APPENDIX A.1A: Concordance Table to the Executive Committee's Request for Supplementary Information

CASINO MINING CORPORATION
CASINO PROJECT

CONCORDANCE TABLE TO THE EXECUTIVE COMMITTEE'S REQUEST FOR SUPPLEMENTARY INFORMATION

On January 27, 2015, the Executive Committee requested that Casino Mining Corporation (CMC) provide supplementary information for the Casino Project (YESAB Project No. 2014-0002) to enable the Executive Committee to commence Screening. The Executive Committee considered received comments from various First Nations, Decision Bodies and regulators on the adequacy of the Project Proposal in the preparation of the Adequacy Review Report (ARR). Casino Mining Corporation is providing this Supplementary Information Report (SIR) to comply with the Executive Committee's Adequacy Review Report; CMC anticipates that the information in the SIR and Proposal, when considered together, is adequate to commence Screening.

The Executive Committee has 449 requests for supplementary information related to the Project Proposal submitted on January 3, 2014. Request # refers to the assigned identification number in the ARR. These requests are listed in the concordance table with the corresponding location of the supplementary information withing the SIR. Some responses require detailed technical information, data, and figures. Where necessary, this additional supporting information is provided as appendices to the SIR.

Request #	Request for Supplementary Information	Response
R1	All information and rationale used for the selection of the proposed tailings management facility over alternative disposal methods.	Section A.4.2.1.1 Appendix A.4A Tailings Management Facility Construction Material Alternatives
R2	Alternative dam construction methods to using cyclone sand.	Section A.4.2.1.2 Appendix A.4A Tailings Management Facility Construction Material Alternatives
R3	All information and rationale used to justify the proposed road alignment over alternative alignments.	Section A.4.2.2.1 Appendix A.4B Information on Alternative Access Road Alignments
R4	Identify whether broad-based stakeholder risk assessment processes, such as failure modes and effects analysis, will be completed and/or whether external expert review panels will be used as internal quality controls to guide the project.	Section A.4.3.1
R5	Identify if and how independent regulatory audits will be conducted.	Section A.4.3.2
R6	Describe how best practices, in relation to oversight, will be applied to the Project given the scale and nature of challenges associated with the proposed activities and site.	Section A.4.3.3
R7	A description of all other staging and preparation activities. For example, equipment, fuel, and material staging for the upgrade to the Freegold Road and construction of the Freegold Road Extension.	Section A.4.4.1

Request #	Request for Supplementary Information	Response
R8	Describe the interdependency of and critical path for staging and construction activities.	Section A.4.4.2
R9	Details regarding planned barging activity, including frequency, temporal periods, and types of freight anticipated by barge. Additionally, please describe any ancillary activities associated with barging, such as landing sites and access road.	Section A.4.4.3
R10	The reports that show results of metallurgical testing and sulphur removal performance from 2009 and 2010 bench tests, as well as the 2012 pilot test by G&T.	Section A.4.5.1 Appendix A4.N Scoping Level Assessment of Casino Property Appendix A4.O Advanced Metallurgical Assessment of the Casino Copper Gold Project Appendix A.4P Production of Environmental Tailings Samples for the Casino Deposit
R11	Additional information to support the feasibility of the sulphide removal process. Details should include: a. detailed description of the sulphide removal process; b. how the process will account for variations in the mineral composition of processed ore and the large tonnage of tailings; and c. QA/QC for tailings classification including a detailed schedule for testing.	Section A.4.5.2 Appendix A4.O Advanced Metallurgical Assessment of the Casino Copper Gold Project
R12	Additional information on the NAG tailings, or cyclone sand, produced through the sulphide removal process. Details should include: a. data to show that the sulphide removal will be effective for all ore types; b. sulphide levels required to produce non-acid generating cyclone sand and tailings; c. residual sulphide concentrations; d. how the sulphide removal process will be managed and how the cyclone sand will be monitored and tested during operation to ensure that the required performance limits are consistently achieved; and e. any remedial measures that may be required should the sulphide removal process be shown to be ineffective.	Section A.4.5.3 Appendix A4.N Scoping Level Assessment of Casino Property Appendix A4.O Advanced Metallurgical Assessment of the Casino Copper Gold Project Appendix A.4P Production of Environmental Tailings Samples for the Casino Deposit Appendix A.22H ML/ARD Management Plan

Request #	Request for Supplementary Information	Response
R13	Detailed description of the temporary construction camp including: a. layout of infrastructure such as camp facilities, generators, sewage disposal system, fuel storage, and generators; b. proximity to surface water; c. human-wildlife conflict prevention; and d. fuel storage requirements and capacity of diesel generators.	Section A.4.6.1.1 Appendix A.22A Waste and Hazardous Materials Management Plan Appendix A.12A Wildlife Mitigation and Monitoring Plan
R14	Detailed description of activities required for construction of camp including: a. site preparation such as clearing, grubbing, and disposal of materials; b. construction material volumes and sources (e.g. granular material requirements); and c. anticipated timing and duration of the proposed activities.	Section A.4.6.1.2
R15	Details and information regarding the authorization requirements of the proposed alignment through Settlement Lands.	Section A.4.6.1.3
R16	Discussion of potential impacts to values associated with Settlement Lands and mitigations proposed to address these effects.	Section A.4.6.1.4
R17	Describe progress on the Road Use Agreement and relevant details that informed the Road Management Plan.	Section A.4.6.1.5
R18	A detailed Road Management Plan for the entire Freegold Road. Specific details for the Freegold Road extension should include: a. description of what other users will have access to the Freegold Road extension; and b. description of the legal instruments and measures that will be implemented to control access to the Freegold Road extension.	Section A.4.6.1.6 Appendix A.22E Road Use Plan
R19	Please confirm that the Road Use Plan, the Extension Access Management Plan, and the Traffic Management Plan refer to the same management plan.	Section A.4.6.1.7 Appendix A.22E Road Use Plan
R20	Reconcile the intention to decommission the access road with the need to maintain access in order to monitor and maintain permanent infrastructure. Details should include a detailed discussion of access requirements for on-going monitoring and maintenance of site infrastructure and how these activities will be undertaken if the road is decommissioned.	Section A.4.6.1.8
R21	A breakdown of Project related traffic volumes, by vehicle type, for the Alaska, North Klondike, and South Klondike highways. Provide a comparison against current traffic levels and capacities including seasonal fluctuations.	Section A.4.6.2.1
R22	Implications of projected traffic due to this Project on the Alaska, North Klondike, and South Klondike highways.	Section A.4.6.2.2

Request #	Request for Supplementary Information	Response
R23	Details on fleet management to ensure rapid response to possible accidents or spills.	Section A.4.6.2.3 Appendix A.22B Spill Contingency Management Plan Appendix A.22A Waste and Hazardous Materials Management Plan
R24	Describe if weight restrictions are predicted to interfere with Project logistics including the anticipated frequency for which a special variance permit may be requested.	Section A.4.6.2.4
R25	Describe maximum predicted haulage weights, including maximum anticipated weights for the importation of equipment and infrastructure.	Section A.4.6.2.5
R26	Traffic projections for mine related traffic within Carmacks, detailed by vehicle class and type, prior to the Carmacks by-pass becoming operational.	Section A.4.6.3.1
R27	A traffic management plan for routing traffic through Carmacks prior to the completion of the Carmacks by-pass. Details should include: a. route through Carmacks; b. timing of transportation activities (e.g. daily, weekly and monthly restrictions); c. safety of residents with particular focus given to routes with no pedestrian sidewalks; d. communication with residents within community; and e. congestion aversion.	Section A.4.6.3.2 Appendix A.22E Road Use Plan
R28	Describe the sourcing of primary mine materials, delineating supplies arriving from Skagway from those from British Columbia and elsewhere. Please distinguish between materials such as primary flotation supplies, heap leach supplies, lubricants, fuels, and cyanide.	Section A.4.6.4.1
R29	Confirm that the export plan is, or will be, logistically possible.	Section A.4.6.4.2 Appendix A.4B Information on Alternative Access Road Alignments

Request #	Request for Supplementary Information	Response
R30	Describe, as best as possible (if data are unavailable, please indicate anticipated rates of use), the frequency, weight, size, truck type, and carrying capacity of trucks carrying: a. pebble lime; b. sodium disobutyl dithiophashinate; c. sodium diethyl dithiphoshinate; d. methyl isobutyl caribinol; e. potassium xanthate; f. sodium hydro-sulphide; g. sodium cyanide; h. sodium hydroxide; i. hydrochloric acid; j. sulphuric acid; k. ammonium nitrate; l. diesel; m. lubricants; n. liquefied natural gas; o. ore concentrates; and p. other hazardous materials.	Section A.4.6.5.1
R31	Additional detail in the Water Management Plan that includes all Project components and phases. Details should include: a. appropriate figures and plans illustrating site water management, including flow sheet information such as monthly water volumes; and b. figures, plans, and sections for key collection and conveyance facilities associated with the Project.	Section A.4.7.1
R32	A description of the methodology used to determine flows for storm events including supporting information such as catchment areas, time of concentrations, inclusion of rain and snow melt events, design events, and results.	Section A.4.7.2.1 Appendix A.7A Variability Water Balance Model Report
R33	Detail and describe the methodology and references used to determine the probable maximum precipitation in relation to conveyance channel design and events pond standards.	Section A.4.7.2.2
R34	Typical cross-sections and design drawings of alignments for diversion ditching across the project site with particular focus around the HLF including: a. confining embankment; b. access road section; and c. event ponds area.	Section A.4.7.2.3 Appendix A.4C Feasibility Design of the Heap Leach Facility
R35	A discussion of measures to be taken should one or more sections of the proposed heap leach facility (HLF) diversion ditches be found to be ineffective or should excessive erosion become an issue.	Section A.4.7.2.4

Request #	Request for Supplementary Information	Response
R36	A discussion of alternatives that CMC considered, including justification and rationale for the use of the proposed ditches.	Section A.4.7.2.5 Appendix A.4C Feasibility Design of the Heap Leach Facility
R37	A description of the diversion ditch on the southwest side of the HLF, including a drawing indicating its proximity to the edge of Byrnelson Creek north tributary sub-watershed. Include a discussion of potential effects to and relevant mitigations for this watershed.	Section A.4.7.2.6
R38	Additional information regarding design of channels in the area that will be susceptible to erosion.	Section A.4.7.2.7
R39	Rationale for directing various non-contact water sources into the TMF. Include a discussion of how non-contact water will be managed throughout the life of the Project.	Section A.4.7.2.8
R40	Further rationale for sizing of the water management pond and sedimentation ponds in terms of sediment removal and confirm if the proposed sizes will meet objectives.	Section A.4.7.3.1 Appendix A.4D Report on the Feasibility Design of the TMF
R41	Clarify whether the size of the event pond is for managing return period rainfall events or return period snow melt-rain events.	Section A.4.7.3.2
R42	Details and rationale on the selection of return period design criteria for all the WMP components during all phases of the Project, including long-term closure. Details should include calculation of the failure probabilities.	Section A.4.7.4.1 Appendix A.4C Feasibility Design of the Heap Leach Facility Appendix A.4D Report on the Feasibility Design of the TMF
R43	Detailed information on the sources and quantities of suitable borrow materials.	Section A.4.8.1.1 Appendix A.4C Feasibility Design of the Heap Leach Facility
R44	Clarify whether HLF excavations will be to competent bedrock or weathered bedrock. Provide justification and the criteria used to determine the suitability of the foundation for the HLF.	Section A.4.8.1.2 Appendix A.4C Feasibility Design of the Heap Leach Facility
R45	Details on foundation preparation including drainage management and accommodation of the proposed liner.	Section A.4.8.1.3 Appendix A.4C Feasibility Design of the Heap Leach Facility
R46	Rationale for the sufficiency of a 30 cm thick soil liner.	Section A.4.8.2.1
R47	A description of the composition and potential effects of the overliner on the performance of the liner considering permeability and hydraulic head.	Section A.4.8.2.2

Request #	Request for Supplementary Information	Response
R48	Details on the mitigation and management of leaks from the HLF including during all stages of operations.	Section A.4.8.3.1 Appendix A.4C Feasibility Design of the Heap Leach Facility
R49	Details on the maintenance and repair of the LDRS sump and pumps.	Section A.4.8.3.2
R50	Details on the pipelines, pumps, and related infrastructure connecting the components of the HLF including SART, cyanide, and gold extraction facilities. Include details on pipeline alignments and leak detection measures.	Section A.4.8.4.1 Appendix A.4C Feasibility Design of the Heap Leach Facility
R51	Volumes and sources of water stored in the embankment and the events pond during a 1 in 100 year 24-hour storm event.	Section A.4.8.4.2
R52	Sensitivity analyses for makeup water requirements and water retention requirements for different moisture content values for stacked ore and wetter or dryer climatic conditions. Include a discussion on any implications in relation to HLF and events pond storage capacity.	Section A.4.8.4.3 Appendix A7.A Variability Water Balance Model Report Appendix A7.C Potential Effects of Climate Change on the Variability Water Balance
R53	A description of the HLF solution balance including in wet and dry conditions.	Section A.4.8.4.4 Appendix A7.A Variability Water Balance Model Report Appendix A7.C Potential Effects of Climate Change on the Variability Water Balance
R54	Rationale for the selection of design criteria for HLF events pond and events pond spillway sizing. Include a discussion on potential consequences resulting from larger hydrological events.	Section A.4.8.4.5
R55	Discussion on the potential for the buckling and decreasing efficiency of collection wells for leachate recovery.	Section A.4.8.5.1
R56	Estimates for the approximate tonnage in each ore lift within the HLF.	Section A.4.8.6.1
R57	Clarification on the leach cycle activities and durations.	Section A.4.8.6.2 Appendix A4.C Feasibility Design of the Heap Leach Facility

Request #	Request for Supplementary Information	Response
R58	Identify additional metallurgical test work that has been undertaken or is planned prior to/during construction and operation to improve leach cycle time estimates.	Section A.4.8.6.3 Appendix A.4E Results of Additional Lab Testing of Leach Ore
R59	A discussion on the implications of the following scenarios and provide consideration of options that the mine could implement should the following unforeseen conditions occur during construction and operations: a. leach times that are significantly increased for short or extended times. As an example, if the leach cycle is unexpectedly increased from 60 days to 100 days for an extended time; b. shortages in stockpile capacity for excess oxide ore should the expected HLF stacking rate need to be reduced; c. possible extension of the HLF operation beyond Year 15 due to longer than anticipated leach cycles; and d. requirements for additional gold ore stockpile capacity and/or provisional spare leach pad later during operations since the surface area of the lifts will be reduced as the heap extends upslope.	Section A.4.8.6.4 Appendix A.4F Waste Storage Area and Stockpiles Feasibility Design
R60	Additional details regarding the HLF confining embankment giving consideration to the varying functions of the structure (i.e. HLF stability, leach solution storage, road traffic, and housing services). Details should include: a. construction methods and design of the section of the access road situated between the confining embankment toe and the events pond; b. measures incorporated into its design to protect any buried services and the confining embankment drainage blanket; and c. clarification regarding whether or not the confining embankment drainage blanket will extend under the road and daylight in the tailings management facility area.	Section A.4.8.7.1
R61	A detailed schedule for the works required to construct the HLF and commence leaching operations. Consideration should be given to key QA/QC requirements and contingency planning for scheduling delays.	Section A.4.8.8.1
R62	Implications of scheduling delays or suspension of HLF construction.	Section A.4.8.8.2
R63	Details on the specialized personnel required to construct, operate, maintain, monitor and oversee the HLF.	Section A.4.8.8.3
R64	The missing Section 4.4.4 of the project proposal.	Section A.4.8.8.4
R65	Additional justification and rationale for the “high” hazard classification for the tailings management facility. In addition, provide details on construction and design implications of using an “extreme” hazard classification.	Section A.4.9.1.1
R66	If available, comparisons with other similar sand embankments or compacted sand dams, and/or natural analogs within similar environments. The discussion should include details on permeability, stress, strength, and performance of these structures.	Section A.4.9.1.2 Appendix A.4D Report on the Feasibility Design of the TMF

Request #	Request for Supplementary Information	Response
R67	Detailed rationale for the selection of the factor of safety during dam construction.	Section A.4.9.1.3
R68	Evidence demonstrating that the stability of the proposed TMF dam can be achieved through a post-closure period lasting thousands of years. Include a discussion on technically feasible options for managing the risk to downstream areas in perpetuity.	Section A.4.9.1.4
R69	An explanation on the likelihood and implications of saturation of the TMF dam's foundation, drains, and lower portions.	Section A.4.9.2.1
R70	Justification and rationale for using a factor of 1.5 for ground motion amplification for potential slip surfaces in the embankment foundation.	Section A.4.9.2.2
R71	Clarification if V_{s30} is site specific and how it was derived.	Section A.4.9.2.3
R72	Mean peak ground acceleration values derived from EZ-FRISK.	Section A.4.9.2.4
R73	Explanation of the difference between Natural Resources Canada spectral periods and the spectral periods presented in the report on the feasibility of the TMF.	Section A.4.9.2.5
R74	Explanation on monitoring and remediation activities that may be required during closure including the extent of remediation required in event of an MDE.	Section A.4.9.2.6
R75	Reassess and model the IDF and PMP using modern storm expansion techniques. In addition, provide: a. a full description of the methodology used; and b. rationale for using a 100-year design snowpack.	Section A.4.9.3.1 Appendix A.4D Report on the Feasibility Design of the TMF Appendix A.4G Updated Hydrometeorology Report
R76	Rationale for not constructing an emergency spillway for the TMF during operations.	Section A.4.9.4.1 Appendix A.4D Report on the Feasibility Design of the TMF
R77	A discussion on potential consequences of HLF failure resulting in displacement of water in the TMF.	Section A.4.9.4.2 Appendix A.4C Feasibility Design of the Heap Leach Facility
R78	A discussion and details of the methodology used to determine closure spillway requirements and relevant data such as time distribution of rainfall and relevant hydrographs.	Section A.4.9.4.3
R79	Discussion of the potential for closure spillway blockages and expected extent of maintenance and monitoring the spillway.	Section A.4.9.4.4
R80	Identify mitigations, with appropriate thresholds for implementation, and monitoring activities for closure spillway related erosion, both in the spillway channel and downstream water bodies.	Section A.4.9.4.5

Request #	Request for Supplementary Information	Response
R81	A dam breach analysis with water/tailings inundation modeling consistent with the Canadian Dam Association's dam safety guidelines including: a. probable maximum flood inundation map showing the maximum extent of flooding relating to a sudden full storage embankment breach extending to when expected flooding is within the natural water channels; b. an assessment of environmental and human impacts associated with a release of tailings; c. an assessment of potential impacts to First Nation Settlement Lands; d. an assessment of impacts to downstream infrastructure; e. mitigation measures in the event of a tailings breach; and f. for each proposed breach scenario a cross section of the critical TMF embankment, proposed loading factors, and each scenario's factor of safety.	Section A.4.9.5.1
R82	Rationale for the proposed thickness of the core and downstream filter, considering the dam height and permanent performance requirements.	Section A.4.9.6.1 Appendix A.4D Report on the Feasibility Design of the TMF
R83	Rationale for the ceiling of 12 percent fines in cycloned sand to be used in embankment construction including a discussion of frost susceptibility and drainage characteristics.	Section A.4.9.7.1
R84	Provide testing or analyses to demonstrate that pore pressures, shear strength, angles of friction, and contraction of cyclone sand is acceptable at all pressures found in the TMF embankment.	Section A.4.9.7.2 Appendix A.4R Report on Laboratory Geotechnical Testing of Tailings Materials
R85	Clarification on the specific gravities of cyclone overflow and underflow.	Section A.4.9.7.3 Appendix A.4D Report on the Feasibility Design of the TMF
R86	Justify the upper range of 2.0 m for proposed lift heights of cyclone sand.	Section A.4.9.7.4
R87	Supporting evidence for the absence or presence of faults and fractures within the TMF and embankment areas including their activity.	Section A.4.9.8.1 Appendix A.4D Report on the Feasibility Design of the TMF

Request #	Request for Supplementary Information	Response
R88	Additional drill results, with detailed analysis and discussion, to provide an accurate characterization of the hydraulic conductivity and identification fault/shear zones within the embankment foundation.	Section A.4.9.9.1 Appendix A.4D Report on the Feasibility Design of the TMF Appendix A.4L Report on Revised Tailings Management Facility Seepage Assessment
R89	Details regarding the cut off trench and seepage control for the TMF embankment including: a. clarification on the depth of the cut-off trench and justification based on the depth of overburden and fractured bedrock; b. an updated cross section of the TMF embankment that includes the cut off trench and associated seepage barrier; c. a profile diagram of the cut off trench showing its depth across the dam core, along with available information on the depth of overburden and fractured bedrock; d. a discussion of measures to address fractured bedrock; and e. a discussion on the use of a grout curtain to control seepage	Section A.4.9.9.2 Appendix A.4D Report on the Feasibility Design of the TMF
R90	Further characterization of the dam foundation materials to confirm the presence and distribution of permafrost.	Section A.4.9.10.1
R91	Details regarding plans to ensure embankment foundations do not incorporate frozen and/or frost susceptible soils during construction.	Section A.4.9.10.2
R92	A detailed schedule for the works required to construct the TMF before and during operations. Consideration should be given to key QA/QC requirements and contingency planning for scheduling delays and freezing conditions.	Section A.4.9.11.1
R93	Implications of scheduling delays or suspension of dam construction during the nine month construction period.	Section A.4.9.11.2
R94	A review of relevant examples of sand embankment dams constructed in cold weather environments. This review should identify challenges, potential issues, and solutions surrounding sand placement and QA/QC.	Section A.4.9.11.3
R95	Methods of erosion control during dam construction.	Section A.4.9.11.4
R96	Description of ground surface conditions currently in relation to overburden and vegetation and any modification in preparation for the construction and filling of the TMF.	Section A.4.9.11.5 Appendix A.4D Report on the Feasibility Design of the TMF
R97	Discussion on any hydrological changes expected from changing ground thermal conditions and any monitoring to this effect.	Section A.4.9.11.6 Appendix A.4D Report on the Feasibility Design of the TMF
R98	Confirmation that natural or artificial liners are not included as part of the technical design of the TMF embankment.	Section A.4.9.11.7

Request #	Request for Supplementary Information	Response
R99	Confirmation of the availability of non-frost susceptible materials for the construction of the dam core. Include a discussion that demonstrates that the material with a 20 percent or more fines is not a frost susceptible material.	Section A.4.9.12.1 Appendix A.4D Report on the Feasibility Design of the TMF
R100	Please provide the Mine Site Borrow Materials Assessment Report (VA101-325/16-3). If not part of the assessment report, include detailed information about: a. the locations of borrow sources; b. description of dimensions of borrow source excavations including area and depth of excavations; c. the estimated quantities of suitable borrow material available; d. the quantity of borrow material required for engineered mine components; e. proposed mitigation measures to minimize potential adverse effects associated with the development and use of the proposed borrow sites; and f. alternatives in the event that dam core material cannot be sourced at the site in sufficient quantities.	Section A.4.9.12.2 Appendix A.4Q Mine Site Borrow Materials Assessment Report
R101	A discussion on the thawing and containment of borrow and embankment excavations.	Section A.4.9.12.3
R102	Clarification on the use of filter-graded zones between the waste rock shells (if selected) of the starter dam and the overlying tailings shells (e.g. to prevent possible future deformation of the tailings shells).	Section A.4.9.13.1
R103	The missing information referenced in footnote No. 6 on p. 4-54 of the proposal related to Table 4.3-7 (Inflow Design Flood and Earthquake Design Ground Motion).	Section A.4.9.14.1
R104	For the LNG storage facilities, regasification facilities, and mobile fueling stations, provide: a. a detailed description for all facilities related to LNG including location, design, construction, operation and closure; b. measures for the safety of Project personnel including separation distances from office and living areas; c. design measures and operating procedures to prevent a cascading accident; and d. a list of standards and codes that will apply to design and operation of the each component identified above.	Section A.4.10.1.1 Appendix A.22G LNG Management Plan
R105	Identification of potential hazards to LNG facilities at the Casino Mine site associated with seismic activity, extreme weather events, wildfire, unstable terrain, and degradation of discontinuous permafrost, and a quantitative assessment of the related risk to those facilities.	Section A.4.10.1.2 Appendix A.22G LNG Management Plan

Request #	Request for Supplementary Information	Response
R106	Identification of the potential supplier of LNG from British Columbia and the established supplier of LNG from Alaska. Indicate the nature of any supply agreements that are in place. Indicate the nature of any uncertainties about the LNG facility in British Columbia being operational by the time LNG is required at the Casino Mine site. Provide documentation to confirm that the facility in Alaska will be able to supply LNG in sufficient quantity to meet the needs of the Casino Mine, should LNG not be available from the proposed facility in British Columbia. Describe the Casino Mining Corporation's fallback plan in the event that LNG is unavailable from either identified source, or is not available in sufficient quantity. Indicate whether an alternative source of electrical power might be required in such a case. Assess the effect of the above scenarios on the project's economic feasibility.	Section A.4.10.1.3
R107	The earthquake design basis for the LNG storage tank at the mine site.	Section A.4.10.1.4 Appendix A.22G LNG Management Plan
R108	A description of diesel storage facilities along with anticipated rates of use and storage volumes for each stage of the Project.	Section A.4.10.2.1
R109	A table or tables that summarize the following information for each major mine component: a. where appropriate, dimensions, mass, volume, centroid and elevation; b. reclamation characteristics (slope aspects, cover type and depth, volume required, re-vegetation type); c. source controls (e.g. liners, compacted graded drained foundations, and covers over reclaimed features) and any features associated with fluid management and stabilization and/or water management and treatment; and d. geotechnical protocols and results (e.g. FOS).	Section A.4.11.1.1 Appendix A.4C Feasibility Design of the Heap Leach Facility Appendix A.4D Report on the Feasibility Design of the Tailings Management Facility Appendix A.4F Waste Storage Area and Stockpiles Feasibility Design
R110	Conservative considerations for the long-term operational and maintenance requirements for the site.	Section A.4.11.1.2
R111	Analysis of closure options including long-term and short-term costs, care and maintenance requirements, and long-term environmental risks. The options analysis should include: a. open pit; b. tailings management facility; c. heap leach facility; d. stockpile areas; and e. water management and treatment.	Section A.4.11.2.1 Appendix A.4H Cold Climate Passive Treatment Systems Literature Review
R112	Discuss and if necessary update the conceptual closure plan to take into account the most recent Government of Yukon Reclamation and Closure Planning for Quartz Mining Projects, Plan Requirements and Closure Costing Guidance (Government of Yukon, 2013).	Section A.4.11.2.2

Request #	Request for Supplementary Information	Response
R113	Clarify what is meant by regular or infrequent site presence or what degree of on-site presence is envisioned (e.g. yearly during summer, once every 10 years, or site presence in step with closure stage).	Section A.4.11.2.3
R114	Justification and clarification of the proposed five year post-closure monitoring period given that actual closure conditions will not be established for about 95 years (pit discharge) and other closure conditions are not fully known or presented here (e.g. time for contaminated groundwater sources to report to TMF/seepage).	Section A.4.11.2.4
R115	Examples of successful similar treatment systems with similar contaminant loads, flows and climate.	Section A.4.11.3.1 Appendix A.4H Cold Climate Passive Treatment Systems Literature Review
R116	Initiation of laboratory studies to confirm the effectiveness of the wetlands as a water treatment system for the purpose of closure and to inform future field studies. The Executive Committee expects that results from these studies will be provided throughout the assessment process.	Section A.4.11.3.2 Appendix A.4K Metal Uptake in Northern Constructed Wetland
R117	Detailed plans on field studies to support and refine the effectiveness of the wetland water treatment system. Details should include: a. a preliminary schedule for studies; b. location and sequencing of field scale studies; and c. any required activities, such as earthworks, required for field studies.	Section A.4.11.3.3
R118	Details on any proposed pilot studies for the bioreactor system associated with the HLF.	Section A.4.11.3.4
R119	An assessment of uncertainty associated with the performance of the proposed passive treatment system.	Section A.4.11.3.5
R120	Prediction of a worst case scenario of downstream water quality assuming no treatment system. Predictions should extend as far downstream as necessary to demonstrate no further exceedances of the CCME surface water quality objectives attributed to the mine (or 90th percentile of background for those constituents that naturally exceed CCME).	Section A.4.11.3.6
R121	A discussion of contingency, alternative, or additional treatment options that could achieve water quality objectives should the passive treatment system not be viable or perform as required.	Section A.4.11.3.7
R122	A discussion of the requirements and merits for conventional treatment as the treatment method.	Section A.4.11.3.8 Appendix A.4H Cold Climate Passive Treatment Systems Literature Review

Request #	Request for Supplementary Information	Response
R123	A discussion and rationale on how the design of the north end of the tailings management facility wetlands will accommodate a range of possible flows from the pit lake.	Section A.4.11.3.9 Appendix A.7B Water Quality Predictions Report
R124	Details and design considerations for the remotely operated solar powered decant valves. Details should include: a. infrastructure requirements; b. monitoring and maintenance requirements, including an estimated timeframe; c. contingency planning related to malfunctions, inappropriate feedback and interaction; and d. case studies where such systems are effectively used;	Section A.4.11.3.10
R125	Details and rationale on the proposed storage and disposal of low-grade ore. Details should include: a. detailed geochemical characterization of material in the low-grade ore stockpile; and b. supporting evidence and rationale as to why leaving this material on surface to continue to generate acid and metal contaminants before much later disposal in the pit is any more beneficial than disposing same under water in the TMF when this material is first encountered.	Section A.4.11.4.1
R126	Details and discussion on groundwater collection and/or infiltration suppression to manage seepage through the low grade ore stockpile.	Section A.4.11.4.2
R127	A detailed discussion on lake stratification or mixing in relation to discharge including: a. any evidence or assumptions for lake mixing or stratification; and b. stratifications or mixing impacts to discharge water quality and the tailings management facility wetlands.	Section A.4.11.4.3 Appendix A.7B Water Quality Predictions Report
R128	Additional analysis to inform and update the Conceptual Closure and Reclamation Plan to address potential pit wall instability in post-closure.	Section A.4.11.5.1 Appendix A.4I Open Pit Geotechnical Design
R129	A sensitivity analysis examining the effect of less stable pit walls and show how the additional waste rock would be managed if the wall slopes had to be relaxed.	Section A.4.11.5.2
R130	A description of the barrier to prevent access to pit walls.	Section A.4.11.6.1
R131	Results and analysis of testing of heap leach facility detoxification using samples and conditions similar to an exhausted heap of friable ore approximately 150 m high.	Section A.4.11.7.1
R132	A discussion on alternative mitigation measures that may be required if heap leach facility rinsing and detoxification is not successful. The discussion should include examples of successful heap rinsing at comparable sites where materials of a similar nature, mass and northern location have been encountered.	Section A.4.11.7.2 Appendix A.4J Laboratory Evaluation of the SO2/Air and Peroxide Process
R133	Describe how fluid impoundment behind the HLF embankment will be prevented at closure.	Section A.4.11.7.3

Request #	Request for Supplementary Information	Response
R134	Additional details on the design basis and requirements for cover materials. Details should include: a. cover modeling and assessment including validation of assumed infiltration rates; b. availability and location of sufficient construction materials to meet the design requirements; c. composition of materials to be used for the cover system including mineral soil, topsoil, and vegetation; d. range of expected performance of proposed cover systems; and e. long-term monitoring and maintenance requirements.	Section A.4.11.8.1
R135	Feasibility level design details for the winter seepage mitigation pond cut-off wall and cut-off trench/barrier. Include a discussion of how the structures are to be constructed.	Section A.4.11.9.1
R136	Rationale for the construction of a cut-off barrier only after operations.	Section A.4.11.9.2 Appendix A.7B Water Quality Predictions Report
R137	Additional details about the winter seepage mitigation pond dam should include: a. proposed design standards (e.g. Canadian Dam Association Safety Guidelines); b. cross-sections; c. construction materials; d. consequence of failure classification; e. detailed foundation characterization; and f. monitoring and maintenance requirements.	Section A.4.11.9.3
R138	Demonstrate that the rate of discharge from the proposed winter seepage mitigation pond can be controlled in response to downstream flow rates within Casino Creek in order to meet downstream water quality objectives. Details should include WSMP capacity to handle excess water that is not discharged due to low flow conditions in Casino Creek.	Section A.4.11.9.4 Appendix A.7A Variability Water Balance Report
R139	Detailed plans for establishing vegetation on the downstream slope of the tailings management facility west and main embankments. Details should include: a. examples of successful projects where vegetation was established on similar slopes under similar climatic conditions as supporting rationale for the proposed closure and reclamation plan; b. a conceptual schedule for the site vegetation studies and feasibility level site vegetation designs, including the maintenance expectations; and c. a description of the estimated feasibility level costs of site vegetation upon mine closure account for the site-specific conditions.	Section A.4.11.10.1
R140	Further discussion regarding site infrastructure that may not be conducive to climax vegetation in closure. Include measures that you will implement to ensure long-term integrity of this reclaimed infrastructure.	Section A.4.11.11.1

Request #	Request for Supplementary Information	Response
R141	Additional details in the Conceptual Closure and Reclamation Plan with regard to temporary or early closure. Details should include: a. water and solution management and any requirements for water treatment; b. infrastructure requirements (e.g. ability of heap leach facility or tailings management facility to accommodate temporary or early closure); c. identify critical points in the project life cycle where temporary or early closure is most probable and most challenging; and d. length of time project could remain in temporary closure before discharge would be required.	Section A.4.11.12.1
R142	Contingency measures or alternatives that may be required in the event of early closure if passive treatment system field trials have not been completed or are shown to be unsuccessful.	Section A.4.11.12.2
R143	Update the CCRP and security estimates based on the Government of Yukon's updated guidance document: Reclamation and Closure Planning for Quartz Mining Projects, Plan Requirements and Closure Costing Guidance (Government of Yukon, 2013).	Section A.4.11.13.1
R144	Additional justification and discussion on security estimates. Details should include: a. all major mine components; b. all reclamation and closure stages; c. consideration of temporary or early closure; d. consideration of accidents and malfunctions; and e. consideration of effects of the environment.	Section A.4.11.13.2
R145	The following documents referenced in the Conceptual Closure and Reclamation Plan (Appendix 4A): a. R&C Environmental Services, 2010 b. pers.comm. J. Marsden, 2013	Section A.4.11.14.1 Appendix A.4J Laboratory Evaluation of the SO2/Air and Peroxide Process
R146	A detailed description of waste management for the Project including: a. location and size of all facilities associated with waste management; b. detailed description of waste storage facilities including the waste management facility, landfill, incinerator, land treatment facility, and sewage treatment plant; c. detailed description of waste management at the various facilities; d. anticipated volumes of waste at various stages of the Project; e. details on special waste and hazardous waste handling including anticipated volumes; and f. a more detailed waste management plan.	Section A.4.12.1 Appendix A.22A Solid Waste and Hazardous Materials Management Plan
R147	A detailed discussion on the short and long-term stability of mine infrastructure and surrounding slopes in the upper Casino Creek watershed due to permafrost degradation. Consideration should be given to the effects of permafrost degradation related to site infrastructure and climate change.	Section A.6.2.1.1

Request #	Request for Supplementary Information	Response
R148	Maps and relevant references showing permafrost distribution within the mine site as well as the Freegold Road, the airstrip and the airstrip access road.	Section A.6.2.1.2
R149	A detailed thermal modeling analysis of the proposed TMF and associated infrastructure on foundation conditions to support engineering design (including determination of embankment height, width of right of way, safety margin, etc.) and to assess the effects of the Project on the ground thermal regime. Include a detailed discussion and analysis about potential impacts to mine infrastructure from altered foundation conditions.	Section A.6.3.1.1
R150	An analysis of how climate change has been incorporated into the thermal erosion analysis to support Project design and the impact assessment.	Section A.6.3.1.2
R151	The depths at which ground temperatures have been measured for each cable installed in 1994.	Section A.6.4.1.1
R152	The ground temperature readings for all thermistor cables (from 1994 to 2013) in the same format (graphs of ground temperature with depth at a given time) which will allow an assessment of the impacts of recent climate warming (from 1994 until now) on permafrost.	Section A.6.4.1.2
R153	A discussion of whether ground temperature monitoring is planned for the proposed alignment of the Freegold Road Extension.	Section A.6.4.1.3
R154	Please clarify the assumption that permafrost might have low ice content based on the comparison between depth of permafrost and depth to groundwater.	Section A.6.4.1.4
R155	Clarification of the legends used in the baseline terrain maps as well as a simpler interpretation (label) of the units, especially those with multiple capital letters and integers. This will help establish the baseline surficial geology (terrain).	Section A.6.4.1.4
R156	Develop and present a site-specific terrain hazard classification scheme for the mine site, the Freegold Road, and the airstrip and airstrip access road, consistent with the YESAB draft guidance document titled Geohazards and Risk: A Proponents Guide to Linear Infrastructure (YESAB, 2014).	Section A.6.6.1.1
R157	Clarification of whether an ice-rich permafrost distribution map has been considered in the terrain hazard classification scheme	Section A.6.6.1.2
R158	An assessment of potential water quality under a broader range of hydrologic conditions, including: a. the ability to manage waters during wet, dry and average years; b. the receiving water effects during typical and extreme summer and winter low flows (7Q20 and 7Q10); and c. the water storage and receiving water effects during freshet and event flow.	Section A.7.2.1.1 Appendix A.7A Appendix A.7B
R159	An assessment of the potential effects of climate change on source loadings and receiving water effects.	Section A.7.2.1.2 Appendix A.7A Appendix A.7C

Request #	Request for Supplementary Information	Response
R160	An assessment of potential water quality under a broader range of operating/closure scenarios, including permit limits, atypical operations, accident scenarios, with and without passive treatment.	Section A.7.2.1.3 Appendix A.7B
R161	Additional baseline water quality data for key water sampling locations on a minimum monthly basis for a minimum period of one year to estimate seasonal variability. The Executive Committee expects that results from ongoing water quality data collection will be provided throughout the assessment process.	Section A.7.3.1.1 Appendix A.7D Updated Appendix B5 to Appendix 7A
R162	An analysis regarding dataset robustness, which should at a minimum include additional analysis of central tendency (i.e. standard deviation) and could include better description of data distribution, data variance and other summary statistics where data is not normally distributed to aid in understanding the robustness of the present water quality dataset.	Section A.7.3.1.2 Appendix A.7D Updated Appendix B5 to Appendix 7A
R163	Additional details on water sampling protocols and field sampling methodologies. Details should include: a. filtration protocol/methodology (e.g. field filtered, filtered in lab); b. sample handling and preservatives protocol; and c.analytical hold times, chain of custody, etc.	Section A.7.3.1.3
R164	Clarify whether water quality parameters being monitored and conclusions are being drawn from total metals content, dissolved metals content, or both. Discuss whether elevated metals were a result of additional metals associated with higher suspended sediments.	Section A.7.3.1.4 Appendix A.7D Updated Appendix B5 to Appendix 7A Appendix A.7F The Effect of Acid Rock Drainage on Casino Creek
R165	Further discussion and clarification on baseline data from the existing adit. Details should include: a. rationale as to the limited amount of data from the adit; and b. an analysis for loadings (mass-balance) at additional points along the pathway from the adit to site W4.	Section A.7.3.1.5
R166	Toxicity testing and evaluation on water quality samples using early-life stages of salmonid and non-salmonid fish species, invertebrate species, and aquatic plant species.	Section A.7.3.1.6 Appendix A.7G Toxicity Testing Reports
R167	Clarify and provide further justification for the use of water monitoring stations W18, M18, and H18.	Section A.7.3.1.7 Appendix A.7B Water Quality Predictions Report
R168	Toxicity and bioaccumulation testing and evaluation on sediment quality samples.	Section A.7.3.2.1 Appendix A.7G Toxicity Testing Reports

Request #	Request for Supplementary Information	Response
R169	Baseline hydrological information for streams and rivers downstream of W16 on Dip Creek and the Yukon River (e.g. Klotassin River and White River), inclusive of the Yukon River at the respective point of confluence.	Section A.7.4.1.1
R170	Provide estimates of flow rates for the Yukon River either at the point of confluence with Britannia Creek or at the point of planned water withdrawal from the Yukon River;	Section A.7.4.1.2
R171	Confirm whether on-going hydrometric monitoring will continue to improve the reliability of described baseline flow characteristics.	Section A.7.4.1.3
R172	Survey cross-sections of the stream gauging stations as well as an assessment of the accuracy of the measured peak flows considering the rating curve data.	Section A.7.4.1.4
R173	Confirm whether hydrometric monitoring station W1 that was discontinued in 2011 will be re-established. If not, provide rationale as to chosen approach.	Section A.7.4.1.5
R174	Discuss the use of stage-discharge measurements prior to 2011 (measurements which did not include benchmarks) in developing rating curves. Discuss the implications of only using data from 2013 and onwards in developing rating curves.	Section A.7.4.1.6
R175	A detailed description of the methodology used to select the Big Creek drainage as a regional surrogate watershed to develop the synthetic flow series. Consideration should be given to developing a focussed regional relationship using the larger and more current data set.	A.7Section A.7.4.1.7
R176	Update tables 5.1-2, 5.2-1, and 5.3-1 in Appendix 7B, Hydrology Baseline Report to include discharge estimates (e.g. cubic meters per second or liters per second.	Section A.7.4.1.8
R177	A discussion on, and if necessary reassess, the values identified in Tables 5.2-1 and 5.3-1 of Appendix 7B (Hydrology Baseline Report) given that a comparison with regional hydrometric data suggests that values presented are higher than regional values.	Section A.7.4.1.9
R178	The following referenced report: Knight Piésold Ltd. 2010 Hydrometeorology Report (Ref. No. VA101-325/3-1, June 2010)	Section A.7.4.1.10 Appendix A.4G Updated Hydrometeorology Report
R179	An update and overview of current hydrogeology baseline information. Details should be provided for the following: a. whether additional conductivity studies are being done in the TMF Main Embankment area and rationale for the selected approach; b. characterization of hydrogeology in the open pit area outside the immediate footprint; and c. characterization of hydrogeology in the gold ore, supergene oxide/low grade ore, and low grade ore stockpile areas.	Section A.7.5.1.1 Appendix A.7M 2013-2014 Groundwater Data Report
R180	Additional discussion and supporting rationale on groundwater seepage from the open pit area to the Canadian Creek drainage. The discussion should include implications to base flows during operations and water quality during closure and post-closure.	Section A.7.5.1.2

Request #	Request for Supplementary Information	Response
R181	The following document for review: Knight Piésold Ltd. Revised Tailings Management Facility Seepage Assessment (Ref. No. VA101-325/8-13, December, 2012).	A.7Section A.7.5.1.3 Appendix A.4L Revised Tailings Management Facility Seepage Assessment
R182	Additional detail and rationale to indicate that samples collected for geochemical characterization of ore, waste rock, and tailings, provide a statistically representative dataset. Details should include: a. results of sensitivity analysis and gap analysis of geochemical characterization program; b. summation of geochemical sampling program relative to rock lithology and alteration types; and c. if current sampling is found to be incomplete, please update accordingly with a suitable number of samples for ABA, as well as appropriate kinetic testing.	Section A.7.6.1.1 Appendix A.7H Appendix A2 to Casino Waste Rock and Ore Geochemical Static Test Assessment Report: Cross-Sections
R183	Complete cross-section and long-sectional diagrams of the open pit. Diagrams should include: a. all sample locations; b. all geologic units and lithologies; c. ore body outline; and d. any other data that will increase understanding of the deposit geology.	Section A.7.6.1.2 Appendix A.7H Appendix A2 to Casino Waste Rock and Ore Geochemical Static Test Assessment Report: Cross-Sections
R184	The following referenced reports: a. Lorax Environmental Service Ltd. (2009) Casino Phase I Geochemical Assessment Report prepared for Western Copper Corporation, January, 2009. b. Lorax Environmental Services Ltd. (2010) Casino Phase II Geochemical Assessment Report, prepared for Western Copper Corporation, January 2010.	Section A.7.6.1.3
R185	Describe or otherwise comment upon the added dimension of lithology in their analysis.	Section A.7.6.1.4
R186	Information on and description of the “FZ” lithology listed in Table 3-2 report titled Casino Waste Rock and Ore Geochemical Static Test Assessment (Appendix 7D, Lorax, Dec 3, 2013).	Section A.7.6.1.5
R187	Clarify why there are only about 12 percent of HYP samples included in the shake flask extraction testwork when the HYP type makes up almost 37 percent of the alteration types.	Section A.7.6.1.6 Appendix A.7I Casino Kinetic Testwork 2014 Update for Ore, Waste Rock and Tailings
R188	Rational as to why there are no values presented for uranium and fluoride despite having identified them as parameters of interest.	Section A.7.6.1.7

Request #	Request for Supplementary Information	Response
R189	Details on: mining sequence; production of ore and waste types relative to lithology and alteration; and blending schedule. Details should include: a. an ore/waste production schedule (tables and figures) broken down by lithologic/alteration units and tonnages mined; and b. demonstration that the mixing CAP and SUP material with HYP material could be implemented and will be an effective mitigation.	Section A.7.6.1.8 Appendix A.4F Waste Storage Area and Stockpiles Feasibility Design Appendix A.22H ML/ARD Management Plan
R190	Update and provide a discussion of on-going kinetic testwork. Provide any results and demonstrate how those results may inform the Project. Details should include: a. discussion on whether any of the tests recommended by Knight Piésold have been conducted or initiated; b. any additional laboratory reports that are available; and c. discussion on what experiments/test work will be conducted prior to starting construction of the heap.	Section A.7.6.1.9 Appendix A.7I Casino Kinetic Testwork 2014 Update for Ore, Waste Rock and Tailings
R191	Details demonstrating the ore beneficiation process proposed to produce suitable concentrate. Details should include the process steps, reagents to be used, and resulting concentrates and wastes generated.	Section A.7.6.1.10 Appendix A.4M Processing Flow Sheets Appendix A.22H ML/ARD Management Plan

Request #	Request for Supplementary Information	Response
R192	For the Freegold Road upgrade and extension, access road borrow sources, airstrip, airstrip access road, and mine site borrow sources, provide additional details and information on: a. all geological materials, including estimates of volumes, that will be excavated, exposed or otherwise disturbed; b. geochemical characterization, analysis, and interpretation on representative samples for those geological materials; c. consideration of potential effects and appropriate mitigation measures associated with excavating, exposing, or disturbing those materials.	Section A.7.6.1.11 Appendix A.22H ML/ARD Management Plan Appendix A.7J Preliminary Risk Assessment Metal Leaching and Acid Rock Drainage Appendix A.7K Casino Mine Site Borrow Sites ML/ARD Potential Appendix A.12A Wildlife Mitigation and Monitoring Plan V.1.2 Appendix A.22A Waste and Hazardous Materials Management Plan Appendix A.22C Sediment and Erosion Control Management Plan Appendix A.22D Invasive Species Management Plan
R193	The following referenced report: Lorax Environmental Services Ltd. (2012) Casino Road: Preliminary Risk Assessment Metal Leaching and Acid Rock Drainage.	Section A.7.6.1.12 Appendix A.7J Preliminary Risk Assessment Metal Leaching and Acid Rock Drainage
R194	Details and justification on the depth of reaction and loadings source of 2.0 m for the face of the embankment when the active oxidation zone will initially be over a much deeper zone and will evolve downward over time. Justify the loading rates in the source term as a function of the oxidation zone only.	Section A.7.6.2.1
R195	Clarify the loadings as either runoff on the embankment slope and/or the downward infiltration that will eventually daylight as seepage from the embankment.	Section A.7.6.2.2 Appendix A.7B Water Quality Predictions Report

