *Harmful if swallowed.*
Europe Safety Phrases	**S: 46 –** *If swallowed, seek medical advice immediately.*

Allowable Tolerances: Residues of diethylene glycol are exempted from the requirement of a tolerance when used in accordance with good agricultural practice as inert (or occasionally active) ingredients in pesticide formulations applied to growing crops only. Use: deactivator, adjuvant for formulations used before crop emerges from soil. Residues of diethylene glycol are exempted from the requirement of a tolerance when used in accordance with good agricultural practice as inert (or occasionally active) ingredients in pesticide formulations applied to growing crops only. Use: deactivator for formulations used before crop emerges from soil, stabilizer.

FIFRA Requirements: Residues of diethylene glycol are exempted from the requirement of a tolerance when used in accordance with good agricultural practice as inert (or occasionally active) ingredients in pesticide formulations applied to growing crops only. Use: deactivator, adjuvant for formulations used before crop emerges from soil. Residues of diethylene glycol are exempted from the requirement of a tolerance when used in accordance with good agricultural practice as inert (or occasionally active) ingredients in pesticide formulations applied to growing crops only. Use: deactivator for formulations used before crop emerges from soil, stabilizer.

FDA Requirements: Diethylene glycol is an indirect food additive for use only as a component of adhesives.

16. OTHER INFORMATION

Prepared for Megaloid Laboratories by Peter Bursztyn, (705) 734-1577
*Data from **RTECS**, **HSDB** (Haz. Substance Data Base), **Cheminfo** (CCOHS), **IUCLID** Datasheets (ESIS – European Chem. Substance Info. System), & others.*
Preparation Date: ***June 2001*** *Revision Date*: ***December 2003, October 2006, October 2009; October 2012***

Please ensure that this MSDS is given to, and explained to people using this product.

MATERIAL SAFETY DATA SHEET

SECTION 1 PRODUCT AND COMPANY IDENTIFICATION

PRODUCT

Product Name: CAT HYDO ADVANCED 10
Product Description: Base Oil and Additives
MSDS Number: 19993
Intended Use: Hydraulic fluid

COMPANY IDENTIFICATION

Supplier: **Imperial Oil Products Division**
240 4th Avenue
Calgary, ALBERTA. T2P 3M9 Canada

24 Hour Environmental / Health Emergency Telephone	519-339-2145
Transportation Emergency Phone Number	519-339-2145
Product Technical Information	1-800-268-3183
Supplier General Contact	1-800-567-3776

SECTION 2 COMPOSITION / INFORMATION ON INGREDIENTS

No Reportable Hazardous Substance(s) or Complex Substance(s).

SECTION 3 HAZARDS IDENTIFICATION

This material is not considered to be hazardous according to regulatory guidelines see Section 15.

HEALTH EFFECTS

Low order of toxicity. Excessive exposure may result in eye, skin, or respiratory irritation. High-pressure injection under skin may cause serious damage.

NFPA Hazard ID:	Health:	0	Flammability:	1	Reactivity: 0
HMIS Hazard ID:	Health:	0	Flammability:	1	Reactivity: 0

NOTE: This material should not be used for any other purpose than the intended use in Section 1 without expert advice. Health studies have shown that chemical exposure may cause potential human health risks which may vary from person to person.

SECTION 4 FIRST AID MEASURES

INHALATION

Remove from further exposure. For those providing assistance, avoid exposure to yourself or others. Use adequate respiratory protection. If respiratory irritation, dizziness, nausea, or unconsciousness occurs, seek

immediate medical assistance. If breathing has stopped, assist ventilation with a mechanical device or use mouth-to-mouth resuscitation.

SKIN CONTACT

Wash contact areas with soap and water. If product is injected into or under the skin, or into any part of the body, regardless of the appearance of the wound or its size, the individual should be evaluated immediately by a physician as a surgical emergency. Even though initial symptoms from high pressure injection may be minimal or absent, early surgical treatment within the first few hours may significantly reduce the ultimate extent of injury.

EYE CONTACT

Flush thoroughly with water. If irritation occurs, get medical assistance.

INGESTION

First aid is normally not required. Seek medical attention if discomfort occurs.

SECTION 5 FIRE FIGHTING MEASURES

EXTINGUISHING MEDIA

Appropriate Extinguishing Media: Use water fog, foam, dry chemical or carbon dioxide (CO2) to extinguish flames.

Inappropriate Extinguishing Media: Straight streams of water

FIRE FIGHTING

Fire Fighting Instructions: Evacuate area. Prevent run-off from fire control or dilution from entering streams, sewers or drinking water supply. Fire-fighters should use standard protective equipment and in enclosed spaces, self-contained breathing apparatus (SCBA). Use water spray to cool fire exposed surfaces and to protect personnel.

Unusual Fire Hazards: Pressurised mists may form a flammable mixture.

Hazardous Combustion Products: Smoke, Fume, Aldehydes, Sulphur oxides, Incomplete combustion products, Oxides of carbon

FLAMMABILITY PROPERTIES

Flash Point [Method]: >200C (392F) [Estimated ASTM D-92]
Flammable Limits (Approximate volume % in air): LEL: 0.9 UEL: 7.0
Autoignition Temperature: N/D

SECTION 6 ACCIDENTAL RELEASE MEASURES

NOTIFICATION PROCEDURES

In the event of a spill or accidental release, notify relevant authorities in accordance with all applicable regulations.

PROTECTIVE MEASURES

Avoid contact with spilled material. See Section 5 for fire fighting information. See the Hazard Identification

Section for Significant Hazards. See Section 4 for First Aid Advice. See Section 8 for advice on the minimum requirements for personal protective equipment. Additional protective measures may be necessary, depending on the specific circumstances and/or the expert judgment of the emergency responders. For emergency responders: Respiratory protection: respiratory protection will be necessary only in special cases, e.g., formation of mists. Half-face or full-face respirator with filter(s) for dust/organic vapor or Self Contained Breathing Apparatus (SCBA) can be used depending on the size of spill and potential level of exposure. If the exposure cannot be completely characterized or an oxygen deficient atmosphere is possible or anticipated, SCBA is recommended. Work gloves that are resistant to hydrocarbons are recommended. Gloves made of polyvinyl acetate (PVA) are not water-resistant and are not suitable for emergency use. Chemical goggles are recommended if splashes or contact with eyes is possible. Small spills: normal antistatic work clothes are usually adequate. Large spills: full body suit of chemical resistant, antistatic material is recommended.

SPILL MANAGEMENT

Land Spill: Stop leak if you can do so without risk. Recover by pumping or with suitable absorbent.

Water Spill: Stop leak if you can do so without risk. Confine the spill immediately with booms. Warn other shipping. Remove from the surface by skimming or with suitable absorbents. Seek the advice of a specialist before using dispersants.

Water spill and land spill recommendations are based on the most likely spill scenario for this material; however, geographic conditions, wind, temperature, (and in the case of a water spill) wave and current direction and speed may greatly influence the appropriate action to be taken. For this reason, local experts should be consulted. Note: Local regulations may prescribe or limit action to be taken.

ENVIRONMENTAL PRECAUTIONS

Large Spills: Dyke far ahead of liquid spill for later recovery and disposal. Prevent entry into waterways, sewers, basements or confined areas.

SECTION 7 HANDLING AND STORAGE

HANDLING

Prevent small spills and leakage to avoid slip hazard. Material can accumulate static charges which may cause an electrical spark (ignition source). When the material is handled in bulk, an electrical spark could ignite any flammable vapors from liquids or residues that may be present (e.g., during switch-loading operations). Use proper bonding and/or earthing procedures. However, bonding and earthing may not eliminate the hazard from static accumulation. Consult local applicable standards for guidance. Additional references include American Petroleum Institute 2003 (Protection Against Ignitions Arising out of Static, Lightning and Stray Currents) or National Fire Protection Agency 77 (Recommended Practice on Static Electricity) or CENELEC CLC/TR 50404 (Electrostatics - Code of practice for the avoidance of hazards due to static electricity).

Static Accumulator: This material is a static accumulator.

STORAGE

The container choice, for example storage vessel, may effect static accumulation and dissipation. Do not store in open or unlabelled containers. Keep away from incompatible materials.

SECTION 8 EXPOSURE CONTROLS / PERSONAL PROTECTION

Exposure limits/standards for materials that can be formed when handling this product: When mists / aerosols can occur, the following are recommended: 5 mg/m³ - ACGIH TLV, 10 mg/m³ - ACGIH STEL.

NOTE: Limits/standards shown for guidance only. Follow applicable regulations.

ENGINEERING CONTROLS

The level of protection and types of controls necessary will vary depending upon potential exposure conditions. Control measures to consider:

No special requirements under ordinary conditions of use and with adequate ventilation.

PERSONAL PROTECTION

Personal protective equipment selections vary based on potential exposure conditions such as applications, handling practices, concentration and ventilation. Information on the selection of protective equipment for use with this material, as provided below, is based upon intended, normal usage.

Respiratory Protection: If engineering controls do not maintain airborne contaminant concentrations at a level which is adequate to protect worker health, an approved respirator may be appropriate. Respirator selection, use, and maintenance must be in accordance with regulatory requirements, if applicable. Types of respirators to be considered for this material include:

No special requirements under ordinary conditions of use and with adequate ventilation.

For high airborne concentrations, use an approved supplied-air respirator, operated in positive pressure mode. Supplied air respirators with an escape bottle may be appropriate when oxygen levels are inadequate, gas/vapour warning properties are poor, or if air purifying filter capacity/rating may be exceeded.

Hand Protection: Any specific glove information provided is based on published literature and glove manufacturer data. Glove suitability and breakthrough time will differ depending on the specific use conditions. Contact the glove manufacturer for specific advice on glove selection and breakthrough times for your use conditions. Inspect and replace worn or damaged gloves. The types of gloves to be considered for this material include:

No protection is ordinarily required under normal conditions of use.

Eye Protection: If contact is likely, safety glasses with side shields are recommended.

Skin and Body Protection: Any specific clothing information provided is based on published literature or manufacturer data. The types of clothing to be considered for this material include:

No skin protection is ordinarily required under normal conditions of use. In accordance with good industrial hygiene practices, precautions should be taken to avoid skin contact.

Specific Hygiene Measures: Always observe good personal hygiene measures, such as washing after handling the material and before eating, drinking, and/or smoking. Routinely wash work clothing and protective equipment to remove contaminants. Discard contaminated clothing and footwear that cannot be cleaned. Practise good housekeeping.

ENVIRONMENTAL CONTROLS

See Sections 6, 7, 12, 13.

SECTION 9 PHYSICAL AND CHEMICAL PROPERTIES

Typical physical and chemical properties are given below. Consult the Supplier in Section 1 for additional data.

GENERAL INFORMATION

Physical State: Liquid
Colour: Amber
Odour: Characteristic
Odour Threshold: N/D

IMPORTANT HEALTH, SAFETY, AND ENVIRONMENTAL INFORMATION

Relative Density (at 15 C): 0.87
Flash Point [Method]: >200C (392F) [Estimated ASTM D-92]
Flammable Limits (Approximate volume % in air): LEL: 0.9 UEL: 7.0
Autoignition Temperature: N/D
Boiling Point / Range: > 316C (600F)
Vapour Density (Air = 1): > 2 at 101 kPa
Vapour Pressure: < 0.013 kPa (0.1 mm Hg) at 20°C
Evaporation Rate (n-butyl acetate = 1): N/D
pH: N/A
Log Pow (n-Octanol/Water Partition Coefficient): > 3.5
Solubility in Water: Negligible
Viscosity: 42 cSt (42 mm2/sec) at 40°C | 6.7 cSt (6.7 mm2/sec) at 100C
Oxidizing Properties: See Hazards Identification Section.

OTHER INFORMATION

Freezing Point: N/D
Melting Point: N/A
Pour Point: -33°C (-27°F)
DMSO Extract (mineral oil only), IP-346: < 3 %wt

SECTION 10 STABILITY AND REACTIVITY

STABILITY: Material is stable under normal conditions.

CONDITIONS TO AVOID: Excessive heat. High energy sources of ignition.

MATERIALS TO AVOID: Strong oxidizers

HAZARDOUS DECOMPOSITION PRODUCTS: Material does not decompose at ambient temperatures.

HAZARDOUS POLYMERIZATION: Will not occur.

SECTION 11 TOXICOLOGICAL INFORMATION

ACUTE TOXICITY

Route of Exposure	Conclusion / Remarks
Inhalation	
Toxicity (Rat): LC50 > 5000 mg/m3	Minimally Toxic. Based on test data for structurally similar materials.
Irritation: No end point data.	Negligible hazard at ambient/normal handling temperatures. Based on assessment of the components.
Ingestion	
Toxicity (Rat): LD50 > 5000 mg/kg	Minimally Toxic. Based on test data for structurally similar materials.

Skin	
Toxicity (Rabbit): LD50 > 5000 mg/kg	Minimally Toxic. Based on test data for structurally similar materials.
Irritation (Rabbit): Data available.	Negligible irritation to skin at ambient temperatures. Based on test data for structurally similar materials.
Eye	
Irritation (Rabbit): Data available.	May cause mild, short-lasting discomfort to eyes. Based on test data for structurally similar materials.

CHRONIC/OTHER EFFECTS

Contains:

Base oil severely refined: Not carcinogenic in animal studies. Representative material passes IP-346, Modified Ames test, and/or other screening tests. Dermal and inhalation studies showed minimal effects; lung non-specific infiltration of immune cells, oil deposition and minimal granuloma formation. Not sensitising in test animals.

Additional information is available by request.

CMR Status: None.

--REGULATORY LISTS SEARCHED--

1 = IARC 1	3 = IARC 2B	5 = ACGIH A1
2 = IARC 2A	4 = ACGIH ALL	6 = ACGIH A2

SECTION 12 ECOLOGICAL INFORMATION

The information given is based on data available for the material, the components of the material, and similar materials.

ECOTOXICITY

Material -- Not expected to be harmful to aquatic organisms.

MOBILITY

Base oil component -- Low solubility and floats and is expected to migrate from water to the land. Expected to partition to sediment and wastewater solids.

PERSISTENCE AND DEGRADABILITY

Biodegradation:

Base oil component -- Expected to be inherently biodegradable

BIOACCUMULATION POTENTIAL

Base oil component -- Has the potential to bioaccumulate, however metabolism or physical properties may reduce the bioconcentration or limit bioavailability.

SECTION 13 DISPOSAL CONSIDERATIONS

Disposal recommendations based on material as supplied. Disposal must be in accordance with current applicable laws and regulations, and material characteristics at time of disposal.

DISPOSAL RECOMMENDATIONS

Product is suitable for burning in an enclosed controlled burner for fuel value or disposal by supervised incineration at very high temperatures to prevent formation of undesirable combustion products.

REGULATORY DISPOSAL INFORMATION

Empty Container Warning Empty Container Warning (where applicable): Empty containers may contain residue and can be dangerous. Do not attempt to refill or clean containers without proper instructions. Empty drums should be completely drained and safely stored until appropriately reconditioned or disposed. Empty containers should be taken for recycling, recovery, or disposal through suitably qualified or licensed contractor and in accordance with governmental regulations. DO NOT PRESSURISE, CUT, WELD, BRAZE, SOLDER, DRILL, GRIND, OR EXPOSE SUCH CONTAINERS TO HEAT, FLAME, SPARKS, STATIC ELECTRICITY, OR OTHER SOURCES OF IGNITION. THEY MAY EXPLODE AND CAUSE INJURY OR DEATH.

SECTION 14 TRANSPORT INFORMATION

LAND (TDG): Not Regulated for Land Transport

LAND (DOT): Not Regulated for Land Transport

SEA (IMDG): Not Regulated for Sea Transport according to IMDG-Code

AIR (IATA): Not Regulated for Air Transport

SECTION 15 REGULATORY INFORMATION

WHMIS Classification: Not controlled

This product has been classified in accordance with hazard criteria of the Controlled Products Regulations and the (M)SDS contains all the information required by the Controlled Products Regulations.

CEPA: All components of this material are either on the Canadian Domestic Substances List (DSL), exempt, or have been notified under CEPA.

Complies with the following national/regional chemical inventory requirements: AICS, IECSC, DSL, EINECS, ENCS, KECI, PICCS, TSCA

The Following Ingredients are Cited on the Lists Below:

Chemical Name	CAS Number	List Citations
ZINC DITHIOPHOSPHATE	68649-42-3	6

--REGULATORY LISTS SEARCHED--

1 = TSCA 4 3 = TSCA 5e 5 = TSCA 12b

2 = TSCA 5a2 4 = TSCA 6 6 = NPRI

SECTION 16 OTHER INFORMATION

N/D = Not determined, N/A = Not applicable

THIS SAFETY DATA SHEET CONTAINS THE FOLLOWING REVISIONS:

Revision Changes:
Section 09: Pour Point C(F) was modified.
Section 09: Relative Density was modified.
Section 16: MSN,MAT ID was modified.
Section 15: Canadian List Citations Table was modified.
Section 01: Product Identification Product Name was modified.
Section 06: Protective Measures was added.
Section 06: Accidental Release - Protective Measures - Header was added.

WHMIS Classification: Not controlled

The information and recommendations contained herein are, to the best of Imperial Oil's knowledge and belief, accurate and reliable as of the date issued. Imperial Oil assumes no responsibility for accuracy of information unless the document is the most current available from an official Imperial Oil distribution system. The information and recommendations are offered for the user's consideration and examination, and it is the user's responsibility to satisfy itself that they are suitable and complete for its particular use. If buyer repackages this product, legal counsel should be consulted to insure proper health, safety and other necessary information is included on the container. Appropriate warnings and safe-handling procedures should be provided to handlers and users. Alteration of this document is strictly prohibited. Except to the extent required by law, republication or retransmission of this document, in whole or in part, is not permitted.

2. Hazards identification

Physical state : Liquid. [Clear.]
Odor : Sulfur [Slight]
OSHA/HCS status : This material is considered hazardous by the OSHA Hazard Communication Standard (29 CFR 1910.1200).
Emergency overview : DANGER!
This product contains material(s) that are absorbed through the skin. Toxic by inhalation, in contact with skin and if swallowed. Corrosive to the eyes, skin and respiratory system. Causes burns. Do not breathe vapor or mist. Do not ingest. Do not get in eyes or on skin or clothing. Contains material that can cause target organ damage. Contains material which may cause cancer. Risk of cancer depends on duration and level of exposure. Contains material which may cause heritable genetic effects, based on animal data. Contains material which may cause birth defects, based on animal data. Contains material which can cause developmental abnormalities. Avoid exposure during pregnancy. Contains material which can impair male fertility. Contains material which can impair female fertility. Use only with adequate ventilation. Keep container tightly closed and sealed until ready for use. Wash thoroughly after handling.

Routes of entry : Dermal contact. Eye contact. Inhalation. Ingestion.

Continued on next page

2. Hazards identification

Potential acute health effects

Inhalation : Toxic by inhalation. Can cause target organ damage. Corrosive to the respiratory system. May cause burns to mouth, throat and stomach. Exposure can cause lung irritation, chest pain and edema, which may be fatal.

Ingestion : Toxic if swallowed. Can cause target organ damage. Ingestion may cause gastrointestinal irritation and diarrhea.

Skin : Corrosive to the skin. Causes burns. Prolonged or repeated contact with skin or mucous membrane may result in irritation symptoms, such as redness, blistering, dermatitis etc. Toxic in contact with skin. This product contains material(s) that are absorbed through the skin. Can cause target organ damage. and symptoms similar to those listed under inhalation or ingestion.

Eyes : Corrosive to eyes. Causes burns. Direct contact with the eyes can cause irreversible damage, including blindness.

Potential chronic health effects

Chronic effects : Adverse symptoms may include the following:
lead(II) methanesulphonate: anemia, paralysis, muscle weakness, headache, dizziness/vertigo, constipation, insomnia, metallic taste, death.
methanesulphonic acid:

Target organs : Contains material which may cause damage to the following organs: blood, kidneys, the nervous system, the reproductive system, mucous membranes, bladder, peripheral nervous system, gastrointestinal tract, upper respiratory tract, skin, eyes, central nervous system (CNS).

Carcinogenicity : Contains material which may cause cancer. Risk of cancer depends on duration and level of exposure.

Mutagenicity : Contains material which may cause heritable genetic effects, based on animal data.

Teratogenicity : Contains material which may cause birth defects, based on animal data.

Developmental effects : Contains material which can cause developmental abnormalities.

Fertility effects : Contains material which can impair male fertility. Contains material which can impair female fertility.

California Prop. 65 : **WARNING:** This product contains a chemical known to the State of California to cause cancer and birth defects or other reproductive harm.

Medical conditions aggravated by over-exposure : Pre-existing respiratory, skin and digestive disorders and disorders involving any other target organs mentioned in this MSDS as being at risk may be aggravated by over-exposure to this product.

3. Composition/information on ingredients

Name	CAS number	% by weight
lead(II) methanesulphonate	17570-76-2	50-60
methanesulphonic acid	75-75-2	0.1-1.0

Any ingredient not listed in Section 3 is non-regulated or present in the product in concentrations below legal disclosure limits.

Continued on next page

4 . First aid measures

Eye contact : Get medical attention immediately. Chemical burns must be treated promptly by a physician. Check for and remove any contact lenses. Immediately flush eyes with running water for at least 60 minutes, keeping eyelids open. Provide a readily-accessible eyewash facility and quick-drench safety shower.

Skin contact : Get medical attention immediately. In case of contact, immediately flush skin with plenty of water for at least 60 minutes while removing contaminated clothing and shoes. Provide a readily-accessible eyewash facility and quick-drench safety shower. Chemical burns must be treated promptly by a physician. Remove contaminated clothing and shoes. This product contains material(s) that are absorbed through the skin. See inhalation and ingestion. Wear appropriate personal protective equipment. Avoid direct contact with the human body. Wash contaminated clothing before reuse. Clean shoes thoroughly before reuse.

Inhalation : Get medical attention immediately. Chemical burns must be treated promptly by a physician. Move exposed person to fresh air. If it is suspected that fumes are still present, the rescuer should wear an appropriate mask or self-contained breathing apparatus. Keep person warm and at rest. If not breathing, if breathing is irregular or if respiratory arrest occurs, provide artificial respiration or oxygen by trained personnel. It may be dangerous to the person providing aid to give mouth-to-mouth resuscitation. If unconscious, place in recovery position and get medical attention immediately. Maintain an open airway. Loosen tight clothing such as a collar, tie, belt or waistband. Move affected person to fresh air. Do not induce vomiting unless directed to do so by medical personnel. If vomiting occurs, the head should be kept low so that vomit does not enter the lungs.

Ingestion : Get medical attention immediately. Wash out mouth with water. Remove dentures if any. Move exposed person to fresh air. Keep person warm and at rest. Do not induce vomiting unless directed to do so by medical personnel. If vomiting occurs, the head should be kept low so that vomit does not enter the lungs. Never give anything by mouth to an unconscious person. If unconscious, place in recovery position and get medical attention immediately. Maintain an open airway. Loosen tight clothing such as a collar, tie, belt or waistband. If not breathing, if breathing is irregular or if respiratory arrest occurs, provide artificial respiration or oxygen by trained personnel.

Protection of first-aiders : No action shall be taken involving any personal risk or without suitable training. It may be dangerous to the person providing aid to give mouth-to-mouth resuscitation. Wear suitable protective clothing, gloves and eye/face protection. If it is suspected that fumes are still present, the rescuer should wear an appropriate mask or self-contained breathing apparatus. Wash contaminated clothing thoroughly with water before removing it, or wear gloves.

5 . Fire-fighting measures

Flammability of the product : In a fire or if heated, a pressure increase will occur and the container may burst. Reacts violently when water is added to this product.

Extinguishing media

Suitable : Use an extinguishing agent suitable for the surrounding fire.

Not suitable : None known.

Special exposure hazards : Promptly isolate the scene by removing all persons from the vicinity of the incident if there is a fire. No action shall be taken involving any personal risk or without suitable training. Fire water contaminated with this material must be contained and prevented from being discharged to any waterway, sewer or drain.

Hazardous combustion products : carbon oxides
sulfur oxides
metal oxide/oxides

Special protective equipment for fire-fighters : Fire-fighters should wear appropriate protective equipment and self-contained breathing apparatus (SCBA) with a full face-piece operated in positive pressure mode.

Continued on next page

6 . Accidental release measures

Personal precautions : No action shall be taken involving any personal risk or without suitable training. Evacuate surrounding areas. Keep unnecessary and unprotected personnel from entering. Do not touch or walk through spilled material. Do not breathe vapor or mist. Provide adequate ventilation. Wear appropriate respirator when ventilation is inadequate. Put on appropriate personal protective equipment (see section 8).

Environmental precautions : Avoid dispersal of spilled material and runoff and contact with soil, waterways, drains and sewers. Inform the relevant authorities if the product has caused environmental pollution (sewers, waterways, soil or air). Water polluting material. May be harmful to the environment if released in large quantities.

Large spill : Stop leak if without risk. Move containers from spill area. Approach release from upwind. Prevent entry into sewers, water courses, basements or confined areas. Wash spillages into an effluent treatment plant or proceed as follows. Contain and collect spillage with non-combustible, absorbent material e.g. sand, earth, vermiculite or diatomaceous earth and place in container for disposal according to local regulations (see section 13). The spilled material may be neutralized with sodium carbonate, sodium bicarbonate or sodium hydroxide. Dispose of via a licensed waste disposal contractor. Contaminated absorbent material may pose the same hazard as the spilled product. Note: see section 1 for emergency contact information and section 13 for waste disposal.

Small spill : Stop leak if without risk. Move containers from spill area. Dilute with water and mop up if water-soluble. Alternatively, or if water-insoluble, absorb with an inert dry material and place in an appropriate waste disposal container. Dispose of via a licensed waste disposal contractor.

7 . Handling and storage

Handling : Put on appropriate personal protective equipment (see section 8). Eating, drinking and smoking should be prohibited in areas where this material is handled, stored and processed. Workers should wash hands and face before eating, drinking and smoking. Avoid exposure during pregnancy. Do not get in eyes or on skin or clothing. Provide a readily-accessible eyewash facility and quick-drench safety shower. Do not breathe vapor or mist. Do not ingest. Avoid release to the environment. Use only with adequate ventilation. Wear appropriate respirator when ventilation is inadequate. Keep in the original container or an approved alternative made from a compatible material, kept tightly closed when not in use. Empty containers retain product residue and can be hazardous. Do not reuse container. Always add acids to water and basic solutions slowly and cautiously. Never add water to acids. The extreme heat generated can cause a violent reaction.

Storage : Store in accordance with local regulations. Store in original container protected from direct sunlight in a dry, cool and well-ventilated area, away from incompatible materials (see section 10) and food and drink. Separate from alkalis. Separate from oxidizing materials. Keep container tightly closed and sealed until ready for use. Containers that have been opened must be carefully resealed and kept upright to prevent leakage. Do not store in unlabeled containers. Use appropriate containment to avoid environmental contamination. Avoid contamination by any source including metals, dust and organic materials. Provide a readily-accessible eyewash facility and quick-drench safety shower.

Keep container tightly closed. Keep container in a cool, well-ventilated area.

8 . Exposure controls/personal protection

Product name	Exposure limits
lead(II) methanesulphonate	**OSHA Final Rule (United States, 1989).** TWA: 50 µg/m³ 8 hour(s). **NIOSH REL (United States, 2001).** TWA: 0.05 mg/m³ 10 hour(s). **OSHA PEL 1989 (United States, 1989).** TWA: 50 µg/m³ 8 hour(s). **ACGIH TLV (United States, 2/2010).** TWA: 0.05 mg/m³, (as Pb) 8 hour(s). **OSHA PEL 1989 (United States, 3/1989).** TWA: 50 ug/m³, (as Pb) 8 hour(s). **ACGIH TLV (United States, 5/2004). Notes: Substance identified by other sources as a suspected or confirmed human carcinogen. 1995-1996 Adoption. Substances for which the TLV is higher than the OSHA Permissible Exposure Limit (PEL) and/or the NIOSH Recommended Exposure Limit (REL). See CFR 58(124) :36338-33351, June 30, 1993, for revised OSHA PEL. See Notice of Intended changes. Identifies substances identified in the BEI documentation for Methemoglobin inducers (for which methemoglobin is the principle toxicity) and organophosphorous cholinesterase inhibitors are part of this notation.** TWA: 0.05 mg/m³ 8 hour(s). Form: All forms **OSHA PEL 1989 (United States, 3/1989). Notes: Sec. 1910.1025 Lead.** TWA: 50 µg/m³ 8 hour(s). Form: All forms

Consult local authorities for acceptable exposure limits.

Recommended monitoring procedures : If this product contains ingredients with exposure limits, personal, workplace atmosphere or biological monitoring may be required to determine the effectiveness of the ventilation or other control measures and/or the necessity to use respiratory protective equipment.

Engineering measures : Use only with adequate ventilation. Use process enclosures, local exhaust ventilation or other engineering controls to keep worker exposure to airborne contaminants below any recommended or statutory limits. Provide a readily-accessible eyewash facility and quick-drench safety shower. Processes should be designed to minimize airborne and skin exposure to hazardous substances.

Hygiene measures : Wash hands, forearms and face thoroughly after handling chemical products, before eating, smoking and using the lavatory and at the end of the working period. Appropriate techniques should be used to remove potentially contaminated clothing. Wash contaminated clothing before reusing. Ensure that eyewash stations and safety showers are close to the workstation location. Eating, drinking and smoking should be prohibited in areas where this material is handled, stored and processed. Take off immediately all contaminated clothing. Contaminated work clothing should not be allowed out of the workplace.

Personal protection

Respiratory : Use a properly fitted, air-purifying or air-fed respirator complying with NIOSH if a risk assessment indicates this is necessary. Respirator selection must be based on known or anticipated exposure levels, the hazards of the product and the safe working limits of the selected respirator. Risk assessments should be completed by a Certified Industrial Hygienst.

Hands : Chemical-resistant, impervious gloves complying with an approved standard should be worn at all times when handling chemical products if a risk assessment indicates this is necessary. The user must check that the final choice of type of glove selected for handling this product is the most appropriate and takes into account the particular conditions of use, as included in the user's risk assessment. Risk assessments should be completed by a Certified Industrial Hygienst.

Continued on next page

8 . Exposure controls/personal protection

Eyes : Avoid contact with eyes. Safety eyewear should be used when there is a likelihood of exposure. Direct contact with the eyes can cause irreversible damage, including blindness. Use safety eyewear designed to protect against splash of liquids.

Skin : Avoid contact with skin and clothing. Wear suitable protective clothing. Body garments used should be based upon the task being performed (e.g., lab coat, chemical resistant protective suit, sleevelets, synthetic apron, gauntlets) to avoid exposed skin surfaces. Wash contaminated clothing thoroughly with water before removing it, or wear gloves.

Environmental exposure controls : Emissions from ventilation or work process equipment should be checked to ensure they comply with the requirements of environmental protection legislation. In some cases, fume scrubbers, filters or engineering modifications to the process equipment will be necessary to reduce emissions to acceptable levels.

9 . Physical and chemical properties

Physical state : Liquid. [Clear.]

Flash point : Not available.

Auto-ignition temperature : Not available.

Flammable limits : Not available.

Color : Colorless.

Odor : Sulfur [Slight]

pH : <2

Boiling/condensation point : Not available.

Melting/freezing point : Not available.

Relative density : 1.7

Vapor pressure : Not available.

Vapor density : Not available.

Odor threshold : Not available.

Evaporation rate : Not available.

VOC : 0 g/l

Solubility : Easily soluble in the following materials: cold water and hot water.

10 . Stability and reactivity

Stability : The product may not be stable under certain conditions of storage or use. See "Possibility of Hazardous Reactions" for further information.

Conditions to avoid : No specific data.

Incompatibility with various substances : Reactive with oxidizing agents, alkalis.

Hazardous decomposition products : Under normal conditions of storage and use, hazardous decomposition products should not be produced.

Other Hazardous decomposition products : sulfur oxides (SO_2, SO_3 etc.), lead oxides

Hazardous polymerization : Under normal conditions of storage and use, hazardous polymerization will not occur.

Aquatic ecotoxicity

Product/ingredient name	Result	Species	Exposure
methanesulphonic acid	Acute EC50 1.7 mg/L Acute LC50 >770 mg/L	Daphnia Fish	24 hours 96 hours

13 . Disposal considerations

Waste disposal : The generation of waste should be avoided or minimized wherever possible. Empty containers or liners may retain some product residues. This material and its container must be disposed of in a safe way. Dispose of surplus and non-recyclable products via a licensed waste disposal contractor. Disposal of this product, solutions and any by-products should at all times comply with the requirements of environmental protection and waste disposal legislation and any regional local authority requirements. Avoid dispersal of spilled material and runoff and contact with soil, waterways, drains and sewers.

Disposal should be in accordance with applicable regional, national and local laws and regulations.

Refer to Section 7: HANDLING AND STORAGE and Section 8: EXPOSURE CONTROLS/PERSONAL PROTECTION for additional handling information and protection of employees.

Safety data sheet

1. Identification of the substance/mixture and of the company/undertaking

Product identifier

MAGNAFLOC® 351

Relevant identified uses of the substance or mixture and uses advised against

Relevant identified uses: flocculation agent

Details of the supplier of the safety data sheet

Company:
BASF SE
67056 Ludwigshafen
GERMANY
Global Mining Solutions

Telephone: +49 621 60-52555
E-mail address: product-safety-oilfield-applications@basf.com

Emergency telephone number

International emergency number:
Telephone: +49 180 2273-112

2. Hazards Identification

Label elements

According to Regulation (EC) No 1272/2008 [CLP]

The product does not require a hazard warning label in accordance with GHS criteria.

According to Directive 67/548/EEC or 1999/45/EC

Directive 1999/45/EC ('Preparation Directive')

The product does not require a hazard warning label in accordance with EC Directives.

Classification of the substance or mixture

According to Regulation (EC) No 1272/2008 [CLP]

No need for classification according to GHS criteria for this product.

According to Directive 67/548/EEC or 1999/45/EC

Possible Hazards:
May cause some eye irritation which should cease after removal of the product.
May cause some irritation to the respiratory system if dust is inhaled.
Prolonged contact with the product can result in skin irritation.
This type of product has a tendency to create dust if roughly handled. It does not burn readily but as with many organic powders, flammable dust clouds may be formed in air.
Very slippery when wet.

Other hazards

Assessment PBT / vPvB:
According to Annex XIII of Regulation (EC) No.1907/2006 concerning the Registration, Evaluation, Authorisation and Restriction of Chemicals (REACH): The product does not contain a substance fullfilling the PBT (persistent/bioaccumulative/toxic) criteria or the vPvB (very persistent/very bioaccumulative) criteria..

3. Composition/Information on Ingredients

Mixtures

Chemical nature

polyacrylamide

4. First-Aid Measures

Description of first aid measures

Remove contaminated clothing.

If inhaled:
If difficulties occur after dust has been inhaled, remove to fresh air and seek medical attention.

On skin contact:
Wash thoroughly with soap and water.

On contact with eyes:
Wash affected eyes for at least 15 minutes under running water with eyelids held open.

On ingestion:

Rinse mouth and then drink plenty of water. Check breathing and pulse. Place victim in the recovery position, cover and keep warm. Loosen tight clothing such as a collar, tie, belt or waistband. Seek medical attention. Never induce vomiting or give anything by mouth if the victim is unconscious or having convulsions.

Most important symptoms and effects, both acute and delayed

Symptoms: No significant symptoms are expected due to the non-classification of the product.

Indication of any immediate medical attention and special treatment needed

Treatment: Treat according to symptoms (decontamination, vital functions), no known specific antidote.

5. Fire-Fighting Measures

Extinguishing media

Suitable extinguishing media:
dry powder, foam

Unsuitable extinguishing media for safety reasons:
water jet

Additional information:
If water is used, restrict pedestrian and vehicular traffic in areas where slip hazard may exist.

Special hazards arising from the substance or mixture

carbon oxides, nitrogen oxides
The substances/groups of substances mentioned can be released in case of fire. Very slippery when wet.

Advice for fire-fighters

Special protective equipment:
Wear a self-contained breathing apparatus.

Further information:
The degree of risk is governed by the burning substance and the fire conditions. Contaminated extinguishing water must be disposed of in accordance with official regulations.

6. Accidental Release Measures

Personal precautions, protective equipment and emergency procedures

Use personal protective clothing.

Environmental precautions

Do not discharge into drains/surface waters/groundwater.

Methods and material for containment and cleaning up

For small amounts: Pick up with suitable appliance and dispose of.
For large amounts: Contain with dust binding material and dispose of.
Spilled product which becomes wet or spilled aqueous solution create a hazard because of their slippery nature. Avoid raising dust.

Reference to other sections

Information regarding exposure controls/personal protection and disposal considerations can be found in section 8 and 13.

7. Handling and Storage

Precautions for safe handling

Breathing must be protected when large quantities are decanted without local exhaust ventilation. Handle in accordance with good industrial hygiene and safety practice. Forms slippery surfaces with water.

Conditions for safe storage, including any incompatibilities

Further information on storage conditions: Store in unopened original containers in a cool and dry place. Avoid wet, damp or humid conditions, temperature extremes and ignition sources.

Storage stability:
Avoid extreme heat.

Specific end use(s)

For the relevant identified use(s) listed in Section 1 the advice mentioned in this section 7 is to be observed.

8. Exposure Controls/Personal Protection

Control parameters

Components with workplace control parameters

Particles, not otherwise specified, respirable

Particles, not otherwise specified, inhalable

Exposure controls

Personal protective equipment

Respiratory protection:
Suitable respiratory protection for lower concentrations or short-term effect: Particle filter with medium efficiency for solid and liquid particles (e.g. EN 143 or 149, Type P2 or FFP2)

Hand protection:
Chemical resistant protective gloves (EN 374)
Suitable materials also with prolonged, direct contact (Recommended: Protective index 6, corresponding > 480 minutes of permeation time according to EN 374):
e.g. nitrile rubber (0.4 mm), chloroprene rubber (0.5 mm), polyvinylchloride (0.7 mm) and other
Supplementary note: The specifications are based on tests, literature data and information of glove manufacturers or are derived from similar substances by analogy. Due to many conditions (e.g. temperature) it must be considered, that the practical usage of a chemical-protective glove in practice may be much shorter than the permeation time determined through testing.
Manufacturer's directions for use should be observed because of great diversity of types.

Eye protection:
Safety glasses with side-shields (frame goggles) (e.g. EN 166)

Body protection:
light protective clothing

General safety and hygiene measures
Handle in accordance with good industrial hygiene and safety practice. Ensure adequate ventilation.
Wearing of closed work clothing is recommended.

9. Physical and Chemical Properties

Information on basic physical and chemical properties

Form:	powder
Colour:	off-white
Odour:	odourless
Melting point:	
	The substance / product decomposes therefore not determined.
Flash point:	
	not applicable
Ignition temperature:	350 °C
Solubility in water:	Forms a viscous solution.
Explosion hazard:	not explosive
Fire promoting properties:	not fire-propagating

Other information

Bulk density: approx. 800 kg/m3

10. Stability and Reactivity

Reactivity
No hazardous reactions if stored and handled as prescribed/indicated.

Corrosion to metals: No corrosive effect on metal.

Chemical stability

The product is stable if stored and handled as prescribed/indicated.

Peroxides: 0 %
The product does not contain peroxides.

Possibility of hazardous reactions
The product is not a dust explosion risk as supplied; however the build-up of fine dust can lead to a risk of dust explosions.

Conditions to avoid
Avoid extreme temperatures. Avoid humidity.

Incompatible materials

Substances to avoid:
strong acids, strong bases, strong oxidizing agents

Hazardous decomposition products

No hazardous decomposition products if stored and handled as prescribed/indicated.

11. Toxicological Information

Information on toxicological effects

Acute toxicity

Experimental/calculated data:
LD50 rat (oral): > 2,000 mg/kg (OECD Guideline 401)

Irritation

Experimental/calculated data:
Skin corrosion/irritation rabbit: non-irritant (OECD Guideline 404)

Serious eye damage/irritation rabbit: non-irritant

Respiratory/Skin sensitization

Experimental/calculated data:
Non-sensitizing.

Other relevant toxicity information

The product has not been tested. The statements on toxicology have been derived from products of a similar structure and composition.

12. Ecological Information

Toxicity

Toxicity to fish:
LC50 (96 h) > 100 mg/l, Oncorhynchus mykiss (static)
(under static conditions in the presence of 10 mg/L humic acid)

Aquatic invertebrates:
LC50 (48 h) > 100 mg/l, Arcatia tonsa

Persistence and degradability

Information on: Polyacrylamide
Elimination information:
Not readily biodegradable (by OECD criteria).

Bioaccumulative potential

Assessment bioaccumulation potential:
Based on its structural properties, the polymer is not biologically available. Accumulation in organisms is not to be expected.

Mobility in soil (and other compartments if available)

Information on: Polyacrylamide
Assessment transport between environmental compartments:
Adsorption to solid soil phase is expected.

Results of PBT and vPvB assessment

According to Annex XIII of Regulation (EC) No.1907/2006 concerning the Registration, Evaluation, Authorisation and Restriction of Chemicals (REACH): The product does not contain a substance fullfilling the PBT (persistent/bioaccumulative/toxic) criteria or the vPvB (very persistent/very bioaccumulative) criteria..

Additional information

Other ecotoxicological advice:
The product has not been tested. The statements on ecotoxicology have been derived from products of a similar structure and composition.

13. Disposal Considerations

Waste treatment methods

Dispose of in accordance with national, state and local regulations.

Contaminated packaging:
Packs that cannot be cleaned should be disposed of in the same manner as the contents.
Uncontaminated packaging can be re-used.

14. Transport Information

Land transport

ADR

Not classified as a dangerous good under transport regulations

RID

Not classified as a dangerous good under transport regulations

Inland waterway transport
ADN

Not classified as a dangerous good under transport regulations

Sea transport
IMDG

Not classified as a dangerous good under transport regulations

Air transport
IATA/ICAO

Not classified as a dangerous good under transport regulations

15. Regulatory Information

Safety, health and environmental regulations/legislation specific for the substance or mixture

If other regulatory information applies that is not already provided elsewhere in this safety data sheet, then it is described in this subsection.

Chemical Safety Assessment

Chemical Safety Assessment not yet performed due to registration timelines

16. Other Information

Due to the merger of CIBA and BASF Group all Material Safety Data Sheets have been reassessed on the basis of consolidated information. This may have resulted in changes of the Material Safety Data Sheets. In case you have questions concerning such changes please contact us at the address mentioned in Section I.

Vertical lines in the left hand margin indicate an amendment from the previous version.

The data contained in this safety data sheet are based on our current knowledge and experience and describe the product only with regard to safety requirements. The data do not describe the product's properties (product specification). Neither should any agreed property nor the suitability of the product for any specific purpose be deduced from the data contained in the safety data sheet. It is the responsibility of the recipient of the product to ensure any proprietary rights and existing laws and legislation are observed.

Material Safety Data Sheet

Zinc

1 . Product and company identification

Common name : Zinc

Code : 3025/26

Product type : Pure Metal

Synonym : Zinc Anode ; Zinc (SHG Zinc) ; Zinc Ball round; Zinc ball, Flat Top

Trade name : Zinc

Material uses : Alloying. casting

Validation date : **1/11/2013.**

Contacts : In Canada:
AIM
9100 Henri Bourassa East
Montreal, QC
H1E 2S4
(514) 494-2000

In the United States:

International: (352) 323-3500

In case of emergency : INFOTRAC
North America: (800) 535-5053
International: (352) 323-3500

2 . Hazards identification

Physical state : Solid.

OSHA/HCS status : This material is considered hazardous by the OSHA Hazard Communication Standard (29 CFR 1910.1200).

Emergency overview : WARNING!

CAUSES RESPIRATORY TRACT, EYE AND SKIN IRRITATION. CAN CAUSE TARGET ORGAN DAMAGE.

Avoid contact with skin and clothing. Avoid breathing dust. Keep container closed. Use only with adequate ventilation. Wash thoroughly after handling. Do not ingest.

Routes of entry : Inhalation.

Potential acute health effects

Eyes : Irritating to eyes.

Skin : Irritating to skin.

Inhalation : Irritating to respiratory system.

Ingestion : No known significant effects or critical hazards.

Medical conditions aggravated by over-exposure : Pre-existing disorders involving any target organs mentioned in this MSDS as being at risk may be aggravated by over-exposure to this product.

See toxicological information (section 11)

3 . Composition/information on ingredients

Name	CAS number	%
Zinc	7440-66-6	100

4 . First aid measures

Eye contact : Check for and remove any contact lenses. Immediately flush eyes with plenty of water for at least 15 minutes, occasionally lifting the upper and lower eyelids. Get medical attention immediately.

Skin contact : In case of contact, immediately flush skin with plenty of water for at least 15 minutes while removing contaminated clothing and shoes. Wash clothing before reuse. Clean shoes thoroughly before reuse. Get medical attention immediately.

Inhalation : Move exposed person to fresh air. If not breathing, if breathing is irregular or if respiratory arrest occurs, provide artificial respiration or oxygen by trained personnel. Loosen tight clothing such as a collar, tie, belt or waistband. Get medical attention immediately.

Ingestion : Wash out mouth with water. Do not induce vomiting unless directed to do so by medical personnel. Never give anything by mouth to an unconscious person. Get medical attention immediately.

Protection of first-aiders : No action shall be taken involving any personal risk or without suitable training. If it is suspected that fumes are still present, the rescuer should wear an appropriate mask or self-contained breathing apparatus. It may be dangerous to the person providing aid to give mouth-to-mouth resuscitation.

5 . Fire-fighting measures

Flammability of the product : May be combustible at high temperature.

Products of combustion : Decomposition products may include the following materials:
metal oxide/oxides

Extinguishing media

Suitable : Use an extinguishing agent suitable for the surrounding fire.

Not suitable : None known.

Special exposure hazards : Promptly isolate the scene by removing all persons from the vicinity of the incident if there is a fire. No action shall be taken involving any personal risk or without suitable training.

No specific fire or explosion hazard.

Special protective equipment for fire-fighters : Fire-fighters should wear appropriate protective equipment and self-contained breathing apparatus (SCBA) with a full face-piece operated in positive pressure mode.

Special remarks on fire hazards : Massive metal is nonflammable. Dust and powders may be flammable.

Special remarks on explosion hazards : Dust and powders may form an explosive mixture with air.

6 . Accidental release measures

Personal precautions : No action shall be taken involving any personal risk or without suitable training. Evacuate surrounding areas. Keep unnecessary and unprotected personnel from entering. Do not touch or walk through spilled material. Provide adequate ventilation. Wear appropriate respirator when ventilation is inadequate. Put on appropriate personal protective equipment (see Section 8).

Environmental precautions : Avoid dispersal of spilled material and runoff and contact with soil, waterways, drains and sewers. Inform the relevant authorities if the product has caused environmental pollution (sewers, waterways, soil or air).

Methods for cleaning up : Move containers from spill area. Approach release from upwind. Prevent entry into sewers, water courses, basements or confined areas. Vacuum or sweep up material and place in a designated, labeled waste container. Dispose of via a licensed waste disposal contractor. Note: see section 1 for emergency contact information and section 13 for waste disposal.

7 . Handling and storage

Handling : Avoid contact with eyes, skin and clothing. Keep container closed. Use only with adequate ventilation. Avoid breathing dust. Wash thoroughly after handling. Do not ingest.

Storage : Store in accordance with local regulations. Store in original container protected from direct sunlight in a dry, cool and well-ventilated area, away from incompatible materials (see section 10) and food and drink. Keep container tightly closed and sealed until ready for use. Containers that have been opened must be carefully resealed and kept upright to prevent leakage. Do not store in unlabeled containers. Use appropriate containment to avoid environmental contamination.

8 . Exposure controls/personal protection

Consult local authorities for acceptable exposure limits.

Engineering measures : Use only with adequate ventilation. If user operations generate dust, fumes, gas, vapor or mist, use process enclosures, local exhaust ventilation or other engineering controls to keep worker exposure to airborne contaminants below any recommended or statutory limits.

Personal protection

Eyes : Safety eyewear complying with an approved standard should be used when a risk assessment indicates this is necessary to avoid exposure to liquid splashes, mists or dusts.

Skin : Personal protective equipment for the body should be selected based on the task being performed and the risks involved and should be approved by a specialist before handling this product.

Respiratory : Use a properly fitted, air-purifying or air-fed respirator complying with an approved standard if a risk assessment indicates this is necessary. Respirator selection must be based on known or anticipated exposure levels, the hazards of the product and the safe working limits of the selected respirator.

Hands : Chemical-resistant, impervious gloves complying with an approved standard should be worn at all times when handling chemical products if a risk assessment indicates this is necessary.

Hygiene measures : Wash hands, forearms and face thoroughly after handling chemical products, before eating, smoking and using the lavatory and at the end of the working period. Appropriate techniques should be used to remove potentially contaminated clothing. Wash contaminated clothing before reusing. Ensure that eyewash stations and safety showers are close to the workstation location.

9 . Physical and chemical properties

Physical state : Solid.

Molecular formula : Zn

Dispersibility properties : Not dispersible in the following materials: cold water and hot water.

Solubility : Insoluble in the following materials: cold water and hot water.

10 . Stability and reactivity

Stability and reactivity : The product is stable.

Conditions of instability : Stable in normal conditions. Over melting point, will emit toxic metallic oxides.

Incompatibility with various substances : Highly reactive or incompatible with the following materials: acids and alkalis. Incompatibilities : ACIDS, STRONG BASES, CHLORINE, BROMINE. Acids, Ammonium nitrate, Barium dioxide, Barium nitrate, Bromine pentafluoride, Bromine trifluoride, Cadmium, Carbon disulfide, Chlorates, Chlorine, Chlorine trifluoride, Chromic anhydride, Ethyl acetoacetate and Tribromoneopentyl alcohol, Fluorine, Hydrazine mononitrate, Hydroxylamine, Lead azide; Magnesium, Barium nitrate and Barium dioxide; Magnesium chloride, Nitric acid, Performic acid, Potassium chlorate, Potassium nitrate, Potassium peroxide, Selenium, Sodium chlorate, Sodium peroxide, Sulfur, Tellurium, Water, Zinc peroxide--NFPA 491M Reactions with other materials : Reactions with common materials : No data

10 . Stability and reactivity

Hazardous decomposition products : Under normal conditions of storage and use, hazardous decomposition products should not be produced.

Hazardous polymerization : Will not occur.

Conditions of reactivity : Non-flammable in the presence of the following materials or conditions: open flames, sparks and static discharge, heat, shocks and mechanical impacts and oxidizing materials.
Massive metal is nonflammable. Dust and powders may be flammable.

Slightly explosive in the presence of the following materials or conditions: open flames, sparks and static discharge.
Dust and powders may form an explosive mixture with air.

11 . Toxicological information

Chronic effects on humans : **CARCINOGENIC EFFECTS**: Classified A5 (Not suspected for humans.) by ACGIH, 4 (Probably not for humans.) by IARC, None. by NIOSH.
Causes damage to the following organs: skin.

Other toxic effects on humans : This product may cause serious illness in case of inhalation.
Fumes and/or dusts produced by this product may be hazardous in case of ingestion.
This product may be hazardous in case of skin contact (irritant, sensitizer), of eye contact (irritant).

Special remarks on toxicity to animals : No additional remark.

Special remarks on chronic effects on humans : Repeated and prolonged contact may cause skin irritation or dermatitis.
Massive metal is not harmful. Overexposure to fumes may cause irritation to the respiratory tract, digestive system and to the eyes.

Special remarks on other toxic effects on humans : Prolonged and repeated contact may cause skin irritation or dermatitis. MOLTEN METAL can cause severe BURNS! Fumes may irritate eyes, digestive system and respiratory tract.

Specific effects

Carcinogenic effects : No known significant effects or critical hazards.

Mutagenic effects : No known significant effects or critical hazards.

Teratogenicity / Reproductive toxicity : No known significant effects or critical hazards.

Sensitization

Ingestion : No known significant effects or critical hazards.

Inhalation : Irritating to respiratory system.

Eyes : Irritating to eyes.

Skin : Irritating to skin.

12 . Ecological information

Environmental precautions : No known significant effects or critical hazards.

Toxicity of the products of biodegradation : The products of degradation are more toxic than the product itself.

13 . Disposal considerations

Waste disposal : The generation of waste should be avoided or minimized wherever possible. Empty containers or liners may retain some product residues. This material and its container must be disposed of in a safe way. Dispose of surplus and non-recyclable products via a licensed waste disposal contractor. Disposal of this product, solutions and any by-products should at all times comply with the requirements of environmental protection and waste disposal legislation and any regional local authority requirements. Avoid dispersal of spilled material and runoff and contact with soil, waterways, drains and sewers.

13 . Disposal considerations

Disposal should be in accordance with applicable regional, national and local laws and regulations. Local regulations may be more stringent than regional or national requirements.

The information presented below only applies to the material as supplied. The identification based on characteristic(s) or listing may not apply if the material has been used or otherwise contaminated. It is the responsibility of the waste generator to determine the toxicity and physical properties of the material generated to determine the proper waste identification and disposal methods in compliance with applicable regulations.

Refer to Section 7: HANDLING AND STORAGE and Section 8: EXPOSURE CONTROLS/PERSONAL PROTECTION for additional handling information and protection of employees.

14 . Transport information

Regulatory information	UN number	Proper shipping name	Class	PG*	Label	Additional information

Notice to reader

To the best of our knowledge, the information contained herein is accurate. However, neither the above-named supplier, nor any of its subsidiaries, assumes any liability whatsoever for the accuracy or completeness of the information contained herein.
Final determination of suitability of any material is the sole responsibility of the user. All materials may present unknown hazards and should be used with caution. Although certain hazards are described herein, we cannot guarantee that these are the only hazards that exist.

Appendix I – FMC Inventory of Spill Response Materials and Supplies

SPILL RESPONSE MATERIALS AND SUPPLIES

FARO MINE COMPLEX

Ware house Inventory:

1. Spill Kit For Aggressive Fluids
   - 3 disposable hazardous material bags
   - 3 pairs of goggles
   - 2 pairs of silver shield plastic disposable gloves
   - 3 pairs of disposable coveralls
   - 5 yellow absorbent pads
   - Four 4' sock absorbent lengths

2. Chemical Spill Kit
   - 2 disposable bags
   - 1 pair of rubber gloves
   - 4 absorbent socks 12' length
   - 6 absorbent pads
   - 1 pair of goggles
   - 1 spill response hand book

3. Universal Spill Kit
   - 5 disposable bags
   - Ten 4' absorbent
   - 50 absorbent sheets
   - 4 absorbent pads
   - Seven 12' absorbent socks

4. 2 packs of 200 universal/haz-mat absorbent sheets 17"x19"
5. 2 roles of SBS2-9 32x150'x3/8 yellow absorbent material
6. 1 role of 2' absorbent barrier 100'
7. 200 absorbent pads for oil spillage
8. Two 1.8"diameter 12' absorbent socks

Diesel fuel station:

1. Universal Spill Kit
   - 5 disposable bags+ ties
   - Ten 4' absorbent socks
   - 50 absorbent sheets
   - 4 absorbent pads
   - Seven 12' absorbent socks

Gas fuel station:

1. Universal Spill Kit
   - 8 absorbent pads
   - Four 12' socks
   - 50 absorbent sheets
   - 1 emergency response handbook
   - 1 pair of rubber gloves and goggles

Faro Guardhouse Lab:

1. Chemical Spill Kit #1
   - treats up to 1 ltr
   - 4 ltr of chemical (absorbent)
   - 1 pair of chemical gloves
   - 1 pair of chemical apron
   - 1 pair of chemical booties
   - 1 pair of chemical pants
2. Chemical Spill Kit #2
   - treats up to 8 ltr of acid and base (absorbent)
   - 14 ltr of base neutralizer absorbent
   - 14 ltr of acid neutralizer absorbent
   - 2 sets of glasses
   - 1 sponge
   - 2 pairs of gloves
   - 1 scupper
   - 1 spill bag
   - 1 spill response book

Appendix J – FMC Emergency Contact List

Emergency Contact List

For the purposes of emergency response on site, all external notification/requests for assistance will be coordinated through Faro Security.