Request #	Request for Supplementary Information	Response
R196	Justify the depth of oxidation on the tailings beach and show the effect and implications of oxidation on the loadings associated with the infiltrating porewater and tailings seepage.	Section A.7.6.2.3 Appendix A.7B Water Quality Predictions Report
R197	The text on page 4-66 refers to Figure 4.1.4 yet this could not be found, or appears to be mislabelled. Please provide this figure for review.	Section A.7.6.3.1
R198	Casino Cross Sections (Appendix A2 – in LORAX (2013) Casino Geochemical Static Test Assessment, 3-Dec-13, J862-5).	Section A.7.6.3.2 Appendix A.7H Appendix A2 to Casino Waste Rock and Ore Geochemical Static Test Assessment Report: Cross-Sections
R199	Supplemental Unsaturated Kinetic Test Results (Appendix B – LORAX (2013) Casino Geochemical Source Term Development, 4 December, J862-5).	Section A.7.6.3.3 Appendix A.7L Casino Geochemical Source Term Development: Appendix B
R200	The following referenced report: Himmelright, J. R., 1994: The effect of natural acid rock drainage on Casino Creek. Prepared for Pacific Sentinel Gold Corp. August 1994.	Section A.7.6.3.4 Appendix A.7F The Effect of Acid Rock Drainage on Casino Creek
R201	Re-run the numerical groundwater model with updated groundwater baseline data.	Section A.7.7.1.1
R202	A copy of the updated Modflow numerical groundwater model and all input data used in the modeling runs including: a. a copy of all model outputs as summary tables and figures; and b. further discussion of assumptions used in the modeling.	Section A.7.7.1.2
R203	Discuss whether the open pit lake seepage predicted by the numerical model, to Casino Creek after closure, is assessed in the overall loadings to the TMF and the downstream environment. If not, provide rationale for its exclusion.	Section A.7.7.1.3 Appendix A.7B Water Quality Predictions Report
R204	If the majority of the predicted seepage, from the open pit lake, of 12 L/s will report to the upper groundwater system in Casino Creek: a. identify what the predicted magnitude of the remaining seepage will be; and b.identify where the remaining seepage is predicted to report to and what the effect of that seepage will be.	Section A.7.7.1.4

Request #	Request for Supplementary Information	Response
R205	Discuss whether the potential for preferential flow through faults below the TMF were considered and if not, discuss why and if so, discuss what were the results and implications for water quality downstream of the TMF.	Section A.7.7.1.5 Appendix A.4D Report on the Feasibility Design of the Tailings Management Facility Appendix A.4L Revised Tailings Management Facility Seepage Assessment
R206	Clarify whether hydraulic conductivity values of the tailings and embankment materials are estimates or laboratory measured values. If they are estimates, please indicate if, and when laboratory testing will be conducted.	Section A.7.7.1.6 Appendix A.4L Revised Tailings Management Facility Seepage Assessment
R207	Update the numerical groundwater model to specifically include the seepage recovery pond and calculate the seepage recovery pond's efficiency including the flux of untreated water that will bypass the pond.	Section A.7.7.1.7
R208	Justification for using a series of steady state models rather than one transient model to predict groundwater flows.	Section A.7.7.1.8
R209	A description of how the numerical groundwater model is to be used and updated during the mining process in order to improve mine management and predictions for closure. Indicate when any updates would be released during operations.	Section A.7.7.1.9
R210	Groundwater level data between the proposed TMF and the Dip Creek watershed. The area of greatest concern is along the watershed divide just beyond the eastern end of the main embankment.	Section A.7.7.1.10 Appendix A.7M 2013-2014 Groundwater Data Report Appendix A.7N Extension of Numerical Groundwater Modelling to include Dip Creek Watershed
R211	A NW-SE geological cross-section (same approximate orientation as the main embankment) from the TMF to Dip Creek since this could demonstrate potential groundwater flow pathways across the topographic divide.	Section A.7.7.1.11
R212	Numerical groundwater flow modeling that extends into the Dip Creek watershed and eliminates the assumption of a no-flow boundary. Modeling should consider the potential for subpermafrost groundwater flow across the topographic divide. Modeling the seepage from the TMF should consider three dimensional flow from the TMF in order to consider not only vertical flow through or beneath the dam but also horizontal flow around the dam and potentially into Dip Creek tributaries.	Section A.7.7.1.12

Request #	Request for Supplementary Information	Response
R213	Map of the elevation of the base of permafrost and data on deep permafrost conditions east of the proposed tailings management facility.	Section A.7.7.1.13 Appendix A.7N Extension of Numerical Groundwater Modelling to include Dip Creek Watershed
R214	Justification for not including the subsurface distribution of permafrost (in particular lower hydraulic conductivity of frozen ground as a barrier to groundwater flow) in the numerical groundwater flow modeling.	Section A.7.7.1.14
R215	A discussion of the effect of permafrost distribution on the observed and modelled patterns of groundwater flow.	Section A.7.7.1.15
R216	Discussion of hydraulic conductivities of frozen and unfrozen hydrostratigraphic units. Details should include: a. estimates of frozen and unfrozen hydraulic conductivities of all rock materials subject to permafrost; and b. how thermal changes (due to facility construction and climate change) will affect the groundwater regime.	Section A.7.7.1.16
R217	A discussion and consideration of a numerical permafrost model to assess the effects of the mine components on permafrost distribution in the mine footprint.	Section A.7.7.1.17
R218	A discussion on the discrepancies between the Inferred Spatial Distribution of Permafrost (Figure 2.3 of Appendix 7C) and the Groundwater Recharge Zones (Figure 3.4 of Appendix 7E).	Section A.7.7.1.18
R219	A discussion of how recharge distributions were modified and their potential effects on the numerical groundwater flow model.	Section A.7.7.1.19
R220	A new figure combining both the recharge and permafrost distributions so that it is possible to identify where the distributions overlap and differ.	Section A.7.7.1.20
R221	Complete groundwater modeling on the period of time that the TMF is dewatered to allow construction of the TMF wetlands.	Section A.7.7.1.21
R222	Modeling for seepage flow rates from the water management pond if the water level exceeds desired levels.	Section A.7.7.1.22
R223	Verification methods for seepage flow not captured by the water management pond.	Section A.7.7.1.23
R224	An assessment of potential water quantity under a broader range of hydrologic conditions, including: a. the ability to manage waters during wet, dry and average years; b. the receiving water effects during typical and extreme summer and winter low flows (7Q20 and 7Q10); and c. the water storage and receiving water effects during freshet and event flow.	Section A.7.8.1.1 Appendix A.7A Variability Water Balance Model Report

Request #	Request for Supplementary Information	Response
R225	An assessment of the potential effects of climate change on water balance.	Section A.7.8.1.2 Appendix A.7A Variability Water Balance Model Report Appendix A.7C Potential Effects of Climate Change on the Variability Water Balance
R226	An assessment of potential water quantity under a broader range of operating/closure scenarios, including permit limits, atypical operations, and accident scenarios.	Section A.7.8.1.3 Appendix A.7A Variability Water Balance Model Report
R227	Provide sensitivity analysis for the site water balance model identifying: a.the potential impact of variation in assumed values for key water balance model parameters; and b. the potential impact of temporal change in the assumed distribution of precipitation and snowmelt.	Section A.7.8.1.4 Appendix A.7A Variability Water Balance Model Report Appendix A.7B Water Quality Predictions Report
R228	Identify if the results of the sensitivity analysis materially affect the Water Management Plan for the project proposal, and if yes, update the Water Management Plan.	Section A.7.8.1.5 Appendix A.7A Variability Water Balance Model Report
R229	A description of how the water balance model is to be used and updated during the mining process in order to improve mine management and predictions for closure. Indicate when any updates would be released during operations.	Section A.7.8.1.6 Appendix A.7A Variability Water Balance Model Report Appendix A.7C Potential Effects of Climate Change on the Variability Water Balance
R230	Provide the reasoning for selecting Big Creek as the most representative long-term hydrometric station for generating site synthetic stream flow data.	Section A.7.8.1.7
R231	Re-run the water quality model with updated water quality baseline data.	Section A.7.9.1.1
R232	A copy of the GoldSim model and all input data used in the assessment.	Section A.7.9.1.2 Appendix A.7B Water Quality Predictions Report

Request #	Request for Supplementary Information	Response
R233	A copy of all model outputs as summary tables and figures.	Section A.7.9.1.3 Appendix A.7B Water Quality Predictions Report
R234	A discussion of assumptions used in the modeling.	Section A.7.9.1.4 Appendix A.7B Water Quality Predictions Report
R235	Any additional information that the Proponent may have used in their assessment so as to facilitate an independent calculation of potential water quality effects by reviewers.	Section A.7.9.1.5 Appendix A.7A Variability Water Balance Model Report
R236	A description of how the water quality model is to be used and updated during the mining process in order to improve mine management and predictions for closure. Indicate when any updates would be released during operations.	Section A.7.9.1.6
R237	An explanation of how loadings from embankment runoff and embankment seepage relate to the conceptual flow diagram in Figure 7-2 in LORAX (2013) Casino Geochemical Source Term Development, 4 December, J862-5. In addition, please confirm that those loadings were included in the water quality model.	Section A.7.9.2.1 Appendix A.7B Water Quality Predictions Report
R238	Additional details and rationale supporting the use of site specific water quality objectives (SSWQO) for certain contaminants of concern. Details should include: a. justification for not using CCME guidelines to develop SSWQO; b. demonstration that aquatic biota remain protected to the same degree as provided by the CCME guidelines; c. how SSWQO account for chronic/long-term acceptable limits; and d. consideration for the new, hardness-dependent, long-term limit for cadmium now available from CCME.	Appendix A.7A Variability Water Balance Model Report Appendix A.7B Water Quality Predictions Report Appendix A.7E 2008 Environmental Studies Report: Final
R239	Predictions for pH in table 7.4-3 (Water Quality Model Parameters and CCME and BC MOE Guidelines) and Tables 7.4-8 through 7.4-10 (Summary of Predicted Water Quality in Casino Creek at M18 and W4 and Dip Creek at W5).	Section A.7.10.1.2 Appendix A.7B Water Quality Predictions Report
R240	Predictions for toxicity, pH, and radium 226 in the tailings management facility pond and the winter seepage mitigation pond. Provide a discussion on how these parameters address the limits under the Metal Mining Effluent Regulations.	Section A.7.10.2.1 Appendix A.7B Water Quality Predictions Report

Request #	Request for Supplementary Information	Response
R241	An assessment of potential water quality effects extending downstream to include water monitoring station W16 and, if necessary, as far downstream to demonstrate no further exceedances of the CCME surface water quality objectives attributed to the mine (or 90th percentile of background for those constituents that naturally exceed CCME). The assessment should consider scenarios both with and without use of the passive treatment system.	Section A.7.11.1.1
R242	Additional rationale supporting the use of station M18/W18 as the receiving environment for the Project. Consideration should be given to: a. how this site fits within the intent of CCME; and b. to what degree does contribution of water from Brynelson Creek provide a buffer for the project meeting CCME or site specific water quality objectives for the protection of aquatic resources.	Section A.7.11.1.2
R243	Expected length of time PAG materials will be exposed to oxygen and water before submersion in the TMF and any expected resulting acid generation.	Section A.7.12.1.1 Appendix A.7I Casino Kinetic Testwork 2014 Update for Ore, Waste Rock and Tailings
R244	An analysis of scenarios that may cause exposure of PAG materials considering variation of meteorological factors, vegetative interception, and seepage losses. Details should include: a. an analysis of successive dry years on TMF water balance and its implications on PAG tailings and waste rock oxidizing due to low water levels; b. the minimum annual precipitation required to maintain PAG materials below the water table in the TMF; c. scenarios during closure that would cause the water table in the TMF to be low enough to allow oxidation of the PAG materials; and d. the potential effects associated with metals mobilization under these scenarios.	Section A.7.12.1.2 Appendix A.4D Report on the Feasibility Design of the Tailings Management Facility
R245	A plan describing mitigations in case unsuitable (e.g. elevated metal concentrations) water is encountered via pit dewatering (i.e. prior to sufficient storage developed on-site).	Section A.7.13.1.1
R246	Details on the characterization of groundwater and flow patterns near the adit.	Section A.7.14.1.1
R247	A comprehensive description of the adit including: a. physical characteristics (e.g. incline or decline, dimensions, length); and b. extent of fracturing.	Section A.7.14.1.2
R248	How and when the adit will be reclaimed. Describe implications of reclamation on surrounding groundwater and infrastructure such as the HLF.	Section A.7.14.1.3
R249	Reasons for missing data at regional climate stations (i.e. was the station not operated for budget considerations or did an extreme weather event destroy the station).	Section A.8.2.1.1

Request #	Request for Supplementary Information	Response
R250	Rationale for a linear orographic factor at the Project site for 24-hour extreme events considering available data and any terrain effects.	Section A.8.2.1.2
R251	Additional rationale for developing the precipitation return period events (e.g. extreme rainfall). Details should include the methodology for developing the 200 and 1000-year return period events as well as rationale for using the Gumbel distribution.	Section A.8.2.1.3
R252	Discussion of the role of aspect in relation to climate variables at the Project site.	Section A.8.2.1.4
R253	Justify the use of only Pelly Ranch in building climate baseline data at the Project site for periods where data are unavailable for the Project location.	Section A.8.2.1.5
R254	Confirm that on-site meteorological data collection is ongoing. Provide raw and processed data and recalculate precipitation estimates and measures of variability.	Section A.8.2.1.6
R255	Clarification regarding the climate variables that have been utilized as part of project safety and design as well as an explanation for why those climate variables have been chosen.	Section A.8.2.1.7
R256	Clarification regarding the values used when considering climate change projections and their interactions with the project.	Section A.8.2.1.8
R257	Additional information on wind speed/direction sensor position and height.	Section A.8.2.1.9
R258	Develop a more robust estimate of evaporation and evapotranspiration using air temperature, relative humidity, wind speed and solar radiation.	Section A.8.2.1.10
R259	A discussion on how variability and uncertainty associated with the impacts of climate change was considered in Project safety and design and how those impacts will be mitigated, particularly with respect to permafrost thaw and hydrological changes.	Section A.8.3.1.1
R260	In planning the design and construction of the mine, a greater range of potential change should be considered (and not just the mean). For example, if the range of precipitation change is projected to be between 5 and 25 percent, design considerations should not be limited to a mean (15 percent) but should address the potential maximum (25 percent). Please clarify what values were used when considering climate change projections and their interactions with the Project.	Section A.8.3.1.2
R261	Clarification on the calculations related to the projected rate of increase of flow, including details on how historical trends for Big Creek have been taken into consideration in the projection as well as how the potential maximum increase has been addressed.	Section A.8.3.1.3
R262	The CALPUT and CALMET input files such that a recreation of the model is possible.	Section A.8.4.1.1 Appendix A.8A Emissions Inventory for Construction and Operations
R263	Details on the specifications of ambient air monitoring and meteorological equipment.	Section A.8.4.1.2

Request #	Request for Supplementary Information	Response
R264	An analysis of wind directions compared to other regional sites.	Section A.8.4.1.3
R265	A detailed emission inventory for construction and operational activities.	Section A.8.4.1.4 Appendix A.8A Emissions Inventory for Construction and Operations
R266	Clarification if mitigations, such as ultra-low sulphur fuel, proposed for air quality were reflected in model parameters. If not, results of the air quality model with the mitigations reflected in model parameters.	Section A.8.4.2.1
R267	If predicted air quality, after mitigations, results in exceedances, provide mitigations for identified exceedances.	Section A.8.4.2.2
R268	The raster data generated from the CALPUFF model in a standard GIS format.	Section A.8.4.3.1
R269	A description of predicted exceedances including concentrations and predicted frequency.	Section A.8.4.3.2
R270	Details on the compositions of dust generated by the mine and how this is expected to compare with the proposal's baseline data.	Section A.8.5.1.1
R271	Details on volumes of water required for dust management and clarification if this water was accounted for in overall water use requirements.	Section A.8.5.1.2
R272	Update to Table 22.3-2 to include a conclusive list of proposed mitigation measures for potential project effects on air quality.	Section A.8.6.1.1
R273	An updated Section 10 of the proposal which reflects the current *Fisheries Act* (Fisheries Protection Provisions). This updated section should include the identification of project components likely requiring a paragraph 35(2)(b) *Fisheries Act* authorization.	Section A.10.2.1.1 Appendix A.10A Updated Fish Habitat Offsetting Plan
R274	Proposed charge weights to be used for different project activities including the operation of the mine pit, and construction of infrastructure site pads and access roads. Indicate setback distances from fish-bearing waters for each activity and an analysis of potential effects based on this information.	Section A.10.3.1.1 Appendix A.10A Updated Fish Habitat Offsetting Plan Appendix A.10B Fish Habitat Evaluation: Instream Flow and Habitat Evaluation Procedure Study
R275	Baseline data for the creek intersected by the proposed airstrip, Taylor Creek, and other Casino Creek tributaries lacking baseline data including: a. the existing condition, including quality and relative abundance, of the fish habitat; and b. the species and life stages of fish present.	Section A.10.4.1.1
R276	A discussion of fish populations, densities, and diversity in downstream watercourses including lower Dip Creek and the Klotassin River.	Section A.10.4.1.2

Request #	Request for Supplementary Information	Response
R277	Maps demonstrating fish presence, assumed absence, or observed absence by stream segment. Include the stream channel intersected by the proposed airstrip, Casino Creek tributaries such as Taylor Creek, and the Freegold Road. Where fish are assumed as absent, provide rationale.	Section A.10.4.1.3
R278	Maps demonstrating fish habitat quality and fish distribution by species for watercourses including Casino Creek and its tributaries, Dip Creek downstream of its confluence with Casino Creek, and Britannia Creek and its tributaries. Include any seasonal barriers to movement.	Section A.10.4.1.4
R279	A table or other tool identifying the location in the proposal of supporting baseline information for each of the potentially impacted watercourses.	Section A.10.4.1.5
R280	Information on the time of year each of the water bodies potentially affected by the Project are likely to be used by the various life stages of each fish species.	Section A.10.4.1.6
R281	Appendices A through E for Appendix 10 A – Casino Project Fish and Aquatic Resources Baseline Report, November 12, 2013, by Palmer Environmental Consulting Group Inc.	Section A.10.4.2.1
R282	A description of the detailed methods used to calculate the estimated reductions in flow and wetted area from baseline conditions in all watercourses affected. (EcoMetrix)	Section A.10.5.1.1 Appendix A.10B Fish Habitat Evaluation: Instream Flow and Habitat Evaluation Procedure Study
R283	An indication of and rationale for the selected minimum in-stream flow threshold. (EcoMetrix)	Section A.10.5.1.2 Appendix A.10B Fish Habitat Evaluation: Instream Flow and Habitat Evaluation Procedure Study
R284	The full documents cited as KPL 2013 and Normandeau, November 2013. (EcoMetrix)	Section A.10.5.1.3 Appendix A.10B Fish Habitat Evaluation: Instream Flow and Habitat Evaluation Procedure Study

Request #	Request for Supplementary Information	Response
R285	A discussion of the extent to which the identified overwintering and spawning habitat in the affected portion of Casino Creek is actively used by Arctic grayling for these stages, and the potential effects of the Project to this habitat.	Section A.10.5.1.4 Appendix A.10A Updated Fish Habitat Offsetting Plan Appendix A.10B Fish Habitat Evaluation: Instream Flow and Habitat Evaluation Procedure Study
R286	A discussion of the potential fish barrier proposed to be installed above the Casino- Brynelson Creek confluence. This discussion should include: a. a description of the barrier proposed, and details regarding its installation; and b. identification of alternative mitigations to the physical fish barrier in this location to prevent winter kill and fish stranding.	Section A.10.5.2.1
R287	The degree of risk for fish stranding to actually occur in Casino Creek due to low water flow attributed to the operation of the tailings management facility.	Section A.10.5.2.2 Appendix A.10B Fish Habitat Evaluation: Instream Flow and Habitat Evaluation Procedure Study
R288	A discussion of and rationale for the diversion of this drainage around the airstrip. This discussion should consider alternatives, such as allowing the drainage to pass underneath the airstrip.	Section A.10.5.3.1 Appendix A.10A Updated Fish Habitat Offsetting Plan Appendix A.10B Fish Habitat Evaluation: Instream Flow and Habitat Evaluation Procedure Study
R289	A discussion of the potential for seasonal stranding of fish in the lower portion of the dewatered channel.	Section A.10.5.3.2
R290	An updated Fish Habitat Compensation Plan to align with the new requirements of the *Fisheries Protection Provisions* of the new *Fisheries Act*.	Section A.10.5.4.1 Appendix A.10A Updated Fish Habitat Offsetting Plan

Request #	Request for Supplementary Information	Response
R291	A detailed description of the physical habitat simulation model. Details should include: a. data used in the model (habitat and hydrological) and methods for field data collection; b. locations of all transects (of each mesohabitat type - riffle, pool and glide) on each watercourse; c. habitat suitability indices (HSI) curves for Arctic grayling in all life stages which consider site specific conditions; d. species and life stage periodicity chart highlighting the seasonal use of the study area by different life stages of the target species, and a discussion of whether migration patterns were considered in the model; e. discussion of whether seasonal use by life stage requirements of target species was considered in the model; f. target flow velocities for low, mid and high flows, with a comparison to the baseline and projected flows for construction, operation and closure phases, indicating and providing rationale for the selected minimum in-stream threshold; g. discussion of impacts to Britannia Creek from reduced flows in Canadian Creek as flow is redirected to the pit; and h. a comparison of percent reduction in flow for areas affected by reduced stream flows considering natural variability observed in stream.	Section A.10.5.5.1 Appendix A.10B Fish Habitat Evaluation: Instream Flow and Habitat Evaluation Procedure Study
R292	A detailed description of the habitat evaluation procedure. Details should include: a. methods and assumptions for the calculation of habitat lost; b. summary of HSI values for each variable; c. identification of and rationale for habitat types included; and d. data and methods used to calculate habitat gains, including from all proposed compensation options.	Section A.10.5.5.2 Appendix A.10B
R293	Clarification of whether the estimated habitat loss in Dip Creek was accounted for in the total habitat loss calculation for the proposed airstrip tributary diversion channel.	Section A.10.5.6.1
R294	Clarification of, and rationale for, the methods used to calculate the figures in Table 4-5: in-stream habitat impacts and in-stream habitat gains. This clarification should include the calculation of 4753 m^2 as identified in Table 4-5, based on the proposed airstrip diversion channel width of 2.5 m and length of 1 509 m.	Section A.10.5.6.2 Appendix A.10A Updated Fish Habitat Offsetting Plan
R295	Clarification of whether the assumed fish bearing streams (those of less than 20 percent gradient) were included in the habitat evaluation procedure analysis for habitat loss and compensation.	Section A.10.5.7.1
R296	Identification and rationale for the type(s) of habitat created by ford restoration.	Section A.10.5.8.1 Appendix A.10A Updated Fish Habitat Offsetting Plan

Request #	Request for Supplementary Information	Response
R297	Clarification of whether clear-span bridges are proposed for all fish-bearing watercourses. If culverts will be installed on some fish-bearing creeks, please provide rationale, mitigations, and incorporate habitat losses into the habitat compensation plan.	Section A.10.6.1.1
R298	Details on existing crossing structures no longer used for portions of the Freegold Road upgrade once the road is re-aligned.	Section A.10.6.2.1
R299	Details on when and how the Nordenskiold River bridge pier will be constructed.	Section A.10.6.3.1
R300	The quality and type of fish habitat (e.g. highly suitable spawning and/or rearing habitat, confirmed spawning habitat, and migratory channel) potentially affected by the Nordenskiold River bridge. Discussion should include identification of potential effects of the bridge and the pier, focusing on potential long-term morphological changes to the river in contrast to natural morphological changes.	Section A.10.6.3.2
R301	The fish species (and their life stages) present in the area potentially affected by the Nordenskiold River bridge. Discussion should include identification of potential effects of the bridge and the pier.	Section A.10.6.3.3
R302	A list of stream crossings for the Freegold Road including stream name, kilometre marker, crossing properties and the type of crossing, considering DFO's definition of clear-span crossing.	Section A.10.6.4.1
R303	An assessment of the overall erosion and sedimentation risk that will form the basis for designing and ultimately preparing an erosion and sediment control plan for the Freegold Road Upgrade, Airstrip Access Road and Casino Mine site.	Section A.10.6.5.1
R304	Identification of fish-bearing and non fish-bearing reaches of affected watercourses in the Map Series 3 (overall erosion and sedimentation risk) of the Erosion and Sedimentation Risk Assessment Report.	Section A.10.6.5.2
R305	Discussion on the methods of monitoring for erosion and sedimentation during all phases of the Project.	Section A.10.6.5.3 Appendix A.10A Updated Fish Habitat Offsetting Plan Appendix A.22C Sediment and Erosion Control Management Plan
R306	Discussion of and rationale for the exclusion of W16 or other downstream locations from monitoring throughout the life of the Project.	Section A.10.7.1.1
R307	The information related in Section 7.4.5.1 and 7.4.5.2.	Section A.10.8.1.1
R308	Discussion of the potential effects of the construction, operation, and possible decommissioning of other project infrastructure on habitat (such as fens and tors) with elevated potential for rare species.	Section A.11.2.1.1 Appendix A.12A Wildlife Monitoring and Mitigation Plan Appendix A.22C Sediment and Erosion Control Plan

Request #	Request for Supplementary Information	Response
R309	Discussion of the potential effects of the construction, operation, and possible decommissioning of the airstrip and airstrip access road on proximate vegetation and wetlands. In particular, this discussion should identify impacts to downslope wetlands.	Section A.11.2.1.2 Appendix A.12A Wildlife Monitoring and Mitigation Plan Appendix A.22C Sediment and Erosion Control Plan
R310	An update to Figure 3.1 with the ecosystem types identified in the large vegetation polygon overlapping with the centre of the airstrip.	Section A.11.2.1.3
R311	Discussion of the use of “Loss of Vegetation Associations” and “Wetlands and Riparian Vegetation Associations” as indicators for vegetation health.	Section A.11.3.1.1 Appendix A.12A Wildlife Monitoring and Mitigation Plan Appendix A.22C Sediment and Erosion Control Plan
R312	A clear mitigation (buffer zone and avoidance) and management plan (where avoidance cannot be achieved) to support the residual effect assessment, for both the construction and operation of the project components.	Section A.11.3.1.2 Appendix A.10A Fish Habitat Offsetting Plan Appendix A.22C Sediment and Erosion Control Plan
R313	Details on a conceptual integrated management plan for project activities affecting vegetation. Details should include: a. proposed buffer zones around wetlands, valuable vegetation associations or sites, and riparian areas which also consider the needs of wildlife for movement corridors; b. species to be used for re-vegetation; c. timeframe for re-vegetation and reclamation activities; d. measures to monitor success and take corrective actions as necessary; and e. control of invasive species.	Section A.11.4.1.1 Appendix A.10A Fish Habitat Offsetting Plan Appendix A.22C Sediment and Erosion Control Plan Appendix A.22D Invasive Species Management Plan
R314	The correct references for each place in Section 12 that this error text appears.	A.12.2.1.1
R315	Discussion on the effects to wildlife for caribou, wood bison, and Dall sheep, related to predator-prey systems affected by the Freegold Road, airstrip and airstrip access road, through all project phases. This discussion should: a. use the most current data and information available; b. include changes to population dynamics; and c. include areas of wildlife concentration, such as mineral licks.	A.12.3.1.1 Appendix A.12A Wildlife Mitigation and Monitoring Plan

Request #	Request for Supplementary Information	Response
R316	Describe how wildlife crossing areas will be implemented. Details should include: a. the schedule and methods for data collection and analysis regarding the determination of high use wildlife crossing areas along the access roads; and b. how crossing areas may change seasonally and annually.	A.12.3.2.1
R317	Detail on road maintenance activities (e.g. road salt, road margin vegetation management for wildlife, etc.), and other mitigations (such as reducing the frequency of traffic, having periods of time with no traffic, etc.), with a particular emphasis on key wildlife areas. This discussion should include rationale for the effectiveness of mitigations.	A.12.3.3.1 Appendix A.22E Road Use Plan Appendix A.12A Wildlife Mitigation and Monitoring Plan
R318	Wildlife monitoring and adaptive response strategies.	A.12.3.3.2 Appendix A.12A Wildlife Mitigation and Monitoring Plan
R319	Alternative mitigation measures to reduce or eliminate negative effects on wildlife in the event that the Proponent does not have full legal authority to operate and manage the road.	A.12.3.3.3 Appendix A.22E Road Use Plan Appendix A.12A Wildlife Mitigation and Monitoring Plan
R320	Further discussion on the potential indirect effects to wildlife from harvesting.	A.12.3.3.4 Appendix A.12B Wildlife Baseline Report
R321	A discussion of noise associated with the Project in relation to the habitat suitability model using the most recent reference materials available. This discussion should include consideration of noise from all Project activities.	A.12.4.1.1
R322	A discussion of objectives for evaluating model assumptions for caribou disturbance, monitoring movement and potential changes in predation, and setting adaptive management thresholds to support actions which may mitigate adverse effects.	A.12.4.1.2 Appendix A.12A Wildlife Mitigation and Monitoring Plan
R323	A discussion of potential Project effects to the Fortymile caribou herd supported by available data.	A.12.4.1.3
R324	Discussion of the development of the RSF model, including all inputs. Consideration should be given to concerns raised by the Government of Yukon.	A.12.4.1.4
R325	Discuss how the RSF model: a. reflects the distribution of high quality habitat across the Klaza caribou herd's range; and b. accounts for the variability in caribou distribution based on environmental facts and among years.	A.12.4.1.5

Request #	Request for Supplementary Information	Response
R326	Discussion of the potential bias in the estimated winter range.	A.12.4.1.6 Appendix A.12B Wildlife Baseline Report
R327	Winter range map or maps that are representative of caribou use since the late 1980s.	A.12.4.1.7 Appendix A.12B Wildlife Baseline Report
R328	An evaluation of the Klaza caribou herd use of the local study area during summer, using the most recent GPS radio-collar data provided by the Government of Yukon.	A.12.4.1.8 Appendix A.12B Wildlife Baseline Report
R329	A discussion of how the Project may affect (e.g. fire suppression) the Dawson Range's fire regime and its corresponding implications to caribou and caribou habitat.	A.12.4.1.9
R330	Population survey data and demographic models for moose to determine sensitivity to change from potential additional predation or hunting pressure.	A.12.4.2.1
R331	Moose harvest data by sex, including an estimate of First Nations harvest, as well as a population model and sensitivity analysis.	A.12.4.2.2 Appendix A.12B Wildlife Baseline Report
R332	Mitigation measures for displacement/mortality of moose near roads.	A.12.4.2.3 Appendix A.12A Wildlife Mitigation and Monitoring Plan
R333	Detailed design of the pipeline with rationale. If a final design cannot be selected at this stage, please provide detailed design alternatives, and include the potential effects associated with each. In the event that design has not been finalized, please provide the schedule and methods for moose monitoring efforts to inform development of the pipeline.	A.12.4.2.4 Appendix A.12A Wildlife Mitigation and Monitoring Plan Appendix A.12B Wildlife Baseline Report
R334	A discussion of and rationale for the selected model. This discussion should include: a. rationale for the ratings assigned to the subalpine and low boreal zones, as well as the selection of north-facing slopes, which considers the comments made by the Government of Yukon; and b. an explanation of Figure 4.3 in the Wildlife Baseline Report showing habitat quality class, which includes statistical support for each of the bars.	A.12.4.2.5 Appendix A.12C Moose Late Winter Habitat Suitability Report
R335	A discussion of and rationale for a 300 m zone of influence. This discussion should consider increasing the zone to at least 500 m.	A.12.4.2.6 Appendix A.12C Moose Late Winter Habitat Suitability Report

Request #	Request for Supplementary Information	Response
R336	Detail on baselines survey efforts, including den surveys, and including routes taken.	A.12.4.3.1 Appendix A.12B Wildlife Baseline Report
R337	Additional data (one year minimum) on bear den presence and distribution within the project area.	A.12.4.3.2
R338	Discussion regarding the dates provided by the Government of Yukon for grizzly bear denning and how these dates may affect or be affected by project activities.	A.12.4.3.3
R339	Details on the Habitat Suitability and Habitat Effectiveness models, including: a. additional clarification on why habitat types were rated as presented; for example, alpine habitat is rated as 'low' (0) value in the spring. For bears, alpine has high habitat value in spring; b. clarification on traffic projections; c. clarification on the dates used to define the different seasons in the HE model; d. clarification on the coefficients used to develop the HE model; and e. clarification on disturbance events considered in the development of the models.	A.12.4.3.4 Appendix A.12B Wildlife Baseline Report
R340	Details on the Security Areas model, including: a. rationale (including reference if possible) for the selection of the 2300 m asl as the threshold for available security areas, as opposed to 1900 m asl; b. clarification on traffic projections; and c. clarification on disturbance events considered in the development of the model.	A.12.4.3.5 Appendix A.12B Wildlife Baseline Report
R341	A discussion of and rationale for the use of a qualitative assessment, as opposed to quantitative, for grizzly bear mortality.	A.12.4.3.6
R342	Clarification of and rationale for the grizzly bear density estimate for the area.	A.12.4.3.7
R343	More information on Table 8.1 of the grizzly bear effects assessment, including: a. proportion of males and females harvested; b. a discussion of how the numbers relate to the population estimate; and c. a discussion of the population-level effects of direct mortality.	A.12.4.3.8
R344	A discussion on the mortality estimate from the mine site, Freegold Road, and airstrip and airstrip access road. Discussion should include: a. conflict kills and road kills; b. consideration of high traffic roads vs. low traffic trails and different traffic types; c. assumptions used for mortality risk assessment related to the Freegold Road and mine site; and d. clarification of and rationale for the quota identified for annual allowable human- caused mortality.	A.12.4.3.9 Appendix A.12A Wildlife Mitigation and Monitoring Plan

Request #	Request for Supplementary Information	Response
R345	Collared pika colony occupancy data to accurately predict species' current abundance and distribution. If occupancy data is unavailable, proposed methods for collecting such data prior to habitat alteration.	A.12.4.4.1 Appendix A.12B Wildlife Baseline Report
R346	A habitat suitability model and related analyses, which identifies potential denning habitat of wolverines in the local study area and regional study area.	A.12.4.5.1 Appendix A.12B Wildlife Baseline Report
R347	A risk assessment for wolverines which considers the habitat suitability model. The assessment should identify potential effects to natal and maternal den sites and proposed measures for avoiding disturbance of females with kits.	A.12.4.5.2 Appendix A.12A Wildlife Mitigation and Monitoring Plan Appendix A.22A Waste and Hazardous Materials Management Plan
R348	Areas of use by the little brown myotis within the LSA and RSA, particularly for roosting and foraging.	A.12.4.6.1 Appendix A.12B Wildlife Baseline Report
R349	If baseline data is unavailable, proposed mitigation and monitoring efforts for the species.	A.12.4.6.2 Appendix A.12A Wildlife Mitigation and Monitoring Plan Appendix A.12B Wildlife Baseline Report
R350	Baseline information for Dall sheep or, if unavailable, proposed mitigation and monitoring measures, particularly in relation to the Freegold Road.	A.12.4.7.1 Appendix A.12B Wildlife Baseline Report
R351	Discussion of alpine breeders as key indicator species, which considers their associated priority for conservation and the project's potential effects on this group.	A.12.5.1.1
R352	The location of alpine meadows in the local study area and regional study area.	A.12.5.1.2
R353	The results of baseline surveys for short-eared owl, horned grebe, and common nighthawk pre-construction surveys (i.e. dusk call playback surveys) and a description of plans for mitigation and monitoring of potential adverse effects cause by the Project.	A.12.5.2.1
R354	Additional detail on the mortality risk to birds including identifying areas of highest risk.	A.12.5.3.1 Appendix A.12A Wildlife Mitigation and Monitoring Plan

Request #	Request for Supplementary Information	Response
R355	Details on the rusty blackbird model. Details should include model inputs and assumptions and indicate whether and how it accounts for small wetlands.	A.12.5.4.1
R356	Discussion regarding the models for olive-sided flycatcher and short-eared owl, including categorization of high quality habitat types. Consideration should be given to an expanded model for the short-eared owl and olive-sided flycatcher.	A.12.5.4.2
R357	A map showing observation sites and potential breeding locations for horned grebes within the project footprint.	A.12.5.4.3
R358	Rationale behind decreasing habitat quality ratings one class, as opposed to two in some cases.	A.12.5.5.1
R359	Proposed mitigations for effects of chronic noise on bird species.	A.12.5.5.2
R360	Discussion of and rationale for buffer sizes around active bird nests.	A.12.5.5.3 Appendix A.12A Wildlife Mitigation and Monitoring Plan
R361	Confirmation on whether the cliff-nesting raptor survey involved re-visiting previously documented nests.	A.12.5.6.1
R362	A figure showing the aerial route followed during cliff-nesting raptor surveys within the local study area and regional study area.	A.12.5.6.2
R363	Rationale for the size of the proposed buffers around cliff-nesting raptor nests.	A.12.5.7.1 Appendix A.12A Wildlife Mitigation and Monitoring Plan
R364	Methods used to identify wetlands, including open-water wetlands and small ponds.	A.12.5.8.1
R365	Information displaying the locations of these wetlands and ponds, and their distribution across the LSA.	A.12.5.8.2
R366	Discussion of potential effects to these wetlands and ponds, and any associated mitigations.	A.12.5.8.3 Appendix A.12A Wildlife Mitigation and Monitoring Plan
R367	An effects assessment of the TMF wetlands, as they relate to waterfowl.	A.12.5.9.1 Appendix A.12A Wildlife Mitigation and Monitoring Plan
R368	Monitoring and mitigations to prevent waterfowl from utilizing the TMF wetlands and other mine water bodies (events pond, pit lake, etc.). Details should include effectiveness of proposed mitigations.	A.12.5.9.2 Appendix A.12A Wildlife Mitigation and Monitoring Plan

Request #	Request for Supplementary Information	Response
R369	Clarification on the meanings of “unacceptable levels of trace metals” and “limited effects” in relation to waterfowl, and rationale for the statement that despite unacceptable levels of trace metals shown by water quality monitoring, resulting effects to waterfowl will be limited.	A.12.5.9.3
R370	Rationale for how water quality mitigation measures alone will address concerns around waterfowl exposure to elevated levels of trace metals.	A.12.5.9.4 Appendix A.12A Wildlife Mitigation and Monitoring Plan Appendix A.7B Water Quality Model Report
R371	Clarification as to whether Figure 8.2 in Section 12B refers to only passerine bird species or to upland birds in general.	A.12.5.10.1
R372	The potential effects of climate change on key indicator species over the life of the Project.	A.12.6.1.1
R373	Discussion of monitoring and adaptive management measures to be implemented to detect and mitigate potential effects of the Project in the context of climate change.	A.12.6.1.2 Appendix A.12A Wildlife Mitigation and Monitoring Plan
R374	Details on the timing, spatial boundaries, frequency, and general methods of monitoring surveys for caribou, moose, carnivore dens, pika colonies, obligate alpine breeders, waterfowl, and bird species at risk.	A.12.7.1.1 Appendix A.12A Wildlife Mitigation and Monitoring Plan
R375	Discussion and rationale on the Proponent’s position that the boom and bust cycle to be either minimal or acceptable within the context of Yukon. Consideration should be given to the contribution of annual taxes, royalties and GDP to the Yukon economic base and the scale of the Project.	Section A.15.2.1.1 Appendix A.13A Economic Impacts of the Casino Mine Project
R376	A description of what measures will be put in place to reduce the effects of boom and bust cycles.	Section A.15.2.1.2
R377	Identify specific conditions and scenarios where the Project might operate on a reduced scale.	Section A.15.2.1.3
R378	Details regarding any specific methods that the Proponent intends to use to enable local and Yukon businesses to supply or service the Project.	Section A.15.3.1.1 Appendix A.22F Socio-Economic Management Plan
R379	Details regarding any specific methods that the Proponent intends to use to enable First Nation businesses to supply or service the Project.	Section A.15.3.1.2 Appendix A.22F Socio-Economic Management Plan

Request #	Request for Supplementary Information	Response
R380	A detailed plan on how the proponent intends to monitor and manage socio-economic effects. This plan should include: a. objectives, indicators, and monitoring methods; b. thresholds and triggers for action; and c. adaptive management strategies.	Section A.15.4.1.1 Appendix A.22F Socio-Economic Management Plan
R381	The following referenced report: MNP LLP. 2013. Economic Impacts of the Casino Mine Project. March 2013. Casino Mine Corporation.	Section A.13.4.1.1 Appendix A.13A Economic Impacts of the Casino Mine Project
R382	A plan on how the Proponent intends to meet their commitment to hire within Yukon including: a. anticipated training programs; b. a monitoring mechanism including indicators; c. how the plan has or will involve communities and First Nations considering Chapter 22 of the Umbrella Final Agreement; d. implementation timelines; and e. apprenticeship and co-op opportunities.	Section A.14.2.1.1 Appendix A.22F Socio-Economic Management Plan
R383	Transportation alternatives for potential employees in Yukon communities outside of Whitehorse during each Project phase.	Section A.14.3.1.1
R384	Details of the “hiring policy that encourages the employment of workers from Yukon and in particular the rural communities of the LSA” and workforce opportunities for residents in Carmacks and Pelly Crossing and citizens of affected FNs.	Section A.14.3.1.2 Appendix A.22F Socio-Economic Management Plan
R385	Assumptions supporting migration estimates, including between communities in Yukon and how downward population pressures were considered.	Section A.14.4.1.1
R386	A breakdown of direct Project employment projected for each affected community. Please indicate if employees are new, existing, or returning residents or from other communities in Yukon.	Section A.14.4.1.2
R387	Clarify if the flexible rotations, counselling services, and adaptive management are the mitigation strategies for the proposed shift structure as suggested in the proposal. Please elaborate in detail for each mitigation strategy.	Section A.14.5.1.1 Appendix A.22F Socio-Economic Management Plan
R388	Details on how CMC will accommodate cultural and community events, including funerals and potlatches, in its proposed shift structure.	Section A.14.5.1.2 Appendix A.22F Socio-Economic Management Plan
R389	Rationale for the determination of high resilience as the context for possible effects to community vitality. In addition, provide a discussion on the implications of using a more conservative estimate of resiliency.	Section A.16.2.1.1 Appendix A.22F Socio-Economic Management Plan

Request #	Request for Supplementary Information	Response
R390	A plan for of how community well-being will be monitored, including: a. a clear definition of community wellbeing and community vitality, and how the community has been involved in the process of definition; b. indicators to monitor and evaluate the level of community well-being and vitality in each affected community; c. methods of monitoring each indicator; d. how the Proponent will communicate monitoring results; and e. any monitoring efforts outside of Pelly Crossing and Carmacks.	Section A.16.3.1.1 Appendix A.22F Socio-Economic Management Plan
R391	A description of how these suggested valued components can be incorporated into the Project's management, effects monitoring, and community involvement.	Section A.16.4.1.1
R392	A Heritage Management Plan including: a. a description of input from First Nations including Traditional Knowledge; b. a range of mitigation measures; c. heritage resource management framework; d. definitions and objectives; and e. a monitoring and evaluation mechanism.	Section A.18.2.1.1 Appendix A.18A Casino Summary Heritage Report Appendix A.18B Casino Heritage Sites Summary
R393	A table summarizing the number of historical and archaeological sites, their relative location in relation to the mine site, the Freegold Road Upgrade, the Freegold Road Extension, the airstrip location and associated borrow sites. Within that table include additional details such as: a. characterization of predicted disturbance; b. proposed Mitigation; c. description of the site; d. if applicable, the Project component footprint that the site overlaps; and e. site name, date of discovery, general location and traditional territory.	Section A.18.3.1.1 Appendix A.18B Casino Heritage Sites Summary
R394	Clarification regarding whether avoidance is possible for the five historic sites located along the Freegold Road Extension. If not, a description of next steps and proposed mitigations is required.	Section A.18.4.1.1 Appendix A.18B Casino Heritage Sites Summary
R395	Clarification on the specific efforts and processes undertaken by the Proponent to gather TK and TLU in order to inform the proposal. A description of what TK or TLU information the Proponent received for the purposes of drafting the proposal.	Section A.2.2.1.1 Appendix A.2A
R396	A TK and TLU study for the Project.	Section A.2.2.1.2
R397	A review of effects from resource projects and effects on TLU in a northern context.	A.2.2.1.3
R398	A framework for monitoring effects to TLU resulting from the Project.	Section A.2.2.1.3 Appendix A.22F
R399	An assessment of impacts of the Project on traditional economy.	Section A.2.2.1.4

Request #	Request for Supplementary Information	Response
R400	A discussion of the potential effects of the Project to commercial, recreational and Aboriginal fisheries (e.g. Arctic grayling and Chinook salmon). This discussion should include: a. a geographic scope that includes areas downstream of Dip Creek up to and including the White River; b. consideration of the changes in rearing, spawning, and overwintering habitat; c. a consideration of the migratory nature of various fish species; and d. potential fish kills and stranding.	Section A.19.2.1.1
R401	Description of any identified plant species of traditional, cultural, or economic importance within the Project footprint. Include a description of any efforts to engage First Nations or other land users in identifying plants of concern.	Section A.19.3.1.1
R402	Any ground studies that sought to identify and map plants of concern.	Section A.19.3.1.2
R403	If, during consultation with First Nations, any concerns were raised on impacts to important areas of wildlife harvest.	Section A.19.4.1.1
R404	A monitoring plan for induced hunting effects along the Freegold Road, either independently or in conjunction with First Nations.	Section A.19.4.1.2
R405	Description of discussions with and feedback from affected trapline concession holders including how many trapline concession holders were contacted and responded.	Section A.2.3.1.1
R406	Description of discussions with and feedback from affected outfitting concession holders including how many outfitting concession holders were contacted and responded.	Section A.2.3.1.2
R407	A summary of any geographically specific important areas for outfitting or trapping that overlap or may be affected by the Project and the species involved.	Section A.19.5.1.1
R408	A description of any contact or discussions between CMC and mineral rights holders in relation to the road.	Section A.2.4.1.1
R409	A rationale for why tenure No. 334151 is not considered in the effects assessment.	Section A.19.6.1.1
R410	A mitigation strategy for the cabin located at the southern edge of a proposed borrow pit and what if any measures will be in place to ensure continued access. In addition, identify whether the owner has been contacted or not. If so, please provide information regarding the outcome of this contact.	Section A.19.6.1.2
R411	Details regarding how the noise model accounted for seasonal variability.	Section A.9.2.1.1
R412	Details how the collected baseline data informed modeling or if other sources were used.	Section A.9.2.1.2
R413	Rationale on model selection including model limitations.	Section A.9.2.1.3
R414	Rationale on why noise levels in Carmacks and the FGR were not modeled.	Section A.9.2.1.4
R415	Identification of reference equipment used to calculate sound pressure levels.	Section A.9.2.1.5