External Resources and Emergency Response Agencies within the Yukon

AIR POLLUTION EMERGENCY
Lead Agency– Faro EMO 994-2728 including EPB (667-5683)

Support Agency(ies):
- Yukon EMO [(667-5220)] including EHS (667-8355) [633-6202]
- MHO (667-5716) [333-3168 or 668-4191]
- EnvHS (667-8391) [668-3204]

Because of the wide-ranging health and safety issues, the local and Yukon EMO would coordinate the response and support Public Health and Environmental Health monitoring programs.

BOMB THREATS
Lead Agency–RCMP [(911)] in Faro 994- 5555

Support Agency(ies):
- Fire Department
- EMS
- Faro EMO 994-2728
- Yukon EMO [(667-5220)

CHEMICAL, BIOLOGICAL, RADIOACTIVE, NUCLEAR EVENT (CBRN)
Lead Agency–RCMP [(911)] in Faro 994-5555

Support Agency(ies):
- Fire Department
- EMS
- Faro EMO 994-2728
- Yukon EMO [(667-5220)]

Various response teams may be deployed to respond support the specifics of the incident, i.e. CBRN identification, HAZMAT, ERAP, etc.

DAM FAILURES
Lead Agency– YEC (393-5300) [393-5355]

Support Agency(ies):
- Faro EMO 994-2728
- Yukon EMO [(667-5220)]
- PSEPC[(250-363-3621)] [(867-445-7737)]

Threatened communities would activate their EMO as well as the Yukon's EMO and attempt to mitigate impacts. Emergency power supply may be one of many short-term requirements.

EARTHQUAKES
Lead Agency– Faro EMO 994-2728

Support Agency(ies):
- Yukon EMO [(667-5220)]
- PSEPC [(250-363-3621)] [(867-445-7737)]

Local and Yukon EMOs would be activated in keeping with the scale of the emergency. Support may be coordinated with other provinces, territories, states and PSEPC.

ENERGY SHORTFALL
Lead Agency– Yukon EMO [(667-5220)] Upon Declaration of Emergency

Support Agency(ies):
- Natural Resources Canada (667-3957) [633-4910]
- Energy, Mines, & Resources (667-3130)
- ESS (667-5688) [668-1040]

Fuel shortages may require fuel rationing and the requirement to establish allocation priorities. ESS would be anticipated to look after potential evacuees.

EVACUATION
Lead Agency–Faro EMO 994- 2728

Support Agency(ies):
- RCMP 994-5555
- ESS (667-5688) [668-1040]
- EHS (667-8355) [633-6202]
- Yukon EMO [(667-5220)]

The Municipalities of the Yukon are responsible for implementing their own emergency plans during an event. Where the emergency is large and overwhelming, the municipalities can request assistance from Yukon EMO.

FLOODS on FEDERAL LANDS
Lead Agency– PSEPC[(250-363-3621)] [(867-445-7737)] or Yukon First Nation (393-9200)

Support Agency(ies):
- Faro EMO 994-2728
- Yukon EMO [(667-5220)]
- Transportation Engineering (Highways & Public Works) (667-8820) [668-7816]

FIRES

URBAN
Lead Agency–Faro Fire Dept. 994- 2222

Support Agency(ies):
- Adjacent Fire Departments
- Faro EMO 994-2728
- Fire Marshal's Office (667-5217) [633-3161 or 333-3941]

WILDLAND
Lead Agency–Wildland Fire Management, Protective Services, YG Fire Reporting Line [(1-888-798-3473)]

Support Agency(ies):
- Faro Fire Dept. 994-2222
- Yukon EMO [(667-5220)]
- RCMP 994-5555

HIGHWAY CLOSURES & INFORMATION
Lead Agency– Highways & Public Works (667-3710) [334-3794]

Support Agency(ies):
- RCMP 994-5555
- Faro EMO 994- 2728
- Yukon EMO [(667-5220)]

If Highways and Public Works are not available, the RCMP is authorized to close Yukon highways when conditions are unsafe and normally do so in off-hour periods. Conditions that may close Yukon highways are (but not limited to) floods, forest fires, weather conditions, landslides, etc.
Highway Information: Yukon 24/7 Recording 456-7623 or toll free 877-456-7723

HUMAN EPIDEMIC
Lead Agency–MHO (667-5716) [333-3168 or 668-4191] YCDC (667-8323)

Support Agency(ies):
- ESS (667-5688) [668-1040]
- EHS (667-8355) [633-6202] Yukon EMO [(667-5220)]

Local and Yukon EMO may be activated to support emergency operations, logistics, asset deployment, communications, emergency personnel recruitment/services.

ICE JAMS
Lead Agency– PSEPC[(250-363-3621)] [(867-445-7737)]

Support Agency(ies):
- Faro EMO 994- 2728
- Yukon EMO [(667-5220)]

LANDSLIDES (including Avalanches)
The location of the landslide may determine whether Highways, Municipal Engineering, Municipalities, First Nations or the private sector takes a lead role. The EMO may assist where the impacts are overwhelming.
Lead Agency–Various

Support Agency(ies):
- RCMP 994-5555
- Faro EMO 994-2728

MASS CASUALTY INCIDENT
Lead Agency–Faro EMS 994-4444

Support Agency(ies):
- RCMP [(911)] in Faro 994-5555
- Faro EMO Faro 994-2728
- Yukon EMO [(667-5220)]

Incidents involving multiple casualties may require the activation of Emergency Health Services emergency plans. National Emergency Stockpile System (NESS) items may be deployed (i.e. the mobile hospital, casualty collection units and emergency feeding unit) with authorization from ESS or EHS Director. Support agencies may be called upon to assist in casualty collection, perimeter security, communications support or transportation services.

MINE DISASTER
Lead Agency–Mine Company/WCH&SB–Mine Rescue [(667-5450)]

Support Agency(ies):
- Faro EMS 994-4444
- Faro EMO 994-2728

Specialty rescue services are required in certain mine disasters. The mining company, in compliance with Mine Rescue experts from WCHSB, develops specialized rescue capabilities. Local response agencies would support rescue efforts. Emergency Medical Services may be fully engaged in the event of mass casualties (see Mass Casualty Incident).

PANDEMIC
Lead Agency–PHAC – will notify provincial or territorial MHO of the presence of disease MHO (667-5716) [333-3168 or 668-4191]

Support Agency(ies):
- EHS (667-8355) [633-6202]
- ESS (667-5688) [668-1040]

Local and Yukon EMO(s) would also be activated to support Emergency Operations, logistics, asset deployment, communications, emergency personnel recruitment/services, etc.

POWER OUTAGE
Lead Agency– For Faro - Yukon Energy Corp. 393-5324 or 393-5355

Support Agency(ies):
- Faro EMO 994- 2728
- Yukon EMO [(667-5220)]

Restoration of power is the responsibility of the Utility. Should a power outage affect a community, the local EMO may be able to cope with local resources. Should additional assistance be required, a request would be made to Yukon EMO.

SEARCH AND RESCUE

GROUND & INLAND WATER

Non Park Land
Lead Agency–RCMP 994-5555

Support Agency(ies)
- Faro SAR Team – Bill Wood Team Leader 994- 2425

Body Recovery
Lead Agency–Coroner [(667-5317)]

Support Agency(ies)
- RCMP 994-994-5555
- Faro SAR Team – Bill Wood Team Leader 994-2425

URBAN (Heavy Rescue) – Collapsed structures
Lead Agency–Faro Fire Dept 994-2222

Support Agency(ies):
- Faro EMS 994-4444
- WCHSB–Mine Rescue [(667-5450)]
- Faro EMO Faro 994-2728
- Yukon EMO [(667-5220)]

SPILLS–DANGEROUS GOODS INCIDENTS

ALL SPILLS IN THE YUKON ARE TO BE REPORTED TO THE 24 Hr. NUMBER 867- 667-7244.
Lead Agency–Spills Line [(667-7244)]

Support Agency(ies):

- Various – Lead Agency to contact support agency(ies) as required.

Lead agencies have been designated pursuant to a "Letter of Understanding for Government Response to Spills in the Yukon Territory".

TERRORIST ATTACK
Lead Agency–RCMP (ERT) or National Joint Forces Team (JFT)

Support Agency(ies):

- Faro EMO Faro 994-2728
- Yukon EMO [(667-5220)]

1 INTRODUCTION

This document, the Faro Mine Complex (FMC) Emergency Management Response Plan is written to clearly define what action is required in the event specific high risks actually happen.

1.1 PURPOSE

The aim of this document is to provide the Faro Mine Management with detailed guidance on how to respond to various emergency situations that could occur during normal operations. That is:

- What type of incident could occur;
- What general type of emergency response is required; and
- Any special response requirements.

The information contained in this document has been prepared to act as a guide only and may require some additional responses, depending on the circumstances of the individual emergency situation.

1.2 SCOPE

The FMC Emergency Management Response Plan applies to all TEES team members, sub-contractor team members and all other site visitors.

1.3 IMPLEMENTATION

1.3.1 Who Has Responsibilities - Training Required

The ***Mine Site Manager*** is responsible for the effectiveness of emergency response within the area of responsibility. This includes responsibility for ensuring Emergency Plans and Procedures are periodically tested and reviews conducted to ensure they remain effective.

The ***Mine Site Manager*** is also likely to act as the ***Incident Commander*** (i.e. leader of the Incident Command Team) should a local emergency occur within their area of responsibility. This person will be required to have an understanding of the various responses that may be used to help manage an emergency situation.

Supervisors are responsible for ensuring the development and implementation of the local Area Emergency Plans as appropriate that will utilize response information contained in this document

The **Mine Manager/** ***Health and Safety Coordinator*** is responsible to ensure the Emergency Management System is maintained, including this Plan and associated Procedures. This includes communicating any changes to relevant Managers as soon as practicable and ensuring the training of any team members in effective emergency response.

Team Members assigned particular roles or tasks under the FMC Management Response Plan (e.g. emergency procedures) are responsible for carrying out those roles or tasks to the best of their ability and training.

1.3.2 Who Else Should Know - Awareness Required

This information is important to the safety of everyone associated with the FMC and is to be used by all team leaders. This information must be communicated to any new team leaders through formal induction or instruction so the various requirements are understood and acknowledged.

2 DEFINITIONS

DM&R – Disaster Management & Recovery; This is a process whereby a disaster is managed at a level appropriate for the disaster. This process generally involves the senior management team of the organisation who manage the organisation throughout the period while the organisation is directly and immediately affected by the disaster and then follows through the recovery process to restore normal operations.

Emergency Response; This is the processes applied by a team of people to treat an emergency on a local scale. This generally involves the ERT, or emergency response team.

2.1 GLOSSARY OF ACRONYMS

[ ] Denotes "after hours" contact number(s)

EHS	Emergency Health Services (Health & Social Services)
EnvHS	Environmental Health Services
EMO	Emergency Measures Organization
EMS	Emergency Medical Services
ERT	Emergency Response Team – RCMP
ESS	Emergency Social Services (Health & Social Services)
MHO	Medical Health Officer (Health & Social Services)
PHAC	Public Health Agency of Canada
PSEPC	Public Safety & Emergency Preparedness Canada
SAR	Search and Rescue
WCHSB	Workers Compensation Health and Safety Board
YG AAM	Yukon Government Assessment and Abandoned Mines

3 DETAILS

3.1 APPLICABLE LEGISLATION & STANDARDS

This document has been developed to help ensure compliance with the Occupational Health and Safety Regulations, November 1, 2006 as shown on the Yukon Workers' Health and Safety Board website (www.wcb.yk.ca). This plan has been developed with consideration of:

- identified hazards that might cause an emergency;
- assessment of the risks of an emergency occurring; and
- the means for dealing with such emergencies.

This plan also considers the means for managing and controlling an emergency situation including the provision of training, equipment, facilities, team members and procedures.

3.2 POTENTIAL EMERGENCY INCIDENTS

3.2.1 Emergency Risk Analysis

A high level analysis to determine the types of probable incidents that could occur at FMC has been undertaken. This included:

- A review of FMC risk assessments to identify potential emergency response requirements; and
- A review of similar operations risk assessments and emergency response plans.

This analysis identified incidents with high risk. Each of these were then reviewed to determine the type of response required. The specific responses to these incidents form the basis of the FMC Management Response Plan.

This Chart shows the following information:

a. Potential incidents identified from the above analysis;
b. Types of impacts that could be detrimental to the FMC and TEES, including:
    - assets (A)
    - profit (P)
    - team member safety and health (SH)
    - environment (En)
    - other people e.g. community, family/ friends of team members (OP)
    - company image, reputation, public perception etc. (CI)

The risk assessment considered the types of impact however the risk rating is based on health and safety risk only at this time.

3.2.1.1 Risk Rating Tables

POTENTIAL CONSEQUENCE OF THE INCIDENT				PROBABILITY OF THIS OCCURRING AGAIN					RISK ASSESSMENT SCORE	
4	3	2	1	A	B	C	D	E		
1 – Could kill, permanently disable or cause very serious damage **2 –** Could cause serious injury (major LTI) or major damage **3 –** Could cause typical MTC / LTI or moderate damage **4 –** Could cause First Aid injury or minor damage **5 –** Couldn't cause injury or damage				**A** = ALMOST CERTAIN TO HAPPEN **B** = LIKELY to happen at some point **C** = MODERATE, possible, it might happen **D** = UNLIKELY, not likely to happen **E** = RARE, practically impossible					**Low** **16-25**	**Work your plan**
									Moderate **11-15**	**Re-evaluate the control measures in order to reduce the overall risk.**
									High **4-10**	**Re-evaluate the control measures with the Supervisor. Determine lower risk options.**
									Critical **1-3**	**Job shut down for re-evaluation with Superintendent and the job team.**

Consequence	Probability A	B	C	D	E	Risk Assessment Category
1	1	2	4	7	11	Critical
2	3	5	8	12	16	High
3	6	9	13	17	20	Moderate
4	10	14	18	21	23	Low
5	15	19	22	24	25	

FMC Probable Emergency Incidents Chart

Figure 1 – Potential Incident, Impacts & Risk (Page 1 of 3)

POTENTIAL INCIDENT	Main Impacts	Likelihood*	Consequence*	Level Of Risk	Risk Rank	COMMENTS
Section 3.5 Natural Disasters						
3.5.1 Major Earthquake/Seismic Event	A, SH, En, OP	E	1	M	11

3.6.4 Light Vehicle Accident/ Incident	SH	Unlikely (D)	Catastrophic (5)	Extreme	7	Liquid spill (fuel etc.)
3.6.5 Heavy Vehicle Accident/ Incident	CI, SH, En	Unlikely (D)	Catastrophic (5)	Extreme	7	Liquid spill (fuel, hydraulic oil)

Figure 1 – Potential Incident, Impacts & Risk (Page 2 of 3)

Section 3.7 On-site Surface continued						
3.6.6 Hazardous Substance Release	P, SH, En, Cl	D	1	H	7	E.g. chemical, diesel fuel
3.6.7 Water Treatment Plant Failure	P, CI, SH, OP	D	1	H	7	E.g. pumping systems, clarifier
3.6.8 Fire/ Explosion	A, SH, En, OP, Cl	D	1	M	7	Site Wide Damage
3.6.9 Building Collapse	A, P, SH, En	E	1	M	11	WTP, Shop
3.6.10 Working at Height Accident/ Incident	SH, OP	D	2	M	12	
3.6.11 Confined Space Accident/ Incident	SH	D	2	M	12	
3.6.12 Malicious Damage (Arson etc)	A, P, SH, En	D	2	M	12	
3.6.13 Bomb Threat	SH	D	4	L	21	Threat only (no explosion)
3.6.14 Armed hold up/ Hostage situation	SH, CI	E	1	M	11	

3.3 DISASTER MANAGEMENT RESPONSE PLAN

This Disaster Management Response Plan describes the detailed Emergency Management response to the potential critical incidents identified in Section 3.0. Each of these detailed responses includes the following information:

- The main “threats” associated with the incident
- How the incident may be notified (aside from emergency telephone/ radio call)
- Alarms or methods to alert persons of an emergency
- The management response required (i.e. who should be notified, what action should be taken)
- Any special instructions
- Possible contacts for specialist advice

The detailed response to each potential incident is described in Sections 3.6 and 3.7 below.

These should be used as a guide only and are not “all inclusive”. That is, there may be additional response steps or the steps may be in a different order of execution, depending on the circumstances of the individual emergency situation.

3.5 NATURAL DISASTERS

3.5.1 Major Seismic Event/Earthquake

A major earthquake or seismic event may cause damage to mine infrastructure and result in a significant disruption to operations or injury to team member(s)

Main Threats:	• Collapse of mine infrastructure (e.g. Dike Failure, underground workings, pit walls, mine access ways, surface buildings or structures &, rock dump slide) • Loss of access to open pit (loss of ramps, portal etc) • Release of contaminated water and tailings into the environment • Induces major fire/explosion (e.g. fuel storage) • Disruption to security/communications • Injury to team member(s)
Likely Alarms:	• Earthquake likely to trigger security/ other site alarms
Response:	• Initiate affected area(s) Evacuation Alarms Code 1 • Assess likely impact • Call-out Emergency Response Team • Secure access to all areas using Emergency Response Team and other people as required • Initiate appropriate emergency response (e.g. first-aid, fire, persons trapped, explosion etc) • Notify Faro Community Health Centre of possible need for assistance (if several casualties) • Notify Faro EMO • Notify Mine Site Manager • Mine Manager will immediately report any injuries/ major damage to authorities: YG - AAM, WCHSB • Mine Site Manager to initiate Chain of Command, if required • Advise other areas on site as required • Advise adjacent operations, if required • Conduct damage assessment of affected area or entire site using competent team members. • Notify site employees and contractors of proposed actions as required • Maintain security of affected area until Mine Site Manager calls for a stand down
External Help	• WCHSB – Mine Rescue if specialized rescue services are required
Lead Agency:	• Faro EMO
Support Agency(ies):	• Yukon EMO • Faro Community Health Centre

- RCMP if fatality
- Spills Line
- Geotechnical Expert (independent advice/ assist with recovery plan)

3.5.2 Open Pit Wall / Ramp Failure

Open Pit wall or access ramp failures are often preceded by cracking and ground movements, which may be visible. Regular monitoring of pit walls crests and berms may help identify any potential failures.

If a sudden failure occurs, evacuation to a safe place within the pit itself is usually the best course of action. Egress from the pit can then be made once an access way is cleared. The possibility of having to evacuate injured persons quickly over the pit wall (if no vehicle access) may require Emergency Response Team call-out.

Main Threats:

- Injury to team member(s)
- Loss of access to open pit (loss of ramps, pit walls ect)
- Introduction of clean water into contaminated water body
- Loss of assets (power line, pipe line, barge, pumps ect)
- Disruption of operations
- Adverse impact on Company image

Response:

- Initiate affected area(s) Evacuation
- Assess likely impact
- Consider Emergency Response Team call-out, if required
- Initiate appropriate emergency response (first-aid/medical/search/pit evacuation/rope rescue, etc)
- Notify Faro Community Health Centre of possible need for assistance (if several casualties)
- Secure access to all areas using Emergency Response Team & other people as required
- Notify Faro EMO if required
- Notify Mine Site Manager
- Mine Site Manager will immediately report any injuries/ major damage to authorities: YG - AAM, WCHSB
- Mine Site Manager to initiate Chain of Command, if required
- Notify RCMP (if potential fatality)
- Advise other areas on site as required
- Advise adjacent operations if required
- Conduct damage assessment of affected area or entire site using competent team members
- Notify site employees and contractors of proposed action as required
- Maintain security of affected area(s) until Mine Site Manager calls a stand down
- Initiate appropriate investigation (may need to maintain security of area

	until completed)
External Help	• Faro EMO
Lead Agency:	• RCMP if fatality • WCHSB – Mine Rescue if specialized services are required
Support Agency(ies):	• Yukon EMO • Faro Community Health Centre • EMS • Geotechnical Expert (independent advice/ assist with recovery plan)

3.5.3 Inrush into Open Pit

An inrush of water, mud or tailings into an open pit is only likely to occur following a major flood event or dike failure. Establishment of an evacuation process in case of major rainfall may alleviate the need for an emergency response.

If a sudden inrush does occur, evacuation from the pit or moving to a safe place within the pit itself is the best course of action. This will depend on the location of the inrush and volume of material involved. Egress from the pit can then be made once the inrush has stabilized. The possibility of having to evacuate injured persons quickly over the pit wall (if no vehicle access) may require Emergency Response Team call-out.

Main Threats:	• Injury to team members • Adverse impact on Company image • Introduction of clean water into contaminated water body
Alarms:	• Initiate affected area(s) Evacuation alarm
Response:	• Assess likely impact • Consider Emergency Response Team call-out, if required • Initiate appropriate emergency response (first-aid/ medical/ search/ pit evacuation/ rope rescue, etc) • Notify Faro Community Health Centre of possible need for assistance (if several casualties) • Secure access to area(s) using Emergency Response Team & other people as required • Notify Mine Site Manager • Mine Site Manager will immediately report any injuries/ major damage to authorities: YG - AAM, WCHSB • Mine Site Manager to initiate Chain of Command, if required • Notify Faro EMO • Notify RCMP if potential fatality • Notify Environmental Coordinator (if any likely environmental impact) • Maintain security of affected area(s) until Mine Site Manager calls a stand down

	• Initiate appropriate investigation (may need to maintain security of area until completed)
External Help	• PSEPC
Lead Agency:	• RCMP if fatality
Support Agenc(ies):	• Faro EMO
	• Yukon EMO
	• Transportation Engineering (Highways & Public Works)
	• Faro Community Health Centre
	• Geotechnical Expert (independent advice/ assist with recovery plan)

3.5.4 Animal Attack

An attack by wildlife (bear, wolverine, moose etc).

Main Threats:	• Team member attacked by Wildlife (bear, moose, wolverine)
Likely Alarms:	• Code 1 call
	• ERT & Medic
Response:	• Assess likely impact of incident
	• Initiate appropriate emergency response (e.g. first-aid, conservation officer etc)
	• Notify RCMP if fatality
	• Notify Faro Community Health Centre if required assistance
	• Notify Faro Conservation Officer
	• Notify Mine Site Manager
	• Mine Manager will immediately report any injuries/ major damage to authorities: YG - AAM, WCHSB
External Help **Lead Agency:**	• RCMP/ Conservation Officer
Support Agency(ies)	• Faro Community Health Centre

3.5.5 White Out

A white out may occur which stops all operations, travel and significantly hampers emergency response capability. Persons could be trapped in various areas on the mine site.

Main Threats:	• Severe cold, very low visibility, possible high winds
	• Loss of essential supplies (fuel, food etc)
	• Loss of power, heat, communications
	• Injury to team member(s)
Notification:	• As per extreme weather procedure
Likely	• Watch for warning issued by Environment Canada

Alarms:	
Response:	• Obtain up-to-date information from Environment Canada • Assess likely impact • Check status of site essential supplies (fuel, food etc) with Materials Team members • Notify Mine Site Manager • Mine Manager willimmediately report any injuries/ major damage to authorities: YG - AAM, WCHSB • If appropriate shutdown of all operations • Notify contractors & team members of proposed action • As per extreme weather procedure
External Help	• Faro EMO (if not affected by same condition)
Lead Agency:	
Support Agency(ies):	• Yukon EMO

3.5.6 Severe Electrical Storm

Electrical storms are common events during summer and early autumn. All critical equipment should be properly grounded or protected by lightning arrestors. Activities in the open should be stopped. If struck by lightning, cardiac arrest is likely, so quick response is essential.

Some hazardous activities (e.g. working near open water) should also be checked.

Main Threats:	• Team member(s) struck by lightning • Lightning initiating fire or explosion • Disruption to power/ security systems/ communications
Notification:	• May get some advance warning from weather service • Observations of severe lightning strikes/ almost instantaneous thunder • Could be some major power disturbances
Alarms:	• Code 1 call (if fire/ explosion) • Site wide radio call (to stop work & evacuate area)
Response:	• Notify all team members of approaching storm(s) • Initiate evacuation alarms, if fire or explosion • Call-out Emergency Response Team if support required • Initiate appropriate emergency response (first-aid/ medical/ fire) • Notify Faro Community Health Centre if required assistance • Isolate any energy sources or hazardous substances (e.g. power, gas, diesel, chemicals, etc) • Consider shut-down of operations, if storm/s severe • Notify Mine Site Manager

	• Mine Site Manager will immediately report any injuries/ major damage to authorities: YG - AAM, WCHSB • Mine Site Manager to initiate DM&R, if required • Inspect affected areas to assess damage (once safe) • If rubber-tired equipment struck by lightning, park up in secured/ isolated area for 24 hours • Maintain security of affected areas until Mine Site Manager calls a stand down
External Help **Lead Agency:**	• Faro EMO
Support Agency(ies)	• Faro Community Health Centre • Faro Volunteer Fire Department • Yukon EMO

3.5.7 Severe Rain Storm/ Flood/ Freshet

A flood could possibly result from a severe rain storm or an intense thawing season creating a severe freshet

Main Threats:	• Open pit in-rush, damage to dike • Release if contaminated water into environment and infrastructure such as: ditches, diversions, retention ponds, dikes ect • Flood damage to site facilities • Injury to team member(s) • Wet/slippery roads increase potential for heavy equipment & light vehicle accidents
Notification:	• Likely to be notified through Environment Canada.
Likely Alarms:	• Storm/weather alert issued by Environment Canada
Response:	• Obtain up-to-date information from Environment Canada • Notify all team members of approaching rains/flood or high temperature during thaw • Assess likely impact • Monitor drainage/access roads/haul roads and pit/ramp road conditions • Consider closing/ barricading access roads, haul roads or pit/ ramp roads, if affected • Advise Faro Community Health Centre of possible need for assistance (if several casualties) • Check status of site essential supplies (fuel, chemicals, etc) • If flooding likely to be severe or road conditions hazardous, consider

	closure of all operations • Keep heavy equipment and operators on call in case of emergency repair work to occur on road, diversions, ditches, ponds, berms, ect • Notify Mine Site Manager • Mine Site Manager will immediately report any injuries/ major damage to authorities: YG - AAM, WCHSB • Mine Site Manager to initiate Chain of Command, if required • Notify contractors, team members and suppliers of proposed action • If flooding of inspection areas and pits likely, withdraw workforce and stop operations • If inrush occurs, refer to incidents as required
External Help **Lead Agency:**	• Faro EMO
Support Agency(ies)	• Faro Community Health Centre • Yukon EMO • Transportation Engineering (Highways & Public Works) • RCMP if fatality • Faro Community Health Centre • Pump/ Hire Local Contractors

3.5.8 Communicable Disease Outbreak: Human Epidemic

Infectious diseases can be introduced through poor hygiene, contaminated water or food, or contact with other infected persons. They include Legionnaires disease, Influenza, various types of food poisoning, Hepatitis, etc.

As this could involve diseases of a “sensitive” nature,” it is important to maintain confidentiality and avoid undue panic. The Faro Community Health Center must be notified of any “reportable” diseases.

Main Threats:	• Team member illness • Adverse reaction/ panic by other team members
Notifications:	• members reporting sick/ severely ill
Alarms:	• None
Response:	• Isolate infected person(s) from other team members • Initiate appropriate medical response • If medical emergency occurs, contact Faro Community Health Centre if major outbreak and need to evacuate team members to the Health Centre • Notify Mine Site Manager • Mine Manager will immediately report any injuries/ illness to authorities:

	YG - AAM, WCHSB • Mine Site Manager to initiate Chain of Command, if required • Consider independent advice from external medical source (e.g. Whitehorse General Hospital) • Notify MHO (Medical Health Officer) • Assess situation and consider team member briefing (using accurate medical information)
External Help **Lead Agency:** **Support Agency(ies)**	• MHO (Medical Health Officer- Health and Social Services) • ESS (Emergency Social Services) • EHS (Emergency Health Services) • Faro EMO • Faro Community Health Centre

3.6 ON SITE ACCIDENT/ INCIDENT

3.6.1 Vehicle Accident

An accident involving a light and/or heavy vehicle on the YG maintained access road may require some response from site. This type of incident has potential to result in multiple casualties; e.g. if heavy equipment collides with light vehicle/s. An accident involving TEES operated heavy equipment is also likely to have an impact on Company image, particularly if fatalities occur.

Main Threats:	• Injury to operator/ other team member(s) involved • Environmental impact (if spillage results) • Impact to Company image/ reputation
Response:	• Assess likely impact • Initiate appropriate emergency response (first-aid/ medical/ fire/ triage/vehicle extrication) • Advise Faro Community Health Centre of possible need for assistance (if several casualties) • Determine what cargo was being carried (e.g. if any chemicals, Dangerous Goods, waste, etc) • Call-out Emergency Response Team if required • Secure area using Emergency Response Team members or other people as required • Notify RCMP • Notify Mine Site Manager • Mine Manager will immediately report any injuries/ major damage to authorities: YG - AAM, WCHSB

	• Notify Environmental Coordinator (if any likely environmental impact) • Mine Site Manager to initiate Chain of Command, if required • Maintain security of affected area until RCMP/ Mine Site Manager calls a stand down
External Help **Lead Agency:**	• Faro EMO
Support Agency(ies):	• Faro Community Health Centre • Spills Line • Yukon EMO • RCMP • Chemical Supplier/ Transport Company

3.6.2 Heavy Equipment Break Through Ice

An accident involving a heavy vehicle in the FMC area (open pits, IMP, CVP) may require some response from site. This type of incident has potential to result in multiple casualties depending on how many may be involved.

Main Threats:	• Injury to truck or equipment driver/ other team member(s) involved • Environmental impact (if spillage results)
Response:	• Call-out Emergency Response Team members • Initiate appropriate emergency response (ice rescue/first-aid/ medical/ fire/ triage/vehicle extrication) • Advise Faro Community Health Centre of possible need for assistance (if several casualties) • Secure area using Security Department or Emergency Response Team members or other people as required • Notify Mine Site Manager • Mine Site Manager will immediately report any injuries/ major damage to authorities: YG - AAM, WCHSB • Notify Environmental Coordinator (if any likely environmental impact) • Mine Site Manager to initiate Chain of Command, if required • Maintain security of affected area until Mine Site Manager calls a stand down
External Help **Lead Agency:**	• Faro EMO
Support Agency(ies)	• Faro Community Health Centre • Yukon EMO • Spills Line

3.6.3 Dangerous Goods Truck Accident

An accident involving a truck carrying significant quantities of hazardous substances or Dangerous Goods (e.g. lime, diesel fuel, compressed gases, etc) in the FMC will require response from the site.

The presence of leaking hazardous material and possibility of fire / explosion and having to cut persons out using hydraulic cutting equipment may require an Emergency Response Team. Accurate identification of the type/s and quantities of hazardous materials involved is essential.

Main Threats:	• Injury to truck driver/ and other member(s) involved • Injury to team members responding to accident • Environmental impact • Impact to Company image/ reputation
Response:	• Assess impact • Initiate appropriate emergency response (first aid/medical/fire/triage/Hazmat/vehicle extrication) • Call-out Emergency Response Team members if required • Advise Faro Community Health Centre of possible need for assistance (if several casualties) • Notify RCMP if fatality • Notify Faro EMO • Secure area Emergency Response Team members or other people as required • Notify Mine Site Manager • Mine Manager will immediately report any injuries/ major damage to authorities: YG - AAM, WCHSB • Notify Environmental Coordinator if environmental impact • Mine Site Manager to initiate Chain of Command, if required • Maintain security of affected area until Mine Site Manager calls a stand down
External Help **Lead Agency:**	• Spills Line
Support Agency:	• Faro Community Health Centre • Faro EMO • Yukon EMO • RCMP if fatality • Chemical Supplier/ Transportation Company (for information)

3.6.4 Light Vehicle Accident/ Incident

Accidents involving light vehicles on site will require response from site team members and or Emergency Response Team. The presence of leaking fuel and possibility of having to cut persons out using hydraulic cutting equipment may require an Emergency Response Team call-out or Local EMO

Main Threats:	• Injury to team member/s • Adverse impact on company image
Alarms:	• Code 1
Response:	• Call-out Emergency Response Team members • Initiate appropriate emergency response (first-aid/ medical/ fire/ vehicle extrication) • Notify Faro Community Health Center • Notify RCMP if fatality • Notify Faro EMO • Secure area using Emergency Response Team members or other people as required • Notify Mine Site Manager • Mine Manager will immediately report any injuries/ major damage to authorities: YG - AAM, WCHSB • Mine Site Manager to initiate Chain of Command, if required • Maintain security of affected area until Mine Site Manager calls a stand down • Initiate appropriate investigation (may need to maintain security of area until completed) • Arrange clean-up using crane, excavator, loader etc.
External Help **Lead Agency:**	• RCMP if fatality
Support Agency(ies)	• Faro Community Health Centre • Faro EMO

3.6.5 Heavy Vehicle Accident/ Incident

Accidents involving heavy vehicles (e.g. trucks, cranes, loaders, dump trucks, graders etc) on site will require response from Emergency Response Team members.

An accident involving a heavy vehicle-light vehicle collision has the potential for multiple injuries. If heavy equipment is carrying hazardous substances, environmental impacts may also occur. The presence of leaking fuel and possibility of having to cut persons out using hydraulic cutting equipment may require Emergency Response Team call-out or Faro EMO.

Main Threats:	• Injury to vehicle driver/ other team member(s) involved • Environmental impact (e.g. if carrying hazardous substances) • Impact to Company image/reputation
Response:	• Assess impact • Consider Emergency Response Team call-out, if required • Initiate appropriate emergency response (first

	aid/medical/fire/triage/Hazchem/vehicle extrication) • Advise Faro Community Health Centre of possible need for assistance (if several casualties) • Isolate any energy sources or contain hazardous substances (e.g. power if hit power line, gas, diesel, chemicals, etc.) • Notify RCMP if fatality • Notify Faro EMO • Secure area using Emergency Response Team members or other people as required • Notify Mine Site Manager • Mine Site Manager will immediately report any injuries/ major damage to authorities: YG - AAM, WCHSB • Notify Environmental Coordinator (if any likely environmental impact) • Mine Site Manager to initiate Chain of Command, if required • Notify Spills Line • If rubber-tired equipment strikes power line or tires subject to heating or fire, park up in secured/isolated area for 24 hours (Tire Fire/Explosion) • Maintain security of affected area until Mine Site Manager calls a stand down • Initiate appropriate investigation (may need to maintain security of area until completed) • Arrange clean-up using crane, excavator, loader etc.
External Help **Lead Agency:**	• 24 Hour Spills Line
Support Agency(ies):	• Faro Community Health Centre • RCMP if fatality • Faro EMO

3.6.6 Hazardous Substance Release

A release of a hazardous substance can impact people over a wide area, particularly those working down-wind of the release. Common hazardous substances that could be released are lime, compressed gas, etc. If a major release, an area evacuation should be the initial response.

Main Threats:	• Injury to team members • Injury to team members responding to accident • Environmental impact • Impact to Company image/ reputation
Alarms:	• Code 1
Response:	• Call-out Emergency Services team members with full BA gear (Code 1)

	• Initiate Area Evacuation Alarm • Initiate appropriate emergency response (first aid/medical/fire/Hazmat/assisted evacuation) • Advise Faro Community Health Centre of possible need for assistance (if several casualties) • Determine likely location and source of release, if safe • Determine likely quantity of hazardous substance • Check MSDS for treatment & control advice • Isolate any energy sources or hazardous substances release (if safe) • Notify Mine Site Manager • Mine Manager will immediately report any injuries/ major damage to authorities: YG - AAM, WCHSB • Mine Site Manager to initiate Chain of Command, if required • Notify RCMP if fatality • Advise Local EMO, if require assistance • Secure area using Emergency Response Team members or other people if required • Notify Environmental Coordinator (if any likely environmental impact) • Maintain security of affected area until Mine Site Manager calls a stand down • Initiate appropriate investigation (may need to maintain security of area until completed) • Arrange clean-up or neutralization based on MSDS or supplier's instructions
External Help **Lead Agency:**	• 24 Hour Spills Line
Support Agency(ies):	• Faro EMO • Faro Community Health Centre • Faro RCMP if fatality • Yukon EMO

3.6.7 Water Treatment Plant Failure

System failure at the Faro Mill WTP or Vangorda/Grum WTP may occur during the water treatment season. Examples of a failure are pumping systems, containment tanks, lime delivery systems, electrical components, etc.

Main Threats:	• Injury to team member(s) • Environmental Impact • Impact to Company image/ reputation

	• Assess impact
Response:	• Consider Emergency Response Team call-out, if required
	• Isolate any energy sources or hazardous substances (e.g. turn off power/ pumping systems, chemical addition, etc)
	• Initiate appropriate emergency response (first-aid/ medical/ fire/ entrapment rescue/ HAZMAT procedure etc)
	• Advise Faro Community Health Centre of possible need for assistance (if several casualties)
	• Notify Mine Site Manager
	• Mine Site Manager will immediately report any injuries/ major damage to authorities: YG - AAM, WCHSB
	• Mine Site Manager to initiate Chain of Command, if required
	• Notify Environmental Coordinator (if any likely environmental impact)
	• Secure area using Emergency Response Team members
	• Maintain security of affected area until Mine Site Manager calls a stand down
	• Initiate appropriate investigation (may need to maintain security of area until completed)
	• Initiate appropriate containment of contaminated water released
External Help **Lead Agency:**	• 24 Hour Spills Line
Support Agency:	• Local EMO
	• Yukon EMO

3.6.8 Fire/Explosion

A fire/ Explosion has the potential to result in loss of a key component for the care & maintenance of the site. The initial response should be to evacuate the area to a safe distance and wait for expert assistance.

Main Threats:	• Injury to team member(s) in all work areas
	• Damage to mine infrastructure (depends on location)
	• Disruption to site care and maintenance
	• Adverse impact on Company image
Alarms:	• Code 1
Response:	• Call out Emergency Response Team with full BA gear, if required
	• Initiate area evacuation to muster station
	• Secure area at safe distance (at least 1 km) Emergency Response Team members
	• Maintain *exclusion zone* of at least 1 km radius (do not attempt to

	extinguish fire) • Initiate appropriate emergency response (first-aid/medical/assisted evacuation) • Notify Faro Community Health Centre of possible need for assistance (if several casualties) • Notify Mine Site Manager • Mine Site Manager will immediately report any injuries/ major damage to authorities: YG - AAM, WCHSB • Notify Faro EMO/ Faro Volunteer Fire Department • Notify EMS if mass casualty incident • Mine Site Manager to initiate Chain of Command, if required • Notify WCHSB – Mine Rescue if specialized rescue services are required • Maintain security of affected area until Mine Site Manager calls a stand down (and fire is extinguished) • Arrange clean up of area(s)
External Help **Lead Agency:**	• EMS if mass casualty incident • WCHSB – Mine Rescue if specialized rescue services required • RCMP if fatality • Faro EMO/ Faro Volunteer Fire Department
Support Agency(ies):	• Yukon EMO • Faro Community Health Centre

3.6.9 Building Collapse

Building collapse can be the result of a seismic event, explosion or major structural failure. The area that poses the most risk is the Faro Mill WTP. The initial response should be to evacuate the area to a safe distance and wait for expert assistance.

Main Threats:	• Injury to occupant(s) and team member(s) • Damage to infrastructure/assets • Adverse impact on Company image
Alarms:	• Code 1
Response:	• Call out Emergency Response Team (Code 1) • Initiate area evacuation alarms & evacuate to safe locations (e.g. designated Muster points may be too close) • Secure area at safe distance using Emergency Response Team members or other people • Initiate appropriate emergency response (first-aid/medical/assisted evacuation/ fire fighting/rescue) • Advise Faro Community Health Centre of possible need for assistance (if several casualties)

	• Notify Mine Site Manager • Mine Site Manager will immediately report any injuries/ major damage to authorities: YG - AAM, WCHSB • Mine Site Manager to initiate Chain of Command, if required • Notify WCHSB – Mine Rescue if specialized rescue services are required • Notify RCMP if fatalities • Notify Faro EMO/ Faro Volunteer Fire Department if require assistance • Arrange for expert assistance (e.g. collapse building search) through RCMP • Maintain security of affected area until Mine Site Manager calls a stand down
External Help	• WCHSB – Mine Rescue if specialized rescue services are required
Lead Agency:	• RCMP if fatality • EMS if mass casualty • Faro EMO/ Faro Volunteer Fire Department
Support Agency(ies):	• Faro Community Health Centre • Yukon EMO • Faro SAR through Faro RCMP

3.6.10 Working At Heights Accident/ Incident

Team members work at heights on a daily basis, particularly around processing plants. Should a person fall, it may be necessary to undertake “height rescue” using site team members.

This type of event could involve a person being suspended from fall arrest equipment and being seriously injured or otherwise incapacitated. The possibility of having to extract injured persons (possibly using rope rescue) will require Emergency Response Team call-out.

Main Threats:	• Injury to team member(s)/ Emergency Response Team member(s) • Adverse impact on Company image (if serious injury)
Response:	• Call-out Emergency Response Team members • Assess situation to identify appropriate rescue method (e.g. rope rescue, use of crane with man-basket/ cherry picker etc) • Isolate any energy sources (e.g. power) or hazardous substances, if required • Initiate appropriate emergency response (first-aid/medical/rope rescue/call for back-up equipment etc) • Advise Faro Community Health Centre of possible need for assistance (if several casualties) • Notify Mine Site Manager • Mine Site Manager will immediately report any injuries/ major damage to authorities: YG - AAM, WCHSB • Mine Site Manager to initiate Chain of Command, if required

	• Notify RCMP if fatality • Notify Faro EMO if require assistance • Maintain security of affected area until Mine Site Manager calls a stand down • Initiate appropriate investigation (may need to maintain security of area until completed)
External Help	• WCHSB – Mine Rescue if specialized rescue services are required
Lead Agency:	• RCMP if fatality • EMS if mass casualty • Faro EMO
Support Agency(ies):	• Faro Community Health Centre • Yukon EMO

3.6.11 Confined Space Accident/ Incident

Team members work in confined spaces several times a year on the Faro Mine Site. This tends to be a high risk/ low frequency type of accident/ incident. However, the hazards involved may not be unique to confined spaces but, are always exacerbated by the enclosed nature of the confined space.

Main Threats:	• Injury to team members/emergency response team members • Adverse impact on Company image (if serious injury)
Response:	• Call-out Emergency Response Team members • Assess situation to identify appropriate rescue method and equipment (e.g. rope rescue) • Isolate any energy sources (e.g. power) or hazardous substances, if required • Initiate appropriate emergency response (first-aid/medical/rope rescue/call for back-up equipment etc) • Advise Faro Community Health Centre of possible need for assistance (if several casualties) • Notify Mine Site Manager • Mine Site Manager will immediately report any injuries/ major damage to authorities: YG - AAM, WCHSB • Mine Site Manager to initiate Chain of Command, if required • Notify RCMP if fatality • Notify WCHSB – Mine rescue if specialized rescue services are required • Notify Faro EMO if require assistance • Maintain security of affected area until Mine Site Manager calls a stand down • Initiate appropriate investigation (may need to maintain security of area until completed)
External Help	• WCHSB – Mine Rescue if specialized rescue services are required
Lead Agency:	• RCMP if fatality

	• EMS if mass casualty • Faro EMO
Support Agency(ies):	• Faro Community Health Centre • Yukon EMO

3.6.12 Malicious Damage

Malicious damage can involve any intentional act by a team member/ contractor/ visitor that is intended to disrupt operations or damage equipment or property.

Examples are setting fires (arson), sabotaging equipment, opening valves to chemicals or other hazardous materials, etc. Malicious intent is often difficult to identify as the deliberate act may be well concealed. Any suspicion that acts may be deliberate should be notified to the RCMP for formal investigation.

Main Threats:	• Injury to team member(s) • Loss of assets (if fire/ explosion occurs) • Disruption to production
Response:	• Consider Emergency Response Team call-out, if required • If fire or explosion, evacuate affected area/s • Initiate appropriate emergency response (first-aid/medical/ fire Hazchem response/assisted evacuation, etc) • Notify Faro Community Health Centre of possible need for assistance (if several casualties) • Isolate any energy sources or hazardous substances (e.g. power, gas, diesel, chemicals, etc) • Secure area using Emergency Response Team • Notify Mine Site Manager • Mine Site Manager will immediately report any injuries/ major damage to authorities: YG - AAM, WCHSB • Mine Site Manager to initiate Chain of Command, if required • Notify RCMP • Maintain security of affected area/s until Mine Site Manager calls a stand down
External Help **Lead Agency:**	• RCMP
Support Agency(ies):	• Faro Community Health Centre • Faro EMO • Faro Volunteer Fire Department

3.6.13 Bomb Threat

Bomb threats are usually made to administration staff by telephone and must be taken seriously. The key aspect here is to remain calm and try to record as much detail as possible about the threat itself.

Main Threats:	• Potential for injury to team member(s) • Impact on person receiving the call/ threat • Disruption to mine site care & maintenance
Alarms:	• Radio Communication Only
Response:	• Person receiving call to remain calm and record information regarding the threat using the "Bomb Threat Check-list" • Initiate area evacuation, if required (but keep people calm) • Notify Mine Site Manager • Mine Site Manager will immediately report any injuries/ major damage to authorities: YG - AAM, WCHSB • Notify RCMP • Initiate appropriate emergency response (first-aid/medical/search/assisted evacuation, etc) • Await RCMP arrival/ instructions • Notify Faro Community Health Center if injuries occur • Notify Faro EMO • If bomb detonates, treat as "Explosion" • Arrange counselling for affected persons, including person who received Bomb Threat • Maintain security of affected area(s) until Mine Site Manager calls a stand down • Assist RCMP with investigation
External Help **Lead Agency:**	• RCMP
Support Agency(ies):	• Faro EMO • Yukon EMO • Faro Volunteer Fire Department • Faro Community Health Centre • EMS

3.6.14 Armed Hold-Up/ Hostage Situation

An armed hold-up at the mine may result in a hostage situation. In all cases, site team members should cooperate with demands made and not attempt to aggravate or apprehend armed robbers. The key aspect here is to remain calm and try to record as much detail as possible about the offenders.

Main Threats:	• Injury/ harm to team member(s) • Impact on company image/ reputation
Response:	• Instruct team members to remain calm and not resist demands • Notify RCMP • Notify Mine Site Manager • Mine Site Manager will immediately report any injuries/ major damage to authorities: YG - AAM, WCHSB • Initiate appropriate emergency response (e.g. first-aid, evacuate), depending on location of armed offenders • Do not announce an emergency call (may distress armed offenders) • Secure area at safe distance using Emergency Services Team members • Allow armed offenders to depart site (i.e. do not attempt to apprehend or hinder) • Await RCMP arrival/ instructions • Isolate and treat/ comfort those involved (while awaiting RCMP arrival) • Mine Site Manager to initiate Chain of Command, if required • Arrange counselling for affected person(s) • Maintain security of area until a stand down has been called by the Mine Site Manager
External Help **Lead Agency:**	• RCMP • Faro EMO (may be requested to for support) • Faro Community Health Centre

Appendix A

Back Pumping I.P. to Faro Pit with Godwin

Back Pumping I.P. to Faro Pit with Godwin

Risk	Outcome	Trigger
Loss of power. Loss of barge.	Exceeding manageable levels in the IP pond	Within 1 meter of spillway
Unable to transfer water from IP to Faro Mill		Loss of barge
DVTP down		
inundation of water due to heavy freshet		
Steps	**Mitigation**	**Time Frame**
	Back pump from IP to Faro Pit/Faro Mill	
1	Isolate power to C-cans at IP	.5 day
2	install Godwin at IP close to water line	.5 day
3	connect suction line and float to Godwin	.5 day
4	install 6" x 14" reducer to Godwin discharge	.5 day
5	disconnect 14" main line from C-can	.5 day
6	connect Godwin discharge to 14" main line	.5 day
7	Move to Faro Mill	
8	disconnect 14" line where enters into Faro Mill only if bypassing Faro Mill	.5 day
9	add 1000 ft. of 14" DR13.5 tie into 24" line to Faro Pit across from old tailings pump house	No line available. Dependent upon lead time. 4-6 weeks
10	start Godwin	
11	check for discharge at faro pit	

APPENDIX B

Faro Pit Pumping – Bypass Mill to I.P.

Faro Pit Pumping – Bypass Mill to I.P.

Risk	Outcome	Trigger
Loss of capacity to treat water in the Faro Mill	Unable to process water through Faro Mill	loss of clarifier/thickener tanks/power/head box
	lower levels of treatment capacity	
Steps	**Mitigation**	**Time Frame**
1	daily inspections	
2	shut down Faro Barge pump	
3	ensure containment of uncontrolled discharge from Faro Mill	
4	Disconnect 30” line across from crusher transfer tower – install 30” x 24” reducer (this reducer is *required)	*follow up on lead time for reducers
5	Extend line 24” for approximately 900’ to 20” x 20” x 20” directional “Y”.	this material is on site
6	Connect 24” line to 24” x 20” reducer (*required). Set values at 24” x 24” x 24” “T” at I.P. to I.P. Make sure value 24” to C.U.P. is closed!	
7	start Faro Barge pump	
8	balance recharge with discharge from IP to CVP	one week to set up Faro Mill depending on lead time for reducers
9	DVTP would need to be in place in order for this to be completed.	three weeks to set up CVP
10		total ~4 weeks

APPENDIX C

I.P. Pumping – Bypass Mill to Faro Pit

I.P. Pumping – Bypass Mill to Faro Pit

Risk	Outcome	Trigger
this has never been done before with the IP pumping system	Unable to process water through Faro Mill	loss of clarifier/thickener tanks/power/head box
inundation of water due to heavy freshet	beyond capacity of DVTP	Within 1 meter of spillway
		beyond capacity of DVTP
Steps	**Mitigation**	**Time Frame**
1	Disconnect 14" line at old coal stock pile 14" x 14" x 4" air relief "T". Extend 14" line approximately 1000' toward sludge drop box.	
2	Connect 14" line to 24" line from old tailings building to Faro Pit (1000' x 14" x DR 13.5 pipe is required).	
3	Pending pump and line pressures and volume delivered, a booster pump may be required in line (88 HP or Godwin) to transfer required volume to Faro Pit.	
4	This would require additional reducers 14" x 8" and 6" x 14" for Godwin pump and a transfer sump or in line adaptor for 88 HP pump and 10" x 14" reducer (all would be required).	lead time for reducers
5	Time line for all of the above will vary depending on availability of materials required.	No line available. Dependent upon lead time. 4-6 weeks

APPENDIX D

Thickener Tank Failure

Thickener Failure

Risk	Outcome	Trigger
thickener fails to the point where by we have to shut down the thickener tank	reduced treating capacity through the Faro Mill	uncontrolled discharge due to tank failure
Steps	**Mitigation**	**Time Frame**
1	daily inspection	
2	yearly inspections on tank	
3	shut down Faro Pit barge	
4	Remove overflow collection boxes and piping from thickener and modify clarifier to same configuration as thickener to increase output.	
5	Extra manpower would be required to accomplish this modification in a timely manner of 2-3 weeks.	2-3 weeks

APPENDIX E
Clarifier Failure

Reduced Flow to Clarifier

Risk	**Outcome**	**Trigger**
clarifier fails to the point where by we have to shut down the clarifier tank	reduced treating capacity through the Faro Mill	uncontrolled discharge due to tank failure
Steps	**Mitigation**	**Time Frame**
1	daily inspection	
2	yearly inspections on tank	
3	shut down Faro Pit barge	
4	close feed valve to clarifier	1 day

APPENDIX F

Power Loss

Loss of power scenario at the FMC

Risk	Outcome	Mitigation	Time Frame
Loss of power between Faro and Whitehorse	No power to site	Notify Yukon Energy to supply power from diesel plant	Yukon Energy has a procedure for the transfer. This would not be days and would only be done during main dewatering season.
Loss of pit isolation transformer	Loss of power to Faro and Grum	Utilize old freshwater pump house feeder. Build two spans to the existing pit power line.	one week
Damage to T-2 sub	Loss of power to 3E MCC. Loss of power to guardhouse and IP	Run 600v temporary jumpers from 3 MCC to 3 E MCC. Run 600v temporary jumper from /33MCC to / 70 MCCPut guardhouse and IP on Cummins standby gen set and run one 150 hp pump at IP.	IP and guardhouse would be powered immediately. Jumpers could take one week. A decision would need to be made as to how long repairs to T-2 sub would take and act accordingly.
Damage to Faro pit 1000 KVA transformer that feeds Faro barge pumps.	Loss of power to Faro pit pumps	Get the 1000 KVA transformer from little creek dam and relocate it to the Faro pit. Hang small bank at LCD for 30 hp pumps.	One week
69 KV power line falls into Grum pit	Loss of power to Grum WTP and VG pumps	Jumper the 4160é69 KV sub at the Faro end and run 4160v to VG pumps. Also jumper the line feed from 5B1 and 5B2 together to feed Grum WTP. If the pumps won't start a 1 meg diesel generator would be required.	One to two weeks depending on the number of qualified people available.
Grum sub falls into Grum pit	Same as above	Same as above	Same as above
Grum 5B1 or 5B2 breaker fail at sub	Loss of power to VG pumps or loss of power to Grum WTP depending on breaker.	Tie powerlines together inside sub.	One day, cable is already in place.
VG barge or booster switch house fails and is unrepairable.	Unable to pump water fromVG pit to Grum WTP.	Modify 5 KV switch gear currently in pit electrical shop.	Two weeks
69 KV repeater transformer fails.	No power to the repeater. Site loss of phones, internet and repeater.	Power repeater with gas genrator until replacement transformer is installed.	1-day.
Loss of power from Faro	Total loss of power from Yukon Energy.	Put guard house on cummins gen set S-007. If necessary run one pump at IP to mill. Run Cat gen set S-005 and pump from thickener to Faro pit.	
Loss of power to V15 C-can	Unable to manage water from seeps	Move in portable light plant to power pump. Portable heater would be insatalled for heat to C-can	2-days
Loss of power to S-Well	Unable to manage water from seeps	Move in the Deutz generator and instal 208 to 600 transformer	2-days
Zone II C-can	Unable to manage ground water	Move in the Cat generator the old Deutz building for the S-well. Back feed power line to Zone II.	1-day

AAM Site Access Management Approach 1

Authorized Users versus Non-authorized 1

Controlled Access Points 1

Access Restrictions 2

AAM Site Access Management Approach

Assessment and Abandoned Mines (AAM) is responsible for the management of the Faro Mine Complex (FMC) and as such, needs to be able to ensure the health and safety of those that use the area, while maintaining environmental protection. In order to facilitate this mandate the FMC area is covered by Order-in-Council 2008/168 (OIC 2008/168) as well as the land reserve 2008-2582. Both of these mechanisms cover a geographical area greater than the disturbed area of the former mine site, allowing for the additional works required to support execution of a long term remedial solution. AAM recognizes that there are many traditional and contemporary activities that take place within the OIC and reserve, or that require that people to pass through them en route to outlying areas.

AAM's goal is to provide access to the FMC to those who need it while having in place a strategy to restrict access for unauthorized users who have no recognized purpose on the site. This document describes the access management strategies that AAM applies to effectively balance these competing needs. For the purposes of describing access management strategies, the "site" or "FMC" refers to the disturbed area of the former mine site, not the area covered by the OIC and land reserve.

Authorized Users versus Non-authorized

Members of the public who wish to access the FMC for existing known uses are considered authorized recreational users providing they are within pre-defined areas (see attached Site Access Crossing Points map), or are crossing the site at designated points to access areas beyond. These users include hunters, hikers, ATV riders and snowmobilers. People holding or using trapping and guiding concessions are also considered authorized users.

Non-authorized users are those that either do not have a specific purpose to be on site (such as a contractor or employee) or are NOT accessing an area pre-defined for recreational, traditional or big-game outfitting purposes within or outside the site.