Request #	Request for Supplementary Information	Response
R416	Confirmation that the noise modeling accounts for air traffic, shovels, cycloning, blasting, the concrete batch plant, and HLF crushing operations and revised predictions if these are not included in the original proposal.	Section A.9.2.1.6
R417	A revision of the section on accidents and malfunctions to address worker and public health and safety.	Section A.21.2.1.1 Appendix A.22B Spill Contingency Management Plan
R418	Clarification of the procedures that will be established in the event of a Level II Emergency Event, as defined in the conceptual Emergency Response Plan, and how these procedures rely on existing infrastructure and services.	Section A.21.3.1.1 Appendix A.22B Spill Contingency Management Plan
R419	For accidents on the Freegold Road, a description of how emergency services will be coordinated, and where these services will come from.	Section A.21.3.1.2 Appendix A.22E Road Use Plan
R420	A description of any discussions between CMC and protective and emergency services regarding increases in traffic and therefore and increase in accidents on the Freegold Road, Alaska Highway or Klondike Highway?	Section A.21.3.1.3 Appendix A.22G LNG Management Plan Appendix A.22A Waste and Hazardous Materials Management Plan Appendix A.22B Spill Contingency Management Plan
R421	Details regarding on-site personnel, equipment, and services that are provided based on anticipated requirements.	Section A.21.3.1.4
R422	Describe and outline how would the mine site be evacuated in different seasons. Details should include: a. length of time an evacuation would require; and b. logistics for transportation.	Section A.21.3.2.1
R423	The rationale for two hours, or 682 m^3, as the minimum capacity for water storage for on- site firefighting capacity.	Section A.21.4.1.1 Appendix A.4M Processing Flow Sheets
R424	Confirmation of where off-site emergency fire services for the Project will come from.	Section A.21.4.1.2
R425	A description of the human element in fire suppression and equipment available including: a. the level of training will be available to workers in fire suppression; b. a description of firefighting infrastructure will be on-site; and c. a description of any equipment available for first responders.	Section A.21.4.1.3
R426	An elaboration on the need or absence of need for non-water jet firefighting methods.	Section A.21.4.1.4

Request #	Request for Supplementary Information	Response
R427	Description of the consideration of fire at the cyanide, LNG, or explosives facilities.	Section A.21.4.1.5 Appendix A. 22G LNG Management Plan
R428	A description of any plans to train and familiarize first responders with the Project and associated hazards, infrastructure, and layout.	Section A.21.4.1.6
R429	Rationale for the statement in Section 20.3.4.4 that wildfire will not cause a shutdown of the mine for more than 24 hours.	Section A.20.2.1.1
R430	Implications to the Project if a wildfire results in a mine shutdown, or access road closure, for more than 24 hours.	Section A.20.2.1.2
R431	A description of any medical infrastructure that will be in place on-site regarding medical emergencies, and the depth of nursing, pharmaceutical, and first aid services that CMC forecasts as being available on-site.	Section A.21.5.1.1
R432	Details on the capacity to provide medical treatment planned in event of a potential delay to emergency response. Please describe this in terms of both the ability to provide emergency medical care for multiple casualties concurrently as well as in terms of overall duration and level of care.	Section A.21.5.1.2
R433	Considering the remote nature of the Freegold Road, a description of medical and communication capacity along the Freegold Road and its extension including the need or absence of need for any helipads.	Section A.21.5.1.3
R434	A description of how a destination medical facility will be chosen and the threshold for medevac.	Section A.21.5.1.4
R435	Details of a Human Health Monitoring Plan.	Section A.22.2.1.1
R436	Any description of spill infrastructure along public highways or the Freegold Road upgrade and extension.	Section A.22.3.1.1 Appendix A.22B Spill Contingency Management Plan
R437	A complete list of floatation circuit and heap leach chemicals with their anticipated on-site storage capacities and rates of use.	Section A.22.3.2.1 Appendix A.4M Processing Flow Sheets Appendix A.22B Spill Contingency Management Plan
R438	A detailed Cyanide Transportation Management Plan. Details should be Yukon-focused, and in particular the Freegold Road to the Project site.	Section A.22.3.3.1 Appendix A.22B Spill Contingency Management Plan

Request #	Request for Supplementary Information	Response
R439	Clarification regarding handling, storage, and use of cyanide at the Project site. Details should include: a. description of unloading process and area for solid sodium cyanide (NaCN); b. details on storage of solid NaCN in bulk bags; c. the process for moving: the solid NaCN from the unloading area to the storage area in the adsorption, desorption and recovery building; the solid NaCN from the storage area to the NaCN mix tank; and the NaCN from the mix tank to the liquid NaCN storage tank; d. use of level indicators and high-level alarms for the liquid NaCN mix and storage tanks; e. ventilation requirements for the solid NaCN in the cyanide storage area within the adsorption, desorption and recovery building; and f. ambient air monitoring requirements within the solid NaCN storage area, liquid NaCN mixing area and liquid NaCN storage area to protect workers.	Section A.22.3.3.2 Appendix A.4M Processing Flow Sheets
R440	A detailed management plan for LNG.	Section A.22.3.3.3 Appendix A.22G LNG Management Plan
R441	A detailed management plan for explosives and its constituents.	Section A.22.3.3.4 Appendix A.22A Waste and Hazardous Materials Management Plan
R442	An assessment of risk for the transportation of LNG, cyanide, ammonium nitrate, and other hazardous materials with focus on sensitive areas such as major bridge and culvert crossings.	Section A.22.3.3.5 Appendix A.22C Sediment and Erosion Control Plan Appendix A.22B Spill Contingency Management Plan
R443	A more detailed description of what will be included in the Emergency Response Plan for emergencies related to cyanide. Details should include: a. potential cyanide failure scenarios appropriate for the site-specific environmental and operating circumstances; b. specific response actions such as clearing site personnel and advising potentially-affected communities; c. use of cyanide antidotes and first aid measures for cyanide exposure; and d. control of releases at their source and containment, assessment, mitigation and future prevention of releases.	Section A.22.3.3.
R444	A comprehensive Human Health Risk Assessment for each stage of the Project.	Section A.22.4.1.1

Request #	Request for Supplementary Information	Response
R445	Add a valued component and assessment for worker health and safety to the Project proposal.	Section A.5.2.1.1
R446	Describe how emergency and non-emergency services in Carmacks were factored into Project plans and design. Consideration should be given to health, law enforcement, conservation, and other government services.	Section A.21.6.1.1
R447	A detailed characterization of potential major mine infrastructure failures and proposed response measures to these events.	Section A.21.7.1.1
R448	An updated discussion regarding the likelihood and consequence of a TMF embankment failure considering the entire lifetime of the facility (i.e. in perpetuity) in light of updated site condition characterization and dam break/inundation analysis as outlined in other sections of the Adequacy Review Report.	Section A.21.7.1.2
R449	A Mine Infrastructure Failure Response Plan that includes consideration of updated site condition characterization and dam break/inundation analysis as outlined in other sections of the Adequacy Review Report.	Section A.22.5.1.1

APPENDIX A.2A: Traditional Knowledge Bibliography

MEMORANDUM

Date:	December 1 2014
To:	CMC
From:	Hemmera
Re:	Casino: Bibliography of Reviewed Traditional Knowledge (TK) Literature

This document lists the traditional knowledge literature reviewed by the Hemmera team in order to prepare specific content excerpts for Casino's technical team as they prepare supplementary information for the project proposal. The listing reflects suggestions provided through comments on the YESAB On-line Registry, Hemmera's suggested documents and other sources uncovered through the exercise of retrieving these sources. The focus was first on Northern Tutchone specific information, then on Yukon information and lastly approaches for North of 60. The documents listed below were each reviewed for relevant information as it relates to the topics of vegetation, wildlife, birds and fish, as well as more holistically as they related to traditional ecological knowledge or traditional land use.

TAILINGS MANAGEMENT FACILITY CONSTRUCTION MATERIAL ALTERNATIVES (REF. NO. VA101-325/3-2)

EXECUTIVE SUMMARY

The Casino Copper-Gold Project is a venture by Western Copper Corporation to develop an Open Pit copper-gold-molybdenum mine in the Yukon Territory. The project is located in the Dawson Range Mountains of the Klondike Plateau approximately 300 km northwest of Whitehorse, Yukon Territory, Canada.

Pre-feasibility design studies completed in 2008 for the Tailings Management Facility (TMF) utilised Non Acid Generating (NAG) mine waste rock for embankment construction. However, recent geochemical characterisation of the mine waste indicates there is potential for the large majority of the NAG material to have metal (copper) leaching potential, and is therefore likely not suitable for embankment construction. Consequently, a study has been carried out to evaluate alternative embankment construction options and alternative tailings disposal technologies for the TMF. The evaluation is based on conceptual designs and preliminary cost estimates developed to provide a comparative cost assessment only.

The following three options have been considered for dam construction and/or tailings disposal and management:

- Use of local borrow materials to replace mine waste rock for construction of the tailings embankment,
- Cyclone sand construction of the tailings embankment, and
- Development of a dewatered tailings (dry stack) facility.

The design basis for the TMF is to provide secure storage of approximately 974 million tonnes of tailings and 838 million tonnes of potentially acid generating and metal leaching waste rock and overburden. The expansion potential of each TMF option has also been examined, to accommodate a potential increase in total mined ore production to approximately 1.2 billion tonnes.

The comparative evaluation of the three TMF options has included consideration of the potential advantages and short-comings of each option. Economic, environmental, design and operating factors have been assessed, including consideration of TMF construction and operation in cold climate conditions. The findings of the comparative assessment indicate that the use of cyclone sand for embankment construction is the preferred option and provides the most efficient and cost effective design concept for the TMF. However, it may be necessary to utilize earth/rockfill materials in the initial years of operations to accommodate any shortfall of cyclone sand availability for construction of staged embankment expansions. Embankment staging, sand cell construction sequencing and integration with rockfill placement schedules (if required) will need to be examined in more detail for future design studies. Suitable earth/rockfill materials may also be required to provide erosion protection for the cyclone sand embankment, and to satisfy embankment stability requirements.

WESTERN COPPER CORPORATION
CASINO COPPER-GOLD PROJECT

TAILINGS MANAGEMENT FACILITY CONSTRUCTION MATERIAL ALTERNATIVES
(REF. NO. VA101-325/3-2)

SECTION 1.0 - INTRODUCTION

1.1 BACKGROUND

The Casino Copper-Gold Project is a venture by Western Copper Corporation to develop an Open Pit copper-gold-molybdenum mine in the Yukon Territory. The project is located in the Dawson Range Mountains of the Klondike Plateau, approximately 300 km northwest of Whitehorse, Yukon Territory, Canada, as shown on Figure 1.1. This area is somewhat unique in that the region was not glaciated during the Wisconsin Advance. The deposit is hosted by the Casino Complex, a suite of igneous intrusive rocks, with an intense hydrothermal alteration overprint. The deposit will be mined using Open Pit methods with a nominal mill throughput of 100,000 tonnes/day (tpd) of ore.

Pre-feasibility design studies completed in 2008 for the Tailings Management Facility (TMF) utilised Non Acid Generating (NAG) mine waste rock for embankment construction. However, recent geochemical characterization of the mine waste indicates that there is potential for the large majority of the NAG material to be metal (copper) leaching, and therefore likely not suitable for embankment construction. Consequently, a study has been carried out to evaluate alternative embankment construction options and alternative tailings disposal technologies for the TMF.

The primary objective of this study is to determine the preferred design concept for mine waste management (waste rock and tailings) and construction of tailings embankments.

1.2 SCOPE OF WORK & DESIGN BASIS

Following discussions with Western Copper Corporation, the following three options have been considered for dam construction and/or tailings disposal and management:

- Use of local borrow materials to replace mine waste rock for construction of the tailings embankment
- Cyclone sand construction of the tailings embankment, and
- Development of a dewatered tailings (dry stack) facility.

Development of the design concept for each TMF option considers construction material availability, tailings production rates and embankment material requirements over the operating life of the TMF. Consideration has also been given to development of the TMF, using a combination of cycloned sand construction and local borrow materials.

The conceptual design for each TMF option has been developed using the design basis and criteria defined for the Pre-Feasibility study completed in 2008 (974.4 million tonnes of tailings over an operating life of 28 years). However, it is now assumed that no mine waste rock will be suitable for embankment

construction other than waste material from the oxide cap zone in the Open Pit (approximately 8.5 million tonnes). All other waste rock is assumed to require subaqueous disposal within the TMF, comprising approximately 837.6 million tonnes of Potentially Acid Generating (PAG) and Metal Leaching (ML) waste rock and overburden. It is assumed that suitable processing of the tailings stream will be provided (pyrite separation) to ensure that the majority of the tailings are non-reactive (geochemically innocuous), and suitable to produce cyclone sand for embankment fill, or for placement as filtered (unsaturated) tailings within a "dry stack" tailings facility. All potentially reactive tailings and waste rock materials are to be accommodated by subaqueous disposal within the TMF.

This report presents a comparative scoping level evaluation for staged development of the TMF for each of the three options. The potential advantages and short-comings of each TMF option are highlighted, including consideration of construction and operation in cold climate conditions. Preliminary order of magnitude initial capital, sustaining capital and operating costs, including costs for material preparation, transport and placement, have been prepared to facilitate a comparative assessment of the economics of the three TMF options.

The expansion potential of each TMF option has also be examined, up to a potential total mine production of approximately 1.2 billion tonnes of ore (resulting in approximately 1.2 billion tonnes of tailings and 1 billion tonnes of waste rock).

A summary of the design basis and operating criteria adopted for the three TMF options is summarized in Table 1.1. The conceptual design for each of the three options, presentation of the potential issues which influence the selection of these options and a comparative assessment (with consideration of environmental, design, operating and economic factors) are provided in the following sections.

SECTION 2.0 - LOCAL BORROW MATERIALS

2.1 DESIGN CONCEPT

The design concept for this option is the same as that developed previously for the pre-feasibility design study completed in 2008, with the exception that the majority of waste rock from Open Pit development is assumed to be not suitable for use as embankment fill due to its acid generating or metal leaching potential.

Embankment construction for this option is assumed to be primarily from rockfill. Suitable waste rock from the Open Pit is assumed to be available to construct the Stage I (starter) dam using NAG material from the oxide cap. Embankment construction to facilitate staged expansion of the TMF will be carried out using suitable rockfill materials sourced from local quarrying. A schematic arrangement of the TMF for this option is illustrated on Figure 2.1.

The embankments will be constructed as water-retaining zoned structures with a low permeability core zone and appropriate filter and transition zones to prevent downstream migration of fines. The core zone will include a seepage cut-off keyed into competent rock in the foundation. Information from previous geotechnical investigations at the site indicates that residual soils in the area may provide suitable low permeability borrow fill for use in construction of the embankment core zone and seepage cut-off.

The embankments are designed as full section embankments, with 2H:1V upstream and downstream slopes. Staged expansions of the embankments will utilize the centreline method of construction. A typical section through the Main Embankment is shown on Figure 2.2. An embankment height of approximately 303 m (Elevation 1,008 m) is required at the deepest section for storage of 974.4 million tonnes of tailings (including approximately 49 million tonnes of pyritic tailings) and 837.6 million tonnes of PAG and ML waste rock. The depth-area-capacity (storage) relationship for this facility is given on Figure 2.3.

Tailings slurry will be discharged from the mill circuits at about 55% solids by total mass of slurry. It is assumed that approximately 95% of the tailings will be delivered to the TMF as geochemically innocuous material following pyrite separation. The remaining 5% of the total tailings comprises potentially reactive pyritic tailings discharged by a separate pipeline into a cell contained within the northern end of the TMF, remote from the embankment. Given the elevation difference between the mill and the TMF, the tailings will flow by gravity through a single pipeline, with provision for energy dissipation as required. The slurry is typically discharged through one or several off-takes, from header pipes situated around the periphery of the TMF and its confining embankments. The tailings solids settle out of the slurry and released water accumulates in a surface water (supernatant pond). Clear water from this pond is pumped back to the mill for re-use in the process.

Specific overall features of this TMF option are listed below:

- Two earth-rockfill, zoned embankments, referred to as the Main and West Embankments
- Tailings distribution system
- Reclaim water system
- PAG/ML waste storage area

- Pyritic tailings storage area
- Supernatant (surface water) pond, and
- Seepage collection ditches and ponds/sumps.

A summary of the design basis and operating criteria for this TMF option is included in Table 1.1.

Expansion of the TMF to provide additional storage capacity for tailings and PAG/ML waste rock is possible. An embankment height of approximately 320 metres is required to accommodate an increase in mine production to 1.2 billion tonnes of ore (approximately 1,193 million tonnes of tailings and 1,036 million tonnes of waste rock). This increase in embankment height requires approximately 5 million m^3 of additional embankment fill. The relatively minor increase in embankment height (5% increase in height for a 20% increase in storage capacity) is due to the favourable storage efficiency of the TMF in the later years of operations.

2.2 DESIGN AND OPERATING CONSIDERATIONS

Key design considerations that need to be included in the evaluation of use of local borrow materials for dam construction include the following:

- Availability of borrow materials. The quantity of shell zone material required for the Main and West Embankments (excluding the Stage I dam) is approximately 105 million m^3. The source of this material has yet to be defined. For this study, it is assumed that this material will be sourced from a quarry operation within 5 km of the Main Embankment.
- The geochemical characteristics of rockfill borrow materials would need to be assessed to confirm that they are not potentially acid generating or have metal leaching potential.
- Site investigations and testing will be required to characterize the availability and suitability of potential rockfill quarry locations.
- Any NAG waste rock material determined to have no metal leaching potential can be used to supplement local borrow materials in embankment construction. The unit cost for mine waste rock will likely be less than that associated with rockfill sourced by local quarrying.
- Placement of a buttress against the downstream shell of the Main Embankment may be required to ensure long-term stability and integrity of the TMF due to the height of the final dam (exceeding 300 m). Embankment stability analyses will need to consider the condition of underlying foundation soils and the impact of high confining stresses on the shear strength of the rockfill materials (with consideration of rock type, distribution of rockfill particle sizes, density and durability).

2.3 CAPITAL AND OPERATING COSTS

Capital and operating costs associated with this TMF option, including the use of local borrow materials for embankment construction is presented in Table 2.1. The following assumptions have been made in developing the cost estimate:

- The estimated unit rate for the clearing, stripping and grubbing of the TMF Embankment footprint is \$0.40/m^3 (based on 2008 Pre-Feasibility Design Study).
- Capital, operating and power costs associated with the tailings distribution and water reclaim systems are based on the cost estimate developed for the 2008 Pre-Feasibility Design Study.

- The capital costs for the tailings distribution and water reclaim systems include a bulk thickened tailings pipeline (pipe, energy dissipation, anchoring, valves), a pyritic tailings pipeline (pipe, pipeline flotation and anchoring), and a water reclaim system comprised of a floating pump-station with piping and anchors.
- The equipment and maintenance cost per year for the tailings distribution and reclaim systems is approximated as 15% of the initial capital cost.
- The estimated unit rate for haulage, placement and compaction of rockfill material from the Open Pit used in the Stage I (starter) dam is $\$3.00/m^3$ (based on the 2008 Pre-Feasibility Design Study).
- The estimated unit rate for haulage, placement and compaction of core (low permeability fill material) and filter zone material in the embankments is $\$11.80/m^3$ (based on the 2008 Pre-Feasibility Design Study).
- The estimated all-in capital and operating cost for the use of local borrow (rockfill) materials in embankment construction (shell zones) is $\$8.60/m^3$ (pro-rated from other projects of similar size). On a per tonne of shell zone material basis, the overall cost is estimated at $4.30/tonne (based on an assumed compacted fill density of 2.0 tonne/m^3).

A summary and comparative assessment of the estimated costs for this TMF option with the other two options is provided in Section 5.0.

SECTION 3.0 - CYCLONE SAND EMBANKMENT

3.1 DESIGN CONCEPT

Embankment construction for this option is assumed to be primarily from cyclone sand material. The sand fraction of the bulk tailings is extracted by cycloning the tailings slurry. The resulting sandy underflow product can be used as a construction material provided that it can be placed, drained and compacted sufficiently to ensure embankment stability and preclude potential for liquefaction during seismic shaking. Suitable waste rock from the Open Pit is assumed to be available to construct the Stage I (starter) dam using NAG material from the oxide cap. Embankment construction to facilitate staged expansion of the TMF will be carried out primarily using cyclone sand material. A general arrangement of the TMF for this design option is illustrated on Figure 3.1.

There is ample precedent in North America for tailings dam construction using cyclone sand, but this technique has not been used for large tailings dams in the Yukon. Examples of mine operations in British Columbia, where cyclone sand is used to construct the tailings dams include the Kemess, Gibraltar and Highland Valley mines. To accommodate cold operating conditions in the winter months the construction season at Gibraltar is typically from March to October. Longer cycloning operations for sand fill construction have apparently been possible at the Kemess mine. Dam construction typically runs 6 to 10 months of the year at Highland Valley. During the remainder of the year, tailings are used to construct an upstream beach between the dam and the tailings supernatant pond. Numerous cyclone sand embankments are utilized at mining operations in other regions of the world, including Anglo's Los Bronces mine, Southern Peru Copper's Quebrada Honda mine, and the Los Quillayes tailings impoundment operated by Minera Los Pelambres in Chile (constructed with cyclone sand to a maximum height of approximately 175 m). Several large cyclone sand dams have been constructed to dam heights in the range of approximately 150 m to 200m and are often located in seismically active areas.

The particle size distribution of the Casino mill tailings is a key consideration for determining the suitability of the bulk tailings to provide cyclone sand fill material of suitable quality and sufficient quantity. Coarser tailings are preferred, as a higher sand fraction or 'split' can be realized. A low percentage of fines is also preferred, in order to promote rapid drainage and to facilitate compaction. Two stage cycloning will be required to achieve the desired sand product (low fines content).

Similar to the TMF option utilizing only local borrow materials, the embankments will be constructed as water-retaining zoned structures with a low permeability core zone, appropriate filter and transition zones to prevent downstream migration of fines, and a seepage cut-off keyed into competent rock in the foundation. Information from previous geotechnical investigations at the site indicates that residual soils in the area may provide suitable low permeability borrow fill for use in construction of the embankment core zone and seepage cut-off. Staged expansions of the embankments will utilize the centreline method of construction with a minimum downstream slope of 3H:1V. A typical section through the Main Embankment is shown on Figure 3.2. An embankment height of approximately 290 metres (Elevation 990 m) is required at the deepest section for storage of 755.7 million tonnes of tailings (including approximately 49 million tonnes of pyritic tailings) and 837.6 million tonnes of PAG and ML waste rock. Approximately 219 million tonnes of the stored tailings will be utilized as cyclone sand fill for embankment construction. The depth-area-capacity (storage) relationship for this facility is given on Figure 3.3.

Cell construction using narrow sand deposition panels will be required for raising the downstream shell of the embankments. The panel method involves the construction and maintenance of long, narrow cells along the face of the embankment. A schematic of the panel construction sequence is shown on Figure 3.4. Selected photographs from an operating mine, where dozers are used to place and compact cyclone sand in cells, are included with this report.

The amount of sand that can practically be placed in the TMF embankment fill zones is dependent on a number of factors. If a coarse mill grind is assumed (approximately 45% sand fraction), this suggests that a recovery of about 35% to 38% of the feed can be practically split out for use as sand fill. However, seasonal factors may limit operations to about 9 months of the year, reducing cyclone sand production by about 25%. This results in about 25% of the total mill feed being available annually as suitable sand fill material for embankment construction. For this study, it is assumed that the cyclone sand plant would operate at 90% availability. Also, other water management and environmental factors may tend to further reduce the volume of material that is available to be placed in embankment fill zones.

It is assumed that approximately 95% of the tailings will be geochemically innocuous material following pyrite separation. The remaining 5% of the total tailings comprises potentially reactive pyritic tailings discharged by a separate pipeline into a cell contained within the northern end of the TMF, remote from the embankment. A summary of the design basis and operating criteria for this TMF option is included in Table 1.1.

It is estimated that approximately 5.1 million m^3 (8.1 million tonnes) of cyclone sand fill material can be produced annually using the production factors presented in Table 1.1. This volume may be less than the annual fill volumes required for staged expansions in the early years of operations. Any shortfall of embankment fill material would need to be made up with rockfill from Open Pit stripping (if available and geochemically innocuous) and/or suitable fill material from local borrow sources or quarries. It is estimated that in each of the first five years of operations, approximately 0.7 million m^3 of rockfill will be required to supplement the shortfall in cyclone sand production.

Significant features of the cyclone sand design concept required for the TMF include the following:

- A two stage cyclone sand plant.
- The cyclone sand plant will be located at an elevation such that discharge of sand and combined cyclone overflow can be achieved by gravity. Relocation of the cyclone plant may be required later in the project life.
- The cyclone sand plant will be fed directly from the mill using off-take connections from and to the existing bulk tailings pipelines. This arrangement will maintain the operational ability to bypass the cyclone plant and continue to deposit bulk tailings directly into the TMF when required.
- An additional water inflow of approximately 5,000 m^3/hr is required at the cyclone sand plant during operations. This will be used to reduce the solids content of the primary and secondary cyclone feeds and to fluidize the sand to enhance gravity transport, reduce pipeline pressures and minimize sand pumping costs. Supply of the additional water will come from a dedicated floating reclaim pump-station located within the TMF. A single dedicated pipeline will connect this floating pump-station to the cyclone sand plant.
- The cyclone underflow (sand fraction) will be pumped as required and discharged by gravity from the cyclone sand plant as a slurry of approximately 55% solids by weight, through one of several steel

pipelines laid from the cyclone station. These lines will be laid across a downstream bench below the crest of the TMF confining embankment and extended at intervals down the downstream face for deposition of sand into confining "cells" for use as construction material. The provision of several lines enables the relocation of discharge points, on-going pipeline maintenance and the continuous placement of sand, allowing zones of previously deposited sand material to drain and be compacted by earthmoving equipment.

- The fine cyclone overflow material (fine tailings) will be returned back into the existing bulk tailings discharge pipelines, immediately downstream of the cyclone sand plant, and discharged directly into the TMF from existing off-takes in pipelines laid along the upstream embankment crest and around the periphery of the TMF. Additional pumping will be provided as required.
- Additional solids collection and water recovery measures will be required at the downstream embankment toe. These include sediment collection ponds, drainage recovery pumping and pipeworks systems, plus a seepage recovery pond and pump-back system. These components are required to collect fine sediments and water recovered from the draining sand fill. The sediments will need to be removed by dredging or excavation on at least an annual basis and all water will be pumped back into the TMF through dedicated pipelines. Back-up pumping and power will be required.
- During the winter months and at other times when the cyclone sand plant is not operating, bulk tailings discharge will be rotated sequentially into the TMF from offtakes in the bulk tailings pipelines.

Expansion of the TMF to provide additional storage capacity for tailings and waste rock is possible. An embankment height of approximately 310 metres is required to accommodate an increase in mine production to 1.2 billion tonnes of ore. Assuming full production (100,000 tpd), approximately 5 million m^3 of cycloned sand can be produced annually. This volume may exceed the additional volume of cycloned sand required for expansion due to the favourable storage efficiency of the TMF in the later years of operations.

3.2 DESIGN AND OPERATING CONSIDERATIONS

Key design and operating considerations that need to be included in the evaluation of cyclone sand material for embankment construction include the following:

- Embankment height, stability and seismic resistance. This limits the sand placement options and would likely necessitate construction using sand cells, where additional vibratory compaction would be required to ensure a sufficiently dense, high strength and liquefaction resistant material.
- Cold winter conditions that will reduce the construction period, partly due to the potential for freezing and ice entrainment in the sand fill and partly because of snow drifting in the sand cells.
- Tailings particle size distribution. The tailings grind is fundamental in determining the 'split' that can be achieved by cycloning (i.e. the percentage of the tailings stream that can be separated and used as sand fill for construction). Clean sand, with a low fines content, will be required for placement in the sand cells, in order to facilitate rapid drainage and subsequent compaction. It is anticipated that the fines content (% passing a #200 sieve) of the cyclone sand will need to be less than 15%, in order to maximize fill placement rates and to ensure adequate compaction and drainage.
- The availability of cyclone sand needs to be matched with the filling schedule for the TMF, to ensure adequate embankment heights are provided well in advance of the rising tailings surface. The Stage 1 (starter) embankment must be high enough to allow sufficient quantities of sand to be produced and

placed to facilitate subsequent embankment raises. A hybrid approach (combination of rockfill and cyclone sand) may be necessary to offset any shortfall of cyclone sand available for construction during the operating life of the TMF. The sequencing of sand cell construction in relation to the requirements for embankment crest raising and the associated rockfill placement schedules will need to be carefully evaluated in subsequent design studies. Similarly, the timing, logistics and operating requirements for pipeline management and relocations will also need to be evaluated for future design studies.

- If a combination of cyclone sand and rockfill is utilised for embankment construction, additional filter and drainage layers will be required at the base of sand zones to prevent the migration of tailings sand into underlying rockfill and to provide drainage for the transport of water released from the sand.
- The possibility of windy conditions at the site must be considered. The problem can be exacerbated during cold winter conditions as a 'freeze drying' process tends to destroy capillary tensions in partially saturated sand, making it more susceptible to dusting. This will be a significant environmental consideration. Appropriate provisions will need to be incorporated to prevent wind blown dusting. This will most likely mean that the cyclone sand material will have to be capped with erosion resistant fill material, particularly during the cold winter months, when it may be impractical and/or impossible to continue with active sand placement.
- Only clean (geochemically innocuous) bulk tailings can be cycloned to produce sand fill material for embankment construction. No potentially acid generating or metal leaching materials can be used for embankment construction. Management of the potentially reactive pyritic tailings stream during system maintenance or breakdown needs to be coordinated to ensure that total tailings that include the pyrite stream are not directed to the cyclone sand plant.
- Water management is a major consideration, as protection of downstream fisheries resources is a fundamental requirement. Downstream cyclone water recovery systems will need to include appropriate provisions for containment of fines washed out of the cyclone sand fill, along with additional water collection ponds and water recovery systems. The provision of back-up pumps and a standby power supply must be considered for pump-back systems. The water management aspects of the cyclone sand systems will be major environmental considerations. These will need to be carefully considered to ensure appropriate levels of environmental protection are maintained, both during operations and after closure.
- The requirement for a very large embankment may warrant the installation of multiple or movable sand plants, particularly if the use of cyclone sand as a construction material is to be maximized.
- To accommodate cyclone sand plant maintenance or downtime (primarily during the winter months), valves and pipeworks will need to allow bulk tailings to be delivered directly to the TMF for discharge.
- Placement of a buttress against the downstream shell of the Main Embankment, or an overall flattening of the slope, may be required to ensure long-term stability and integrity of the TMF due to the height of the final dam (280+ metres). Embankment stability analyses will need to consider the condition of underlying foundation soils and the impact of high confining stresses on the shear strength of the cyclone sand material.

3.3 CAPITAL AND OPERATING COSTS

Capital and operating costs associated with the cyclone sand TMF option are presented in Table 3.1. The following assumptions have been made in developing this cost estimate:

- The estimated unit rate for the clearing, stripping and grubbing of the TMF Embankment footprint is $0.40/m^3 (based on 2008 Pre-Feasibility Design Study).
- Capital, operating and power costs associated with the tailings distribution and water reclaim systems are based on the cost estimate developed for the 2008 Pre-Feasibility Design Study.
- The capital costs for the tailings distribution and water reclaim systems include a bulk thickened tailings pipeline (pipe, energy dissipation, anchoring, valves), a pyritic tailings pipeline (pipe, pipeline flotation and anchoring), a water reclaim system comprised of a floating pump-station with piping and anchors, and a water reclaim system for the cyclone plant comprised of a floating pump-station, piping, and head tank.
- The equipment and maintenance cost per year for the tailings distribution and reclaim systems, cyclone plant and associated items is approximated as 15% of the initial capital cost.
- The estimated unit rate for the haulage, placement and compaction of rockfill material from the Open Pit used in the Stage I (starter) dam is $3.00/m^3 (based on 2008 Pre-Feasibility Design Study).
- The estimated unit rate for the haulage, placement and compaction of core and filter zone material in the embankments is $11.80/m^3 (based on 2008 Pre-Feasibility Design Study).
- The estimated all-in capital and operating cost for local borrow materials in the embankments is $8.60/m^3 (pro-rated from other projects of similar size). On a per tonne of shell zone material basis, the overall cost is estimated at $4.30/tonne (based on an assumed compacted fill density of 2.0 tonne/m^3).
- The estimated all-in capital and operating cost for cycloned sand placement for embankment construction is $3.60/m^3 (pro-rated from information provided by other projects). On a per tonne of sand basis, the overall cost is estimated at $2.25/tonne (based on an assumed compacted dry density of 1.6 tonne/m^3)
- Capital costs for cyclone plant and associated infrastructure have been based on information provided by other projects. The capital costs for the cyclone plant and associate infrastructure comprise cyclone clusters, booster pump-stations, valves, pipeworks, cyclone plant earthworks/concrete/steel, electrical, and offtakes.

A summary and comparative assessment of the estimated costs for this TMF option with the other two options is provided in Section 5.0.

SECTION 4.0 - DEWATERED TAILINGS 'DRY STACK'

4.1 DESIGN CONCEPT

This option considers the use of dewatered (filtered) tailings for storage within a "dry stack" facility. A dry stack facility can be used to store the majority of the tailings and would require significantly less material for the confining embankments, compared to disposal by conventional tailings slurry discharge. However, a separate facility is still required to provide subaqueous storage and confinement of potentially reactive waste rock (PAG and ML) and pyritic tailings, and to provide a facility for water management (including recovery to the mill) and contingency storage for those periods when the dry stack facility or dewatering plant is not operational.

Filtered tailings are produced using pressure or vacuum forces in presses, drums or belt filtration units. The tailings are typically dewatered to a moist, cake-like consistency, with water contents sufficiently low to achieve an unsaturated tailings material. The dewatered tailings are transported by conveyors or trucks to a 'dry stack' where they can be compacted in lifts to improve density and stability and enable the ability for machinery to work on the impoundment surface to facilitate on-going expansion.

Pyritic tailings (assumed to be approximately 5% of the total tailings) and all PAG and ML waste rock from open pit stripping will be deposited within a Potentially Reactive (PR) waste facility located in the Casino Creek valley south-east from the Open Pit. The dry stack facility accommodating all non-reactive tailings will be located immediately downstream of this impoundment.

A general arrangement of the dry stack facility and adjacent PR waste facility is shown on Figure 4.1. Specific features of the mine waste facilities are listed below:

- One earth-rockfill, zoned embankment
- Non-reactive tailings distribution system
- Pyritic tailings distribution system
- Dewatered tailings distribution system
- Reclaim water system
- Reactive waste storage area
- Pyritic tailings storage area
- Supernatant (surface water) pond, and
- Seepage collection ditches and ponds/sumps.

It is assumed that the dry stack tailings facility will accommodate approximately 90% of the total tailings stream. The dewatered tailings will be placed and compacted in conjunction with a perimeter berm constructed from waste rock and/or local borrow materials. Filtered tailings will be produced at a dewatering plant, likely established in the area west of the dry stack facility, where the proposed plant site is currently situated. It is assumed that the dewatered tailings will be delivered to the dry stack either by truck or by conveyor. A typical section through the dry stack facility is shown on Figure 4.2. The depth-capacity (storage) relationship for the dry stack tailings facility is given on Figure 4.3. The final height of the dry stack facility required for storage of 487.2 million m^3 (876.9 million tonnes) of dewatered tailings is approximately 226 metres (Elevation 991 m). This is based on an assumed in situ average tailings dry

density of 1.8 tonnes/m^3. It is likely that an underdrain system will be required to ensure drainage and maintain unsaturated conditions within the filtered tailings pile.

The PR waste facility is required for storage of all pyritic tailings (assumed to be 5% of the total tailings stream) and all mine waste rock identified as Potentially Acid Generating (PAG) or with Metal Leaching (ML) potential. Additionally, it is assumed that approximately 5% of the non-reactive tailings will be discharged into this facility. This will be required during periods when the tailings dewatering plant is not operating (e.g. due to maintenance or unscheduled shutdown) or due to unfavourable weather conditions inhibiting tailings placement in the dry stack facility. The confining embankment for the PR waste facility will have a similar design concept to that described for the local borrow embankment option. The facility has been designed to permanently store 97.4 million tonnes of pyritic and bulk tailings (69.6 million m^3 at an assumed average dry density of 1.4 t/m^3) and approximately 837.6 million tonnes of PAG and ML waste rock which will be stored in the Reactive Waste Storage Area contained within the PR waste facility. The final embankment height is approximately 280 m (Elevation 1,025 m). The depth-area-capacity relationship for the PR waste facility is shown on Figure 4.4.

Expansion of the PR waste facility and dry stack facility to provide additional storage capacity is possible. However, expansion of the PR waste facility would encroach on the proposed location of the low grade ore stockpiles east of the mill site. For the dry stack facility a final tailings elevation of approximately 940 m is required to accommodate an increase in mine production to 1.2 billion tonnes of ore (approximately1,074 million tonnes of tailings assuming 90% of the total tailings). For the PR waste facility an embankment height of approximately 305 metres is required to store approximately 119 million tonnes of tailings (pyritic tailings and 5% of the non-reactive tailings) and 1,036 million tonnes of waste rock. This increase in embankment height requires approximately 2 to 3 million m^3 of additional embankment fill.

The overall configuration of the dry stack tailings facility and adjacent PR waste facility has been developed to minimize disturbed area (impoundment footprint), minimize the contributing catchment area (to simplify water management requirements), and to enable the non-reactive tailings dry stack to provide an additional seepage barrier between the PR waste facility and downstream receiving waters.

Embankment slope revegetation and reclamation could occur incrementally during staged expansion of the dry stack facility. Reclamation at closure would consist of revegetating the final surface of the impoundment. Decommissioning of ancillary facilities such as the tailings filtering and dewatering plant would occur at the time other project facilities were dismantled.

A summary of the design basis and operating criteria for the dry stack facility and PR waste facility is included in Table 1.1.

4.2 DESIGN AND OPERATING CONSIDERATIONS

Tailings physical characteristics, such as particle size distribution (percent fines), strongly influence the ability to dewater the tailings solids sufficiently for them to be handled and placed in a compacted dry stack. The presence of excessive fines in the tailings may make it impractical to achieve a workable “dry” tailings product.

The storage of dry tailings can be beneficial, but it is not a method that can be applied in all circumstances. Operational problems may occur as a result of filtering equipment breakdown or a failure of filters to achieve performance requirements, resulting in a variable product. The filtering and transport of dry tailings to the storage area can be very costly in comparison to conventional pumping of tailings slurry, particularly if the slurry can flow under gravity, without pumping. Handling and placement of dewatered tailings in the dry stack facility will add to labour and equipment costs. In an environment with a potential water surplus, such as Casino, water management and water balance requirements may be challenging with a dry stack facility.

In the event of a planned (maintenance) or unplanned halt to operations at the dewatering plant or delivery system, it will be necessary to provide an alternative method for tailings discharge to avoid mill shut-down. This can be achieved by installing a backup pipeline system to the PR waste facility.

Dry stack tailings facilities by nature are expected to have little seepage, but this may not be the experience in practice. Seepage controls have been required at La Coipa Mine in Chile, the Mineral Hill Mine in Montana and the Raglan Mine in Quebec. At Greens Creek Mine in Alaska, a continuous addition of organic carbon to the tailings is required to assure their long-term chemical stability in order to meet water quality requirements.

The cold climate at the Casino site will present challenges during winter operations, including the need to prevent snow or ice accumulations on the tailings dry stack. Dust emissions from the dewatered tailings surface will be difficult to manage during dry spells, particularly if there is strong wind exposure. Wind blown dusting can worsen in winter months, as freeze-drying and other frost processes can loosen the tailings surface. The moderately wet climate may cause problems during the summer months, as excessive moisture addition can result in rapid degradation of trafficability and prevent adequate compaction.

The filtered tailings stack would be susceptible to instability, due to any residual ice lenses or localized liquefaction, if the pile becomes saturated due to rainfall, snow entrainment or percolation from runoff. The risk of embankment stability issues is also high for the PR waste facility due to the need to provide subaqueous storage for the entire impoundment surface, resulting in a water pond immediately upstream of the embankment (no tailings beach).

The above issues will be exacerbated by the need to produce a consistent dewatered tailings product that satisfies performance requirements for a large tonnage, high production rate (100,000 tpd) operation.

4.3 CAPITAL AND OPERATING COSTS

The filter plant required to dewater the bulk tailings stream at Casino would be a very large, expensive structure, due to the high production rate (100,000 tpd). Operating requirements and costs would also be substantial. Filter plants of comparable size are currently unprecedented. The requirement for any backup or bypass system would add significantly to capital costs.

Capital and operating costs for the incremental costs associated with filtered tailings are presented in Table 4.1. The following assumptions have been made in developing this cost estimate:

- The estimated unit rate for the clearing, stripping and grubbing of the TMF Embankment footprint is $\$0.40/m^3$ (based on 2008 Pre-Feasibility Design Study).
- Capital, operating and power costs associated with the tailings distribution and water reclaim systems are based on the cost estimate developed for the 2008 Pre-Feasibility Design Study.
- The capital costs for the tailings distribution and water reclaim systems include a bulk thickened tailings pipeline (pipe, energy dissipation, anchoring, valves), a pyritic tailings pipeline (pipe, pipeline flotation and anchoring), and a water reclaim system comprised of a floating pump-station with piping and anchors.
- The equipment and maintenance cost per year for the tailings distribution and reclaim systems, filtration plant and conveyor system is approximated as 15% of the initial capital cost.
- The estimated unit rate for the haulage, placement and compaction of rockfill material from the Open Pit used in the Stage I (starter) dam is $\$3.00/m^3$ (based on 2008 Pre-Feasibility Design Study).
- The estimated unit rate for the haulage, placement and compaction of core and filter zone material in the PR waste facility Main Embankment is $\$11.80/m^3$ (based on 2008 Pre-Feasibility Design Study).
- The estimated all-in capital and operating cost for local borrow materials in the PR waste facility Main Embankment is $\$8.60/m^3$ (pro-rated from other projects of similar size). On a per tonne of shell zone material basis, the overall cost is estimated at $4.30/tonne. (This is based on an assumed compacted fill density of 2.0 tonne/m^3).
- The estimated all-in capital and operating cost for the placement and compaction of filtered tailings is $\$2.70/m^3$ (pro-rated from other projects of similar size). On a per tonne of shell zone material basis, the overall cost is estimated at $1.50/tonne. (This is based on an assumed compacted dry density of 1.8 tonne/m^3).
- The estimated unit rate for the haulage, placement and compaction of the underdrain material throughout the dry stack facility foundation is $\$11.80/m^3$ (based on 2008 Pre-Feasibility Design Study).
- Capital costs for filtration plant, conveyor system and associated infrastructure have been based on information provided by other projects.

A summary and comparative assessment of the estimated costs for this option with the other two TMF options is provided in Section 5.0.

SECTION 5.0 - TMF ALTERNATIVES ASSESSMENT

5.1 GENERAL

A comparative scoping level evaluation has been carried out for the three TMF options described in the preceding sections. The potential advantages and short-comings of each TMF option have been examined, including consideration of construction and operating factors for a large scale mine waste management plan in cold climate conditions. The preferred TMF option will be that which is best suited to the site-specific circumstances and requirements. No “one size fits all” solution is available to address every particular and unique environmental, design and operational issue. The chosen option will aim to apply the best available and most appropriate technology, with a commitment to best management practices and cost effectiveness.

Primary design and operating, environmental, and economic considerations for the three TMF options are discussed in the following sections.

5.2 DESIGN AND OPERATING CONSIDERATIONS

Design and operating considerations include adapting to inevitable changes and variability in the mill throughput (production rate and material composition); embankment stability requirements, construction material availability and suitability, TMF seepage control, tailings handling and delivery, pipeline and pumping systems reliability, flexibility and redundancy, tailings deposition and reclaim water management, water management, and closure requirements.

The water management system for the cycloned sand and dry stack options will be more complex than that required for a conventional tailings management system as utilised for the option using local borrow materials for embankment construction. Two reclaim water systems are required to provide mill process water and feed water for the cycloned sand plant. Also, two mine waste facilities (dry stack and PR waste facility) with very different design and operating requirements are required for the dewatered tailings option.

A TMF that utilises local borrow materials for embankment construction will require a significant quantity of suitable rock/earthfill material that is characterised as non-potentially acid generating and does not exhibit metal leaching potential. Potential locations to source this material are currently not defined.

Placement of embankment fill during the winter months using local borrow (rockfill) materials will be less challenging compared to the other two TMF options. Embankment construction using local borrow materials can be performed year round, although the efficiency of construction operations will likely be less during the winter months. Cyclone sand production and placement may be limited to about 9 months of the year, due to the cold winter climate at the Casino site. Bulk tailings discharge into the TMF will be required during any cessation in cyclone sand production. The availability of cyclone sand for embankment construction is dependent on a number of factors and may not meet embankment construction material requirements at certain times during operations. However, shortfalls in sand production can be balanced with suitable (geochemically innocuous) rockfill from open pit stripping and/or from local borrow sources or quarry.

The dewatered tailings option requires two individually managed facilities, both of which will have their own operating requirements and challenges. The need to operate two facilities will only add to the complexity of the mine waste management plan. All of the design and operating issues identified with the use of local borrow materials for embankment construction will also apply to the PR waste facility. The dewatered tailings option incorporates filtered tailings production technologies and delivery systems that are without precedent for the scale of operation anticipated for the Casino project, particularly for the cold winter conditions experienced at the site. Therefore, there are inherent risks in proceeding with this technology for the Casino project, unless appropriate contingency measures are incorporated in the mine waste management plan.

The static and seismic stability of the confining embankments is an important consideration for each of the TMF options, due to the large dam heights required. The TMF option that utilises local borrow for embankment construction requires a final embankment exceeding 300 m in height. A final embankment height of 290 m is required for the cyclone sand option. Although the dewatered tailings option requires a lower final embankment height (about 280 m), the stability and integrity of the dry stack and PR waste facilities will likely have a higher risk of potential issues associated with embankment stability and integrity, as discussed in Section 4.2.