Controlled Access Points

Some areas of the site and the surrounding area have been traditionally used by First Nations and local area users. AAM does not intend to restrict access to these areas. These locations include the following areas on the attached Site Access Crossing Points map:

- The outfitter camp/cabin;
- 6. Hunting cabin;
- 9. Points for tea water collection;
- 10. Shooting range;
- 16. Registered trapline; and,
- 17. The outfitter base.

In addition to the sites themselves, there are access roads and parking areas associated with these areas that are necessary, and they include:

- 2. Road used by the outfitter and hunters;
- 3. Parking area to access hunting area northeast of the Faro Pit;
- 8. Parking area to cross the Haul Road; and,
- 11. The parking area at the fork of the Access Road.

Access points 7 and 12 are crossings of the Haul Road with signs warning the site operations staff to slow sown. In addition, site operations staff must adhere to speed limits on signage posted on the Haul Road.

For those who wish to access the pre-defined areas for recreational and traditional activities it is AAM's preference that they check-in with the gatehouse so site operations staff are aware of their general locations and can inform staff to take precautions as necessary.

Access Restrictions

In general, AAM intends to restrict access outside of the areas listed above, under the authority of the reserve. Gates will be installed in the following locations (see the attached map):

- 5. The fork in the trail that leads to the Faro diversion and Pit, and,
- 13. The trail where ATVs access the Grum side.

These areas do not provide substantive opportunities to access recreational or known traditional activities, and lead to the Faro and Grum Pits, raising significant health and safety concerns. It should be noted that in both instances alternate access across the site is available.

Site 4, on the attached map, a parking area on the Faro side, will also be closed with those accessing that side of the site directed to park vehicles at site 3. This will create one area for site operations staff to monitor.

Map

Faro Mine Site Access Crossing Points

1. Outfitter hunting camp/cabin and horse corral by gravel pits northwest of the site.
2. Road used by outfitter and hunters to access hunting camp and horse corral northwest of site.
3. Parking area to access hunting area northeast of Faro Pit.
4. Parking area to access hunting area northeast of Faro Pit.
5. Fork in the trail where hunters get confused and follow the Faro Creek Diversion road onto the site.
6. Hunting cabin off Access Road.
7. Crossing point on the Haul Road on the Faro side, leads to trapping concession and hiking trail.
8. Parking area to cross Haul Road.
9. Point for tea water collection.
10. Shooting range off Access Road.
11. Parking area at the fork of Access Road and newly opened access route to Grum Side used by hunters, outfitters and hikers.
12. Crossing point on the Haul Road on Grum side, leads to outfitter base camp. Also Town of Faro marked trail to Mount Mye.
13. All terrain vehicle trails near Grum Waste Rock. (Currently overgrown and not actively used)
14. Gate at AEX Road blocking access to the site.
15. AEX Road.
16. Registered trapline and hunting area northeast of site.
17. Outfitter base northeast of site.

YG Environment Signage

Conservation Officer erected four signs regarding moose harvest management in the area. When the maximum allowable harvest is reached, additional signs are posted by the Conservation Officer asking hunters to voluntarily cease hunting in the zones.

Ecofor Consulting Ltd. (Ecofor) prepared this plan on behalf ofAssessment and Abandoned Mines.

James Mooney and Kevin Wilson (Owner) would like to thank the staff at Assessment and Abandoned Mines, Government of Yukonfor the opportunity to prepare this plan and for providing us with assistance.

Ecofor is solely responsible for any errors evident in this document.

MANAGEMENT SUMMARY

Ecofor Consulting Ltd., (Ecofor) is pleased to provide Assessment and Abandoned Mines (AAM) with this Heritage Resources Management Plan (HRMP) to ensure the immediate and ongoing protection and management of heritage resources within their existing developments and planned work at the Faro Mine Complex. This plan presents action items and communication protocols to assist AAM staff,their contractorsand subcontractors with the orderly and successful management of heritage resources within the Faro Mine Complex. This document is intended to be reviewed by the Ross River Dena Council (RRDC), Liard First Nation (LFN) and the Heritage Resources Unit of the Department of Tourism and Culture prior to implementation.

The action items begin with ensuring each known heritage site is flagged and signed. This will include making sure each known site is flagged with 1" wide yellow flagging tape marked in black with "**No Work Zone**". Signage will be added to each site with clear wording stating "**No Disturbance Zone**". A poster will be created and put on display at Faro Mine Complex officereminding staff of the protected status of heritage resources; that known sites are marked (showing the type of flagging and signage used); and what to do in case of chance finds. Any proposed ground disturbance activities, in areas that have not been the subject of heritage impact assessment, will be reviewed by heritage assessment staff prior to ground disturbance.

A communications protocol will be used between equipment operators and the site manager to review areas of planned impacts compared to known heritage resources prior to heavy equipment use. The entire staff will be reminded of the protected status of heritage resources and instructed on what to do during each step in the management plan. Sites recorded in the future will be flagged and signed in the same manner noted above.

AAM, their contractors and subcontractors will continue to inform the Heritage Resources Unit and relevant First Nations of heritage resources identified and any planned and accidental impacts to heritage resources. If sites are planned to be impacted then individual site mitigation plans will be developed and implemented. If any sites are the subject of mitigation efforts they will remain flagged and signed as noted above and project impacts will be avoided until directed by the Heritage Resources Unit that the mitigation measures, and reporting measures have been completed.

1.0 INTRODUCTION

This Heritage Resources Management Plan (HRMP) is designed specifically for the ongoingidentification, protection, and management of heritage resources at theFaro Mine Complex.These action items and communication protocols presented here are intended to be used moving forward for the entire remediation project.

The Faro Mine Complex and surrounding area had not been the subject of heritage resources impact assessments until 2013. Previous to this study there were no previously recorded heritage sites within or near the assessment areas, and no others recorded in the larger vicinity. In 2012, Ecofor Consulting Ltd. (Ecofor) completed a Heritage Resources Overview Assessment for the Proposed Faro Mine Remediation Project (Mooney and Smith 2012) which identified likely resources to be found in the area and areas evaluated to contain potential for heritage resources. The following year Ecofor conducted a Historic Resource Impact Assessment of the Proposed Faro Mine Interim Works Borrow Areas (Mooney 2013). The purpose of study was to assess potential impacts to heritage resources through reconnaissance survey and selected shovel testing across the proposed borrow areas.

During the assessment seven (7) areas were subsurface tested and four (4) were found to contain prehistoric artifacts. In addition a number of modern use areas were identified and recorded across the proposed project area. The results of these efforts have been submitted to the developer, the Heritage Resources Unit, and corresponding First Nations. As sites were found in the field they were assessed for their site significance and the potential impacts by proposed developments and management recommendations were presented on a site by site basis. The locations of these sites were flagged by Ecofor.

1.1 Scope of Plan

The objectives of this plan were to protect and manage heritage resources during ongoing and future reclamation activities on site,as well as any development. The protection and managementsteps include direction to:

- Flag and sign known sites to prevent impacts;
- Create, place and annual review of a heritage resources management poster for the site;
- Provide communication protocols to manage future ground disturbances and chance finds to avoid impacts to heritage resources.

These objectives will be met through a combination of field work and continued communication between AAM, the Heritage Resources Unit, the Ross River Dena Council (RRDC), and Liard First Nation (LFN).

1.2 Plan Format

Section 2 reviews relevant legislation and definitions while Section 3presents the action items and communication protocols. Section 4 lists the references cited.Appendix I presents the known locations of heritage resources in the Faro Mine Complex. Appendix II presents the Yukon Heritage Resources

Policy for Heritage Resource Management on Yukon Lands. Appendix III presents the Guidelines Respecting the Discovery of Human Remains and First Nation Burial Sites in the Yukon.

2.0 RELEVANT LEGISLATION

Heritage resources in the Yukon are protected and managed under provisions of the Yukon First Nations Umbrella Final Agreement (UFA), Chapter 13 and the enabling legislation: the Yukon *Historic Resources Act*, and the Inuvialuit Final Agreement. Yukon Heritage Resources prepared an operational policy that communicates the Yukon Government's position on ownership and management of heritage resources. This policy document is attached as a reference in Appendix II.

Besides the *Historic Resources Act,*the HRMP was prepared with the following additional legislation in mind so that heritage resources may be protected and managed including chance finds:

- The Placer Mining Regulation (O.I.C. 2003/59) – under the Placer Mining Act specifically Schedule 1 Operating Conditions, Section E regarding historic objects and burial grounds;
- The Quartz Mining Regulation (YOIC 2003/64) – under the Quartz Mining Act specifically Schedule 1 Operating Conditions, Section E regarding historic objects and burial grounds; and,
- The Land Use Regulation under the Territorial Lands (Yukon) Act – specifically Section 9 (Prohibitions).

2.1 Heritage Resources Protection and Long Term Curation of Materials Collected

Heritage resources (with the exception of heritage sites identified in First Nation Final Agreements, and ethnographic objects) on non-settlement Yukon lands are considered the property of all Yukoners and are held in trust for all Yukoners, and are managed by the Yukon Government.

Heritage resources on First Nation Settlement lands are owned and managed by the First Nation. In this case the Faro Mine Complex area does overlap with some of the First Nation Interim Protected lands, Ross River Dena Council block S-11B falls within the Order-in-Council 2008/168 boundary, and the southeast corner of the Study Area is close to the Ross River Dena Council Interim Protected Land block R-11A

Under the *Historic Resources Act* and the Archaeological Sites Regulations heritage contactors prepare required written reports as well as artifacts and materials collected in the field for long term record keeping and artifact curation. This includes preparing artifact catalogs, labeling artifacts, packaging and preparing artifacts to meet specific long term curation goals as needed. In order to ensure proper completion of permit requirements, heritage contractors submit interim and final reporting as well as collected materials to the Yukon Heritage Resources to review. After the permit reporting and artifact curation preparation requirements are met, then the Heritage Resources Unit would submit materials to appropriate First Nations as requested for further management or continue to hold the materials at the direction of the First Nations.

2.2 Resource Definitions

The UFA does not provide specific definitions of heritage resources but it does distinguish the types of resources. Part 6 of the *Historic Resources Act* provides more detailed definitions.Presented below are general definitions used in the common practice of heritage resource impact assessments.

A *Site* is an area or a place, or; a parcel of land which contains heritage resources or objects.

Ethnographic objects refer to an item of material culture relating to the history and traditional culture of an ethnic group.

Historic Sites contain heritage resources that are greater than 45 years in age and posses significant heritage value. By convention, historic sites date to the period for which written records are available; in this case, the historic period commences with the arrival of the Hudson's Bay Company in the early-mid 19th century. Historic sites may include cabins, caches, camps, brush camps, and any other man-made structures, features or objects that date between about 1960 and 1830.

Archaeological or Prehistoric Sites generally represent use before European contact and are found on or under the ground surface, and may consist of the remains of ancient camps, including hearths, animal bone and stone tools and debris. In this usage, an Archaeological Site equates to a Prehistoric Site (a site that dates to the period before written history). Note, however, that in heritage resource management usage, archaeological resources are viewed as resources that are in subsurface context (buried) and may also include historic period objects and features.

*Proto-historic Sites*can be viewed as prehistoric sites from a time period which includes the effects of foreign historic cultures but lacks the first hand written descriptions of that area. For example, in the Yukon the proto-historic period ends with the appearance of first hand written descriptions in the mid 1800s. However the proto-historic time period extends back thru time when foreign materials such as "drift-iron" from ship wrecks on the west coast, or foreign trade items were carried into the Yukon. Examples of foreign historic materials which predate the mid 1800s found in prehistoric contexts usually represent this proto-historic period.

Palaeonotological Resources include the fossilized, mummified, or skeletal remains of previous life forms. These resources may be found in sedimentary rock formations, or eroding streams and creeks and contain a great deal of information concerning past environments. The most common of these resources include the skeletal remains of ice age mammals which are often associated with dark humic deposits. These remains may date from approximately ten of thousands to many hundreds of thousands of years before present.

Human remains means non-fossilized remains of human bodies that are found outside a recognized cemetery or burial site.

3.0 HERITAGE RESOURCES MANAGEMENT PLAN TASKS

The proposed HRMP action items and communication protocols presented below incorporate communications between AAM, the Heritage Resources Unit, the RRDC and the LFN, and are intended to be reviewed by each party listed above and implemented as soon as possible. The site flagging and communication protocols are intended to be carried forward through any future ground disturbing activities located within the Faro Mine Complex.

3.1 Action Items

Action Item 1: Flagging and Signage of Known Heritage Sites

Ecofor staff and a RRDC participant will return to the Faro Mine Complexin 2014 to reflag and add signage to each known heritage site in the project area including those along and near roadways and within proposed borrow pits. Table 1 presents the known sites to be reflagged.

Table 1. Known Sites to be Flagged and Signed within the Faro Mine Complex

Borden Number or Temp Site #	Class	Site Size	Features
KcTq-1	prehistoric	5 x 15 m	isolated lithic tool
KcTq-2	prehistoric	surface find	small lithic scatter
KcTq-3	prehistoric	5 x 18 m	small lithic scatter
KcTq-4	prehistoric	5 x 10 m	small lithic scatter

A 30 m buffer will be marked around each known site with strips of 1" wide yellow flagging tape with black printing that states "**No Work Zone**". Each site will be marked by durable signage that states "**No Disturbance Zone**".

Action Item 2: Creation and Placement of Heritage Resource Warning& Information Poster

Ecofor and AAMwill prepare and produce a poster and place it in a prominent location at the Faro Mine Complex (for example the board room or entrance area) which will display the following:

- a reminder of the protected status of heritage resources;
- how the sites are marked in the field;
- what to do prior to ground disturbance activities; and
- what to do in case of a chance finds discovery.

Ecofor will review the information on this poster with AAM staff and the site managers. Site managers or contractors will review this poster and the HRMP with all current and future staff atthe Faro Mine Complex. This poster will be reviewed and revised each year to allow for additional information that may need to be updated.

Action Item 3: Heritage Resources Review of any Future Ground Disturbances

A qualified archaeological consultant will review any future or planned ground disturbing efforts. Any potential ground disturbing efforts will be reviewed for any previous heritage assessment efforts and if the target has not been previously reviewed by heritage staff then they will be reviewed in the field prior to ground disturbing activities.

If any of the proposed ground disturbing plans are evaluated in the field to contain heritage resources, the resources will be recorded, flagged, and signage installed as noted in action item 1. If a location is evaluated in the field to possess potential for buried heritage resources sub-surface testing will be conducted and if resources are identified they will be recorded, and the site will be flagged and signed as listed in action item 1.

Action Item 4: Flagging and Signage of Newly Recorded Heritage Sites

All heritage sites recorded in relation to the Faro Mine Complex in the future will be flagged and signed as per action item 1. All heritage sites recorded in relation to the Faro Mine Complex will be subjected to this HRMP or the subsequent plan.

3.2 Communication Protocols

Communication Protocol 1: Ground Disturbing Activities

Prior to any new ground disturbing activities the relevant equipment operators will request approval from the appropriate contract manager. The manager will review the location of the planned disturbance against previously recorded heritage site locations. If any sites have been recorded in or near the planned ground disturbance location the manager will review the location of the heritage sites with the equipment operators in the field, on foot, and provide directions to avoid impacts to the flagged and signed 30 m buffer area.

Communication Protocol 2: Chance Finds Procedures

It is possible that heritage resources as noted above may be accidentally discovered during further remediation efforts. These resources may range in size from small flakes and chips of debitage remaining from stone tool manufacturing, up to large historic structures such as cabins. Other possible heritage resources include culturally modified trees, fire cracked rock, historic adits, cache pits, house pits, paleontological remains, isolated prehistoric tools of wood, bone, antler, and isolated historic items.

If any additional heritage resources are identified, all work in the immediate area will cease. The resources will be left in place, recorded (see below), and the area of the find will be protected from further impacts. The manager will be notified of the type, amount, and location of the find. Information collected and passed on regarding the chance find will include:

- GPS location of the find;
- Date and time when the find was identified;
- Approximate size of find and type of materials present;
- Description of setting and access to the location of the find; and
- Digital photographs of the find(s) and general area of the find.

The manager will then contact the Heritage Resources Unit to discuss further management options and notify the appropriate First Nation contacts. If the area can be protected and immediate salvage operations are not required then a resource specific or site specific mitigation plan may be developed to recover data and information as per direction of the Heritage Resources Unit and the appropriate First Nation. If immediate salvage is required to ensure safety of exposed or isolated materials the remains or artifacts may be recorded as noted above, collected, and temporarily stored on site with manager.

If the remains include paleontological remains then the Yukon Paleontologist will also be contacted.

If human remains are identified during operations, all work in the area will immediately cease and further impacts to the area will be prevented, and the R.C.M.P will be notified. If the R.C.M.P. and Coroner determine that the remains were from a historic burial, the First Nation(s) and Yukon Heritage Resources Unit will be notified, as per the Guidelines Respecting the Discovery of Human Remains and First Nation Burial Sites in the Yukon (Appendix III).

As part of the ongoing and continuing efforts to increase awareness of the possible heritage resources that may be found in the area, and those that have been recorded, multiple copies of the booklet entitled *Handbook for the Identification of Heritage Sites and Features* (Gotthardt and Thomas 2005) will be left at the Faro Mine Complex guardhouse to be shared with current and future management and staff.

3.2.1 Heritage Resources Contact Information

Mary Maje, YESAA Coordinator Ross River First Nation General Delivery Ross River, YT Y0B 1S0 Ph. (867) 969-2097 Fax. (867) 573-3902 rrdyesaa@northwestel.net	Chief Brian Ladue Ross River First Nation General Delivery Ross River, YT Y0B 1S0 Ph. (867) 969-2277 or 78 Fax. (867) 573-3902 rrdadm@yknet.ca

RCMP Faro Detachment PO Box 310 Faro, YT Y0B 1K0 Phone: 867-994-2677 Fax: 867-994-2452	

Communication Protocol 3: Planned Impact of Known Sites

Some heritage sites may be planned to be impacted prior to construction. If these sites are planned to be impacted then approval for impact must be granted by the Heritage Resources Unit. In most cases sites to be impacted will be subjected to a data recovery mitigation plan and fieldwork efforts. In the case of prehistoric archaeological sites, detailed block excavation of a significant sample of the site is often used to collect and record information from the site prior to site impact. In the case of other resources more detailed photographic, ethnographic, informant, and archival research may also be used to document a resource before it is impacted.

Each heritage resource at the Faro Mine Complex will be flagged for avoidance as noted above. If any sites have received data recovery excavations and/or other mitigation efforts these efforts and results must be reviewed by the Heritage Resources Unit and applicable First Nations prior to final approval for the site to be impacted. Until such approval, each site area will remained flagged and signed to avoid additional impacts. Only after approval for impact has been granted may the site be impacted.

Please Note: Some site management recommendations may include construction monitoring after mitigation efforts have been approved.

Communication Protocol 4:
Continued Communication with First Nations and the Heritage Resources Unit

It is imperative that communications regarding newly recorded heritage sites and resources, or impacts to heritage sites or resources be passed along in a timely manner to the Heritage Resources Unit and applicable First Nations. All results from the heritage assessments and mitigation efforts must also be shared in a timely manner with the Heritage Resources Unit and the applicable First Nations.

Yukon
Tourism and Culture

Operational Policy for Heritage Resources Management on Yukon Lands

This document has been developed to communicate the Yukon Government's position on ownership and management of heritage resources in the context of the development assessment and review process in the Yukon. The Operational Policy for Heritage Resources Management is based in the provisions of the Yukon First Nations Umbrella Final Agreement (UFA), Chapter 13 and the enabling legislation: the Yukon *Historic Resources Act,* and the Inuvialuit Final Agreement. In the implementation of the legislation, Yukon Government is acting to protect and manage heritage resources on behalf of all Yukoners.

Ownership and Management Authority – Moveable Heritage Resources
Yukon Government is identified as the responsible authority for heritage resource management on non-settlement (Yukon) lands based on the specific provisions concerning ownership of moveable heritage resources in the UFA, Chapter 13 (13.3.3):

- Government owns all moveable and documentary heritage resources that are not "ethnographic resources directly related to culture and history of Yukon First Nation people".

Significant management direction is provided by the UFA in the use of the term '**moveable**' in connection with heritage resources. Anticipating the requirement to manage heritage resources in future land developments and activities, the option to move heritage resources with the objective of protection is fundamental in the UFA Chapter 13.

Ownership and Management - Heritage Sites
UFA 13.8.1 Ownership and management of Heritage Sites in a Yukon First Nation's Traditional Territory shall be addressed in that Yukon First Nation Final Agreement. Examples of heritage sites that have been identified in First Nation Final Agreements: Fort Selkirk, Forty Mile, Rampart House, Lansing Post, Tagish Post, Canyon City, Lapierre House, Tr'ochëk.

With the exception of heritage sites set out in FNFA as per 13.8.1, heritage sites and non-moveable heritage resources (structures/built heritage) are governed by Laws of General Application (*Historic Resources Act*). Ownership vests in Yukon Government.

Designation of Heritage Sites under the *Historic Resources Act* ensures sites are protected from activity or development impacts. Sites or areas of historical significance in theYukon, beyond those listed in FNFA, may also be nominated for designation under the HRA. The nominations are reviewed by the Yukon Heritage Resources Board, who then recommends to the Minister that a site be designated as a Yukon Historic Site.

Heritage Resources – Definitions
The UFA Chapter 13 does not provide definitions of heritage resources, but makes the distinction among types of heritage resources as follows (13.3.6.): ethnographic objects directly related to the culture and history of Yukon Indian People, palaeontological objects, and archaeological objects. Definitions for these terms are provided in *Historic Resources Act* (Part 6 Historic Objects and Human Remains – Definitions). Generally, palaeontological objects are the fossil remains of ancient plants and animals; archaeological objects are abandoned objects that are older than 45 years. For operational purposes, "**moveable ethnographic objects directly related to the culture and history of Yukon Indian People**" (UFA 13.3.2) are objects that were

known to have been owned or used by First Nations individuals or families within living memory[1]. 'Direct' indicates the line of ownership for the object is unbroken or can be reconstructed. As per UFA 13.3.5 – if an object cannot readily be determined to be ethnographic, it is held in custody by Yukon Government until its nature has been determined.

Protection of Heritage Resources

Accidental discovery of heritage resources (UFA 13.8.7) – heritage resources discovered during construction or excavation are protected under Laws of General Application (*Historic Resources Act, Mining Land Use Regulations; Land Use Regulations*). The *Historic Resources Act* (64) prohibits destruction or alteration of a heritage resource except in accordance with a historic resources permit.

Report of Findings

> *Historic Resources Act* Part 6 Report of Findings:
> 71(1) Every person who finds an object that is or that likely is a historic object, or remains that are or that likely are human remains, shall immediately report the find to the Minister.
> (2) If the object is found on settlement land the finder shall also report the find to the Yukon first Nation which governs the settlement land.
> Quartz and Placer Mining Land Use Regulations – E Historic objects and burial grounds
>
> > **9 .** Any sites containing archaeological objects, palaeontological objects or human remains or burial sites discovered in the course of carrying out an operation must be immediately marked and protected from further disturbance and, as soon as practicable, the discovery reported to the Chief (of Mining Land Use).

In respect of UFA 13.4.8, 13.7.1, Yukon Government provides to First Nations archaeological, palaeontological and historic site inventories and research reports on heritage resources found in their traditional territories.

First Nation Burial Sites

Procedures to manage and protect First Nation burial sites have been established by the Yukon Government and Yukon First Nations: "Guidelines Respecting the Discovery of Human Remains and First Nation Burial Sites in the Yukon". http://www.tc.gov.yk.ca/pdf/respecting_guidelines.pdf . General provisions include:

- Restrict access to preserve dignity of the site
- Newly discovered sites/accidental discovery
  - RCMP/Chief Coroner to be informed
  - If determined to be a First Nation burial, First Nation to be informed
  - general rule no further disturbance

Heritage Resource Assessment and Permits

Standard archaeological impact assessment and mitigation procedures are followed to guide heritage resources assessment in the Yukon. The Government of British Columbia Archaeological Impact Assessment Guidelines are the recommended guideline for Yukon and are comparable to standards used in other Canadian jurisdictions: http://www.tsa.gov.bc.ca/archaeology/docs/impact_assessment_guidelines/in dex.htm

Heritage assessments ideally are undertaken in cooperation with affected First Nations. Archaeological consultants are required to communicate with affected First Nations prior to undertaking field research. A First Nation may choose not to provide oral history or traditional knowledge input to the consultant, however. In such cases, the First Nations may keep confidential information on traditional use areas, subsistence resources and

[1] Ethnographic objects of themselves may not be informative of ownership. Many historic objects (for example, guns, axes, knives) were used equally by all Yukoners and attribution of ownership (for example to Nacho Nyak Dun vs. Selkirk First Nation vs. a non-First Nation trapper) cannot be made without direct knowledge of who made or used the object or in whose former camp the object was found. Therefore knowledge or memory of historic use is critical in determining if the objects are ethnographic.

cultural values and work independently with the Yukon Environmental and Socio-Economic Review board to ensure concerns with these values are addressed for a particular project.

Under the *Yukon Environmental and Socio-Economic Assessment Act*, heritage resource assessment is generally required for all activities that will impact or will potentially impact heritage resources. All heritage resource assessments are required to be carried out under permit:

Historic Resources Act

> **62** No person shall search or excavate for historic objects or human remains except in accordance with a historic resources permit. *S.Y. 1991, c.8, s.61.*

Archaeological Sites Regulation

> **3.** No person shall survey and document the characteristics of an archaeological site without a Class 1 or Class 2 permit.
>
> **4.** No person shall excavate, alter, or otherwise disturb an archaeological site, or remove an archaeological object from an archaeological site, without a Class 2 permit.

APPENDIX III - Guidelines Respecting the Discovery of Human Remains and First Nation Burial Sites

Guidelines Respecting the Discovery of Human Remains and First Nation Burial Sites in the Yukon

With approvals as of August 1999

This document was prepared pursuant to provisions of
Yukon First Nation Final Agreements
and the Yukon Transboundary Agreement with the Gwich'in Tribal Council

Introduction and Background

The treatment of every burial site requires respect. Legislation of various types protects burial sites and cemeteries from being disturbed. Government agencies and First Nations keep and consult records of known sites so that land use plans or proposals can avoid such sites.

There are many historic and First Nation graves in the Yukon however which are no longer marked and which may be disturbed accidentally through land use or development. Other sites may be disturbed by natural forces, such as erosion, leading to the exposure of human remains.

As more people travel in backcountry areas, for work or pleasure, it is expected that the number of such discoveries may increase. It is important therefore to have guidelines for reporting, investigating and managing such sites in a coordinated and effective manner, to give them proper respect.

Yukon First Nation (YFN) Final Agreements (Section 13.9.0) and the transboundary agreement with the Gwich'in Tribal Council (Tetlit Gwich'in) (Section 9.5) require the development of procedures to protect and manage YFN or TG burial sites, and specify certain actions when such sites are discovered.

Consistent with these obligations, these guidelines were developed at two workshops held jointly in March and October l998, involving First Nation Elders, heritage and implementation staff, the RCMP, Coroner and other Yukon and federal government officials.

Purpose

To provide direction on the reporting, identification, treatment and disposition of human remains found outside of recognized cemeteries in the Yukon, to ensure these remains are respected and protected consistent with legislation and Yukon land claims agreements.

Scope and Application

These guidelines apply to anyone who discovers human remains or grave goods outside of recognized cemeteries in the Yukon, and to the Yukon, Federal and First Nation government officials involved in protecting and caring for such sites.

The guidelines reflect existing practices in many ways. They do not replace legislation or regulations protecting burial sites, but are intended to integrate obligations contained in Yukon land claim agreements with land use permitting regimes and the Development Assessment Process . These guidelines may apply on Settlement Lands at the discretion of each First Nation. Government approval is required for management plans for sites on non-Settlement Land.

Existing known burial sites that are marked or otherwise recorded are protected by existing legislation. Management plans for these sites may be developed on a case by case basis.

Burial sites discovered within the boundaries of a designated heritage site may be subject to the management plan for that site.

The guidelines do not apply within National Historic Sites or National Parks. Parks Canada has its own guidelines respecting burial sites and human remains.

Evaluation and Revision of Guidelines

The implementation of these guidelines will be evaluated as necessary to ensure that they are fulfilling their purpose.

GUIDING PRINCIPLES

All human remains, and items found at graves (grave offerings, markers etc.) shall be treated with respect and dignity regardless of their cultural affiliation.

Actions taken following the discovery of sites will be consistent with Yukon and transboundary land claim agreement provisions respecting Yukon First Nation and Tetlit Gwich'in Burial Sites.

Each discovery will be handled on a case by case basis in consultation with the affected parties, in a coordinated and timely manner.

Definitions - see Appendix 1

Land claims provisions - see Appendix 3

Guidelines Respecting the Discovery of Human Remains and First Nation Burial Sites

See also Figure 1.

These guidelines cover five steps: discovery and notification; site protection and investigation; investigation and reporting; and site disposition or management agreements. A final step, arbitration, is provided for where no disposition agreement is reached.

1. Discovery and Notification

If human burial remains are accidentally discovered the following guidelines apply:

a) The finder will immediately cease any further activity at the site and report the site to the RCMP.

b) *If the finder is operating under a land use licence or permit*, the site must also be reported immediately to the land manager/permitting authority, as set out on the permit. The land manager/permitting authority shall confirm that the site is reported to the RCMP.

c) Based on the information it receives, the RCMP will notify: 1) the Coroner's office if the site is of a forensic or criminal nature; or 2) both the First Nation(s) in whose Traditional Territory the Site is located and the Heritage Branch, if the site is a suspected historic or First Nation burial site.

2. Site Protection and Identification

a) the land manager/permitting authority shall take reasonable measures to protect the site from environmental factors and any form of unauthorized interference or disturbance.

b) based on the evidence reported at the scene, the RCMP/Coroner will investigate the site and make a preliminary determination as to the nature of the remains.

c) *if the site is of a criminal or forensic nature* (potential crime scene or missing person), then the Coroner's office and police will assume authority over the site/remains.

d) Heritage Branch may recommend that an archaeologist assist police or coroner in the preliminary assessment of the site.

e) *If the site is **not** of police/coroner interest* then the Director, Heritage Branch, the affected First Nation(s) and the land manager will assume interim responsibility for protection and investigation of the site. If it's a suspected First Nation site, the Heritage Branch and First Nation would assume this responsibility.

f) the Director, Heritage Branch, the affected First Nation(s) and land manager shall take reasonable measures to restrict access and ensure that the human remains and any grave offerings are not further disturbed pending the investigation and identification of the remains. The RCMP may be consulted about protecting the site.

Figure 1

Guidelines respecting the Discovery of Human Remains and First Nation* Burial Sites

2. Site Protection and Investigation
-protection/no disturbance or access

If not a criminal matter, Heritage Branch takes lead with affected FN or transboundary group. RCMP may assist if requested.

- *First Nation, Minister*
- *permitting authority - person may continue activity*

with FN consent. If consent is not provided, proceed according to terms and conditions of arbitrator(UFA 26.7.0 TG Ch.18)

or

- *rebury, relocate or remove remains*
- *restrict/specify access if necessary and possible*
- *may designate existing or new site as burial site/cemetery or heritage site*
- *management plan (jointly prepared/approved by FN and Government on Non-Settlement Lands)*

Maps, inventories, reports, plans, agreements.

**the Tetlit Gwich'in will be involved in steps to protect and manage Tetlit Gwich'in burial sites discovered within their Primary Use Area (Fort McPherson Group Trapping area within the Peel River Basin).*

g) Where human remains are at risk of being destroyed or damaged, the Minister of Tourism for Heritage may issue a stop work order prohibiting any further activities and may make an agreement with the First Nation or the Tetlit Gwich'in or land owner or user for any investigation, excavation, examination and preservation and removal of the remains, consistent with land claim provisions. (s.*72, Historic Resources Act- This would address concerns about unknown remains.)*

Existing site inventories, land use records, affected First Nations and community elders, and military authorities, should be consulted as soon as possible about possible identification of the remains.

Some examination of the site/remains may be required to determine its cultural affiliation and age, and whether or not the site is modern or historic.

3. Investigation and Reporting

a) The Heritage Branch/land manager will direct an archaeologist or qualified examiner to carry out an investigation under any required permits, in consultation with the affected First Nation and other affected parties, to make an initial report citing, if possible*, the cultural affiliation of the human remains.

b) Within a reasonable time to be specified by the Minister, and the affected First Nation(s), the archaeologist or qualified examiner shall deliver a written report and any notification not yet made, to:

- the Minister, and the affected First Nation(s) if appropriate;
- the Director of the Heritage Branch;
- the land manager/permitting authority;
- any other representative of the interred, if known.

c) The written report shall attempt *to identify:

- the representative group of the interred;
- the geographic boundaries of the site;
- the grave offerings or other heritage resources that may be associated with the remains or the site.

d) The archaeologist or examiner may, with the agreement of the proper authority and the representative of the interred, if known, remove all or part of the human remains for further analysis or for temporary custody where the remains may otherwise be at risk.

e) Any exhumation, examination and reburial of human remains from a YFN/TG burial site shall be at the discretion of the affected YFN/TG; and if ordered by an arbitrator pursuant to land claim provisions, will be done or supervised by the YFN or Tetlit Gwich'in.

*it is often difficult to determine the cultural ancestry or affiliation of fragmentary human remains

3.1 Reporting

a) If the site is determined to be a Yukon First Nation Burial Site, or Tetlit Gwich'in burial site, the appropriate representative will be contacted in writing to provide further direction on the disposition of the remains. *

b) A person carrying out Government or First Nation authorized activity where a First Nation site is discovered can continue that activity with the consent of the First Nation in whose Traditional Territory the Yukon site is located. The consent of the Tetlit Gwich'in is required if the site is in the Tetlit Gwich'in primary use area. If consent is denied, the person can seek terms and conditions from an arbitrator about continuing the activity (see Section 5).

c) If after the final report, the human remains are found to be those of a different aboriginal people than those mentioned previously, the proper authority of that group shall be notified in order that they may assume the role of the representative.

d) Where a site is **not** found to be a Yukon First Nation or Tetlit Gwich'in burial site, or a military or mariner's burial site, the Director, Heritage Branch may publish notice of the discovery in a newspaper or other public notice seeking information on the remains.

4. Site Disposition Agreement (Management Plan)

4.1 When the site or remains are identified

a) The site shall not be disturbed and the Director, Heritage Branch or First Nation if on Settlement Land, shall initiate discussions towards entering into a site disposition agreement with the representative of the interred.

b) If the site is a Yukon First Nation Burial Site or a Tetlit Gwich'in burial site on non-settlement land, there must be joint approval of the site management plan by the Yukon First Nation in whose Traditional Territory the site is located and the Government. If the site is a Tetlit Gwich'in burial site located off Tetlit Gwich'in land but in the primary use area, the management plan must be jointly approved by the Tetlit Gwich'in and the Government.

c) Decisions regarding reburial, relocation or other disposition should be determined on a case by case basis in consultation with those concerned and in a timely manner.

Site disposition agreements shall determine such things as:
1. the interim care of the human remains*;*

2. the scope and extent of analysis to be performed on the human remains, if any;
3. the exact location of the place where the human remains are to remain or to be interred;
4. the style and manner of disinterment, if applicable;
5. the style and manner of reinterment, if applicable;
6. the time period in which disinterment and reinterment is to take place;
7. the procedures relating to, and the final disposition of any grave offerings discovered with the human remains and any additional analysis of them;
8. the provision for future maintenance of the cemetery or site where the human remains are to be located;
9. access to the site and ways to prevent disturbance;
10. any other issue agreed upon.

*it is often difficult to determine the cultural ancestry or affiliation of fragmentary human remains

4.2 When no representative is identified or no disposition is specified:

If disposition is not specified by a representative, or the remains are not claimed or no affiliation is established within a reasonable time, the Minister, or First Nation if on Settlement Land, shall with the necessary permits and approvals provide for the following disposition:

a) cover and leave the remains where they were found and have the site recorded as a burial site/ heritage site, if on land suitable for a burial site; or
b) have the remains disinterred and reinterred in the nearest appropriate cemetery; or
c) remove the remains from the site for analysis and may have them reinterred in a recognized cemetery or;
d) may act as the temporary repository of the remains.

(Where the remains were found on Settlement Land but are not considered First Nations remains, the Government may remove the remains in consultation with the First Nation.)

5. Arbitration

a) If no disposition agreement or management plan is reached within a reasonable time the matter may be referred to arbitration for settlement. If this matter concerns a Yukon First Nation Burial Site, this shall be done pursuant to 26.7.0 of the UFA; or Chapter 18, if the matter concerns a Tetlit Gwich'in site in the primary use area.

6. Records

a) A record of the site and a report of the discovery and disposition plan shall by kept by the Government and the affected First Nation(s)/representative for future reference to protect the site.

b) Access to information about discovered sites will be addressed in any site management plan developed under these guidelines, and will be protected under the *Access to Information and Protection of Privacy Act*, and the *Historic Resources Act* or *any similar First Nations legislation.*

Appendix 1

Definitions

burial site

the location of any human grave or remains that have been interred, cremated or otherwise placed, and include ossuaries, single burials, multiple burials; rock cairns; cave or cache burials etc. not situated within a cemetery

First Nation Burial Site

This refers to a Yukon First Nation Burial Site or a Tetlit Gwich'in burial site, which is defined as: a place outside a recognized cemetery where the remains of a cultural ancestor of a Yukon Indian Person (or the Tetlit Gwich'in) have been interred, cremated or otherwise placed."

[from the Definitions section of the *Umbrella Final Agreement for the Council for Yukon Indians (now Council of Yukon First Nations) and the Transboundary Agreement between Canada and the Gwich'in Tribal Council*]

human remains

mean the remains of a dead human body and include partial skeletons, bones, cremated remains and complete human bodies that are found outside a recognized cemetery" *(adapted from Historic Resources Act)*

grave offering

any object or objects associated with the human remains which may reflect the religious practices, customs or belief system of the interred.

historic

under the Historic Resources Act this generally means something older than 45 years.

land manager

Agency responsible for the administration of the land on which the site is located. For example, currently territorial parks are managed by Yukon Parks and Outdoor Recreation; gravel pits and rural airports are administered by Community and Transportation Services. Settlement Land is administered by the First Nation. Private land is administered by the land owner. (Burial sites may not be disturbed on any land without proper authorization.)

Recognized cemetery

a defined area of land that is set aside for the burial of human bodies.

representative

means a descendant of the interred or of the person whose remains are found, or where no descendant survives or is identified, an official representative of the appropriate First Nation in whose Traditional Territory the burial site is located or the closest culturally affiliated group, religious denomination, military or marine authority as evidenced by the location or mode of burial.

Where no representative can be determined the Minister shall act as the representative on Non-Settlement Lands and on Settlement Lands at the discretion and with the consent of the First Nation

representative group

means the appropriate Yukon First Nation or the closest culturally affiliated group, religious denomination, military or marine authority as evidenced by mode and style of burial which is willing to act as a representative.

Site disposition agreement

means a written agreement to be reached between the Director of the Heritage Branch and the representative of the interred regarding the disposition of the remains, including any disinterment and reinterment, and management plan

Management plan

means a plan to identify the roles of the representative, Government and land owner or manager respecting the care and protection of the site, including a consideration of site records, site access, and ways to protect a site from disturbance.

Appendix 2

Land Claims Provisions Relating to Burial Sites

13.9.0 Yukon First Nation Burial Sites*

13.9.1 Government and Yukon First Nations shall each establish procedures to manage and protect Yukon First Nation Burial Sites which shall:

13.9.1.1 restrict access to Yukon First Nation Burial Sites to preserve the dignity of the Yukon First Nation Burial Sites;

13.9.1.2 where the Yukon First Nation Burial Site is on Non-Settlement Land, require the joint approval of Government and the Yukon First Nation in whose Traditional Territory the Yukon First Nation Burial Site is located for any management plans for the Yukon First Nation Burial Site; and

13.9.1.3 provide that, subject to 13.9.2, where a Yukon First Nation Burial Site is discovered, the Yukon First Nation in whose Traditional Territory the Yukon First Nation Burial Site is located shall be informed, and the Yukon First Nation Burial Site shall not be further disturbed.

13.9.2 Where a Person discovers a Yukon First Nation Burial Site in the course of carrying on an activity authorized by Government or a Yukon First Nation, as the case may be, that Person may carry on the activity with the agreement of the Yukon First Nation in whose Traditional Territory the Yukon First Nation Burial Site is located.

13.9.3 In the absence of agreement under 13.9.2, the Person may refer the dispute to arbitration under 26.7.0 for a determination of the terms and conditions upon which the Yukon First Nation Burial Site may be further disturbed.

13.9.4 Any exhumation, examination, and reburial of human remains from a Yukon First Nation Burial Site ordered by an arbitrator under 13.9.3 shall be done by, or under the supervision of, that Yukon First Nation.

13.9.5 Except as provided in 13.9.2 to 13.9.4, any exhumation, scientific examination and reburial of remains from Yukon First Nation Burial Sites shall be at the discretion of the affected Yukon First Nation.

13.9.6 The management of burial sites of a transboundary claimant group in the Yukon shall be addressed in that Transboundary Agreement.

*This is an excerpt from the Umbrella Final Agreement between Canada, the Council for Yukon Indians and the Government of the Yukon (l993),Ch. 13, pp. 128-129, and subsequent Yukon First Nation Final Agreements.

9.5. Tetlit Gwich'in Burial Sites*

9.5.1 Government and Tetlit Gwich'in shall each establish procedures to manage and protect Tetlit Gwich'in burial sites which shall:

(a) restrict access to Tetlit Gwich'in burial sites to preserve the dignity of Tetlit Gwich'in burial sites;

(b) where the Tetlit Gwich'in burial site is outside the primary use area *(Fort McPherson Group Trapping Area)*, require the joint approval of government and the Yukon First Nation in whose traditional territory the Tetlit Gwich'in burial site is located for any management plans for the Tetlit Gwich'in burial site;

(c) where the Tetlit Gwich'in burial site is on land in the primary use area which is not Tetlit Gwich'in Yukon land, require the joint approval of government and the Tetlit Gwich'in for any management plans for the Tetlit Gwich'in burial site; and

(d) provide that, subject to 9.5.2, where a Tetlit Gwich'in burial site is discovered, the Yukon First Nation in whose traditional territory the Tetlit Gwich'in burial site is located or the Tetlit Gwich'in, if the Tetlit Gwich'in burial site is in the primary use area, shall be informed and the Tetlit Gwich'in burial site shall not be further disturbed.

9.5.2 Where a person discovers a Tetlit Gwich'in burial site in the course of carrying on an activity authorized by government, a Yukon First Nation or the Tetlit Gwich'in, as the case may be, that person may carry on the activity with the agreement of the Yukon First Nation in whose traditional territory the Tetlit Gwich'in burial site is located or the Tetlit Gwich'in if the Tetlit Gwich'in burial site is in the primary use area.

9.5.3 In the absence of agreement under 9.5.2, the person may refer the dispute to arbitration under chapter 18 of this appendix for a determination of the terms and conditions upon which the Tetlit Gwich'in burial site may be further disturbed.

9.5.4 Any exhumation, examination and reburial of human remains from a Tetlit Gwich'in burial site ordered by an arbitrator under 9.5.3 shall be done by, or under the supervision of, the Tetlit Gwich'in.

9.5.5. Except as provided in 9.5.2 to 9.5.4, any exhumation, scientific examination and reburial of remains from Tetlit Gwich'in burial sites shall be at the discretion of the Tetlit Gwich'in**.**

SECTION 1

Introduction

The existing Intermediate Dam (ID) spillway does not have the capacity to safely pass a moderate or major flood event without potentially overtopping and failing the dam, given a breach of the Rose Creek Diversion (RCD) dike and flooding of the Intermediate Impoundment (IP).) The Down Valley Interim Hydraulic Upgrades work package provides an upgrade to the hydraulic capacity of the ID spillway to safely pass a 1-in-500-year flood event, approximately equal to 115 cubic metres per second (m^3/sec), which is the sum of the peak flow into the RCD plus runoff from the watershed contributing to the IP. The increase in hydraulic capacity of the ID spillway will be accomplished by raising the effective height of the dam and by increasing the cross-sectional area of the spillway. The proposed work also includes improvements of the RCD to pass the 1-in-500-year flood event with freeboard.

These improvements to the ID and the RCD have been designed in accordance with the Faro Mine Remediation Medium Term Work Plan (Government of Yukon [YG], 2012).

On March 27, 2013, CH2MHILL prepared the Task Authorization 016A Down Valley Interim Hydraulic Upgrades Phase 1 Design Definition. This report was updated by the Task Authorization 016 Down Valley Interim Hydraulic Upgrades Phase 2 Basis of Design Report (BODR), published on November 25, 2013, as part of the Conceptual Design Phase (30 percent) submittal. The 30 percent BODR is updated by this 60 percent BODR. The BODR is a living document. It will be updated to a final BODR at the Detailed Design Phase (90 percent).

1.1 Task Authorization Purpose

CH2M HILL Canada Limited (CH2M HILL) is providing engineering, regulatory, and management support to the YG for submittal of the Faro Mine Remediation Project Proposal (Project Proposal) to the Yukon Environmental and Socio-economic Assessment Board. It may take several years (estimated at 2 to 4 years) to prepare the Project Proposal, and several more years (estimated at 4 to 6 years), to perform the final design, prepare contract documents, obtain a water licence, and initiate implementation of the final closure measures. It is therefore necessary that certain interim remediation activities take place to manage potential risks to human health and safety and to the environment at the Faro Mine Complex (FMC) during this interim period.

This Draft BODR was prepared to support the 60 percent design. The purpose of the Down Valley Interim Hydraulic Upgrades is to protect the ID until implementation of the final closure plan. It consists of the following project components:

- Increase the ID spillway capacity by deepening the spillway channel.
- Protect the ID spillway channel by placing gabion mattress on the channel surface and gabion cells on the channel sidewalls.
- Raise the effective ID crest by use of gabions and a geomembrane.
- Raise the crest of the RCD dike while meeting freeboard criteria.
- Remove vegetation and other debris from the RCD dike.
- Repair riprap and slope sloughing at some locations in the RCD.

Improvements to the ID spillway and crest are detailed in Section 5. Proposed modifications to the RCD are presented in Section 6.

1.2 Justification for Action

The existing ID spillway (with a capacity of 32 m^3/sec) cannot safely pass a moderate or major flood event without overtopping and potentially breaching the dam. Such ID failure may cause an environmentally damaging discharge of metals-laden tailings to the Rose Creek Valley, Anvil Creek, and the Pelly River. The discharge could result in a significant or major loss of critical fish and wildlife habitat that would be impractical or impossible to restore.

Failure of the Secondary Dam in 1975 within the Rose Creek Valley resulted in a loss of wildlife habitat, with little recovery evident more than 35 years later. Based on the threat to the environment and cultural values, KCB (2008) estimated that the ID has a "High" risk classification. This classification was made in the absence of a formal dam breach and inundation study. YG will be conducting dam breach and inundation studies for the ID and the Cross Valley Dam (CVD) in the near term. These studies will assess downstream consequences of dam failure and may result in a modification of the hazard classifications for these facilities.

In accordance with Canadian Dam Association (CDA) regulations, the required capacity of the permanent ID spillway depends on the hazard classification of the dam. A hazard classification of "High" requires safe passage of an inflow design flood (IDF) with a magnitude of 1/3rd between a 1-in-1,000-year flood event and the probable maximum flood (PMF); a hazard classification of "Extreme" requires safe passage of an IDF equal to the PMF. The permanent spillway construction, however, is a major undertaking that is impractical to implement during Phase 2B because of (1) limitations in time and funding and (2) the need to first submit the permanent spillway concepts to Yukon Environmental and Socio-economic Assessment Board and regulators for environmental and socio-economic assessment and approval before its final design and implementation. The Down Valley Interim Hydraulic Upgrades are intended to temporarily protect the ID until implementation of the final closure plan.

Results of hydraulic analyses demonstrate that the proposed interim upgrades will increase the ID spillway capacity to 115 m^3/sec, equal to the estimated 1-in-500-year flood event peak flow, assuming attenuation of flood flows through the North Fork Rock Drain (NFRD) on the North Fork of Rose Creek (NFRC). Peak flood flows will also be attenuated as the flood is routed through the ID impoundment. Estimates of flow attenuation through the NFRD are discussed in Section 4.2.

An increase in ID spillway capacity will also provide mitigation for other RCD failure mechanisms. These include: (1) failure of the RCD dike by piping or slope instability during moderate flood events, (2) landslide or debris flow originating on the mountainous slopes to the south of the RCD that would block the RCD and cause overtopping of the RCD dike, and (3) icing buildup in the RCD resulting in overtopping of the RCD dike.

1.3 Scope of Work

The scope of work for the Design Definition Phase includes the work elements discussed in the following sections.

1.3.1 Design Criteria and Basis of Design

The following tasks were performed to establish a basis for the Down Valley Interim Hydraulic Upgrades design:

- Define design criteria for the Down Valley Interim Hydraulic Upgrades, including the NFRD.
- Perform hydrological and hydraulic analyses to estimate the flows for the IDF, which is the 1-in-500-year flood event for the interim upgrades.
- Evaluate the adequacy of the NFRD to remain stable during large flood events. Perform ravelling and slope stability evaluations to gain an understanding of embankment stability. Consider other potential failure modes such as wash-out of finer particles in the schistose fill resulting in piping.
- Prepare the BODR, addressing including the following:
  - Project description, project objectives, and design criteria
  - Hydrologic and hydraulic analyses
  - Stability analyses of the NFRD
  - Pipeline relocations design criteria

1.3.2 Surveying & Mapping

In 2010, Challenger Geomatics Ltd. set nine permanent control monuments at the FMC. Permanent control points have been selected near the project area and identified on the drawings to be used for construction staking. All control monuments and project mapping data is based on the following datum:

- Horizontal Geodetic Datum: North American Datum of 1983 Canadian Spatial Reference System Epoch 2002 (NADD83 CSRS)
- Map Horizontal Projection: Universal Transverse Mercator Zone 8 North
- Vertical Geodetic Datum: Canadian Geodetic Vertical Datum of 1928 Height Transformation version 2.0 (CGVD28 HT version 2.0)
- Units: Metres

Light detection and ranging (LiDAR) data and aerial photos of the FMC were acquired by BGC Engineering (BGC) and Terra Remote Sensing Inc. for YG. The data was acquired in October 2011, with a proprietary camera and LiDAR system mounted in the same aircraft; the photography and LiDAR were taken simultaneously. The data was used to develop the contours of the project area, as shown on the construction staking drawings and InRoads digital terrain models (DTM). The DTMs are used for design as well as determining earthwork quantities.

In August 2012, CH2M HILL acquired aerial photography and aerial triangulation files from Eagle Mapping through its subconsultants, Peregrine Aerial Surveys Inc. and 4DGIS Ltd., respectively. The aerial photography is referred to as follows:

- Project Area: Low-altitude photography
- Extended Area: High-altitude photography

The planimetric mapping shown on the drawings was gathered at approximate true 3D elevations using low-altitude stereo photography. Features gathered included major flow lines, major water edges, road edges, culverts, buildings, aboveground utilities, fences, walls, and major berms. The mapping scale is 1:600. Water lines were provided in Microstation V8i curve string format, and a stroked polyline (line string) format for optimized use in a geographic information system and other software.

A bathymetric survey was conducted by Challenger Geomatics, Ltd. on 4 and 5 July 2013 to define the topography beneath the water surface for the impound area upstream from the NFRD. This data was incorporated into the project mapping files and DTMs.

1.3.3 Drawings

This task entails preparation of conceptual, advanced, and detailed drawings of the planned upgrades. See Appendix A, Advanced Design Drawings (60 percent).

1.3.4 Field Exploration Program

The increase in hydraulic capacity of the ID spillway will be accomplished by raising the effective height of the dam and by increasing the cross-sectional area of the spillway. Raising the dam will be accomplished by embedding a vertical geomembrane in a longitudinal trench and extending the geomembrane up and over a single row of gabions, whereas the spillway capacity increase will be accomplished by excavating the bottom of the existing spillway channel and hardening it with gabion mattresses.

A field exploration program was performed in 2013 to support the design of the Down Valley Interim Hydraulic Upgrades. The Task Authorization Request (TAR) 16 Data and Analysis Report is in progress and will be bound and submitted separately from this report. The scope of the fieldwork included the following:

- Seven test pits were excavated on the crest of the ID to confirm the depth to the top of the ID core material and to obtain information about trench stability for the geomembrane installation.
- Three test pits were excavated within the ID spillway channel to assess difficulty excavating the channel.
- Fieldwork was conducted to evaluate requirements for increasing the hydraulic capacity of the RCD. The length of the RCD was field-mapped to determine the following:
  - Locations and areas along the channel bank requiring vegetation removal

  - Locations and areas where sloughing of the dike slopes has occurred and zones where riprap has ravelled or slid into the channel
  - Areas or zones of depressions in the RCD dike crest, including an estimate of the extent and depth of the depressions
- Periodic flow monitoring was performed during the spring freshet in the NFRC, upstream and downstream from the NFRD. Stage readings were obtained at NF1 and NF2 monitoring locations. Discharge was measured just downstream from the NFRD or at the X2 monitoring location. Flow was previously measured in 2005 and 2006 at five locations (R7 gauge, NRFC 20/21 upstream from the NFRD pond, the NFRD pond, NRFC 22/23 downstream from the NFRD, and X2 gauge) (BGC, 2006). This data was used to evaluate the flood attenuation characteristics of the NFRD, as well as the potential for pounding behind the Haul Road embankment.
- Two geotechnical boreholes were advanced at the downstream toe of the NFRD to obtain samples for laboratory testing, to estimate the shear strength and index properties of the foundation material.

1.3.5 Hydraulic and Hydrologic Analysis and Modelling

Hydrological and hydraulic analyses were performed to estimate the flows (discharge) for the design flood event. These flows were determined separately for the South Fork Rose Creek (SFRC), NFRC, south slope area discharging to the RCD, and tailings area discharging to the ID impoundment. The task includes the following hydrological and hydraulic modelling components:

- Hydrology:
  - Determine the design peak instantaneous discharge for NFRC, SFRC, south slope, and tailings area catchments
  - Determine design flood hydrographs for the 1-in-500-year flood event for NFRC, SFRC, south slope, and tailings area catchments
- Hydraulics:
  - Evaluate attenuation characteristics of the NFRD by estimating the flow-through capacity of the NFRD. Field stage and discharge measurements upstream and downstream from the NFRD were used as an initial starting point for determining flow-through characteristics during normal and low flow conditions. Theoretical relationships were used to estimate flow-through capacity during large floods, since field observations are not available to validate flow-through characteristics during such events.
  - Perform one dimensional (1D) hydraulic modelling to route the 1-in-500-year flood event flows from the NFRC, SFRC, south slope, and tailings area catchments to the RCD and tailings areas. Create design hydrographs at the head of the RCD, RCD downstream of the overflow weir, and the ID impoundment for the design recurrence interval event.
  - Perform two dimensional (2D) hydraulic modelling to route the 1-in-500-year flood event through the tailings, the RCD, the overflow weir, Intermediate Impoundment, and the ID spillway.
  - Model the overflow weir to estimate requirements for bypassing the 1-in-500-year flood event without overtopping.
  - Model the ID spillway with the proposed improvements in place.
  - Complete 2D model simulations to evaluate the effect of vegetation removal in the RCD.
  - Perform breach analysis of the NFRD to evaluate downstream flood inundation levels and incremental damage to the dams in the tailings area. Run the 2D model to simulate propagation of flood waves for embankment breach during the 1-in-500-year flood event for different NFRD flow-through scenarios, i.e. for different impoundment volumes and heights. The purpose of performing breach analyses for various flow-through assumptions is to develop an understanding of how sensitive the consequence of

NFRD failure is to the flow-through capacity and blockage of the NFRD. This information can assist in decision making for the interim period and for final closure.