The use of cyclone sand fill in embankment construction provides a corresponding reduction in impoundment storage requirements, resulting in a reduced embankment height. The final embankment for the cyclone sand option is approximately 18 metres lower than the TMF option using only local borrow (rockfill) materials. This is relatively minor given the large quantity of sand tailings that will be utilised in embankment construction, but is due to the storage characteristics of the TMF in the later years of operations (large storage capacity increase for a small increase in TMF height).

A review of the design and operating considerations suggests that a mine waste management plan that utilises local borrow materials or cyclone sand for embankment construction are the preferred options. However, both options have specific design and operating issues that will need to be examined in more detail for future design studies.

5.3 ENVIRONMENTAL CONSIDERATIONS

Selection of a preferred TMF option requires consideration of several environmental factors. These include the following potential key factors:

- Impact to fisheries resources
- Stream flow impacts and mitigation opportunities
- Wildlife considerations
- Dusting
- Geochemical considerations (oxidation of reactive materials)
- Biological and social impacts
- Impacts to ground and surface waters, and
- Opportunities for concurrent reclamation and closure requirements.

For the three TMF options presented in this study, the cyclone sand option has the smallest footprint within the Casino Creek valley. The TMF embankment constructed of local borrow materials will create an impoundment only slightly larger than the cyclone sand option. However, it will also include a large disturbance area outside of the TMF associated with the large borrow area(s) required to provide sufficient rockfill material. The dewatered tailings dry stack facility and adjacent PR waste facility will create the largest disturbance area. This TMF option also has the largest direct catchment area and will likely have the largest impact on water resources.

Impacts to air quality related to dusting due to construction traffic and wind blown sand from the tailings embankments will be higher for the cyclone sand and tailings dry stack facilities. Appropriate provisions to manage dusting will be required for these two options.

The review of environmental factors and considerations indicates that the dewatered tailings option will have the largest environmental impact.

5.4 ECONOMIC CONSIDERATIONS

Preliminary order of magnitude initial capital, sustaining capital and operating costs, including costs for material preparation, transport and placement, have been prepared to facilitate a comparative economic assessment of the three TMF options. The economic evaluation considers capital and operating costs associated with storage of tailings and waste rock for the full mine life. A summary of the estimated capital and operating costs for the three TMF options is provided in Table 5.1. Additional details of the estimated capital and operating costs for each of the three TMF options are presented in Tables 2.1, 3.1 and 4.1.

The cycloned sand and dewatered tailings (dry stack) options have larger initial capital costs compared to the option using only local borrow material for embankment construction. The initial capital cost for the cyclone sand option is approximately $20 million more than the local borrow materials option. This is primarily due to the high initial capital costs associated with construction of a cyclone sand plant and associated infrastructure. The initial capital cost for the dewatered tailings option is approximately three times greater than the local borrow materials option and cyclone sand option. High initial capital costs for the dewatered tailings option are associated with the tailings dewatering (filtration) plant, tailings transportation (conveyor/truck delivery system) and provision of a PR waste facility to accommodate subaqueous disposal of PAG and ML waste material and pyritic tailings.

The local borrow materials and dewatered tailings options have significantly larger sustaining capital costs compared to the cyclone sand option. The sustaining capital cost for the cyclone sand option is approximately $410 million less than the local borrow materials option and approximately $1,225 million less than the dry stack option. This is primarily due to the lower unit rate of fill material used for embankment construction. The local borrow materials option has the smallest operating cost of the three options due to lower power requirements.

The use of cyclone sand for TMF embankment construction has the potential to utilize approximately 220 million tonnes of tailings sand which will displace 275 million tonnes of rockfill from within the

embankments. The total savings associated with the use of cyclone sand over locally quarried rockfill is in the order of $270 million over the operating life of the facility.

A review of the economic considerations suggests that the mine waste management plan that is the most economical over the life of the project is the cyclone sand option.

SECTION 6.0 - SUMMARY AND CONCLUSIONS

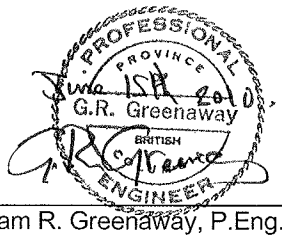
The following three options have been considered for dam construction and/or tailings disposal and management:

- Use of local borrow materials to replace mine waste rock for construction of the tailings embankment
- Cyclone sand construction of the tailings embankment, and
- Development of a dewatered tailings (dry stack) facility.

In addition to development of a dry stack facility, the dewatered tailings design concept requires provision of a second facility to accommodate subaqueous disposal of all potentially reactive waste rock and tailings materials. This potentially reactive waste facility is also needed to provide contingency storage for water management, and for time periods when the dewatering plant is not operational or dewatered tailings placement is not possible due to adverse climatic conditions.

A comparative evaluation of the three TMF options has included consideration of the potential advantages and short-comings of each option. Economic, environmental, design and operating factors have been assessed, including consideration of TMF construction and operation of a large scale mine waste management plan in cold climate conditions.

The findings of the comparative assessment indicate that the use of cyclone sand for embankment construction is the preferred option and provides the most efficient and cost effective design concept for the TMF. However, it may be necessary to utilize earth/rockfill materials in the initial years of operations to accommodate any shortfall of cyclone sand availability for construction of staged embankment expansions. Embankment staging, sand cell construction sequencing and integration with rockfill placement schedules (if required) will need to be examined in more detail for future design studies. Suitable earth/rockfill materials may also be required to provide erosion protection and minimise dusting for the cyclone sand embankment, and to satisfy embankment stability requirements. Use of cyclone sand as embankment fill reduces the amount of solids that are stored within the TMF by a volume roughly equivalent to the volume of sand used for construction. This allows for either additional storage capacity or a reduced embankment height.



It is noted that the potential cost advantage for cyclone sand is sensitive to assumptions relating to the cost of using local borrow (rockfill) material as an alternative embankment construction material. In particular, if rockfill haulage costs are reduced by implementation of efficient material delivery systems and/or borrow locations that shorten the overhaul distance to the TMF embankment, then the cost advantage for the cyclone sand construction method may be less. It will be important to evaluate potential local borrow alternatives in conjunction with the cyclone sand option.

SECTION 7.0 - CERTIFICATION

This report was prepared, reviewed and approved by the undersigned.

TABLE 1.1

WESTERN COPPER CORPORATION
CASINO COPPER-GOLD PROJECT

SUMMARY OF DESIGN BASIS AND CRITERIA

Print Jun/15/10 11:54:43

ITEM	DESIGN CRITERIA
1 MINE PRODUCTION	
Ore Production	• Total Ore Milled = 980.3 Million tonnes (Mt) • Total Ore Milled - Expansion Case = 1,200 Million tonnes (Mt) • Throughput = 100,000 tpd • Mine Life = 28 years • % Concentrate = 0.6
2 WASTE ROCK	
Waste Rock Production	• PAG & ML waste rock produced from Year -1 to Year 23 • Subaqueous disposal within TMF • Total PAG & ML material produced = 837.6 Mt • Total PAG & ML material produced - Expansion Case = 1,035.7 Mt • Total non-PAG & non-ML material produced from oxide cap (used in starter embankment shell zone) = 8.6 Mt • 2.0 t/m^3 - in situ average density (estimated)
3 TAILINGS	
Local Borrow Materials and Cyclone Sand Options	• 974.4 Mt tailings storage • 1,192.8 Mt tailings storage - Expansion Case • Two tailings streams ◦ 95% bulk tailings (non-reactive) ◦ 5% pyritic tailings (discharged separately) • 1.2 t/m^3 - in situ average dry density for Years 1 to 2 (estimated) • 1.3 t/m^3 - in situ average dry density for Year 3 (estimated) • 1.4 t/m^3 - in situ average dry density for Years 4 to 28 (estimated)
Dewatered Tailings Option	• 90% of tailings dewatered and placed in Dry Stack facility ◦ 1.8 t/m^3 - in situ average dry density for Years 1 to 28 (estimated) • 10% of tailings stored in Potentially Reactive waste facility (5% pyritic tailings, 5% filtered tailings) ◦ 1.4 t/m^3 - in situ average dry density for Years 1 to 28 (estimated)
4 CYCLONE SAND	
Cyclone Sand Option	• 35% of bulk tailings solids assumed produced by cyclone sand plant as sand fill suitable for embankment construction (based on expected tailings particle size distribution) • Cyclone sand production begins in Year 1. • Cyclone sand production for average 9 months per year. • Cyclone sand plant availability is 90%, during 9 month period. • Compacted cyclone sand dry density = 1.6 t/m^3.

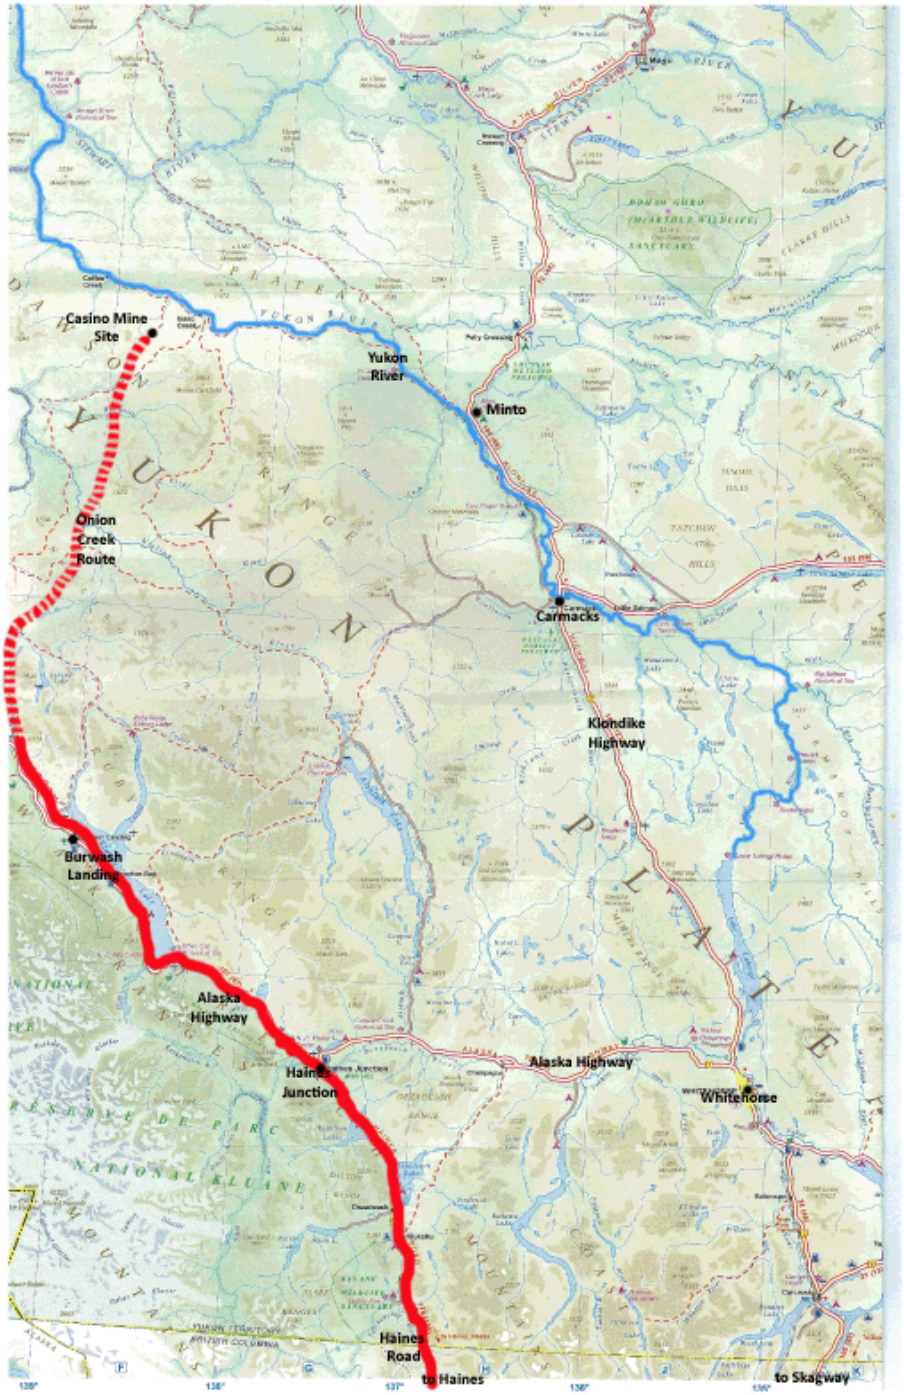
Executive Summary

1 OVERALL FINDINGS

This report is a scoping and pre-feasibility study to examine transportation options for concentrate from the proposed Casino Mine in the Central Yukon to a deep-sea port. The Mine expects to produce about 250,000 tonnes of dry copper concentrate per annum during its 25 years of expected life. It is also expected that about 75,000 tonnes of supplies will need to be hauled into the Mine each year. The distance from the Mine to tide water is approximately 600 km, depending on the chosen route and port site.

A review was done of five transportation modes which showed that trucking will provide the most convenient and cost-effective modes for transportation.

An analysis has been undertaken of seven alternative routes for an all-weather road access to the Mine capable of operation throughout the year. The analysis included consideration of the Ports of Skagway and Haines as sea-water ports for the Mine.



It has been concluded that Haines will likely to provide the most advantageous port for both concentrate exports and mine supply imports. A trucking route using Onion Creek and the Haines Road will provide the most economic alignment in terms of haul distance, road construction costs and terrain traveled.

The recommended route, shown in Figure ES 1, will follow the existing winter road south of the Mine, across the Nisling River Valley and the south along Onion Creek to the Alaska Highway north of Burwash Landing. This will require construction of 187 km of new mine haul road. The route would then follow south on the paved Alaska Highway and Haines Road for 408 km to Haines.

It is expected that the cost of construction of the mine haul road will be $91M in year 2007 dollars and that it will cost about $2.5 M per annum to maintain. The land transportation costs of transporting concentrate out from the Mine to the Port of Haines and transporting supplies from the Port into the Mine will be $156/tonne in net present value terms. For purposes of this evaluation it was assumed that B-train dump trucks would be used to haul concentrate outbound and standard Tridem trucks would be used to haul supplies inbound. This cost will fall to $114/tonne if coal is added as a backhaul to the transportation logistics.

The economic cost of hauling concentrate to the Port of Haines on the Onion Creek Route was further analyzed with a back haul of coal. This analysis, along with other economic assessments and major assumptions, are discussed in Chapters 6 and 7. No consideration at this time has been made of the shipment from the Port of Haines to an oversees smelter, likely to be located in east Asia.

Figure ES-1
Recommended Onion Creek Route from Casino Mine to the Alaska Highway and then south on the Haines Road to Haines

2 ALTERNATIVE TRANSPORTATION MODES

Chapter 2 of this study considers five modes of transportation:

- Barge
- Pipeline
- Rail
- Air
- Truck

It was concluded that trucking presents the most reliable means of transporting concentrate and supplies to and from the Mine. All the modes noted above would require some form of road access. Trucks can operate in all seasons and in extremely cold conditions that can be expected at the Casino Mine and on the Klondike Plateau. The main focus of this report therefore has been on trucking and truck routing.

3 TRUCKING CONSIDERATIONS

North America's large trucking industry has developed the ability to function in extreme weather and terrain conditions. Concentrate can be transported by several different haulage methods:

- Side –dumps trailers (b-trains or tridems)
- Bulk tank trailers
- Standard Containers on high-boy trailer
- Heavy-duty plastic bags on high-boy trailers

Chapter 3 of the report addresses a number of trucking considerations and reports on the existing Yukon Infrastructure, including construction and maintenance requirements. An all-weather road with a properly designed gravel surface can be maintained for a high level of operation throughout the year, except with the possibility of load restrictions during spring thaw. Winter operations will require a strict program of road maintenance, including stockpiling of sand in order to maintain optimum truck turn-around times. Routes through mountainous conditions will require more road maintenance, and may have to be closed during extreme weather conditions when truck haulage may not be possible.

4 CANDIDATE TRUCK TRANSPORTATION ROUTES

The alternative truck transportation routes are shown in Figure ES 3, the map titled "Road Transportation Corridor Options" and further detailed in Chapter 4. They are based primarily on 1:50,000 contour mapping with 50 m contour intervals and an understanding of the terrain gained from a brief over-flight of the routes. The road corridors where plotted on the map taking into consideration the observed soil conditions and road gradients. This data can be seen on the spreadsheets entitled "Estimated Site Conditions" in Appendix B. The "Estimated Site Condition" data sheets also give assumed road gradients for both favourable and adverse hauls. The truck haul times (Truck Turn Around times) was based on this information.

The road and earthwork quantities together with the construction cost estimates are shown in Appendix C. They were based on the terrain information and typical road cross sections shown in Appendix D.

Seven candidate routes have been studied for possible access of an all-weather road from the mine site to the Yukon highway system. Chapter 4 describes these corridors in more detail. These routes are illustrated on Figure ES-4 and Figure 4.1 and are shown in more detail in Appendix 1. Each route was considered with a port destination of Skagway and Haines; the “a” routes are to Skagway and the “b” routes are to Haines.

- Route 1 - Onion Creek
- Route 2 - Aishihik Lake
- Route 3 - East Route
- Route 4 - Wolverine Creek
- Route 5 - Klaza River
- Route 6 - Yukon River
- Route 7 - Hayes Creek

The overall transportation characteristics of each route are summarized in the Figure ES-2 below. This table does not take into account the backhaul of coal. Figure ES-2 is further expanded in Figure ES-3 which shows the transportation costs for concentrate haul to the port and the costs of backhauling both coal and mine supplies. The truck operating considerations and the trucking cost analysis are described in Chapters 5 and 6.

Based on available information, Route 1,Onion Creek Route, appears to provide the lowest road construction costs, and the lowest over all transportation costs to both the port of Haines and Skagway. This route along with the Route 4, the Wolverine Cr Route is reported as likely to present the least difficulties in permitting.

The present value cost of the Onion Creek to Haines route is $53 million less than the next best option, the Onion to Skagway route. The other candidate routes have significantly higher costs.

Figure ES 2
Summary of the Costs of Mine Road Routes and Truck Haulage without Coal Back Haul

Route #	Route Name	Distance of New and Upgraded Road (km)	Estimated Cost of Construction ($M)	Land Transportation Cost per tonne of haulage to HAINES ($)	Land Transportation Cost per tonne of haulage to SKAGWAY ($)
1	Onion Creek	187	91	156	173
2	Aishihik Lake	323	106	170	174
3	East Route	280	107	216	174
4	Wolverine Creek	138	154	221	177
5	Klaza River	273	169	228	186
6	Yukon River	205	189	246	202
7	Haines Creek	210	193	273	193

5 PORT CONSIDERATIONS AT HAINES AND SKAGWAY

Skagway or Haines are the only practical terminals for concentrate shipments from Casino Mine. The characteristics of these two ports are analyzed in Chapter 7. Skagway offers an existing operating concentrate terminal albeit with shared use capacity limitations. The land cost transportation to Skagway is estimated to be $53 million higher than to Haines. Pilotage, tug assistance, and ship operating costs are likely to be similar at Skagway and Haines. Haines offers the possibility of a dedicated terminal and upland areas although these will have to be developed for use by the Mine.

Both Skagway and Haines appear to have facilities able to receive and ship both inbound mine supplies and outbound concentrate shipments. Haines appears to offer the closest port and the best flexibility for port development by the Mine for their terminal requirements.

6 RECOMMENDATION

The results of this scoping study show that the Onion Creek route to the Port of Haines provides the most economical and flexible options for truck routing and port facilities.

In order to confirm the suitability of the Onion Creek routes, road construction and land transportation cost assumptions will need to be confirmed. Similarly a terminal facility at Haines will require further investigation. This will include conceptual site development plans, order of magnitude development costs and capacity assessments for bulk shipping. Further investigations will also be required to confirm the location of the overseas smelter as the destination for the concentrate. This will allow the cost of shipping to be included in the overall transportation costs. Similarly, if coal is to be transported inbound to the Mine, an understanding of the origin

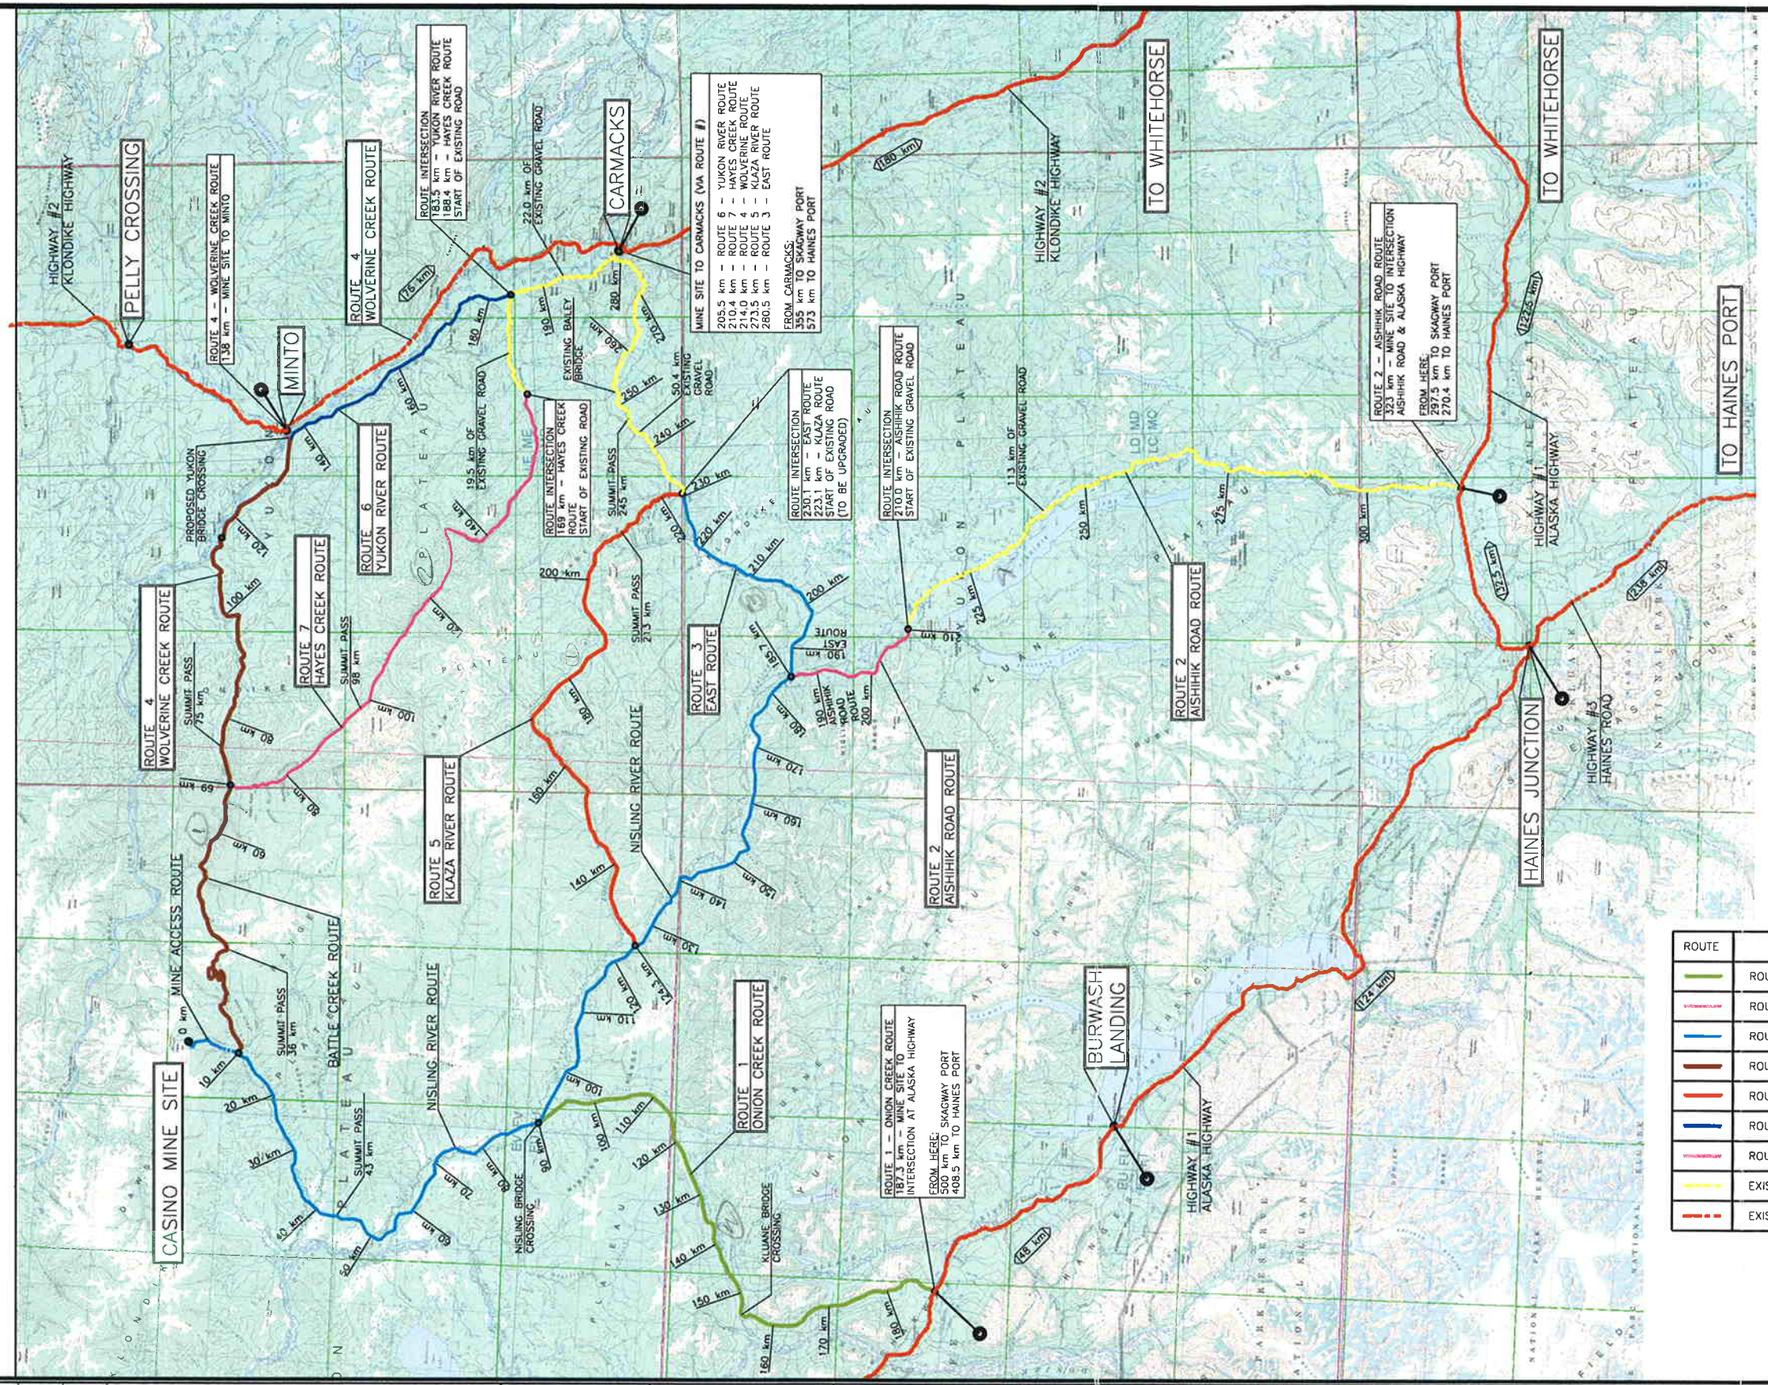


Figure ES-3
Summary of Transport Costs

Description	Side Dump Trucking $/Year Concentrate	Side Dump Trucking $/Year Coal	Tridem Trucking Supplies $/Year	Road Maintenance $/Year	Concentrate Terminal Charges $/Year	Coal Terminal Charges $/Year	Total $/Year
1. 275,000 Tonnes Wet Concentrate	$25,286,250			$2,511,387	$2,750,000		$30,547,637
2. 275,000 Tonnes Wet Concentrate plus back haul coal	$13,772,000	$13,772,000		$3,139,234	$2,750,000		$33,433,234
3. 75,000 Tonnes from Haines incremental cost			$7,902,750				$7,902,750
4. 75,000 Tones of supplies from Whitehorse incremental cost			$6,621,000				$6,621,000

Note: The shaded portion of the table provides costs for the Onion Creek Route for both concentrate hauling to the Ports of Skagway and Haines using B-Train Side Dump Trucks, and backhauling of coal to the mine. All the other route costs do not include the backhauling of coal.

1 Transportation Requirements for the Casino Mine Project

The Casino Mine expects to produce about 250,000 tonnes of dry concentrate per annum over an expected Mine life of 25 years. If this was to be increased by 10% to allow for the bulking of moist concentrate, this will result in an annual haul of 275,000 tonnes and a daily shipment of 820 tonnes per day, which will have to be moved from the Casino Mine site. It is estimated that approximately 75,000 tonnes of mining supplies and provisions will have to be hauled into the Mine every year.

The Mine site is about 190 km west of Minto along the Yukon River. The approximate elevation of the Mine is 1,400 m and is on the west side of the Dawson Range. The Dawson Range, with peaks above 2,000 m, runs NW to SE, west of the Yukon River.

Figure 1-1
Yukon Highway System

2 Methods of Transporting Concentrate

There are five possible methods of transporting concentrate to a tidal port.

- By barge along the Yukon River;
- By concentrate pipeline to a trans-shipment point;
- By rail if the Alaska-Canada Rail Link is built;
- By air using heavy-duty transport aircraft; and
- By truck along a specially prepared gravel mining road and paved Yukon highways.

The following is a description of each method and its application to the transportation requirements of the Casino Mine. The first three methods present logistical challenges and are costly to implement and to operate. Trucking would provide the Mine with the flexibility and versatility, despite the long length of the haul to the port.

2.1 CONVENTIONAL TUG-AND-BARGE OR SELF-PROPELLED BARGE ON THE YUKON RIVER

The Yukon River was used as a transportation route by steam paddle-wheelers during the 1890s and the early part of the 20th century. There were more than 20 steamers operating this route in the late 1890s. The reported travel time was 36 hours from Bennett Lake to Dawson City, a distance of 600 km. The return journey against the fast-flowing Yukon River current took nearly 5 days. The Yukon River, in the late summer and early fall, flows at approximately 60 m/s (in excess of 10 knots). This is a strong current even for modern barge traffic.

The Yukon River, over the section between Bennett Lake and Minto, had two tricky rapids to negotiate. The first was at Whitehorse, where travelers had to walk while the ferry captains negotiated the rapid. A hydro-electric dam has been built at this location, thus blocking the river for navigation between Bennett Lake and Whitehorse. The second set of rapids, the “Five Finger” Rapids, is between Carmacks and Minto, and was the site of a number of steam paddlewheel ferry mishaps in the early 1900s. There are unconfirmed reports that some of the rocks in the rapid have been removed by dynamiting but there remains a steep drop in the river at this point.

The River flows ice-free for four months between June and October. It is often possible to build an ice bridge across the River from late November until March. The ability to build an ice bridge varies from year to year and this appears to have been the case from the 1890s until the present. Severe ice flows are often present in the River in April and May, preventing River traffic.

If barges are to be used to transport concentrate, there are a number of restrictions:

- The River is only open to barge traffic for four months – June to October;
- The River current is very strong and tugs would require large engines;
- The Five Finger Rapids and other rapids may still present an obstacle; and
- Sandbars and shallow channels, especially in reaches of the River downstream from the Mine.

It is conceivable that barges could be used to transport concentrate along the Yukon River for 160 km, from Britannia Creek (approximately 20 km north of the Mine) upstream to Minto, where it could be transferred to trucks for transport along the Klondike Highway to Skagway. The River between Britannia Creek and Minto appears to be deep enough for barge traffic and there are no known rapids. Barges could also travel to a truck trans-shipment point at Carmacks or Whitehorse.

Barges can be pulled by tugs that require up to 4 metres of draft. Barges can also be self-powered and can operate in water depths of 3 metres. Utility barges can hold up to 1,000 or 2,000 tonnes and one tug could pull several barges at the same time.

It is also conceivable that barges could be used to transport concentrate from Britannia Creek downstream to Dawson City or to further transhipment points. It may also be possible to barge to the mouth of the Yukon River and beyond. Barging to Dawson City or further west and then transferring to a truck would involve a very long truck haul to a seaport. Barging to the mouth of the Yukon River would be difficult due to sandbars in the river and due to the shallow seabed at this point in the Gulf of Alaska. The shallow seabed will make it difficult for access to concentrate carriers. The possibility may also exist of barging all the way to the location of a smelter in Eastern Asia but utility barges of 1000 to 2000 tonnes are small for ocean travel..

Concentrate could be carried to a Britannia Creek barge port by pipeline or truck. It is likely that a slurry pipeline would be a preferred means of transportation since a winter road along Britannia Creek would be extremely steep, with grades in excess of 15%. A concentrate shed would have to be built at the barge port to store concentrate for at least 8 months of the year. This shed will have to store up to 250,000 m3 of concentrate, and would be susceptible to contamination. Furthermore, by this method, a large fleet of barges and trucks would only be operational for 4 months of the year.

Operational supplies would still have to be transported to the Mine by some means – either by a winter road or by air. Both these operations are costly and dependent on weather. This would limit the flexibility of the mining operation and would add to the costs of transportation.

Barging is not considered a feasible option for Casino Mine, owing primarily to the limited barging season and the difficulties of operating on the Yukon River. One of the advantages of using barges is that their means of travel does not need infrastructure. However, for Casino Mine, barging will always have to be undertaken in conjunction with road, pipeline or air transportation which will offset any cost advantages of barging.

2.2 HOVER BARGE

Hover barges have been used in the past on the Yukon River. Two hover barges pulled by a cable, with a payload capacity of 160 tons, provided round the clock, roll-on, roll-off, ferry crossing services during the construction of the Trans Alaskan pipeline project in the late1970s. Operating in sub-zero temperatures, over 100,000 tons of equipment was shipped per month. The two "Yukon Princesses" (illustrated on Figure 2.1 below ferried trucks across the Yukon River to support construction of the pipeline. The barges were prefabricated and assembled on site in 10 weeks. At the location needed for the pipeline, high current speeds, winter ice and fluctuating water levels precluded the use of a conventional cable ferry. Each barge had two 700 hp engines driving air fans. Pulled by a cable, a crossing of 1.6 km took 20 to 30 minutes.

Hover barges do present an alternative to a bridge over the Yukon River but to operate along the River for any distance presents propulsion challenges. Owing to their weight, size and shape, hover barges are not able to navigate themselves. They require a cable in order to cross rivers or inlets. Redfern Mine in Northern BC is proposing to use an amphibious tug to tow a hover barge. This tug cannot operate in winter and has a crawler arrangement to travel over sandbars and stretches of shallow water which raises environmental concerns. The hovering mechanisms are known to be mechanically unpredictable and fuel consumptive.

For the same reasons as described above for conventional barging, hover barging is not considered a feasible option for Casino Mine. The main rationale for considering a hovercraft is that it can navigate over ice, sand and swift flowing rivers. The need to propel the hover barge by some conventional means limits its year-round usefulness and negates its hovering properties.

Figure 2-1

2.3 CONCENTRATE PIPELINE

Concentrate pipelines are becoming more common in the mining industry, and their operating characteristics are becoming better understood by mining companies. The constitution of the slurry depends on the type of rock that is milled, together with its abrasive properties. Most slurry pipelines operate under gravity, with pump stations only for emergency use. Problems are reported with pipelines operating in extremely cold conditions, but this can be overcome by heating the slurry.

It is conceivable that a slurry pipeline could be built from the Mine due north to a barge port on the Yukon River at Britannia Creek, a distance of about 20 km, as discussed above.

The second concept would be to carry concentrate in a pipeline to Minto or Carmacks, a distance of 200 or 300 km, and then trans-ship to a truck for transportation to Skagway along the Klondike Highway. This could be a year-round operation. It would be susceptible to freezing, and would require a holding shed and a pipe bridge across the Yukon River.

The construction of a concentrate pipeline also involves the construction of a road for purposes of pipe and pump station supply, pipe assembly and regular maintenance. Concentrate pipelines usually require an additional water pipeline for the return of slurry water to the mill. A Typical concentrate pipeline costs about $1 million/km and the return water pipeline about $0.5 million/km. Storage tanks would be required at both the mill and the end of the pipeline, and a de-watering tank would also be required at the end of the pipeline. As a rule of thumb, the capital cost of a pipeline is twice the cost of a mine haul road. However, the operation of a pipeline is half the cost of maintaining a truck haul fleet.

2.4 RAIL TRANSPORTATION

Rail is usually the preferred method of transporting bulk cargos over long distances. Rail costs for coal, which is transported across British Columbia, is five times cheaper than by truck. The problem is that a rail line is five to ten times more expensive to build and to maintain. The State of Alaska has recently been studying an Alaska-Canada rail link between Fairbanks and the North American rail network in northern British Columbia. One of the potential corridors for this rail link is the Nisling River between Beaver Creek and Carmacks. This potential project is in the early pre-feasibility planning stage and cannot yet be justified commercially. If such a project was to proceed immediately, it would take eight to ten years to complete.

Construction of the Alaska-Canada Rail Link is not likely to happen immediately, and the possibility of a rail link for future transportation of Casino Mine concentrate is unlikely to materialize during the first part of the Mine’s life.

2.5 HEAVY-DUTY TRANSPORT AIRCRAFT

Heavy-duty cargo aircraft can carry approximately 50 tonnes, which is the same as a highway truck. Concentrate could be shipped in containers or sacks directly from the landing strip at the Mine to a port such as Haines or to an alternative port in Alaska or British Columbia. While this option is feasible, it is expensive. A truck costs approximately $100 an hour to operate, while a Hercules transport plane costs approximately $9,000 an hour. A round trip for a truck to the Mine site is approximately 36 hours, while a round trip for a plane would be closer to 4 hours. Air transportation would be an order of magnitude greater than truck travel. If concentrate was to be carried by aircraft, there would still be a need for a road to transport supplies into the Mine site.

Air transport is unlikely to be feasible for Casino Mine, due primarily to the cost.

Figure 2-2
Existing Runway at the Casino Mine Site

2.6 TRUCK TRANSPORTATION

Trucking presents the most reliable means of transporting concentrate in the Yukon and has been made the focus of this report.

A number of options were investigated for the location of an all-weather road from the Mine site to the Yukon Territory Highway network that would permit truck transportation to either the ports of Skagway or Haines. Truck transportation is flexible and can be undertaken year-round. Concentrate can be carried by truck in a number of different kinds of containers. Different truck/trailer combinations can also be used for standard highway and private mining roads. Road transportation presents challenges in the form of road construction, operation and maintenance.

Overall, North America has a large trucking industry that has learned to adapt to transportation in extreme weather and terrain conditions.

3 Trucking Considerations

A number of possibilities need to be addressed in considering truck transportation.

- How is the concentrate to be carried?
- How is it to be loaded and unloaded?
- Existing Yukon highway infrastructure
- What truck and trailer combinations should be considered?
- What kind of road pavement should be considered?
- Should hauling be undertaken in one stage or several stages?
- What kind of road construction should be considered – winter only or all-season roads?
- What geometry of road should be considered – one-way only or two-way?
- Should the Mine be considering a private or a public road and the likelihood of future reclamation of this road?

Figure 3-1

3.1 HOW IS THE CONCENTRATE TO BE CARRIED BY TRUCK?

There are four haulage methods commonly used by mining companies to transport concentrate by truck:

- By side-dump trailers;
- By bulk tank trailers;
- By standard containers on flat trailers;
- By heavy-duty plastic bags or sacks (tote bags) on flat trailers.

Each of the above methods can carry concentrate so as to prevent any spillage of mineral or potential contaminants. Concentrate shipping companies and smelting companies usually require concentrate to be delivered with a maximum moisture content of 8%. This concentrate texture appears to be almost dry and cannot be pumped as a slurry, so any trans-shipment requires either transferring with loading equipment or adding additional water. Water is bulky and heavy to transport, so the drier the concentrate, the more economical it is to haul. Water mixed with concentrate is often heavily contaminated.

Trucks can operate throughout most weather conditions. In the summer, roads have to be treated with a road salt such as calcium chloride to suppress dust. During winter months, roads need to be kept gravelled to ensure traction. The operating costs for a truck are higher in extremely cold conditions. During the spring break-up, load restrictions apply on all roads and trucks normally can only carry up to 80% of their regulation weight.

The common method of transporting concentrate in North America is with side-dump, B-train truck/trailers. These trailers can be loaded by a conveyor belt or by front-end loader and can be easily dumped within a concentrate storage shed. Trailers can also be fitted to carry containers for the return transportation of supplies to the Mine. The maximum payload for a B-train is 41 tonnes.

Transport by standard steel container can be environmentally secure and is easy to trans-ship. Containers can be transported from a mine and loaded onto a ship and only emptied at the smelter. If the concentrate needs to be trans-shipped to the concentrate carrier ship at a North American port, it can be tipped into the vessel. Container handling has become a highly specialized activity and containers of various sizes can be easily manoeuvred by fork-lifters, intermediate-sized cranes, or derrick cranes. The problem with containers is that each weighs two or more tonnes and this adds to the gross weight of transportation.

A standard container (a TEU or 20-foot equivalent unit) weighs 2.2 tonnes and has approximate dimensions of 8-foot wide, 8-foot high and 20-foot long. It can be easily loaded onto a flatbed truck in a Tridem or B-train combination. It can take a payload of up to 21.6 tonnes. A double container, which is 40-foot long, weighs 3.8 tonnes, and can take a payload up to 26.5 tonnes.

Transportation by plastic bags weighing one or two tonnes is becoming a more common form of trans-shipment. No extra weight has to be carried, as in the case of containers, and the bags can be easily handled by fork-lifters and cranes. The problem with concentrate bags is that they are known to leak and can be punctured during transportation or trans-shipment.

3.2 HOW WILL THE CONCENTRATE BE LOADED AND UNLOADED?

Most spillage and contamination of concentrate occurs at the point of its loading and unloading. The fewer points at which concentrate is handled in its raw state will provide better quality control and environmental compliance.

If concentrate is to be transported by pipeline or a tanker trailer it can be pumped directly from the mill to the pipeline or trailer and then again pumped to a ship or barge. Concentrate in this form generally has a high water content and has to be de-watered before conveyance to an ocean-going ship. This water is often highly contaminated and needs to be specifically treated or returned to the mill.

Loading and unloading of concentrate with a maximum moisture content of 8%, required by concentrate ships, can be handled by loaders, forklift or derrick cranes if it is conveyed loose in a container or in plastic bags.

3.3 EXISTING YUKON HIGHWAY INFRASTRUCTURE

The Yukon is well served with surfaced roads, which traverse the more populated South-Western part of the Territory and provide access to ports in Southeast Alaska. Figure 3-2 shows the road infrastructure of the Yukon in relation to the continental road network. Figure 3-3 illustrates the location of various focal points for the export of commodities in the Yukon, Alaska and Northern B.C. Exhibit 3-4 gives an indication of distances from Whitehorse to ports and centres in the Yukon and Alaska.