1.3.6 Evaluation of North Fork Rock Drain

The NFRD provides a porous conduit for conveyance of NFRC flows through the Haul Road. A pool forms on the upstream side of the Haul Road embankment as water enters the rock drain. During the freshet, flood events, and other higher flows, the size of the pool increases as flows exceed the flow-through capacity of the rock drain. The rock drain reduces flow velocity, attenuates flows downstream, and collects sediment and debris.

Because failure of the Haul Road embankment during an extreme high flow event has the potential to adversely impact RCD and the ID, analyses were conducted to evaluate: (1) the flow-through capacity of the rock drain, and (2) the stability of the structure under high flow conditions.

The Golder Associates (Golder) design and some inspection reports of the NFRD were reviewed. The results of this review are provided in Appendix I. The appendix also includes a review of the design, construction, and performance of rock drains in general.

The stability evaluations considered the following: (1) slope stability failure under various water levels, and (2) ravelling failure initiated by high discharge velocities exiting the downstream toe of the rock drain. The results of these analyses are provided in Appendix B. These evaluations were performed because it was practical to do and useful to gain understanding of the embankment stability. It is noted, however, that there are other potential failure modes that could be more critical, but are difficult or impossible to evaluate. One such failure mode is wash-out of finer particles in the schistose rockfill resulting in a preferential seepage path and eventual piping of the embankment.

1.3.7 Future Work

The Medium Term Plan identifies the following additional work to be completed for the Down Valley Interim Hydraulic Upgrades:

- Final design, including preparation of detailed, and final contract documents
- Procurement assistance, including preparation of tender-ready subcontract documents plans and specifications and contract assistance
- Permitting
- Construction management, including services during construction and onsite inspections

The work will be initiated and completed within 3 fiscal years. A field investigation and preparation of the 30 percent design was completed and submitted November 25, 2013. Advanced Design (60 percent) and Detailed Design (90 percent) will be completed in the 2013/2014 fiscal year; Final Design (100 percent) and preparation for procurement will be completed in the 2014/2015 fiscal year; procurement will be conducted in 2015/2016 fiscal year; and construction will be conducted in 2016/2017 fiscal year. The construction will be conducted during the summer of 2016 (see Appendix G, Construction Schedule).

SECTION 2

Background

2.1 Description of Existing Elements

Approximately 28.6 million cubic metres (m^3) of flotation-derived process tailings were deposited in the Rose Creek Tailings Area between 1969 and 1998. The tailings are contained by a series of three dams constructed across the Rose Creek Valley. Faro Mill production records indicate that the tailings have an average concentration of lead, zinc, and copper equal to 0.8 percent, 1.3 percent, and 0.12 percent, respectively. Oxidation of the sulfides results in production of low pH (acidic) water with elevated concentrations of sulfate, zinc, and other metals. These metals are toxic to aquatic and terrestrial life.

The existing ID spillway has a capacity of about 32 m^3/sec when the pool reaches the top of the dam core (Northwest Hydraulic Consultants, Ltd. [NHC], 2006). The 1-in-500-year flood event is estimated to have a flow equal to approximately 115 m^3/sec, which includes attenuation by the North Fork Rock Drain and by the Intermediate Impoundment. NHC [2006] estimated that a 1-in-500-year flood event, without attenuation by the NFRD, would have a flow equal to 132 m^3/sec at the ID spillway.

The RCD channel is approximately 4.7 kilometre-long and conveys Rose Creek around the Rose Creek Tailings Area. The diversion was originally designed to carry a 1-in-50-year flood event (approximately 79 m^3/sec) with 1 m of freeboard. It was later modified to convey approximately 140 m^3/sec, approximately equal to the estimated 1-in-500-year flood event without flood attenuation of the NFRD (BGC, 2006; NHC, 2006).

The RCD dike includes a lowered “overflow weir” section which provides an initiation point for overtopping of the RCD dike during flood events. The overflow weir is armored with riprap and large diameter riprap which, by inspection, appears to reduce its erodibility. The existing condition of the RCD is such that vegetative growth and other channel maintenance related issues have decreased the flow capacity at the overflow weir to less than the 1-in-50-year flood flow before overtopping.

Because the RCD dike was constructed on top of frozen ground, the condition of the dike and its performance during large storm events is uncertain. In a large storm event, the overflow weir or another location along the RCD dike could fail, resulting in flooding of the Intermediate Impoundment and overtopping the ID. Depending on the magnitude of the storm event, overtopping the dam could result in minor erosion failures, or under extreme events, could potentially breach the dam. An ID failure and breach would result in tailings-laden water flowing into the Cross Valley Dam Pond, through the CVD, spillway and beyond into Rose Creek and the downstream environment.

2.2 Proposed Project Components

The proposed Down Valley Interim Hydraulic Upgrades will consist of the following elements:

- Increase the existing ID spillway capacity by: (1) increasing the effective depth of the existing spillway channel and (2) increasing the effective height of the ID embankment crest. The proposed modifications will enable the ID Spillway to pass the 1-in-500-year flood event including attenuation by the NFRD and the Intermediate Impoundment, with a freeboard of 1.0 m. The analysis assumes that the overflow weir has completely eroded, resulting in the entire RCD flow being conveyed into the Intermediate Impoundment.

- Protect the ID spillway channel from erosion by installing gabion mattresses along the bottom and gabion retaining structures along the side walls.
- Relocate the existing effluent piping within the ID spillway.
- Increase the RCD capacity to pass the 1-in-500-year flood event by raising the RCD dike by approximately 0.5 m, removing vegetation within the RCD and along the RCD dike slope and 5 m beyond the toe, and repairing or restoring slopes on the RCD banks.

2.3 Design Criteria

The development of design criteria for the Down Valley Interim Hydraulic Upgrades project is discussed in this section. The proposed improvements are intended to reduce risk for an interim period only; therefore, the design criteria for this project are less stringent than the criteria for final closure. To provide context and background, the final closure design criteria are also provided in this section. These criteria, specifically the level of seismic and flood loading, generally depend on the hazard classification of the dam.

The design criteria presented here apply to the following project elements:

- ID
- CVD
- Overflow weir
- RCD
- NFRD

2.3.1 Hazard Classification

The CDA dam safety guidelines (CDA, 2007) are used to classify the hazard level of a dam based on the impacts on the public and the environment from the effects of a dam failure.

2.3.1.1 Intermediate Dam

The most severe consequences of a dam breach are associated with the ID, which contains more than 11.9 million m^3 of copper, lead, and zinc-laden tailings that are toxic to aquatic and terrestrial life. The total tailings volume of all three impoundments (original, secondary, and intermediate) is 28.6 million m^3 (Robertson GeoConsultants Inc., 1996). KCB (2008) estimated that the ID has a “High” risk classification; however, the estimate was made in the absence of a formal dam breach and inundation study. YG will be conducting dam breach and inundation studies for the ID and the CVD in conjunction with the 2014 dam safety evaluation.

Improvements to increase the capacity of the ID spillway consist of two elements: (1) enlarging and reinforcing of the spillway, and (2) moderately raising the effective dam crest. Analysis results presented in this BODR indicate that the modifications proposed in the Medium Term Plan (YG, 2012) will result in an increase in capacity sufficient to safely pass a 1-in-500 year flood event. The analysis described herein confirms this estimate. The proposed modifications will increase the safety of the ID in the interim period while the field investigation, planning, and design take place to construct a spillway for final closure.

2.3.1.2 Cross Valley Dam

The CVD has the same hazard classification as the ID. The main hazard from a CVD breach is not only the uncontrolled release of water from the Cross Valley Dam Pond, but sudden release of the polishing pond could also cause significant danger to the ID. The ID does not have filter and drainage systems in the lower part of the embankment below the downstream bench, and instead depends on the polishing pond to provide a counterbalancing hydrostatic head to reduce seepage and the need for filtering. A sudden drawdown of the pond is likely to result in significant seepage from the saturated ID downstream slope, which in turn could lead to progressive sloughing, even more seepage, possible backward erosion, and eventually could result in piping or loss of the crest from larger slope stability failures.

No changes are proposed to the CVD spillway. Its spill capacity of about 300 m^3/s significantly exceeds the new updated ID spillway capacity of 115 m^3/s.

TABLE 2-1
Dam Classification – CDA 2007
Faro Mine Remediation Project

Dam Class	Population at Risk [a]	Incremental losses		
		Loss of Life [b]	Environmental and Cultural Values	Infrastructure and Economics
Low	None	0	Minimal short-term loss No long-term loss	Low economic losses; area contains limited infrastructure or services
Significant	Temporary only	Unspecified	No significant loss or deterioration of fish or wildlife habitat Loss of marginal habitat only Restoration or compensation in kind highly possible	Losses to recreational facilities, seasonal workplaces, and infrequently used transportation routes
High	Permanent	10 people or fewer	Significant loss or deterioration of *important* fish or wildlife habitat Restoration or compensation in kind highly possible	High economic loses affecting infrastructure, public transportation, and commercial facilities
Very High	Permanent	100 people or fewer	Significant loss or deterioration of *critical* fish or wildlife habitat Restoration or compensation in kind possible but impractical	Very high economic losses affecting important infrastructure or services (e.g., highway, industrial facility, storage facilities for dangerous substances)
Extreme	Permanent	More than 100 people	Major loss of *critical* fish or wildlife habitat Restoration or compensation in kind impossible	Extreme losses affecting critical infrastructure or services (e.g., hospital, major industrial complex, major storage facilities for dangerous substances)

[a] Definitions for population at risk:

None = There is no identifiable population at risk, so there is no possibility of loss of life other than through unforeseeable misadventure.

Temporary = People are only temporarily in the dam-breach inundation zone (e.g., seasonal cottage use, passing through on transportation routes, participating in recreational activities).

Permanent = The population at risk is ordinarily located in the dam-breach inundation zone (e.g., as permanent residents); three consequence classes (high, very high, extreme) are proposed to allow for more-detailed estimates of potential loss of life (to assist in decision making if the appropriate analysis is carried out).

[b] Implications for loss of life:

Unspecified = The appropriate level of safety required at a dam where people are temporarily at risk depends on the number of people, the exposure time, the nature of their activity, and other conditions. A higher class could be appropriate, depending on the requirements. However, the design flood requirements, for example, might not be higher if the temporary population is not likely to be present during the flood season.

2.3.1.3 Secondary Dam

A breach of the Secondary Dam (SD) could lead to a loss of tailings into the environment, but the magnitude of such a tailings loss would be much smaller and more contained than the tailings loss associated with an ID breach. Whereas the ID and CVD need to accommodate hydraulic (flood) loading, as well as seismic (earthquake) loading, the SD only needs to be designed for seismic loading. Seismic loading could cause liquefaction of the dam foundation, and specifically at the locations where Rose Creek sediments are present in the foundation of the dam. At the West Limb, which is the curved portion of the SD that crosses the valley roughly north to south, tailings are present on the downstream toe of the SD. These tailings would prevent failure of the dam during seismic loading even if the foundation soils liquefy. Even if some tailings loss would occur along this portion, the tailings are likely to be contained within the Intermediate Impoundment.

A breach of the East Limb of the SD, which is the portion of the SD parallel to the RCD and without tailings at the toe, could result in tailings flowing into the RCD. It is noted that the likelihood of tailings loss is low even when losing a portion of the East Limb crest; given that the upper layers of the secondary tailings are not saturated and given the relatively small height of about 4.6 m. KCB (2008) did not estimate the risk classification for this dam.

2.3.1.4 North Fork Rock Drain

Although the Haul Road embankment, including the NFRD, was not designed or intended to impound water, it will likely retain a significant pool of water temporarily during very large flood events. The retained volume depends on the flow-through capacity of the rock drain. A high flow-through capacity would result in a smaller volume of retained water; whereas a low flow-through capacity would result in larger volumes of water retained. Because of the uncertainty in the adequacy (stability) of the NFRD to serve as a water-retaining structure under flood conditions, a breach analysis was conducted to evaluate the potential effects on the RCD and ID if failure of the NFRD occurs during a 1-in-500-year flood event. Because flow-through capacity during large storm events is uncertain and difficult to evaluate or estimate, sensitivity analyses were conducted for different flow-through assumptions, including different assumptions of blockage by debris.

2.3.2 Preliminary Design Criteria for Final Closure

Table 2-2 provides the CDA guidelines (CDA, 2007) for required spillway capacity and stability under earthquake conditions based on the dam risk classification. Design criteria for the tailings and other dams at the FMC facilities are not only dictated by the CDA classification of the dams, but were also a condition of the expired water licence. Clause 58 of the expired water licence (Water Use Licence QZ03-059) states that a final closure and reclamation plan for the FMC facilities shall incorporate the following design standards and requirements:

- All decommissioned tailings-related facilities and structures shall be designed to withstand the maximum credible earthquake and the PMF
- Long term physical stability of all watercourses and tailings deposits shall be ensured, with minimum post-operational maintenance
- The long-term water quality in Rose Creek downstream from the tailings facilities shall comply with the *Canadian Water Quality Guidelines for the Protection of Aquatic Life* (Canadian Council of the Ministers of the Environment, 1999)

Based on both the requirements of the expired water licence as well as the CDA guidelines, the recommended design criteria for final closure for each of the dams are interpreted as follows:

- The ID and SD shall be required to withstand an earthquake event with a recurrence interval of 10,000 years, which can be considered the maximum credible earthquake. These dams shall also be required to withstand or pass the PMF.
- The final closure concepts for the CVD have not been determined at this time, but it is unlikely to continue to function as a polishing pond. In the future it is likely to be operated in a dewatered state and will only contain significant amounts of liquid when needed for emergency storage. Since it will generally be empty, it is not considered necessary to design the dam for the maximum credible earthquake, but to design it to withstand

the 1-in-500-year earthquake. Considering hydraulic loading, however, it is recommended that the CVD be required to pass the PMF, since it would contain a significant pool during flood loading conditions. In addition, the CVD is the last dam in a series of dams, where the upstream dams (SD and ID) will be required to pass the PMF.

- Similarly, the final closure concepts for the NFRD have not been established. If the structure is retained in its current configuration, it could act as a temporary impoundment during large to very large floods. The likelihood of having a large flood occurring at the same time as a large earthquake is remote. It is therefore anticipated that the NFRD will only have to be designed for a 1-in-500-year earthquake, since there will be no significant pool and associated consequence of failure for most of the time. Given that the ID needs to be designed for the PMF, and the fact that a breach of the NFRD could result in overtopping and breach of the RCD dike and the ID, it is anticipated that the NFRD will also be required to pass the PMF.

TABLE 2-2
CDA Dam Safety Guidelines – Suggested Design Flood and Earthquake Levels for Use in Deterministic Assessments
Faro Mine Remediation Project

	Annual Exceedance Probability	
Dam Class [a]	**Inflow Design Flood [b]**	**Earthquake Design Ground Motion**
Low	1/100	1/500
Significant	Between 1/100 and 1/1,000 [d]	1/1,000
High	1/3 between 1/1,000 and PMF [e]	1/2,500[f]
Very high	2/3 between 1/1,000 and PMF [e]	1/5,000[f]
Extreme	PMF[e]	1/10,000

[a] As defined in Table E4-1 Dam Classification – CDA 2007.

[b] Extrapolation of flood statistics beyond 1/1,000-year flood (10^{-3} annual exceedance probability) is discouraged.

[c] Annual exceedance probability levels for earthquake design ground motion are to be used for mean rather than median estimates of the hazard.

[d] Selected on the basis of incremental flood analysis, exposure, and consequences of failure.

[e] PMF has no associated annual exceedance probability. The flood defined as "1/3 between 1/1,000 year and PMF" or "2/3 between 1/1,000 year and PMF" has no defined annual exceedance probability.

[f] The earthquake design ground motion value must be justified to demonstrate conformance to societal norms of acceptable risk. Justification can be provided with the help of failure modes analysis focused on the particular modes that can contribute to failure initiated by a seismic event. If the justification cannot be provided, the earthquake design ground motion should be 1/10,000.

2.3.3 Design Criteria for the Interim Period

The final closure plan for the FMC will take several years to prepare and initiate construction, therefore it is necessary to provide adequate levels of security of the dams and to implement early remediation activities necessary to manage potential risks to human health and safety, and to the environment during the interim work. Until the closure conveyance strategy and structures are agreed upon and implemented, it is proposed that the existing conveyance structures are designed to safely convey a 1-in-500-year flood event. The criteria will be consistent with the conditions of the expired water licence (Water Use Licence QZ03-059), which states:

> *40. The Rose Creek Diversion shall have a capacity to carry a 1:500 year design flow.*
>
> *41. The spillways on the Intermediate Dam and the Cross Valley Dam shall have a capacity to carry a 1:500 year design flow of Rose Creek.*
>
> *42. The overflow structure on the Rose Creek Diversion Dam shall be maintained to ensure that peak flows can freely pass through it.*

To justify this criteria, the likelihood of a 1-in-500-year flood event during an interim period of 10 years was compared with the likelihood of exceeding the design flows for typical design diversions for constructing high hazard dams; typically, the diversions are designed for a 10- to 20-year flood event with the diversion in place for 2 to 3 years. The likelihood that a 10-year flood or greater could occur during a 2-year construction period is 18 percent, whereas the likelihood that a 1-in-500-year flood event or greater could occur during a 10-year period is 2 percent. If it is assumed that the PMF would have a recurrence interval of 10,000 years, the likelihood that it could occur during a 100-year period is about 1 percent. It appears appropriate that the tailings dams be designed for a flood event with a much lower annual probability of occurrence than for a temporary diversion, given that the consequence of failure for the tailings dams could be significantly higher than consequence of failure of typical diversion works. On the other hand, it also seems appropriate to design it to a flood event with a higher annual probability of occurrence than that of the permanent dam.

Since the NFRD will be in operation for the interim period, flood flows through the NFRC will be attenuated by the structure. To calculate the 1-in-500-year flood event flows, as required in the design criteria stipulated by the water licence, the effects of attenuation of the NFRD will be taken into account. Flow-through calculations indicate that the NFRD could attenuate peak flows during a 1-in-500-year flood event by 18 to 38 percent. Peak flows could be further attenuated by a reduction in flow-through capacity at the NFRD caused by debris blockage or other processes that may occur during a flood of such magnitude. It is recommended that some modest amount of freeboard (for example, 0.5 m) be included in the capacity estimation for the RCD.

The specific approaches and assumptions for each of the project elements are discussed below.

2.3.3.1 ID Spillway and Crest

The following approach is incorporated for design improvements to the ID spillway:

- Assume that the IDF (1-in-500-year flood event) will be directed onto the Intermediate Impoundment, due to a breach of the RCD dike.
- Proposed improvements to the ID spillway and crest will increase the spill capacity such that the spillway will be able to accommodate the 1-in-500-year flood event flowing into the RCD. The improvements will consist of two elements:
  - Enlarging the spillway channel by excavating the bottom of the channel, and hardening or reinforcing the excavated channel using gabions on the side slopes of the channel and a gabion mattress along the bottom of the channel
  - Raising the effective dam crest elevation by excavating a trench into the top of the dam core and installing a geomembrane vertically in the trench between the dam core and the crest surface, and placing a single row gabion cells along the embankment crest to raise the effective crest of dam.

2.3.3.2 Rose Creek Diversion Overflow Weir

The following applies for designing improvements to the overflow weir:

- Although the overflow weir has been referred to as a “fuse plug” in previous studies, there is uncertainty whether this structure will breach soon after being overtopped. The existing structure is heavily armored with large diameter riprap and conveys overflow or breached flows out onto the tailings area through a dedicated relief channel.
- Since it is not desirable that the overflow weir breach for floods smaller than the 500-year flood event, the structure will be raised to prevent overtopping for floods less than this event. No other structural modifications to this structure are being considered to achieve specific breach performance criteria for the interim period. Both scenarios: full breach or overflow without breaching is considered plausible after the 500-year flood event flows are exceeded. For final closure, it is anticipated that this structure will be replaced with a hardened overflow structure with sufficient spill capacity to pass the PMF.

- The overflow weir provides an outlet for flows higher than the 1-in-500-year flood event to prevent overtopping of the RCD dike over its downstream reaches. The crest of the overflow weir will be raised to contain the 1-in-500 year flood event with zero freeboard.

2.3.3.3 Rose Creek Diversion

The following applies for designing interim improvements to the RCD:

- The RCD dike will accommodate the 1-in-500-year flood event with a 0.5 m freeboard.
- In addition to raising the crest of the RCD dike to meet freeboard criteria, vegetation needs to be removed from the dike and riprap; several slopes which have sloughed or are otherwise unarmoured will be repaired.

  Reasons for vegetation removal include the following: (a) allow proper inspection, surveillance, and monitoring for seepage, cracking, displacement, and any other signs of distress in the dike; (b) allow access for operations and maintenance activities; (c) prevent root-related damage, such as shortened seepage paths through the dike or its foundation, and voids in the dike or its foundation due to decayed roots or fallen trees; and (d) limit those habitat characteristics that encourage the creation of animal burrows.
- Slope repair to augment and replace riprap erosion protection is necessary to maintain uniform protection against erosive water forces up to the crest elevation of the RCD dike. Dike slopes will be graded to 2:1 (horizontal to vertical), and armoured with appropriately sized riprap. The higher gradient stepped sections of the RCD which are armoured with large diameter riprap do not require extensive treatment except to replace large boulders which may have been displaced from the dike side slopes. Note that riprap placement is not required on the RCD dike embankment upstream of the overflow weir due to the wide channel geometry and low predicted channel velocities.

2.3.3.4 North Fork Rock Drain

The following applies for designing interim improvements to the NFRD:

1. The adequacy of the Haul Road embankment, including the NFRD, as a water-retaining structure should be considered in the context of the objective of the Down Valley Interim Hydraulic Upgrades, which is primarily to protect the ID until implementation of the final closure plan. If a 500-year flood could result in failure of the Haul Road embankment, the objective of the Down Valley Interim Hydraulic Upgrades would be compromised. Perform breach analyses of the NFRD to evaluate the consequences of failure of the NFRD under the 1-in-500-year flood event. Perform stability evaluations and review design and as-build information of the NFRD to evaluate its likelihood of failure.
2. Maintenance should be conducted on the upstream face of the NFRD to remove debris.
3. In order to develop a better estimate of the flow through capacity of the NFRD, the pool elevation should be measured during significant storm events. Stream flow should be measured upstream and downstream of the Haul Road.

2.3.3.5 North Fork Rock Drain Flood Attenuation Approach

The haul road embankment contains a 70-m-wide zone constructed of calcium-silicate rock. This zone, which is centered on the pre-existing channel, is the NFRD. On both sides of the NFRD, the Haul Road embankment fill consists of schistose rock. The BGC report titled *Task 22D: North Fork Rock Drain*, dated September 15, 2006, provides a basis for evaluation of flood attenuation through the NFRD. The report provides details of the as-built conditions of the NFRD, as well as summaries of construction observations and the design criteria used for the original design.

The flow of water through the rockfill does not follow Darcy's Law, but follows rules related more to turbulent flow. The first memorandum in the BGC report describes the theoretical basis for flow-through rockfill, and recommends that the Wilkins equation be used to estimate flow through the NFRD.

The historical stage (pond level) -discharge relationships developed by Golder (1986, 1988) and BGC (2006) for smaller flood events (spring freshet flows) are used as the initial bases for flood attenuation. To provide a

conservative estimate of peak flow rates during non-breach events for the RCD, zero plugging by debris and a high flow-through capacity is assumed. For evaluation of breach impacts, a medium flow-through scenario, low flow-through scenario, and a low flow-through scenario with increasing levels of debris blockage was considered to determine what conditions may lead to an overtopping of the ID crest.

SECTION 3

Evaluation of North Fork Rock Drain

3.1 Description and Basis of Design

The basis of design of the NFRD is available as documented in the Golder Design Report (1986). Following construction in 1987, Golder inspected and assessed the performance of the rock drain (Golder, 1991, 1993).

To date, the NFRD has performed satisfactorily. The maximum recorded flow through the structure as of 2009 was 22 cubic metres per second (m^3/sec)(Ferris, 2009). The following list summarizes the key design information specified by Golder (1986), as summarized by BGC Engineering (BGC, 2006):

- The drain was to be constructed from calcium-silicate rock, whereas the remainder of the Haul Road could be constructed of schistose rock.
- The design flood for this structure was the 100-year return period flood event (70 m^3/sec).
- The width of the calcium-silicate rock drain was intended to be 70 m, centered on the pre-existing creek channel
- The construction of the NFRD included rock end-dumped from the final road elevation; the final height was approximately 55 m. This method resulted in a natural sorting of the rock, with the largest rocks at the base of the road and the fine material near the top.
- The assumed slope of the upstream and downstream faces of the drain was 37 degrees, the angle of repose for calcium-silicate rock.
- The design assumed that the drain would consist of the lower 3.6 m of the causeway. The representative grain size was assumed to be 0.3 m, given the likely maximum particle size and an allowance for particle breakage due to the overlying weight of the rockfill.
- To determine the capacity of the drain, it was assumed no flow occurred in the upper portions of the rock drain (above 3.6 m drain). The routing analysis indicated that the 100-year flood would produce a 40-m deep pool on the upstream side of the drain, and that the mean annual flow would result in an 11-m deep pool.
- The downstream face of the drain (if left at the assumed angle of repose, 37 degrees) was considered to be unstable under high flows, because of seepage forces. The design included the construction of a “fillet” of large diameter rock, to be installed at the downstream toe. The fillet, which was intended to stabilize the toe from seepage forces, was to have a minimum slope of 3H:1V, and extend to 15 m or more above the toe of the drain. This fillet was never constructed.
- The original design included the construction of an emergency overflow spillway and the abandonment of the NFRD; the spillway was never built and the NFRD remains.

Photos and descriptions indicate that the Haul Road embankment was constructed across an unprepared foundation surface on the valley bottom. Trees, peat, topsoil, and other native materials were not removed prior to construction of the Haul Road embankment and NFRD. During construction, a bulldozer was used to position large rocks in the channel of the NFRC. Outside the calcium-silicate NFRD prism, the Haul Road embankment was constructed of similarly end-dumped schistose (phyllite) rock. This rock is considerably less durable and more prone to breakdown than the calcium-silicate comprising the rock drain.

3.2 North Fork Rock Drain Failure Consequence

Stability of the Haul Road embankment, including the NFRD, must be considered in the context of the objective of the Down Valley Interim Hydraulic Upgrades, which is primarily to protect the ID until implementation of the final closure plan. If a 500-year flood is likely to result in failure of the Haul Road embankment, the objective of the Down Valley Interim Hydraulic Upgrades could potentially be compromised. To evaluate the consequences of

failure under the 1-in-500-year flood event, breach analyses of the Haul Road embankment were performed. The analyses were performed for the following: (1) a best estimate flow-through scenario, (2) a low flow-through scenario, and (3) a low flow-through with 25-percent blockage scenario.

The breach analyses and downstream inundation results are presented in Section 4.

Results from the breach analyses indicate that for the best-estimate scenario (resulting in a relatively smaller pool retained by the NFRD), a breach of the NFRD would result in flows that should be contained within the RCD. Overtopping of the SD, the RCD dike, or the ID would not occur.

For the low flow-through scenario and low flow-through with 25-percent capacity reduction scenario, the flood wave resulting from the breach would exceed the RCD capacity, resulting in overtopping of the RCD dike, spill onto the Secondary Tailings Area and the Intermediate Impoundment. The flood wave would exceed the capacity of the proposed ID spillway and overtop the ID.

The potential breach mechanism assumed in the breach analysis is piping through the schistose fill material or through the foundation.

3.3 North Fork Rock Drain and Haul Road Embankment Stability

3.3.1 Reference Documentation

Available documentation on the Haul Road embankment and the NFRD was reviewed to evaluate the adequacy of the structure as a water-retaining structure. Summaries of the most pertinent reports are provided below, but its contents are discussed in more detail in Appendix I. This documentation includes:

- Evaluation report by BGC Engineering (BGC, 2006), which included theoretical analyses, reference to experience with through-flow rockfill dams, and practical experience gained at Faro through monitoring of flows through the NFRD under low flow conditions. The studies also included description of visual inspections and a limited geotechnical exploration program consisting of two test pits on the crest of the Haul Road embankment. It is noted in the report that there are significant uncertainties and unknowns associated with the studies. For example, BGC concluded that *"Definition of 'best estimate' flow through relationship for the NFRD is difficult due to the unknown material properties of the drain and the assessment of how much water flow will be possible through the schistose rock."* To account for the uncertainty in flow-through, BGC considered a range of flow-through capacities to predict flow-through discharge and impoundment volumes.
- Design Report by Golder (1986), which provides a discussion of the design of the flow-through rock drain and its adequacy at conveying the design flows. The report includes a discussion of potential failure modes for the rock drain including: (1) deposition of sediment within the calcium-silicate rock, (2) downward migration of fines within the haul road embankment, and deposition of these fines within the rock drain, (3) degradation of the coarse rock fragments over time, and (4) potential glaciation (freezing) within the rock drain. Golder (1986) concluded that these failure modes were not expected to be problematic for the performance of the rock drain. However, the report does not include discussion of the performance of the adjacent schistose rockfill zones with high ponding levels, or potential failure modes associated with the foundation of the NFRD.
- The British Columbia Rock Drain Research Program report, *Mined Rock and Overburden Piles* (Minalta and Piteau, 1999), summarized rock drain case histories (particularly through review of a case history at Line Creek waste rock dump) and made general design recommendations. The NFRD construction was compared to these general design recommendations.

Other reports that were not available but are discussed in BGC (2006) include:

- Report by EBA Consulting Engineering (EBA, 1987, as noted by BGC, 2006) documenting foundation investigations prior to Haul Road construction. According to EBA (1987, as noted by BGC, 2006), the sub-soils consisted mainly of till, but a buried peat layer was encountered in 3 of the 5 test pits, and alluvial silt, sand, and gravel was encountered in another test pit. Numerous boulders were encountered at all locations. The ground encountered in the test pits (April) was frozen. The seasonal frost contained up to 20 percent ice by

volume. The permafrost at Test Pit 3 consisted of a "pliable soil" matrix with stratified and randomly oriented clear ice formations (up to 15 percent by volume).

3.3.2 Precedence

BGC (2006) noted that there is successful precedent in Canada, and elsewhere, to use "flow-through rockfill" in mine rock waste dumps, which has saved the cost of culverts or diversion works around the waste dumps. The precedent, however, does not include reliance of the mine waste dumps as water-retaining dams, but perhaps as temporary non-engineered pervious barriers to flow-through.

Comparing the construction of the NFRD with the general recommendations provided in the British Columbia Rock Drain Research Program report, *Mined Rock and Overburden Piles* (Minalta and Piteau, 1999), it was concluded that the Haul Road embankment does not include elements which should be included in engineered rockfill water retaining dams. These elements include:

- Geotechnical investigations should be performed to determine the conditions in the foundation, particularly whether soft soils (clay or silt) are present. If so, special measures will be needed in dump construction, such as building the dump in limited lifts to preclude foundation failure, which could introduce fine erodible sediment into the rock drain. [*The Golder design was based on drilling performed at a location approximately 400 m downstream from the NFRD, however, a test pit exploration was performed at the NFRD location by EBA (EBA, 1987, as noted by BGC, 2006) just prior to construction; Some peat and organic clay layers in the order of 1 to 2 ft thickness were encountered, but foundation soils consist mainly of "sand till and silt"*.]
- Where fine grained erodible soil is present in the valley floor, a bottom layer of gravel or small size rockfill should be placed to protect against scour and the introduction of fines into the streamflow. [*According to construction-era photographs duplicated by BGC (2006), no such layer was placed beneath the NFRD.*]
- Depending on results of field investigations, materials testing, and stability analyses, specific measures may have to be taken to improve marginal to poor foundations to ensure that in situ conditions meet or exceed analysis and design assumptions. Foundation preparation measures which may be required include clearing, stripping, or removal of poor or weak soils, installation of specific underdrainage measures, and preloading of the site. [*Golder (1986) did not mention foundation conditions or specific measures to improve in situ conditions. Construction era photographs in BGC (2006) indicate that no foundation preparation measures were implemented during NFRD construction, with the exception of bulldozer placement of large boulders within the existing stream channel.*]
- The Rock Drain Research Program report (Minalta and Piteau, 1999) did not discuss the treatment of materials adjacent to rock drains, which the NFRD schistose embankment fill materials would experience during flood flows required for the Down Valley Interim Hydraulic Upgrades evaluations. [*The balance of the Haul Road embankment was built with less competent schistose rock, using full-height end-dumping techniques, and without any significant site preparation such as removal of trees and surface organics such as peat.*]

BGC (2006) identifies evidence of sediment and wood debris accumulation at the entrance to the NFRD. It also mentions precedent of instability of the mine waste dump located immediately west of the NFRD. The scope of BGC's work included an assessment of natural hazards of the terrain in the North Fork Rose Creek Basin and the natural slopes above the Rose Creek Diversion Canal. However, it did not include potential hazards from man-made structures (such as those from the canals, dikes, waste rock dumps, roads, and dams). This issue adds to the uncertainties in assessing the reliability of the Haul Road embankment and NFRD, even in an interim flood flow attenuation role.

Also noted is the fact that potential blockage of debris on the NFRD face and plugging of the interstitial space within the NFRD by soil or other material arising from man-made activities had not been examined by BGC (2006), nor assessed during this study. Effects of sediment produced by erosion of the Faro Waste Dump and the upper (predominantly sand and gravel) part of the embankment, are examples of this type of contamination.

3.3.3 Stability Analyses

Ravelling and slope stability evaluations were performed to gain an understanding of the embankment stability. It is noted, however, that there are other potential failure modes that could be more critical, but do not readily lend themselves to quantitative analyses. One such failure mode is wash-out of finer particles in the schistose rockfill resulting in preferential seepage paths and eventual piping of the embankment. Another such failure mode is piping through the foundation under significant flood pool conditions. Because only two out of numerous potential failure modes were considered in analyses, the results of these analyses should not be considered a complete measure of the stability of the rock drain.

The two potential failure modes considered under estimated flood pool conditions include:

- Ravelling failure initiated by high discharge velocities exiting the downstream toe
- Slope stability failure with high phreatic surfaces in the embankment

The analyses and results are provided in Appendix B.

Results from the ravelling analysis suggest that there should be an adequate margin of safety against slope ravelling under high flow-through conditions. By inspection, the reported as-constructed D_{50} diameter of the NFRD (1 m) is more than 3 times as large as the critical D_{50} diameter for the worst-case 1-in-500-year flood event flow.

The slope stability analysis was performed to develop a general understanding of the influence of the impounded water on stability of the Haul Road embankment. It is noted that there is significant uncertainty in the properties assumed in the analyses as described in Appendix B. As a result, the slope stability analysis results represent an estimate of slope stability based on the information that is known and the parametric manipulations which have been performed.

The factors of safety developed for all slope stability cases analyzed meet the recommended minimum criteria, indicating that global slope stability issues should not be a major issue for the embankment. It should be noted that, during the life of the structure, shallow surface sloughing is a likely occurrence on the upstream or downstream face. While this sloughing is not considered to be critical to overall stability of the embankment, the effects of the sloughing could have other impacts on conditions near the toe of the embankment, particularly if left unchecked. For example, sloughing of finer material onto the NFRD slope surface could impair the flow-through. Signs of sloughing need to be monitored and maintenance performed as needed.

3.3.4 Conclusions

The objective of the interim improvements is to prevent an environmentally damaging discharge of metals-laden tailings to the Rose Creek Valley and downstream creeks and rivers. Based on a review of the design and construction records of the NFRD, this objective cannot be met with a sufficiently high degree of confidence by relying on the haul road embankment to act safely and reliably as a flood retarding structure during a 500-year flood event. To achieve a high confidence level, more positive measures will have to be implemented to pass large flood events safely at the Haul Road embankment and NFRD. One such measure might include installation of culverts or tunnels under the embankment.

In the absence of such measures, a risk analysis might be helpful in determining acceptability of the Haul Road embankment and NFRD in the interim period. Since the probability of a 500-year flood occurring within a 10-year interim period is 2 percent, and the conditional probability of failure of the Haul Road embankment given this flood event is less than 1, the probability of failure of the Haul Road embankment would be less than 2 percent over a 10-year period. A risk analyses would not only consider the 500-year flood, but would combine the probability of failures during the interim period with the consequence of failure for the full range of flood loading up to the 500 year event. It is recommended that such a risk analysis be performed if: (1) it is not possible for YG to take more positive measures to ensure the reliability of the Haul Road embankment, or (2) if YG is not willing to accept a risk (not well understood at this time) that could exceed generally accepted tolerable risk guidelines.

SECTION 4

Hydrotechnical Analysis and Modelling

4.1 Hydrology

4.1.1 Summary

A detailed description of the hydrology analysis is contained in this section and includes a description of previous hydrologic studies and flood hydrograph development. Peak flow rates for the SFRC, NFRC, and catchment areas contributing to the RCD and ID spillway are based on results from previous hydrologic studies. Peak flow rates for the 1-in-500-year flood event are:

- SFRC 1-in-500-year flood event peak flow = **49 m^3/sec**
- NFRC 1-in-500-year flood event peak flow at NFRD = **72 m^3/sec**
- Additional NFRC 1-in-500-year flood event peak flow downstream of NFRD = **1.9 m^3/sec**
- South slope adjacent to RCD, discharging to head of RCD, 1-in-500-year flood event peak flow = **7.5 m^3/sec**
- South slope adjacent to RCD, discharging to RCD downstream of overflow weir, 1-in-500-year flood event peak flow = **5.4 m^3/sec**
- North Slope and tailings area, discharging to ID Impoundment, 1-in-500-year flood event peak flow = **9.4m^3/sec**

Flood hydrographs were developed for the SFRC, NFRC at the NFRD, additional NFRC flows downstream of the NFRD, south slope adjacent to the RCD (discharging to the head of the RCD), south slope adjacent to the RCD (discharging downstream of the overflow weir), and the tailings area (discharging to the ID impoundment). The shape and timing are based on a non-dimensional hydrograph created from an observed flood event on Vangorda Creek, while the peak instantaneous discharge is as listed above.

4.1.2 Previous Hydrologic Studies

Previous hydrologic studies for the FMC have generally focused on determining instantaneous peak flows for a range of recurrence interval events. The studies have relied on regional analyses to determine discharge yield based on catchment area for a range of flood events. Regional analyses involve using runoff records from gauges in a geographic region that are expected to be hydrologically similar to catchments in the FMC. The recurrence interval events for the gauges containing longer periods of record are typically fit with a curve relating drainage area to peak flow rate. These curves are then used to predict recurrence interval flood events for the site of interest (Faro mine catchments) based on known drainage areas for various locations.

NHC (2001) conducted a regional analysis based on data obtained from seven regional gauges. At the time of the study, the period of record represented by the gauges ranged from 14 years to 37 years. The catchment areas for the gauges ranged from 91 square kilometres (km^2) to 7,250 km^2. Instantaneous peak discharges were estimated for the 1-in-2-, 1-in-50-, 1-in-100-, 1-in-200-, and 1-in-500-year return period flood events. NHC and BGC (2004) updated the return period flood estimates from NHC (2001) using additional stream gage observations. As part of the study, they also added an estimate of the mean annual flood and the 1-in-1,000-year return period flood.

Another regional study was conducted by Hydrotechnical Consulting (2006) to determine average daily flows for the 1-in-2-, 1-in-100-, 1-in-200-, 1-in-500-, and 1-in-1,000-year flood events. The recurrence interval floods were determined for flow durations ranging from 1 to 365 days. Using plots of peak discharge vs. catchment area, a relatively constant discharge per square kilometer was observed for flow records representing catchment areas ranging from 13.7 km^2 to 7,250 km^2. This observation led to the conclusion that catchment response to floods could be estimated by using recurrence interval estimates from a single gauge with the most extensive period of record (because catchment unit discharge during recurrence interval events appeared to be independent of total catchment area).

SRK Consulting (SRK) performed a regional analysis to estimate instantaneous peak discharges on Vangorda Creek, as part of a draft design report for the Vangorda Creek Diversion (SRK, 2010). Relationships between catchment area and peak instantaneous flood discharge were developed for the 1-in-2-, 1-in-100-, 1-in-200-, and 1-in-500-year flood events. Upper envelope and best-fit equations were developed for the 1-in-500-year flood event.

A PMF analysis was conducted by Water Management Consultants (2006) for the Rose Creek watershed. The PMF study applied the 24-hour probable maximum precipitation (Taylor and Hale, 2006) to the Rose Creek catchment. The antecedent conditions assumed saturated soil conditions and a shallow snowpack across the entire Rose Creek catchment. The HEC-HMS software was used to simulate the rainfall-runoff processes occurring during the probable maximum precipitation event. Outflow hydrographs at the NFRD, SFRC outlet, and lower end of the diversion channel (assumed to be near gauge X14) indicate that the PMF response to the probable maximum precipitation occurs over a period of approximately 2 to 3 days. Peak flows occur between 16 and 17 hours after the initiation of the probable maximum precipitation event for all catchments. The analysis assumed that the NFRD would not be in place during the PMF, and therefore no attenuation was modelled through the NFRD. Peak flood discharges on the NFRC and SFRC were estimated to be approximately 384 and 300 m^3/sec, respectively. Peak flood discharge at the lower end of the diversion channel was estimated to be approximately 692 m^3/sec.

A HEC-HMS model was recently completed by CH2M HILL (2013a) to perform continuous simulation hydrologic modelling for the entire FMC. The model was calibrated based on 8 years of flow and meteorological data gathered at the site with a focus on spring freshet estimation and rainfall-runoff events during the snow free season. The model was investigated for its potential use in estimating flood discharges for the 1-in-50-, 1-in-100-, 1-in-500-, and 1-in-1,000-year recurrence interval flood events. Because the HEC-HMS model developed by CH2M HILL is intended for continuous hydrologic simulations, modelling recurrence interval events would require determining antecedent conditions for each of the events in the study. Detailed monitoring data for key parameters such as snow water equivalent, soil moisture, rainfall, and temperature do not exist at an appropriate density within the study area or with sufficient periods of record to allow for determination of likely conditions that would produce an estimated recurrence interval event. Based on the insufficiencies in available data to predict basin conditions leading to a recurrence interval event, it was determined that the current HEC-HMS model would not be a suitable tool for estimating flood discharges in this study.

Table 4-1 summarizes the peak discharge estimates from the regional analyses and the PMF analysis at various FMC locations. Locations of these features are included on Figure 4-1.

South Slope adjacent to RCD, discharging to RCD downstream of overflow weir	5.4
North Slope and tailings area, discharging to ID Impoundment	9.4

4.1.3 Flood Hydrograph Development

In order to determine flow attenuation in the NFRD, a hydrograph representing inflow conditions upstream of the NFRD is required. To route flows appropriately to the head of the RCD, hydrographs representing the attenuated NFRC flows, additional NFRC flows downstream of the NFRD, SFRC, and the portion of the south slope adjacent to the RCD that discharges to the head of the RCD are required. The inflow, retention, and potential attenuation characteristics of NFRC flows and the subsequent downstream hydrograph after combining SFRC and south slope flows will not be reflected if steady state peak flows were used for the analysis.

Design flood hydrographs were developed for the 1-in-500-year recurrence interval flood event at various FMC locations. A non-dimensional hydrograph shape proposed by NHC (2001) was used to create the design flood hydrographs. Design hydrographs are defined by several parameters including the peak discharge, shape (e.g. slope of rising and falling limbs), timing (e.g. duration of rising and falling limbs), and total volume (which is a function of the peak discharge, shape, and timing parameters). The following sections describe the methods used to develop these portions of the design hydrograph and verify that they are suitable for use in the investigation and design of Down Valley Interim Hydraulic Upgrades elements. Figure 4-2 shows the developed 1-in-500-year design hydrographs.

4.1.3.1 Peak Discharge

As discussed in Section 4.1.1, previous hydrologic studies have focused primarily on peak instantaneous discharges. These relationships are well-defined and have been verified by several studies. The instantaneous peak discharges for the 1-in-500-year flood event design hydrographs were selected in accordance with previous studies. Table 4-2 summarizes the peak instantaneous discharges used in this study.

4.1.3.2 Shape and Timing

The shape and timing of design flood hydrographs depends on the meteorological forcing and runoff response characteristics of the catchment. Extreme, typically short-duration, rainfall events provide the meteorological forcing in rain-dominated hydrological systems. Subsequent catchment runoff response times are usually short (on the order of hours to several days). In snowmelt dominated systems peak runoff is typically in response to warming conditions that cause an accumulated snowpack to melt and contribute to stream flow. Catchment response times are typically longer for snow dominated systems than for rain dominated systems. However, snow dominated systems can still experience periods of heavy rainfall that produce a more rapid runoff response within the catchment. Rain-on-snow events can produce particularly high runoff rates for a catchment, since rain falling on a snowpack can quickly increase the internal temperature of the snowpack to a point where rapid melting of the snowpack occurs.

Hydrographs for gradual snowmelt are generally of long duration (on the order of weeks to months) with mild rising and falling limb slopes. A hydrograph resulting from gradual snowpack melt could exhibit the same peak discharge as a hydrograph resulting from an isolated rainfall event (without snowpack). However, the volume associated with the snowmelt hydrograph would be greater than the volume associated with the rainfall event. Catchment parameters such as soil type, vegetation type and areal cover, average hill slope, watercourse slope, and the presence of features such as wetlands and retention basins all influence how a catchment will respond to

a particular hydrograph shape. For some catchments, short peaked hydrographs with relatively small volumes may cause considerable damage while for others response times and storage components may dampen the impact of such an event. Some catchments may experience problems due to prolonged flooding while others exhibit, for example, stream routing or sufficient soil infiltration capacities to effectively handle high volume floods of a prolonged and gradual nature.

The non-dimensional flood hydrograph proposed by NHC (2001) is based on an observed flood on Vangorda Creek in May 1993. The overall hydrograph shape and distribution appears to be consistent with a late spring rain-on-snow runoff event. However, without detailed meteorological data at the FMC it is difficult to determine with certainty what runoff condition the non-dimensional hydrograph represents. A rainfall driven hydrograph without snowmelt would be expected to exhibit a basin response time on the order of 1 to 2 days. A rain-on-snow driven event would be expected to have a basin response time on the order of several days, which is consistent with the non-dimensional hydrograph timing. Environment Canada climate normals from the Faro Airport meteorological station indicate that snow persisted through approximately April 10, 1993 at an elevation of 716.6 m. Since snowmelt for the FMC catchments lag Faro Airport snowmelt by several weeks (maximum catchment elevation of approximately 1,870 m for the NFRC catchment) it is possible that a lingering, but near-melt-state snowpack in May 1993 was available to contribute to runoff in combination with a rainfall event.

The duration of the hydrograph is 20 days and is defined on a daily time step. Table 4-3 summarizes the ratios of daily discharge to event peak discharge that define the hydrograph shape. The peak of the hydrograph occurs on day 10, which is the midpoint of the design hydrograph.

[a] Q_{peak} is defined for each catchment in Table 4-2.
Daily flow, Q, is determined by multiplying Q_{peak} by the non-dimensional ratio.

4.1.3.3 Hydrograph Volume and Runoff Yield

The dam breach analysis described in Section 4.3.4 is highly dependent on the volume of water that could potentially be impounded behind the NFRD. Routing flows through the RCD and tailings area are also dependant

on hydrograph volume, since the volume associated with design events may have to fill storage areas prior to contributing to spillway flows (at the ID, for example) or increased channel flows. Therefore, the total volume associated with each event hydrograph has been evaluated to determine if the duration and shape of the hydrograph are reasonable.

The non-dimensional hydrograph in Table 4-3 represents a runoff event where approximately 14 percent of the total volume is represented by the rising limb. The 3-day period making up the hydrograph peak contains 61 percent of the overall volume, with the falling limb of the hydrograph representing the remaining 25 percent of the runoff volume.

The 1-in-500-year annual precipitation at the Faro Airport has been estimated as 451 mm. Precipitation values at the FMC would be greater than values at the Faro Airport due to differences in elevation and observed patterns of greater precipitation at Anvil and other sites. In previous work performed by CH2M HILL (CH2M HILL, 2013a), the factors used for adjusting Faro Airport precipitation to FMC precipitation were split between rainfall (6.8 percent) and snowfall (25 percent).

According to Environment Canada climate normals for the Faro Airport (1971-2000) average annual precipitation equals 316 mm. Of this, rain accounts for 214.4 mm (67.8 percent) while snow accounts for the remaining 101.6 mm (32.2 percent). If these rain and snow percentages are assumed for a year in which the a 1-in-500-year flood event occurs, and the rain and snow fractions are factored up by the previously used factors of 6.8 percent and 25 percent respectively, the 1-in-500-year annual precipitation at the Faro Dump meteorological station is estimated to be 508.1 mm.

Table 4-4 summarizes the total discharge volume and associated runoff depth for each catchment. Compared to the 1-in-500-year precipitation of 508.1 mm, the runoff volumes represent a significant portion of the available annual precipitation. Runoff depths from the NFRC and SFRC catchments during the 1-in-500-year flood event represent approximately 40 to 45 percent of the available 1-in-500-year annual precipitation. Observed spring freshet volumes at the R7 gage for low magnitude flood events (during water year 2003, 2005, 2007, and 2010) indicate that the freshet has typically represented approximately 20 to 30 percent of the annual runoff volume. The NFRC and SFRC ratios calculated for the 1-in-500-year design hydrographs appear reasonable since the 1-in-500-year flood could conceivably lead to a greater percentage of the annual runoff occurring during the freshet period.

Runoff depths from the smaller catchments range from approximately 70 to 100 percent of the available 1-in-500-year annual precipitation. These ratios are higher than those predicted for the larger NFRC and SFRC catchments and it is likely that the hydrograph volumes presented in Table 4-4 are conservative estimates. However, because the contributions from these smaller catchments are insignificant compared with the contributions of larger basins such as the NFRC and SFRC, this level of conservatism is assumed to be appropriate for the current design.

TABLE 4-4
Discharge Volume and Runoff Depth associated with 1-in-500-year hydrograph
Faro Mine Remediation Project

Catchment Description	Catchment Area (km^2)	Runoff Volume (m^3)	Equivalent Runoff Depth (mm)
NFRC upstream of NFRD	118	24,274,470	206
SFRC	73	16,520,130	226
South Slope discharging to head of RCD	6.8	2,528,590	372
North Slope and tailings area discharging to ID spillway	9.1	3,169,167	348
South Slope discharging to RCD downstream of overflow weir	4.5	1,820,585	405
NFRC downstream of NFRD	1.2	640,580	517

4.2 North Fork Rock Drain Flow Attenuation Characteristics

4.2.1 Summary

A detailed description of the analysis of the NFRD flow attenuation characteristics is contained in this section and includes a description of the theoretical basis of flow through the rockfill, historical measurement of flow through the NFRD, and estimates of flow-through capacity of the NFRD. Flow through the NFRD was estimated using the Wilkins equation and results in attenuation of the 1-in-500-year flood event peak flowrate for the NFRC. High, moderate, and low discharge scenarios for flow through the NFRD are based on using a range of values to estimate flow through the NFRD. Additionally, low flow-through scenarios were modelled assuming a 25-, 50-, and 75-percent reduction in flow-through capacity to estimate the potential flow-through when debris or other conditions may cause a reduction in performance at the NFRD.

4.2.2 Theoretical Basis of Flow through Rockfill

BGC (2006) summarizes the hydraulics of flow through rockfill structures. In general, Darcy's Law does not apply for rockfill structures because of turbulent flows that occur in the larger void spaces of the rockfill. The high Reynolds numbers lead to scenarios where Darcy's Law is invalid. The most commonly used equation for computing flow through rockfill is the Wilkins equation (Leps, 1973 and Hansen et al., 2004, as cited in BGC, 2006):

$$Q = nAWm^{0.5}i^{0.54} \quad (1)$$

where:

Q: flow (m^3 per second)
n: porosity (-)
A: cross-sectional area of flow (m^2)
W: Wilkins' empirical constant, 5.243
m: hydraulic mean radius (m)
i: hydraulic gradient (m per m)

The hydraulic mean radius is calculated using the following equation (Hansen et al., 2004, as cited in BGC, 2006):

$$m = \frac{ed}{6r_e} \quad (2)$$

where:

e: void ratio (-)
d: dominant particle diameter (m)
r_e: particle surface area efficiency, taken to be 1.3 for coarse angular rock

The dominant particle diameter for rockfill is typically assumed to be equal to the D_{50} diameter (where D_{50} is the particle size at which 50 percent of the materials are finer [by weight]) (Leps, 1973, as cited in BGC, 2006). Because the seepage gradient in a flow-through situation varies with position within the structure, an "effective" or representative hydraulic gradient can be used to refine the analysis (Hansen et al., 2004, as cited in BGC, 2006):

$$i_{eff} = 0.8A_R^{-3/2}(h/H)^{1.4} \quad (3)$$

where:

i_{eff}: effective hydraulic gradient (m per m)
A_R: aspect ratio, defined by $A_R = \frac{1}{H} \times \left(B_u + B_c + {}^{B_d}/_2\right)$
h: upstream water level (m)
H: height of rockfill structure (m)
B_u: width of upstream portion (m)
B_c: width of central portion (m)
B_d: width of downstream portion (m)

4.2.3 Historical Measurement of Flow through the North Fork Rock Drain

The width of the NFRD is assumed to be 70 m (perpendicular and centered over to the pre-existing creek channel) as noted by BGC (2006). The total height of the coarsest calcium-silicate rock composing the core of the NFRD is assumed to be 3.6 m (BGC, 2006). Based on construction photographs (BGC, 2006), it is assumed that coarse rock is present above the 70-m-by-3.6-m core to an elevation of approximately 1,121 m, effectively increasing the area of coarse flow-through rock to approximately 70 m by 33 m. Outside of the assumed 70-m-by-33-m coarse rock core, it is assumed that schistose rock was used to construct the remainder of the Haul Road.

During the design of the Haul Road, it was assumed that the representative particle size (D_{50}) of the calcium-silicate and coarse rock core would be 0.3 m. The original Golder design (1986) conservatively assumed that there would be no flow through the schistose rock.

Initial routing analyses during the design of the NFRD assumed that a 40-m-deep pool would be present during the 1-in-100-year flood (70 m^3/sec), while the mean annual flood (7 m^3/sec) would produce an 11-m-deep pool (BGC, 2006).

Monitoring of water surface elevations upstream from the NFRD and flow on the NFRC downstream (to develop a stage-discharge curve) was conducted in 2005 and 2006 and more recently in 2012 and 2013. In 2005 and 2006, flow was measured at five locations (R7 gauge, NRFC 20/21 upstream from the NFRD pond, NFRD pond, NRFC 22/23 downstream from the NFRD, and X2 gauge) (BGC, 2006). Water levels were determined by using electronic sensors, staff gauges, or direct survey methods. The BGC (2006) report shows measured water surface elevations and downstream discharge for the NFRD (Figure 18, Memorandum 2). Peak flow during the 2005 and 2006 monitoring was approximately 22.5 m^3/sec in 2005 at gauge X2. The maximum pond elevation corresponding to the peak discharge was approximately 1,096.5 m, or 8.6 m above the pond sensor elevation of 1,087.9 m. The majority of discharge data collected during the monitoring period ranges from 1 to 6 m^3/sec. Pond elevations for lower discharges range from approximately 1,089 m to 1,093 m, or 1.1 m to 5.1 m above the pond sensor elevation of 1,087.9 m.

BGC plotted upstream and downstream water surface elevations and calculated hydraulic gradients through the NFRD during 2005 and 2006 (BGC, 2006, Figure 19, Memorandum 2). Gradients were observed to be approximately 0.015 metres per metre (m/m) for low pond water surface elevations (near 1089.5 m). The highest reported gradient of approximately 0.03 m/m corresponds to a pond water surface elevation near 1,093 m. The relationship between hydraulic gradient and pond water surface elevation appears to be approximately linear within the measured range (BGC, 2006, Figure 20, Memorandum 2).