Figure 3-2
Infrastructure in Western Canada and Alaska

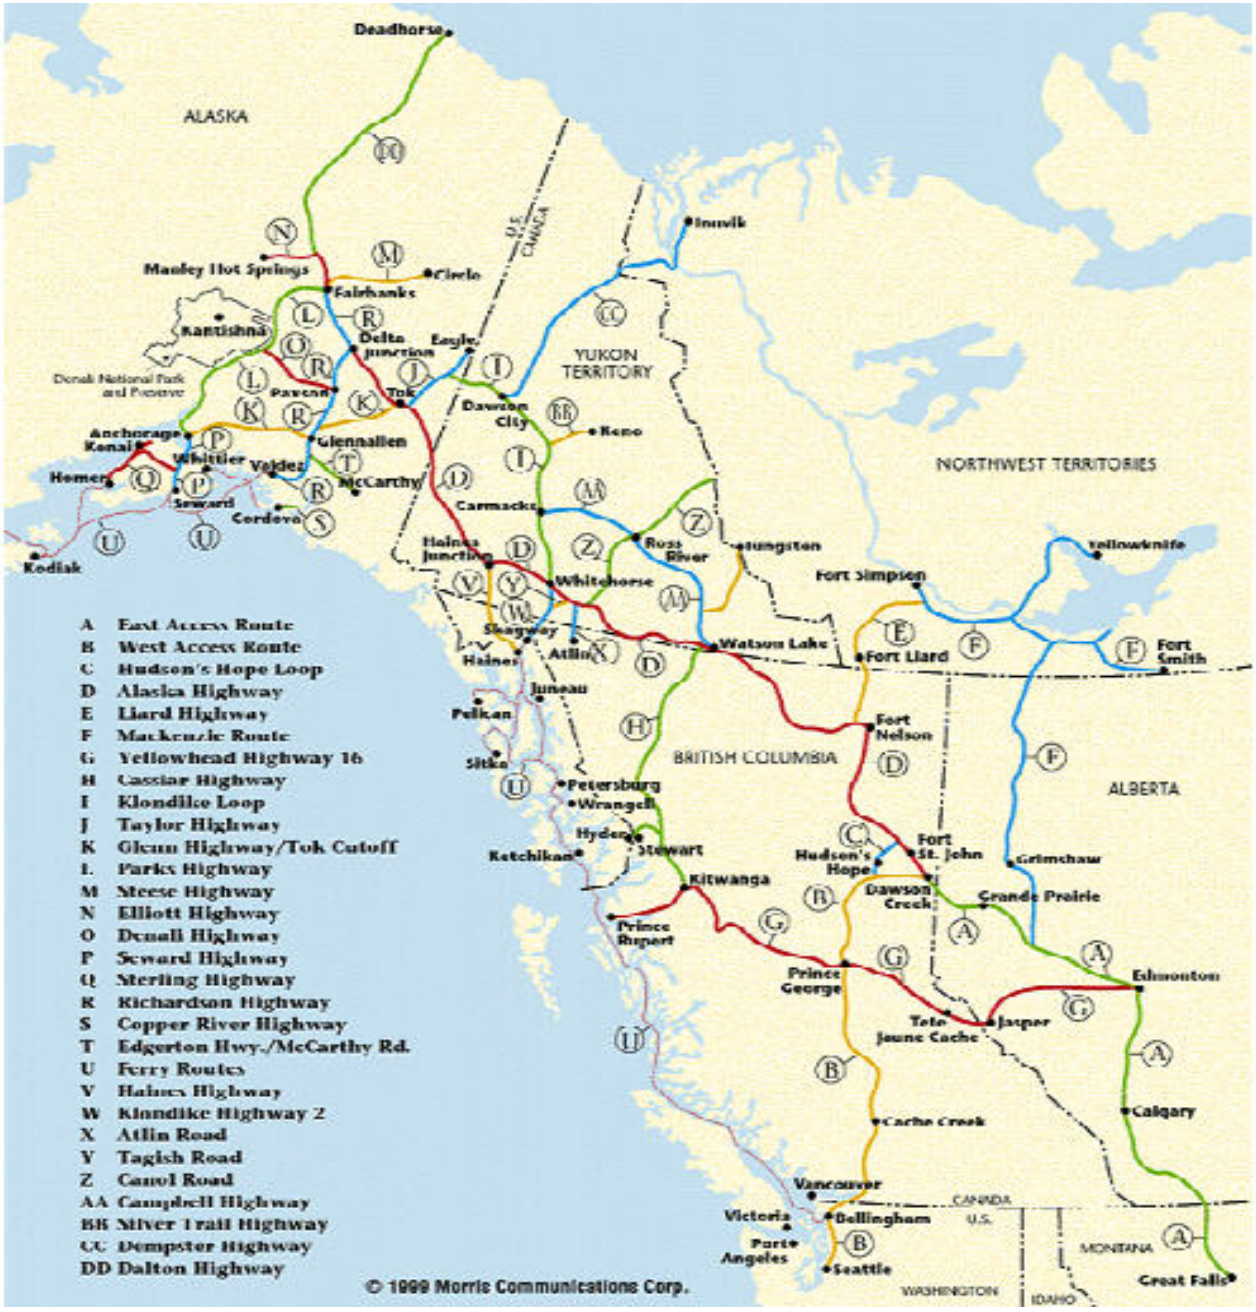

Figure 3-3
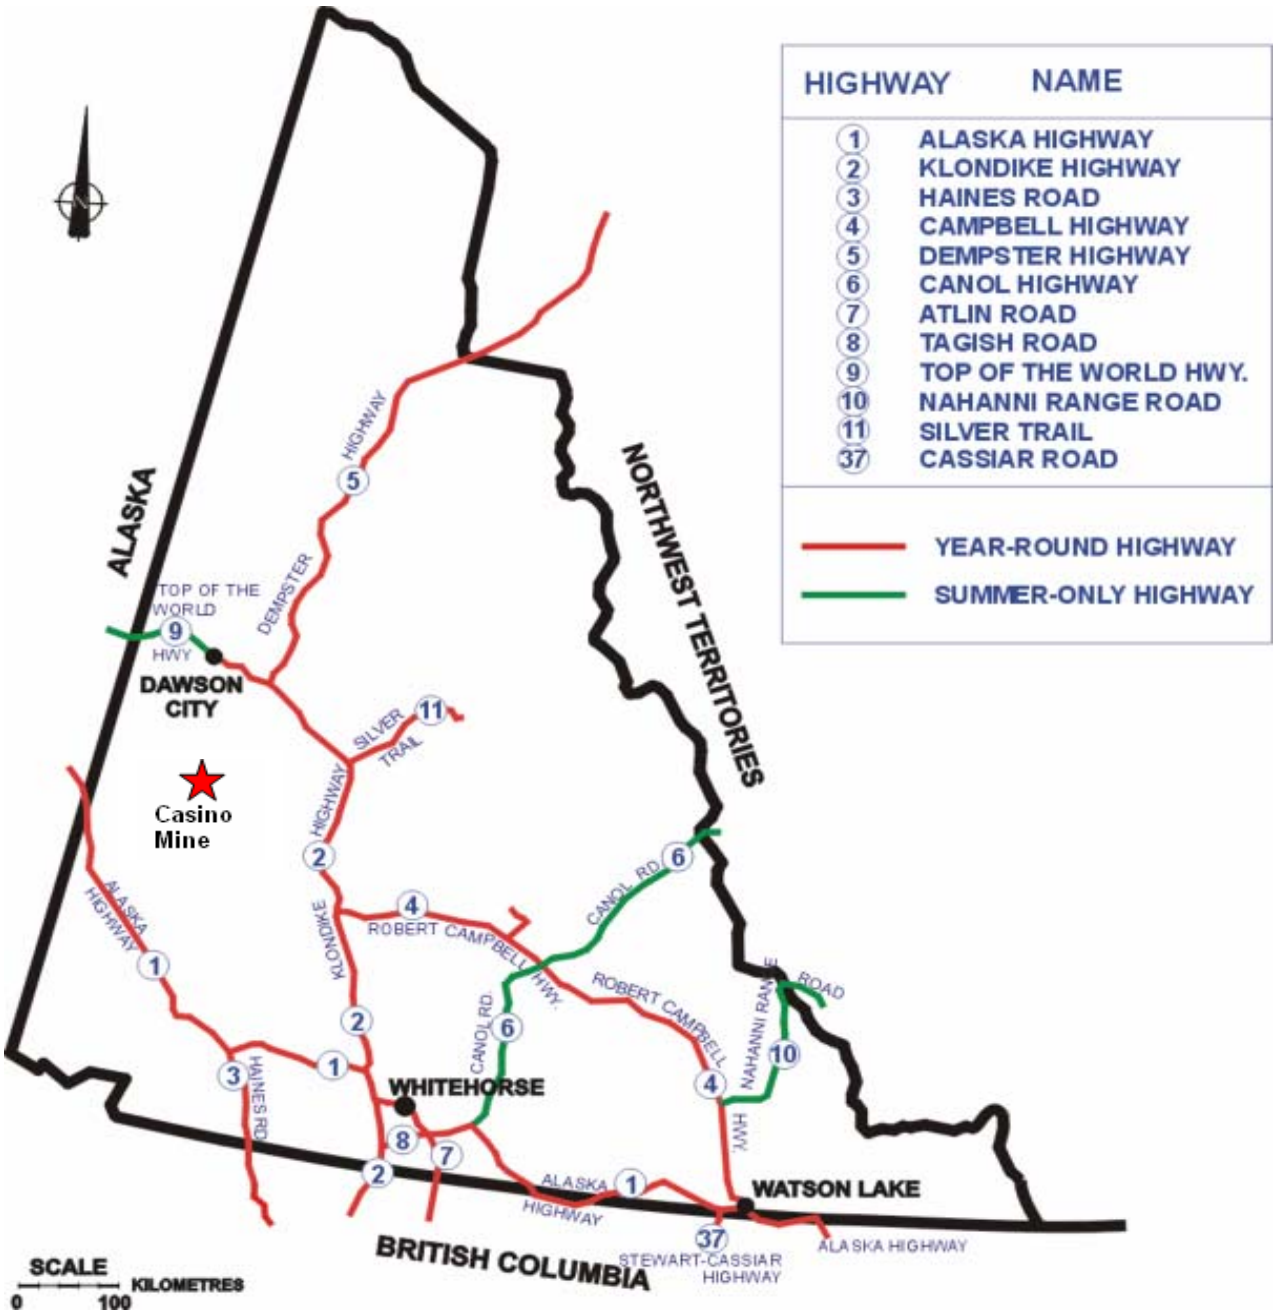
Focal Points for the Export of Commodities

The main highway across the Yukon is the Alaska Highway, which originates in Dawson Creek, BC and runs for 909 km through the Yukon from the BC border east of Watson Lake to the interior Alaska border at Beaver Creek. The Klondike Highway follows the old gold-rush trail from Skagway through Whitehorse to Dawson City. Whitehorse is the centre of travel in the Yukon. The following table summarizes distances to the nearest ports and centres from Whitehorse1, indicating the remote nature of the Yukon.

Figure 3-4
Distances from Whitehorse



Principal Ports	Distance (km)
Skagway, AK	177
Haines, AK	396
Stewart, BC	1,050
Prince Rupert, BC	1,438
Seward, AK	1,234
To Other Northern Centres	
Fairbanks, AK	951

Carmacks	176
Watson Lake	453
Dawson Creek	1,426
Prince George	1,622
Inuvik	1,222

3.4 TRAFFIC LEVELS ON YUKON HIGHWAYS

Yukon Highways are illustrated on Figure 3-5. The Alaska Highway and the Haines Highway were built in 1943 as military pioneer roads. They were improved as gravel roads during the 1950s and substantially upgraded in the 1980s. These two principal highways are well-paved and well-maintained. They carry a small amount of traffic compared with provincial highways in BC and Alberta. The highest vehicle movements are within the Whitehorse area, between Whitehorse and Skagway and between Whitehorse and Haines Junction. In 2005 the annual average daily traffic (AADT) on the Alaska Highway was approximately 500 vehicles per day, rising to 800 during summer months (SADT). This compares with AADT of 1350 and an SADT of 1820 on BC Highway 16 at the Highway 37 junction.

The highway from Haines to Interior Alaska is the main connection from Fairbanks to Juneau and Seattle by way of the Alaska ferry service (the Alaska Marine Highway). Relatively few vehicles use this highway, which in 2005 averaged 188 vehicles per day during the summer and 112 vehicles per day over the rest of the year.

Figure 3-5
Yukon Highways

The Klondike Highway between Skagway, Whitehorse and Dawson City, is built to the same standards as the Alaska Highway and Haines Road. South of Minto it carried an average of between 200 and 400 vehicles per day in 2005, with 400 to 600 per day during summer months. The Dempster Highway, a gravel highway of over 1,000 km, carries only 100 vehicles per day on average, and 180 vehicles per day during summer months.

The capacity of a rural highway varies with its distance from major cities and the desired speed. A Yukon highway with an operating speed of 110 km/h would have a capacity of approximately 8,000 to 10,000 vehicles per day for a Level of Service C. This would indicate the consistent presence of short convoys of vehicles at any given point and the continuous need for overtaking.

The traffic on most highways in Canada has been growing at 2% per annum over the last 20 years. In the Yukon, traffic was declining at the turn of the century due to decreased economic activity and decreased tourism. Traffic in 2005 was between 5 and 10% less than in the year 2000. This may have reversed between 2000 and 2007 with renewed mineral activity.

3.5 PAVEMENT STRENGTH OF EXISTING HIGHWAYS

All principal roads in the Yukon have been designed to withstand standard highway loading based on approximately 2000 standard truck movements per day. A standard highway truck illustrated in Figures 3-6 and 3-7 is a semi-trailer with three axles and gross vehicle weight of 40 tonnes with a wheel base of 22.7m. At present, approximately 5% of the traffic on Yukon Highways (approximately 60 trucks) use the Alaska Highway per day. Most of these trucks are carrying goods for the re-supply of Yukon and Interior Alaska communities.

A representative pavement section on the Haines Highway is reported in “Status of Reconstruction” – Public Works Canada 1992, and consists of:

- Bituminous surface treatment
- 150mm base course
- 250mm sub-case

This section of the Highway, which was reconstructed in 1989/1990, was assumed the start of the current design life. On assessment the design life of the Highway compared the number of Equivalent Standard Axle Loads (ESALs) with the number to which the pavement is assumed to have actually been subjected based on the traffic volumes estimated to have used the road. The conclusion reached is that In fact, the Government of the Yukon is planning to repave both the Alaska and the Haines Highways in the next 5-10 years.

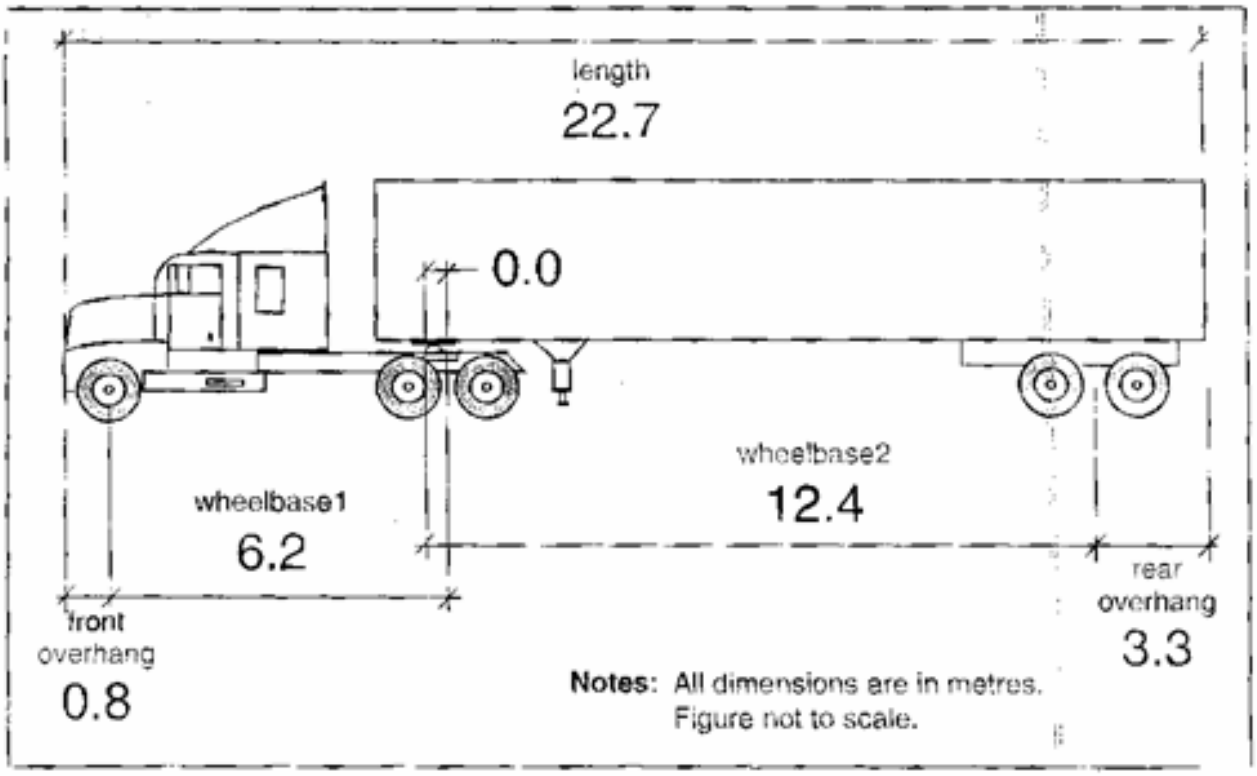
All Yukon highways are subject to load restrictions during the spring thaw period, when the surface layers of a highway do not have the same strength as when they are either frozen or completely thawed. This period can last for six to eight weeks between April and June, and most trucks are only allowed a gross vehicle weight of 20% of the maximum axel loading.

There is evidently sufficient capacity on Yukon highways to accommodate three to five times more vehicles than the current traffic levels. If the number of trucks using these highways is to increase substantially, or if this load class of truck is to increase, the pavements will have to be strengthened and climbing lanes added on steep gradients.

3.6 WHAT TRUCK AND TRAILER COMBINATION CAN BE CONSIDERED?

For reference, the following diagrams of standard highway trucks have been taken from the Geometric Design Guide of Canadian Roads by the Transportation Association of Canada. The maximum truck axle loading is 80 kN (18,000 lbs) and its allowable gross vehicle weight (GVW) is 63 tonnes.
A semi-trailer (or tridem) combination, the most common configuration on North American roads, is illustrated on Figure 3-6. It is a versatile transporter for carrying all kinds of commodities including bulk cargoes and supply components. Due to axel load considerations, it can carry a maximum payload of up to 32 tonnes.

Figure 3-6
Dimensions of a WB-20 Tractor-Semi-Trailer (or a 3-Axle Tridem Truck)



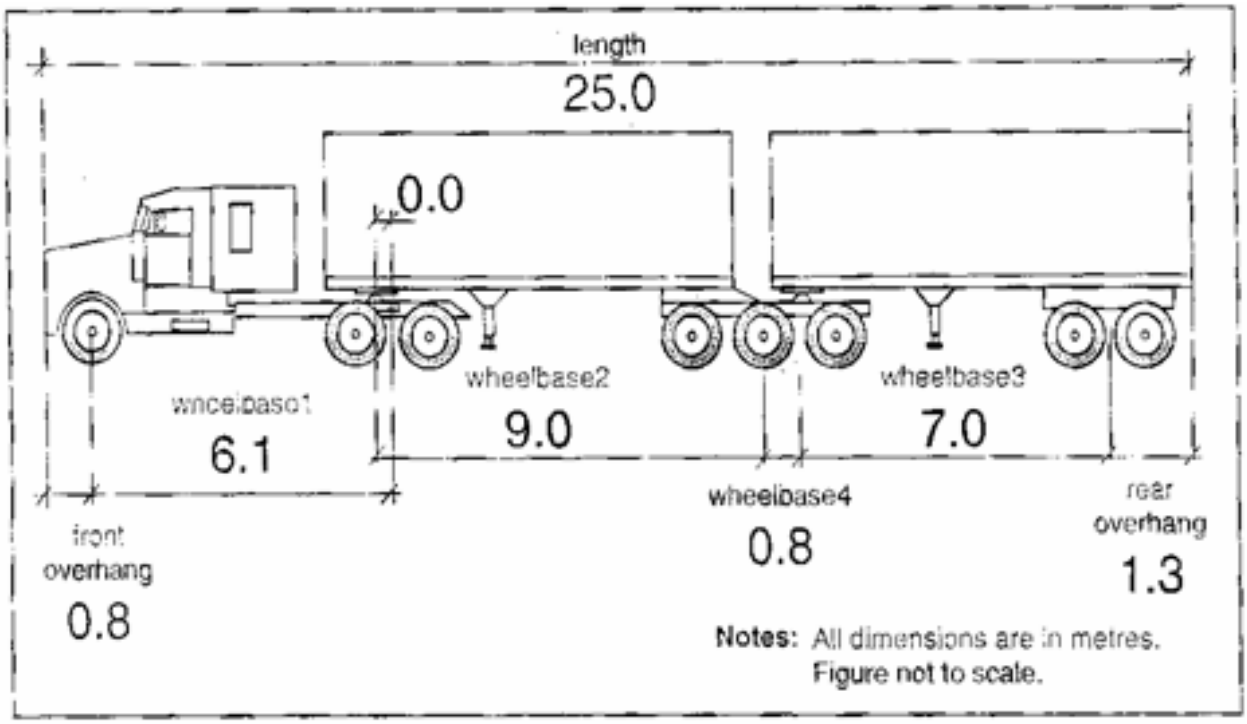


Figure 3-7
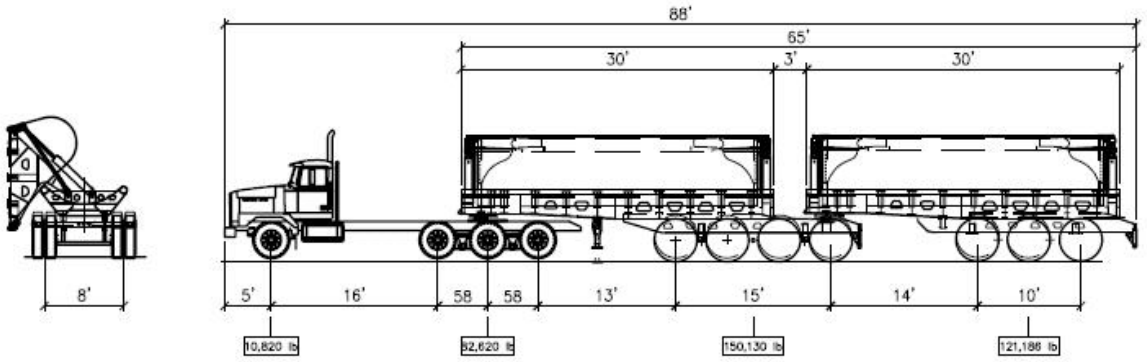
B-Train Double (BTD) Dimensions



Note: Fifth wheel offset set to zero to yield the maximum swept path in a turn.

A B-Train combination is illustrated on Figure 3-7. This configuration, with flatbed cargo compartment or side-dump trailers, is similar to a typical ore-bearing truck design vehicle used in Northern Canada and in the State of Alaska. It is subject to the same GVW and axle loading on public highways as the semi-trailer. Its additional axle allows it to carry up to 41 tonnes of payload depending on its tire arrangements.

On off-highway conditions, as on private mining roads, the B-Train, illustrated on Figure 3-8, can carry up to 150 tonnes (200 US tons) of concentrate. The problem with operating such large trucks is that they are usually purpose-made by only a few suppliers. It would usually require a mining company to purchase these trucks or require an operating company to purchase them as part of a long-term trucking contract. Trucks that are permitted for Yukon and Alaska Highway use are easily available in a competitive trucking industry and truckers can be readily hired to undertake the transportation needs of mines.

Figure 3-8
Typical Ore Bearing Vehicle

The B-train arrangement that has been used on the Red Dog Mine since 2004 is illustrated on Figure 3-9. It is reported to operate with gross vehicle weights of 160-180 tonnes and a specially-designed gravel pavement to carry these loads.

For purposes of this scoping study, it has been concluded that the Mine will use trucks that can be licensed on public highways in both the Yukon and Alaska. The economic assessment undertaken in Chapters 6 and 7 has assumed that outbound concentrate trucks will be standard B-train doubles with side-dumping capability and that inbound supplies will be hauled on a standard tractor-semi-trailer truck combination. Oversized trucks were not considered in this study.

Figure 3-9
2004 Red Dog Side-Dump Concentrate Carrier

An illustration of the layout of the Red Dog Haul Road in north-west Alaska is shown on Figure 3-10 below. It is reported to be a two-lane, 9.0m wide gravel road and has been in operation for 15 years. Most of the road is in level terrain but the northern part of the road is mountainous with some fairly sharp curvature and 5% to 6% grades. Much of the terrain south of the Casino Mine is similar to the Red Dog terrain, indicating that similar heavy-haul vehicles could be considered for use as off-highway vehicles.

Figure 3-10
The Red Dog Road and Terrain

3.7 WHAT KIND OF ROAD PAVEMENT SHOULD BE CONSIDERED FOR A MINE ROAD?

The three highways of interest to Casino Mine, the Alaska Highway, the Haines Highway and the Klondike Highway, have all been constructed to full highway strength for vehicles licensed under the Canadian Motor Vehicle Act and licensed in the State of Alaska.

Off-highway trucks can operate on private roads such as mine access roads with a pavement structure consisting of a gravel sub-grade with 1.0 to 1.5 metres of graded gravel surface. The surface is applied with a solution of magnesium chloride to reduce dust.

3.8 WHAT KIND OF ROAD GEOMETRY SHOULD BE CONSIDERED: ONE WAY ONLY OR TWO-WAY?

The construction of mine access roads is a large overhead to a new mine undertaking and has a significant impact on the operation of the mine and on the cost of the mineral.

A mine access road can be built for operating speeds up to 80 kph. This will determine the curvature to be designed for the horizontal and vertical alignment. The width of the road could be 5.0 metres for a one-way operation, which would need to be closely controlled for safety. It could be up to 8.0 metres for a two-way operation.

3.9 WHAT KIND OF ROAD CONSTRUCTION SHOULD BE CONSIDERED?

The Casino Mine could consider an all-weather road or a winter-only road. A winter road would operate for 3 to 4 months (December to March) under freezing conditions. An all-weather road provides a mine with operating flexibility for incoming supplies and outgoing concentrate haulage. An all-weather road with a properly designed gravel surface can be maintained for a high level of operation throughout the year, with only a requirement for load restrictions (80% of regulated load) during the spring thaw. A winter road could only be used for 3-4 months and may be inoperable during periods of temporary winter thaw.

Winter maintenance requires a strict program of weather monitoring, clearing, salting and sanding. Under such protocol, trucks can operate at summer speeds even in extremely cold conditions.

A strictly private road could be developed on the Onion Route or Wolverine Route (see Chapter 4 below) and would be subject to the Mine's de-commissioning plan. A route along Aishikik Lake or along the Nisling River would follow the historic Dalton Trail and could be developed with the Yukon government because of its heritage interest.

The Mine should consider developing an all-season road capable of operating trucks throughout the year and using the most economical route for this purpose. Such a route can be designed for an operating life the same as the proposed life of the Mine and would be de-commissioned when the Mine is closed.

3.10 SHOULD THE ROAD BE PRIVATE OR PUBLIC?

Casino Mine could consider a private or a public road from either the Klondike or the Alaska Highways. A public road could attract public funding for capital and maintenance works but the road would have to be open to the public and to other mineral interests. A private road would be operated only by the Mine and could be gated and used only by Mine vehicles. Such a road would be subject to the same permitting requirements as a public road and may bring greater risk to the transportation operations.

The Mine should pursue an access road in conjunction with the Yukon government. This may provide a cost advantage to the Mine involving shared costs or construction and annual maintenance. If the government wishes to maintain the road beyond the Mine's life, it could assume full ownership at that time.

3.11 SHOULD HAULING BE UNDERTAKEN IN ONE STAGE OR SEVERAL STAGES?

The Mine could consider a single truck haul from the Mine site to the port. The Mine could also operate a 2-stage operation using heavy ore carriers between the Mine site and the Yukon highway system and then transfer loads or trailers to a highway carrier. It could also consider a 2-stage operation involving a standard B-Train truck combination with two trailers on public highways and a C-Train combination with three trailers off-highway. Chilean and Australian companies are known to operate up to five trailers on flat, open terrain.

For purposes of this study, it has been assumed that a one-stage operation will be used and that highway permitted trucks will operate on both the Mine road and public highways.

4 Alternative Mine Road Routes

Exploration mining activities at the proposed Casino Mine Site are shown in Figure 4-1. Seven candidate routes were considered for an all-weather Casino Mine access road. These routes are described briefly below and are illustrated on Figure 4-2. They are summarized with the total haul distances on the table in Figure 4-12. A summary of the estimated construction cost for each route is shown in Figure 4-13. A tabulated description of the physical conditions and gradients of the alternative routes is provided in Appendix B. Preliminary cost estimates for the construction of each of the alternative routes is shown in Appendix C. Typical cross-sections for the Mine access road in various conditions are shown in Appendix D and a socio-environmental map of the central Yukon is shown together with the alternative routes in Appendix E.

It has been noted that the Dawson Range is a major wildlife habitat and that animal migrations will affect the final road alignment. Several First Nations Bands have formed defined relationships with certain mining companies and have established binding agreements. These precedents can be used as reference for future agreements.

Figure 4-1
Present Casino Mine Exploration Site

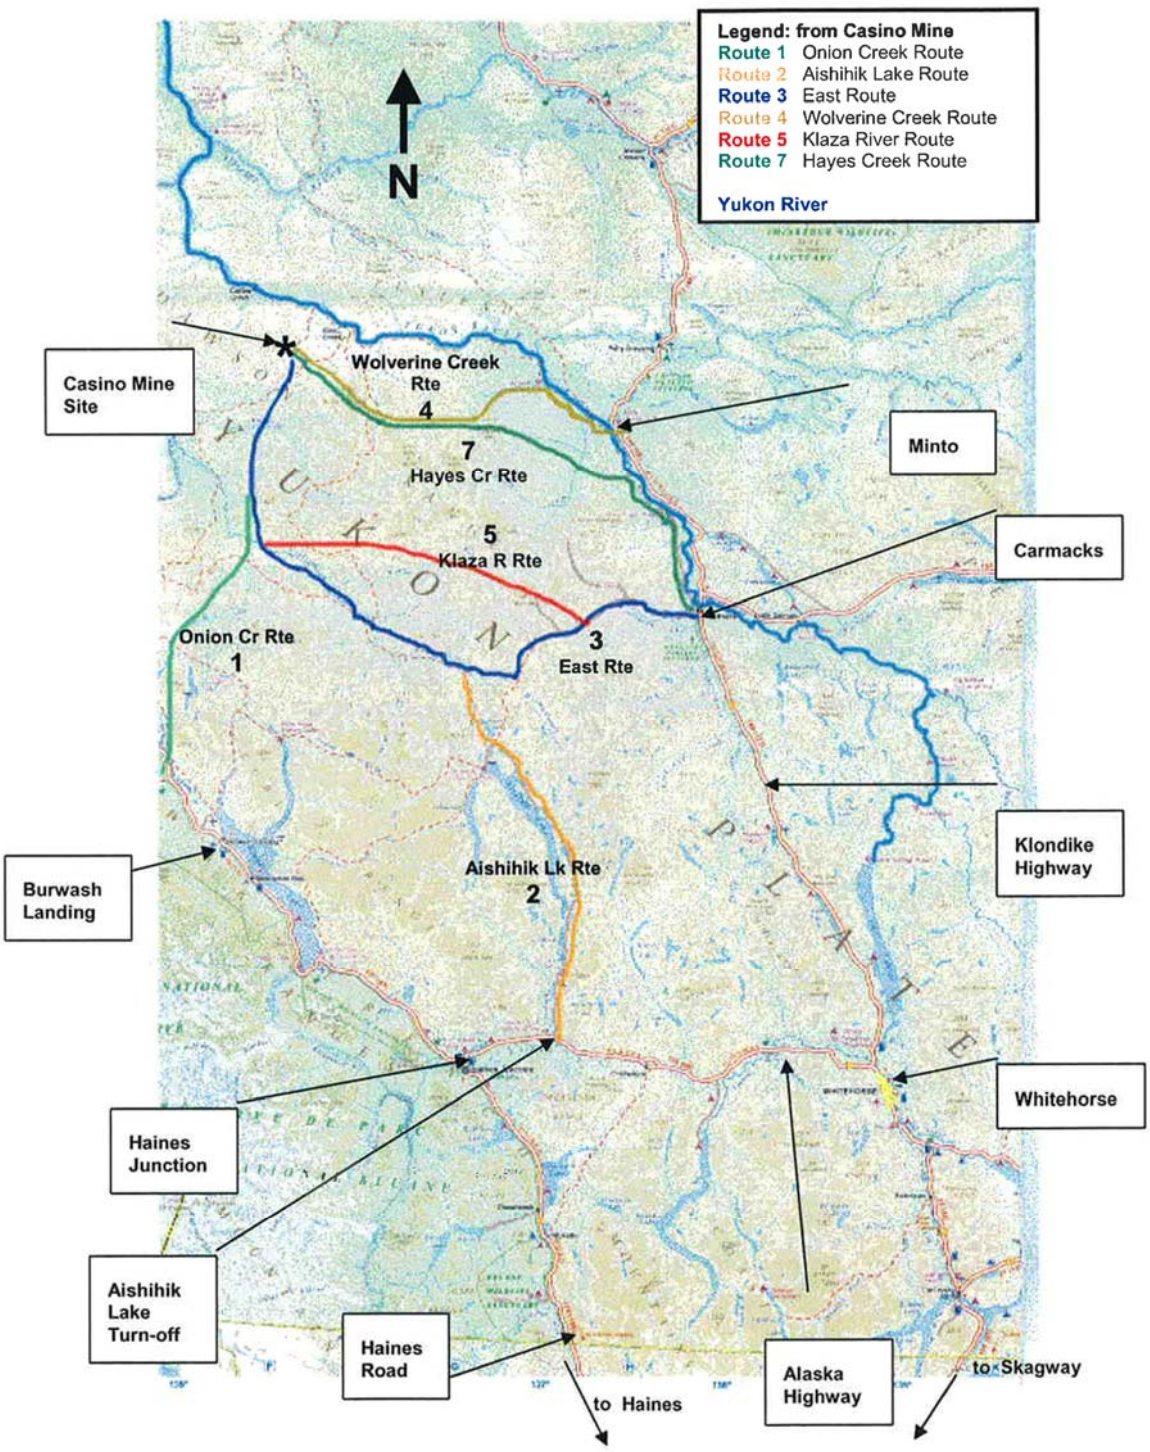
4.1 ROUTE 1 - ONION CREEK ROUTE

There is an existing 190 km winter road from the Casino Mine site to the north of Kluane Lake on the Alaska Highway. This route has been used by Casino Mine for earlier transportation of exploration equipment. It follows a route through the wetland north of the Nisling River Valley. The terrain is mainly flat below the mine site and crosses the large flat valleys of the Nisling and Donjek Rivers before crossing the Nisling Range and the Kluane River.

Much of this route is extremely swampy in the summer and fall, with evidence of large volumes of peat underlying the surface. Such a route makes a good winter road when frozen. It would require excavation of unsuitable material and significant quantities of gravel to create a summer road.

A number of winter roads connect to Casino Creek and to the proposed Mine site. These are shown on Figure 4-3. A modification of the south-west bound winter road was investigated following the higher ground on the east of Casino Creek, south of the Mine. The same alignments were used on Routes 2 and 3 – the Aishihik Lake and East Routes. Where these routes cross the Nisling River, Route 1 would follow Onion Creek in a south-westerly direction to a crossing of the Kluane River, and then south on the east slopes of the Donjek River to the Alaska Highway.

Figure 4-2
Illustration of Candidate Routes from Casino Mine (Not to Scale)



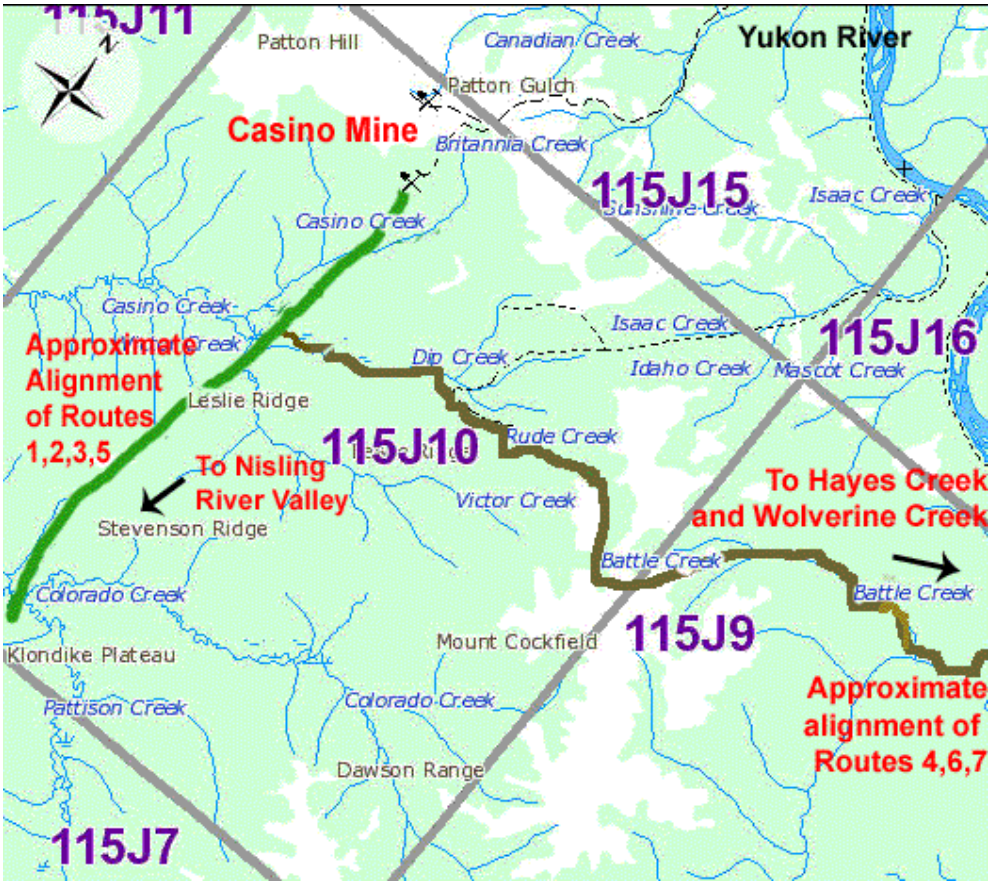


Figure 4-3
Indication of Alternative Alignments at Casino Mine

A preliminary assessment of the Onion Creek alignment showed an even profile following higher terrain where possible above the wetlands of the Casino and Nisling Rivers for 187 km from the Mine to the Alaska Highway. The feasibility of the Onion Creek Route will need more geotechnical assessment to investigate the availability of gravel deposits and to assess the foundation conditions of the preferred alignment and extent of peat deposits. Much of the route across the Nisling River valley will have to be on an embankment. A major river structure is likely to be required at the crossing of the Kluane River. This route would favour haulage route 1b to the Port of Haines.

The Onion Creek route appears to avoid much of the sensitive wildlife and First Nations areas and appears to be relatively straightforward for permitting. 85 to 95 km from the Mine un-surveyed First Nations lands highlight areas that are traditional fishing and spawning grounds. Further south, First Nations timber and quartz mine claims are located.

Burwash Caribou and Grizzly habitats are wildlife concerns along Onion Creek. These may require mitigation during the route development and further study will be required to determine their significance.

Figure 4-4
Onion Creek leading out of the flat Nisling River Valley

Figure 4-5
Nisling River Valley South of Casino Mine

4.2 ROUTE 2 - AISHIHIK LAKE ROUTE

This route would follow the same alignment as Route 1 from the Mine and east of the wetland to a crossing of the Nisling River close to Onion Creek. It would then follow the south slopes of the Nisling River Valley, before turning south to follow along the existing, summer-only Aishihik Lake Road to the Alaska Highway.

Approximately 210 km of new road will be required across level terrain and a further 113 km on the existing recreational road on the east side of Aishihik Lake would need to be upgraded. No major river structures would be required. This route also has historic significance, since it follows the Dalton Trail, which was the original route in gold rush times to Dawson City from Haines.

This route appears to be feasible. It will have the same concerns as Route 1 about wetland in the Nisling Valley but follows southern slopes and an established road to the Alaska Highway, 33 km east of Haines Junction. This route could allow haulage on Routes 2a or 2b to ports at either Skagway or Haines.

Nisling River Valley Area, which is common to both the East and Aishihik routes, is currently only accessible by air or boat during the summer months. Due to its remoteness, the area supports a healthy population of wood bison. There is also evidence of wild sheep and moose. The presence of these species may cause concerns when trying to permit a route along the Nisling River. There may be considerable resistance to permitting along the Nisling River. Up-grading the existing Aishihik Road would require agreements from both the Champagne and Aishihik First Nations.

Figure 4-6
The North End of Aishihik Lake

4.3 ROUTE 3 - EAST ROUTE

This route would start at Casino Mine and, as with Routes 1 and 2, would follow the same eastern slopes of Casino Creek to a crossing of the Nisling River close to Onion Creek, then follow along the southern slopes of the Nisling River valley. Before the headwaters of the Nisling River, it would join the existing Mansen Mine Road, which is an existing Yukon secondary highway to Carmacks and the Klondike Highway.

This route appears to be relatively flat and feasible. It will contain sections of wet, peat terrain, but it mostly follows sloping ground with the potential of surface gravel. It would require construction of 230 km of new road and upgrading of 50 km of existing secondary road. No major river structures will be required. The same permitting considerations apply to the East Route as they do to the Aishikik Lake Route. This route would favour haulage on route 3a to the Port of Skagway.

Figure 4-7
Nisling River Valley

Figure 4-8
Mansen Mine Road West of Carmacks

4.4 ROUTE 4 - WOLVERINE CREEK ROUTE

The Wolverine Creek Route is the most northern route from the Casino Mine to the Yukon Highway system, as illustrated in Figure 4-2. It would follow the steep Rude Creek from Casino Creek east to a pass over the high point of the Dawson Range as illustrated in Figure 4-3. It would then continue over extremely steep and rugged mountainous terrain along Battle Creek to the headwaters of Hayes Creek. The route then follows more moderate terrain to the headwaters of Wolverine Creek which leads down to the Yukon River and the existing Minto Mine Road. Minto Mine maintains a barge ferry crossing across the Yukon River to Minto, which is on the Klondike Highway.

The section over mountainous terrain is approximately 69 km and will involve switch-backs and steep grades (10 – 14%). It will also require expensive maintenance for operations in the winter. The more moderate section between Hayes Creek and the Minto Mine Road is about 45 km. The existing road from the Wolverine Creek to the barge is 24 km. A new bridge would have to be built across the Yukon River to enable all-season access.

The total length of new and upgraded road from Minto to the Casino Mine will be about 140 km in mostly steep terrain. This compares with 180 km of new road on the Onion Creek Route in flat terrain. This Wolverine Creek would favour haulage on Route 3a to the Port of Skagway.

The major portion of this route is on the edge of key wildlife areas, and is unlikely to present significant opposition to permitting. Bridging the Yukon River at Minto will present environmental impacts to recreational groups and the Federal Department of Fisheries and Oceans.

Figure 4-9
Steep Terrain looking up Battle Creek in the Dawson Range

Figure 4-10
Minto Mine Road and the Barge Crossing at Minto

4.5 ROUTE 5 - KLAZA RIVER ROUTE

This route is similar to Route 3 but instead of following the Nisling River east to the Mansen Mine Road it would follow the more mountainous route of Klaza Creek. The purpose of pursuing this route was to avoid the wetland of the Nisling River. It would be a slightly shorter section of new road than the East Route, 223 km instead of 230 km, and is likely to be more costly to build and to operate. This route would favour haulage on Route 4a to the Port of Skagway.

It is anticipated that the route along the Klaza River and Hayes Creek (Route 7) may receive environmental resistance to their development. These areas are a caribou winter range and are considered necessary for sustaining First Nations hunting traditions. Wildlife studies will be needed to support approval of both these routes.

4.6 ROUTE 6 - YUKON RIVER WEST ROUTE

This is an extension of the Wolverine Creek Route (Route 4). Instead of crossing the Yukon River at Minto, the road would connect with the Klondike Highway at Carmacks. It would add 76 km of new road but would not require a bridge across the Yukon River. This route would favour haulage on Route 6a to the Port of Skagway.

The environmental issues here are similar to the Wolverine Creek route, except more objections can be expected from wildlife, tourist and sport-fishing interest groups due to its proximity to the Yukon River.

4.7 ROUTE 7 - HAYES CREEK ROUTE

This route, also illustrated in Figure 4-2, would take the same alignment as Route 4 east of the Casino Mine and over the Dawson Range to Hayes Creek. It would then descend southward down Hayes Creek to the existing Yukon secondary road, known as the Freegold Road, which would be followed to Carmacks and the Klondike Highway. No crossing of the Yukon River is necessary for this route.

The total length of new and upgraded road from the Mine to Carmacks on this Hayes Creek Route is 210 km, compared to 135 km from the Mine to Minto on Route 4. It would follow much of the same terrain as the Wolverine Creek Route. This Hayes Creek Route would favour haulage on Route 7a to the Port of Skagway.

The environmental concerns of this route are the same as the Klaza River route since it follows known wildlife habitat.

5 Truck Operational Considerations and Assumptions

A fleet of trucks and trailers would be purchased or leased by the Mine. This fleet would conform to the operating requirements and trailer combinations discussed in Section 3.5. It is likely that a B-Train truck combination will be required for concentrate hauling and a semi-trailer (Tridem) combination will be required for supply haulage.

Major Assumptions
Figure 5-2 Major Assumptions

Major Assumptions (other details available on request)	
Total of overheads as % of total trucking cost (profit, ins, admin, working capital)	20.7%
Cost of capital based on current prime rate	5.25%
Assumed grade of dry concentrate	25%
Winter operations cost adjustment factor	1.06
% of time for winter operations	50%
Bulk terminal charge per wet tonne	$10.00
Ship cost to Orient per wet tonne	$60.00
Tonnes of dry concentrate shipped per year	250,000
Assumed moisture content of concentrate	10%
Tonnes of trucked mine supplies per year	75,000
Cost of diesel fuel for trucks	$1.215
Base wages for truck drivers per hour	$22.25
Base wages for truck mechanic per hour	$28.00
Wage burden	1.3
Lump sum overnight allowance per truck trip to marine terminal	$150.00
Estimated cost of B-train set	$313,767
Estimated cost of Tridem set	$239,206
Cost of a tire	$460.00
Assumed tractor life in years	5
Assumed trailer life in years	8
Assumed payload of B-train trucks in tonnes	40.5
Assumed payload of Tridem trucks in tonnes	32.0
Average payload for B-trains allowing for spring load limits	38.13
Average payload for Tridems allowing for spring load limits	30.13
Assumed equipment spares	20%
Assumed speed on paved roads in km/h, on moderate grades	80

Major Assumptions (other details available on request)	
Assumed speed on paved roads in km/h, flat and moderate grades	70
Assumed days of operations on Wolverine and Hayes routes	320
Assumed days of operations on Onion, Aishihik, East and Klaza routes	335
Assumed days of year when 75% GVW loading applies (variable)	50
Assumed mine life in years	25

5.1 SUPPORTING INFRASTRUCTURE

In addition to the haul fleet, supporting infrastructure will be required for the handling of the concentrate. This will include the following components:

- A concentrate storage shed at the Mine and the Port sites to handle approximately 1 month's supply of concentrate or 40,000 tonnes; a storage shed can cost $5.0m and would be designed for negative air pressure to contain concentrate dust;
- Truck loading and wash-down facilities at both the Mine and the Port site;
- Truck fuelling facilities at both the Mine and the Port site;
- Haul fleet maintenance shops and administration offices at a convenient location at either the Mine or the Port site;
- A conveyor system at the Mine for the loading of concentrate from the Mill;
- A conveyor system at the Port to load concentrate from the concentrate shed to the concentrate ship carrier
- The cost of fueling, conveying and wash-down infrastructure at both the Mine and the Port is likely to exceed $10 M.

5.2 TRUCK PERFORMANCE MODELS

Several truck suppliers, such as Cummins and Caterpillar, provide performance characteristics for their standard truck fleets. The Society for Automobile Engineers (SAE) publishes procedures for the charting of vehicle performance but these are confined to standard tractor/trailer units operating on paved highways. The Forest Engineering Research Institute of Canada (FERIC) has developed a truck simulation model for off-highway truck operations on unpaved roads. This model is reported to simulate performance of logging trucks and estimates fuel consumption, travel speeds, and driver characteristics for typical forestry roads. This model is restricted to members of FERIC.

At a more detailed stage of the Mine development, it would be advisable to procure one of the above models for a precise analysis of the truck performances on the selected route. At this stage, a more simplified approach based on Exhibit 3.6.6 has been used to estimate truck haul speeds based on reports of trucking operations in northern British Columbia. This method has used the following assumptions for a standard fully-loaded typical side-dump B-train truck/trailer arrangement operating uphill or downhill:

- Average speed on the paved Alaska Highway, Haines Road and Klondike Highway = 60 - 80kph
- For assumed specifics on the variables route, see tables in Appendix B.

5.3 TYPICAL TRUCK SUPPLIERS

For purposes of this assessment, it has been assumed that the Mine will use side-dump B-train 7-axle tractor/trailer units with gross vehicle weights of 63 tonnes. These vehicles provide a payload capacity of approximately 41 tonnes and a combination currently retails for approximately $313,000. A Tridem set currently retails for $240,000.
Suppliers of these trucks include Kenworth, Peterbilt and Western Star. All these suppliers have operations in Northern British Columbia and the Yukon.

5.4 A POSSIBLE LOGISTICS PLAN

The following is an outline of a possible Casino Mine logistics plan. It is intended as a template upon which a more detailed plan can build with more information as it becomes available.

- The Mine is expected to produce 250,000 tonnes per year (t/y)
- The Mine will require a reverse haul of supplies of approximately 75,000 t/y or 250 t/day in the form of grinding balls, lime, reagents, lines explosives and living requirements.
- An all-season road will allow trucking all year round and likely 320 days/year
- The haul of concentrate to a port site is likely to have a bulking factor of 10% requiring 250,000 x 1.1 = 275,000 t/y or 900 t/day of transportation
- Yukon Highway regulations allow gross vehicle weight of 63 t
- Nominally each highway truck combination can carry 41 t of concentrate or supplies
- Hence Casino Mine would require 900 t/day = 22 standard truck loads/day - 41 t/truck
- If the Mine used containers, each container can only carry 18 – 20 t/load, requiring 22 – 25 trucks will be needed.
- Average distance from the Mine to Skagway is approximately 600 km
- Assume 22 truck + 3 spares for a probably fleet of 25 trucks
- The estimated volume of Casino trucks on a public highway will be approximately 2 trucks/h in each direction. This is equivalent to about 10 passenger vehicles/h in each direction

6 Trucking Cost Analyses

6.1 SUMMARY OF TRUCKING COST ANALYSIS

A total of 14 route options for the transportation of concentrate from the Mine to the Ports of Skagway and Haines were analyzed, along with the reverse haul of mine supplies and coal. Trucking costs were estimated by an explicit analysis that took into account variables about: grades, road surface types, distances, varying seasonal payloads, cycle time analyses, current estimated prices for labour, fuel and equipment and many other factors. Further analysis taking into account the different costs of new road construction and maintenance was carried out. Rough allowances for terminal costs and ship costs were added to arrive at a total transport cost estimate.

The analysis combined the capital cost of road construction, road maintenance costs, truck purchase costs, truck operating costs and supplies shipment amounts by means of discounted cash flow analysis in various forms and allocations to arrive at the figures shown in the tables and graphs that follow. The analysis was based on the use of B-Train trucks (40.5 tonne maximum payload) for the haul of concentrate on the four southern routes (routes 1, 2, 3 and 5). Tridem trucks (32 tonne maximum payload) were assumed for use on the three northern, mountainous routes (routes 4, 6 and 7).

Figure 6-1 summarizes the total costs of transportation in terms of dollars per wet tonne of concentrate. Note that the comparison of routes assumes no coal backhaul. The Onion Creek Route, which is the recommended route, has the coal backhaul shown at the top of this table. Figure 6-2 shows the same table as Figure 6-1 converted to dollars per/lb. of copper.

Figure 6-3 is a bar charge showing the total land transportation costs and Figure 6-4 shows the make-up of these costs. Figure 6-5 shows only the costs of trucking mine supplies from a Port to the Mine.

Appendix A provides the detail of the net present value analysis for each of the candidate routes. The analysis also provides a breakdown of the cycle times used to calculate the return trip time and the number of trucks that will be required for both the portage of concentrate and mine supplies.

6.2 TRUCKING OF CONCENTRATES

Options for the transport of concentrates include bulk or containerized shipments through Skagway or Haines. In bulk, the lowest cost route is through Haines with an estimated FAS cost of $226 per tonne delivered to an oriental smelter port. This figure includes: trucking to Haines [$92 per tonne], allocated road capital and maintenance [$36 per tonne], allocated supply trucking [$29 per tonne], an allowance for port charges [$10 per tonne] and allowance for sea freight [up to $60 per tonne]. Skagway has an existing small scale bulk terminal for shipping concentrates. Investments to expand storage and materials handling capacity would be required to handle Casino concentrates. At Haines, no bulk materials handling facilities exist, but space for facilities exist in at least two sites. Both Skagway and Haines have existing under-used RORO barge facilities that can probably be used to store and transfer containers. Container capacity assessments and logistical investigations have not been carried out.

Trucking of Mine Supplies

Both Skagway and Haines have existing under-used RORO barge facilities that could be used to transport inbound mine supplies. At this stage, the capacity to handle the necessary volume of mine supplies appears to be available. However, the capacity to add outgoing shipments of concentrate in containers as a back haul requires further investigation. Using the lowest cost route, mine supplies brought in through Haines and along the Onion Creek route, have a trucking cost estimated at $105 per tonne. Other components of the total transport cost of supplies have not been estimated and the logistics of mines supplies transport have not been investigated.

6.3 TRUCKING OF INBOUND COAL FOR POWER GENERATION

Working with the assumption that the volumes of inbound coal and outbound concentrates are similar, the back haul of coal using the returning concentrate trucks offers reduced trucking costs to both commodities. On the lowest cost route and, based on an equal cost allocation, the cost of trucking drops to $50 per tonne from $92 per tonne for each of concentrates and coal. The ability to handle inbound coal at Skagway is not obvious. However, at Haines, at least two port sites may lend themselves to the purpose of coal handling. The ability to handle both concentrates and coal at Haines probably exists, but determining a workable arrangement for costing purposes requires further study.

How the coal should arrive at Haines and in what shipment sizes, also requires examination to arrive at an estimate for the cost of coal. With an estimate for the cost of imported coal, it would be possible to evaluate the option of sourcing coal from Yukon's Division Mountain mine site near Breaburn. To estimate the cost of Division Mountain coal, it will necessary to estimate the coal trucking cost and assume that the East Route will be selected. To estimate the cost of imported coal, it is necessary to combine the: FOB loading port cost of coal, shipping cost, receiving terminal capital and operating costs, and back haul trucking cost to the Casino Mine. One potential advantage of sourcing coal from Division Mountain is the commercial reality that the Division Mountain's coal deposit is, for practical purposes, isolated from currently volatile and relatively high international steam coal prices. In short, it may be possible to negotiate a long term price agreement for Division Mountain coal that is lower than current international prices.

Lowest Cost Land Route

The lowest cost land transport route, the Onion Creek route to Haines has a total land transport cost of $156 per wet tonne of concentrate when concentrate trucking, road costs and supplies trucking are combined and allocated. For the Onion Creek route, concentrate trucking is $92 per tonne and supplies trucking is $105 per tonne, when costed alone. Although two other routes have concentrate trucking costs almost almost as low (namely, $93 per tonne and $96 per tonne on Rt#2, the Aishihik Route), the allocated cost of highway construction and maintenance is far lower on the Onion Creek route. The Onion Creek route's road cost of $36 per tonne is the deciding factor in the selection of this route. For example, the next lowest road costs are $48 per tonne on the Aishihik Route and $45 per tonne on Rt#3, the East route. The East route concentrate trucking cost and supplies trucking costs are higher as well, $98 per tonne and $148 per tonne respectively.

6.4 PORT TERMINAL COSTS

The port terminal handling costs at Skagway and Haines cannot be distinguished without a conceptual layout and order of magnitude capital cost estimate. That said, there are significant operational and capacity differences between the two ports. These differences are discussed in the sections describing the ports of Skagway and Haines. The terminal charge of about $10 per wet tonne of concentrate in the estimate is slightly higher than typical Vancouver market rates for concentrate terminal handling. The Western Copper's capital and operations obligations at Haines and Skagway are unknown at this time.

6.5 SHIPPING COST

An explicit calculation based on the costs of ships and their operation is likely to result in a ship cost in the order of $30 per wet tonne of concentrate. However, shipping markets are currently highly volatile. Ship costs as high as $60 per wet tonne of concentrate have been reported recently. The higher figure was used in the estimate.

6.6 OTHER LOGISTICAL ISSUES

Adding inbound coal to the transport system, opens a wide range of potentially advantageous logistical opportunities. In addition, to reducing the allocated cost of concentrate trucking, the logistical implications of inbound coal have the potential to reduce: capital costs of port development at Haines, overall environmental protection costs, smelting costs, and, marine transport costs for concentrate and for mine supplies. (Refer to Further Work Required on page 2 for a list of logistical options.) Furthermore, as discussed above, sourcing coal from Division Mountain mine site also re-opens the land route selection question.

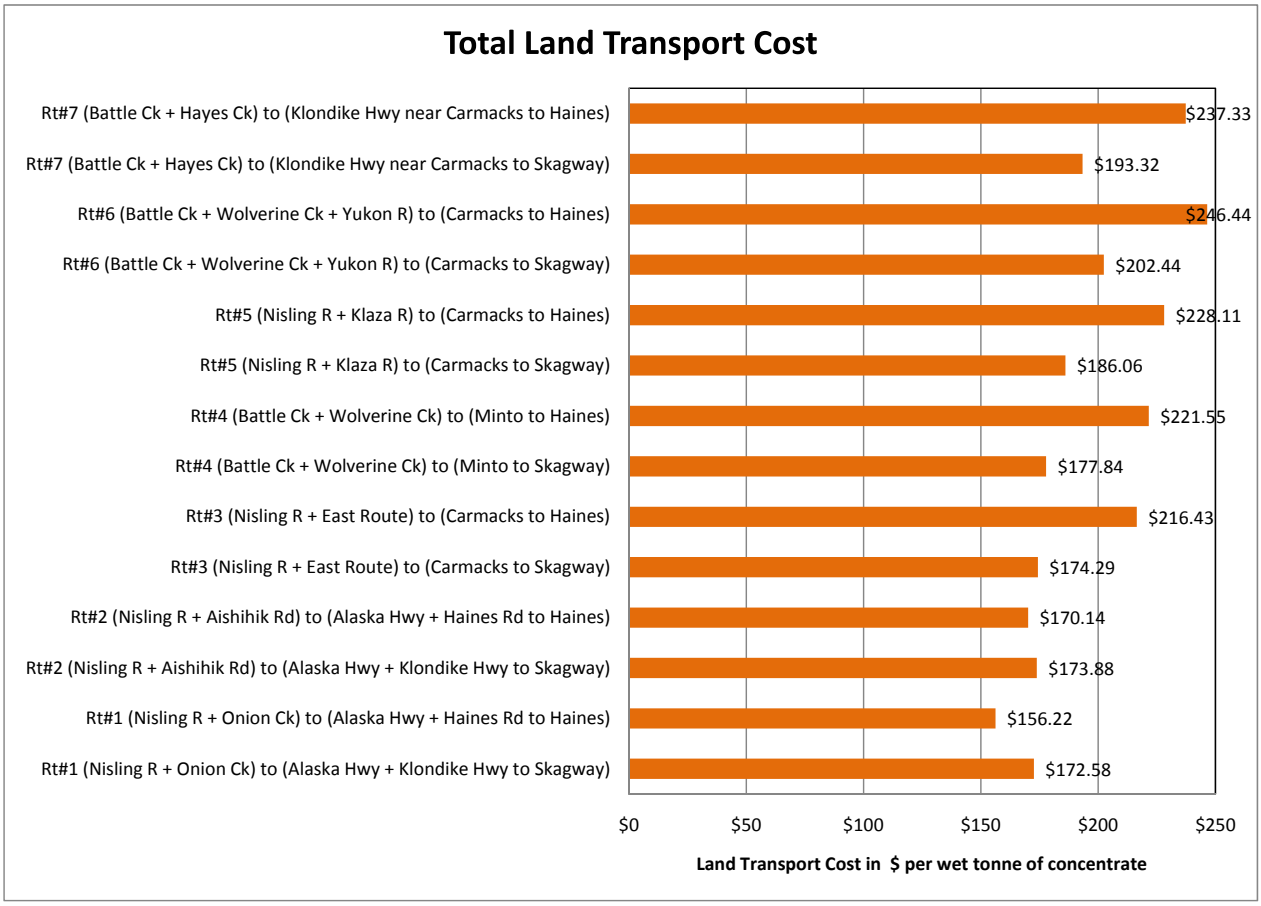
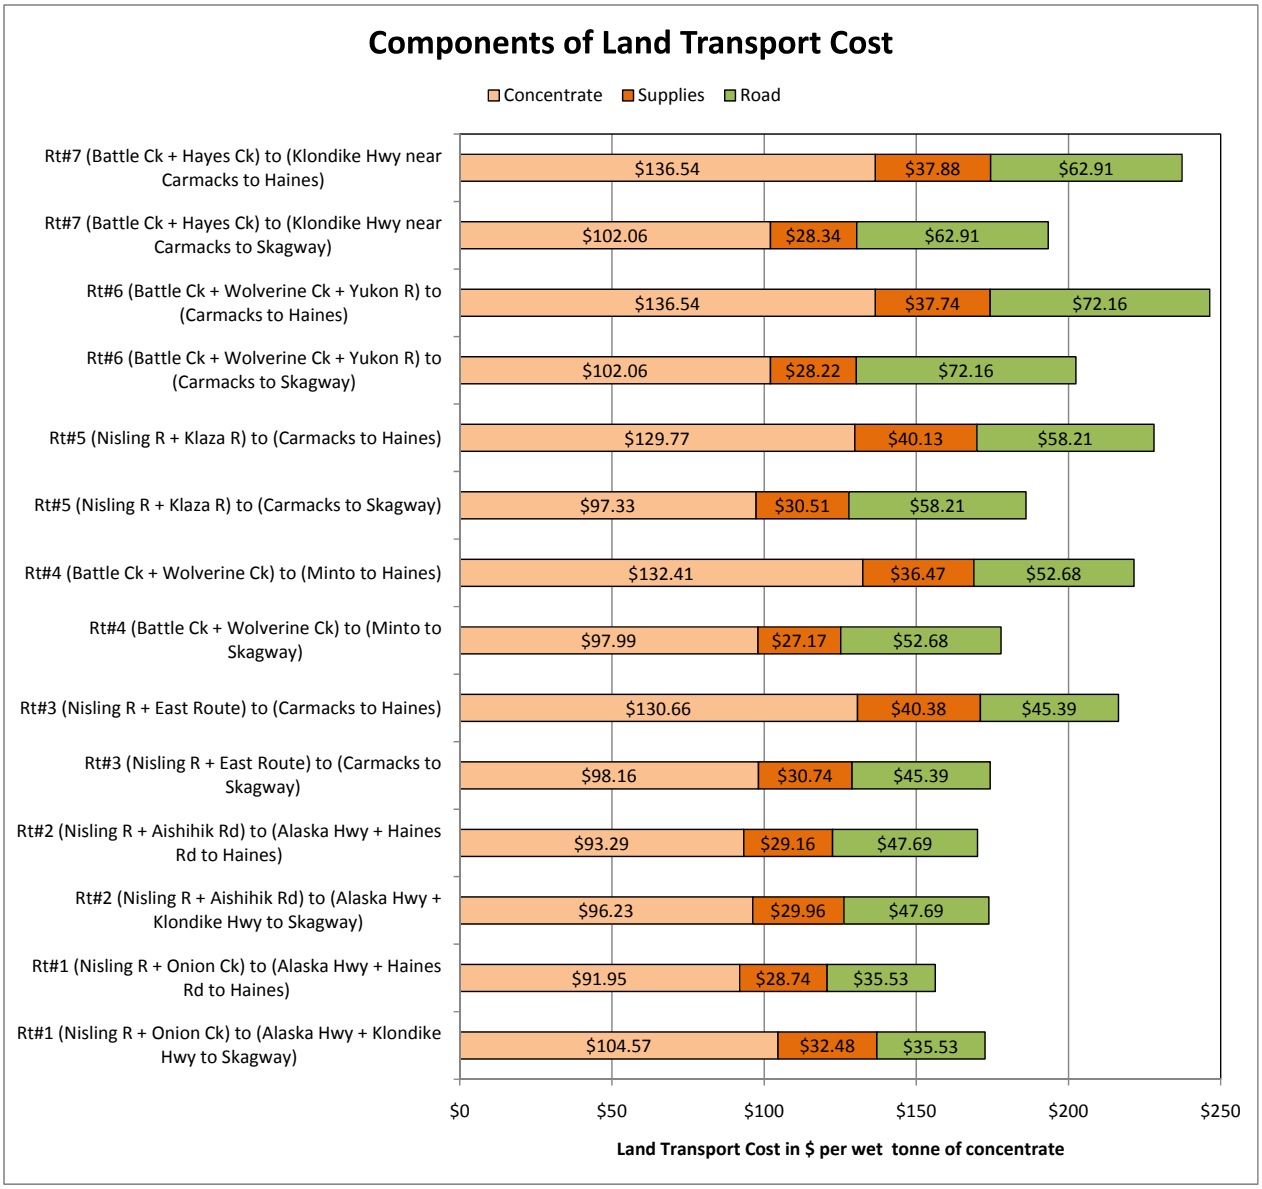
Note: Calculations for $ per lb of Cu assume a concentrate grade of 25%.

Figure 6-3
Summary of Total Land Transportation Costs





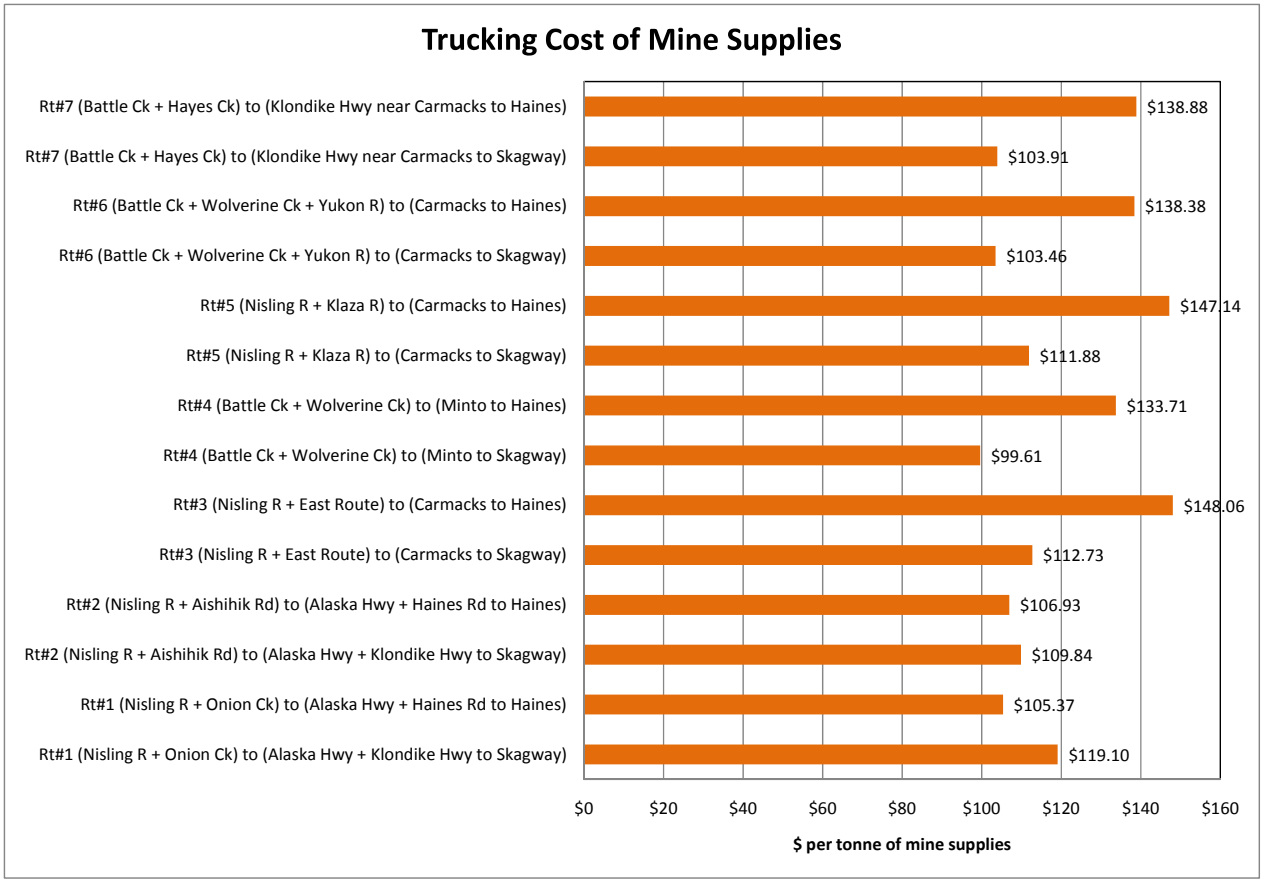


Figure 6-4
Summary of the Components of Land Transportation Costs

Note: The cost of mine supplies has been allocated to the total transport cost of concentrates. Similarly, the road capital and maintenance component of total transport cost has been allocated to the total transport cost. The option to return haul coal in the concentrate trucks is not included in the table above.

Figure 6-5
Trucking Costs of Mine Supplies using a fleet of Tridem Trucks

7 Overview of Port Conditions at Haines and Skagway

7.1 OVERVIEW

For more than 100 years, Skagway has been the Yukon's main port outlet. The port has a demonstrated capacity to handle hundreds of thousands of tonnes of concentrates and similar quantities of general cargoes. The existing narrow gauge White Pass Railway formerly delivered mineral concentrates from the Yukon's Faro Mine to Skagway's bulk concentrate terminal. Skagway's mostly containerized general cargoes arrive by barge to a floating barge ramp which leads to an inter-modal yard. The general cargoes are carried by truck to the Yukon and Alaska.

The main issue at Skagway is capacity. The potential for expansion is very limited. Since the end of large scale concentrate exports in the 1980's, the cruise trade has expanded to take up much of the berthing capacity at Skagway, including the concentrate dock.

7.1.1 Ship Berths

All of the existing and potential ship berthing positions are taken up by cruise ships in summer during day hours. In summer, concentrate loading would have to take place at night. To completely free the concentrate dock for bulk handling, it would be necessary to re-construct the existing Alaska State Ferry terminal to be a dual purpose cruise and ferry facility. It also may be possible construct a separate dedicated bulk barge berth at the seaward end of the concentrate deep sea berth.

7.1.2 Anchorages

There are no deep sea vessel anchorages at Skagway in Taiya Inlet. The nearest anchorages are near Haines, about 24 km to the south in Lutak Inlet. At higher throughput levels, the shuttling to and from distant anchorages will add to the overall cost of shipping concentrate through Skagway. In summer, cruise ships will occupy the concentrate dock in the day time leaving free time for concentrate ships at night. Concentrate ships, depending of the size of their shipments and the number of mines using Skagway, may have to fill partial loads and then shift off to an anchorage before returning the next night to Skagway to complete their loading plan. Additional costs to shippers for: tug assist, pilotage, port charges, lines charges and ship idle time could occur.

7.1.3 Cargo Storage Areas

The concentrate terminal and adjacent vacant lands provide a potential maximum development area of about 2.7 ha. More area could be available if the existing helicopter terminal were re-located. However, finding a suitable new location near the helicopter terminal's cruise ship customers will be difficult in the confined port areas of Skagway. Finding space for bulk storage for concentrates is also complicated by the need to have separate stockpiles for each mineral and each mineral shipper. There does not appear to be space for coal storage as well as concentrates.

7.1.4 Multi-Lateral Agreements

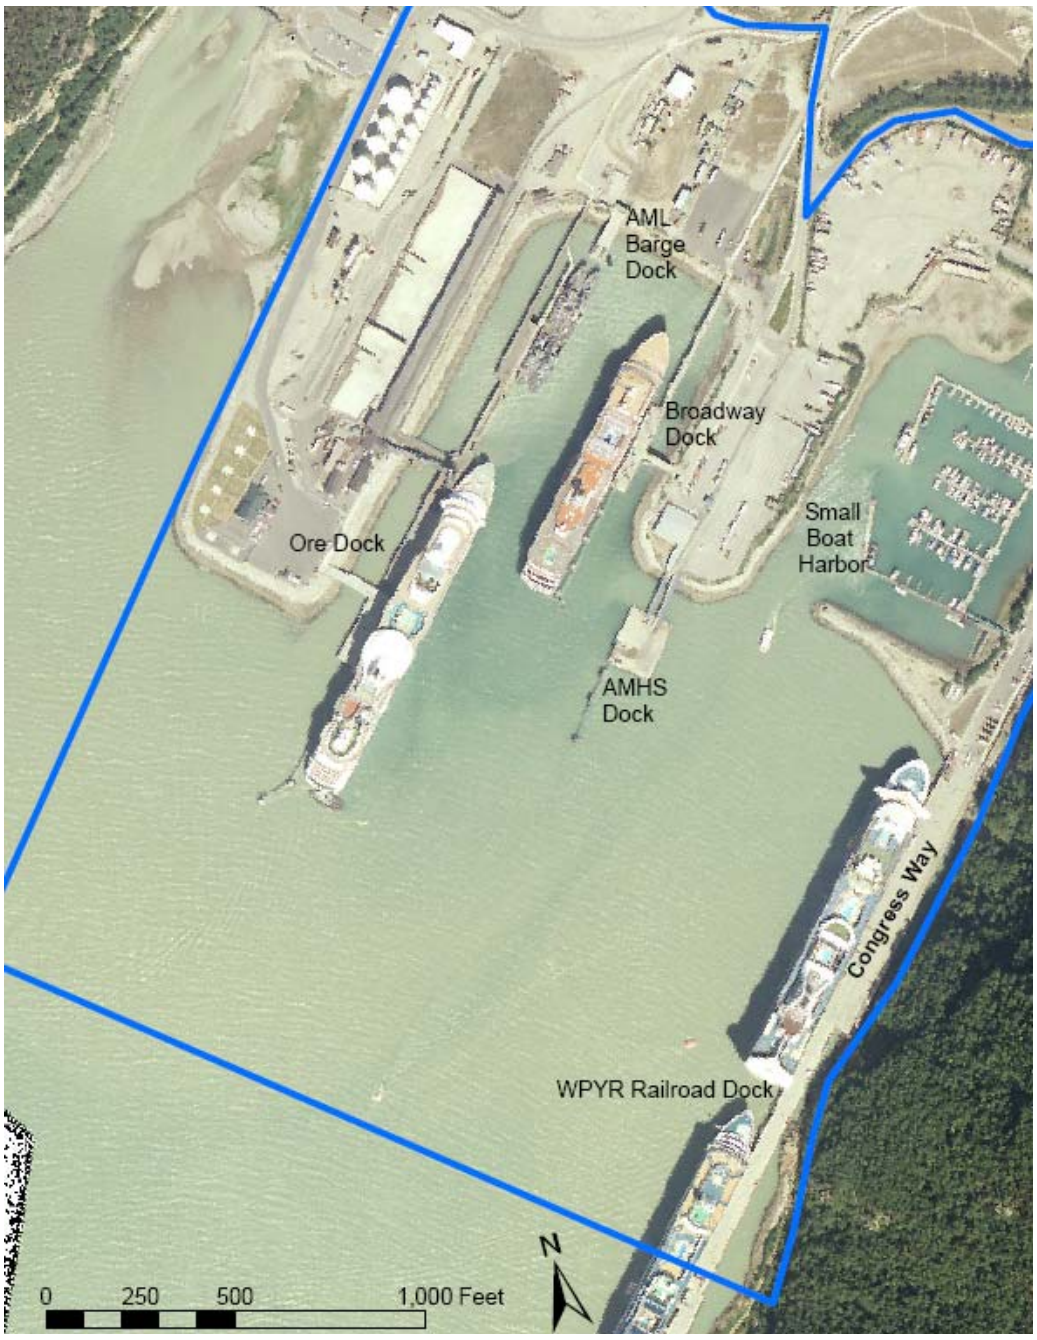
Use of the Skagway concentrate terminal will require a series of multi-lateral agreements with AIDEA, the owner of the terminal site, White Pass, the owner of the concentrate dock, and Sherwood Copper, the current user of the facility.

7.1.5 Advantages and Disadvantage of using the Port of Skagway

Advantages:

- Skagway's concentrate terminal has an existing dock, ship loader and newly constructed materials handling infrastructure created for Sherwood Copper's new shipments copper concentrates from its Minto project. The facility upgrade costs to accommodate the Minto shipments are about $10 million. To some extent, the client will benefit from this investment by others. As well, to some extent, the existing wharf and shiploader and concrete storage pad may be available for shared use at lower costs than for new dedicated facilities.
- As a new shipper, the client's Casino project would be able share in the costs of existing services infrastructure.
- The elapsed time to begin shipping through the concentrate terminal in Skagway is likely to be less than for a new dedicated terminal to be built elsewhere.

Disadvantages:



- The existing wharf and shiploader are low capacity assets. In summer, the wharf must be shared with daytime visits by cruise ships. Structurally, the wharf itself may be sufficient for perhaps handy-max sized bulk vessels at most. Further investigations are needed to determine whether lower cost larger bulk vessels can use the wharf. The shiploader is reported to have a maximum capacity of 900 tonnes per hour, with a continuous average capacity that is less than this figure. For modern bulk shipping, this is a relatively low handling rate. Given the limitations concerning berthing space and the current high idle time cost of bulk carriers, a 900 tonnes per hour maximum rate may prove to be costly and/or insufficient. Furthermore, the ship loader is fixed in its position; ships must be warped along the dock to reach next hold in their loading plans. Typically, a ship loading plan requires five holds to be loaded in two or three stages for a total of 12 or more loading passes. Allowing 20 to 30 minutes to warp the ship and slew the loader into position for each pass, a considerable amount of berth time would be lost.
- There are no anchorages at Skagway. In summer, concentrate ships would have to seek anchorage in Lutak Inlet (near Haines) and would sometimes have to interrupt night time loading to make way for cruise ships arriving in the morning. (Cruise ships have priority at the dock.) There would be additional costs for tug assistance, pilotage and lines charges.
- The limited expansion space for product storage, the low capacity ship loader, the limited amount available berth time, and the need for concentrate trucks to travel through the main tourist area of Skagway raise questions about the maximum practical throughput capacity of the concentrate terminal. If the client joins the terminal as the third or fourth shipper through Skagway, there may be some capacity risks. Further investigation, to assess Skagway's concentrate terminal capacity is recommended.
- There does not appear to be space for the storage and receiving of coal. While a self-discharging coal barge could conceivably moor at the concentrate dock, finding space for cargo storage would be difficult. Furthermore, in summer, the already crowded berth schedule would add to the difficulties described above for concentrate ships.

Figure 7.1.1
Skagway, Alaska

The concentrate terminal is to the left. Space for expansion is limited.
The white line ellipse shows the location of bulk facilities.

Figure 7.1.2
Skagway in Summer

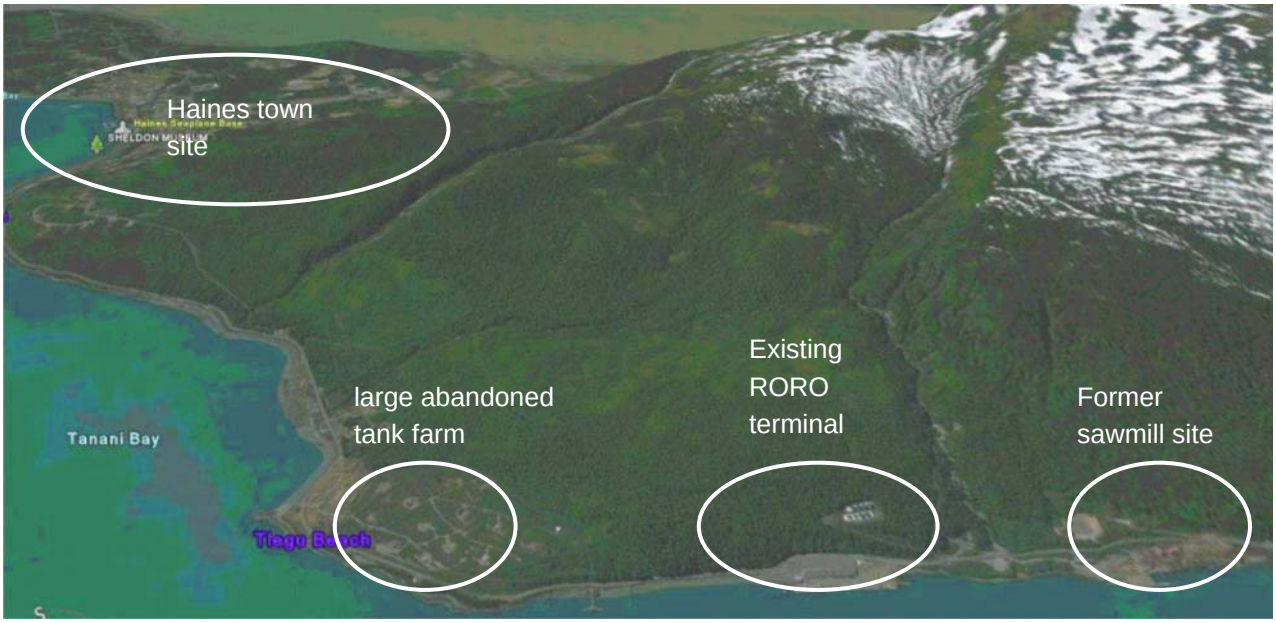
In summer, cruise ships take up all available deep sea berths during the day. Note the cruise ship moored at the concentrate terminal.

Figure 7.1.3
Skagway Concentrate Dock

The fixed ship loader slows ship loading considerably.

Figure 7.1.4
Skagway RORO Terminal

Skagway has the capacity to handle container shipments by barge. Mine supplies and/or containerized concentrates could be handled.



7.2 PORT OF HAINES

7.2.1 Overview

Haines was established as a supply port for the construction of the Alaska Highway and oil pipeline by the US Military in 1943. The Borough of Haines has established port industrial areas on the shores of Lutak inlet, about 4 kilometres north of the town. Potential terminal sites include: part of a multi-modal terminal of about 6 hectares, an abandoned tank farm of about 34 hectares and a former saw mill site of about 8 hectares.

Conversations with the Borough of Haines indicate strong interest in having a concentrate terminal in this area. At this time, there are no known obvious major social issues that would preclude development on the industrial shores of Lutak Inlet. The Borough appears to be flexible about ownership and operations management.

Figure 7.2.1

7.2.2 Advantages and Disadvantages of using the Port of Haines

Advantages:

- The complexities and risks associated with multi-lateral agreements required at Skagway would be avoided.
- The ship berth could be dedicated to the client thereby reducing some port costs.

- Site development could be optimized to suit the client's requirements. At Skagway adjustments and compromises connected with the small site area and working with an existing user could be avoided.
- Road grades approaching Haines are slightly less onerous than at Skagway.
- There is a greater potential for expansion at Haines and also the possibility of profitable sharing of infrastructure costs from future mineral shippers.
- Social issues at Haines may be less complex than at Skagway where port operations and truck transport mixes closely with tourism and tourists. At Haines, the townsite, tourist activity and its residential areas are four kilometres away from the potential port sites.
- The land transport costs to Haines are expected to be lower than for the other routes to Skagway. The present value of the estimated land transport cost advantage for using the Onion Creek route to Haines instead of the next best route is $41 million. Applying some of this cost advantage towards the higher capital cost of a terminal at Haines may be appropriate.
- There appears to be space for the receiving and storage of: mine supplies, concentrates and coal.
- Marine conditions, topography and site development do not appear to present obvious difficulties.
- There is a fuel tank farm near to the existing RORO terminal. There does not appear to be any obvious impediment to expanding the tank farm.

Disadvantages

- The capital cost to develop terminal facilities at Haines is likely to be higher than at Skagway.
- It will probably take longer to develop a new terminal at Haines than to become an additional user at Skagway.

Figure 7.2.2
Port Sites at Haines

Port Sites at Haines, Alaska – Haines has three port sites about 50 metres wide by 300 metres long bordering a quiet bay that offers anchorage for deep sea vessels. Increasing the size of these sites is possible with cuts into the hillsides. The port sites are away from the town and options for by-pass road and rail alignments are probably feasible. The favourable sea conditions will probably allow the option of floating bulk barge-to-ship transfer terminals. For receiving mine supplies, the existing RORO container and truck/trailer could be expanded.

One option for overcoming site development problems at Haines would be to use floating bulk transfer terminals.

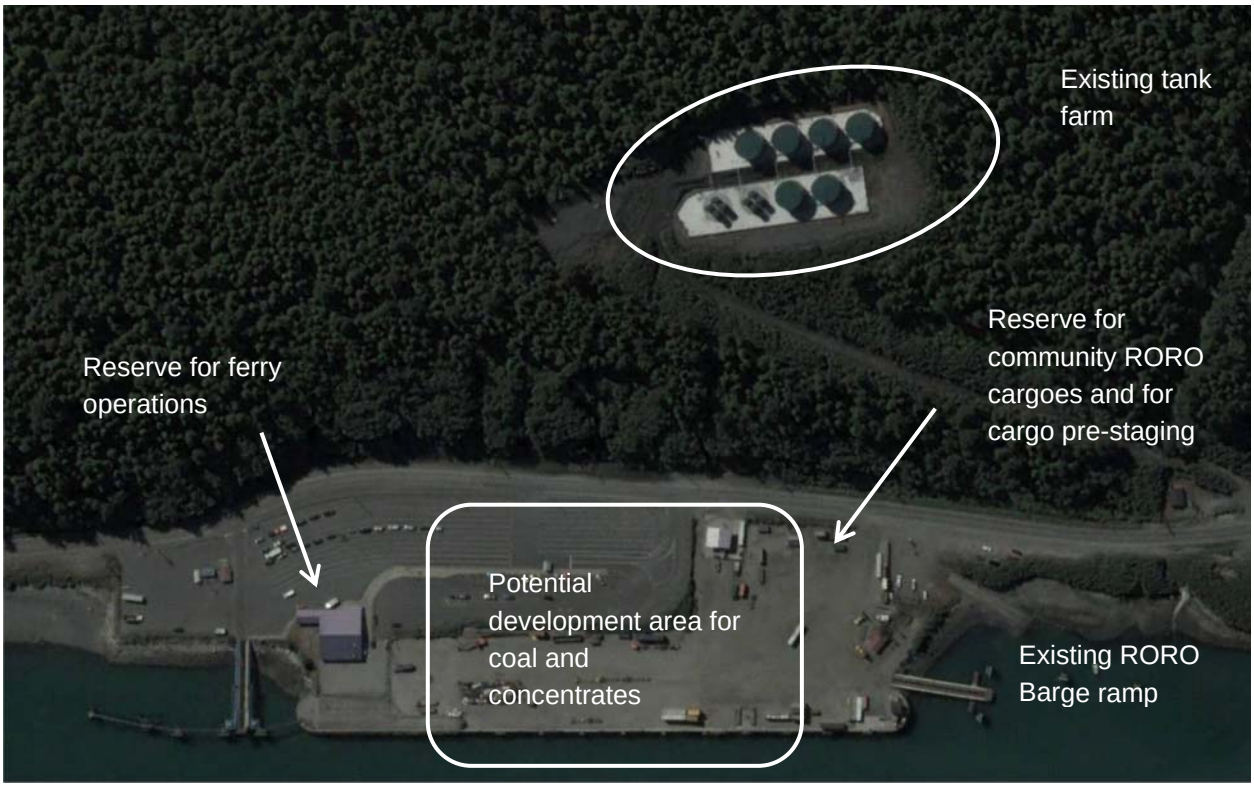


Figure 7.2.3
SeaBulk Cape Size Transfer System

Figure 7.2.4
SeaBulk Transshipper

Figure 7.2.5
Haines' RORO Terminal

This RORO Terminal, called Lutak City Dock, is used by Alaska Ferries and by RORO barge services; the space for both functions is under utilized. The nearby tank farm provides fuel storage and may have expansion potential.

7.2.3 Possible Development at Haines's RORO Terminal

With the addition of Casino mine project cargoes, four cargo handling areas would be active: the ferry operations area, the coal storage and handling system, the concentrates storage and handling system and the RORO cargo area. In the RORO cargo area, Casino cargoes would mix with community cargoes. The addition of Casino cargoes to RORO operations may be an advantage to the town if it encourages a more frequent and higher level of service. Either containerized concentrate handling or bulk handling may be feasible. For coal deliveries, barge delivery rather than deep sea ship delivery would probably be required. The large deep sea shipment sizes common in the coal trades could not handled at the RORO terminal. If concentrates are to be shipped in bulk in deep sea vessels, deep sea berthing structures would have to be constructed. The Haines RORO terminal is owned by the Borough of Haines.

The following are details of the existing Haines RORO Termina:

- Name – Lutak City Dock
- Site area – 6.4 ha including 2 used by Alaska State Ferry Terminal; part paved, part gravel
- Berth Face – 305 metres
- Water depth – 11 metres
- Activity – AML weekly container container barge and general cargo service; Delta Western inbound petroleum tanker barge and outbound truck distribution
- Status – owned by the Borough of Haines

Figure 7.2.6
Former Sawmill Site
Potential Terminal Site at Haines for a coal port.

7.2.4 Possible Development at the former Sawmill Site as a Coal Terminal

The former sawmill site is large enough to accommodate bulk coal received from deep sea vessels and bulk concentrates. However, the cost of site development and the necessarily larger scale materials handling and storage requirements would result in higher development costs than at the RORO site, Lutak City Dock. Extensive site leveling, demolitions and filling would be required. This site is privately held. There is an existing timber wharf but it is in poor condition and is probably unsalvagable. Similarly, it is unlikely that any of the derilict mill structures on the site can re-used.

The following are the details of the potential Site:

- Name – Chilkoot Lumber Property
- Site Area – 8 ha
- Water depth – 11 metres
- Status – private and for sale; industrial zoned

Figure 7.2.7
Example of a Coal Terminal – Middle Point at Campbell River

The Middle Point Coal Terminal near Campbell River on Vancouver Island is a potential model for coal and/or concentrate operations at Haines. The terminal has an enclosed truck receiving building, a completely enclosed coal storage building and covered conveyors leading to the barge loader. These dust control measures will probably be required at the Haines RORO terminal to ensure compatibility with ferry and community RORO operations. The storage capacity is 15,000 tonnes and the loading rates in 2,000 tonnes per hour. The Middle Point barge terminal is also a potential source of coal to be delivered to Haines. The smaller scale of coal operations from this terminal may be a good match for the Casino mine project's requirements. Barge back hauls of containerized concentrates to reach Vancouver area container terminals may be logistically and economically convenient.

Figure 7.2.9
Example of Gravel Loading Terminal – Port McNeill, BC

The gravel trades operating on Vancouver Island and in other locations in the waters between Vancouver Island and the mainland are a potential opportunity for low cost coal transport to Haines. Self-discharging bulk vessels similar to the vessel shown in Figure 9 may be available to bring coal to Haines as a backhaul for gravel shipments. These self-discharging vessels would be essential if coal were to be received at Haines at the former saw mill site. The long booms on these vessels allow high speed discharge to sites with minimal port facilities. Suitably placed mooring dolphins would be sufficient for this vessel; the vessel's boom swings overland to discharge the coal.

7.3 FURTHER WORK REQUIRED

This brief analyses of the Ports of Skagway and Haines together with the potential use as a terminal facility by Casino Mine requires further substantiation. The following is a indication of further work that the Mine may wish to undertake to select the port that will best satisfy the needs of the projected mining operations.

- Further analysis is needed to substantiate the selection between the Onion Creek routes, to Skagway and to Haines. Further work is also required to substantiate the selection of Haines as the optimal port for the purposes of Casino Mine. Conceptual site development plans and order of magnitude development costs are needed. Capacity assessments for bulk shipping out of Skagway and Haines are needed. If further analysis confirms that the land transport route to Haines via the proposed Onion Creek mine road is the lowest cost option, the higher expected capital investment at Haines may be justified.
- Given their current market volatility, ship costs require further investigation to assess the likely range of ship transport costs.
- The transport logistics of incoming coal and supplies and, outgoing concentrates requires further investigation. The outcomes of the investigations are likely to have a material affect on costs. Logistical options recommended for study would include:
- Barge transport of coal from Middle Point (on Vancouver Island) to Haines or Skagway and, possibly, the backhaul of containerized concentrate to Vancouver container terminals;
- Barge transport of coal from Ridley Terminals (near Prince Rupert) to Haines or Skagway and, possibly, the backhaul of containerized concentrate to Prince Rupert's container terminal;
- Deep sea transport of offshore or locally sourced coal in self-discharging vessels to Haines. Such a service may include coal supply as a low cost back haul for the gravel trades now operating in south coast B.C.;
- Direct truck haul of Division Mountain coal (near Breaburn, Yukon) 310 km to the Casino on an eastern road route passing near to Western Copper's Carmacks property;
- Coal imports at Haines may favour the logistics for containerized concentrates out and containerized back hauls of mine supplies in. A coal receiving facility at Haines may take up the limited land available for bulk storage and handling. Since some port land must reserved for the community's RORO truck-trailer/container storage needs, adding concentrate and mine supplies containers to Haines' existing RORO transport system may be logistically convenient. At the port terminal, container handling and environmental protection capital investment costs are likely to be much lower than for bulk handling.
- The commercial advantages and disadvantages of containerized concentrate with respect to smelting services should be examined. Containerization and use of water and rail links, may provide Western Copper with a greater range of smelting options, both in Canada and, in Asia.

Notes:

- The left most column of costs shows year by year road maintenance for grading and sanding.
- The six truck cost columns on the right show the year by year sum of costs for: fuel, lub/oil, tires, driver wages, truck maintenance, overheads, licensing, and the periodic end of life purchases of new trucks and trailers. The variation of truck costs year by year reflects age related truck maintenance and purchases of replacement tractors and trailers.
- The two columns on the far right show the costs for bulk trucking, loaded in and loaded out. These columns contain the costs that would be relevant if coal were the back haul for concentrates shipped out.