In 2012 and 2013, stage monitoring was conducted at NF1 and NF2 (See Figure 4-1). Discharge measurements were conducted at X2 and NF2 primarily during the months of May through September. Figure 4-3 shows measured water surface elevations and downstream discharge data. Peak flow during the 2012 and 2013 monitoring was approximately 8.2 m^3/s in 2012 (as measured at the X2 gauge). A peak flow of 10.7 m^3/s was recorded at the X2 gauge on 11 June, 2012 but no upstream water surface elevation is available at the NF1 gauge on this day. Figure 4-4 shows upstream and downstream water surface elevations for 2012 and 2013. Similar to measurements in 2005 and 2006, upstream water surface elevations are observed to generally fall between the elevation range of 1,089 m to 1,094 m. Figure 4-5 shows hydraulic gradients for 2012 and 2013. Gradients of approximately 0.015 and 0.035 m/m for pond elevations of 1089 m and 1094 m, respectively, demonstrate agreement between BGC reported values in 2005/2006 and new measurements in 2012/2013.

In addition to stage and discharge data, two dye tests were conducted. The first dye test was conducted on 11 September, 2013 and the second test was conducted the following day. Discharge measurements at NF2 on 12 September, 2013 indicate that flow on the NFRC was approximately 2.5 m^3/s. The water surface elevation at NF1 on 11 September, 2013 was measured as 1090.3 m. Rhodamine was injected at two separate locations upstream from the NFRD and the breakthrough curve was measured at two locations downstream from the NFRD. Figures 4-6 and 4-7 show the injection and measured breakthrough curves. Residence time of rhodamine within the NFRD is observed to be approximately 1 hour for both dye tests. The flow-through relationships

observed during the 2005, 2006, 2012, and 2013 monitoring campaign are applicable to low flow (approximately 1 to 22 m^3/sec) conditions.

Flow-through relationships during low probability recurrence interval floods and the PMF cannot be directly extrapolated from observed data, because the conditions within the NFRD are not homogenous with increasing height of the rockfill. The observed flow-through relationships can be used to determine if theoretical methods for calculating flow through the NFRD are valid within the range of approximately 1 to 22 m^3/sec and for pond elevations up to approximately 1094 m. Additionally, the dye test data can be used to support conclusions that flow-through characteristics within the 70-m wide calcium-silicate zone are relatively consistent (i.e. the assumption of coarse rock characteristics across the 70-m width appears valid) and that residence times in the NFRD are rather short (i.e. for hydraulic routing conducted with a minimum of 1 hour time steps, little to no lagging is required since outflows from the NFRD are expected to respond quickly to changes in upstream water surface elevation). The following sections describe the methods for calculating theoretical flow through the NFRD and estimating the flow capacity and attenuation characteristics of the NFRD.

4.2.4 Estimate Flow-Through Capacity of the North Fork Rock Drain

At the time of design and construction of the NFRD structure, the designer proposed a stage-discharge relationship for the ponded area behind the NFRD (see Figure 4-8) (Golder, 1986, as cited in BGC, 2006). The exact methods used to determine the flow-through relationship are not clearly stated. However, the report states that the only area considered for flow-through was the 70-m-by-3.6-m zone of calcium-silicate rock (total discharge area of approximately 250 square metres [m^2]). This assumption produced a stage-discharge curve that was quickly discarded based on observations of flow-through for the NFRD. The work conducted by BGC (2006) and the additional observations from 2012 and 2013 indicate that discharge is likely greater than predicted by the original stage-discharge relationship at higher water surface elevations upstream from the NFRD. Figure 4-8 shows the Golder 1986 stage-discharge relationship along with the observed 2012 and 2013 stage and discharge (stage and discharge as observed by BGC, 2006 are similar to those observed during 2012 and 2013). Similarly, 1988 and 1993 measurements produced stage-discharge curves that predicted larger discharges than those presented in the original design (BGC, 2006, Figure 1).

The Wilkins equation can be used to estimate theoretical flow-through the rockfill. The predicted discharge is related to the following:

- Dimensions of the NFRD structure
- Cross-sectional area available for flow
- Characteristics of the rockfill (permeability, particle size distribution, dominant grain size)
- Hydraulic gradient developed within the NFRD structure

BGC (2006) examined each of the controlling factors in their previous report. For this analysis, the parameters have been revisited and updated where necessary or appropriate. Where no additional information is available to modify the analysis conducted by BGC, similar parameter values and assumptions are used in the current flow-through analysis of the NFRD structure.

4.2.4.1 North Fork Rock Drain Structure Dimensions and Impounded Storage Volume

LiDAR data collected October 3, 2011, were used to determine approximate dimensions of the NFRD and develop stage-storage curves for the area upstream from the NFRD. DTMs created from the LiDAR data represent the ground surface elevation, but do not contain any topographic information below the water surface. A bathymetric survey was conducted by Challenger Geomatics, Ltd. on 4 and 5 July 2013 to define the topography beneath the water surface for the impounded area upstream from the NFRD. The survey data were used to create a DTM representative of the elevations below the water surface. This DTM was merged with the LiDAR-based DTM to create a seamless DTM representative of the ground elevations above and below the water surface. Based on this DTM, the minimum elevation upstream from the NFRD is estimated to be approximately 1,087.82 m. The volume of impounded water during low flow conditions (when the upstream water surface is at approximately elevation 1,090 m) is estimated to be approximately 10,800 m^3.

Figure 4-9 shows an aerial photograph of the NFRD and other features of the FMC. Cross sections were extracted from the DTM upstream from the NFRD, along the Haul Road centerline, and downstream from the NFRD. A profile through the NFRD was also extracted from the DTM. Figure 4-10 presents the cross sections (facing downstream) and Figure 4-11 shows the NFRD profile. Figure 4-10 indicates that the minimum elevation of the Haul Road is approximately 1,131 m. The low point in the Haul Road does not coincide with the channel portion of the cross section upstream or downstream from the NFRD. Along the approximate flow path centerline through the NFRD, the Haul Road elevation is approximately 1,144 m, which is 56 m above the minimum elevation of 1,087.82 m upstream from the NFRD and approximately 59 m above the approximate toe elevation of 1,085 m downstream from the NFRD. The approximate base width of the NFRD is 197 m. Rather than contributing to flows on the NFRC, water surface elevations in excess of 1,131 m would result in overtopping flows that would contribute flow to the SFRC catchment. BGC (2006) reports that personal communications received from FMC personnel indicates at a water surface elevation of 1,128 m flow would enter the buried Zone II pit, which is undesirable. The maximum desired water surface elevation upstream from the NFRD was assumed to be 1,125 m, which would provide 3 m of freeboard.

Figure 4-12 shows the stage-storage curve associated with the impounded area behind the NFRD. At an elevation of 1,131 m the impounded volume is approximately 16,900,000 m^3. At elevations of 1,128 and 1,125 the impounded volume is approximately 13,500,000 m^3 and 10,600,000 m^3, respectively.

4.2.4.2 Cross-sectional area available for flow and characteristics of the rockfill

The minimum area available for flow would be the 70-m-by-3.6-m calcium-silicate zone used by Golder to estimate the stage-discharge relationship for the NFRD following construction (Golder, 1986, as cited in BGC, 2006). The stage-discharge relationships have been shown to underestimate flow-through characteristics of the NFRD, so the actual area available for flow-through is likely greater. If coarse rock above the calcium-silicate zone or the adjacent schistose rock is assumed to convey a portion of the flow through the NFRD then the available flow-through area would increase. It is assumed that coarse rock, similar in characteristics to the calcium-silicate core, was used to construct the 70-m wide portion of the Haul Road embankment above the portion that was specially designated for construction using the calcium-silicate.

Detailed grain-size distributions for material used in the NFRD are not available and are difficult to evaluate in-situ due to the large size of the embankment and the large size of the constituent rockfill. Table 4-5 summarizes notes by the design engineer regarding grain-size at various locations within the NFRD (Golder, 1987, as cited in BGC, 2006).

TABLE 4-5
Grain-size Distributions within NFRD
Faro Mine Remediation Project

Height above Toe (m)	Approximate Elevation[a] (m)	D_{50} (m)	D_{65} (m)	Notes
7	1,095	0.3	0.5	--
10	1,098	--	--	Grain-size estimated to be slightly larger than rock 7 m above the toe (estimate of D_{50} or D_{65} not provided)
17	1,105	0.15	0.5	
55	1,143	--	--	Absence of fine material. Fines stated to be evident within upper 10 m of fill.

[a] Location of measurements is not specified. Measurement location is assumed to be at approximately the centerline of the flow-through zone. Toe elevation at this location is 1,087.82 m.

If the location where grain sizes are reported corresponds to the approximate centerline of flow through the NFRD, then the Haul Road surface elevation at this location is approximately 1,144 m. Fines present to a depth of 10 m would result in fine material extending down from the Haul Road surface to an approximate elevation of 1,134 m. Thus, the height of 55 m (elevation 1,143 m) where no fines were observed would appear to be in

contrast to the statement that the upper 10 m of the Haul Road (elevation 1,134 to 1,144 m at the flow-through centerline) contains fine material. The estimated height by the design engineer could have been made at a location other than the flow-through centerline, or be referenced to a toe elevation other than 1,087.82 m.

To account for differences in estimates of height, it was assumed that the maximum height of the calcium-silicate rock is at approximate elevation 1,121 m, which represents a coarse rockfill zone height that is half of the coarse rockfill zone width. Estimated D_{50} values from Golder, 1987 (as cited in BGC, 2006) and independent estimates by BGC, 2006 indicate that rock sizes within this 70-m wide core range from 1 m at the toe to approximately 0.2 m towards the upper extent of the coarse fill. Estimates of the average D_{50} range from approximately 0.3 to 0.7 m. The assumed total area of coarse calcium-silicate rock available for flow-through is approximately 2,300 m^2.

It was assumed that the adjacent schistose rock likely conveys some flow, although the dominant rock size is probably smaller than the calcium-silicate zone and therefore the schistose rock would convey less flow than the calcium-silicate zone. The extents of the schistose rock available for flow-through were assumed to coincide with the portion of the embankment that would route flows to the NFRC catchment and extend to a maximum elevation of 1,131 m. At high water surface elevations, flow through the haul road embankment that would ultimately route to the SFRC was assumed to be negligible. The assumed total area of schistose rock available for flow-through is approximately 8,600 m^2.

Figure 4-13 shows the assumed flow-through area for the coarse rock (including the calcium-silicate core) and the adjacent schistose rock. Figure 4-14 shows the predicted flow-through available area versus water surface elevation developed from the cross section upstream from the NFRD embankment.

4.2.4.3 Hydraulic gradient developed within the North Fork Rock Drain structure

The hydraulic gradient through the NFRD structure was measured in 2005 and 2006 by BGC and calculated from 2012 and 2013 observations of stage at NF1 and NF2. The available hydraulic gradient information represents the total gradient between the upstream and downstream ends of the NFRD. Detailed gradient data within the NFRD have not been measured. The hydraulic gradient information that is available only represents discharges within the range of approximately 1 to 22 m^3/sec. It would be difficult to measure the hydraulic gradient within the NFRD structure itself, so using the overall hydraulic gradient (from the upstream side of the NFRD structure to the downstream side of the NFRD structure) would likely be the most appropriate method for determining a reasonable hydraulic gradient value. An effective hydraulic gradient can be calculated using Wilkins equation (3) to represent the potential gradient at flows greater than 22 m^3/sec.

4.2.4.4 Stage-Discharge Relationships for the North Fork Rock Drain

Similar to the BGC 2006 methods, stage-discharge relationships for the NFRD were estimated by assuming a range of possible parameters to represent the flow-through area and characteristics of the rockfill within the NFRD. Assumptions were also made about the extent and behaviour of the calcium-silicate and schistose rock zones. Using a range of values results in potentially high, moderate, and low discharge scenarios for flow through the NFRD. Estimating potential upper and lower limits for flow-through provides a range of potential scenarios during recurrence interval events. Each scenario is briefly summarized as follows:

- **High-Flow Scenario**: The high-flow scenario is similar to the scenario presented by BGC (2006). The dominant rock size for the entire embankment is assumed to be 0.25 m. The void ratio for both calcium-silicate and schistose rock is assumed to be approximately 0.4. While it is possible that the void ratio of certain portions or pockets of the schistose rock may change as some particles breakdown, if there is not significant settlement the overall void ratio of the schistose rock may not be changed significantly. A high void ratio of 0.4 was selected for the schistose rock to obtain higher flow-through capacities including a higher upper bound estimate for high flow-through. Since a zero flow was assumed for the schistose rock in the low-flow scenario, this facilitates consideration of a wider range in flow-through capacities.
- **Medium-Flow Scenario**: The medium-flow scenario assumes that the dominant rock size for the calcium-silicate zone is approximately 0. 25 m. The dominant rock size for the schistose is assumed to be 0.05 m. The void ratio for both rock types is again assumed to be approximately 0.4. The entire schistose and calcium-

silicate area shown on Figure 4-13 is available for flow-through, but the smaller dominant diameter for the schistose rock will reduce flows through this zone compared with the calcium-silicate zone.

- **Low-Flow Scenario**: The low-flow scenario assumes that there is no flow through the schistose rock. All flow through the NFRD is conveyed through the calcium-silicate zone, which is assumed to have a dominant rock size of 0.25 m and the available flow-through area as depicted on Figures 4-13 and 4-14. The void ratio for the calcium-silicate rock is assumed to be approximately 0.4.
- **Low-Flow Scenario plus 25-Percent Reduction in Flow-Through Capacity:** The low-flow plus 25-percent reduction in flow-through capacity scenario assumes the same parameters as the low-flow scenario, but imposes a 25-percent reduction in flow-through capacity. This capacity reduction is intended to represent a minor blockage resulting from conditions such as debris racking on the NFRD face or plugging of interstitial spaces within the NFRD by soil or other material.
- **Low-Flow Scenario plus 50-Percent Reduction in Flow-Through Capacity:** The low-flow plus 50-percent reduction in flow-through capacity scenario assumes the same parameters as the low-flow scenario, but imposes a 50-percent reduction in flow-through capacity. This capacity reduction is intended to represent a mid-range blockage resulting from conditions such as debris racking on the NFRD face or plugging of interstitial spaces within the NFRD by soil or other material.
- **Low-Flow Scenario plus 75-Percent Reduction in Flow-Through Capacity:** The low-flow plus 75-percent reduction in flow-through capacity scenario assumes the same parameters as the low-flow scenario, but imposes a 75-percent reduction in flow-through capacity. This capacity reduction is intended to represent a major blockage resulting from conditions such as debris racking on the NFRD face or plugging of interstitial spaces within the NFRD by soil or other material.

Stage-discharge relationships for the six flow scenarios are presented in Figures 4-15 and 4-16. Figure 4-15 shows the stage-discharge curves compared to observed 2012 and 2013 stage-discharge data and with the original Golder, 1986 stage-discharge curve shown for reference. The high and medium flow-through scenarios appear to provide the best match to observed data. At impounded water surface elevations less than approximately 1,105 m, the low flow-through scenarios assuming 25-, 50-, or 75-percent reduction in flow-through capacity generally predict a discharge that is less than the 1986 stage-discharge relationship, providing a conservative estimate of flow-through. At impounded water surface elevations greater than approximately 1,105 m, all scenarios predict discharges that exceed the 1986 stage-discharge relationship.

Figure 4-16 shows the stage-discharge curves extended to a maximum water surface elevation of 1,131 m. The behaviour of the flow through curves is observed to diverge for water surface elevations above approximately 1,100 m. Since observed stage-discharge data is valid only for low flow conditions (water surface elevations less than approximately 1,094 m) the validity of the curves for the 1-in-500-year flood event cannot be verified. The six scenarios provide an envelope within which the true stage-discharge relationship is likely to fall, and they also account for potential flow-through capacity reduction at the NFRD.

4.2.5 Routing 1-in-500-Year Hydrograph through North Fork Rock Drain

Level pool reservoir routing was conducted to evaluate the attenuation of the 1-in-500-year inflow hydrograph under the six flow-through scenarios. The attenuated flows at the downstream end of the NFRD were routed downstream using a hydraulic model to create design flood hydrographs for the RCD (see Section 4.3.3). Figures 4-17 and 4-18 show the results of the level pool routing through the NFRD (only the portion of the hydrograph focusing on the flood peak is shown for clarity). Table 4-6 summarizes the peak flow results at the downstream toe of the NFRD, flow reduction compared to the unattenuated peak flow of 72 m^3/sec, and maximum impounded water surface elevation and volume upstream of the NFRD during the 1-in-500-year design flood. Figure 4-19 also shows the extents of impounded water upstream of the NFRD for each scenario.

TABLE 4-6
NFRD Attenuated Peak Discharge and Impounded Water Surface Elevation, 1-in-500-Year Flood Event
Faro Mine Remediation Project

Scenario	Peak Flow, no Attenuation (m^3/sec)	NFRD Attenuated Peak Flow (m^3/sec)	Percent Reduction in NFRD Peak Flow (m^3/sec)	Maximum Impounded WSEL (m)	Storage Volume (m^3)
High Flow-Through	72	59	18%	1,101.9	838,042
Medium Flow-Through		54	25%	1,104.3	1,241,193
Low Flow-Through		45	38%	1,108.0	2,071,410
Low Flow-Through (25-Percent Reduction in Flow-Through Capacity)		40	44%	1,110.2	2,671,369
Low Flow-Through (50-Percent Reduction in Flow-Through Capacity)		34	53%	1,113.3	3,701,514
Low Flow-Through (75-Percent Reduction in Flow-Through Capacity)		23	68%	1,118.5	6,077,155

The uncertainty in flow-through parameters as well as the potential for plugging and flow-through capacity reduction of the NFRD results in a wide range of estimates for downstream peak discharge, upstream water surface elevation, and impounded volume. The six flow-through scenarios predict peak flow attenuation ranging from 18- to 68-percent and maximum impounded water surface elevations ranging from 1,101.9 m to 1,118.5 m. The storage volumes behind the NFRD for these scenarios range from 838,042 m^3 to 6,077,155 m^3. Measurements of the impounded water surface elevation and subsequent downstream discharge during peak flow periods (such as the spring freshet), especially at flows greater than 10 m^3/s, would provide the additional data necessary to verify which curves (high, medium, or low flow-through) best represent the actual flow-through conditions for the NFRD. Ideally, data collected over several years and spanning a range of stages and discharges could be used to create a stage-discharge curve that is specific to observed flow-through characteristics of the NFRD structure and not based on theoretical relationships. A stage-discharge curve such as this could be periodically updated to account for recent observations and could be used as an indicator of the NFRD performance. That is, if flow-through capacity of the NFRD was decreasing over time due to plugging of the interstitial space by fine material or debris, the continuous monitoring and updating of the site specific stage-discharge curve could provide advance notification and verification of such behaviour.

Together the stage-storage curve and theoretical stage-discharge curves were used to route the 1-in-500-year flood event down NFRC to the RCD, where hydrographs were combined with 1-in-500-year hydrographs from other catchments to determine RCD peak flows and the 1-in-500-year hydrograph shape for the RCD and ID tailings area.

4.3 Hydraulic Modelling

4.3.1 Summary

Using topographic and bathymetric data available for the FMC, RCD, and proposed improvements, CH2M HILL prepared 1D and 2D hydraulic models to evaluate hydraulic conditions for the 1-in-500-year flood event.

The 1D hydraulic model was used to route flood hydrographs from the NFRC, SFRC, south slope catchment, and tailings catchment area to the RCD or ID impoundment (depending on modelling assumptions). The NFRD and upstream impoundment were included in the 1D model to estimate attenuation characteristics of the NFRD during the 1-in-500-year flood event under a non-breach scenario. Results of routing the 1-in-500-year flood event flows and assuming high flow-through conditions for the NFRD are as follows (peak flows without attenuation are shown in brackets for reference):

- Head of RCD 1-in-500-year flood event peak flow = **111 m^3/sec** [*130 m^3/sec*]
- RCD, downstream of overflow weir, 1-in-500-year flood event peak flow = **116 m^3/sec** [*136 m^3/sec*]
- ID impoundment 1-in-500-year flood event peak flow = **121 m^3/sec** [*140 m^3/sec*]

Routing 1-in-500-year flood event flows through the NFRD and the associated shift in timing of hydrograph peaks between the NFRC and other catchments results in a reduction in peak flow of approximately 20 m^3/sec for the RCD and at the ID impoundment.

The 1-in-500-year flood event was modelled assuming a breach of the NFRD to estimate downstream impacts during such an event. Because of the uncertainty in the adequacy (stability) of the NFRD to serve as a water-retaining structure under severe flood conditions, it was important to perform breach analysis to develop an understanding of the consequence of a NFRD breach. The information can be used to make decisions during the interim period, as well as a basis for developing concepts for final closure. Breach analyses were initially performed for an average case, assumed to correspond to medium flow-through conditions at the NFRD, and then for progressively reduced flow-through capacities at the NFRD until significant overtopping of the ID crest occurred due to the breach flood wave.

Two methods for predicting breach parameters were used. The Froehlich (2008) method predicts shorter breach development time with smaller final breach geometry, while the Von Thun and Gillette (1990) method predicts longer breach development time with larger final breach geometry. The two separate, but internally congruent, breach methods were used to evaluate the sensitivity of breach peak flows to the assumed breach progression mode. After verifying that the two breach parameter estimation methods provided consistent results, the Von Thun and Gillette (1990) method was used to analyze breach impacts at the ID under three breach scenarios:

- Breach Scenario 1 (assume breach occurs at maximum impounded WSEL during the medium flow-through scenario)
  - Total volume of water impounded upstream of NFRD at start of breach = **1,241,193 m^3**
  - RCD peak flowrate (including flows from SFRC, south slope, and tailings area catchments) = **640 m^3/sec**
- Breach Scenario 2 (assume breach occurs at maximum impounded WSEL during the low flow-through scenario)
  - Total volume of water impounded upstream of NFRD at start of breach = **2,071,410 m^3**
  - RCD peak flowrate (including flows from SFRC, south slope, and tailings area catchments) = **1,262 m^3/sec**
- Breach Scenario 3 (assume breach occurs at maximum impounded WSEL during the low flow-through and 25-percent reduction in flow-through capacity scenario)
  - Total volume of water impounded upstream of NFRD at start of breach = **2,671,369 m^3**
  - RCD peak flowrate (including flows from SFRC, south slope, and tailings area catchments) = **1,669 m^3/sec**

The 2D hydraulic model was used to route flood hydrographs from the upstream end of the RCD through the RCD and for the adjacent tailings area and ID spillway. Performance of the conveyance facilities and improvements to the RCD and ID spillway were evaluated during the 1-in-500-year flood event using the 2D model. The three NFRD breach scenarios were also evaluated with the 2D model. Following are the significant results from these model simulations:

- ID Spillway Results with 1-in-500-year flood event flow rate
  - Flow rate over the spillway = 115 m^3/sec (no flow simulated in the RCD)
  - Water surface elevation at ID = 1,048.6 m
  - Freeboard at ID = 1.0 m
- RCD Results with 1-in-500-year flood event flow rate
  - Existing dike (right bank) does not meet 0.5 m freeboard requirements downstream from fuse to steepened reach.

  - Removal of vegetation from the right bank of the RCD would reduce WSELs from 0.05 to 0.10 m
  - Removal of vegetation from the right and left banks of the RCD would reduce WSELs from 0.10 to 0.15 m
- Breach Scenario 1 (assumes no blockage and medium flow-through condition)
  - Water surface elevation at ID = approximately 1,049.3 m
  - Freeboard at ID = 0.3 m
  - No overtopping of ID or CVD
- Breach Scenario 2 (assumes no blockage and low flow-through condition)
  - Maximum water surface elevation at ID = approximately 1,049.9 m
  - Overtopping of ID and CVD
- Breach Scenario 3 (assumes 25 percent blockage and low flow-through condition)
  - Maximum water surface elevation at ID = approximately 1,050.1 m
  - Overtopping of ID and CVD

4.3.2 Description of 1D Hydraulic Model

To route flood hydrographs through the NFRD and downstream on the NFRC and also from the SFRC to the upstream end of the RCD, CH2M HILL used HEC-RAS version 4.1.0, a 1D hydraulic model developed by the U.S. Army Corps of Engineers Hydrologic Engineering Center. The HEC-RAS model was created using HEC-GeoRAS version 10, which allows HEC-RAS geometry elements to be defined in a geographic information system environment and results in a georeferenced, spatially consistent hydraulic model. The topography of the NFRC and SFRC catchments results in flow paths that are more easily defined than for the RCD and tailings area. As a result, the 1D hydraulic model was considered to be sufficient for routing flood hydrographs to the upstream end of the RCD.

Computational results from the 1D model include depth, average velocity, and WSEL for each cross section defined in the model domain. Estimating these parameters for the continuous surface requires interpolating the 1D hydraulic model results in between the defined cross sections and is one of the notable differences between 1D and 2D hydraulic models, which provide more continuous data across a surface.

4.3.2.1 Spatial Extent

The upstream extent of the model for the NFRC is the ponded area upstream from the NFRD. The total length of the NFRC from the NFRD ponded area to the confluence of the NFRC and SFRC (which corresponds to the upstream end of the RCD) is approximately 2,600 m. The upstream cross section for the SFRC is approximately 1,700 meters upstream from the confluence of the NFRC and SFRC. The model extends approximately 500 m downstream from the confluence of the NFRC and SFRC. Extending the model such that the 1D and 2D model domains overlap reduces the potential for edge effects in the 1D hydraulic model due to proximity to the downstream boundary that could cause instabilities when 1D model results are transferred to the upstream boundary in the 2D hydraulic model.

4.3.2.2 Units and Datum

The 1D model is based on LiDAR data dated October 3, 2011, bathymetric survey data upstream from the NFRD dated July 4 and 5, 2013, and cross section surveys along the NFRC channel dated August 20 to August 27, 2013. All computational data are reported in metric units, CGVD 28 vertical datum, and NAD83 CSRS horizontal datum.

4.3.2.3 Bathymetry

Cross sections were extracted from a single DTM that includes the bathymetry of the ponded area upstream from the NFRD. Cross sections representing the portion of the NFRC channel that is below the water surface were used to define the average channel dimensions and depth of the NFRC channel. These channel dimensions were manually entered into the model geometry to essentially create a low flow pilot channel for the NFRC.

4.3.2.4 Geometry Elements

HEC-RAS geometry elements were used to describe features such as the NFRD, NFRC, and SFRC. The river centerline was manually digitized in HEC-GeoRAS based on the site aerial photograph. Cross section alignments were also manually defined, using topographic contours developed from the LiDAR data to digitize contours that were approximately orthogonal to the predominant flow direction. The impounded area upstream from the NFRD was modelled as a storage area element, using the stage-storage curve (Figure 4-12) to define the storage capacity. An inline structure element was used to represent the geometry of the Haul Road embankment. The flow-through characteristics of the NFRD were modelled as a gate structure with a user-defined rule curve to match the stage-discharge relationships as defined in Figure 4-16.

A lateral structure was used to define the boundary between the NFRC and SFRC catchments, since flood flows may result in flow leaving the NRFC catchment and entering the SFRC catchment. Ineffective flow areas were used in ponded areas to delineate locations where water is likely to accumulate, but no appreciable downstream velocity is anticipated. Two corrugated metal pipe culverts (diameters of 1.78 and 3.65 m) approximately 900 m downstream from the NFRD were not included in the hydraulic model to improve model stability and because the culverts are not anticipated to affect the timing of the hydrograph routing (if the culvert capacity is exceeded during a flood event then flows would overtop the site access road and continue to flow downstream on the NFRC). Also, removal of structures such as culverts is commonly performed for hydraulic models when low probability flood events (and particularly breach scenarios) are being modelled since these structures are not designed for such events and can reasonably be assumed to fail at some point during the flood.

Figure 4-20 shows a plan view of the HEC-RAS model geometry.

4.3.2.5 Upstream and Downstream Boundary Conditions

The HEC-RAS model was developed assuming a subcritical flow regime. This assumption is commonly applied to 1D hydraulic models and generally has little effect on the timing of routed hydrographs. Under the subcritical flow assumption, calculated WSELs in areas where flows tend toward a supercritical regime may be higher than what would actually occur since supercritical flows are associated with lower WSELs than subcritical flows. The assumption of subcritical flow improves model stability and provides a conservative estimate of inundation extents during a flood event.

Subcritical flow requires a downstream boundary condition. A normal depth calculation based on the slope at the downstream end of the model was used to establish the boundary condition. The approximate channel slope of 0.0013 m/m at the head of the RCD was used as the downstream model boundary condition. Internal boundary conditions consist of the starting WSEL in the ponded area upstream from the NFRD and the initial flow through the NFRD. These boundary conditions were initially set based on the starting hydrograph flow and the assumed flow-through scenario (high, medium, low).

4.3.2.6 Unsteady Flow Data

Hydrographs for the NFRC, SFRC, south slope catchment, and tailings area catchment were developed as part of the hydrology analyses and are shown in Figure 4-2. Previous hydraulic analyses indicate the RCD has capacity to convey flows up to approximately 70 m^3/sec (CH2M HILL, 2013b). To reduce model computational time the hydrographs were truncated to flows that are above 20 m^3/sec for the NFRC hydrographs. Since SFRC flows are less than NFRC flows (typically 70 percent of predicted NFRC flows) this results in truncated RCD flows below approximately 35 m^3/sec. Flows less than 35 m^3/sec are assumed to be fully conveyed in the RCD on both rising and falling hydrograph limbs and are assumed to not contribute to volume accumulation in the tailings area behind the ID and will not contribute to ID spillway flows.

4.3.2.7 Model Calibration

Ideally, model calibration would be accomplished by comparing measured and simulated WSEL values for a known discharge. Because no calibration data are available for the high flows analyzed, the model was calibrated by adjusting the channel and floodplain roughness (Manning's *n*) within a range of reasonable values (0.025 to 0.040 for the main channel and 0.04 to 0.07 for the floodplain) to test the sensitivity to roughness and match the

simulated results to previous modelling. A constant roughness value of 0.040 was selected for the main channel and a constant value of 0.055 was selected for the floodplain.

Applying a constant roughness value of 0.040 for the main channel is a conservative approach, based on professional engineering judgment and referencing *n* value tables as presented by Chow (1959). The roughness value of 0.055 for the floodplain is representative of areas of low to medium density vegetation and is also selected based on professional engineering judgment and referencing *n* value tables as presented by Chow (1959).

4.3.2.8 Model Simulations

The 1D hydraulic model was used to route flows on the NFRC and SFRC during the 1-in-500-year flood event. Only the high flow-through scenario was routed to the RCD using the 1D model under a non-breach scenario since this case minimizes the attenuation of flow through the NFRD and thus provides an estimate of the maximum flow for the RCD and ID impoundment. Breach analyses were performed the medium flow-through scenario, low flow-through scenario, and low flow-through scenario assuming a 25-percent reduction in flow-through capacity. These scenarios best represent the average anticipated flow-through and subsequent worst case reduced capacity conditions.

4.3.3 1D Hydraulic Routing of Design Flood Hydrographs – Non-Breach Scenario

Routing the attenuated NFRC flows to the head of the RCD produces a hydrograph that exhibits a reduced peak flow and that is also delayed in time compared to the original design hydrographs as presented in Figure 4-2. The 1D hydraulic model was used to create hydrographs that represent combined NRFC and SFRC flows, taking into account the attenuation of flows through the NFRD. This attenuated hydrograph was combined with hydrographs for the south slope and tailings areas to produce final design hydrographs for the RCD and ID spillway. Two RCD design hydrographs were created along with one hydrograph to represent the tailings area and ID spillway flows.

The hydrograph at the head of the RCD includes the entire catchment area of the NFRC, SFRC, and the portion of the south slope catchment that contributes flow near the head of the RCD. Total catchment area for the head of the RCD flows is approximately 199 km^2. The hydrograph for the RCD, downstream of the overflow weir, includes the additional south slope catchment area of approximately 4 km^2 that contributes flows to the RCD, but would not contribute flows through the overflow weir area in the event of a overflow weir failure. Total catchment area for the RCD flows downstream of the overflow weir is approximately 203 km^2. The hydrograph for the tailings area and ID spillway includes the entire catchment area contributing to the head of the RCD, plus the tailings and surrounding area that drains to the ID spillway. Total catchment area for the ID spillway is approximately 208 km^2.

Table 4-7 summarizes the contributing catchment area, peak flow rates assuming no attenuation through the NFRD, and attenuated peak flow rates for the high flow-through scenario under a non-breach condition. Figures 4-21 through 4-23 show the inflow hydrographs and final design hydrographs for the three locations.

TABLE 4-7
RCD and ID Spillway 1-in-500-year Peak Discharge
Faro Mine Remediation Project

Location	Catchment Area (km^2)	Peak Flow, no Attenuation (m^3/sec)	Attenuated Peak Flow (m^3/sec)	Percent Reduction in Peak Flow (m^3/sec)
Head of RCD	192	130	111	15%
RCD, downstream of overflow weir	203	136	116	15%
Tailings area and ID Impoundment	208	140	121	14%

4.3.4 1D Hydraulic Routing of Design Flood Hydrographs – Breach Scenarios

4.3.4.1 Breach Analysis Approach

As the hydraulic modelling results suggest, behaviour of the NFRD during a 1-in-500-year flood event is subject to uncertainties related to the flow-through capacity of the NFRD. The range of flow-through conditions depend on factors such as rock size, extent of calcium-silicate versus schistose rock, quality of rock over time (relative to breakdown of schistose rock or vertical migration of fines), and blockage of the upstream face or plugging of interstitial spaces causing a reduction in flow-through capacity. Measured stage-discharge data during high flow events approaching the 1-in-500-year flood event is the only way to definitively assess the expected behaviour of the NFRD during such an event. Since the hydraulic modelling predicts a wide range in maximum impounded water surface elevation and impounded storage volume, it was determined that breach scenarios under average and increasing worst-case conditions would provide an estimate of the potential range of downstream consequences. The breach analysis conducted is subject to key assumptions and limitations described below:

1. The analysis performed assumes that a breach of the NFRD Haul Road embankment is possible. Because the actual flow-through characteristics of the NFRD under higher flow-through rates are not well known, this initial analysis aims to bracket the potential downstream impacts. Standard breach parameter estimation techniques are assumed to apply to the NFRD. These equations are typically based upon data sets of observed failures of earthen or rockfill dams and provide estimates of breach time and breach geometry. While constructed of rockfill material, the NFRD is different in many ways from the earthen or rockfill dams that form the basis for the breach parameter estimation techniques. For instance, the range in rock sizes and rock types used to construct the NFRD and Haul Road embankment differ from many earthen and rockfill dams that are constructed with a specified soil and rock type and typically with tighter restrictions on material gradations and quality. Construction methods for the NFRD (end dumped material with little foundation preparation) also differ from the methods used for typical earthen and rockfill dams (which typically require formal foundation preparation and compaction of materials).
2. The failure mode of the embankment was assumed to be piping. Standard breach parameter estimation techniques typically classify the failure mode as either an overtopping failure or a piping failure. Hydraulic modelling results indicate that failure due to overtopping of the Haul Road embankment is not likely. However, overtopping may be possible in conjunction with a ravelling failure, wherein material is removed from the downstream face of the embankment resulting in an oversteepened slope that could lead to slope failure, lowering of the crest, and overtopping. The potential piping failure modes for the Haul Road embankment include (1) wash-out of finer particles within the schistose fill material leaving concentrated flow paths that could result in piping, and (2) piping through the foundation. For the purpose of the breach analyses it was assumed that a piping failure is more likely than an overtopping failure.

Two standard breach parameter estimation methods were used to model the medium flow-through, low flow-through, and low flow-through with 25-percent reduction in flow-through capacity breach scenarios. The selected methods were Froehlich (2008) and Von Thun and Gillette (1990). These methods were selected because they provide internally congruent breach parameter estimates, but represent different breach progression modes. The Froehlich (2008) breach parameter estimation predicts a faster breach development time and smaller final breach geometry. The Von Thun and Gillette (1990) method predicts a slower breach development time and larger final breach geometry. The methods were checked against other envelope equations and methods for predicting peak breach discharge to verify that the breach hydrographs were reasonable.

The initial breach analysis assumed a medium flow-through condition at the NFRD. The 2D hydraulic model was used to route the breach flows through the ID spillway and evaluate flow conditions at the ID crest. Model results indicated that the ID crest would not be overtopped. Subsequent breach analyses, assuming progressively reduced flow-through capacities at the NFRD, were conducted until significant overtopping of the ID crest was observed. Overall, breach analyses of the NFRD were performed for the medium, low, and low plus 25 percent blockage flow-through cases at the NFRD. The following sections further describe the breach parameter estimates, 2D hydraulic model routing, and results of the breach analyses.

4.3.4.2 Breach Development Time, Geometry, and Initiation

A subset of the 1D hydraulic model was used to model the breach scenarios and produce hydrographs. Model parameters defining the breach include breach development time, final breach bottom width, final breach bottom elevation, side slopes of the failed embankment, weir coefficient (to compute overflow capacity), failure mode (piping or overtopping), piping coefficient (to compute piping flow rate), failure trigger mechanism (timing or water surface elevation), and breach progression.

For the purposes of breach modelling the development time is defined as the time between when the structure exhibits significant erosion and full development of the breach. Breach development time does not include initial sloughing of material, minor erosion, or other processes that occur prior to significant failure. Since most structures are observed to fail relatively quickly after significant erosion is observed, the breach development times that are used for earthen embankments are typically on the order of minutes to hours. Estimates of breach development time using the Froehlich (2008) and Von Thun and Gillette (1990) methods are shown in Table 4-8. Froehlich breach development times are faster (5 to 11 minutes) than Von Thun and Gillette development times (40 to 50 minutes) for the average and worst-case scenarios modelled.

TABLE 4-8
Breach Parameters
Faro Mine Remediation Project

Scenario	Parameter Estimation Method	Breach Development Time (hr)	Final Breach Bottom Width (m)	Breach Side Slopes (H:V)	Impounded Water Surface Elevation at Time of Breach Initiation (m)	Impounded Water Volume at Time of Breach Initiation (m^3)
Medium flow-through (average condition)	Froehlich (2008)	0.08	1.0[a]	0.5[b]	1,104.3	1,241,193
	Von Thun and Gillette (1990)	0.65	4.3	1		
Low flow-through	Froehlich (2008)	0.10	1.0[a]	0.5[b]	1,108.0	2,071,410
	Von Thun and Gillette (1990)	0.68	13.4	1		
Low flow-through with 25-percent capacity reduction	Froehlich (2008)	0.12	1.0[a]	0.5[b]	1,110.2	2,671,369
	Von Thun and Gillette (1990)	0.70	18.9	1		

[a] Final breach bottom width of zero (V-notch) changed to 1.0 to improve model stability.

[b] Default breach side slopes of 0.7 adjusted to account for increasing breach bottom width.

The final geometry of the breach is defined by the bottom elevation, width, and side slopes of the fully developed breach. Default side slopes of 0.7 and 1 for the Froehlich (2008) and Von Thun and Gillette (1990) methods were assumed. If applying side slopes of 0.7 for the Froehlich (2008) scenarios resulted in a negative bottom width or a v-notch bottom configuration, the side slopes were steepened until a bottom width of 1.0 m was attained. This change was primarily made to improve model stability over the v-notch bottom configuration. An elevation of 1,092 m was assumed for the final breach bottom elevation. This elevation corresponds to the top of the NFRD core constructed of calcium-silicate rock and represents the assumption that the large rock at the bottom of the NFRD will be immobile during a breach event. Final breach bottom width controls the overall size of the breach. Breach bottom width estimates using the Froehlich (2008) and Von Thun and Gillette (1990) methods are shown in Table 4-8. Froehlich final breach bottom width is narrower (0 to 1.5 m) than Von Thun and Gillette final width (4.3 to 19 m) for the average and worst-case scenarios. The narrower width predicted by Froehlich is consistent with the shorter overall breach time, since a shorter breach time will result in less material removed from the embankment.

As stated above, the failure method was assumed to be piping. A piping coefficient of 0.5 and a weir coefficient of 1.5 were assumed based on recommended values (U.S. Army Corps of Engineers [USACE], 2010). For all model scenarios, failure was assumed to occur at the maximum impounded water surface elevation. This condition would correspond to the maximum impounded water volume upstream of the NFRD. The maximum impounded water surface elevation does not correspond with the timing of the peak discharge hydrograph, so the analysis assumes that peak discharge rates during a breach scenario are attributable to the maximum release of impounded water and not a combination of release of water during a breach coincident with peak inflows. All scenarios also assume that the breach development is linear (i.e. the breach develops at a constant rate rather than defining a breach development curve).

4.3.4.3 Breach Analysis Results

Both parameter estimation methods produce peak discharge results that are consistent with other envelope equations and peak discharge estimation methods. For the medium flow-through scenario the peak discharge predicted by the Froehlich (2008) method is approximately 383 m^3/sec. The peak discharge predicted by the Von Thun and Gillette (1990) method is approximately 588 m^3/sec. The Froehlich (2008) method predicts a peak discharge of 643 m^3/sec during the low flow-through breach case while the Von Thun and Gillette (1990) method predicts a peak discharge of 1,217 m^3/sec. Peak discharge estimates for the low flow-through plus 25-percent capacity reduction scenario range from 861 m^3/sec to 1,627 m^3/sec for the Froehlich (2008) and Von Thun and Gillette (1990) methods, respectively.

Breach flows were routed to the RCD and adjusted by adding design hydrographs for the downstream NFRC catchment, SFRC, south slope discharging to the head of the RCD, and tailings area. The peak breach discharge for the ID impoundment assuming a medium flow-through scenario ranges from 437 m^3/sec to 640 m^3/sec. Peak breach discharge for the ID spillway assuming a low flow-through scenario ranges from 689 m^3/sec to 1,262 m^3/sec. Peak breach discharge for the ID spillway assuming a low flow-through plus 25-percent capacity reduction scenario ranges from 904 m^3/sec to 1,669 m^3/sec. Breach hydrographs predicting maximum peak flows for both scenarios (average and worst-case) were analyzed using a two-dimensional hydraulic model to evaluate impacts to the ID (see Section 4.3.6). Figure 4-24 shows the breach hydrographs including downstream flows added to represent the conditions at the ID.

4.3.5 Description of 2D Hydraulic Model

For this analysis, to describe inundation continuously over the project reach, CH2M HILL used MIKE 21FM, a 2D hydraulic model developed by Danish Hydraulic Institute Water and Environment. MIKE 21 FM® is a 2D finite element model that uses both quadrangular and triangular grid cells that vary in size and shape throughout the model domain (flexible mesh). Because hydraulics (depth and velocity) can be computed continuously throughout the model network, complex flow paths and overland flow characteristics are simulated more accurately with a 2D model. In contrast, a 1D hydraulic model computes average hydraulics at discrete locations (cross sections) and does not provide continuous data across a surface like the Rose Creek tailings.

Outputs from the 2D model include depth, depth-averaged velocity, and WSEL. Model results are presented as colour-coded contours and velocity vectors overlaid on aerial photographs, facilitating the interpretation of depth and velocity at specific locations of interest. As this project proceeds to future phases, the model can be further refined in order to provide valuable information to designers and other interested parties.

The 2D model was used to simulate hydraulic conditions that result from routing the 1-in-500 year flood event hydrographs. Development of input hydrographs is discussed above in Section 4.2 and includes attenuation of peak flows through the NFRD and routing of flows from the NFRC and SFRC. The 2D model was used to estimate flow rates, depths, velocities, and water surface elevations through the RCD, across the tailings, and over the spillway of the ID.

4.3.5.1 2D Model Development

Model development followed a series of specific steps:

- Generate the digital terrain model

- Discretize (transform the continuous surface into its discrete counterparts) the domain and resolution (computational mesh)
- Define hydraulic structures
- Define the boundary conditions (flow and water levels)
- Map the flow-resistance parameter

Each step of the model development process is described in detail below.

Generate Digital Terrain Model. To represent the channel and pond bathymetry and tailings topography, a single DTM was prepared that covers the extent of the model domain for each modelling scenario. The 2D model is based on LiDAR data dated October 3, 2011. All computational data are reported in metric units, CGVD 28 vertical datum, and NAD83 CSRS horizontal datum.

Discretize Domain and Resolution. The model domain extends from its downstream boundary below the polishing pond upstream to the confluence of the NFRC and SFRC, a distance of approximately 5,000 m. CH2M HILL discretized the model domain using both quadrangular and triangular elements. Quadrangular elements were used to define the channel of the RCDC and the ID spillway (features that require tight boundary fitting). Triangular elements were used to define the tailings areas. Elements in the main channel range from 4 m to 6 m (length scale). The tailings elements are specified with a maximum area of 200 m^2 with the larger elements used in elevated floodplain areas that are not expected to become inundated. The final computational mesh included 46,820 elements. Elevation data were interpolated to the mesh using gridded X-, Y-, and Z-point data extracted from the DTM. Figure 4-25 illustrates the computational mesh in the location of the ID spillway.

Model Hydraulic Structures. Within the model domain, the tailings area includes the spillway of the ID and the RCDC includes the overflow weir. These structures were modelled as open channels.

Upstream and Downstream Boundary Conditions. The MIKE 21 hydraulic model solves the partial differential equations (St. Venant Equations), which require defined boundary conditions at all open boundaries. The model simulations have three open boundaries: two at the upstream extent of the model domain and one at the downstream extent. For analysis of the ID spillway, the two upstream boundaries are defined with the 1-in-500-year flood event hydrographs developed for the RCD and the tailings area. For analysis of the RCD, the upstream boundary associated with the RCD is defined with uniform flow (1-in-500-year flood event peak flow rate equal to 111 m^3/sec upstream of the overflow weir and 116 m^3/sec downstream of the overflow weir). For all model simulations, the downstream boundary is defined with a uniform water level (1,014 m). For the dam breach analysis, the upstream boundaries were defined with the flood wave hydrographs developed with the dam break simulation described in Section 4.3.4.

The downstream boundary condition is defined by the WSEL from previous HEC-RAS model results. For a complete discussion and analysis of the design flows, see Section 4.1

Map Flow Resistance Parameter. Water flow experiences two forms of flow resistance: form drag and skin friction. Both of these affect the hydraulics (i.e., water level, velocity, and shear stress) and the associated forces that contribute to sediment transport (i.e., grain shear stress). Vegetation, plan form geometry, bed forms, and bed and bank particle sizes all contribute to flow resistance. Form drag is only a small component and is accounted for directly in 2D models by modelling the physical features of the system that contribute to form drag. Only skin friction needs to be accounted for separately. MIKE 21 FM® accounts for flow resistance due to skin friction using the Manning coefficient, n; however, the direct model input is its inverse, $M = 1/n$.

CH2M HILL mapped n-values using aerial photographs of the project area based on professional engineering judgement and referencing n value tables as presented by Chow (1959). Within the model domain, there are 7 n-value categories as summarized in Table 4-9. Figure 4-26 illustrates the extent of each category.

TABLE 4-9
Manning Coefficient (*n* values) and M values used in 2D Models
Faro Mine Remediation Project

Land Type	*n* value	M value
Bare Soil (no vegetation)	0.030	33.3
Bare Rock (no vegetation)	0.047	21.3
Small Vegetation	0.080	12.5
Large Vegetation	0.120	8.3
Tailings	0.016	62.5
Invert RCDC (submerged)	0.030	33.3
Submerged Tailings	0.016	62.5
ID Spillway	0.030	33.3

Ideally, model calibration would be accomplished by comparing measured and simulated WSEL values for a known discharge and adjusting the roughness values. Because no calibration data are available for the high flows analyzed, no adjustments were applied to the model roughness. For a given reach, the roughness coefficient in a 2D model is lower than in a 1D model because the roughness coefficient only accounts for resistance associated with skin friction. In contrast, roughness in a 1D model must also include bed and plant form resistance (which is accounted for by the spatial representation of the channel in a 2D model).

Model Calibration. To calibrate the model at the ID spillway, an initial model simulation was run with steady state flow equivalent to the peak flow from the 1-in-500-year flood event hydrograph (121 m^3/sec) to determine if results of the hydraulic modelling are reasonable when compared to results calculated using a broad-crested weir equation. Although flow over the spillway does not behave precisely like flow over a weir, open channel flow passes through critical depth entering the spillway and it is assumed that hydraulic results can be approximated using the weir equation to evaluate the reasonableness of hydraulic model simulations. Results from the hydraulic modelling closely match results calculated with the weir equation for the 30-m-wide spillway with a coefficient of discharge equal to 1.6.

4.3.5.2 Model Simulations

All model simulations use a computational mesh interpolated from topography defined by a DTM that is a composite of proposed improvements and LiDAR data that define existing conditions. For the evaluation of improvements, the following seven models were prepared to simulate discharge through the project reach:

- **Model Scenario 1 – ID spillway and dam modifications modelled with input flow hydrograph with recurrence interval of 500 years.** Model simulations assume that the overflow weir has blown out with subsequent erosion of the right bank levee at that location, resulting in the entire design flow conveyed onto the tailings. Model simulations were run with the 1-in-500-year flood event hydrograph with a 72-hour duration. At the start of the model simulations, the tailings area is assumed to be at full pool elevation of 1,046.5 m. As the simulation runs, water is first conveyed down the RCD, then out the overflow weir opening, across the tailings, and is then impounded by the ID. Inflow causes the headwater behind the dam to increase and exceed the elevation of the hydraulic control point on the spillway at elevation 1,046.5 m. Spillway discharge is a function of the headwater depth that builds behind the ID during the 72-hour simulation period. In this model, the peak inflow from 1-in-500-year flood event hydrograph of 121 m^3/sec is attenuated by storage in the ID to a peak flow rate of 115 m^3/sec conveyed over the ID spillway.
- **Model Scenario 2 – Existing conditions in the RCD and required improvement in the RCD to meet freeboard criteria.** Design criteria specify that the RCD maintain 0.5 m freeboard at the 1-in-500-year flood event flow. This model simulation represents the baseline condition where no improvements have been included. To

determine the water surface elevation that would result from conveyance of the 1-in-500-year flood event flow rate, elevations of the right bank dike including the overflow weir were revised so that the 1-in-500-year flood event flow rate could be conveyed in the RCD without overtopping the right bank. A steady state flow simulation with a continuous flow rate (111 m^3/sec in the upper part of the RCD and 116 m^3/sec downstream of the overflow weir) was run in order to extract water surface elevation data along the continuous length of the channel corresponding to the 1-in-500-year flood event peak flow. At the start of the model simulations, the channel is represented by the LiDAR surface. In this model simulation, 100 percent of the 1-in-500-year flood event flow rate is conveyed through the RCD.

- **Model Scenario 3 – Channel modifications to remove vegetation from the right bank of the RCD.** To evaluate the effectiveness of vegetation removal, Model Scenario 2 (Existing conditions in the RCD) was re-run with a revised roughness map to represent the channel cleared of vegetation on the right bank. Model input requires an evaluation of flow resistance expressed as the Manning roughness coefficient, *n*. Vegetation characteristics are commonly represented with the roughness coefficient. Areas mapped as large and small vegetation on the right bank of the RCD were revised to represent the same channel area without vegetation. For example, areas on the right bank classified as large vegetation (*n*=0.12) were revised to bare rock (*n*=0.047) or bare soil (*n* = 0.03). In this model simulation, 100 percent of the 1-in-500-year flood event flow rate is conveyed through the RCD.
- **Model Scenario 4 – Channel modifications to remove vegetation from both the right and left banks of the RCD.** To evaluate the effectiveness of vegetation removal, Model Scenario 2 (Existing conditions in the RCD) was re-run with a revised roughness map to represent the channel cleared of vegetation on the both the left and right banks. For example, areas on both the left and right banks classified as large vegetation (*n*=0.12) were revised to bare rock (*n*=0.047) or bare soil (*n* = 0.03). In this model simulation, 100 percent of the 1-in-500-year flood event flow rate is conveyed through the RCD.
- **Model Scenarios 5, 6, and 7 – Simulated dam breach at the NFRD.** Three scenarios were considered for the breach analysis. Breach Scenario 1 assumes no blockage and medium flow-through condition for the NFRD. Breach Scenario 2 assumes no blockage and low flow-through condition. Breach Scenario 3 assumes 25 percent blockage and low flow-through condition. The three scenarios are based on breach hydrographs described in Section 4.3.4.3. These hydrographs were input to the MIKE 21 2D model at the upstream end of the RCD. The breach model simulations assume that flow can occur down the RCD, discharge through the overflow weir, and flow over the tailings and down the spillway of the ID. Volumes and peak flows associated with each breach scenario are as follows:

  - Breach Scenario 1 (assume breach of NFRD occurs at maximum impounded WSEL during the medium flow-through scenario)
    - Total volume of water impounded upstream of NFRD at start of breach = **1,241,193 m^3**
    - RCD peak flowrate (including flows from SFRC, south slope, and tailings area catchments) = **640 m^3/sec**
  - Breach Scenario 2 (assume breach of NFRD occurs at maximum impounded WSEL during the low flow-through scenario)
    - Total volume of water impounded upstream of NFRD at start of breach = **2,071,410 m^3**
    - RCD peak flowrate (including flows from SFRC, south slope, and tailings area catchments) = **1,262 m^3/sec**
  - Breach Scenario 3 (assume breach of NFRD occurs at maximum impounded WSEL during the low flow-through and 25-percent reduction in flow-through capacity scenario)
    - Total volume of water impounded upstream of NFRD at start of breach = **2,671,369 m^3**
    - RCD peak flowrate(including flows from SFRC, south slope, and tailings area catchments) = **1,669 m^3/sec**

4.3.6 2D Model Results

4.3.6.1 ID Spillway Capacity (Model Scenario 1)

For the 1-in-500-year flood event hydrograph with 72-hour duration, results are summarized:

- Inflow peak flow = 121 m^3/sec
- Peak flow over the spillway = 115 m^3/sec
- Maximum headwater elevation = 1,048.60 m
- Maximum depth at hydraulic control on spillway = 2.10 m
- Minimum freeboard at ID = 1.0 m

Figure 4-27 illustrates the extent of inundation at the 1-in-500-year flood event flow rate. Figure 4-28 presents the 1-500-year flood event hydrographs from the modelling simulation of the ID spillway.

4.3.6.2 Rose Creek Diversion Existing Condition (Model Scenario 2)

Design criteria specify that the RCD maintain 0.5 m freeboard at the 1-in-500-year flood event flow. Results of this model simulation were used to determine the minimum desired elevation of the right bank to achieve the design criteria of 0.5 m freeboard. Locations and elevations for improvements are specified on the design drawings.

4.3.6.3 Rose Creek Diversion Removal of Vegetation (Model Scenarios 3 and 4)

Modelling was performed to evaluate improvements to the RCD by removal of vegetation. WSEL model results for the base case and the vegetation removal scenarios were compared by subtracting the base case results from the results where the roughness values were decreased to represent removal of vegetation. Positive values indicate a reduction in the WSEL as a result of changing the roughness input. These difference plots are depicted in the following figures, which illustrate the reduction in WSEL:

- Figure 4-29 – Reduction in WSEL due to Vegetation Removal on the Right Bank of the RCD
- Figure 4-30 – Reduction in WSEL due to Vegetation Removal on the Right and Left Banks of the RCD

As shown on the difference plots, vegetation removal from the right bank results in an average reduction in the WSEL from 0.05 to 0.10 m. Removal of vegetation from both banks would reduce the WSEL from about 0.10 to 0.15 m. Removal of vegetation is estimated to reduce the WSEL through the total length of the RCD channel. Based on the results, interim improvements specify that vegetation be cleared from the right bank of the RCD.

4.3.6.4 Dam Breach Analysis (Model Scenarios 5, 6, and 7)

As described in Section 4.3.4, NFRD breach scenarios were developed to investigate potential flooding as a result of breach of the NFRD during the 1-in-500-year flood event flow. The breach model simulations assume flow down the RCD, discharge through the overflow weir, and flow over the tailings and down the spillway of the ID. Modelling assumptions are consistent with analysis of the 1-in-500-year flood event cases for the ID spillway, which assume that 100 percent of the 1-in-500-year flood event flow is conveyed into the tailings impoundment and over the spillway. Initial conditions at the start of model simulations assume that the ID impoundment is at the full pool elevation of 1,046.5 m. Following are key results from the breach simulations:

- Breach Scenario 1 (assumes no blockage and medium flow-through condition)
  - Maximum water surface elevation at ID = approximately 1,049.3 m
  - Freeboard at ID = 0.3 m
  - No overtopping of ID or CVD
- Breach Scenario 2 (assumes no blockage and low flow-through condition)
  - Maximum water surface elevation at ID = approximately 1,049.9 m
  - Overtopping of ID and CVD
- Breach Scenario 3 (assumes 25 percent blockage and low flow-through condition)
  - Maximum water surface elevation at ID = approximately 1050.1
  - Overtopping of ID and CVD

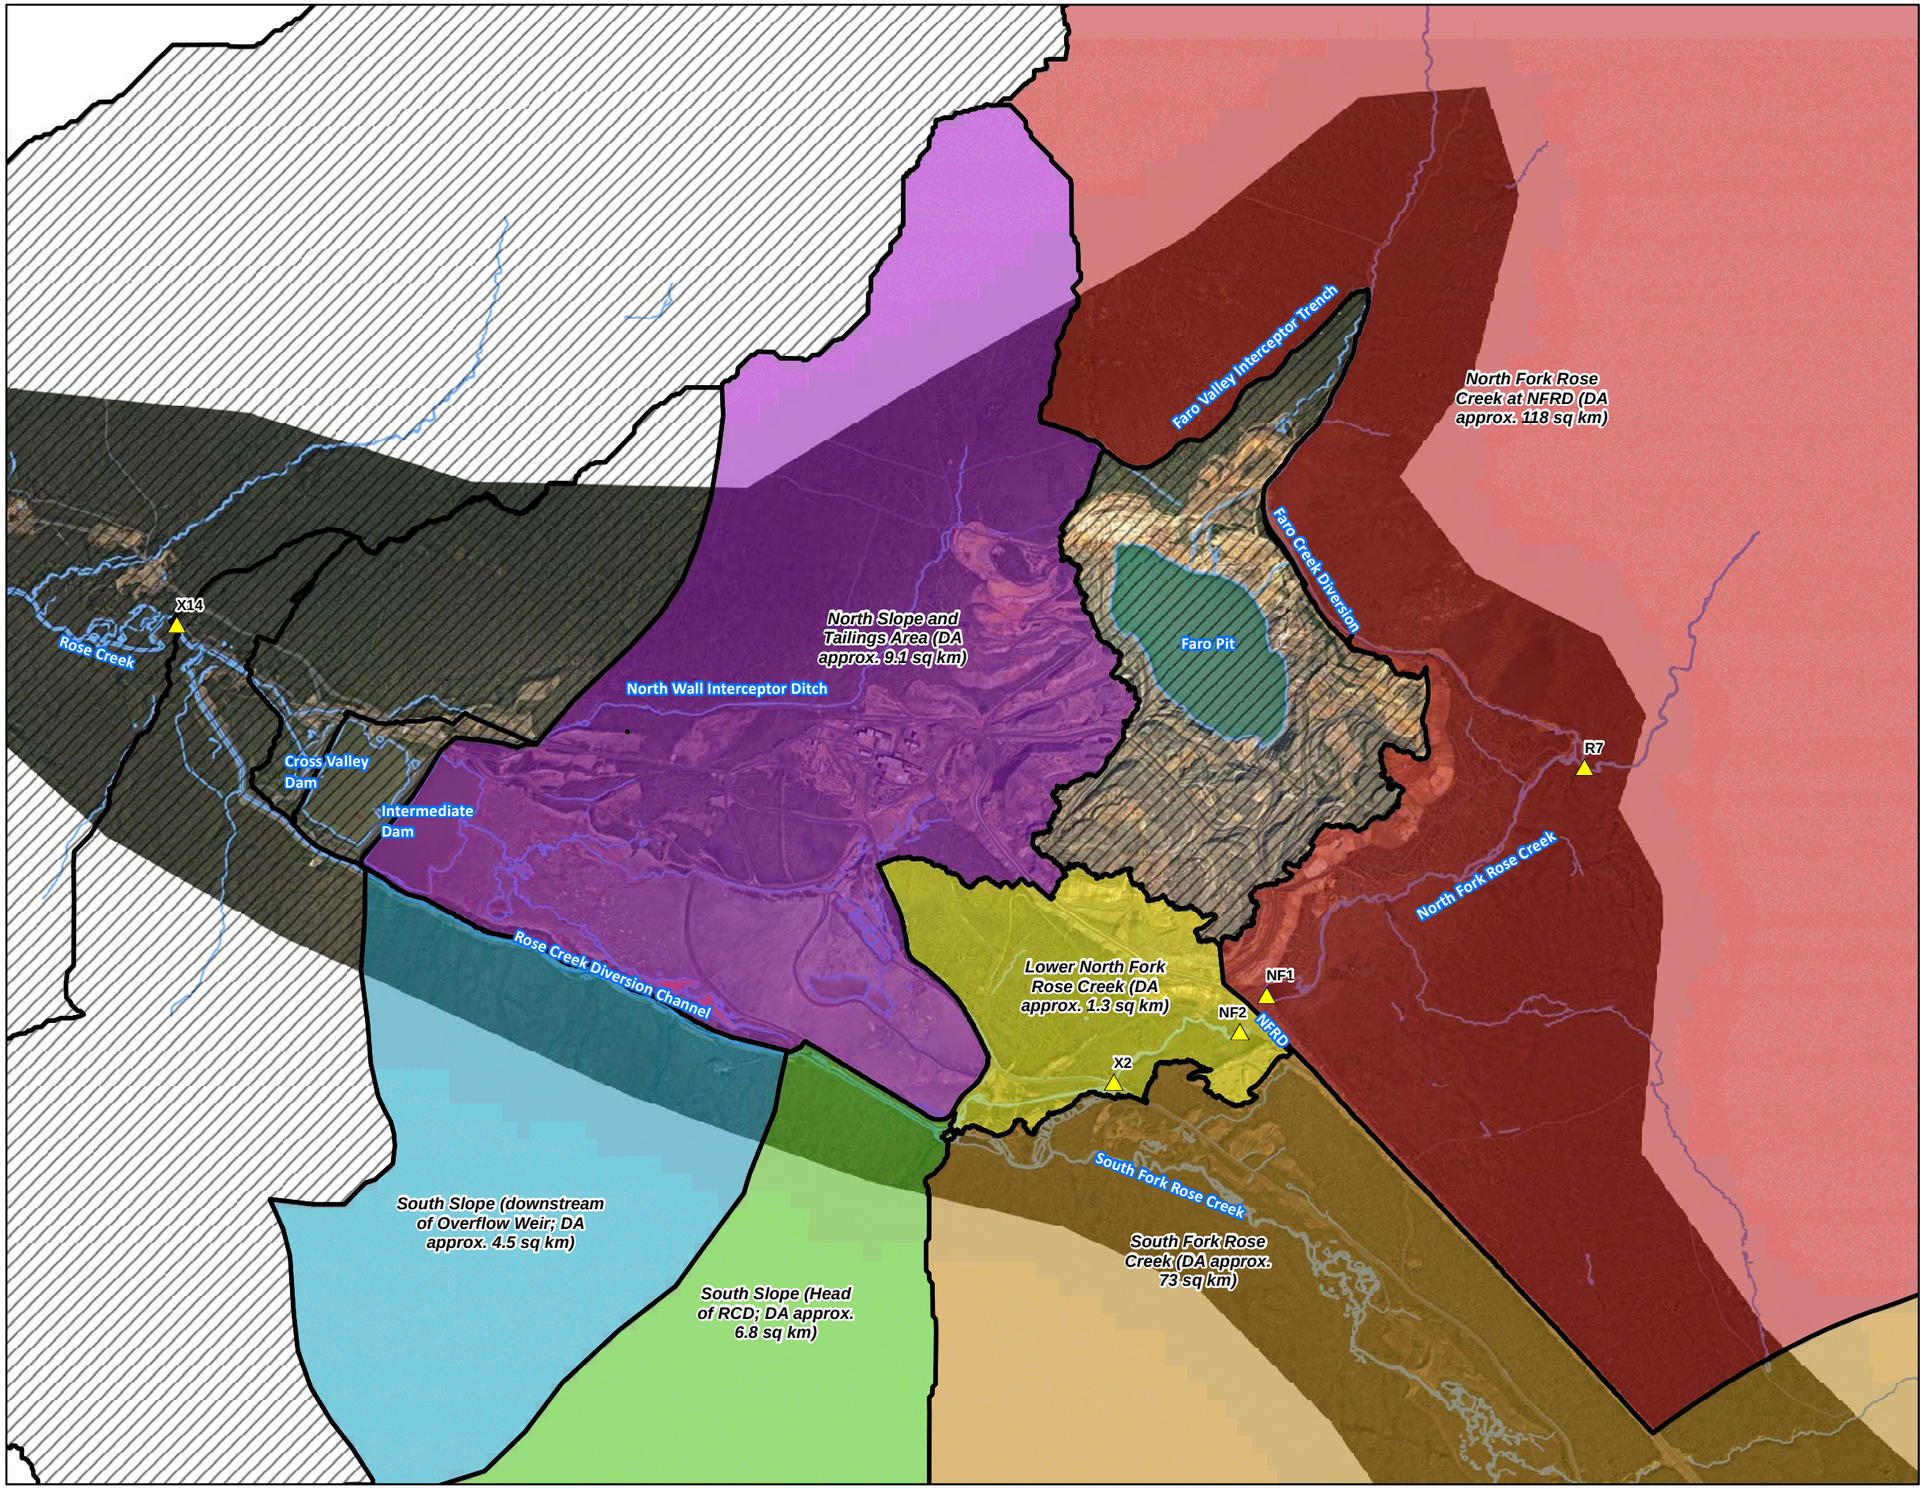
Figures 4-31, 4-32, and 4-33 display breach hydrographs for the medium flow-through condition, low flow-through condition, and low flow-through condition with 25-percent blockage. Table 4-10 summarizes the key information associated with each model simulation. As shown in Figure 4-33 and presented in Table 4-10, the low-flow condition with 25-percent blockage results in overtopping of the ID.

TABLE 4-10
Summary of Breach Simulations
Faro Mine Remediation Project

NFRD Flow-through Condition	Blockage	Peak Flow (m^3/sec)	Maximum WSEL (m)	Overtopping at ID
Medium	Zero	640	1,049.3	No
Low	Zero	1,262	1,049.9	Yes[a]
Low	25%	1,669	1,050.1	Yes

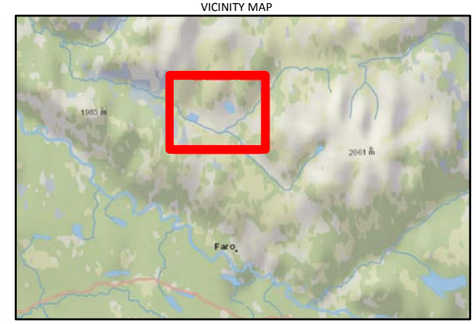
[a] Minimal overtopping of ID crest occurs for breach scenario assuming low flow-through condition and no blockage. This is considered the threshold case.

Breach Scenario 2 is considered to be the threshold case, since minimal overtopping of the ID crest occurs and the duration of overtopping is less than one hour. Based on this analysis, overtopping is expected for any breach scenario with a peak flow discharge greater than approximately 1,200 m^3/sec. This estimate of the overtopping flow is dependent on the following conditions occurring concomitantly.



Initial conditions assume that the ID impoundment is at full pool elevation of 1,046.5 m. This assumption limits storage in the ID impoundment and subsequently reduces potential attenuation of the peak discharge.

- In the model simulation, the RCD is blocked off at the overflow weir so that flow is not conveyed down the RCD once the flood is directed onto the ITA. Model simulations that provide for conveyance down the RDC result in an approximate decrease of 0.3 m in water surface elevations at the ID.
- A low flow-through condition was assumed at the NFRD, the most conservative estimate of flow-through capacity.
- Blockage (25 percent) of flow was assumed at the NFRD which reduces capacity further and results in greater impounded volume at the NFRD.



For the medium flow-through condition, a video animation (extracted from model simulation results) was developed to illustrate how the breach flow wave would propagate through the RCD, across the tailings, over the ID spillway, and over the CVD spillway. Four frames were extracted and compiled for display on Figure 4-34. The extent of inundation showing the depth of water is depicted at the top of each frame and progress on the corresponding flood wave hydrograph is included at the bottom. Following are brief descriptions of the images shown:

- Figure 4-34 illustrates Breach Scenario 1, which assumes a medium flow-through condition at the NFRD with zero blockage. The four frames show the following:
  - **Frame 1 (1 hour 15 minutes simulation time)** – This image captures the simulation before the peak of the flood wave arrives at the head of the RCD. The front edge of the flood wave is flowing over the tailings and has not reached the ID.
  - **Frame 2 (5 hours simulation time)** – This image captures the simulation immediately after the peak of the flood wave arrives at the head of the RCD. The ID impoundment has been filled and flow over the spillway has nearly filled the CVD.

- **Frame 3 (7 hours 30-minutes simulation time) –** This image captures the simulation about three hours after the peak of the flood wave has arrived at the head of the RCD. As the flood wave propagates downstream, both the ID impoundment and the CVD are full.
- **Frame 4 (11 hours 30 minutes simulation time) –** This image captures the simulation 6 hours after the peak of the flood wave has arrived at the head of the RCD. As shown, water levels in the CVD are still at full capacity but water levels behind the ID have decreased as compared to Frame 3.

SECTION 5

Intermediate Dam Spillway and Crest Improvements

5.1 Required Intermediate Dam Spillway Capacity

The intent of the Down Valley Interim Hydraulic Upgrades is to provide a design which modifies the RCD and ID crest/spillway in order to safely pass a 1-in-500-year flood event through the RCTA, including attenuation of this flood on the NFRC by the NFRD. Apart from remediating spill capacity associated with large flood events, an increase in ID spillway capacity would also provide mitigation for other RCD failure mechanisms. These include (1) failure of the RCD dike by piping or slope instability during moderate flood events, (2) landslide or debris flow originating on the mountainous slopes to the south of the RCD that would block the RCD and cause overtopping of the RCD dike, and (3) icing buildup in the RCD resulting in overtopping of the RCD dike.

The 1-in-500-year flood event hydrograph has a peak flow of 121 m^3/sec, which could potentially be discharged over the ID spillway. However, it is unlikely that this flow rate would be reached over the ID spillway. Both of the following scenarios would have to occur at the same time in order for the full flow rate to be conveyed over the spillway:

- None of the flood flow would continue down the RCD and all of the flow would be conveyed onto the tailings. This would only occur if the right bank of the RCD totally breached at the overflow weir location, a new channel was formed because of erosion, and the flood flows completely abandoned the RCD. This would represent the classic pit capture scenario.
- The duration of the 1-in-500-year flood event peak flow would need to be of sufficient length to fill the ITA to about elevation 1,049.0 m. The amount of available storage in the impoundment at the beginning of the flood would determine the necessary duration of inflow to reach a WSEL of 1,049.0 m. As described in Section 4.2, hydraulic modelling assumed that the impoundment is at full pool with a beginning WSEL of 1,046.5 m. The 2D model includes the proposed improvements to the spillway and dam crest with flow input as a 72-hour duration hydrograph that represents the 1-in-500 year flood event. The peak flow of the input hydrograph is 121 m^3/sec and the attenuated peak flow that discharges over the spillway is 115 m^3/sec. Minimum freeboard is 1.0 m.

Based on these considerations, it is unlikely that the flow over the ID spillway will reach the same magnitude as the inflow into the RCD during a large flood event. However, because of uncertainty in the dike performance under large flood events, and based on the design criteria established by the expired water licence, the design ID spillway capacity was established as 115 m^3/sec, which is the 1-in-500-year flood event flow.

5.2 Field Investigations

The purpose of the field investigation was to collect geotechnical information to evaluate the feasibility of embedding a geomembrane in the existing compacted clay core of the ID and extending the geomembrane to provide a seepage cut-off to the crest of the ID. The top of the clay core in the existing ID is about 0.6 to 0.9 m below the crest of the existing dam. The geomembrane would limit the advancement of seepage through the upper portion of the existing ID; the single gabion row would further raise the crest of the ID, with the geomembrane extending over the top of the gabions.

To prevent seepage around the base of the geomembrane, it will need to be embedded some depth into the clay core. A trench will be excavated into the existing ID to allow embedment of the geomembrane.

Seven test pits were excavated in the crest of the existing ID to evaluate the depth and condition of the clay core and the stability of the trench walls in the dam material above the clay core. Three test pits were also excavated in the bottom of the existing ID spillway channel. The details and results of this investigation are described in detail in the CH2M HILL TAR-016 Data and Analysis Report. This document is in progress and will be bound and submitted separately.

The specific objectives of the test pit investigation were:

- Obtain depth of the compacted clay core in the existing ID and variability of the depth across the existing dam crest.
- Assess condition of the top zone of the existing clay core, including composition, width, relative moisture content and density, and presence of any cracks or other defects
- Determine nature of the material overlying the compacted clay core, including the composition and relative density, and the temporary stability of excavation side walls in this material, for construction purposes
- Determine the nature of the materials in the upper 2 m of the spillway channel, including particle size, relative density, and ease of excavation, for construction purposes

The dam core material generally consists of silty, clayey sand and gravel with cobbles. Near the centerline of the dam, the dam core material is within 0.3 m to 0.6 m of the ground surface. On the upstream side of the dam, the top of dam core material becomes deeper, up to a depth of about 1.2 m at a horizontal distance of 1.2 to 1.5 m from the top of the upstream slope. From design and as-built cross sections of the dam, the top surface of the upstream sloping dam core is approximately parallel to the upstream face of the dam, at an offset of approximately 0.9 meters horizontally. Based on these findings, the upstream edge of the installation trench will be located 1 m from the top of the upstream slope, with a depth of 1.5 m.

The subsurface material within the spillway consisted of coarse-grained alluvial soil that a CAT 345C excavator was able to excavate to a depth of more than 2 m. It is noted that there are abundant cobbles and boulders, up to a maximum size of about 60 cm (24 in) in dimension within the upper 0.9 m; this is the existing erosion protection material in the spillway channel. Based on the results of these three test pits, excavation of the bottom of the spillway channel could be easily accomplished with standard earthmoving equipment. Additional testing will be necessary to determine if the material excavated from the spillway is clean. There will be excess material from the excavation of the spillway. During the 90-percent phase, recommendations will be provided on where to stockpile this material and if it will be suitable earth fill material for this project.

5.3 Spillway Improvements

The improvements at the ID spillway consist of excavating the existing channel by a maximum of about 2 m, and placing a 0.45-m-thick gabion mattress on the excavated bottom of the spillway channel. The proposed channel will follow the same footprint of the existing channel, so there will not be any significant widening of the channel. Gabion cells that are 0.9 m by 0.9 m in cross section will be used on the sides of the channel, with configuration as shown on Drawing C-9 in Attachment A. A geotextile will be provided between the gabions and the excavated soil surface to provide separation and filtering.

It is proposed that cobbles screened from the Rose Creek borrow area be used to fill the gabion mattress and gabion cells. See Drawing C-1 in Attachment A.

5.4 Crest Improvements

To raise the effective ID crest, a geomembrane will be installed vertically in a trench between the dam core and the crest surface, and a single row of 0.9 m by 0.9 m gabions will be placed along this line to further raise the effective crest to an estimated elevation of 1,049.6 m. The gabions will be partially embedded (depth of about 0.2 m) in the upper portion of the excavated trench on top of the compacted backfill. It is noted that the ID crest is at an average elevation of about 1,048.9 m and based on the test pit exploration results the top of the dam core at the center of the dam crest varies with a low elevation of about 1,048.3 m. To tie the geomembrane into the existing core, the upstream edge of the installation trench will be located 1 m from the top of the upstream slope, with a depth of 1.5 m. Low-permeability glacial till material will be imported from a nearby borrow area and will be placed in the lower 0.5 m of the installation trench. The material excavated from the trench would be used for backfill in the upper 1.0 m. The crest surfacing will be reinstated as shown on the drawings, by placing a 0.2 m thick layer of gravel and sand at the crest.

Alternatives to the gabions were considered including use of concrete traffic barriers, or placing a 1-m-high soil or waste rock berm. Since no concrete batch plant would be in operation at the time of constructing the Down Valley Interim Hydraulic Upgrades, it was assumed that the barriers would have to be trucked in from Whitehorse. Given that gabion mattresses will be used to harden the spillway channel and that the contractor will already have a gabion installation process in place, a comparative cost estimate indicates that the gabions should be less expensive. In addition, it will be easier to reuse the materials in the gabions as compared to the traffic barriers when these structures are dismantled to implement final closure concepts such as raising the ID. A berm would have a larger footprint than the other two options, could limit vehicular access to the ID crest, and would potentially be more difficult to remove. Also a berm would have a flatter upstream slope with somewhat inferior performance against wave run-up compared to the vertical or near vertical upstream slopes of the other two options.

A freeboard analysis was performed in accordance with technical guidelines from CDA (2007) to determine minimum and normal freeboard requirements. Wind speeds representing the 1-in-2-, 1-in-10-, 1-in-100-, and 1-in-1,000-year annual peak wind were determined by analyzing weather records from the Faro Airport meteorological station (Climate ID 2100517). Normal freeboard was determined by assuming a still pool elevation of 1,046.5 m (inundation corresponding to spillway invert elevation) and accounting for increased water levels due to wave, wind setup, and wave runup conditions during a 1-in-1,000-year wind. Minimum freeboard was determined by assuming a still pool elevation of 1,048.6 m (approximate maximum water surface elevation during a 1-in-500-year flood event) and accounting for wind and wave action during a 1-in-10-year wind. Two wind frequency distributions were considered for determining normal and minimum freeboard due to a suspected statistical outlier in the wind data. The minimum required crest elevation to provide suitable freeboard was determined to be approximately 1,047.5 m (or 1,047.2 m without the outlier) for the normal freeboard case. The minimum required crest elevation for the minimum freeboard case was estimated to be 1,049.6 m (or 1,049.4 m without the outlier). The design crest elevation of 1,049.6 m provides suitable freeboard under both conditions. Additional information regarding the wind analysis and freeboard calculations can be found in Appendix H.

5.5 Replacement of Conflicting Pipeline Conveyance Systems

5.5.1 Existing Pipeline Conveyance systems

This section has been prepared to summarize the design intent and criteria for the relocation, protection, and removal of conflicting existing facilities prior to construction of the new interim emergency spillway. Requirements and parameters are identified for the final design team to execute the scope of work.

This portion of the project involves the replacement, protection, or removal of three existing pipeline conveyance and treatment systems located in or near the spillway construction zone (See Drawings). These are only operated during warm weather months and are as follows:

- The water treatment plant (WTP) effluent pipeline
- The Intermediate Pond conveyance system facilities
- The siphon lime mixing system

Based on conversations with the Yukon Government, the siphon lime mixing system is no longer in operation and will be removed by others before construction begins. Therefore, protection and relocation of the siphon lime mixing system is not required.

Existing WTP effluent pipeline: The existing WTP effluent pipeline in the construction zone is a 600 mm DR 32.5 HDPE gravity pipeline installed in approximately 2001 from the WTP to the beginning of the emergency spillway. The original alignment was on the south side of the access road based on 2004 Google Earth satellite imagery. Later the pipeline was moved to the north side and extended to discharge to the current CVD outlet structures. Two existing wafer type butterfly valves are located at a tee near the Intermediate Pond pump station valve house to divert water to the CVD or the Intermediate Pond depending on water quality. These valves are connected with fittings that allow the required internal disc separation from the thicker walled HDPE pipe and

HDPE fittings. The fittings and valves appear to be in relatively good condition and will be considered for relocation to a new valve location as shown on the drawings.

Existing Intermediate Pond conveyance system facilities: These facilities consist of a conveyance system that currently is used to pump Intermediate Pond water to the old WTP for treatment. Main components near or within the construction zone are:

- A floating barge pump station (2- vertical turbine pumps)
- A pipeline from the barge to a valve house structure. There are no known record-drawings of this pipe material. Based on photos, the pipe material appears to be reinforced high pressure dredge hose.
- A Motor Control Center structure adjacent to the valve house.
- An above ground/buried (under access road) 350 mm diameter DR 9 HDPE piping that is adjacent to the effluent pipeline.
- Overhead electrical power supply.

This facility was installed in approximately 2010 based on record drawings.

Proposed effluent pipeline replacement: A portion of the existing effluent pipeline will be removed, abandoned, and replaced to facilitate the new interim emergency spillway channel. The replacement segment is shown on the drawings. This replacement segment is located on the north side of the access road for the following reasons:

- To provide a perpendicular undercrossing of the new spillway and road while aligning with the existing downstream CVD polishing pond north effluent outlet structure.
- To keep any required excavation away from the ID footprint.
- To maintain a good horizontal and vertical alignment that will maintain the current open channel flow capacity.

Based on the attached profile the existing grade is flatter than the upstream grades. A minimum slope of one percent minimizes excavation and maintains system capacity. However the pipe size will need to be increased from 600 mm to 750 mm because of the flatter slope.

Main scope of work components are:

- Above grade and buried 750 mm DR 17 HDPE piping and associated fittings including but not limited to eccentric reducers
- An insulated trench design to mitigate frost heave and maintain capacity for 5 plus years
- An above grade valve assembly similar to the existing one
- Modifications to use the existing discharge pipeline to the Intermediate Pond
- Removal of the existing 600 mm above grade pipeline downstream from the existing valve assembly
- Abandonment of the existing 600 mm buried pipeline under the access road
- A 2100 mm precast drop manhole to provide the required drop and over 90 degree change in flow direction
- A cased crossing of the new spillway

Proposed Intermediate Pond Conveyance System Protection:

Spillway construction is approximately 20 m from the floating barge pump station. Spillway construction is assumed to occur while the pumps are operating during the warm months. Construction will cause additional silt in the water and a floating silt curtain will be required to protect the pumps.

5.5.2 Pipeline Design Criteria

5.5.2.1 Design Life

The design life for the relocated pipeline is 5 plus years.

5.5.2.2 Pipeline Alignment

Horizontal Alignment

The horizontal alignment is along the north side of the access for the reasons cited in Section 5.5.1.

Vertical Alignment

It is necessary to maintain a minimum one percent slope to maintain supercritical flow. This will prevent any hydraulic jumps which would reduce the maximum capacity.

Maximum Design Capacity

Maximum design capacity is 0.44 m^3/s (7,000 gallons per minute), based on the original 2001 design for an approximate half-pipe flow condition. See Appendix C for the original hydraulic design criteria.

5.5.2.3 Crossings

The pipeline alignment will cross under two roads and the existing ID Spillway. There are no known culverts or buried utility crossings.

5.5.2.4 Loading Conditions

i. Above grade

   1. The pipeline will need to be protected from traffic and occasional rock damage similar to the existing condition.

ii. Buried

   1. Live loads will be based on the Canadian H25 truck wheel load of 9072 kilograms (20,000 lbs).
   2. Earth loads are assumed to be 2243 kilograms per cubic metre (140 lbs/ft3) since we are along the existing access road. We may want to use the existing road backfill material.
   3. The Plastic Pipe Institute design standards will be followed for maximum HDPE pipe deflection, constrained buckling, and thermal movement and associated forces.

5.5.2.5 Trenching and Backfill Design

i. Location

   1. Similar to the existing effluent pipeline, open-cut trenching will be required at the road and emergency spillway crossings

ii. An insulated trench for bury depths less than 3.5 m (11.5 feet) using Styrofoam insulation is assumed to prevent frost upheaval and change in vertical alignment. Other means to prevent frost upheaval will be investigated in the advanced design (90 percent) phase.

iii. Bury depth

   1. Bury depth will vary since the pipeline invert slope must be maintained

iv. Trench Width

   1. Insulated trench width is pipe outside diameter plus 1.5 m to provide room for adequate frost prevention and compaction equipment loads over the pipe

v. Trench Pipe Zone Material

   1. As specified. Refer to Section 31 23 23 in Appendix F for material specification.
   2. Lean concrete, to anchor the HDPE pipeline, ends at the manhole inlet and outlet area

vi. Trench backfill above pipe zone

1. As specified. Refer to Section 31 23 23 in Appendix F for material specification.

5.5.2.6 Pipeline Materials

The HDPE pipeline material is assumed to be the latest PE4710 HDPE resin with either butt fused thermal, electrofused, or flanged joints. Similar to the existing pipeline, outside diameter controlled iron pipe size dimensions will be used.

5.5.2.7 Corrosion Protection

Assume corrosion protection will be required for any above or below grade metal components.

5.5.2.8 Pipeline Appurtenances

Valves

Assume we can use the existing wafer valve assemblies (valves plus fittings) since they have not been in service long.

Drop Manhole

1. Size: A similar (including flow rates) cast-in-place rectangular structure design has been in service for about 20 years. The inside dimensions were a 1.8 m (6.0 foot) square to allow adequate flow equalization for the drop and more than 90-degree change in direction. Therefore, assume a 2,100 mm (84 inch) diameter precast manhole. A vent pipe will be provided to allow air exchange from the interior top of the manhole to the outlet pipe.
2. At grade traffic rated top.

5.5.2.9 Surface Restoration

Roadway surfaces for the buried pipe portions will be restored in-kind.

5.5.2.10 Traffic Control

Assume traffic can be detoured around the construction zones.

5.5.2.11 Ambient Temperature Range

HDPE pipe has a large coefficient of thermal expansion and contraction. Both ambient temperature and associated soil temperature changes will result in either movement or large thermal forces if anchored. The design ambient temperature range is -45° Celsius to 30° Celsius.

5.5.3 Preliminary Wall Thickness Calculations

Pipe Wall Thickness Calculations: Preliminary wall thickness calculations were performed using the latest Plastic Pipe Institute calculator.

5.5.3.1 Purpose and Need

Wall thickness calculations were performed to determine the pipe internal diameter for the hydraulic analysis. HDPE pipe is outside diameter controlled. A 600 mm nominal iron pipe size pipe is manufactured to a 600 mm outside diameter. For solid wall HDPE gravity pipelines, wall thickness is typically controlled by dead and live loads.

5.5.3.2 Modelling Software

The polyethylene piping- calculator by the Plastic Pipe Institute was used to determine pipe wall thickness to resist wall crushing and constrained buckling.

5.5.3.3 Modelling Runs and Results

An assumed 750 mm pipe size was used since the grade was flatter. This was later verified in the hydraulic calculations in Section 5.5.4. The following three different wall thicknesses were used as initial inputs for the

750mm -diameter pipe: DR 32.5, DR 21 and DR 17.The results indicated that a DR 17 wall thickness would resist the heavier Canadian H25 wheel loads and not buckle at a minimum standard safety factor of 2. A minimum pipe cover of 3 feet was assumed. For pipe covers less than 3 feet the pipe will need to be protected. See Appendix D for detailed output results.

5.5.4 Pipeline Hydraulic Analysis

5.5.4.1 Purpose and Need

A hydraulic analysis was performed to verify that the existing pipeline capacity was maintained at the flatter one percent slope. This analysis utilized the original 2001 design criteria presented in Appendix C.

5.5.4.2 Modelling Software

Modelling software for this pipeline gravity flow condition was performed by the Haestad Methods Solutions FlowMaster V8i (Select Series 1) program by Bentley Systems Inc. The original 2001 design calculations were first validated with this program.

5.5.4.3 Modelling Runs and Results

The program validation gave the same results as in 2001, with approximate 37 to 50 percent full-pipe flow conditions. It was discovered that the original calculations were competed for a 600 mm DR17 HDPE pipe. Apparently, the DR was later changed to 32.5 which would give a higher flow capacity but lower resistance to deflection when buried. Results for the minimum one percent slope indicated that a 750 mm nominal diameter DR 17 pipe would perform well. The DR 17 wall thickness was determined from loading calculations as indicated above. See Appendix E for detailed output results.

SECTION 6

Rose Creek Diversion Improvements

6.1 Diversion Flow Capacity

Design criteria require that the crest elevation of the overflow weir be high enough to prevent overtopping for flows less than 111 m^3/sec(the 1-in-500-year flood event flows), and the dike crest downstream from the overflow weir not overtop for flows less than 116 m^3/sec (the un-attenuated 1-in-500-year flood event flows). Hydraulic modelling results for the RCD predict that the existing configuration does not provide adequate capacity to convey the 1-in-50-year flood event flow of 71 m^3/sec before overtopping the overflow weir. Using these results, it was determined that the crest of the overflow weir will have to be raised by about 0.8 m to an elevation greater than 1,058 m to prevent overtopping of the structure for flows of less than 111 m^3/sec in the RCD. As flood flows exceed 111 m^3/sec, the newly-raised overflow weir will begin to overtop. For the purposes of evaluating the RCD capacity, it is conservatively assumed that the overflow weir will not erode during overtopping, and flood waters in excess of the 1-in-500-year flood flows will spill at this location as the flood levels continue to rise. Hydraulic modelling results were used to determine how high the dike will have to be raised downstream from the overflow weir so that overtopping does not occur during a 1-in-500-year flood event; the right bank of the dike will have to be raised by a maximum of about 0.8 m till plus 0.2m of road surface to prevent overtopping.

6.1.1 Geologic Hazards

It is considered possible that mass wasting, slope wash, activation of existing alluvial fans, forest fires, melting of permafrost, earthquakes, and other phenomena are all plausible mechanisms for initiation of coarse sediment deposition into the RCD channel, and that such events could initiate a breach. Such phenomena could coincide with a 1-in-500-year flood event or could occur more frequently. In 2006, BGC performed a natural hazards assessment for the slopes south of the RCD. In this review, BGC identified the alluvial fans near the downstream weir section of the RCD channel as the primary geologic hazard, but also noted that no significant debris accumulation occurred in this area during the period reviewed (1979 to 2003). BGC (2006) also noted the mechanisms previously mentioned.

For Down Valley Interim Hydraulic Upgrades purposes, mitigation of these hazards is not deemed practical. It is noted, instead, that the redundancy provided by maintaining adequate capacity to pass the 1-in-500-year flood flows through the ID and CVD spillways is expected to be an adequate safeguard against RCD breach. Initiation of this breach is expected to occur at the overflow weir section. Because of the unpredictability of these geologic events, CH2M HILL recommends regular inspection and maintenance of the RCD during the interim period to maintain adequate channel capacity.

6.2 Historical Performance of the Rose Creek Diversion Dike

6.2.1 Diversion Construction

Construction of the RCD began in early October 1980 and was completed 12 months later. Most excavation for the diversion can be classified as common excavation and included frozen and unfrozen soil as well as fractured rock. A smaller amount (about 10 percent of total excavation volume) was classified as rock excavation defined as any material that had to be blasted before it could be excavated.

Details of the diversion construction are detailed by Golder (1982) and BGC (2005a). Common excavation took place from November to April, when temperature records show that average daily temperatures were below freezing. This timing was deliberate to prevent thawing of ice rich materials in the cut slope along the south side of the diversion. A gravel thermal liner was placed over the exposed cut slope before spring to reduce the risk of thaw-induced slope instability.

Winter construction, however, presents disadvantages for dike construction and engineered fill placement. During construction it was very difficult to ascertain the extent of permafrost in the native material. It was noted that

significant volumes of unfrozen material were encountered at depth, but that the excavation surfaces usually froze within 24 hours. Snow also masked the excavation surface and complicated construction inspection. A significant portion of the fill for the RCD dike was placed during March and April, when average air temperatures were below freezing. Additionally, foundation preparation activities at several locations for the dike encountered pockets of organic soils several metres thick. Such soils commonly have low strengths, high water contents, and are prone to high degrees of consolidation (settlement). Golder (1982) reported that stripping activities did not remove all of the organic soils, and unknown extents existed below the prepared subgrade.

6.2.2 Diversion Performance

Golder (1982) details the performance of the diversion during the period from May to September 1981, which was the first thaw season after construction. Their report indicates that virtually no thaw settlements or instability occurred on the south cut slope during the first summer after construction. However, some erosion of the thermal blanket materials occurred as surface water runoff flowed over the top of the cut slope. Subsequently, drainage swales were installed along the crest of the cut slope to direct surface water to rock filled drainage channels placed at selected locations along the diversion.

Instability on the south cut slopes have been observed over the years, and evidence of active sloughing and repaired former sloughs was noted in the recent RCD Inspection Memorandum (CH2M HILL, 2013c). The rock slopes that are more prevalent in the downstream section of the diversion have remained stable since construction.

BGC (2005a) noted that cracking and settlements on the dike were observed in a few localized areas and that there was some seepage along the north toe of the dike during the first thaw season after construction. Dike settlements were thought to be either the result of inadequate compaction of the fill materials during the previous winter, the presence of organic silts in the foundation, or thaw settlement of ice rich permafrost within the foundation soils. In the decades since construction, the crest of the north dike settled a total of about 1 m starting about 300 m upstream from the ID and extending upstream over a 1 kilometre-distance. In the summer of 2004, additional fill was placed along this section of the RCD dike to raise it back to its initial design elevation (BGC, 2005b).

6.3 Field Investigation and Mapping

CH2M HILL performed a field inspection of the existing RCD on July 26 and 27, 2013. The inspection was performed by a CH2M HILL geotechnical engineer who walked the entire length of the RCD from the upper end of diversion to the confluence of the diversion with Rose Creek, a distance of approximately 5 kilometres. During the inspection the conditions of the channel and dike were observed and documented. The purpose of the work was to delineate areas where vegetation removal is needed as well as delineate areas of raveled riprap slopes, erosion, oversteepened slopes, or any other areas that may need maintenance or repair commensurate with the Down Valley Interim Hydraulic Upgrades design criteria. Locations where these conditions were observed were geo-referenced using a handheld Garmin model GPSMap 60CSx global positioning unit, to collect Universal Transverse Mercator coordinates and elevations at the locations. The accuracy of this device varies, but is estimated as ±3 to 4 m during the inspection. All Universal Transverse Mercator coordinates reference the WGS 84 datum. The details and extent of this work are described in detail in the RCD Inspection Memorandum (CH2M HILL, pending), which will be an attachment to the TAR 16 Data and Analysis Report.

A summary of the inspection observations follows in Sections 6.3.1 through 6.3.5.

6.3.1 Vegetation

Significant vegetative growth was noted along the RCD during the inspection. Vegetation sizes observed varied from young forbs to small trees up to approximately 100 mm (4 inch) caliper diameter. Woody vegetation was observed on both the left (diversion side), and right (tailings side) of the diversion dike, and also on the left side of the diversion. The type, distribution, and size of vegetation vary widely along the diversion. In some places, large thickets cover the slopes of the dike and complicate inspection. In other places, the vegetation exists at an acceptable level that is not harmful to the integrity of the dike. There is evidence of pockets of recent vegetation

removal activities, but it is apparent that a thorough vegetation removal program is necessary, along with corrective measures and routine maintenance.

6.3.2 Berm Crest Grading

During the inspection, it was observed that the berm crest was generally uniform without obvious signs of settlement or subsidence. A slight dip less than 0.3 m was observed at a location that is approximately the starting point of a 1-kilometre-section extending upstream where the dike crest was raised in 2004 (BGC, 2005b). At this location, the RCD is higher than the adjacent tailings ponds.

At multiple locations along the dike crest or other access roadways adjacent to the RCD, ruts or puddles were observed in the roadway surface. The grading of the berm crest should be maintained to prevent development of these water-collecting depressions which can serve to soften and destabilize the dike and promote additional rutting. The crest should be graded to direct water off from the dike. Additional crest elevation deficiencies are apparent from review of survey information relative to the predicted 1-in-500-year flood event WSEL, see Appendix A, Drawings C-12, Table 1 for details.

6.3.3 Slope Stability

The RCD dike exhibits evidence of slope instability occurring frequently. Long sections of the dike have tension cracks, slides, scarps, riprap deficiencies, toe bulges, and debris accumulations which are indicative of slopes which have failed or are in the process of failing. Generally, most evidence supports that these failure are relatively shallow. The cause for the instability is likely due to a number of factors, including freeze-thaw, rapid-drawdown stresses following high-water events, low strength (organic) materials in the foundation, poor material compaction during dike construction, and other factors. Many slide areas appear to have been repaired, both for discrete slides as well as for long sections of the dike; monitoring instrumentation such as a slope inclinometer casing appears to have been installed by others. Still, many slides appear active and require corrective action. It is important to note that the presence of thick vegetation in some locations prevents detailed inspection of the diversion slopes. In these areas, vegetation should be removed and maintenance performed.

Geotechnical characterization of the dike strengths and evaluation of dike stability has not been performed. However, slides and sloughs observed in the field generally appear to be relatively shallow and non-threatening with respect to deep-seated failure or reduction of dike freeboard, and further do not appear to appreciably compromise the function of the Class II seepage control liner. Dike slopes exhibit signs of ongoing (active) instability, which is expected to continue into the future. These slides are generally regarded as maintenance issues; active maintenance would prevent problems from advancing and would help maintain uniform erosion protection necessary to pass the design flood.

The potential hazards presented by the observed slope instability include:

- Large slides could compromise the existing seepage control liner and allow seepage into or out of the channel
- Debris accumulations could contribute to channel constriction and reduced flood flow capacity
- Sloughing of erosion protection material could leave dike fill exposed to erosive flows during flood events

6.3.4 Riprap and Large-Diameter Riprap Erosion Protection Material

The riprap and large-diameter riprap armoring of the RCD is not uniform and not consistent. In places, it is apparent that slope instability (discussed in Section 6.3.3) has carried riprap downwards and left portions of the slope exposed; elsewhere, riprap appears to be completely absent. Previous slope repairs included placement of riprap of varying size, shape (rounded vs. angular), and lithology. In some locations, riprap sloughing has impinged somewhat on channel capacity.

The higher-gradient portions of the channel are armored with large-diameter riprap (i.e. large diameter rip rap). The condition of these sections of channel generally appear more uniform than the conventionally-armored channel sections and have fewer signs of distress. There are several locations, however, where these large stones have moved downwards and into the channel, or have left portions of the channel unprotected. Additionally, many locations armored with large diameter riprap have significant vegetative growth. In some cases large voids have been identified behind the large-diameter riprap, and the underlying embankment fill could be subjected to

erosion and scour. The higher-gradient areas on the downstream portion of the RCD have a higher concentration of dense willow growth.

In places where this large diameter riprap has moved downward into the RCDC, there are several channel constrictions or large prominent boulders with a tendency to collect debris.

6.3.5 Overflow weir

The overflow weir portion of the RCD is a depressed section of the berm which permits flow of excess water into the intermediate tailings pond. The structure is referred to as a fuse plug; however, a section is heavily reinforced with large diameter stone, and does not appear to be readily "fusible" in a high water event. The depressed section of the overflow weir is slightly lower than the surrounding berm and would more realistically function as an armored overflow spillway during a high water event. The dike slopes upstream from the overflow weir were observed to be un-armored.

6.4 Rose Creek Diversion Improvements

6.4.1 Vegetation Removal

As described in Section 4.3.6.3, hydraulic modelling was performed to evaluate improvements in RCD capacity by removal of vegetation. Modelling results indicate that removal of vegetation from the left bank of the RCD could result in an average reduction in the WSEL from 0.05 to 0.10 m. Removal of vegetation from both banks would reduce the WSEL from about 0.10 to 0.15 m. Removal of vegetation is estimated to reduce the WSEL through the total length of the RCD channel.

The predicted improvement in diversion capacity by vegetation removal is too modest to warrant removal of vegetation based only on such a criterion. Given the difficult access to the left bank of the diversion, the fact that the vegetation on the left side of the channel is generally shrubby and not prone to toppling into the channel, and that the left bank is not a critical seepage barrier between diversion water and tailings impoundments, it is recommended that vegetation does not need to be removed from the left bank of the diversion.

Trees and other woody vegetation on the dike slopes can have a detrimental effect on the stability and function of the dike, somewhat akin to the impact of vegetation on levee dikes. It is therefore recommended that this type of vegetation be removed from the dike. Policies and criteria regarding the removal of trees and other woody vegetation on levees are evolving and will change in the future as a result of ongoing and future research.

Reasons for vegetation removal are cited in USACE (2009), including:

- Allow proper inspection, surveillance, and monitoring for seepage, cracking, displacement, and any other signs of distress in the embankment or its foundation.
- Allow access for operations and maintenance activities.
- Prevent root-related damage, such as shortened seepage paths through the dike and its foundation; voids in the dike and its foundation due to decayed roots or fallen trees; clogged seepage collector systems; and expansion of cracks in canal linings.
- Limit those habitat characteristics that encourage the creation of animal burrows.

Criteria for this project have been developed by considering the following guidelines:

1. Best Management Practices for Works Affecting Water in Yukon, YG, May 2011
2. Guidelines for Management of Flood Protection Work in British Columbia, British Columbia Ministry of Environment, Lands and Parks, March 1999
3. Environmental Guidelines for Vegetation Management on Flood Protection Works to Protect Public Safety and the Environment, British Columbia Ministry of Environment, Lands and Parks, March 1999
4. Urban Levee Design Criteria, May 2012 (California Department of Water Resources, 2012)

5. USACE Guidelines for Vegetation Management (USACE, 2009)

Based on a review of these guidelines (with more consideration given to the Canadian guidelines), the recommended criteria are as follows:

- Provide a zone free of woody vegetation that extends from the water surface in the channel to a minimum distance of 5 m from the downstream (landward) toe of the dike. Note that the BC guidelines require a minimum 3-m strip beyond the landside toe, but states that the strip could be increased as necessary to facilitate maintenance. Extending the width of the vegetation-free zone to 5 m is consistent with the United States guidelines referenced previously.
- All trees or woody vegetation that are more than 50 mm (2 inch) in caliper diameter or that are more than 2-m tall shall be removed from the vegetation-free zone. This suggested criterion is more lenient than suggested by the guidelines, of which all require that no vegetation, other than trimmed grasses, be allowed to grow in the vegetation-free zone.
- Roots of woody vegetation should generally remain in place to prevent undue disturbance of the slope material, except if determined to be potentially detrimental to the stability of the dike as determined by the Engineer in the field during construction. Where root removal is directed, any excavation or voids in the dike resulting from the above actions shall be backfilled with engineered fill similar to the original dike fill, and shall be compacted to the original compaction specifications, or if no specifications exist, match adjacent compaction.

Further coordination with the YG is needed to refine these suggested criteria and to develop appropriate site-specific vegetation monitoring and removal.

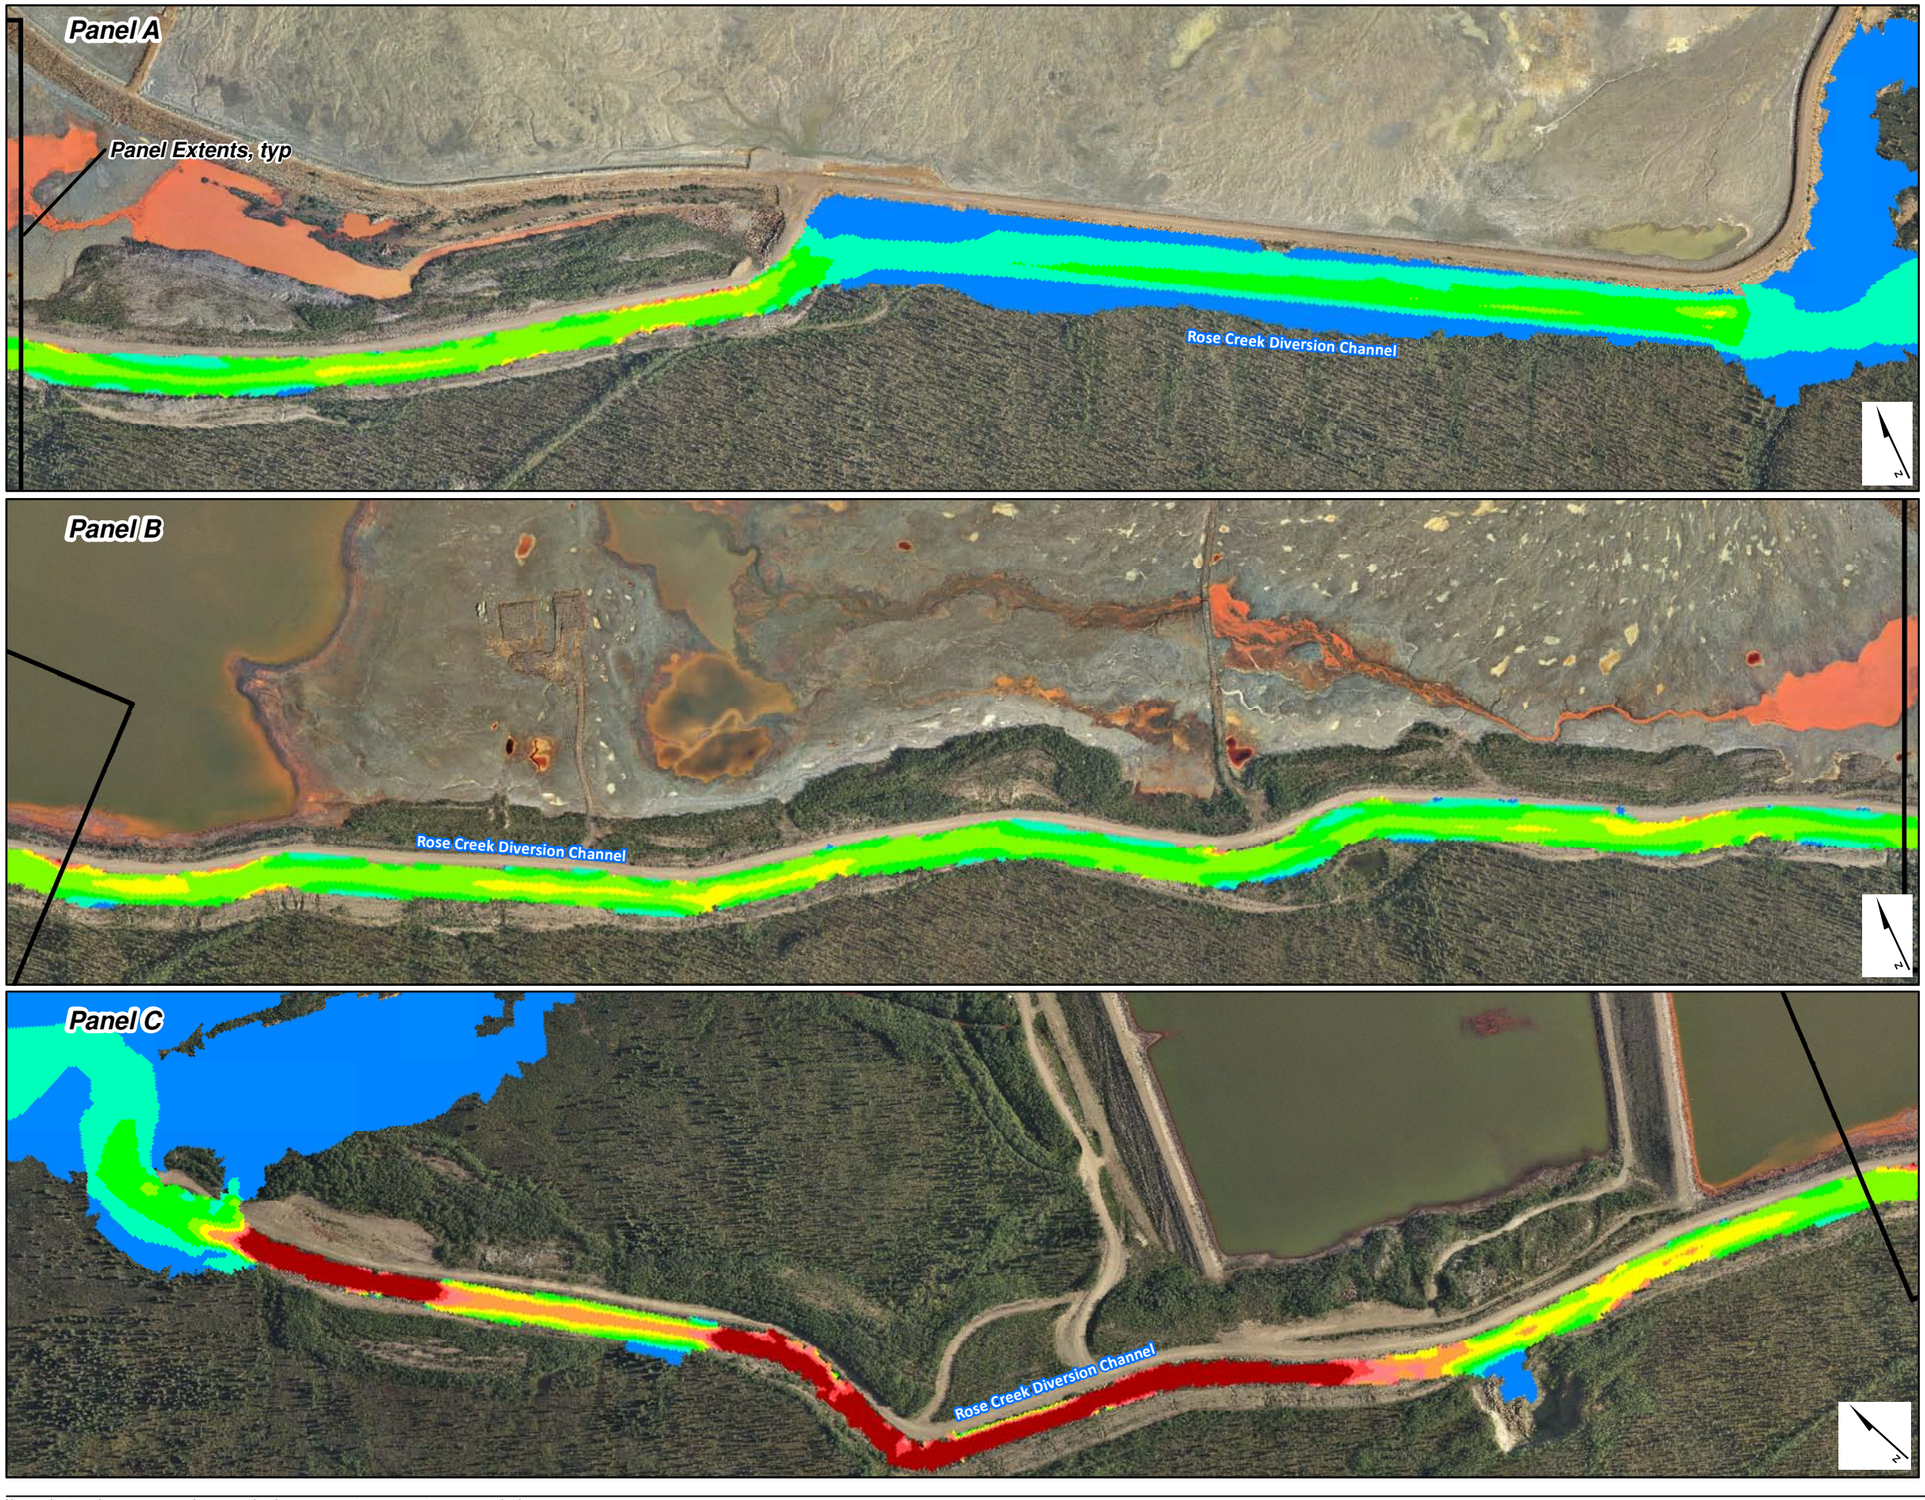
6.4.2 Rose Creek Diversion Dike Crest and Overflow Weir Raise

Hydraulic modelling results were used to determine the locations and extents of dike and overflow weir raises necessary to prevent overtopping of the overflow weir during a 1-in-500-year flood event (zero freeboard condition) and to prevent overtopping of the dike during a 1-in-500-year flood event (0.5 metre freeboard downstream of the overflow weir). Appendix A, Drawing C-12, Table 1 shows the required raise heights with a maximum required raise of about 0.8 m. The raise will be performed using native sand and gravel for the upper 0.5 m, which is the freeboard distance. Compacted glacial till material should be used to extend the seepage barrier to the 1-in-500-year flood event elevation, and appropriate riprap erosion protection should be extended to the top of the raised dike. It is noted that the overflow weir will be raised with low permeability material (glacial till) to the 1-in-500-year flood event elevation (1,058.0 m), with a 200 mm-thick layer of native sand and gravel covering the crest to provide a road surface, i.e., the structure will have a freeboard of 0.2 m.