CASINO COPPER AND GOLD

Overview

History of the Property

- First mineral claims on the property filed as early as 1917
- Since that time, there have been periods of exploration and development by various owners

Location of the Property

- West central Yukon in Dawson Range Mountains
- On Crown Land administered by Yukon Government
- 300 km northwest of Whitehorse, 115 km west of Pelly Crossing
- Mine located within traditional territory of Selkirk First Nation
- Road access will fall within traditional territories of Selkirk and Little Salmon/Carmacks First Nations

3

CASINO COPPER AND GOLD

Casino Trail History

- **Interest in the Casino Trail started around 1960**
- **First official road proposal of the Casino Trail was in 1985**
- **Road construction began in 1986**
- **Casino Trail Local Resource Group formed in 1987**
- **By 1988, 40 km of the Casino Trail had been built**
- **Local Resource Group submitted recommendations in 1989**

4

CASINO COPPER AND GOLD

Casino Trail History

Casino Trail Local Resource Group

Objectives: review existing information, identify environmental and socio-economic concerns

Recommendations (1989):

- Archeological Studies
- Terrain Analysis and Geotechnical Studies
- Wildlife and Fisheries Studies
- Environmental Protection Plan
- Access Control
- Spur Roads Networking Plan
- Wildlife Management Plan
- Maximize local opportunities
- Review of compensation by governments

5

CASINO COPPER AND GOLD

Casino Trail History

Casino Trail baseline studies completed include:

- Socio-economic impact review (1988)
- Terrain Analysis (1986)
- Moose population inventory (1987)
- Raptor nest survey (1988)
- Caribou inventory (1991)

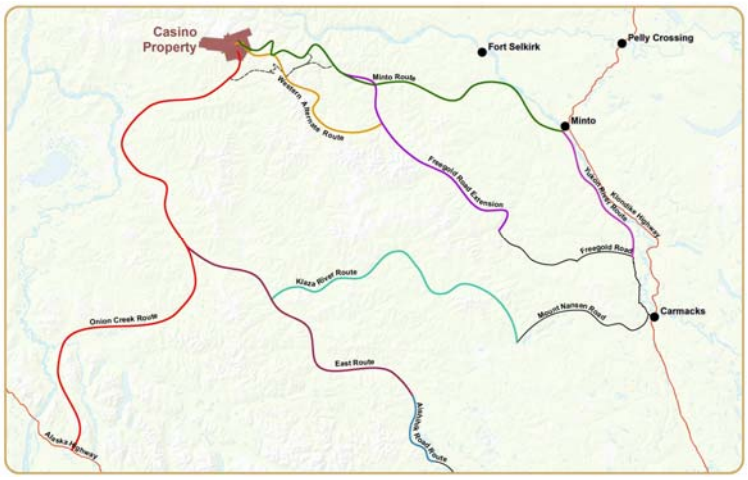
Casino Trail Wildlife Management Plan (1989)

- Key strategies:
  1. Harvest management
  2. Habitat management
  3. Population monitoring
  4. Community participation in wildlife management

6

Current Status

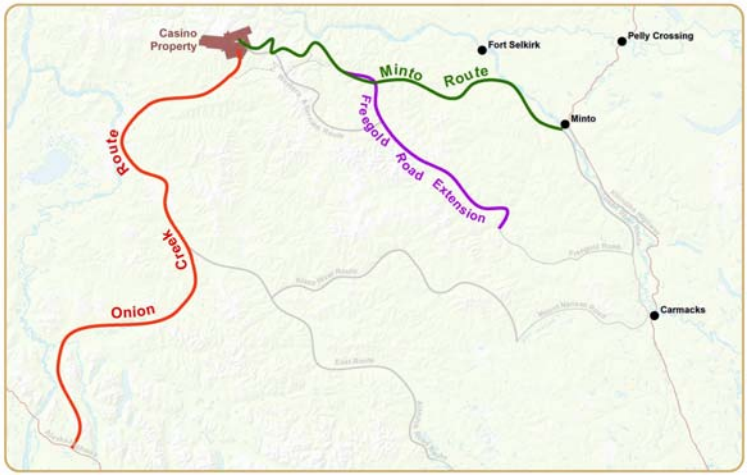
- Developing a Project Proposal for review under YESAA, including access road
- Extensive environmental, engineering and geotechnical studies have been completed over the last 4 years along the route that follows the originally proposed "Casino Trail"
- Discussions continue with Yukon Government about upgrades that will be required along the existing Freegold Road



7

Route Alternatives

- **Seven route alternatives were identified in 2008**
  - Based solely on engineering and cost
- **Each route was assessed based on potential environmental and socio-economics effects, three routes were given further consideration**
  1. Onion Creek
  2. Minto
  3. Casino Trail



8

2008 Route Considerations

9

2008 Preferred Route Candidates

10

Onion Creek Route

Used in 2008 Pre-Feasibility Study

Pros:

- Fewer river crossings
- Lowest cost

Cons:

- Unsettled land claims (crosses withdrawn areas)
- Wildlife sensitive areas (e.g. Kluane Caribou Herd winter range, moose, salmon, outfitting activities)
- Potential to open new access to wilderness areas

Status: No longer considered

11

Minto

Pros:

- Reasonable alternative based on cost and engineering
- Uses some existing road and trails

Cons:

- Crosses settlement land
- Requires bridge across Yukon River
- Potential to open new access to wilderness areas

Status: Not preferred route

12

Freegold Road Extension

Used in 2011 Pre-Feasibility Study Update

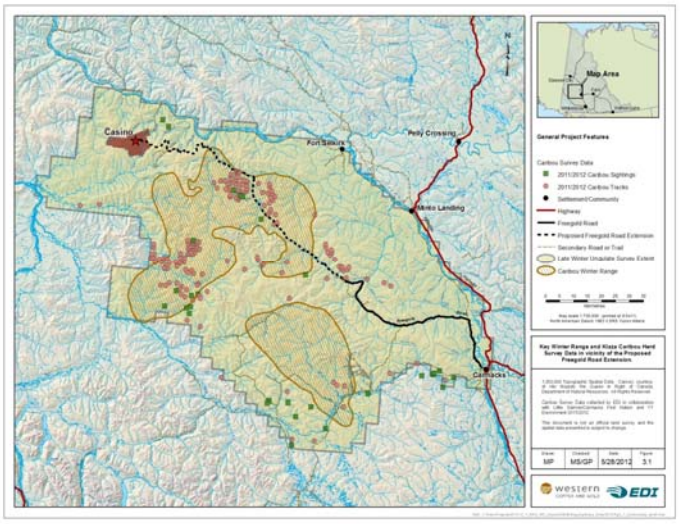
Pros:

- Minimizes new disturbance – follows impacted corridor along metal-rich belt
- Reasonable cost
- Long history of engineering, studies and planning dating back 45 years

Cons:

- Potential to open new access to wilderness areas
- Potential impacts to wintering caribou

Status: Preferred route



13

Freegold Road – Key Issue

- **Crosses the Klaza Caribou Herd winter range**
  - Similar winter distribution in 1987-90 and 2011/12 studies
    - Hayes Creek and Klotassin River
- **Klaza Caribou Herd**
  - Composed of at least 650 animals (2003), today _____
  - Use higher elevation habitats during winter
  - Experience relatively minimal harvest pressure
  - Listed on the *Species at Risk Act*

14

Caribou Winter Distribution

15

Freegold Road Extension
Current Environmental Studies

Caribou studies completed:

- Regional moose and caribou winter distribution surveys (2011/2012)
  - Collaboration with Yukon Government and First Nations governments
- Klaza caribou collaring program and population inventory (2012)
  - Providing support to Yukon Government study

Other studies completed:

- Fish inventory of streams crossing the road (2010/2011)
- Bear den survey (2012)
- Bird surveys (2010/2011)
- Vegetation surveys (2011)
- Rare plant surveys (2010/2012)
- Terrain assessments (2010)

Freegold Road Extension
Engineering Studies

- 2008 – Preliminary examination of route options and analysis
- 2009 – Continued refinement of options
- 2010 – Identification of preferred route, preliminary engineering, and initiation of environmental baseline studies
- 2011 – Continued geotechnical and baseline studies
- 2012 – Completion of engineering feasibility study; Re-examination and analysis of initial access route alternatives

Freegold Road Extension
Community and Government Engagement

- 2008 – Introduction to the project and presentation of route options to Selkirk First Nation
- 2009 – Engagement on baselines studies for Freegold Road extension
- 2010 – Information provided at various meetings, including community meeting in Pelly Crossing
- 2011 – Discuss baseline studies with regulators; presentation of preferred route to Selkirk First Nation
- 2012 – Increased engagement with communities, RRCs, and governments; Issue scoping; Currently seeking resolution to identified issues and concerns (e.g. Klaza Caribou)

Freegold Road Extension Next Steps

Examine options to address caribou concerns

- Seek additional input/advice from stakeholders
- Identify mitigation options
  - New information will inform detailed mitigation
- Follow-up dialog with First Nation governments, Yukon Government, Renewable Resource Councils and others

19

Freegold Road Extension Wildlife Mitigation Options

- Control access
  - Gate the road to control access?
  - No hunting allowed from road?
- Time construction and maintenance to occur when caribou are not present along the road
- Minimize new disturbance in the KCH winter range
  - Place construction camps and borrow pits outside of the winter range
- Reduce speed limits within the winter range
- Hire a local wildlife observer to monitor caribou near the road
- Communicate to drivers when caribou are observed along road
- Trucks will travel in convoys to reduce frequency of disturbance
- Snowbank management to allow wildlife movement across roads

20

Freegold Road Extension Mitigation Actions

- **CMC can work with governments and stakeholders to cooperatively:**
  - Conduct technical/scoping workshop?
  - Update Wildlife Management Plan?
  - Develop Access Management Plan?
  - Monitor licensed and unlicensed wildlife harvest?
  - Work with local trappers to support sustainable management of regional wolf population?
  - Continue support of regional wildlife monitoring
  - Establish environmental working group to review and recommend adaptive mitigation?

Re: YUKON RIVER CROSSING AND MINTO ROUTE RECONNAISSANCE

Dear Mr. Clegg:

The following letter discusses findings from the Casino Mine Access route alternatives reconnaissance trip that took place on Thursday August 9th, 2012. The reconnaissance was completed via helicopter and the team consisted of Patrick Stancombe and Evan Johnson from Associated Engineering and James Hayley from Knight Piesold.

The objective of the trip was to investigate alternative corridors to the Casino Mine that avoid the Woodland Caribou wintering grounds in the Dawson Range. The alternative corridor investigations included the following three elements:

- **Yukon River Bridge** - Yukon River crossing locations and connecting roads near Minto, YT
- **The Minto Route Corridors** - east-west route from Yukon River near Minto west to Hayes Creek.
- **The Wolverine Route Corridor** - Big Creek north to Wolverine Creek and west to Hayes Creek.

Based on available wildlife information, these route alternatives avoid passing through the middle of the Woodland Caribou Wintering Grounds area; however, they all still pass through the northern extents of the Woodland Caribou key Wintering Grounds area.

1 YUKON RIVER BRIDGE

Prior to the trip, Associated Engineering completed a brief desktop study and identified ten potential horizontal crossing locations along the Yukon River. The crossing locations were identified using only high level aerial photography as terrain mapping was not available. The study covered an area from 33 km south of Minto to 26 km north of Minto.

During the field investigation flight, crossing locations further than 5 km south of Minto were eliminated from consideration due to steep terrain found to the west and north of the river. These locations are unsuitable for bridge crossings due to the difficulty of abutment and approach road design. Navigating the steep terrain would likely require road narrowing, speed reductions, retaining walls, and high road construction costs. As the trip continued it became evident that crossing sites closer to Minto and to the north of Minto had narrower river sections and more favourable bank conditions than those of the southern sites. The southern crossing locations do not appear to have any advantages that warrant the additional length of new road required to access them. This eliminated seven crossings.

The three remaining crossings under consideration are:

- Site 1 located 3 km south of Minto,
- Site 2 immediately adjacent to Minto, and
- Site 3 located 26 km north of Minto near the Hell's Gate Rapids.

Crossing Sites 1 and 2 are close to Minto and the Klondike Highway to the east. Crossing Site 3 is approximately 27 km from the Klondike Highway to the east. Photos of the crossing locations can be found in Figure 1, Figure 2, and Figure 3 respectively. The approximate width of the Yukon River from bank to bank is 229 m at Site 1, 288 m at Site 2, and 216 m at Site 3. Required bridge lengths will be considerably longer than the Yukon River widths and will vary depending on the grades and bank conditions of each site. Bridge costs could also vary considerably due to geotechnical considerations. For locations refer to sketches SK012 and SK013.

2 THE MINTO ROUTE CORRIDORS

Two corridor options from the Yukon River to Hayes Creek were investigated: The Minto Landing option using crossing Site 2, and the Hells Gate option using crossing Site 3.

The Minto Landing option requires 24 km of the existing Minto Mine Road West of the Yukon River and 25km of new road through some steep terrain and drainages to reach the Wolverine Creek Valley. There is also steep terrain on the final decent into the Wolverine Creek valley.

The Hells Gate option requires approximately 27 km of new road to connect with the Klondike Highway to the east. To the west, another 25 km of new road climbing steeply away from the Yukon River is required to reach the Wolverine Creek Valley. There is steep terrain located near the banks of the Yukon River and on the final decent into the Wolverine Creek Valley. The steep terrain presents major challenges to locating a road alignment with suitable curves and grades for haul truck operations. For locations refer to sketches SK012 and SK013.

Both corridors eventually connect at the Wolverine Creek Valley approximately 25 km directly west of the Yukon River and start following the valley to the west. Once the road enters the Wolverine Creek valley, the terrain flattens out and it should be possible to locate a road alignment with gentle grades and curves. We anticipate that both options will require a minimum of 4 major bridge crossings on Wolverine and Selkirk Creeks before arriving at the Hayes Creek Valley and joining with the current Freegold Road Extension alignment. It was also noted that sources for borrow material could be scarce near Wolverine Creek and Selkirk Creek. If sufficient material cannot be located near the alignment at regular intervals it will result in longer haul distances and increased road construction costs.

3 THE WOLVERINE ROUTE CORRIDOR

The day prior to our scheduled reconnaissance trip, Jesse Duke, P.Geo. in charge of Western Copper and Gold Corporation's government and community relations, proposed an additional corridor referred to as the Wolverine Route for the team to investigate. The Wolverine Route is a potential route alternative for the Freegold Road Extension that bypasses a portion of the Woodland Caribou winter range. The route would branch to the north off of the Big Creek section of the Freegold Road Extension and follow the Wolverine Creek Valley to Selkirk Creek where it would turn to the west and follow the Selkirk Creek Valley until it rejoined the Freegold Road Extension at Hayes Creek.

Visual field investigation of this route from the helicopter revealed steep terrain and narrow drainage valleys between Big Creek and the southern tip of the Wolverine Creek valley. We were unable to locate a suitable route over the height of land between the two creek valleys during our helicopter flight. Figure 4 shows a photo of some typical steep terrain in this area. It is anticipated that the road grades required along this route would present challenges for winter operations and that even in summer operations reduced speed sections would likely be required along with sections of one-lane road, retaining walls, and reinforced slopes. This route would have high capital and operating costs and would likely have some safety concerns. Further north in the Wolverine Creek Valley, it appeared that a route could be located. The route would require several crossings of the Wolverine Creek before reaching the final stretch along Selkirk Creek west to Hayes Creek.

A debrief meeting with Jesse Duke was held the day following the field investigation along with the environmental team of Michael Setterington and Matt Power of Environmental Dynamics Inc. (EDI) at EDI's offices in Whitehorse. At this meeting we discussed our observations of the Wolverine Route and presented photos of the steep terrain and narrow valleys. Jesse Duke decided that based on our observations, this route would not be investigated further at this time.

4 ADDITIONAL AFTER TRIP DESKTOP STUDY FINDINGS

Subsequent to the field investigation, Associated Engineering acquired 1:50,000 scale mapping and 40 m contour data from Geomatics Yukon. We then prepared conceptual horizontal and vertical alignments for each of the Minto Route corridor options. There are two route alternatives for the Hells Gate corridor option and three route alternatives for the Minto Landing corridor option. All route alternatives follow a common alignment from the Wolverine Creek Valley to the Hayes Creek Valley located mainly along the toe of the south facing valley slopes. The route alternatives are shown in attached sketches SK012 and SK013.

Road lengths from the Casino Mine to the port of Skagway for the roads associated with all the route alternatives and the Freegold Road Extension are shown in the attached Table 1. The table shows that the Minto Landing option routes are 2-4 km longer than the Freegold Road Extension while the Hells Gate option routes are 11-14 km longer.

The Hells Gate option routes have the advantage of avoiding Minto Mine property and First Nations settlement lands, but they are longer, require more new road construction, have more steep terrain sections, and they reduce the likelihood of cost sharing agreements with other road and bridge users. These routes should only be considered if First Nations and private property conflicts arise and cannot be resolved.

Minto Landing option routes are shorter, make use of 24 km of the existing Minto Mine road, and have a higher potential for cost sharing agreements with other road and bridge users. These routes pass through Minto Mine property and First Nations settlement lands.

While it appears that a feasible route from Minto to Hayes Creek can be located, a preferred route has not yet been selected. More detailed mapping is required to identify a preferred route option, confirm the alignment, and estimate cut and fill volumes for cost estimating. We will also need to better understand the environmental, First Nations, private property and geotechnical issues in the area.

5 CONCLUSIONS AND RECOMMENDATIONS

In order to advance the Minto Route corridor options and Yukon River bridge design we recommend the following tasks be completed as a Desktop study. Tasks are listed in the order in which they should be completed.

1. Obtain and Review aerial photos and terrain mapping for the Minto Route study area. Possible mapping sources include PhotoSat Satellite photo terrain mapping data (higher quality and available in spring or summer), LIDAR (higher quality and available in spring or summer), and digitised air photos from Yukon EMR library catalogue (lower quality and available any time).

2. Prepare functional designs of alternative routes using new terrain mapping and building upon initial conceptual alignments and field reconnaissance routes. Includes horizontal and vertical alignment design, cross-sections, identifying stream crossings, preliminary bridge concepts (including Yukon River crossing), and calculating preliminary costs and quantities.

3. Identify constraints and issues including private property, cost sharing possibilities, first nations, environmental, drainage, archaeological, borrow sources, terrain stability, and other potential risks.

4. Preliminary geotechnical testing.

5. Select preferred Minto route option and preferred Yukon River bridge crossing location based on functional designs and alignment issues.

6. Complete a written report discussing route options, alignment issues, selection criteria, and preliminary cost estimates.

Completion of these desktop study tasks will provide the information necessary to move forward with more detailed field investigations and additional engineering work. This will provide the basis to eventually achieve the same design level currently achieved for the Freegold Road extension. These tasks should preferably be completed prior to the spring of 2013 in order to provide sufficient lead time to organise field investigations during the 2013 field season.

Should you have any questions, please contact Ray Korpela or me.

EXECUTIVE SUMMARY

A Feasibility design has been undertaken for a Heap Leach Facility (HLF) at the Casino Copper-Gold Project. The proposed facility is located on a southeast facing hill-slope approximately one kilometre south of the deposit area. HLF operations will commence during pre-production stripping of the open pit. The design was carried out for an ore tonnage of 157.5 million tonnes. The heap leach pad will be stacked with ore and leached from Year -3 through Year 15 of mine operations. The ore will be leached at a nominal rate of 9.125 million tonnes per year. There is potential for stacking of additional ore if the mine production schedule is revised and additional leach ore is identified.

The Feasibility design includes an assessment of the following:

- Geotechnical site conditions
- Design basis and design requirements
- Design of heap leach pad and liner system
- Design of leachate collection system and events pond
- Water management and water balance
- Construction requirements and operational strategy
- Quantities and information for capital cost estimation
- Preliminary monitoring and reclamation requirements, and
- Recommendations for additional site investigations and design studies.

Information provided by site investigations and design studies indicate that the construction and operation of a HLF is possible at this site. However, the cold climate and presence of extensive permafrost requires special design and operational considerations.

The following is a summary of the design features, operational requirements and construction methods which will be required for the proposed facility:

- Pumping of pregnant solution to a gold extraction plant, located southwest of the plant site area.
- Excavation of the pad foundation down to competent bedrock in areas with permafrost to eliminate potential settlement and instability resulting from thawing of ice-rich overburden. These materials will require containment and sediment control upon thawing. The extent of ice-rich overburden throughout the heap leach pad area has been estimated as approximately two metres deep
- An events pond for temporary storage of storm runoff and pregnant solution overflow during shut down will be constructed at the foot of the HLF confining embankment. The events pond will be included as part of the pre-production schedule.
- A composite liner system comprising a LLDPE liner, compacted soil liner and leak detection and recovery system to maximize leachate collection and minimize seepage losses will be constructed over the upper portion of the leach pad. A double composite liner system comprising two LLDPE liners, a compacted soil liner and a geotextile layer will also be constructed in the lower portion of the leach pad (potential ponding area) and events pond and will include a leak detection and recovery system for intercepting and collecting any leakage through the inner liner.
- Borrow materials for the confining embankment, events pond and soil liner construction may utilize suitable overburden (residual and colluvial soils) and weathered bedrock along well

drained, non-frozen, south-facing slopes east or west of the HLF. Suitable non-reactive mine waste rock may also be used for HLF construction.

- The heap leach pad will be developed in five stages by loading in successive lifts upslope from the confining embankment. This will provide initial stability and minimize initial capital costs. The pad will be developed in eight metre lifts constructed at repose bench face angles of approximately 1.4H:1V. Bench widths approximately nine metre wide will be left at the toe of each lift to establish a final overall slope angle of 2.5H:1V.
- Operations will involve the irrigation of a weak cyanide solution over the ore lift and the recovery of pregnant solution by means of solution collection pipes and pumps. The solution will be pumped to the gold extraction plant for metal extraction and recycled for re-use in the leaching process. The irrigation lines will be buried to prevent freezing during winter conditions.

The final heap leach pad required for an ore tonnage of 157.5 million tonnes will have a surface area of approximately 1,501,000 m^2. An events pond will provide storage for excess leachate and storm water runoff. The heap leach pad confining embankment and events pond will require approximately 1,067,000 m^3 of embankment and drainage fill for construction. The required storage capacity for the events pond is approximately 110,000 m^3. The total quantity of geosynthetic liner required for the heap leach pad and confining embankment is approximately 1,587,000 m^2. The total quantity of geosynthetic liner for the events pond is approximately 50,300 m^2.

On-going costs will include foundation preparation and liner installation for expansion of the leach pad up the slope. Other costs associated with the HLF include operational costs and capital costs for leaching services. It is assumed that capital and operating cost estimates will be developed by Others.

Appendix A Water Balance

1 – INTRODUCTION

1.1 PROJECT DESCRIPTION

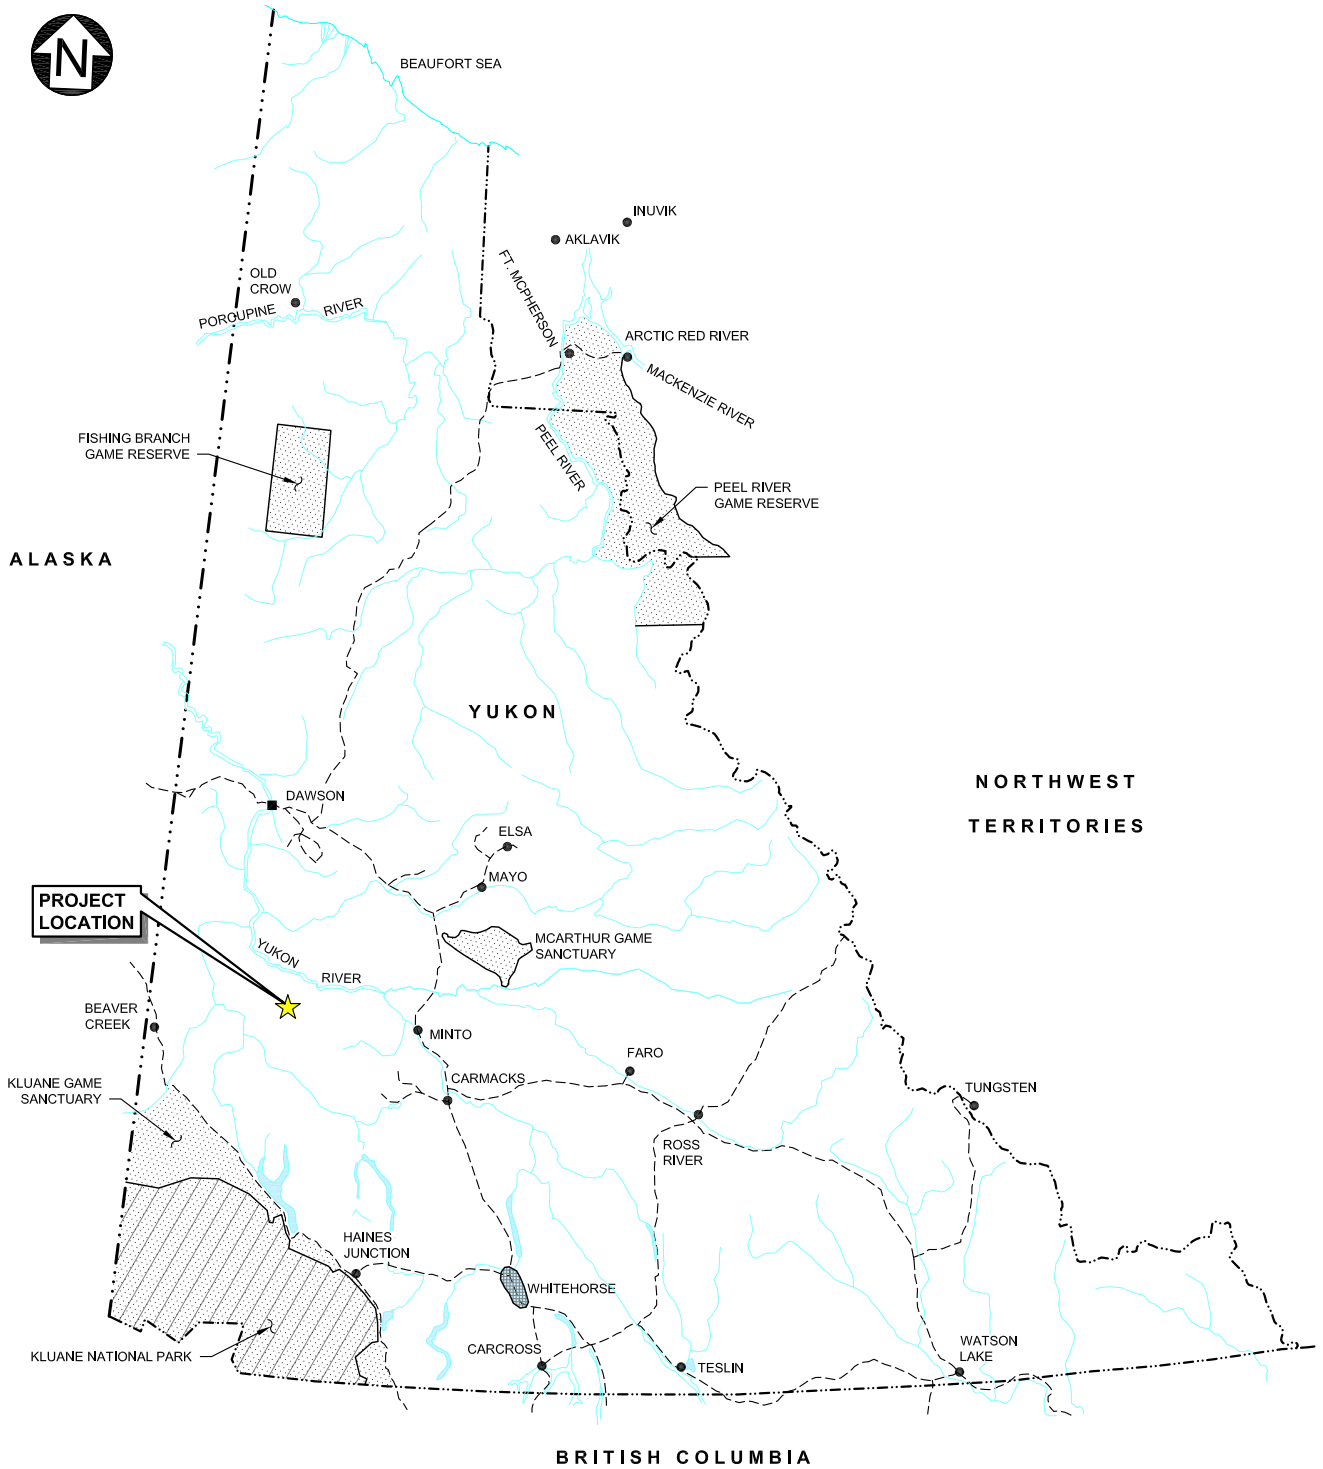
The Casino Copper-Gold Project is a venture by Casino Mining Corporation (CMC) to develop an open pit copper-gold-molybdenum mine located in west central Yukon, Canada. The project is located in the Dawson Range Mountains of the Klondike Plateau approximately 300 km northwest of Whitehorse, Yukon, Canada, as shown on Figure 1.1. The deposit will be mined using open pit methods with a nominal mill throughput of 125,000 tonnes per day (TPD) of ore. Approximately 157.5 Mt of additional mined ore will be processed at the Heap Leach Facility (HLF) located south of the open pit. HLF operations will commence during pre-production stripping of the open pit. The heap leach pad will be stacked with ore and leached simultaneously from Year -3 through Year 15 of mine operations. The ore will be leached at a nominal rate of 9.125 million tonnes per year. The proposed facility is located on a southeast facing hill-slope approximately one kilometre south of the deposit area.

1.2 SCOPE OF WORK

This report presents the Feasibility design of the proposed HLF. The leach pad will comprise a fully contained gold ore treatment facility. The leaching process will involve the irrigation of weak cyanide solution over successive lifts of heaped ore. A total of 157.5 million tonnes (Mt) of ore was assumed for the design (based on the mining schedule issued by CMC on November 7, 2012), with consideration for potential expansion. This report discusses general site conditions, geotechnical implications, design requirements and design aspects for the heap leach pad.

Geotechnical site investigations in the current HLF area were carried out in 1993, 1994, 2011 and 2012. Additional site investigations, design studies and ore characterization will be required to confirm design assumptions and details.

1.3 PREVIOUS STUDIES



A conceptual design for a HLF was conducted by Knight Piésold Ltd. (KPL) in 1994 to 1995 and presented in the “Report on Conceptual Design of Heap Leach Facility” (Ref No. 1833/1, January 24, 1995). This facility was located immediately south of the deposit area and sized to accommodate 36.5 million tonnes of ore, with provision for expansion up to 50 million tonnes. This site was later ruled out due to an increased capacity requirement of leach ore.

A Pre-Feasibility design for a 75 Mt HLF was undertaken by KPL in 2008. The selected facility location was immediately north of the Tailings Management Facility (TMF). Details of this design are presented in KPL report “Pre-Feasibility Design of the Heap Leach Facility” (Ref. No. VA101-325/1-1, April 23, 2008).

A revised Pre-Feasibility design for an 81.6 Mt HLF was carried out by KPL in 2011. This revised Pre-Feasibility design located the HLF in a position deemed more favourable because of its topography and proximity to the deposit area and plant site. The site was located south of the deposit area as shown on Figure 1.2, in an area previously designated but no longer required for storage of Non-Acid Generating (NAG) mine waste rock and overburden. This site is located

upstream and within the same catchment area as the TMF, thereby simplifying water management and minimizing potential environmental impact.

This Feasibility design report further develops the 2011 revised pre-feasibility HLF design. The HLF pad has been expanded to accommodate a total capacity of 157.5 Mt of ore (an additional 75.9 Mt). Further expansion of the site to accommodate additional leach ore within the HLF is also possible if the mine production schedule is revised and additional leach ore is identified.

2 – SITE CHARACTERISTICS

2.1 PHYSIOGRAPHIC SETTING

The project is located in the Dawson Range Mountains of the Klondike Plateau. The area is somewhat unique in that the region was not glaciated during the Wisconsin Advance. The characteristic terrain features are smooth, rolling topography, with moderate to deeply incised valleys. Major drainage channels extend below 1,000 m elevation. Most of the terrain lies between 1,000 m and 1,500 m elevation.

The proposed heap leach facility is located west of the plant site and south of the open pit area. The leach pad is situated on a relatively uniform southeast-facing hillside. The existing topography slopes at approximately 20% (11.5 degrees). The site was chosen for its proximity to the proposed open pit to minimize haul road and ore transport conveyor distances, and to include the leach pad within the same catchment area as the TMF.

A natural drainage channel exists along the middle of the leach pad, where the main leachate collection pipes will be located. The location of the heap leach pad in relation to the overall site and other project components is shown on Figure 1.2.

2.2 HYDROMETEOROLOGY

2.2.1 General

The climate at the Casino Project area is characterized by long, cold, dry winters and short, warm, wet summers, with conditions varying according to altitude and aspect. Streamflow in the region is typically highest in May due to melting of the winter snowpack. Annual peak instantaneous flows commonly occur in this freshet period on larger rivers, but on smaller streams they may also occur in summer or early autumn due to intense rain or rain on snow events. Flows decrease throughout the winter and minimum flows typically occur in March or April.

The climate and hydrology at the Casino Project site have been assessed based on both short-term site data and longer-term regional data. Climatic data were collected on-site at the Project climate station located in the upper Casino Creek sub-watershed at an elevation of 1200 m. The period of site record extends from 1993 to 1994 and from 2008 to 2011. Preliminary streamflow data were collected by Hallam Knight Piésold in 1993 and 1994. A new data streamflow collection program was initiated by AECOM in 2008, with the installation of ten streamflow gauging stations. As of 2012, nine streamflow gauging stations are considered to be in active operation and continue to be operated at present by Knight Piésold Ltd. (KPL). A summary of the hydrometeorological parameters is described below and the detailed analyses are presented in KPL report “Updated Hydrometeorology Report” (Ref. No. VA101-325/8-11, July 9, 2012).

2.2.2 Temperature

The mean annual temperature for the Casino Project area is estimated to be -3 °C, with minimum and maximum mean monthly temperatures of -17 °C and 12 °C occurring in January and July, respectively.

The mean monthly temperature values are presented in Table 2.1.

Table 2.1 Mean Monthly Temperature and Precipitation Values

Location	Parameter	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual
Casino Project Station (El. 1200 m)	Rainfall est.	0	0	0	8	37	62	91	67	47	18	0	0	**330**
	Snowfall est.	32	24	19	9	0	0	0	0	0	20	43	33	**180**
	Precipitation (mm)	32	24	19	17	37	62	91	67	47	38	43	33	**510**
	Temperature (°C)	-16.1	-14.9	-9.5	-0.6	6.5	9.8	12.3	10.3	4.6	-3.6	-12.0	-14.0	**-2.2**

2.2.3 Precipitation and Evaporation

The Mean Annual Precipitation (MAP) for the Casino Project area is estimated to be 510 mm, with 65% falling as rain and 35% falling as snow. The mean monthly values are presented in Table 2.1.

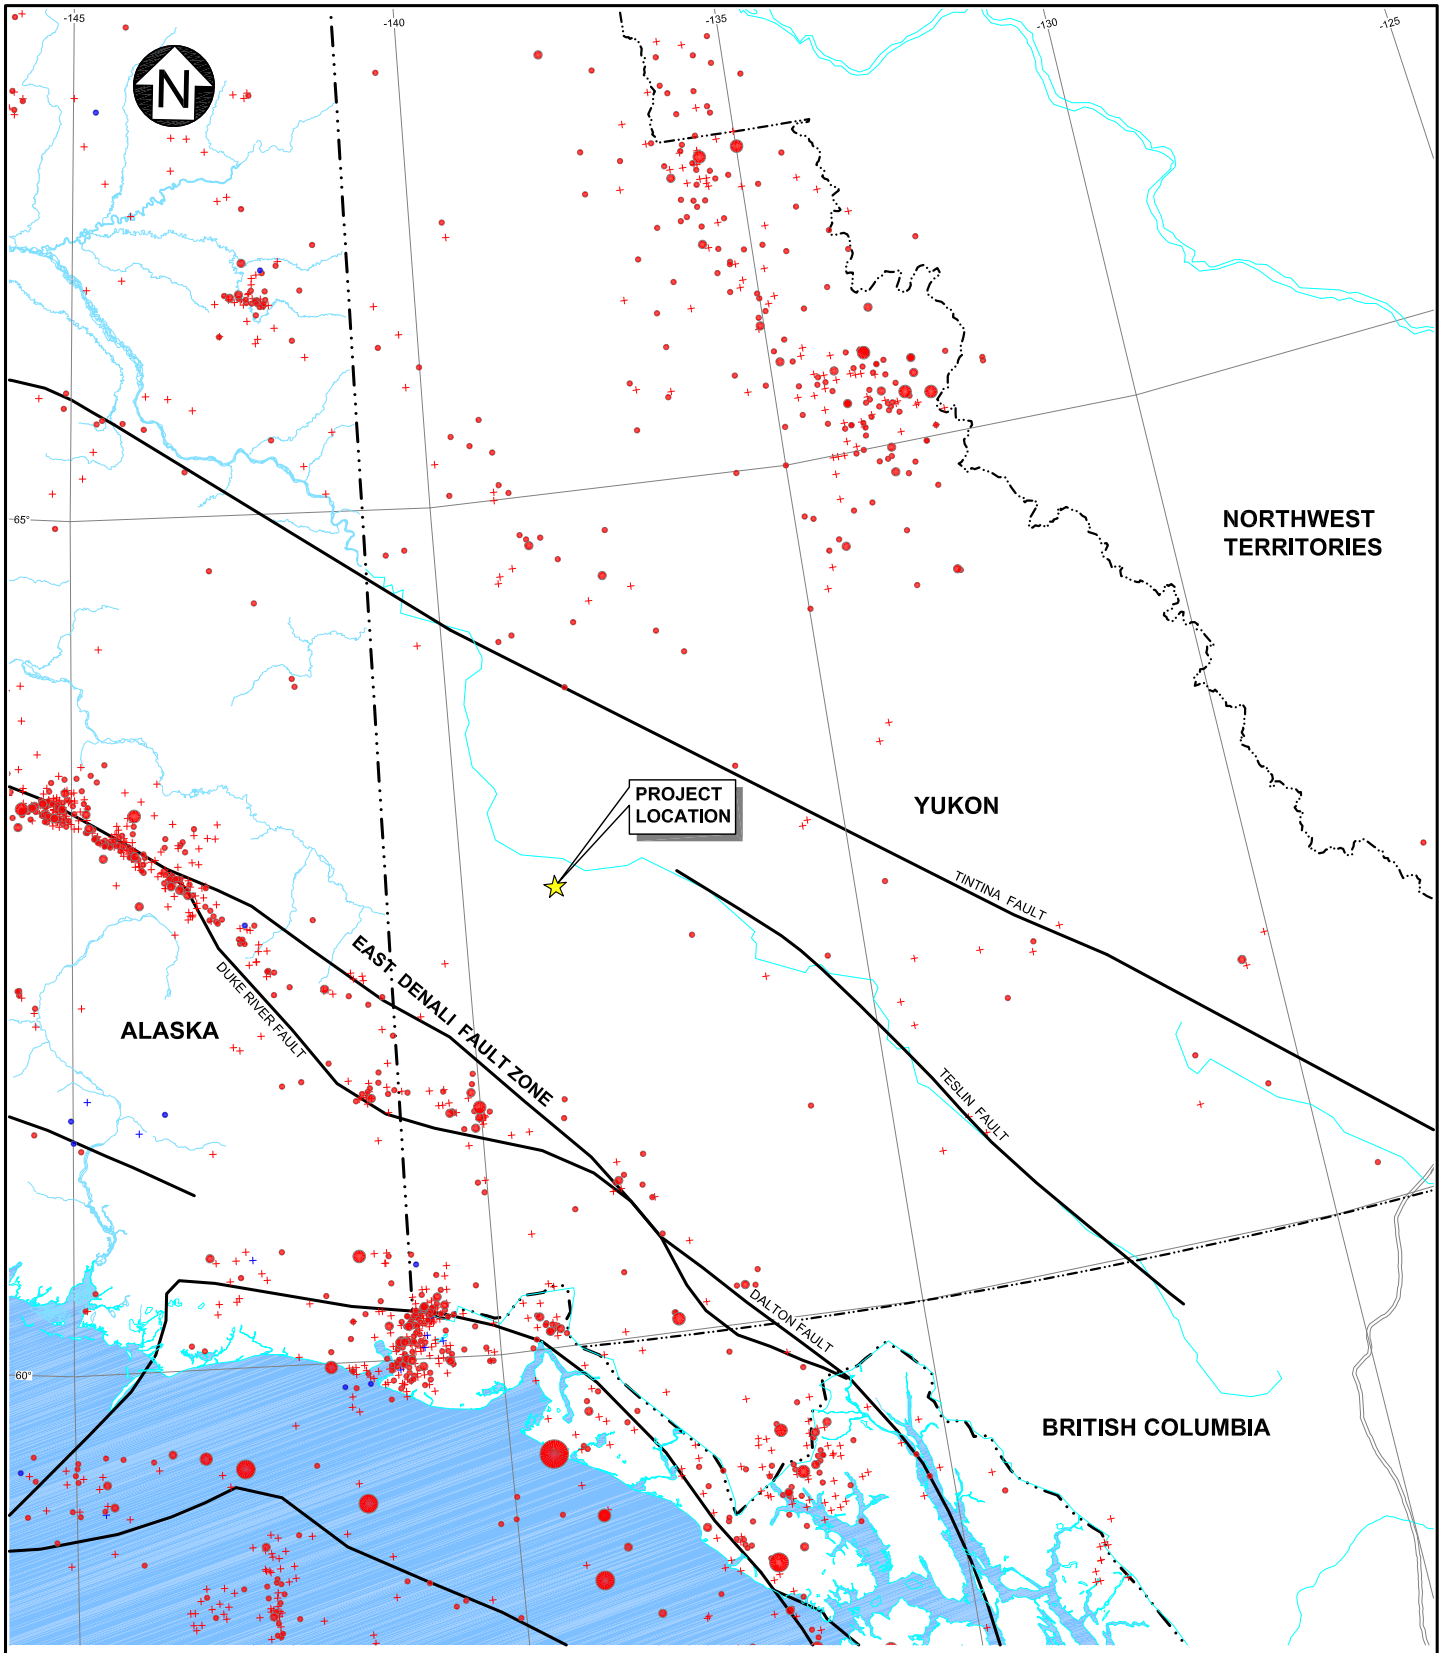
The annual potential evapotranspiration (PET) value for the Casino Project area is estimated to be 300 mm, based on measured temperatures at the Project site climate station, and long-term regional temperature records. Potential evapotranspiration values generally provide reasonable estimates of lake evaporation rates, and are assumed to be appropriate for estimating evaporation from lakes and ponds in the Project area.

2.2.4 Annual Snowfall and Snowmelt

Based on the estimated MAP of 510 mm and a rain/snow ratio of 0.65/0.35, the annual snowfall value for Casino was estimated to be 179 mm. This is generally consistent with the 141 mm mean annual maximum snowpack value (snow water equivalent, SWE), taking into account approximately 40 mm lost to sublimation, recorded in the Project area at the Casino Creek snow course station (09CD-SC01) operated by the Yukon Department of Environment (1977-2011), Water Resources Branch.

Based on the complete years of snowpack data, the average monthly snowmelt distribution for the Casino Project area was estimated to be approximately 20% in April and the remaining 80% in May, although there is considerable variation from year to year.

2.3 SEISMICITY



A review of the regional seismicity has been carried out to enable selection of an appropriate design earthquake event for seismic stability assessment of the HLF.

The region of the southwest Yukon Territory and northwest British Columbia is one of the most seismically active areas in Canada. The seismic hazard in the region is also influenced by the seismically active region of southeast Alaska. The coastal region has experienced many large earthquakes, including events with magnitudes in the range of magnitude 7.0 to 8.0. In 1958 a magnitude 7.9 earthquake occurred along the Fairweather fault (the northern extension of the Queen Charlotte transform fault). The most significant inland zone of seismicity follows the Dalton and Duke River segments of the Denali fault zone through the southwest Yukon. Farther inland there is only

minor seismicity between the Denali and Tintina fault systems, including the region of the Casino Project site.

A probabilistic seismic hazard assessment has been carried out for the Casino project site to provide seismic parameters for design of project facilities. Details and results of the seismic hazard analysis are provided in the KPL report "Feasibility Design of the Tailings Management Facility" (Ref. No. VA101-325/8-10, November, 2012).

Figure 2.1 shows the regional tectonics and historical seismicity of the Yukon and surrounding regions. Review of historical earthquake records and regional tectonics indicates that the Casino Project site is situated in a region of low seismicity and moderate seismic hazard.

3 – DESIGN REQUIREMENTS AND PARAMETERS

3.1 DESIGN OBJECTIVES

The primary design objectives for the proposed heap leach pad are as follows:

- Provide a stable and cost effective configuration for staged heap development
- Effectively collect and convey leachate solutions to the process plant or the events pond while ensuring maximum recovery
- Provide for secure containment of events solutions while monitoring and minimizing losses due to leakage
- Minimize surface runoff entering the leach pad area while providing for the collection of direct runoff from the heap area
- Sequential, staged development and leaching operations with particular emphasis on winter operations, and
- Effective decommissioning and reclamation of all heap leach facility components.

The following sections discuss the storage requirements and design assumptions and parameters for the proposed leach pad. Design features for each component are discussed in Section 5.0.

3.2 DESIGN BASIS AND ASSUMPTIONS

The design storage for the heap leach pad has been based on a requirement for 157.5 million tonnes capacity with the potential for further expansion if required.

Various design assumptions and parameters were used in this Feasibility design and configuration layout of the heap leach pad. The assumptions and parameters used to develop the design are listed below:

- Total ore tonnage: 157.5 Mt
- Ore stacking schedule: 300 days/year
- Ore leaching schedule: 365 days/year
- Annual stacking tonnage: 9,125,000 tonnes/year (max); 6,580,000 tonnes/year (min)
- Mine-run Ore specific gravity (estimate): 2.65
- Constant average depth to bedrock: 2 metres
- Lift thickness: 8 metres
- Dry density of ore heap (estimate): 1.75 t/m^3
- Mine-run ore moisture content: 2%
- Leach pile ore operating moisture content: 12%
- Leach pile ore retained moisture content: 10%
- Ore irrigation rate: 0.29 $m^3/day/m^2$ (12 $L/h/m^2$)
- HLF Irrigation capacity: 1312 m^3/day
- Runoff on heap leach pad: 98.25 %
- Design Storm: 1 in 100 year 24-hour: 53 mm
- Design Storm: 1 in 200 year 24-hour: 56 mm

The Water Management System is designed to accommodate the 1 in 100 year storm event. Spillways are designed for the 1 in 200 year storm event.

Leach ore testing (to determine ore moisture contents and densities) will be required to confirm assumptions for future design studies.

The pad will be constructed in five stages commencing in Year -3 (pre-production stage of the project). It will be loaded in successive eight metre thick lifts for 300 days a year while the leaching process will operate year round. A drip-type irrigation system will be implemented which enables year round leaching operation due to being insulated by the placement of subsequent ore lifts overtop.

Gold ore to feed the HLF will be located in a temporary stockpile east of the open pit, close to the crusher. The ore will be crushed and transported to the pad by conveyor. The locations of the proposed gold ore stockpile, crusher and conveyor alignment are included on Figure 1.2.

4 – GEOTECHNICAL CHARACTERISTICS

4.1 GEOTECHNICAL CONDITIONS

Geotechnical and hydrogeological information in the vicinity of the HLF is derived from the interpretation of KPL drill hole and test pit data within both the HLF and surrounding areas. Several geotechnical site investigation programs were conducted in the area of the HLF in 1993 and 1994 and in 2011 and 2012. Details and results of the site investigations are presented in the following KPL reports:

- Report on Preliminary Surficial Geotechnical Investigations (Ref. No. 1831/1, March, 1994)
- Data Compilation Report on 1994 Geotechnical/Hydrogeological Investigations (Ref. No. 1832/1, February 22, 1995)
- 2011 Geotechnical Site Investigation Data Report Waste Management Facilities (Ref. No. VA101-325/8-5, May 18, 2012), and
- 2012 Geotechnical Site Investigation Data Report (Ref. No., VA101-325/8-14, December, 2012).

The locations of drill holes, test pits, and test trenches excavated in the vicinity of the proposed heap leach facility are shown on Figure 4.1. The majority of the test pits conducted in 2011 were ended due to refusal on frozen ground or boulders.

The HLF is situated on a southeast-facing slope south of the deposit area. Vegetation is comprised primarily of deciduous black spruce with thin moss and forest litter cover. Soil profiles throughout the proposed heap leach pad area typically comprise a thin veneer of organic-rich topsoil and colluvium overlying in situ weathered residual soils or granodiorite bedrock.