6.4.3 Slope Repair and Riprap Augmentation

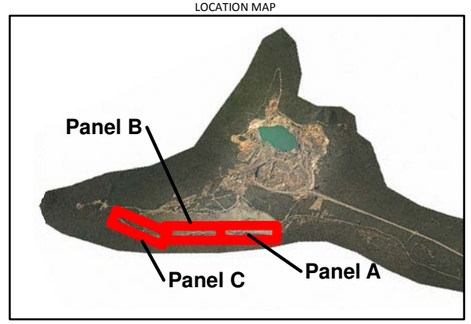
Visual inspection of the existing RCD slopes and comparison with hydraulic modelling results confirmed the need for restoration of the existing channel slope geometry and establishment of uniform erosion protection in order to safely pass the 1-in-500-year flood event. The predicted inundation levels and RCD channel velocities which were considered in the riprap augmentation recommendations are shown in Figure 6-1.

As noted previously, visual observations indicate that the RCD dike is plagued with shallow slides and sloughs occurring frequently. These slides have occurred in the past, are presently moving, and are likely to continue in the foreseeable future. To thoroughly stabilize the dike and minimize the potential for future slides would require re-compaction of dike fill materials, possible flattening of dike slopes, and replacement of channel armour. The time and cost of this level of repair would be prohibitive and not reasonable for the Down Valley Interim Hydraulic Upgrades improvements. As an alternative, it is recommended that some selected problem areas be repaired, and a proactive monitoring and maintenance approach be adopted for the remainder of the dike.



The shallow sloughs on the RCD banks have resulted in deformed cross sections with oversteepened slopes and areas of dike fill which are unprotected by riprap armoring. The nearly 5-kilometre long channel has a multitude of relatively minor deficiencies which are vulnerable to the design flood event, and if left uncorrected, could

continue to worsen. For the purposes of the Down Valley Interim Hydraulic Upgrades, the locations and nature of the various dike deficiencies have been characterized and simplified for purposes of remediation. The necessary remediation techniques will not be the same everywhere, and will require adaptive site-specific field assessment to apply the appropriate construction technique to stabilize the channel for the design event. The field implementation of this solution will require a cooperative field oversight program which assesses the problems at a particular dike section and prescribes an appropriate remediation technique.



The dike deficiencies have been characterized and several generic fixes have been proposed in the advanced design drawings (60 percent) in Appendix A. It is anticipated that the most-common remediation technique will first require the removal of vegetation and accumulated organic matter as described above, localized minor regrading of the dike berm, and placement or augmentation of riprap erosion protection material. Details of these proposed repairs are shown schematically in the drawings.

Several other isolated problems require specific corrective action, which is also called out specifically in the advanced design drawings (60 percent) in Appendix A:

- A few lowered sections of the dike crest must be re-graded to provide adequate freeboard of 0.5 m for the 1-in-500-year flood event and to improve surface drainage, as described in detail in the previous section.
- A few locations which have unnecessary stockpiles of random fill near the top of the slopes should be removed and hauled off the dike crest, to reduce driving forces/weight on top of the slopes.
- In some places, the removal or relocation of boulders or accumulated debris that could potentially collect debris is required. In most (but not all) cases, these boulders are located in the high-gradient sections of channel with large-diameter riprap, and appear to have been moved from their original locations as a result of large flows.

SECTION 7

On-Site Borrow

A total of four potential on-site borrow areas were investigated during the 2013 Field Season as potential borrow sources for the Down Valley Interim Hydraulic Upgrades project. The Calcium-Silicate Waste Rock Borrow area, The Rose Creek Haul Road Borrow Area, and the Rose Creek Borrow Area, and the Granitic Outcrop Borrow Area (see Drawing C-1 in Appendix A for locations). Given the irregular shape of the calcium-silicate waste rock, high sulfate content, and the fact that borrow material in the Rose Creek Borrow Area will already be processed to generate other materials needed for this project, only the Rose Creek Borrow Area is considered a cost-effective and suitable source of cobbles for the gabions. Minor riprap is needed to repair the slopes along the RCD. The riprap needs to be angular and therefore the Rose Creek Borrow Area is not a suitable borrow source. The Granitic Outcrop Borrow Area has been investigated as a riprap source for the Vangorda Creek Diversion project, and is planned to be developed and processed at the same time that the material is needed for this project. Therefore, we are considering Granitic Outcrop Borrow Area the riprap source for the Down Valley Interim Hydraulic Upgrades project. Based on the laboratory results, the borrow areas will be suitable for processing the following materials:

- Rose Creek Haul Road Borrow Area: Glacial Till
- Rose Creek Borrow Area: Cobbles for gabions, pipe zone material, small to intermediate riprap, sand, and gravel
- Granitic Outcrop Borrow Area: Riprap

Several material types will be required for construction of the Down Valley Interim Hydraulic Upgrades project. For the RCD improvements, a well-graded sand and gravel mixture will be used to raise the crest of the dike, with some smaller amounts of glacial till where the low permeability seepage liner needs to be extended to the 1-in-500-year flood event elevation. The sand and gravel mixture would also be used as riprap bedding where riprap repairs need to be performed on the diversion banks. Some of the material excavated from the ID spillway may be able to be re-used for raising the RCD dike crest. The remainder of the material can be stockpiled for later use. It is anticipated that a modest amount of riprap will be required to repair sloughed areas or to augment existing sparse rip rap; as discussed above this riprap is anticipated to come from the Granitic Outcrop Borrow Area.

For construction of the ID spillway improvements, the main borrow material source required would be the cobbles needed in the gabion mattresses and gabion baskets. It is proposed that this material be obtained by processing (screening) the alluvial and glaciofluvial deposits from the Rose Creek Borrow sites. These materials consist mainly of poorly graded gravel with sand and silty gravel with sand. Glacial till to backfill the geomembrane installation trench to raise the ID crest could be obtained from the Rose Creek Haul Road Borrow Area.

A rock processing plant, with a conveyor system, screening plant, and generator, along with excavating equipment are anticipated. All of these processed materials will be used in the elements to be constructed in Down Valley Interim Hydraulic Upgrades. Any excess material will be stock piled at the Rose Creek Borrow Area for later use.

SECTION 8

Cost Estimate

A Class II capital cost estimate has been developed for the 60 percent Design. This type of estimate is based on a 60 percent design level of project definition. This type of estimate is generally prepared to develop a preliminary budget and schedule. The estimate would have semi detailed unit costs with line item descriptions. Expected accuracy would be -5 percent to -15 percent on the low side and + 5 percent to +20 percent on the high side. The Class II capital cost estimate will be submitted and bound separately from the BODR.

The capital cost estimate will be updated to a Class I and submitted with the Detailed Design (90 percent).

SECTION 9

Specifications

CH2MHILL Standard Specification will be used for this project. Detailed specifications are included as part of this Advanced Design (60 percent) and will be included in the Detailed Design (90 percent) deliverables. See Appendix F for the Advanced Design Specifications (60 percent).

SECTION 10

Summary and Recommendations

The work performed for the design of the Down Valley Interim Hydraulic Upgrades, including the results of engineering evaluations performed can be summarized as follow:

10.1 Rose Creek Diversion Design

- Design criteria require that the RCD dike crest has minimum 0.5 m freeboard for a flow of 111 m^3/sec upstream of the overflow weir and 116.2 downstream of the overflow weir, which approximates the 1-in-500-year flood event flows.
- Hydrotechnical analyses were performed to establish the 1-in-500-year flood event elevations in the diversion. The existing conditions model was modified in the location of the overflow weir to allow only flood flows in excess of the 1-in-500-year flood event flow rate (111 m^3/sec upstream and 116 m^3/sec downstream) to discharge through the overflow weir.
- The crest elevation of the overflow weir in this design was set to elevation 1058.2 m, which corresponds to the water surface elevation predicted for the 1-in-500-year flood event flow rate (elevation 1,058.0 m) plus a 200 mm-thick layer of native sand and gravel covering the crest to provide a road surface (i.e., the structure will have a freeboard of 0.2 m). This implies that the overflow weir will have to be raised by about 0.95 m.
- The model results indicate that the existing crest elevation is deficient to contain the predicted 1-in-500-year flood event flows. Over some portions of the dike, it would overtop and at other locations there would not be adequate freeboard. To mitigate this deficiency, the dike crest needs to be raised over some sections of the dike, resulting in a maximum required dike raise of about 0.95 m.
- Apart from the required raise of the dike crest and overflow weir, it is also proposed to remove woody vegetation from the dike and to perform some repairs of slope sloughing and riprap, and to add riprap where slopes are unprotected.

10.2 Intermediate Dam Spillway Improvements

- Because of uncertainty in the RCD dike performance under large flood events, and based on the design criteria established by the expired water licence, the required design ID spillway capacity was established as 115 m^3/sec, which is the 1-in-500-year flood event flow (including attenuation through the NFRD and in the ID impoundment). The existing ID spillway (with a capacity of 32 m^3/sec) cannot safely pass a moderate or major flood event without potentially failing the dam.
- The improvements at the ID spillway consist of excavating the existing channel by a maximum of about 2 m, and placing a 0.45-m-thick gabion mattress on the excavated surface. Gabion cells will be used on the sides of the channel, with a geotextile between the gabions and the excavated soil surface.
- To raise the effective ID crest, a geomembrane will be installed vertically in a trench between the dam core and the crest surface, and a single 0.9 m by 0.9 m gabion row will be placed along this line to further raise the effective crest to an estimated elevation of 1,049.6 m.
- The 2D model was used to evaluate the proposed ID spillway improvements. Model simulations assume that the overflow weir would be completely breached, resulting in the entire design flow conveyed onto the tailings. Model simulations with the 1-in-500-year flood event flow rate routed down the RCD, discharged through the overflow weir, and conveyed over the tailings predict the following:
  - Flow over the spillway = 115 m^3/s
  - Headwater elevation = 1048.6 m
  - Freeboard at ID = 1.0 m

10.3 North Fork Rock Drain Recommendations

The main objective of the interim improvements is to prevent overtopping and breach of the ID during the 500-year flood. Based on a review of the design and construction records of the NFRD, this objective cannot be met with a sufficiently high degree of confidence by relying on the haul road embankment to act safely and reliably as a flood retarding structure during a 500-year flood event. To achieve a high confidence level, more positive measures will have to be implemented to pass large flood events safely at the Haul Road embankment and NFRD. One such measure might include installation of culverts or tunnels under the embankment.

In the absence of such measures, a risk analysis might be helpful in determining acceptability of the Haul Road embankment and NFRD in the interim period. The probability of failure of the structure is less than 2 percent over a 10-year period, but the consequences of failure of the NFRD are potentially large. Breach analyses performed for low flow-through assumptions indicate that an NFRD breach could result in overtopping of the ID.

A risk analyses would not only consider the 500-year flood, but would combine the probability of failures during the interim period with the consequence of failure for the full range of flood loading up to the 500 year event to estimate the risk. It is recommended that such a risk analysis be performed if: (1) it is not possible for the YG to take more positive measures to ensure the reliability of the Haul Road embankment, or (2) if the YG is not willing to accept a risk (not well understood at this time) that could exceed generally accepted tolerable risk guidelines.

Monitoring of the Haul Road embankment and NFRD should continue and maintenance measures should include prevention of blockage of the inlet to the NFRD by removing any buildup of debris.

GENERAL NOTES

1. CONTOURS SHOWN ON DRAWINGS WERE PREPARED BY CRITIGEN CORPORATION FROM LIDAR DATED OCT 2011. PLANIMETRIC MAPPING PREPARED BY CRITIGEN CORPORATION FROM AERIAL PHOTOS DATED AUGUST 2012.
2. EXISTING TOPOGRAPHY, STRUCTURES, AND SITE FEATURES ARE SHOWN SCREENED AND OR LIGHT-LINED. NEW FINISH GRADE, STRUCTURES, AND SITE FEATURES ARE SHOWN HEAVY-LINED.
3. HORIZONTAL DATUM: NAD83, CSRS EPOCH 2002.
4. VERTICAL DATUM: CGVD 28 (HTV 2.0).
5. MAINTAIN, RELOCATE, OR REPLACE EXISTING SURVEY MONUMENTS, CONTROL POINTS, AND STAKES WHICH ARE DISTURBED OR DESTROYED. PERFORM THE WORK TO PRODUCE THE SAME LEVEL OF ACCURACY AS THE ORIGINAL MONUMENT(S) IN A TIMELY MANNER AND AT THE CONTRACTOR'S EXPENSE.
6. EXISTING UTILITIES, PIPELINES, STRUCTURES, AND CONNECTION POINTS ARE SHOWN ON DRAWINGS IN ACCORDANCE WITH AVAILABLE RECORDS. CONTRACTOR SHALL NOTIFY ALL UTILITY OFFICES WHICH ARE AFFECTED BY THE CONSTRUCTION OPERATION AT LEAST TWO WEEKS PRIOR TO COMMENCING EXCAVATION.
7. CAUTION: THERE ARE OVERHEAD UTILITIES IN THE WORK AREA. CONTRACTOR SHALL MAINTAIN REQUIRED CLEARANCE BETWEEN EQUIPMENT AND UTILITIES TO PROTECT ALL PERSONNEL, EQUIPMENT, AND UTILITIES. COORDINATE WITH UTILITY COMPANIES AS NECESSARY.
8. STATIONING AND DISTANCES SHOWN ON THE DRAWINGS ARE BASED ON HORIZONTAL MEASUREMENTS. REFERENCES TO LEFT OR RIGHT ON THE DRAWINGS ASSUME THE DIRECTION OF INCREASING STATION ALONG THE PIPELINE ALIGNMENT.
9. CONTRACTOR SHALL LIMIT CONSTRUCTION ACTIVITIES WITHIN THE WORK LIMITS SHOWN OR SPECIFIED. THIS SHALL INCLUDE, BUT NOT BE LIMITED TO, VEHICLES AND EQUIPMENT, LIMITS OF EXCAVATION, EXCAVATED MATERIAL AND BACKFILL MATERIAL STORAGE. WHERE WORK LIMITS ARE NOT SHOWN LIMIT CONSTRUCTION ACTIVITIES WITHIN ROAD RIGHT-OF-WAYS, UNLESS OTHERWISE SHOWN.
10. IT IS THE CONTRACTOR'S RESPONSIBILITY TO EXPLORE SUBSURFACE CONDITIONS AS NECESSARY PRIOR TO CONSTRUCTION IN ORDER TO DESIGN TRENCH DEWATERING AND SHORING SYSTEMS.
11. CONTOURS ARE TO BE RESTORED TO THE PRE-CONSTRUCTION CONDITION UNLESS OTHERWISE SHOWN.
12. REPAIR OR REPLACE ALL PROPERTY DAMAGED BY CONSTRUCTION.
13. SYMBOLS, LEGENDS, AND PIPE USE IDENTIFICATIONS SHOWN SHALL BE FOLLOWED THROUGHOUT THE DRAWINGS, WHEREVER APPLICABLE. NOT ALL OF THE VARIOUS PIPING COMPONENTS ARE NECESSARILY USED IN THE PROJECT.
14. SYMBOLS SHOWN ON LEGEND ARE GENERIC ONLY. REFER TO PIPING SPECIFICATIONS FOR SPECIFIC END CONNECTIONS.

SECTION 1

Introduction

This report describes the geochemical conditions and processes affecting water-quality at the Faro Mine Complex (FMC). The FMC consists of three main subareas, presented in Figures 6A-1 through 6A-4: (1) the Faro Mine Area, which includes the Faro Pit and the Faro Waste Rock Dumps, (2) the Vangorda/Grum Area, which includes the Vangorda Pit and Waste Dumps and the Grum Pit and Waste Dumps, and (3) the Rose Creek Tailings Area (RCTA). This report presents mine-related water-contamination information for known impacted areas of the FMC.

Seepage and surface water quality data from each of the main FMC areas were compiled to identify trends over time for selected water-quality parameters. Data from the site-wide database (Environmental Quality Information System) were used in the analyses. The data sources included both historical investigations and recent field monitoring investigations. The evolution of water-quality characteristics through time generally results from the ongoing geochemical processes that occur within mine-influenced areas. At the FMC, there are three main contaminant-load contributors: (1) the waste dumps (including the backfilled Zone II Pit), (2) the three open pits (including discrete inputs into the pits [i.e. pit walls, seeps, and surface runoff]), and (3) tailings (RCTA). These contaminant-load contributors and the geochemical reactions that influence constituent concentrations in seepage and surface water are presented in this section.

Metal attenuation can be a result of adsorption to natural organic matter or to secondary oxyhydroxides, or coprecipitation of secondary mineral phases. This attenuation may act to slow the migration of trace metals away from the waste dumps within the shallow groundwater system. These attenuation processes may be more prevalent in the early stages of seep development when pH is near neutral but zinc and sulphate are elevated. Sulphate is a relatively conservative and abundant constituent that generally is a good indicator for acid rock drainage (ARD). Zinc is used as an indicator metal representing several other trace metals that are released during ARD production because of its more consistently higher concentrations, which make the analytical measurements and trends more reliable. For this report, seep water quality characteristics are described by the relative level of contamination based on concentrations of sulphate and zinc, according to the following criteria (CH2M HILL Canada Ltd. [CH2M HILL], 2012):

- Not impacted or minimally impacted: sulphate ≤ 40 milligrams per litre (mg/L) and zinc ≤ 0.05 mg/L
- Slightly impacted: sulphate > 40 mg/L and ≤ 400 mg/L or zinc > 0.05 mg/L and ≤ 0.5 mg/L
- Moderately impacted: sulphate > 400 mg/L and ≤ 4,000 mg/L or zinc > 0.5 mg/L and ≤ 5 mg/L. This corresponds to sulphate and zinc concentrations one order of magnitude greater than the “slightly impacted” range.
- Highly impacted: sulphate > 4,000 mg/L or zinc >5 mg/L. This corresponds to sulphate and zinc concentrations one order of magnitude greater than the “moderately impacted” range.

Sections 2, 3, and 4 of this report describe the results of the contaminant-loading characterization at each of the main FMC subareas. Time series plots for pH, alkalinity, sulphate, iron, zinc, and magnesium were generated for key locations at the FMC and evaluated for changes in chemistry over time. Locations examined for the Faro Mine Area are presented on Figure 6A-1; locations for the Vangorda/Grum Area are presented on Figure 6A-2, and locations for the Vangorda Area are presented on Figure 6A-3. Monitoring locations for the RCTA are presented on Figure 6A-4 and are described in detail in Appendix 6G.

1.1 Waste Rock Dumps

About 300 million tonnes (about 154 million cubic metres) of waste rock are located in areas adjacent to the three open pits in the Faro Mine Area and the Vangorda/Grum Area. Table 1 provides a list of the Main Dumps and the abbreviations (Code) used throughout this document. Mine waste management at the

Faro Mine Area did not involve rigorous segregation; as a result, water draining from the Faro Mine Area Waste Dumps can be poor quality (SRK, 2010). When the Grum Pit was mined, the highly sulphidic waste dump material was separated and placed in the Grum Sulphide Cell, which has been subsequently capped with a low-permeable cover (SRK, 2011). Despite more rigorous segregation practices when the Vangorda Pit was mined, the waste dumps associated with the Vangorda Pit generally contain greater sulphide content than the Faro Mine Area. As a result, water draining from the Vangorda Waste Dumps can be poor quality (SRK, 2010). Waste rock generated from the Vangorda Pit Area contains some of the highest percentages of sulphide at the FMC (SRK, 2006a).

Geochemical loading from the FMC Waste Dumps is controlled largely by the waste rock material composition, as well as how it was placed, relative to the pre-mining topography. Each of the three ore bodies are in topographic low-lying areas. Before the Faro Pit and the Vangorda Pit were mined, creeks flowed across the planned open pits. Before the Grum Pit was mined, it was a low wetland area with a creek flowing away from the area containing the ore body. At the FMC, these creeks generally flow north to south. Therefore, in general, background conditions prevail north of the FMC, and, where impacted by contaminated seepage, water with degraded quality flows south.

Previous borehole data and historical geological information indicate the FMC Waste Dumps are underlain by discontinuous deposits of glacial till, glaciofluvial sediments, and low-permeability bedrock (RGC, 1996). In general, these deposits are thin (less than 10 metres thick), with some notable exceptions near the Grum and Vangorda Pits, where overburden thickness can range up to 70 metres (RGC, 1996). When the FMC Waste Dumps were established, the relatively coarse waste rock material (which has a fairly high hydraulic conductivity) was placed over the native soil, which is less permeable. As a result, water infiltrating the waste rock pile will either continue to infiltrate the native soil or will travel along the paleosurface at the base of the waste dump until it daylights at the toe of the waste rock. The water infiltrating the native soil impacts local groundwater below the waste dump, and could degrade groundwater in downgradient locations. As mine-influenced water migrates through the aquifer system, some constituents move more quickly than others. Sulphate tends to move at the velocity of groundwater because it does not readily react with or adsorb to aquifer materials. Dissolved metals, however, can react with and adsorb to the subsurface matrix, and this geochemical interaction influences the rate of migration. Elevated sulphate concentrations

and decreasing pH are early signs that upgradient ARD reactions are impacting groundwater quality (CH2M HILL, 2013b).

Seepage water from waste dumps can impact surface water quality directly. Most of the seepage occurs at these locations after freshet or large precipitation events. It takes place over a fairly short timeframe, based on observations during the CH2M HILL 2012 field program (CH2M HILL, 2013b) and based on the historical seep sampling program (SRK, 2010). However, several seeps (generally located in pre-mining drainage channels) flow year-round. The seepage from several perennial seeps is currently collected using seepage interception systems (SIS), located at the S-Wells and the Emergency Tailings Area (ETA). In the future, placing covers to minimize infiltration through the waste dump will reduce the quantity of seepage generated.

The main source of contaminants in the Faro Mine and Vangorda/Grum Areas is sulphide-containing waste rock stored in the waste dumps and tailings located within the Rose Creek Valley. The main sulphide ore minerals in the waste dumps are sphalerite (ZnS), galena (PbS), and pyrite (FeS_2). Minor amounts of chalcopyrite ($CuFeS_2$) and arsenopyrite (FeAsS) are also present in a matrix of gangue minerals that include quartz (SiO_2), magnetite (Fe_3O_4), carbonate minerals, and barite ($BaSO_4$) (SRK, 2004). $FeS_2$is the most abundant sulphide mineral at the FMC. The main source of acidity and metals at the FMC is the oxidation of these sulphide minerals in the waste dumps, denoted in the following chemical reaction:

$$2MeS_2 + 7O_2 + 2H_2O \rightarrow 2Me^{+2} + 4SO_4^{-2} + 4H^+$$

Oxygenated water infiltrates the waste dumps and causes sulphides to oxidize, generating sulphate (the oxidized form of sulphide) and acidity, which contribute to increased metal concentrations. When the hydrolysable metals in solution (such as iron and manganese) are exposed to additional oxygen, they may react, causing oxyhydroxides to precipitate and the solution pH to undergo a net lowering, according to the following reactions:

$$2Fe^{+2} + 0.5O_2 + 2H^+ \rightarrow 2Fe^{+3} + H_2O$$

$$2Fe^{+3} + 6H_2O \rightarrow 2Fe(OH)_3 + 6H^+$$

Trace metals (such as zinc) may co-precipitate with or adsorb to the oxyhydroxide precipitates. The degree of co-precipitation or adsorption is highly pH-dependent, and it varies between the trace metals. In general, sulphide-rich rock at the FMC generates acid almost immediately upon exposure; therefore, the sulphide cells at the FMC are characterized as acid-generating (SRK, 2004). The process of sulphide mineral oxidation is tempered by the presence of alkaline mineral phases (i.e., neutralization potential [NP]) that help buffer the solution at a more neutral pH. Carbonate minerals (such as calcite and dolomite) are the most important of these minerals at the FMC. Acid released during the oxidation process will partially dissolve carbonate minerals, and the released bicarbonate ions will help to maintain the pH at circum-neutral values according to the following reaction:

$$3Me^{+2} + Ca(HCO_3)_2 + O_2 + 2H_2O \rightarrow 3Me(OH)_2 + Ca^{+2} + 2CO_2$$

As oxidation proceeds in the exposed natural rock and in the waste materials, the carbonates buffer the pH (and, in turn, the metal mobility) to maintain a chemical semi-steady condition. For most waste dumps at the FMC, the acid potential of the waste materials is greater than the NP of the carbonates. At some point, the NP will be depleted, the pH will drop, and metal concentrations will rise. The long-term remediation plan must consider this eventual condition to effectively treat current and future seepage from the FMC.

There are several stages of ARD development within the waste dumps. These stages are observed at different areas of the FMC, depending on waste dump age, exposure, and mineralogy (SRK, 2004). The first stage of seepage chemistry evolution is characterized by neutral to alkaline pH, with low sulphate and metal concentrations and possible elevated calcium and magnesium cations from carbonate dissolution. Seepage chemistry evolves further through the following processes:

- As sulphide-bearing materials oxidize, the pH may decrease to neutral or slightly acidic with an associated increase in zinc and sulphate concentrations. Calcium and magnesium carbonates still control water chemistry and secondary gypsum ($CaSO_4$), and trace metal (i.e., zinc, copper) carbonates may form. Trace metal adsorption to oxyhydroxide precipitates may also be an important controlling factor.
- When the advanced oxidation of sulphides begins to overcome the available NP within the waste dump, pH begins to decrease. The pH of the seepage may fall below 4 and exhibit high concentrations of iron, aluminum, zinc, sulphate, and other trace metals. While iron and aluminum oxyhydroxides are still likely forming downgradient of sulphide oxidation, the adsorptive trace metal capacity at more depressed pH significantly decreases. In highly sulphidic areas, the pH may fall well below 4, stabilizing between 2.5 and 3, and may contain the highest metal and sulphate concentrations at the FMC.
- In the waning stages of seep evolution, pH may increase as the sulphide minerals with acid-generating potential are exhausted or armoured by oxide rinds and coatings. Metal and sulphate concentrations (except for lead) begin to decrease as pH increases. Lead may increase because of the increased anglesite ($PbSO_4$) solubility resulting from lower sulphate concentrations.

Although seepage chemistry develops within the waste dumps and evolves over time, processes within the receiving environment may still impact the fate of metals, sulphate, and acidity. As the seepage infiltrates the alluvial and till material underlying the waste dumps, some acid neutralization may occur and the trace metal load may attenuate. Metal attenuation can result from adsorption to natural organic matter, precipitation of secondary oxyhydroxides, or co-precipitation with secondary mineral phases. This attenuation may retard the trace metals' migration from the waste dumps within the shallow groundwater system, especially during the early stages of seep development, when pH is near-neutral but zinc and sulphate are elevated. However, the underlying alluvial/till material has a finite adsorptive capacity, and the adsorption process is susceptible to reversal at low pH. As the seep chemistry evolves, becoming more acidic, the underlying alluvial/till material's attenuation capacity is expected to decrease, and the material may ultimately release metals captured during the earlier stages of seep development.

1.2 Open Pits

The three open pits at the FMC (Faro, Grum, and Vangorda) have unique geochemical properties that contribute to the water quality of the lakes therein. Constituents primarily load to the pit lakes through seepage from pit walls and waste dumps. Predicting future water quality conditions in each of the pits is an ongoing process. The following additional factors influence the pit lakes' geochemical compositions:

- The Faro and Vangorda Pits provide storage for water pumped by various water interception systems year-round, so it is possible to operate the water treatment plant (WTP) seasonally. Therefore, groundwater inputs from surrounding waste dumps (e.g., associated with S-wells SIS, Zone II Pit, and the Vangorda seepage collection ditch) are contributing to the load within the pits. Additional remedial system waters may be pumped to the pits in the future; this would further impact the pit lakes water quality (SRK, 2010).
- The Faro Pit received tailings from milling operations from 1992 to 1998. The presence of net acidic, yet alkaline-bearing, tailings complicates the geochemistry of the pit lake. In the short term, these tailings are contributing alkalinity to the water column. The tailings at the bottom of the Pit are not expected to become acid-generating or a significant source of metals, because the subaqueous disposal limits contact with oxygen. Disposing oxidized, alkaline WTP sludge to the Pit would further mitigate potential metal loading from the tailings to the pit water.
- Adding WTP sludge to the bottom of the Grum or Vangorda pits is an ongoing consideration. If the pH at the bottom of the pits drops significantly, the WTP sludge could release trace metals. However, given the alkaline content of the WTP sludge, the sludge may act to raise and buffer the bottom water pH to minimize or prevent trace metal release. The Grum Pit was operated as an in situ biological treatment

system (algal-based bioreactor) by adding nutrients over approximately 10 years. The treatment process was discontinued in 2012. Therefore, the sulphidic pit wall oxidation and the composition of the influent seep chemistry are the main controlling factors for the Grum Pit's future chemistry.

1.3 Rose Creek Tailings Area

Approximately 55 million tonnes of tailings generated from ore processing at the mill operations were deposited in the RCTA over an area approximately 0.7 kilometre wide by 3.7 kilometres long within the former Rose Creek Valley. The mill process that generated the RCTA tailings took place at a pH of greater than 11. Therefore, the tailings material contains some NP even though it is net acidic (i.e., has greater acid-generating capacity than available NP). This NP neutralized some of the acidity while it was generated within the tailings, thereby slowing the acid-generation process. The fine-grained nature of the tailings limits oxygen transfer into the tailings, further slowing the oxidation and consequent acid-generating processes. The rate of oxidation within the tailings was evaluated using samples from the RCTA, and showed an oxidation front moving through the tailings pile over time (RGC, 2012). As this oxidation front migrates through the largely sulphidic tailings material, acidity and high concentrations of metals are released to the pore water. Over time, the pore water is displaced by precipitation infiltration, driving impacted water into the underlying Rose Creek Alluvial Aquifer (RCAA).

Models of the release of contaminants from the RCTA have been based on pore water displacement estimates, combined with pore water quality estimates, to provide time-based estimates of contaminant loadings from the base of the tailings deposit to the RCAA (Gomm Environmental Engineering Consulting, 2010). Once the tailings-impacted water reaches the RCAA, it reacts with the alluvial aquifer sediments and attenuation occurs. The effect of attenuation by the alluvial material is a delayed, sequential release of contaminants over time. Sulphate, which is largely unattenuated, is the first contaminant to migrate from the RCTA source area. Zinc, iron, and other metals are retained through changes in pH that cause precipitation, coprecipitation, and adsorption. As the aquifer material's attenuation capacity declines, either by metals occupying adsorption sites or through decreased pH (which can result in metal desorption), metals (i.e., zinc) are transported downstream of the RCTA, arriving later than the sulphate front. As the alluvial aquifer material's attenuation capacity continues to decline, iron-bearing, highly acidic water will be released downgradient of the RCTA. This process will continue until the RCTA source material is exhausted and the oxidation front moves completely through the tailings pile. Recently, elevated sulphate has been observed in groundwater at the downstream end of the RCTA, at the toe of Cross Valley Dam (CVD). However, trace metals such as zinc, lead, and cadmium are being actively attenuated by existing and newly precipitated oxyhydroxides and by organic material, maintaining concentrations well below levels of concern in the downgradient half of the RCTA.

SECTION 2

Faro Mine Area

The Faro Pit is used as a reservoir to store contaminated for water treatment. Because the pit is pumped to lower the water level, the Faro Mine Area is characterized by a regional groundwater sink (the Faro Pit). waste dumps in the Faro Mine Area are unsaturated and of variable composition. When precipitation infiltrates through the waste dumps, it collects at their bases, near pre-mining topographic lows (Appendix 6G). Depending on the subcatchment area a waste dump is located in, seepage from the waste dumps near the Faro Pit may flow to the Faro Pit, Zone II Pit, North Fork Rose Creek (NFRC), old Faro Creek, Guardhouse Creek, or Rose Creek Valley (Figure 6A-1) (RGC, 1996). Data compiled from samples collected at seepage, surface water monitoring stations, and monitoring wells provide the foundation for the characterization of water-quality conditions in the Faro Mine Area (Figure 6A-1).

2.1 Faro Background Water Quality

Except for seepage collected at the ETA, the S-Wells, or behind the Intermediate Dam, water from the Faro Waste Dumps ultimately flows into Rose Creek, which contributes to Anvil Creek, before flowing into the Pelly River. Faro Creek flows from the north and is diverted around the Faro Pit via the Faro Creek Diversion (FCD) (Figure 6A-1). Water in the FCD flows into the NFRC, northeast of the Faro Northeast Waste Dump. Upstream from the FCD and the NFRC above the confluence of FCD and the NFRC, Faro Creek and NFRC are generally considered unimpacted, and are sampled for background conditions. Two main surface water locations have historically been sampled for background conditions in the Faro Mine Area: (1) Faro Creek, upstream from the FCD (Station FCO), and (2) NFRC, upstream from the confluence with the FCD (Station R7). In 2012, background samples were collected from a new location in Faro Creek, Station FDU, which is upstream from the historical Station FCO sampling location (Figure 6A-1).

2.2 Constituent Loading to the Faro Pit

The Faro Pit lake water quality is monitored at X22B (located on the lake surface at the southwest end of Faro Pit lake, near the pumping barge) and can be described as buffered ARD (Figure 6A-1). It has a neutral pH and is highly impacted based on concentrations of zinc. The dissolved sulphate concentrations have been consistent in recent years, and the zinc concentration has been increasing over time (CH2M HILL, 2013b). As the alkalinity is consumed, the acidity will rise, resulting in an increase in acid mine drainage products. The following sources contribute influent waters that affect water quality in the Faro Pit:

- Seepage from the North Faro Waste Dumps (FVN and FVS)
- The Northeast Faro Waste Dumps (NEU, NEL, NELS, and NEO)
- Pumping from the Zone II Pit (X26)
- Pumping from the S-wells (Figure 6A-1)

Figure 6A-5 shows a summary of the water quality and level of impact at seepage monitoring stations in the Faro Pit area. Water that is not captured by the FCD (including potential leakage from the FCD) flows through the Faro Valley Dumps (FVN and FVS) and seeps into the Faro Pit along the north pit wall (Figure 6A-1). Location A30 is on the north pit wall of Faro Pit and is on the flow path of the historical Faro Creek (Figure 6A-1). The flow in this area is high, and the high flux of oxygenated water through the Faro Valley Dumps (FVN and FVS) may be causing relatively acidic conditions in this area, relative to other seepage areas. The water is highly impacted with a low pH and moderate concentrations of sulphate (545 mg/L) and high concentrations of zinc (47.3 mg/L), based on the criteria outlined in Section 1 (Figure 6A-6). Characteristics of acid mine drainage (i.e., increased sulphate and zinc) have been present and have shown variability since 2002, with concentrations of iron (2.1 mg/L) generally increasing over time (Figure 6A-5). The observed general decrease in alkalinity over time and increased sulphate concentrations

indicate much of the available NP in this area has been consumed, and there is a net acid generation effect on seepage from A30 reporting to the Faro Pit lake (Figure 6A-5).

Seepage from the Northeast Waste Dumps flows either to the Faro Pit or to the NFRC along a pre-mine surface drainage divide (Figure 6A-1). A geochemical characterization of the Northeast Waste Dumps' waste rock materials indicates substantial potential for long-term acid generation (CH2M HILL, 2013c). Water quality results from samples collected from the Northeast Waste Dumps indicate widely variable composition and highly impacted waters. The most highly impacted waters are generally downgradient from the East Sulphide Cell. The two main flows from the Northeast Waste Dumps report to the Faro Pit lake: (1) SRK -FD24 and (2) SRK-FD26 (Figure 6A-1). SRK-FD24, which is west of and topographically lower than the Northeast Sulphide Cell, is characterized as highly impacted water with high concentrations of iron (10.8 mg/L), zinc (40 mg/L), and sulphate (1,060 mg/L) (Figure 6A-7). A review of the data at SRK-FD24 highlights the transition from neutral to acidic conditions over time, marking a distinct stage in the evolution of the Northeast Waste Dump seepage chemistry (Figure 6A-7). SRK-FD26 is a moderately impacted, high-flow monitoring location that follows a pre-mine drainage just north of the former Zone II Pit (Figure 6A-1). Concentrations of sulphate and zinc were 806 mg/L and 5.7 mg/L, respectively, and iron was less than the detection level in samples collected at SRK-FD26 (Figure 6A-7).

In general, very little seepage flows from the south and west pit walls into the Faro Pit. The only other important inputs into the Faro Pit are from the X26 well and the S-wells SIS area (Figure 6A-1). The X26 well maintains groundwater levels through pumping in the former Zone II Pit and contributes water and constituent loading to the Faro Pit lake. Based on the criteria presented in Section 1, groundwater pumped from the Zone II Pit is considered highly impacted, with high sulphate content (3,320 mg/L) and concentrations of zinc that are greater than 20 mg/L (Figure 6A-8). Through time, X26 has maintained one of the highest average zinc (79 mg/L), iron (53 mg/L) and sulphate (2657 mg/L) concentrations of all the inputs into Faro Pit (Figure 6A-8) (DES, 2012,).

The S-wells SIS area is another source of water and constituent loading to the Faro Pit lake (Figure 6A-1). The numerous contaminant sources that contribute to the S-wells area are attributed to the pre-mine topography. The current conceptual site model indicates pre-mining drainage patterns are focusing seepage water from the Intermediate and Main Dumps, towards the S-wells SIS area and ETA, respectively. Monitoring wells (MW-007 and MW-003) have recently been installed through the waste dump into the underlying alluvium upstream of these seepage areas, to evaluate the evolution of seepage chemistry along the flow path of these historical drainages (CH2M HILL, 2012).

Seepage water collected by the S-wells SIS, represented by the water quality observed in SRK08-SPW3, is considered highly impacted. The S-wells area is expected to be a large contributor to increased contaminant loads through time, with sulphate and zinc concentrations greater than 5,000 mg/L and 300 mg/L, respectively, in SRK08-SPW3 (Figures 6A-1 and 6A-8). Alkalinity in SRK08-SPW3 has decreased over time, from 587 mg/L to 401 mg/L, but has remained present to neutralize acidic drainage (Figure 6A-8). Although groundwater quality in the S-wells area was expected to improve with the installation of the SIS, no notable change in water quality (better or worse) was observed. Contaminant concentrations were neither shown to increase, nor to decrease, in groundwater downgradient of the S-wells SIS. Increased concentrations of sulphate and zinc in groundwater monitored by wells southeast of the S-wells SIS (i.e., SRK05-SP3A/B, SRK05-SP1A/B, and SRK05-SP2) indicate the SIS may not be capturing at least a portion of the waste dump seepage.

2.3 Constituent Loading to the North Fork Rose Creek

Seepage water that flows west from the Northeast Waste Dumps and from the former Zone II Pit area (i.e. water that is not captured by the X26 well) contributes to the NFRC, upstream of the North Fork Rock Drain and is represented by the water quality measured at monitoring stations SRK- FD21, SRK-FD05, SRK-FD06, NE1, NE2, and NE3 (Figure 6A-1). Although SRK-FD21 is within the catchment boundary for NFRC, seepage

likely also flows to the Faro Pit (Figure 6A-1). Seepage from SRK-FD21 is highly impacted, with concentrations of sulphate and zinc at 3,200 mg/L and 36.7, respectively (Figure 6A-9). Highly impacted seepage water (based on the criteria outlined in Section 1) has been observed emanating from the west side of the Northeast Waste Dump at SRK-FD05 (Figure 6A-9). SRK-FD05 and SRK-FD06 represent a widespread perennial seep located near the base of the west face of the Northeast Waste Dump (Figure 6A-1). Observed water quality at SRK-FD05 indicates seasonal fluctuations in concentrations of sulphate (692 mg/L [September 2012] to 904 mg/L [June 2013]) and zinc (5.9 mg/L [September 2012] to 8.3 mg/L [June 2013]), with greater concentrations observed in the spring than in the fall, and an overall trend of increasing concentrations through time (Figure 6A-9) (SRK, 2010). The highly impacted seepage waters emanating from the Northeast Waste Dumps support the need for continued monitoring at these locations. Monitoring stations BH 14, A/B, located to the south of SRK-FD05 (Figure 6G-17), indicate groundwater is highly impacted with sulphate (about 2,500 mg/L) and zinc (about 10 mg/L) (Figure 6G-1-3).

Seepage water in the waste dumps adjacent to the Zone II Pit that is not captured by the X26 well continues along a flowpath toward the Zone II Outwash and is further influenced by waste dump seepage (RGC, 2012). Wells near the base of the waste dump (i.e., BH8) (Figure 6G-17) indicate groundwater is highly impacted with sulphate (about 3,000 mg/L) and zinc (greater than 100 mg/L), flowing toward the NFRC (Figure 6G-1-1). Increased concentrations of zinc (greater than 5 mg/L) have also been observed in wells closer to the NFRC (i.e., BH6) (Figure 6G-1-2). SRK-FD08 is the only seepage water monitoring station located within the Zone II Outwash area, and it has been dry during the 2012 and 2013 sampling events (Figure 6A-1). Well P96-6, located downstream of the Zone II Outwash area and upstream of the North Fork Rock Drain, indicates groundwater moderately impacted with sulphate (518 mg/L) and zinc (0.73 mg/L) and seasonal fluctuations where water quality improves (through dilution) during freshet conditions (RGC, 2013).

Downstream from the Zone II Outwash, the NFRC flows southwest at the base of the Intermediate Dump, underneath the Haul Road through the North Fork Rock Drain, and past the S-wells area. As Section 2.2 described, the S-wells area is characterized by highly impacted water that is collected and pumped to the Faro Pit. However, water that is not captured by the S-wells SIS continues down the flowpath toward NFRC and its confluence with the South Fork Rose Creek (Figure 6G-9)

2.4 Constituent Loading to between S-Wells and X23

While the S-wells area and the X23 seepage area are considered “hot spot” seepage areas south of the Main Dump and Intermediate Dump, reduced monitoring takes place between the two locations because significant surface seepage locations have not been identified in this area. However, one well (SRK08-P9) makes it possible to assess the groundwater conditions flowing from the Faro Waste Dumps towards the RCAA in this region (Figure 6G-24). Samples collected in 2012 suggest this area is moderately impacted with sulphate (1,160 mg/L), but not impacted with zinc (0.01 mg/L). Additional monitoring is required to determine whether this area reflects localized impacts from specific waste dumps or represents regional constituent loading because of premining topography and contributions from the waste dumps.

2.5 Constituent Loading to Faro Creek Canyon

Water quality at X23, which is the surface expression of groundwater flow along the pre-mine Faro Creek Channel, is characterized as highly impacted. The most recent (September 2013) concentrations of sulphate (8,750 mg/L) and zinc (1,380 mg/L) were some of the highest concentrations measured at the FMC (Figure 6A-10). Concentrations of iron at X23 were also indicative of highly impacted water, at 613 mg/L. The highly impacted water quality at X23 is not unexpected, as this site of the pre-mine Faro Creek south of Faro Pit includes waste dumps with some of the highest metal and sulfide content in the Faro Mine area, such as the Low-grade Stockpiles “A” and “C” (LGSPA, LGSPC), the Oxide Fines Stockpile (OXSP), Medium-grade Stockpile (MGSP), Stockpiles Base (SPB), Chrusher Stockpile (CHSP), and the Main Dump (MDE, MESC, MDW) (Figure 6A-1). Seepage water from X23 flows across the eastern edge of the ETA and into old Faro Creek Canyon, just south of the mine Access Road. Drainage from the Mill Area also contributes to flow

across the ETA. Along these flowpaths, water interacts with the ETA tailings material before discharging into Faro Creek Canyon. Flow that bypasses the collection system flows through Faro Creek Canyon and continues down an unlined earthen ditch along the northern side of the Intermediate Tailings Impoundment, before flowing out over the western end of the Intermediate Tailings Impoundment and into the Intermediate Dam Pond. A sump interception system at the head of Faro Creek Canyon, just below mine Access Road, is designed to capture the bulk of X23 and Mill Area flows, as well as subsurface flows from the ETA, before they reach Faro Creek Canyon and the flow to the Intermediate Dam Pond. The ETA sump operates seasonally and does not capture all of these inputs year-round. Even when the ETA sump is operating, the sump does not capture all of the flow. Flow that is not captured by the ETA sump (approximately 20 percent of the flow when operating) flows through Faro Creek Canyon at FCS-4 (RGC, 2010). In general, the contaminant concentrations at FCS-4 are slightly less than those in the ETA sump, but follow the general trends observed at the ETA sump (DES, 2012). One exception to the observed trend is the observed decreased constituent concentrations at FCS-4 during freshet conditions, when an influx of “clean” surface runoff dilutes the seepage chemistry.

During the September 2012 field investigations, it was determined that the WTP clarifier, located within the former Mill Building, was leaking at a rate of approximately 2 litres per second. While some of the leakage water is captured in sumps and pumped back to the WTP, the majority flows from the Mill Area into the former Mill Canyon drainage before flowing out over the ETA toward Faro Creek Canyon. Based on samples collected in 2012, the majority of this water appears to be relatively clean (i.e., alkaline pH [greater than 7] and low conductivity) based on field results from September 2012 sampling. However, a fraction of this water is considered highly impacted immediately adjacent to the former Mill Building (CH2M HILL, 2013b). Water that leaks from the Mill Building and is not captured in sumps flows across the ETA to the settling basin north of mine Access Road, which discharges toward Faro Creek Canyon.

FCS-3 monitors seepage from the south side of the mine Access Road near the ETA sump and combines flow from several seeps. The seeps represented by FCS-3 account for approximately half of the total flow to the ETA sump and are considered highly impacted, with sulphate concentrations of 10,700 mg/L (June 2013) and zinc concentrations of 724 mg/L (June 2013).

2.6 Constituent Loading to Guardhouse Creek

There are two main contributors of flow in the Guardhouse Creek area: (1) Upper Guardhouse Creek and (2) Lower Guardhouse Creek. Upper Guardhouse Creek flows adjacent to the Faro Northwest Waste Dump (along the westernmost edge) and may partially flow under the Northwest Waste Dump (Figure 6A-1). Upper Guardhouse Creek ultimately flows to the CVD area, bypassing collection systems, and into Rose Creek (upstream of X14). Although Upper Guardhouse Creek flows through largely unimpacted terrain, there are several seeps (FD16, FD17, FD18) along the westernmost edge of the Faro Northwest Waste Dump that flow into Upper Guardhouse Creek (Figure 6A-1). These seeps, represented by the water quality measured at SRK-FD18, have maintained a slightly impacted status over the past 10 years, with sulphate concentrations generally less than 50 mg/L and zinc concentrations of about 0.1 mg/L (Figure 6A-11). Increasing constituent concentrations to Upper Guardhouse Creek from these seeps indicate the possibility of future water quality impacts, and support the need for continued monitoring of the Northwest Waste Dumps. However, these seeps contribute relatively little flow compared with the large volume of flow in Upper Guardhouse Creek. A downstream surface monitoring station (CH12_102_SG001) established in May 2012 (CH2M HILL, 2013b) yielded low sulphate (10 mg/L) and minor zinc (18 micrograms per litre) concentrations.

In contrast with the relatively unimpacted Upper Guardhouse Creek, Lower Guardhouse Creek originates from waste dump seeps with mine-influenced water quality (SRK-FD01) that flow into a ditch across from the Warehouse Building (Figures 6A-1 and 6A-11). In addition to the waste dump seepage creating Lower Guardhouse Creek, at least some seepage from the Mill Area appears to discharge to the creek (CH2M HILL, 2013b). According to pre-mining maps, this ditch is located in an area that was once a small pond (RGC,

1996). Lower Guardhouse Creek flows from this ditch to the Intermediate Dam Pond, where the water is captured for treatment. Concentrations of sulphate (3,020 mg/L) and zinc (87.7 mg/L) in SRK-FD01 are increasing and reflect highly impacted water (Figure 6A-11). Seepage water discharging from the south toe of the Northwest Lower (NWL) Waste Dump, at location SRK-FD19, contributes to X23 (50 percent of flow) and to Lower Guardhouse Creek (50 percent of flow) (Figure 6A-1) (Gomm Environmental Engineering Consulting, 2010). Water quality at SRK-FD19 is highly impacted, with trends of decreasing alkalinity (from 386 mg/L [September 2002] to 151 mg/L [September 2013]) and increasing sulphate (from 3,810 mg/L [September 2002] to 6,300 mg/L [September 2013]) and zinc (from 51 mg/L [September 2002] to 257 mg/L [September 2013]) (Figure 6A-11).

SECTION 3

Vangorda/Grum Area

The Vangorda/Grum Area is characterized by two localized groundwater sinks (the Grum and Vangorda Pits) and regional groundwater flow toward Vangorda Creek, which drains the area and flows south toward the Pelly River (Figure 6G-10). Similar to the Faro Mine Area, precipitation that infiltrates through the waste dumps collects at their bases, near pre-mining topographic lows (Appendix 6G). Depending on the subcatchment that a particular waste dump is located in, seepage from the waste dumps may flow to the Grum Pit, the Vangorda Pit, or Vangorda Creek (Figures 6A-2 and 6A-3). Data have been compiled from samples collected at seepage locations, surface water monitoring stations, and monitoring wells; these provide the foundation for characterizing water quality conditions in the Vangorda/Grum Area.

3.1 Background Water Quality

Before mining at the Vangorda Pit began, a diversion channel was constructed to divert Vangorda Creek around the Vangorda Pit, minimizing its exposure to mine waste. Background surface water sampling takes place in the main fork of Vangorda Creek at Station V1, immediately upstream of the Vangorda/Grum Area (Figure 6A-3). The water quality of Vangorda Creek at Station V1 is characterized by neutral pH (7.34) and low concentrations of sulphate (11.4 mg/L) and zinc (0.003 mg/L), and is representative of water that has not been influenced by mine materials.

3.2 Grum and Vangorda Pits

Figure 6A-12 shows a summary of the water quality and level of impact at seepage monitoring stations in the Grum Pit area. The Grum Pit receives water from surface runoff within the Grum Pit catchment, as well as groundwater inflow from the surrounding Thalweg aquifer (Appendix 6G). Seepage water samples are collected regularly at GP02 and GP09 (Figure 6A-2). The observed water quality at GP02 is characterized by alkaline pH (8.04) water, slightly impacted with sulphate concentrations of 439 mg/L, and no detectable zinc (Figure 6A-13). Similarly, seepage water quality observed at GP09 is characterized by alkaline pH (7.98) and water slightly impacted with sulphate and zinc (703 mg/L and 0.04 mg/L, respectively) (Figure 6A-13).The water quality of the Grum Pit lake (V23) is characterized by alkaline pH (7.84) and moderately impacted mine water, based on sulphate (435 mg/L) and zinc (3.14 mg/L) concentrations from samples taken in June 2013 (Figure 6A-2). An in situ biological treatment process was initiated within the Grum Pit in 2004 and used until it was discontinued in 2011. The Grum Pit lake is conveyed to the Vangorda Pit and treated at the Grum water treatment plant.

Similar to the Grum Pit, the Vangorda Pit lake is largely the result of surface runoff within the pit catchment area and groundwater flow (Appendix 6G). The Vangorda Pit also receives constituent loading from water pumped from the Grum Pit and water collected in the Grum Creek Collection System, V15 sump, and Little Creek Pond (Figure 6A-3). The Vangorda Pit lake water quality is monitored at location V22 (Figure 6A-3). The current water quality is characterized as slightly acidic pH (6.24) and is highly impacted, based on concentrations of sulphate (857 mg/L) and zinc (52.5 mg/L) measured in June 2013. Concentrations of sulphate and zinc in the Vangorda Pit lake have been increasing steadily during the period of record (CH2M HILL, 2013b). Seasonal fluctuations were observed in the water quality of the Vangorda Pit lake, with decreased sulphate and zinc concentrations during freshet and increased concentrations during low flow conditions (DES, 2012; CH2M HILL, 2013b).

3.3 Grum Waste Dump

The easternmost flank of the Grum Waste Dump was built over the former Grum Creek, where drainage flows toward two contiguous perennial seep locations (SRK-GD01 and SRK-GD02) (Figure 6A-2). These two

seeps indicate moderately impacted water quality, based on sulphate (1,578 mg/L) and zinc (2.3 mg/L) concentrations (Figure 6A-13).

The south-central portion of the Grum Waste Dump is identified by the sulphide-dominant waste rock found in the Grum Sulphide Cell (Figure 6A-2), and has some of the greatest potential (at the FMC) for generating acid and leaching metals. Because of this, to minimize downgradient impacts, it was segregated during mining and capped with a low-permeability cover in 2010 (SRK, 2011).

Seepage collects in a small sump (V15) and along the former Grum Creek downstream of the Grum Waste Dump before flowing to Moose Pond. Water quality at V15 showed moderately impacted water, based on zinc concentrations (4.1 mg/L) measured before the low-permeability cover was installed; concentrations have somewhat stabilized (to observed 2010 concentrations) since the cover has been placed (DES, 2012). The increased contaminant loading at V15 resulted in increased zinc concentrations downstream in Grum Creek (V2); to mitigate this, the V15 seepage path was rerouted to Moose Pond in 2011 (CH2M HILL, 2013b). Sampling of Moose Seep and Moose Well No. 2 confirm that losses from Moose Pond (via infiltration to the surrounding formation) flow towards Vangorda Creek. Facilities are now in place for seasonal water collection from Upper Grum Creek and V15 and pumping to Vangorda Pit. Collection began in 2013.

Time-series plots for the Grum seeps were generated for locations SRK-GD05 and SRK-GD13. SRK-GD05 is located at the southern toe of the Grum Waste Dump, downgradient from the Grum Sulphide Cell (Figure 6A-2). Water at this location is different from other seepage water at the FMC because of its abundant algal growth and hard, white, crusty deposits where the seep emerges from the base of the waste dump. SRK-GD05 is characterized by neutral to alkaline pH (7.32) and water moderately impacted with sulphate (2,330 mg/L) and zinc (2.95 mg/L) (Figure 6A-13). Seep SRK-GD13 is located at the western toe of the southwest Grum Waste Dump with westward flow that ultimately connects with the West Vangorda Creek drainage (Figure 6G-10). Water quality at SRK-GD13 indicates neutral to alkaline pH (7.57) and moderately impacted drainage, based on concentrations of sulphate (1,140 mg/L) and zinc (0.23 mg/L) (Figure 6A-13).

Seepage from the Ore Transfer Pad, located to the northwest of the Grum Pit, is monitored at location SRK-GD23 (Figure 6A-2). Flow from SRK-GD23 travels to Vangorda Creek downstream of the routine monitoring station V27. Water quality at SRK-GD23 is characterized by neutral pH and minimally to moderately impacted drainage, based on concentrations of sulphate (552 mg/L) and zinc (0.45 mg/L) (CH2M HILL, 2013b).

3.4 Vangorda Waste Dump

The Vangorda Waste Dump was constructed on a topographic high point south of the Vangorda Pit (Figure 6A-3). This waste dump is composed of sulphide-rich waste rock with little NP available to buffer acid generation processes. It is surrounded to the south, west, and north by a drainage ditch that collects seepage from the toe of the waste dump. Several transverse drains were constructed beneath the till berm surrounding the waste dump; these direct the seepage toward a perimeter collection ditch and Little Creek Pond, where it is stored before being pumped seasonally to Vangorda Pit. Samples collected from the transverse drains are acidic, with elevated concentrations of iron, zinc, and sulphate. Figure 6A-14 presents a summary of the water quality and level of impact at seepage monitoring stations in the Vangorda area. The greatest impacts were observed in the drains adjacent to the Little Creek Pond, SRK-VD04, and SRK-VD05 (CH2M HILL, 2013b). Station LCD monitors water quality in the Little Creek Pond, which fluctuates seasonally, with decreased concentrations observed during freshet (DES, 2012; SRK, 2010). Although decreased concentrations are observed during freshet, water quality observed at LCD is highly impacted, based on sulphate (6,330 mg/L) and zinc concentrations (1.78 mg/L, but as high as 960 mg/L historically) (Figure 6A-15) (CH2M HILL, 2013b).

Time-series plots were generated for five transverse drains: SRK-VD01, SRK-VD02, SRK-VD03 (V30), SRK-VD04 (V32) and SRK-VD05 (V33) (Figures 6A-3 and 6A-15). The water at all of these locations is classified

as highly impacted, with low pH and elevated concentrations of sulphate and zinc. Values of pH in the transverse drain monitoring locations range from 2.71 (SRK-VD05) to 5.84 (SRK-VD03) (Figure 6A-15). Concentrations of sulphate and zinc range from 1,740 mg/L (SRK-VD01) to 87,400 mg/L (SRK-VD05) and 0.73 mg/L (SRK-VD03) to 87.3 mg/L (SRK-VD01), respectively. These concentrations identify this as one of the most mine-affected areas of the FMC (Figure 6A-15). Continued monitoring of the Vangorda transverse drains is recommended to support future water collection and treatment options.

Monitoring wells V34 through V37 and P2001-1-3 monitor seepage beneath the Vangorda Waste Dump drainage ditch (Figure 6G-31). Current water quality at these locations is characterized by high pH with slightly-to-moderately elevated dissolved sulphate and zinc concentrations (Figure 6G-31). Zinc concentrations are stable at wells V34, V35, and V37, and are increasing at well V36. The observed increases in sulphate concentrations in all four wells suggests that some groundwater from the Vangorda Waste Dump is bypassing the seepage collection system (Appendix 6G and CH2M HILL, 2013b).

Currently, V1, V4, V5, V6A, V17A, V19, V20, V27, and VG Main monitor the surface water along Vangorda Creek and its tributaries (Figure 6A-3). Water quality is characterized by pH ranging from neutral to alkaline, with minimal impacts to water quality. These characteristics suggest Vangorda Creek has experienced minimal impacts from the mining activities to date. However, increasing concentrations of mine-related contamination and evidence of affected waters bypassing the seepage collection system indicate future impacts are possible (Appendix 6H and CH2M HILL, 2013b).

SECTION 4

Rose Creek Tailings Area, Rose Creek Alluvial Aquifer, and Cross Valley Dam

The RCTA generally receives clean groundwater from the south and southeast and receives impacted waters from the FMC, located to the north (Appendix 6G and Figure 6A-4). Locally, tailings contribute to groundwater contamination in the RCTA. Vertical hydraulic gradients measured in multi-level wells within the RCTA indicate the presence of downward gradients between the tailings and the underlying alluvial deposits. This suggests either (1) contaminants mobilized because precipitation infiltrated through the tailings or (2) contaminants that are discharged from the ETA and then enter the tailings could be transported vertically downward and discharged into the underlying RCAA (Appendix 6G). The unlined ditch conveying ETA water from FCS-4 to the Intermediate Dam Pond may also be a substantial source of contamination to the northern portion of the RCAA underlying the RCTA (Figure 6A-4). This assumption is supported by increasing trends in sulphate (from about 1,000 mg/L [January 2006] to about 3,500 mg/L [June 2012]) and zinc (from about 0.1 mg/L [January 2006] to about 11 mg/L [June 2012]). These concentrations were observed in the RCAA underlying the Secondary Tailings in monitoring well P03-06, downgradient of the Faro Creek Canyon (Figures 6G-28 and 6G-1-8) (RGC, 2012). The greatest concentrations of sulphate and metals of interest were observed in tailings porewater in the southeastern (P03-01 and P03-03) and northwestern (P03-06) sections of the Secondary Tailings. Conversely, the lowest concentrations of contaminants occur in groundwater in the southwestern section of the Second Impoundment at P03-05 (Figure 6G-28) (RGC, 2012). In the RCAA area, downgradient from the Faro Creek Canyon and towards the Intermediate Dam Pond, observations over the past 10 to 12 years have noted a gradual increase in sulphate, followed by a lagging increase in zinc (RGC, 2012).

While inputs from the Faro Waste Dumps appear to be impacting the northern portion of the RCAA, the southern portion of the RCAA is generally less impacted, possibly because of “clean” water leaking from the Rose Creek Diversion. This appears evident at the Intermediate Impoundment, where the Rose Creek Diversion is topographically higher than the Intermediate Impoundment (RGC, 2012).

The exception is in the southeastern corner of the RCTA, where oxidation appears to be more rapid in the Second Impoundment and seepage from the tailings appears to be impacting the RCAA. Significant increases in sulphate and zinc concentrations were observed in wells P03-03 (sulphate from about 1,000 mg/L to about 5,000 mg/L and zinc stable at about 0.01 mg/L in P03-03-06) and P03-05 (sulphate from about 400 mg/L to about 800 mg/L and zinc from about 0.01 mg/L to about 10 mg/L in P03-05-02) (RGC, 2012). Care and Maintenance personnel have observed iron stains in the ice covering the Rose Creek Diversion during the low-flow winter months when groundwater input contributes the most flow. This suggests metal-rich groundwater from the RCTA is reaching the Rose Creek Diversion during this time (Cherian, 2010, personal communication)

In addition to the impacts to the RCAA, groundwater in the underlying weathered bedrock downgradient of the CVD shows signs of impact, especially on the northern side of the valley (RCG, 2012). However, while a trend of deteriorating groundwater quality in alluvium and weathered bedrock downgradient of the CVD is evident, the contamination remains limited to major ions (i.e., magnesium and sulphate). The metal plumes (i.e., zinc and iron) currently remain upgradient of the CVD (RGC, 2012). Zinc concentrations in alluvial groundwater remain below 0.5 mg/L downgradient of the Second Impoundment, while concentrations are below 0.1 mg/L beneath the Intermediate Dam and CVD. This has been attributed to metal attenuation by adsorption to iron oxyhydroxides and carbonates (CH2M HILL, 2013a) and also to adsorption to organic matter near CVD (SRK, 2006b).

SECTION 1

Introduction

The intent of this characterization report is to describe the current status of hydraulic facilities at the Faro Mine Complex (FMC), including their existing capacity and condition. It summarizes how these features are maintained and monitored, and their hydraulic functions in relation to the Faro Mine Interim Works (IW). This report is based on external, stand-alone documents, as well as ongoing hydraulic studies. This hydraulics characterization report assesses the available information and data used to characterize the hydraulic functioning of engineered conveyance and impoundment features at the FMC and, where appropriate, references additional, more detailed hydraulic and hydrologic information available from other appendixes in the Interim Works Project Proposal (IWPP). During and after mining operations, considerable effort was expended to monitor the integrity and effectiveness of hydraulic features (i.e., streams, diversions, and impoundments) and related conveyance infrastructure. This document describes these sources of hydraulic data for the FMC and discusses the analysis methods used to characterize the site hydraulics.

Figure 6B-1 shows the FMC area. This report discusses the hydraulic features based on the two main watersheds illustrated in Figure 6B-2: (1) the Rose Creek watershed, which contains the Faro Mine Area, and (2) the Vangorda Creek watershed, which contains the Vangorda/Grum Area.

SECTION 2
Methods

Historically, a number of streams and creeks conveyed runoff through the FMC. To prevent potential surface water contamination associated with mining activities, many of these systems were rerouted via diversions, flumes, and ditches. The resulting hydraulic structures have been studied by various investigators to document site conditions, and, in some cases, original design information is available. Monitoring studies have also documented hydraulic information such as surface water flows and water levels. Relevant site information and data were collected from numerous sources to characterize site hydraulic conditions. CH2M HILL collected and reviewed historical data collection reports, design study reports for FMC activities, and site characterization reports and assessments. Most of these data sets included local, FMC-related data that were collected through post-mining monitoring programs.

2.1 Sources of Data and Information

Supporting data for hydraulic characterization consist of stream flow and water level data collected over various time periods and, where available, design data related to conveyance capacities. Hydraulic characterization also includes information from detailed inspection and analysis reports about the stability, operations, and maintenance of hydraulic features.

2.1.1 Flow Data

Flow data and estimates support the determination of how the FMC hydraulic structures are performing, and could perform in the future.

2.1.1.1 Continuous and Spot Flow Measurements

The *Hydrology Baseline Report, Faro Mine Interim Works* (CH2M HILL, 2013a) provides a detailed summary of available continuous flow measurement data for the FMC. It also discusses quality assurance /quality control processes for this data, to support hydrological characterizations. These characterizations will assist with remediation and closure efforts at the FMC.

2.1.1.2 Regional Analyses

The FMC's flood hydrology is an important consideration for hydraulic assessment, as it represents a condition that occurs very infrequently but presents one of the greatest risks to the integrity and functioning of hydraulic elements (SRK Consulting Engineers and Scientists [SRK], 2010a). Flood estimates have been developed for the FMC using a technique known as Regional Analysis. Regional Analysis consists of fitting the annual series of peak flood rates at a number of flow stations throughout the Yukon and Alaska, for a range of return periods to the FMC flow stations. The analysis identifies trends that could be used to transpose flood estimates from the regional streamflow gauging stations to the FMC (SRK, 2010a).

As the Hydrology Baseline Report (CH2M HILL, 2013a) discusses, AECOM (2009a) documents the most recent regional analysis work, and refines the regional analysis developed for the 1996 *Integrated and Comprehensive Abandonment Plan* report (Robertson GeoConsultants Inc., 1996). AECOM examined available data to develop empirical relationships that can be used to relate a flow statistic (e.g., Mean Annual Runoff) to a catchment characteristic (e.g., drainage area). The regional analysis prepared by AECOM (2009a) was used to develop a site-wide water balance and relationships for mean annual runoff and low flows.

As discussed in the *Stability Analysis Baseline Report, Faro Mine Interim Works* (CH2M HILL, 2013b), Northwest Hydraulic Consultants (NHC) and BGC Engineering (BGC) (2004) conducted a regional analysis based on data obtained from seven regional gauges. During the study, the period of record represented by the gauges ranged from 14 years to 40 years. The catchment areas for the gauges ranged from 91 square kilometres (km^2) to 7,250 km^2. Instantaneous peak discharges were estimated for the mean annual event and for the 1-in-50-year, -100-year, -200-year, -500-year, and -1,000-year return period floods.

As discussed in the Hydrology and Stability Analysis baseline reports, another regional study was conducted as detailed in the *Anvil Range Mining Complex 2005 Seepage Investigation at the Emergency Tailings Area* report (SRK, 2006) to determine average daily flows for the 1-in-2-year, -100-year, -200-year, -500-year, and -1,000-year floods. The recurrence interval floods were determined for flow durations ranging from 1 to 365 days. Using plots of peak discharge versus catchment area, a relatively constant discharge per km^2 was observed for flow records representing catchment areas ranging from 13.7 km^2 to 7,250 km^2. This observation led to the conclusion that the catchment response to floods could be estimated by using recurrence interval estimates from the single gauge with the most extensive period of record (because catchment unit discharge during recurrence interval events appeared to be independent of total catchment area).

Finally, as discussed in the Hydrology Baseline Report, SRK performed a regional analysis for Vangorda Creek as part of a draft design report for the VCD (SRK, 2010a), to estimate instantaneous peak discharge for 1-in-2-year, -100-year, -500-year, and -1,000-year floods.

2.1.1.3 Probable Maximum Precipitation and Probable Maximum Flood

Water Management Consultants and a committee of the Faro Mine Closure Planning Office conducted a 2006 study that examined the Probable Maximum Flood (PMF) event for the Rose Creek catchment in detail (Water Management Consultants, 2006). The development of the PMF and Probable Maximum Precipitation (PMP) was peer-reviewed to confirm that valid assumptions were used and realistic outcomes were developed (CH2M HILL, 2012b).

2.1.2 Annual Reports

Environmental monitoring programs required under the previous water licenses and the current Care and Maintenance contract provide information about the operation and maintenance of hydraulic infrastructure at the FMC (Denison Environmental Services [DES], 2010).

CH2M HILL reviewed the following reports, which summarized the last 6 years of operations and maintenance activity at the FMC, to establish the baseline hydraulic condition:

- Anvil Range Mine Complex – 2006 Annual Environmental Report - License QZ03-059 (Gartner Lee Limited [GLL], 2007)
- Anvil Range Mine Complex – 2007 Annual Environmental Report – License QZ03-059 (GLL, 2008)
- Anvil Range Mine Complex – 2008 Annual Environmental Report – Water License QZ03-059. (AECOM, 2009b)
- Faro Mine Complex Annual Environmental Monitoring and Activity Report 2009 (DES, 2010)
- 2010 Annual Environmental Monitoring and Activity Report – Faro Mine Complex - Faro, Yukon (DES, 2011)
- 2011 Annual Environmental Monitoring and Activity Report – Faro Mine Complex - Faro, Yukon (DES, 2012)
- 2012 Annual Activities Report (Tlicho Engineering and Environmental Services, 2013)

Annual reports are particularly useful for identifying hydraulic issues with conveyance elements that are not included in the annual geotechnical inspections. They provide information about operations and maintenance issues with specific features, and summarize site-wide observations about hydraulic functioning.

2.1.3 Geotechnical Reports

CH2M HILL reviewed the following geotechnical reports, related to the functioning and integrity of hydraulic features (including dams, impoundments, and diversion structures):

- Anvil Range Property 2007 Dam Safety Review – Cross Valley Dam, Intermediate Dam, and Little Creek Dam (Klohn Crippen Berger, 2008)
- 2009 Annual Geotechnical Evaluation and Instrument Review – Various Facilities at Faro Mine, Yukon (BGC, 2010)

- 2010 Annual Inspection – Waste and Water Management Facilities - Vangorda/Grum, Faro Mine Complex, Yukon (SRK, 2011a)
- 2011 Geotechnical Inspection – Waste and Water Management Facilities - Vangorda/Grum, Faro Mine Complex, Yukon (SRK, 2011b)
- Faro Mine Complex - 2011 Annual Geotechnical Review (Klohn Crippen Berger, 2012)

Annual inspection and review reports (Klohn Crippen Berger, 2012; 2008; BGC, 2010), comment on the geotechnical performance of the following structures in the Faro Mine Area:

- Cross Valley Dam (CVD) and emergency spillway
- Intermediate Dam (ID) and emergency spillway
- Rose Creek Diversion (RCD): dike crest, top of backslope, and toe of slope
- North Wall Interceptor Ditch
- North Fork Rock Drain (NFRD)
- Selected portions of the Faro waste rock dumps (WRDs)
- Intermediate Impoundment
- Faro Creek Diversion (FCD), upstream of the Faro Pit

The annual inspection and review reports (SRK, 2011a), (SRK, 2011b), comment on the geotechnical performance and stability of the following structures at the Vangorda/Grum Area:

- Vangorda Waste Dump and seepage collection system
- Little Creek Dam (LCD)
- Vangorda Creek Diversion (VCD)
- Embankments of the Vangorda Water Treatment Plant (WTP) Clarification Pond
- WTP Freshwater Supply Pond
- Grum Interceptor Ditch (GID)
- Sheep Pad Ponds (SPP)
- Lower slopes of the Grum Waste Dump

Appendix 6C describes major facilities in detail and discusses their conditions.

2.1.3.1 Down Valley Interim Hydraulic Upgrades Phase 2 Basis of Design Report

The existing ID spillway does not have the capacity to safely pass a moderate or major flood event without potentially failing the dam. The Down Valley Interim Hydraulic Upgrades (DVIHU) work package, (CH2M HILL, 2014a) and *Down Valley Interim Hydraulic Upgrades Design, Faro Mine Interim Works* (CH2M HILL, 2014b), provide an upgrade of the hydraulic capacity of the ID spillway so that it can safely pass approximately 115 cubic metres per second (m^3/sec), which is the peak flow at the ID spillway for a 1-in-500-year flood event, while maintaining a freeboard of 1.0 metres (m). This estimate of the flood event takes into account attenuation by the Rock Drain and storage by the Intermediate Impoundment. The increase in hydraulic capacity of the ID spillway will be accomplished by raising the effective height of the dam and by increasing the cross-sectional area of the spillway. The 1-in-500-year flood event was selected as the design flood event for the interim improvements. The proposed work includes RCD improvements to safely pass the 1-in-500-year flood event without overtopping the RCD dike.

The intent of the DVIHU project is to address these issues in the interim period, before the permanent solution of increasing the ID spillway capacity by constructing a PMF spillway is implemented as part of the FMRP.

2.1.4 Culvert Survey

The 2012 Field Survey of Existing Features included a survey of all existing (known) culverts within the mine site area (Challenger Geomatics, 2012). The invert elevations at both ends of the culvert were measured using standard survey methods. Other data collected for each culvert included the diameters and material types. Each side of the culvert was photographed, looking upstream and downstream (Challenger Geomatics Limited, 2012).

Attachment 6B-1 includes site plans, culvert photographs, and related data collected during the 2012 field investigation.

SECTION 3
Results

3.1 Hydraulic Component Inventory

The following sections describe the hydraulic components that control surface flows within the Faro Mine Area and the Vangorda/Grum Area.

3.1.1 Faro Mine Area Hydraulic Components

Figure 6B-3 shows the Faro Mine Area hydraulic components.

3.1.1.1 West Valley Interceptor Ditch

The West Valley Interceptor Ditch (WVID) intercepts runoff from the hillsides northwest of the Faro Valley Waste Dump, and redirects it northward to the FCD. The WVID is a simple excavation into the native surficial soil and rock (GLL, 2007), which was built in conjunction with the FCD to direct surface water flow away from the Faro pit as it was being developed.

3.1.1.2 Faro Creek Diversion

The FCD collects uncontaminated surface water from the original Faro Creek Channel upstream of the Faro Pit. It diverts the water around the northeast side of the Pit, into the North Fork Rose Creek (NFRC). The FCD does not collect all of the flow in the old Faro Creek drainage area; some surface flow and groundwater seepage water continues to flow directly into the Faro Pit (GLL, 2007).

3.1.1.3 North Fork Rose Creek

The NFRC is a natural channel that conveys runoff from the upper, undisturbed portion of the FMC catchment, south towards the intersection point with the South Fork Rose Creek (SFRC). The FCD discharges into the NFRC, prior to the creek flowing adjacent to the Northeast WRD. The NFRC passes through the NFRD, adjacent to the Intermediate WRD.

3.1.1.4 North Fork Rock Drain

The Haul Road crossing for the NFRC was constructed as a dumped rockfill structure, called a “rock drain” (BGC, 2006). The NFRD comprises clean waste rock at the base of the road structure, with enough capacity to pass water through the void space.

Although the NFRD is not designed to retain water, it has the ability to temporarily retain a significant volume of water during very large flood events. A breach analysis of the NFRD was performed (CH2M HILL, 2014a), to evaluate the consequences of failure under the 1-in-500-year flood event used for the DVIHU evaluations. The consequences of NFRD breach vary depending on the volume of water retained at the time of breach, which depends on the assumed flow rates through the NFRD. High flow-through rates result in a lower volume of water impounded behind the NFRD, whereas low flow-through rates result in higher volumes of impounded water. The breach analyses were performed for three flow-through rates:

- Best estimate flow-through scenario,
- Low flow-through scenario, and
- Low flow-through with 25-percent reduction in capacity scenario.

For the best estimate flow case, it was found that the NFRD would not be overtopped. For the low-flow case, short duration overtopping is predicted. For the low flow case with 25 percent reduction, longer duration overtopping is predicted. The potential breach mechanism assumed in the breach analysis was piping. Other potential failure mechanisms include progressive ravelling and sloughing of the downstream slope under high flow-through velocities.

Given the severe consequence of breaching the NFRD when assuming a conservative set of flow conditions for a 1-in-500-year flood event, it is reasonable to assume that the likelihood of increased ponding, breaching, and the severity of incremental downstream damage will increase for floods larger than a 1-in-500-year flood. A detailed discussion of the analysis is provided in *Down Valley Interim Hydraulic Upgrades Design, Faro Mine Interim Works* (CH2M HILL, 2014b).

3.1.1.5 South Fork Rose Creek and Fresh Water Supply System

The decommissioned freshwater dam and reservoir in the SFRC represented a large component of the fresh water supply system to the FMC Mill during mine operations. The dam was breached to original ground level in 2004. Some components of the freshwater supply system are no longer in use but remain in place; these include the Pumphouse Pond and the associated building and freshwater pipeline (GLL, 2007).

The Pumphouse Pond is located at the confluence of the NFRC and SFRC, and passes all of the flow from SFRC and most of the flow diverted from NFRC. High flows in the NFRC partially spill into the lower portion of the North Fork Rose Creek Diversion before it discharges to the RCD (GLL, 2007).

3.1.1.6 Rose Creek Tailings Area

The Rose Creek Tailings Area (RCTA) encompasses the tailings impoundment at the base of Rose Creek Valley, about 2.5 kilometres (km) southwest of the Faro Pit (Figure 6B-3). Approximately 28.6 million cubic metres (m^3) of flotation-derived process tailings were deposited in the RCTA between 1969 and 1998. The tailings are contained by a series of three dams (Original Dam, Secondary Dam [SD], and ID) constructed across the Rose Creek Valley (Figure 6B-3). The Original Dam no longer functions as a dam structure, because it is completely enclosed by tailings.

The CVD was constructed as part of the Down Valley Project in the early 1980s. The CVD Pond, downstream from the tailings impoundment dams, serves as a polishing pond for treated effluent for water treatment processes in the Faro mine area. The CVD has the same hazard classification as the ID. The main hazard from a CVD breach is not only the uncontrolled release of water from the CVD Pond, but sudden release of the pond could also cause significant danger to the ID. The ID does not have filter and drainage systems in the lower part of the embankment below the downstream bench, and it depends on the polishing pond to provide a counterbalancing hydrostatic head to reduce seepage and the need for filtering. A sudden drawdown of the pond is likely to result in significant seepage from the saturated ID downstream slope, which in turn could lead to progressive sloughing, even more seepage, possibly backward erosion, and eventually could result in piping or loss of the crest from larger slope stability failures. Based on this potential impact on the ID, the CVD is considered to have the same potential hazard classification as the ID.

A breach of the SD could also lead to a loss of tailings into the environment, but the magnitude of such a tailings loss would be much smaller and more contained than the tailings loss associated with an ID breach. Whereas the ID and CVD need to accommodate hydraulic (flood) loading as well as seismic (earthquake) loading, the SD only needs to be designed for seismic loading. Seismic loading could cause liquefaction of the dam foundation, and specifically at the locations where Rose Creek sediments are present in the foundation of the dam. At the West Limb, which is the curved portion of the SD that crosses the valley roughly north to south, there are intermediate tailings on the downstream toe of the SD. These intermediate tailings would prevent failure of the dam during seismic loading even if the foundation soils liquefy. Even if some tailings loss would occur along this portion, the tailings are likely to be contained within the Intermediate Impoundment.

A breach of the East Limb of the SD, which is the portion of the SD that is parallel to the RCD and where there are no tailings at the toe, could result in tailings flowing into the RCD. It is noted that the likelihood of tailings loss is low even when losing a portion of the East Limb crest; given that the upper layers of the secondary tailings are not saturated and given the relatively small height of about 4.6 metres (m).

The ID is the major Intermediate Tailings Area structure that also contains runoff and flood waters entering the Intermediate Tailings Area from a small residual catchment area. Any potential floodwater routed through the ID spillway would flow into the CVD Pond, and once the CVD Pond's storage capacity was exceeded, water would flow through the CVD spillway down into the Rose Creek Valley, and then into Rose Creek. This routing would

represent a noncompliant release of contaminated water to the environment and would only occur in extreme flood situations to protect the ID. Upstream flows are currently routed around the tailings facility in the RCD, and site water-management activities convey water from the intermediate pond to the water treatment circuit.

3.1.1.7 Rose Creek Diversion

The RCD passes Rose Creek water around the RCTA. The existing RCD is approximately 4,700 m long with a 0.23 to 5.0 percent slope, interrupted by numerous drop weirs. The diversion was originally designed to carry a 1-in-50-year flood event (approximately 79 m^3/sec), with 1 m of freeboard. It was subsequently modified to bypass stream flows of 140 m^3/sec, which is slightly more than the 1-in-500-year flood event (BGC, 2006; NHC, 2006), when neglecting any flood attenuation by the NFRD.

Water from the SFRC and the NFRC enters the upper section of the RCD, which was constructed in 1974 in conjunction with the construction of the secondary dam. The upper section of the RCD is predominantly a straight channel approximately 700 m long that includes riprap for erosion protection (GLL, 2007).

The section of the crest of the dike known as the fuse plug was constructed approximately 1 m lower than the crest of the adjacent dike structure and was armoured with riprap. The fuse plug was constructed to direct flow from the upper section of the RCD into the lower section of the RCD and to ensure that flows in excess of the RCD design flow would be diverted into the Intermediate Impoundment.

The lower section of the RCD below the fuse plug is approximately 4,000 m long and was constructed in 1980 and 1981, in conjunction with the ID development. It passes water along the south side of the Intermediate Impoundment and returns flow into the natural Rose Creek Channel, downstream of the CVD. The Lower Diversion includes a series of boulder-lined drop structures and a sharp bend at the downstream end. The Lower Diversion is constrained by natural slopes on the south side and by a till dike on the north side. In 2004, the dike along portions of the lower RCD was rebuilt to restore the freeboard, which was necessary to safely pass the design flood (1 in 500 year) (GLL, 2007).

Slumping in the containment dike in the upper section of the RCD has limited the success of this rebuild, however, and the RCD's capacity in this section remains below the intended design flood capacity. Addressing this capacity issue is a component of the DVIHU.

3.1.1.8 Upper Guardhouse Creek

Upper Guardhouse Creek collects uncontaminated surface water from the catchment area north of the FMC and directs it to the North Wall Interceptor Ditch.

3.1.1.9 Lower Guardhouse Creek

Lower Guardhouse Creek collects potentially contaminated mill area surface water and discharges it to the intermediate impoundment where it is eventually pumped for treatment.

3.1.1.10 Old Faro Creek Channel

The Faro Pit and Main Dump were constructed through the original alignment of Faro Creek. Old Faro Creek is the part of the original creek alignment that exists downgradient of Faro Pit and the Main Dump. It has become a focal point for surface seepage. It is assumed that a large portion of the seepage originates at the Faro Main Dump and Intermediate WRD, and is subsequently conveyed through the Old Faro Creek Channel (GLL, 2007). The ETA is located in the Old Faro Creek Channel, and this seepage is contained in the ETA.

3.1.1.11 North Wall Interceptor Ditch

The North Wall Interceptor Ditch intercepts runoff and shallow groundwater from the north side of the Rose Creek Valley and diverts it around the north abutment of the CVD (GLL, 2007). It is approximately 3 km long and comprises constructed and natural stream channel reaches. The North Wall Interceptor Ditch has relatively flat channel gradients along the constructed reaches and steep gradients along the natural stream reaches (Kohn Crippen Berger, 2012).

3.1.1.12 K-8 Rock Drain

The K-8 Rock Drain is a mine haul road stream crossing, constructed of coarse waste rock fill. It is located approximately 2.5 km east of the NFRD. It functions as a conduit for water flowing along the northern reach of the K8 Creek to cross the Haul Road. At the creek crossing, the haul road is approximately 55 m high, with a 25-m-wide crest.

3.1.1.13 Faro Mine Area Water Storage Facilities and Pit Water Management

A review of the water elevations for each onsite storage reservoir or pit (e.g., CVD Pond, ID Pond, Faro Pit, and Zone II Pit) in the Faro Mine Area was compiled in two technical memoranda and attached to the *Hydrology Baseline Report, Faro Mine Interim Works* (CH2M HILL, 2013a) as Attachments 6F-4a and 6F-4b. The two technical memoranda summarize the analysis of water management strategies.

Cross Valley Pond

The CVD Pond is part of the active water management program at the FMC. Although the Faro WTP did not discharge treated water to the CVD Pond in 2013, the CVD Pond still requires active management to remove water from inputs such as rainfall and seepage. Operational experience at the FMC indicates the water elevation in the CVD Pond should not be lowered below about 1,027.5 m. If it is, sludge beds could be exposed and sludge particulate suspended, which may impact water quality and the ability to discharge from the CVD Pond.

Intermediate Pond

Water and tailings are retained behind the Intermediate Dam, which is approximately 650 m long, 7 m wide, and 32 m high, with a crest elevation at 1,049.2 m (Klohn Crippen Berger, 2012) and has a spillway elevation of 1,047.7 m (DES, 2012). The water level in the ID Pond has historically ranged between 1,043.0 and 1,047.6 m (DES, 2012; Tlicho Engineering and Environmental Services Ltd. [TEES], 2013a). In 2013, ID Pond water was pumped to the Faro Pit. There are two constraints on the drawdown of water in the ID Pond: (1) a maximum drawdown per day of 40 millimetres (mm) and (2) the operations regime prescribed by KCB (2012) because of concerns about the ID's geotechnical stability (CH2M HILL, 2013a). No changes are recommended for the ID Pond target water levels.

Emergency Tailings Area

In previous years, water from the ETA was collected at a cut-off trench and dual sump and then pumped to the Faro WTP. In 2013, water was not initially collected at the ETA; however, as the season progressed, water was collected and pumped from the ETA to the Faro Pit via the old tailings box and a booster pump located east of the former Mill Building. There is no target elevation for the ETA, but the objective is to collect as much water as practical based on the system capacity. This will limit water of deteriorated quality from seeping downgradient to the ID Pond and the underlying Rose Creek Aquifer, and will reduce the volume of water in the ID Pond.

S-Wells and S-Wells Bypass

The S-Wells are located between the Intermediate WRD and the NFRC and consist of two parts: the S-Wells and the S-Wells Bypass (or Shallow Interception Trench). There were no changes to water management for the S-Wells in 2013. CH2M HILL (2012a) provides additional details about this system.

Zone II Pit

The Zone II Pit is located directly southeast of the Faro Pit and northwest of the NFRC. The pit was mined in the late 1970s and early 1980s and subsequently filled with about 40 million tonnes of unclassified waste rock from mining operations at other areas at the FMC (RGC, 1996). The Zone II Pit base is at an elevation of about 1,094.5 m (RGC, 1996) and the current surface topography is at an elevation of about 1,166 m. If water rose above 1,128 m, it would spill over the buried rim and seep toward the NFRC. Between the base of the Zone II Pit and an elevation of 1,128 m, the backfilled pit has about 480,000 m^3 of storage capacity, assuming 30 percent porosity of the backfilled waste rock (SRK, 2007). In 1991, a pumping well was installed to manage the water level and limit water from migrating towards the NRFC. In 2012, a replacement pumping well (CH12-Z2-PW01) was added.

The water-level elevation at Zone II Pit has been managed at approximately 1,107 m and has ranged between about 1,103 and 1,111 m since October 2010 (DES, 2012). However, this elevation leaves a hydraulic gradient

between the groundwater elevation in the Pit and the stage elevation of the NFRC (about 1,096 m). The expired water licence (QZ03-059) required the groundwater elevation in Zone II Pit to be maintained lower than 50 m below ground (mbg), or 1,116 m.

X26 (Zone II – Old Well)

X26 was not used to dewater the Zone II Pit in 2013. The well is still used to monitor the water elevation in the Zone II Pit. CH2M HILL (2012a) provides additional details about this pumping well. There is no target elevation for this location.

CH12-Z2-PW01 (Zone II – New Well)

During the summer of 2012, CH2M HILL oversaw the drilling and installation of CH12-Z2-PW01. This well extends to a total depth of 77.4 mbg, with a screened interval between 1,091.7 and 1,114.0 m and a sump extending below 1,091.7 m to the end of the hole at 1,088.6 m (CH2M HILL, 2013a). The lithology consisted of waste rock to a depth of approximately 69.45 mbg (1,096.5 m) (i.e., within 2 m of the reported base of the pit). The purpose of this well was to replace X26 and allow the groundwater levels within the pit to be managed so they are lower than those previously achievable. The objective of this deeper well was to lower the groundwater elevation below the stage elevation of the NFRC, to reverse the hydraulic gradient. CH2M HILL understands the water conveyance system installed at this location consists of an insulated high-density polyethylene (HDPE) pipeline, heat-traced for year-round operation. According to the 2011 WMP (Brodie, 2011), the pipeline is positioned to discharge water at 30 m below the surface of the Faro Pit lake. The recommended target elevation for the water level in the Zone II Pit is at or below 1,096 m. Groundwater collection should continue from Zone II Pit year round.

Faro Pit

The Faro Pit receives groundwater seepage, direct precipitation, runoff, FCD seepage, and water from managed sources such as the ID Pond, the ETA, S-Wells, and Zone II Pit. From 2004 until 2012, the water level elevation in the Faro Pit was maintained between approximately 1,140 m and 1,143 m (DES, 2012; TEES, 2013a). During the 2013 treatment season, source areas that used to go to the Faro WTP (which did not operate in 2013) went to the Faro Pit, which raised its water elevation above this range. On September 9, 2013, the Faro Pit water elevation was 1,146.1 m. The end-of-season target elevation (between 1,140 and 1,141 m) and the maximum recommended elevation (1,144.3 m) (DES, 2012) have been exceeded. Dewatering activities are planned to begin at Faro Pit as early as possible in 2014, at a high enough rate to control and reduce the Faro Pit water level and the potential for seepage increases towards Zone II Pit or towards the ETA.

3.1.1.14 Culvert Crossings

Specific hydrology information related to culvert flows and water elevations is limited to monitored locations. This data is discussed in the *Hydrology Baseline Report, Faro Mine Interim Works* (CH2M HILL, 2013a).

3.1.2 Vangorda/Grum Hydraulic Components

The Vangorda/Grum Area consists of a number of significant hydraulic components, including the Vangorda Pit and the Grum Pit. There are also a number of natural creek sections and surface water diversions and impoundments that direct flow eventually to the lower sections of Vangorda Creek and on to the Pelly River. The Vangorda WTP is also in this section of the mine area.

Figure 6B-4 shows the Vangorda/Grum Area hydraulic components.

3.1.2.1 Vangorda Creek Diversion

The Vangorda Pit was constructed in the early 1990s. This required diverting Vangorda Creek around the pit to limit the amount of runoff that entered the pit. The approximately 1,200-m-long VCD was constructed in 1991 around the northern perimeter of the pit (SRK, 2010a). The VCD was realigned between 1991 and 1992 because of the changing footprint of the Vangorda Pit. Since that time, the VCD has been maintained to convey flows but its alignment has not changed (SRK, 2010b). The existing VCD, was designed with a capacity to convey the 100-year return period flow of approximately 10 m^3/sec.

The VCD currently consists of the following components (SRK, 2010a):

- Headworks comprising an 8-m-high earth dam and a 1.5-m-diameter culvert within the dam that directs the water into an 800-m-long, 2,400- mm-diameter, half-round corrugated steel pipe (CSP) culvert section
- A plunge pool or stilling basin located at the end of the culvert sections
- A 3,000-mm-diameter drop-box structure, a 2,000-mm CSP culvert, and a 600-mm outfall culvert conveying the discharge from the plunge pool beneath the Haul Road back into Vangorda Creek
- Two 1,000-mm-diameter culverts at the headworks to provide an emergency spillway (installed 2005) to the Vangorda Pit for events that exceed the 1-in-100-year event

3.1.2.2 Old Vangorda Creek Channel

Natural runoff water collects in the old Vangorda Creek channel downstream of the headworks and northeast of the Vangorda Pit. There is a small catchment area referred to as the Vangorda Watering Hole that is adjacent to the VCD flume. This surface water naturally flows into the Vangorda Pit. Since 2002, this water has been pumped from a natural depression in the old Vangorda Creek channel into the VCD flume during the summer season (Figure 6B-4).

3.1.2.3 Vangorda Northeast Interceptor Ditch

The Vangorda Northeast Interceptor Ditch passes uncontaminated surface runoff water that would originally have flowed directly to Vangorda Creek, around the east and south sides of the Vangorda pit and rock dump area. This diverted water then enters Dixon Creek (DES, 2011).

3.1.2.4 Dixon Creek

Dixon Creek captures unimpacted runoff from the catchment northeast of the Vangorda/Grum Area (DES, 2011).

3.1.2.5 Vangorda Northwest Interceptor Ditch

The Vangorda Northwest Interceptor Ditch is an open ditch excavated into the native soils and surficial bedrock upslope of the VCD flume at the top of the northwest wall of the Vangorda Pit. This ditch passes uncontaminated surface water around the northwest area of the pit to Vangorda Creek, via the VCD plunge pool.

3.1.2.6 Grum Interceptor Ditch

The GID diverts water around the Grum Pit and Grum Overburden Dump. It consists of three reaches: (1) a 900-m-long ditch upslope of the Grum Pit to divert clean water away from the pit, (2) a 900-m-long ditch along the northeast toe of the Grum Overburden Dump, and (3) a 650-m long-ditch to convey flow downhill to Vangorda Creek (Klohn Crippen Berger, 2012).

3.1.2.7 Vangorda WRD Seepage Collection Ditch

Runoff and seepage water from the Vangorda WRD is contaminated with metals, and requires treatment before it can be released to Vangorda Creek. An open ditch around the toe of the WRD intercepts runoff and seepage that would otherwise enter Vangorda Creek directly. The ditch directs water into Little Creek Pond (LCP) for later treatment in the Grum/Vangorda Water Treatment Plant (GLL, 2007).

3.1.2.8 Vangorda/Grum Area Water Storage Facilities and Pit Water Management

A review of the water elevations for each onsite storage reservoir or pit (e.g., Vangorda Pit, Grum Pit, and LCP) in the Vangorda/Grum Mine Area was compiled in two technical memoranda and attached to *Hydrology Baseline Report, Faro Mine Interim Works* (CH2M HILL, 2013a) as Attachments 6F-4a and 6F-4b . The two technical memoranda summarize the analysis of water management strategies.

V15 Seepage Collection Ditch and Moose Pond

Seepage and runoff from the Grum Waste Dump surfaces at V15 and Grum Creek, downgradient from the waste dump on the southeastern side. A collection ditch, installed in 2007, conveys seepage from V15 into an existing ditch routing Grum Creek water to Moose Pond, away from lower Grum Creek. In 2011, in response to continued increasing contaminant levels at V15 and to manage peak spring runoff conditions, the V15 and Grum Creek

Pumping System was installed. The pumping system, located east of the Grum Waste Dump, consists of an insulated and heat-traced, 76-mm HDPE pipeline, a power supply, and pump. The system can redirect seepage from the Grum Waste Dump (V15, Grum Creek, or both) to the Vangorda Pit, year-round. When the system is not operated, discharge flows to Moose Pond. The target objective for the V15 and Grum Creek Pumping System is to limit water of deteriorated quality from seeping to the downstream receiving environment. Currently the system is operated during peak freshet and storm event flows only, with Moose Pond receiving normal flows. As part of the IW, operations may be expanded to year-round to ensure achievement of this target objective.

Little Creek Dam and Pond

The LCP collects runoff and seepage from the Vangorda WRD via a seepage collection ditch. The LCD was completed in 1992 to collect water pumped from the Vangorda Pit and from runoff and seepage at the Vangorda WRD. Water from the LCP was pumped directly to the Vangorda WTP. Once mine operations ceased, water management at the FMC changed. Currently, only runoff from the Vangorda WRD collects behind the LCD. During ice-free periods, this water is pumped to the Vangorda Pit. CH2M HILL (2012a) provides additional details about the system.

Grum/Vangorda Freshwater Supply Pond

When the Vangorda WTP operates, it draws a relatively small amount of freshwater from the Grum/Vangorda Freshwater Supply Pond, which stores some surface runoff that flows into the GID, just upgradient from the water treatment plant. Upon demand, water is pumped from the Freshwater Supply Pond to the WTP, to maintain an adequate supply of mix water in a storage tank located in the WTP (GLL, 2007).

Sheep Pad Ponds

The SPP collect localized runoff from the Grum Overburden Dump and water conveyed from the GID. The SPP are located south of the Grum Overburden Pile. They collect runoff from upslope areas, and discharge to the lower portion of the Vangorda Creek Diversion (KCB, 2012). CH2M HILL (2012a) provides additional details about the system.

Vangorda Watering Hole

The Vangorda Watering Hole is understood to be located in the original Vangorda Creek Channel, upstream from the VCD. Since 2002, a sump at this location has collected runoff from the local catchment and pumped it to the Vangorda Creek Diversion (DES, 2011). CH2M HILL (2012a) provides additional details about the system.

Grum Pit

The Grum Pit receives groundwater seepage, direct precipitation, runoff, and GID seepage. The Adaptive Management Plan (AMP) threshold level to trigger a response to rising water levels (1,210.8 m) was surpassed in October 2011. The trigger and maximum water elevation was set under AMP Event 6 (GLL, 2005) to manage water level increases in the Grum Pit, which was a requirement of the expired water licence (QZ03-059). 2013 was the first year water elevations in the Grum Pit were actively managed. The objective is to prevent water of deteriorated quality from reaching downstream receptors and to provide additional storage capacity to retain water received in the Grum Pit. In August 2013, water transfer from Grum Pit to Vangorda Pit began (TEES, 2013b). SRK (2009) indicated the overflow elevation to be 1,232.3 m, which is the lowest elevation of the Pit walls in the Grum Slot, located at the southern end of Grum Pit. The maximum recommended elevation, 1,213.4 m, allows storage capacity for a 1-week PMF before the water reaches the contact elevation of the overburden and bedrock (at 1,216 m) near the Grum Slot (DES, 2011a). The permeability of the overburden above the bedrock contact was estimated to be about $5x10^{-4}$ metres per second (SRK, 2009). The 2011 Annual Review, AMP Report (DES, 2012) suggests a revised maximum pit water elevation between 1,214.3 and 1,216.1 m, considering potential hydraulic containment south of the pit (CH2M HILL, 2012a provides additional discussion). This suggested elevation range is based on the storage capacity between this range of elevations and the elevation of the potential hydraulic containment, as well as the estimated volume of water that could drain to the Grum Pit during an extreme precipitation event or breach of the Grum Northeast Interceptor Ditch.

3.1.2.9 Culvert Crossings

Specific hydrology information related to culvert flows and water elevations is limited to monitored locations. This data is discussed in the *Hydrology Baseline Report, Faro Mine Interim Works* (CH2M HILL, 2013a).

3.2 Hydraulic Component Baseline Condition

The following sections summarize the hydraulic performance for each of the main hydraulic components within each of the Faro and Vangorda/Grum Areas identified in Section 2, which could impact FMC facilities.

3.2.1 Faro Hydraulic Components

3.2.1.1 West Valley Interceptor Ditch

Maintenance work took place on the WVID from 2002 through 2005. This work substantially restored its effectiveness in passing uncontaminated runoff water to the FCD. The work consisted primarily of bottom-grading and excavating slumped and eroded sections of the WVID (GLL, 2007).

Ongoing site surveillance has indicated the WVID continues to function and, that based on observed performance, it provides adequate capacity. It does not present a substantial hydraulic risk because it conveys limited flows on an intermittent basis, and failures would result in flow being directed to the Faro Pit for containment until implementation of remedial steps.

3.2.1.2 Faro Creek Diversion

In 2002 and 2003, maintenance work took place on sections of the FCD. This work substantially reduced leakage from the FCD to the Faro Pit (GLL, 2007). The work consisted mainly of bottom-grading, excavating a pilot channel for low winter flows, placing a geomembrane liner, and installing riprap erosion protection in select locations. Since 2003, ongoing maintenance has included maintaining roadside ditches, grading a new road surface with an alignment that is further away from weaker areas of the pit wall, repairing/replacing rock covering channel liners, maintaining the Bentomat and Bitumen liners, and removing flow obstructions.

Between January and March 2010, water was observed flowing on top of the ice, along the upper stretch of the FCD (DES, 2011). During the winter, ice is now removed regularly to keep the diversion clear.

The FCD was reported to have performed well throughout 2009 (DES, 2010). It is anticipated that ongoing maintenance will support the function of the FCD for the duration of the IW schedule. FCD failures would result in flow being directed to the Faro Pit for containment until implementation of remedial steps.

3.2.1.3 North Fork Rose Creek

The NFRC is primarily a natural stream system; as such, it is not necessary to manage the creek function through site maintenance. Flow monitors on the NFRC provide subwatershed data that is relevant to understanding the hydraulic function of downstream built stream components, such as the NFRD.

3.2.1.4 North Fork Rock Drain

Appendixes 6C and 5I detail hydrotechnical work related to determining the conveyance capacity and stability of the NFRD. Based on review of the design and construction records of the NFRD and the embankment haul road and given the objective of the interim improvements to prevent overtopping and breach of the ID during the 500-year flood, the Main Haul Road Embankment and NFRD cannot be relied upon to serve as a reliable attenuation barrier and provide protection to the ID and beyond.

A discussion of the NFRD stability is provided in *Down Valley Interim Hydraulic Upgrades Design, Faro Mine Interim Works* (CH2M HILL, 2014b).

3.2.1.5 Rose Creek Diversion

The channel and side slopes of the RCD appear to be stable, with satisfactory rock armour conditions (Klohn Crippen Berger, 2012). Based on observations and regular inspections, maintenance should include clearing ice from the channel (GLL, 2007). It should also consist of repairing the backslope and dike crest and removing woody vegetation from along the banks and from the fuse plug (DES, 2009). *Stability of Major Existing Facilities, Faro*

Mine Interim Works (CH2M HILL, 2013b) and *Down Valley Interim Hydraulic Upgrades Design, Faro Mine Interim Works* (CH2M HILL, 2014b) describe assessments of the RCD's stability and hydraulic functions.

The existing RCD has a design capacity of 140 m^3/sec, without freeboard, which is slightly more than the 1-in-500-year flood event (NHC, 2006). The flow capacity has been reduced by settlement of the dike and growth of vegetation on the side slope of the channel. If storm events result in flows that exceed RCD capacity, the excess water will overtop the RCD dike at the overflow weir/fuse plug. Flow will then discharge into the Intermediate Tailings Area, and flow out through the ID spillway into the CVD Pond.

3.2.1.6 Tailings Facility

Stability of Major Existing Facilities, Faro Mine Interim Works (CH2M HILL, 2013b) and *Down Valley Interim Hydraulic Upgrades Design, Faro Mine Interim Works* (CH2M HILL, 2014b) discuss assessments of stability and hydraulic functioning of the SD, ID, and CVD.

3.2.1.7 North Wall Interceptor Ditch

Klohn Crippen Berger (2012) noted that the North Wall Interceptor Ditch and side slopes appeared to be stable, with sediment deposits upgradient and downgradient from the well-access-road crossing. It also noted moderate to heavy vegetation growth in upper and middle constructed channel reaches (Klohn Crippen Berger, 2012).

GLL (2007) noted the North Wall Interceptor Ditch performed reasonably well through 2005, although erosion and sedimentation caused partial blocking at times. The twin culverts located in the outfall section at Station X5 have also experienced icing problems during the winter months, because of the low flow of water (DES, 2010). Culvert blockages in the North Wall Interceptor Ditch area have been an ongoing issue throughout the FMC's history, and must be cleared periodically (BGC, 2010).

Regular maintenance of the North Wall Interceptor Ditch includes removing ice from the ditch and culverts, as well as clearing deposition and debris to maintain channel and culvert capacity.

3.2.1.8 K-8 Rock Drain

A 2009 geotechnical inspection (BCG, 2010) noted the following observations:

- The upstream face appeared to be in good condition, with no cracking or sloughing.
- Some woody debris and silty material is collected at the base of the upstream face.
- The downstream face appeared to be in good condition.
- The head pond level was normaly during the inspection and the drain appeared to be passing the flows in a satisfactory manner. The upstream pond contained circular "holes" in the surface of the accumulated sediment. Rock was exposed at the base of the holes and flow into the rock drain was concentrated at these locations. It was speculated that sediment accumulated on the upstream surface, raising the water surface, until enough pressure built up to cause a piping event, which washed the sediment through the rock fill structure. Further monitoring was recommended to confirm this assessment.

A subsequent 2011 geotechnical inspection indicated the crest and side slopes of the mine Haul Road at the K-8 Rock Drain appeared to be stable and that the downstream drainage condition was acceptable (Klohn Crippen Berger, 2012).

3.2.1.9 General Faro Mine Complex Care and Maintenance

Annual environmental monitoring programs and related reports provide valuable information about the operation and maintenance activities for hydraulic infrastructure at the FMC. Regular maintenance activities at the FMC take place, in part, to maintain the hydraulic capacity of surface water conveyance components within the drainage system. Hydraulic maintenance includes the following regular activities:

- During winter, steaming road culverts and charging of thaw pipes with glycol for de-icing if required
- Monitoring creeks and diversions on a daily basis for ice build-up during cold periods
- Completing minor repairs and clearing debris and ice from ditches

- Completing road and culvert maintenance as needed, including seasonal snow removal

3.2.2 Vangorda/Grum Area Hydraulic Components

3.2.2.1 Vangorda Creek Diversion

Since the VCD was constructed, it has generally been successful in conveying Vangorda Creek flows around the Vangorda Pit during normal runoff events (SRK, 2010a). The VCD has, however, experienced two flood events within the last 10 years that have caused the water levels in the VCD to exceed the level of its half-round CSP culvert component (CH2M HILL, 2013a). Both events resulted in damage to the VCD. Damage caused by the June 2004 event required extensive channel repairs and the installation of an overflow spillway in the VCD headworks structure to redirect excess flow into Vangorda Pit. The VCD has also experienced slope failures and ice buildup impacts that have compromised the diversion and resulted in significant maintenance requirements. Icing conditions and uplift of the CSP flume in VCD sections with low gradients have resulted in chronic maintenance issues (SRK, 2010a).

Since mining operations ceased in 1998, the VCD has been maintained to limit the flow of runoff to the Vangorda Pit until a long-term management plan for the diversion is developed. The following points summarize current conditions and maintenance issues, which support the need for a long term management plan:

- Existing flume structures require ongoing maintenance and repair to limit plugging of the diversion and erosion of roadway, which would result in discharge to Vangorda Pit.
- Drop structure at the roadway requires ongoing maintenance to limit the risk of plugging and overtopping.
- The VCD does not have capacity to convey peak flows in excess of 10 m^3/sec, which is the 100-year design peak flow event.
- Bank slopes associated with the half-round CSP culvert component of the VCD are at risk of instability and slumping.
- Ice damage impacts the instability of the diversion structures.
- Potential pit wall instability threatens the VCD.
- A stable diversion is a requisite to sustainably support the downstream aquatic habitat provided by the Vangorda flows.

In general, maintaining the function of the existing VCD includes the following tasks:

- Excavating ice from the VCD and defrosting it throughout winter months to prevent overflow
- Excavating ice from the drop box to maintain adequate flow
- Removing debris at the trash racks (at the entrance to the drop box inflow culvert) and at the flume headworks to maintain capacity
- Annually repairing ice-damaged flume sections after freshet, including cross-braces and holes in the CSP
- Repairing VCD slopes to prevent slope instability
- Periodically removing debris from the flume

3.2.2.2 Vangorda Northeast Interceptor Ditch

SRK inspected the Vangorda Northeast Interceptor Ditch uphill of the Vangorda Pit in 2011 and noted it generally performed well (SRK, 2011b). However, the inspection also noted a number of areas along the ditch (primarily in the overburden till) where there have been a number of subsidences that, over time, may restrict the flow in the ditch (SRK, 2011b).

Flow in the Vangorda Northeast Interceptor Ditch is noted to have been intermittent, historically (GLL, 2007). Maintenance takes place as necessary, to remove debris that would compromise the conveyance capacity required for the intermittent flow during significant runoff periods. Maintenance work was performed on the

ditch from 2002 to 2004 (GLL, 2007). In 2010, maintenance work took place to remove slumped gravel (DES, 2010).

3.2.2.3 Vangorda Northwest Interceptor Ditch

Maintenance work takes place, as required, to remove debris and maintain the necessary conveyance capacity.

3.2.2.4 Grum Interceptor Ditch

The 2011 annual geotechnical inspection stated the channel and sideslopes of the GID were stable with light vegetation growth along some portions (Klohn Crippen Berger, 2012). Maintaining the GID includes periodically placing new material to re-armour sections (GLL, 2007).

3.2.2.5 Vangorda Waste Rock Dump Seepage Collection Ditch

The Vangorda WRD Seepage Collection Ditch is an open ditch around the toe of the WRD, which intercepts local runoff and seepage that would otherwise enter Vangorda Creek directly. The ditch directs this surface water to the LCP, where it becomes part of the treatment system (GLL, 2007).

Observations of ditch performance note that ice removal, sediment removal, and bank-grading are necessary to maintain the required capacity. The ditch was also further excavated along the west side of the WRD to provide a more positive gradient to LCP and to improve flow (DES, 2010).

3.2.2.6 V-15 Seepage Collection Ditch and Moose Pond

In 2006, increasing concentrations of zinc were observed at the V-15 seep. Historically, a collection ditch conveyed local runoff and V-15 water to the confluence with Grum Creek and, from there, to Moose Pond. Moose Pond is a natural depression formed in porous sands and gravels that was used by the mine operators as a collection pond for seep water originating from the Grum WRD. Water exfiltrated from the base of the pond, where subsurface attenuation of zinc occurred, before the water re-emerged as a compliant seep near Vangorda Creek. The embankment that separates Moose Pond from Vangorda Creek has been experiencing progressive slumping on its downstream face for several years. In 2011, an excessive meltwater event during freshet caused abundant sedimentation in the pond. These combined events have compromised the stability of Moose Pond to the point that a surface water collection system is now in use to prevent high flow events from entering the pond. The collection system was originally intended to transfer small volumes of seep water to Vangorda Pit; however, it has been necessary to upgrade the collection system so that it can also contain and transfer larger volumes of meltwater that are generated in the vicinity of the Grum WRD during freshet.

3.2.2.7 Little Creek Dam and Pond

A 2011 geotechnical inspection of the LCD revealed that the water level in the pond on May 24, 2011, had been recorded at about 1,109 m (SRK, 2011). This is the normal water level operating condition between about elevation 1,108 m and 1,110 m. No cracks or major settlement were observed and no seepage was observed along the downstream toe of the pond. The inspection revealed that although erosion rills were evident on both the upstream and downstream slopes of the LCD, its upstream and downstream faces did not show evidence of surficial movement, bulging, or instability. The 900-mm CSP emergency spillway and the associated plunge pool were inspected and were found to be in good condition.

Another 2011 geotechnical inspection noted the LCD crest was stable, and slopes with rill erosions had developed on both the downstream and upstream crest shoulders and slopes (Klohn Crippen Berger, 2012). This report also noted that the culvert spillway was in good condition.

As *Stability of Major Existing Facilities, Faro Mine Interim Works* (CH2M HILL, 2013b) discusses, the LCD is inspected daily during the summer months and the pond level is not operated at full supply level. The minimum freeboard (except for short-duration exceedances) is 4.5 m on the 10-m-high dam. Based on observations from periodic dam safety reviews and the annual dam safety inspections, the dam is considered to be stable (Klohn Crippen Berger, 2008, 2012).

3.2.2.8 Sheep Pad Ponds

A 2010 geotechnical inspection indicated the SPP dike had no sign of slope instability, settlement, or cracking (SRK, 2011a). Similarly, a 2011 inspection indicated that the retaining dike embankment was stable (Klohn Crippen Berger, 2012). General maintenance on the upstream section of the spillway channel includes riprap cover replacement over underlying geotextile.

3.2.2.9 General Vangorda/Grum Area Care and Maintenance

Annual environmental monitoring programs and related reports provide valuable information about the operation and maintenance of hydraulic infrastructure at the FMC. Regular maintenance activities at the FMC take place, in part, to maintain hydraulic capacity of surface water conveyance components within the drainage system. This maintenance includes the following regular activities:

- Steaming road culverts and charging thaw pipes with glycol for de-icing if required
- Monitoring creeks and diversions on a daily basis for ice build-up during cold periods
- Completing minor repairs and clearing debris and ice from ditches
- Completing road and culvert maintenance as needed, including seasonal snow removal