The subsurface conditions in the area of the HLF are based on the findings of the geotechnical investigations, and are generally summarized below:

- Topsoil comprises a moist organic-rich silty layer. Coarse talus blocks (boulders) are also common. Topsoil thicknesses vary from approximately 0.1 to 1.0 m.
- Silty sand containing some gravel and cobbles, trace boulders and clay (residual soil and colluvium). Residual soils generally comprise moderately to highly weathered silts and sands with some gravel and trace clay. Ice lenses were found in some test pits which could result in high water contents upon thawing.
- Dawson Range Batholith (Mid-Cretaceous) is the main country rock in the HLF area and is dominantly granodiorite in composition. Aplite was found in 94-352 and a Patton Porphyry Dyke (Upper Cretaceous) was noted in DH11-29. The depth to bedrock varies from 1 to 7.6 m, with an average depth of approximately 2.5 m. The greatest depth to bedrock was encountered at the bottom (southern) end of the HLF area (DH94-453). Weathered Granodiorite has been found to extend to 41 m depth in recent site investigations, but earlier investigations indicated the presence of slightly weathered, competent bedrock.

4.2 HYDROGEOLOGICAL CONDITIONS

The interpreted baseline groundwater conditions are based on piezometric levels in standpipe piezometers throughout the study area. Permeability results are based on packer tests and falling head tests performed in the drill holes and piezometers in the different geological units.

Water level readings were recorded for piezometers 94-352, 94-353, 94-354 (between September and December of 1994) and in DH11-29. The depth from ground surface to water varies from approximately 3 metres in the southwest area of the HLF to 20 metres in the southeast area. The water level in DH11-29 was measured at 12.2 m below ground surface in 2011.

In situ packer and falling head permeability tests were carried out in a number of drill holes within the HLF area during the 1994 and 2011 geotechnical/hydrogeological investigations. Estimates of in situ permeability values, along with supporting hydrogeologic observations are summarized as follows:

- One falling head test was performed in overburden soils in drill hole 94-354 with an estimated permeability of 8×10^{-5} cm/s.
- 14 permeability (slug) tests performed in 1994 in rock ranged from 5×10^{-6} cm/s to 1×10^{-3} cm/s, with a geometric mean value of 1×10^{-4} cm/s.
- Three packer tests and one falling head test performed in rock at DH11-29 indicated permeability values ranging from 3×10^{-6} cm/s to 6×10^{-5} cm/s.

Permafrost has an important effect on groundwater flow. Saturated frozen soil and rock have a much lower permeability when frozen compared to a thawed or unfrozen state.

Water well level elevations in the HLF area range from approximately 1080 to 1230 meters. The highest water levels are located in the upper part of the HLF, which indicates groundwater is flowing southeast and downgradient towards the Meloy Creek valley bottom.

4.3 PERMAFROST

Permafrost, or perennially frozen ground, is discontinuous along Casino Creek valley and is restricted primarily to valley bottoms, north-facing slopes and local shaded areas. Although permafrost was recorded in some areas of the HLF, the area is typically characterized by well-drained colluvial and/or residual sandy soils supporting stands of tall spruce and poplar. Permafrost was most extensive in the upper part of the HLF area, where vegetation consists of shrubs and a few stunted trees. It is less prominent in the more densely forested southeast part of the area. The permafrost table varies from 0.2 to 3 m depth, with an average depth of 1.5 m.

The estimated frost penetration depth for the Casino Project site is estimated to be approximately 5.5 metres in sand and gravel soils (granular) and decomposed/weathered bedrock. A thermistor was installed in DH12-05 during the 2012 site investigation to provide a better understanding of the thermal regime in the bedrock.

Disturbance or removal of the vegetative cover for foundation preparation may result in the melting of permafrost and the development of unstable conditions. It is therefore recommended that all ice-rich overburden encountered during construction be removed along the entire foundation of the HLF. Ground ice is not expected to be significant in bedrock which will likely provide a stable foundation for the pad and other components of the HLF.

4.4 GEOTECHNICAL IMPLICATIONS FOR DESIGN

The information provided by the site investigations has been used to determine geotechnical implications for this Feasibility design. Additional subsurface investigations will be required to confirm foundation conditions for future design studies.

The geotechnical implications for design are as follows:

- Initial foundation preparation for the heap leach pad will involve stripping of thick moss and shrub vegetation and removal of coarse talus blocks along the slope. Topsoil from stripping will be stockpiled for reclamation, as required.
- Frozen, organic and ice-rich colluvium and residual soils may require ripping or blasting to competent, non-frost susceptible bedrock for subgrade preparation. All ice-rich overburden and heavily weathered rock must be removed to prevent potential thaw-settlement resulting from melting permafrost. The bedrock will provide a thaw-stable foundation for the leach pad.
- Depths to competent bedrock over the leach pad area are expected to vary from approximately 1 to 8 metres, based on available information. An average depth of 2.5 m has been assumed for estimating the quantity of foundation excavation required.
- Spoil from excavated ice-rich overburden will require containment and sediment control during thawing.
- Colluvium and residual soils along south-facing slopes east and west of the HLF may provide excellent borrow materials for initial leach pad construction. The finer grained residual silty sands near surface may be utilized as soil liner for embankment and leach pad construction. Coarser grained colluvium, gravelly residual sands and broken, weathered bedrock at depth may be used as general backfill for the leach pad foundation or as fill in embankment construction.
- Foundation drains may be required to relieve groundwater pressures under the pad liners and/or if significant natural seeps are intersected. The drains will likely comprise perforated drain pipe surrounded by drain gravel and filter fabric. The drain gravel may be obtained from crushed borrow quarry rock or alluvial soils from creek beds.
- Diversion and runoff collection ditches constructed around the HLF will likely be founded in overburden. Therefore in order to prevent degradation from thawing permafrost riprap or other erosion protection will be required.

The proposed gold extraction facilities may be sited on competent, hard granodiorite bedrock at shallow depths adjacent to the HLF.

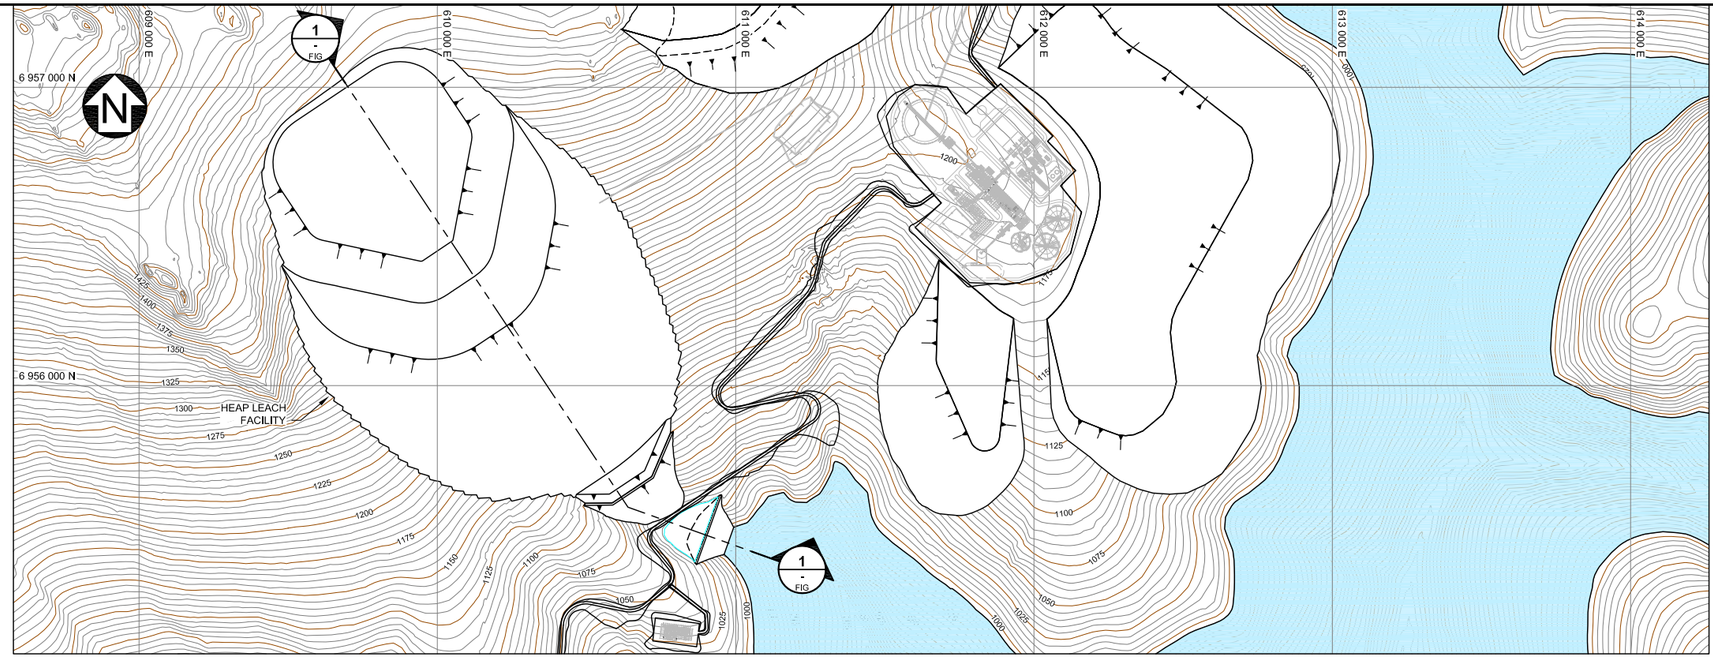
5 – ENGINEERING ANALYSES AND DESIGN

The Heap Leach Facility (HLF) consists of the following system components:

- Heap leach pad
- Liner System
- Leachate collection system
- Events pond
- Stormwater management system, and
- Freshwater supply.

The ore stacking schedule for the heap leach pad has been designed as 'development' stages, with each stage requiring advance expansion of the pad footprint. The HLF will be constructed in five 'pad development' stages, with the pad foundation preparation, liner installation and leachate collection piping developed as the footprint of the leach pad expands upslope to accommodate additional ore lifts. The duration for each stacking stages ranges from three to four years.

The initial HLF development (Stage 1) will also include the complete development of the confining embankment, events pond and perimeter diversion ditches prior to commencing ore stacking and leaching. Table 5.1 presents the stacking schedule, the respective development footprints and ore volume capacities. Figure 5.1 presents the plan and typical section of the final HLF pad, confining embankment and events pond. Figures 5.2 to 5.4 present the staging and the development progress and Figure 5.5 presents the Elevation - Capacity curve for the pad.



Design details for each of the HLF components are discussed further in the following sections.

Table 5.1 Heap Leach Stacking Schedule

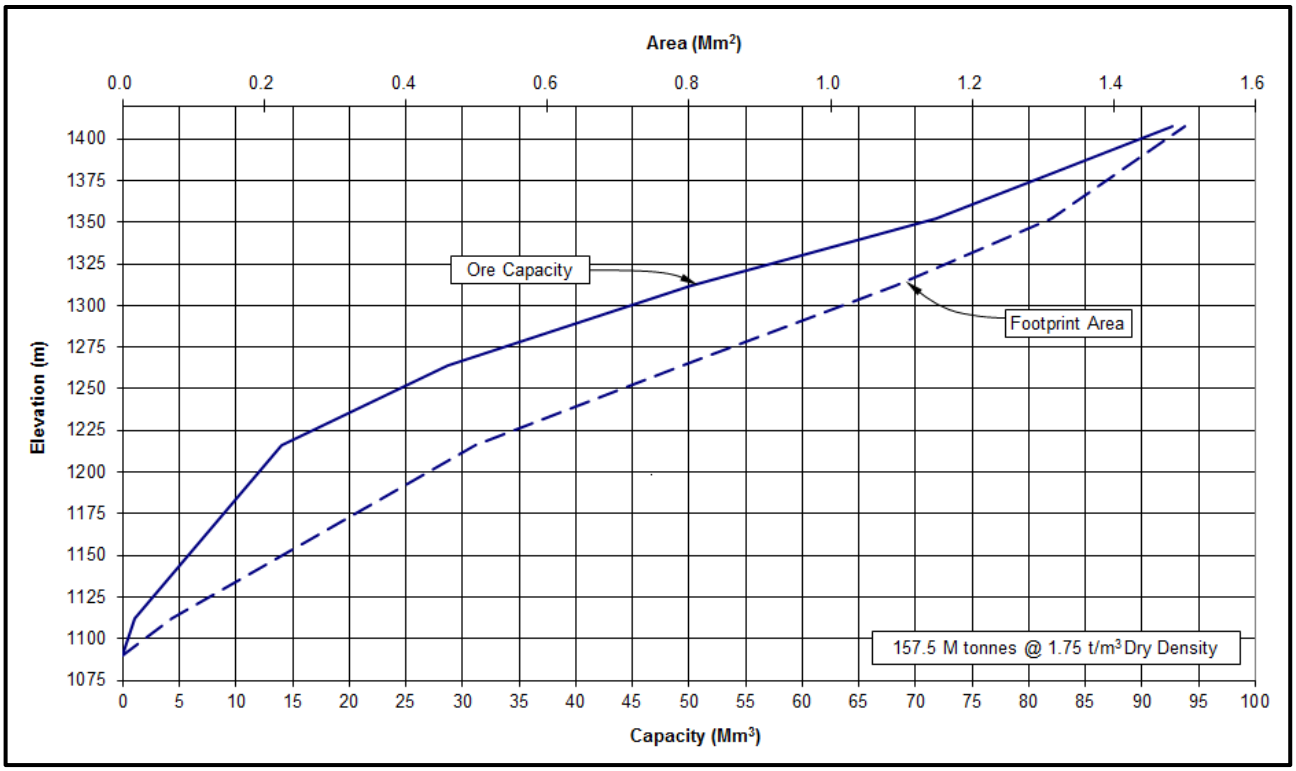

Figure 5.5 Heap Leach Facility: Elevation - Capacity Curve

5.1 HEAP LEACH PAD

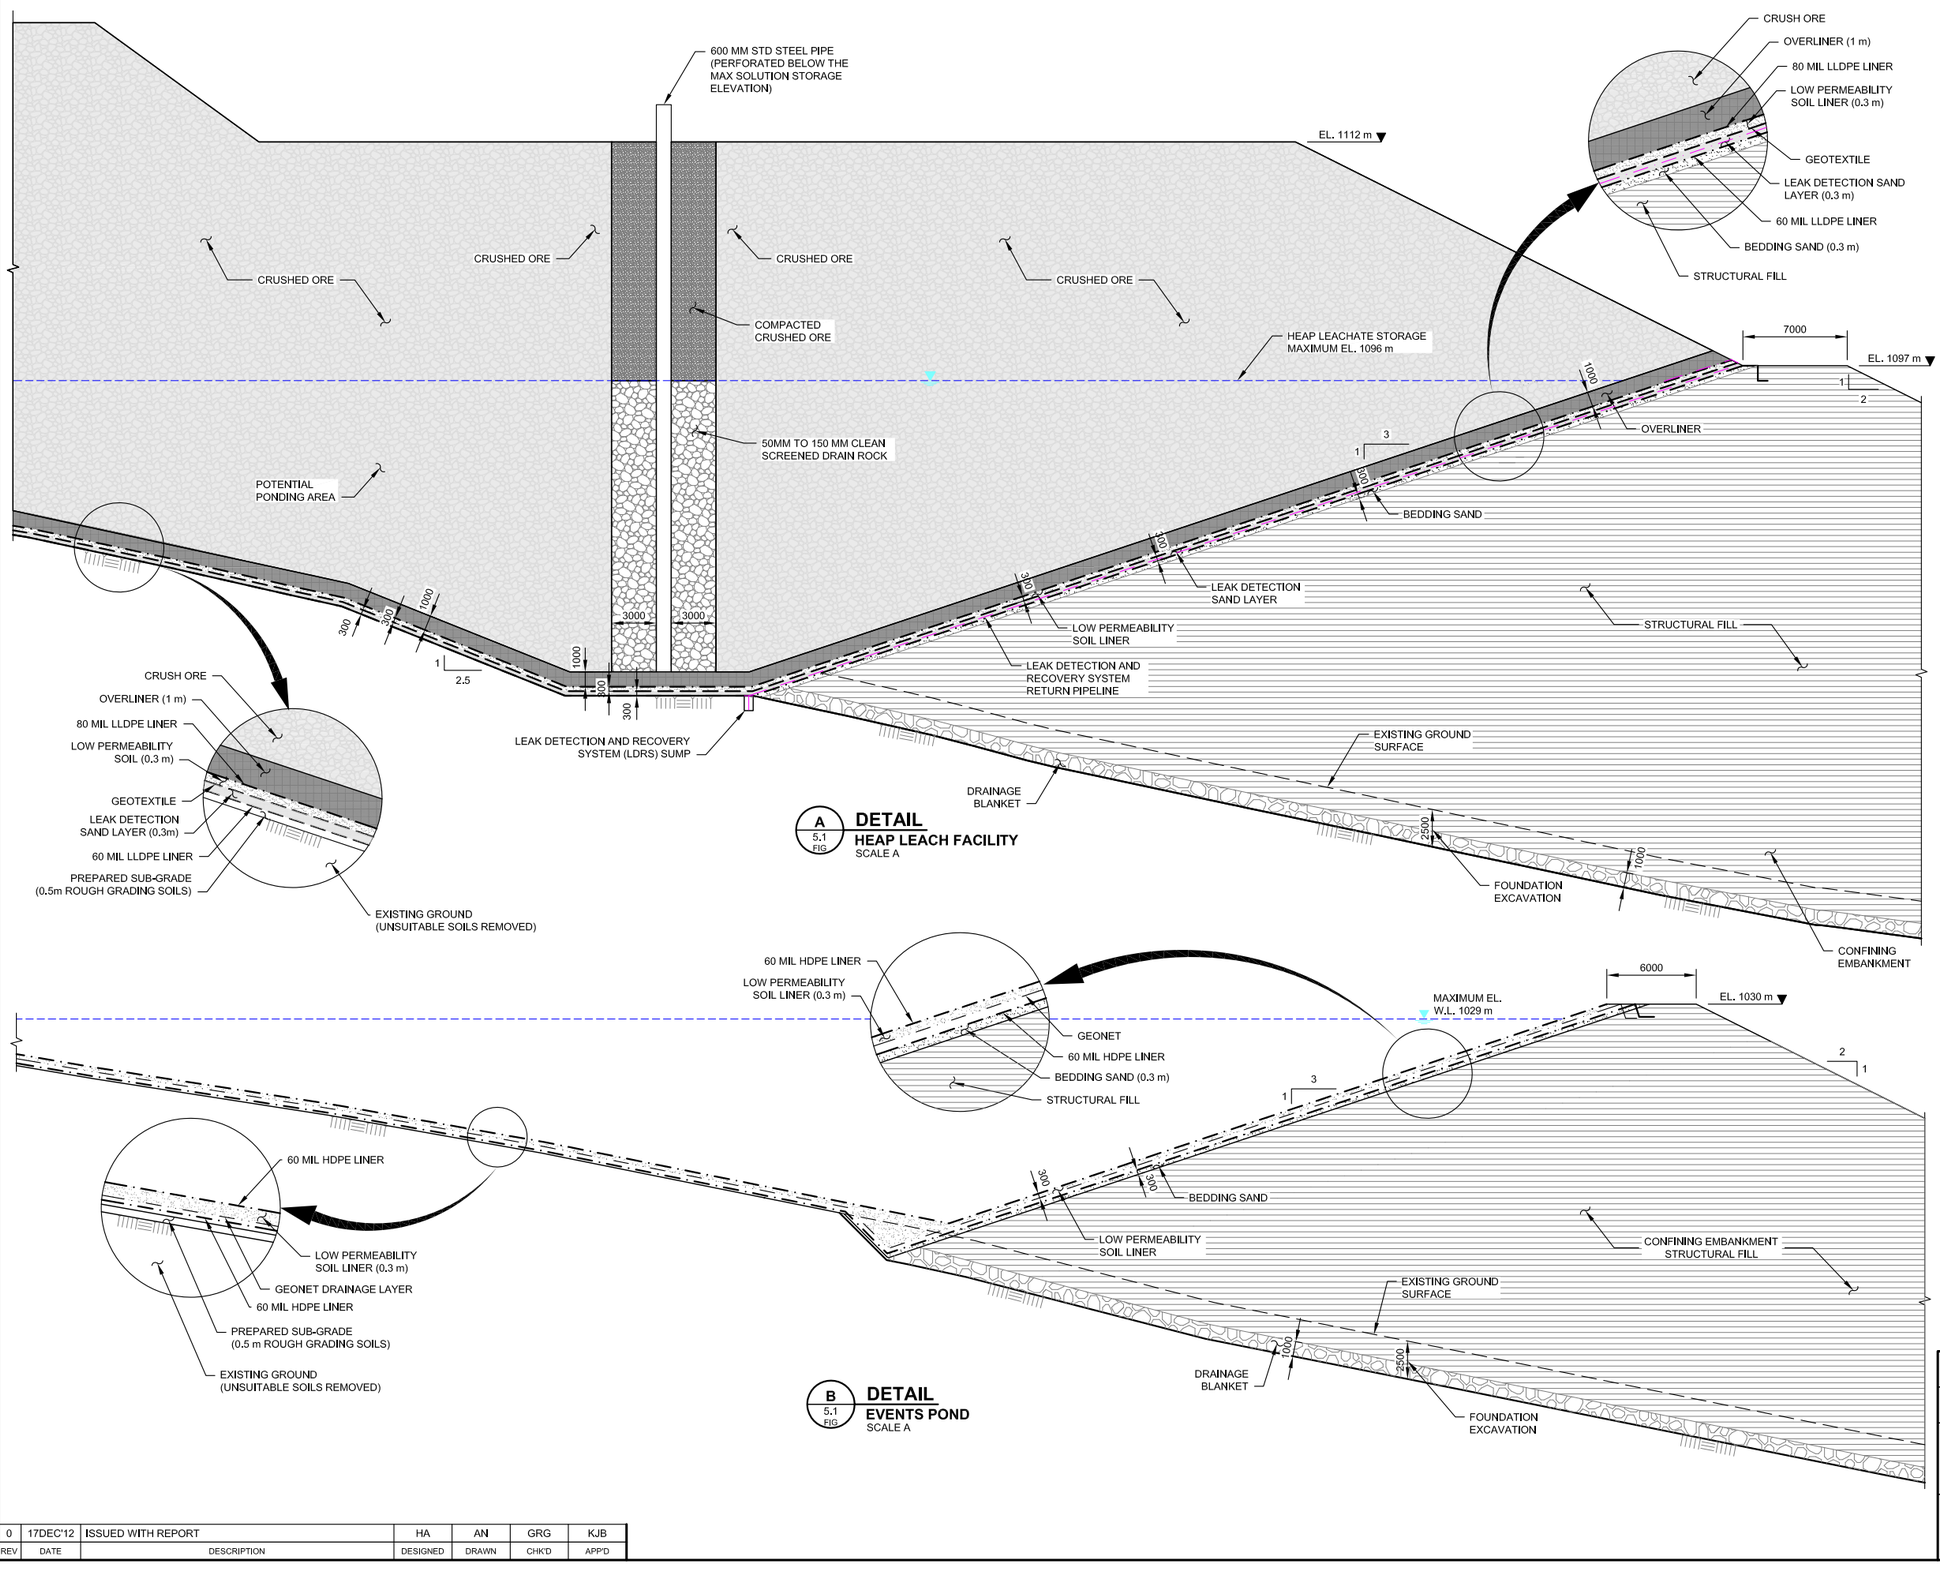
The heap leach pad consists of a confining embankment, pad liner system and leachate collection system to collect and convey the leachate solution to the gold extraction plant, which is located to the southeast of the HLF.

The pad is located on a uniformly sloping sidehill with a slope of approximately 5H:1V (20%) and has an approximate footprint area of 1,501,000 m^2. The heap leach pad is designed to be operated predominantly as a dry heap-leach facility with minimal leachate storage to occur behind the confining HLF embankment.

The following sections outline the general design features and construction aspects for each of the main components of the heap leach pad.

5.1.1 Foundation

At the start of each of the development stages preparation of the pad foundation is required. Foundation preparation entails the stripping of approximately 0.5 metres of topsoil and vegetation and the removal of any talus boulders. The topsoil will be stockpiled at a location north of the HLF (see Figure 1.2) and used for reclamation of the HLF at closure.



The underlying frozen colluvial and residual soils will be excavated down to a competent, stable bedrock foundation. Any ice-rich materials will not be suitable for use as borrow in embankment construction and therefore will be transported to the TMF for disposal. A two metre excavation depth has been estimated in Table 9.1 for foundation preparation to competent ground. In order to provide

a uniformly and positively graded surface to place the pad liner system, rough grading and backfill will be used to level the naturally undulating bedrock surface and to ensure that the pad grading will promote leachate flow to be positively draining towards the leachate collection piping system and sump located at the centre of the embankment upstream toe. A minimum pad grade of 2% is required.

5.1.2 Confining Embankment and Construction

The HLF embankment constructed at the toe of the proposed pad will provide stability to the heap leach pad and provide in-heap storage for solution. As presented on Figure 5.1, the embankment will have a final crest elevation of 1097 m and a crest width of seven metres. The embankment will be constructed with an upstream slope of 3H:1V and downstream slope of 2H:1V. While storage of leachate behind the confining embankment will not normally occur, after significant periods of rainfall or during a process shut-down in-heap storage will be utilized. The confining embankment has been designed with an in-heap storage capacity of approximately 61,000 m^3 (approximately two days irrigation volume). If the storage requirement is greater than this, excess solution will pass over the confining embankment spillway (invert elevation 1096 m) into the Events Pond (see Section 5.4).

Preparation of the embankment foundation will be undertaken in the same manner as the foundation preparation for the Heap Leach pad and will involve stripping the topsoil and excavating the underlying frozen colluvial and residual soils down to component, stable bedrock. The main embankment body will be constructed from structural fill which will consist primarily of locally sourced rock and earth fill. The embankment will be constructed by placing the fill in lifts and compacting to a specified density. It is proposed that the earthfill will be sourced from borrow areas along the south facing slopes adjacent to the HLF and the rockfill will be obtained from talus deposits and new local rock quarries. Suitable non-reactive mine waste rock may also be used if available. A 0.3 metre thick bedding sand layer will be placed over the final upstream slope of the embankment in preparation for installation of the liner system. Details of the liner system is outlined in the following Section and is presented on Figure 5.6.

5.2 LINER SYSTEM

A liner system is used to maximize pregnant solution recovery and minimize environmental operational impacts by minimizing leakage losses of pregnant solution through the bottom and sides of the leach heap pad. The composite liner consists of 'barrier' and 'drainage' layers using a combination of synthetic and natural materials to provide leachate solution containment which meets the required 'accepted standards' for leach pad design. While the Heap Leach Pad is designed to operate as a 'dry' pad with minimal solution storage occurring in-heap storage during normal operating conditions, the liner system was designed to still meet the required performance standards assuming fully saturated solution storage conditions behind the confining embankment.

5.2.1 Liner Design

Two liner systems have been developed for the Heap Leach pad, an engineered single liner design for the upper portion of the leach pad (above the in-heap leachate solution storage elevation) and a composite double liner design for the lower portion of the leach pad which will potentially have leachate solution storage.

The 'Upper' or single liner system, is designed to be installed on the heap leach pad's upper sloped surfaces which positively drain towards the leachate collection pipes and sump. The liner system consists of the following components:

- 1 metre thick overliner (38 mm minus with less than 10% fines content)
- 80 mil (2 mm) linear low-density polyethylene (LLDPE) geomembrane, and
- 0.3 metre thick compacted low permeability soil liner.

The portions of liner that are located directly below the leachate collection pipes will also have Leak Detection and Recovery System (LDRS) layers which consist of the following:

- Non-woven, needle punched geotextile layer, and
- Leak Detection and Recovery System (LDRS)

The 'Ponded' or double liner system is designed to be installed on the heap leach pad's lower slopes which may experience hydraulic loading from in-heap solution storage. Whilst still positively draining towards the leachate collection pipes and sump, the surface grades under the double lined portion may be as low as 2%. The double liner system consists of the following components:

- 1 metre thick overliner (38 mm minus with less than 10% fines content)
- 80 mil (2 mm) linear low-density polyethylene (LLDPE) geomembrane
- 0.3 metre thick compacted low permeability soil liner
- Non-woven, needle punched geotextile layer
- Leak Detection and Recovery System (LDRS), and
- 60 mil (1.5 mm) linear low-density polyethylene (LLDPE) geomembrane.

Figure 5.6 the locations and detailed cross-sections of the two liner systems.

Linear low-density polyethylene (LLDPE) was used for the geomembrane liner systems for the heap leach pad as it has the following benefits (Lupo and Morrison, 2005):

- Generally higher interface friction values, compared to other geomembrane materials
- Ease of installation in cold climates due to added flexibility,
- Good performance under high confining stresses (large heap height), and

- Higher allowable strain for projects where moderate settlement may become an issue.

Laboratory direct shear testing is recommended prior to detailed design to determine the interface shear strength of the liner materials and to confirm strengths are sufficient to provide long-term stability of the HLF. Representative samples of the geomembrane materials should be used for the testing, provided by the project supplier.

5.2.2 Construction

Development of the heap leach liner will be constructed in five development stages, with liner expansions proposed every three to four years to meet ore stacking requirements.

The liner system will be constructed with both the synthetic and natural layers extending to the top of the confining embankment and perimeter berms to provide full containment. The synthetic liners and geotextiles will be anchored and backfilled in a trench along the heap leach pad perimeter and confining embankment crest to ensure that ore loading does not compromise the liners coverage of the heap leach pad footprint by pulling the liner into the pad. Along the embankment toe, all liners will be tied into their corresponding liner layer along the foundation of the pad to provide a continuous liner seal and drainage connection.

A small perimeter berm will also be constructed as part of the liner tie-in around the perimeter of the pad footprint to ensure that heap solution is contained within the pad footprint and to also prevent surface runoff from the adjacent slopes entering the pad collection system.

As noted in Section 5.1.2, a 0.3 metre thick bedding sand layer will be placed on the upslope face of the confining embankment directly underneath the second (bottom) geomembrane liner to provide additional integrity protection to the liner.

5.2.3 Overliner

A protective layer approximately one metre thick of coarse crushed ore will be placed over the entire liner system footprint to protect the liner's integrity from damage during ore placement. The overliner will also double as a drainage layer, promoting leachate solution drainage into the piped leachate collection system, therefore reducing head loading on the liner and maximizing solution recovery.

5.3 LEACHATE COLLECTION SYSTEM

Collection and recovery of the pregnant solution is undertaken by the leachate collection system which works in conjunction with the heap leach liner, overliner and leak detection and recovery systems. The collection system consists of the following pipe and sump components:

- Lateral Collection pipes
- Collection Header pipes
- Main Header Collection pipes, and
- Leachate Collection Sumps.

The leachate collection system is designed to streamline solution collection and facilitate solution conveyance off the pad as quickly as possible thereby reducing the potential risk of leachate solution losses through liner system. The entire piping system is constructed from perforated CPT pipe which is embedded within the one metre thick overliner layer.

The Lateral Collection pipes, which are spaced approximately six metres apart under the entire pad footprint, feed directly into the Collection Header pipes which then flow into the Main Header Collection Pipe. The Main Header Collection pipes are positioned along the centerline of the Heap Leach Pad and terminate at the upstream toe of the confining embankment at the Leachate Collection Sump.

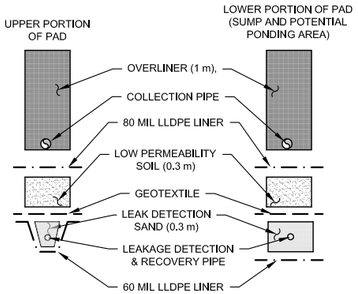
Three Leachate Collection Sumps are located at the toe of the confining embankment, spaced equally across the base width of the heap leach pad. The sumps consist of two sections, the lower 'collection zone' and the upper zone. The lower zone consists of a three-metre thick zone of clean screened gravel (approximate gravel diameter 50 mm to 150 mm) placed around a 600 mm diameter perforated steel vertical riser pipe. The upper zone consists of a three-metre thick zone of compacted crushed ore placed around a 600 mm diameter non-perforated steel vertical riser pipe. The compaction of the crushed ore is critical to ensure that settlement around the vertical riser does not occur and damage the collection system.

As detailed in Section 5.2, the Heap leach pad liner system is designed to be operated as a dry-operation with pregnant leachate solution being pumped out as soon as it collects in the sump thereby reducing the hydraulic head on the liner system. If required however, solution storage in the ore-pore volume behind the confining embankment is possible up to elevation 1096 m before discharging over the confining embankment spillway.

5.3.1 Leak Detection and Recovery System

The Leak Detection and Recovery System (LDRS) is designed to capture and convey any solution which leaks through the overlying geomembrane and low permeability soil layers. As presented in the detail on Figure 5.7, there are two components to the LDRS, the LDRS under the double lined area and the LDRS under the single lined area.

The LDRS under the double lined area consists of a 0.3 metre thick sand layer which is embedded with 100 mm diameter perforated CPT collection pipes. A non-woven needle punched geotextile overlies the LDRS sand layer to prevent particles from the above low permeability soil layer from entering the LDRS, clogging the sand and impeding drainage flow.



The LDRS under the single lined area consists of a network of drainage 'trenches' which contain 100 mm diameter perforated CPT collection pipes surrounded by drainage sand. The trenches are aligned underneath the 'Collection Header' and 'Main Collection Header' pipes which are part of the Leachate Collection system embedded in the above overliner layer. These drainage trenches 'feed' into the LDRS layer underlying the double lined area in the lower heap leach portion.

Any leakage recovered by the LDRS will be conveyed into the LDRS sump at the toe of the confining embankment. A level-switch controlled submersible sump pump will transfer the recovered solution up the embankment slope via a pipe installed within the LDRS sand layer and connect into the main solution recovery line for processing, (refer to Figure 5.6). Monitoring of the leakage recovery will be undertaken through continuous monitoring of the pump hour records.

5.3.2 Leakage Detection Cells

In order to facilitate advanced leak detection source identification, the entire heap leach pad leachate collection system is sub-divided into 16 independently monitored areas or “cells” separated by small cell division berms. Each of these cells has a dedicated leakage detection collection system comprising a drain gravel layer beneath the inner composite liner system which conveys the leakage to a 100 mm diameter perforated collection pipe within the LDRS collection trench. The LDRS ditches flow by gravity at a minimum 0.5 % slope towards the LDRS collection sump structures, located along the right and left sides of the leach pad. The flow rates from the dedicated collection pipes are continuously monitored and measured prior to discharging into a sump. A float switch within the sump triggers a submersible pump which pumps the accumulated solution via a pipeline (located between the two liners on the confining embankment) back onto the heap pad. LDRS collection sumps are shown on Figure 5.7.

5.4 EVENTS POND

The events pond is designed to provide storage for excess leachate and runoff which is generated as a result of rainfall events that cannot be accommodated by the in-heap storage capacity of the HLF. The pond is situated immediately down gradient of the HLF embankment and pond flows are conveyed via the HLF spillway. The plan layout of the Events Pond is included on Figure 5.1. A typical cross-section through the events pond and embankment is included on Figure 5.6.

The events pond is designed to meet the following design criteria:

- Storage capacity to contain the excess HLF leachate and surface runoff from the 1 in 100 year 24-hour storm event without discharge to the TMF
- Spillway designed to discharge the 1 in 200 year 24-hour storm event with a minimum embankment crest freeboard of 0.3 metres.

5.4.1 Storage Requirements

The storage requirement for the Events Pond was established based on containment of the entire estimated surface runoff generated from the HLF during the 1 in 100 year 24-hour storm event. Evaluation of the HFL embankment identified that storage for approximately two days irrigation volume was provided within the in-heap void volume capacity behind the embankment and therefore solution storage within the Events Pond was not required.

Modeling of the HLF storm runoff was undertaken using the Hydrologic Modeling System (HEC-HMS) which was designed by the Hydrologic Engineering Centre (U.S. Army Corps of Engineers) to simulate precipitation-runoff processes of dendritic drainage basins. The model uses site specific data to accurately capture the specific climate and catchment conditions at Site, including storm precipitation intensity distribution, snowmelt, catchment slope, drainage and precipitation losses.

Based on the surface runoff results generated by the model, the following storage requirements for the events pond were identified:

- Total runoff estimate for 1 in 100 year 24- hour storm event 98,600 m^3
- 15% additional capacity buffer 14,300 m^3, and
- Total Events Pond Storage Capacity 112,900 m^3.

Solution stored in the Events Pond will be pumped back to the Heap Leach Pad using the Events Pond pump station. The pump station is designed to be able to empty the 1 in 10 year storm runoff volume (approximately 79,900 m^3) over ten days, and the 1 in 100 year volume (98,600 m^3) over 12.5 days. Depending on the solution processing rate of the gold extraction plant and the available solution storage capacity behind the confining embankment, the actual pump rate will likely need to vary.

5.4.2 Liner System

The engineered double liner system designed for the Events Pond (as shown on Figure 5.6) uses the same design principles as the 'ponded' HLF pad liner system. The liner consists of the following layer configuration:

- 60 mil (1.5 mm) high-density polyethylene (HDPE) geomembrane
- 0.3 metre thick low permeability soil liner

- Geosynthetic 'geonet' drainage layer, and
- 60 mil HDPE geomembrane.

Careful preparation of the existing ground interfacing the lower geomembrane layer is required to ensure that the ground surface conditions are acceptable to install the geomembrane liner without compromising the liner integrity. The liner system installed on the upslope of the Events Pond embankment will have an additional 0.3 metre thick bedding sand layer which will interface with the lower geomembrane layer to protect the integrity of the liner.

Installation of a Leak Detection and Recovery System (LDRS) is not required for the Events Pond as the pond is operated as a dry-facility and will only receive and store runoff water during significant storm events. In the event that leakage does occur through the double liner system, this water will conveyed via the geonet layer to a 1 metre thick drainage blanket which underlies the Events Pond embankment. This drainage blanket discharges directly to the Tailings Management Facility (TMF).

It is recommended that HDPE geomembrane is used for the Events Pond liner system rather than LLDPE. Unlike the heap leach pad, the Events Pond liner system will not be subjected to high confining stresses from ore stacking. Also, HDPE has a higher ultraviolet resistance which is critical for exposed surfaces like that of the Events Pond.

Typical sections showing the location and extent of the Events Pond liner system are shown on Figure 5.6.

5.4.3 Embankment

The embankment will likely be constructed of colluvial and residual soil borrow materials, quarried rockfill, and potentially non-reactive mine waste rock from open pit development. Finer grained residual soils will be selectively utilized on the upstream face to provide a seal zone and an acceptable surface for geosynthetic liner installation.

The embankment is designed with a 2H:1V downstream slope and a 3H:1V upstream slope. These slopes ensure embankment stability. The embankment will be underlain with a 1 metre thick drainage blanket layer to promote and facilitate drainage of any 'leakage' out of the embankment and to discharge into the TMF.

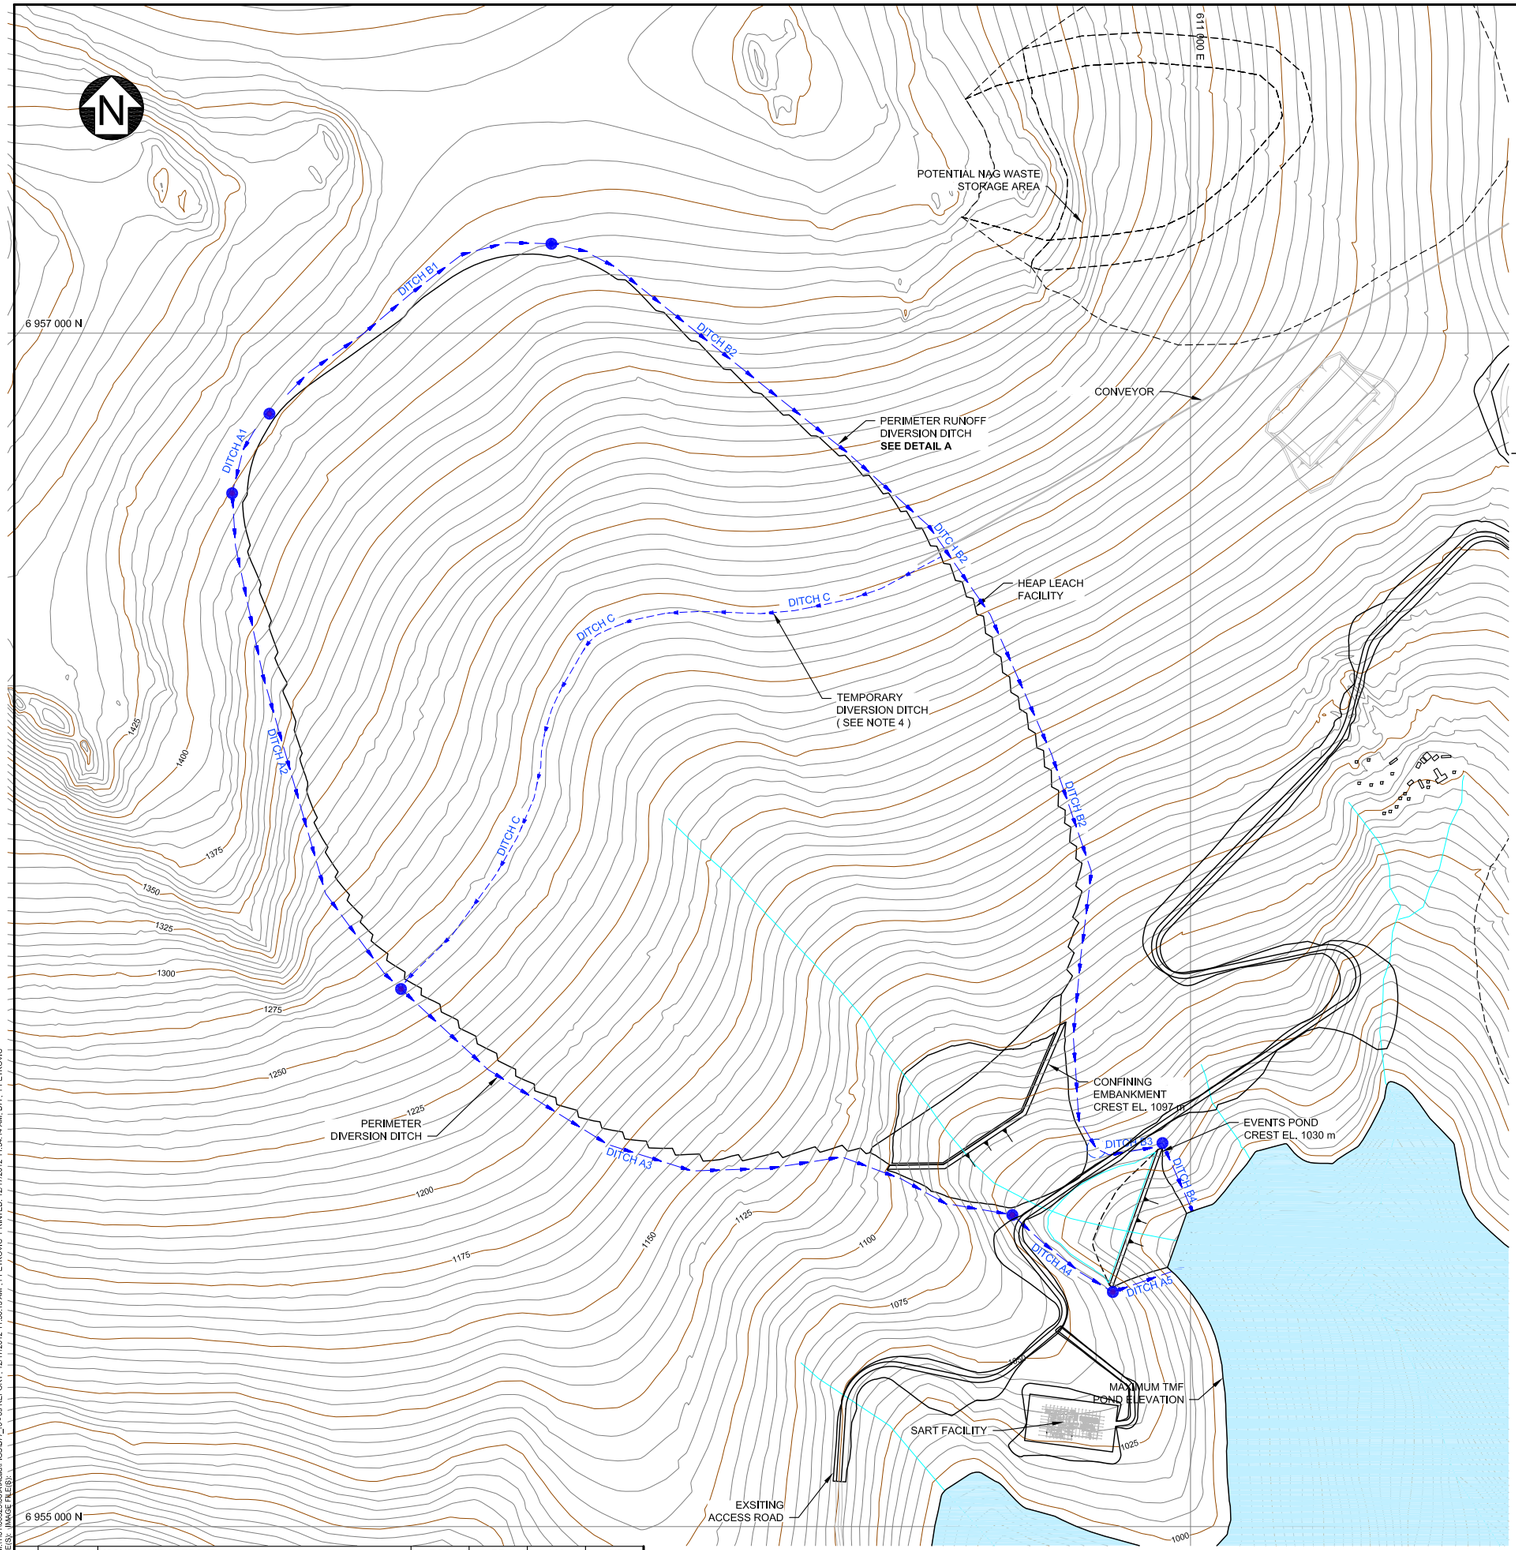
5.4.4 Construction and Operation

The Events Pond will be constructed to full size prior to commencing HLF operations. Construction of the earthfill embankment for the Events Pond involves stripping approximately 0.5 metres of topsoil and 2 metres of overburden beneath the embankment and ponding footprint. The earthfill embankment, pond liner and LDRS system will be constructed directly on competent rock. A solution return pump station will be constructed adjacent to the Events Pond embankment to pump solution back to the HLF in-heap storage for gold-extraction processing or re-use in leaching.

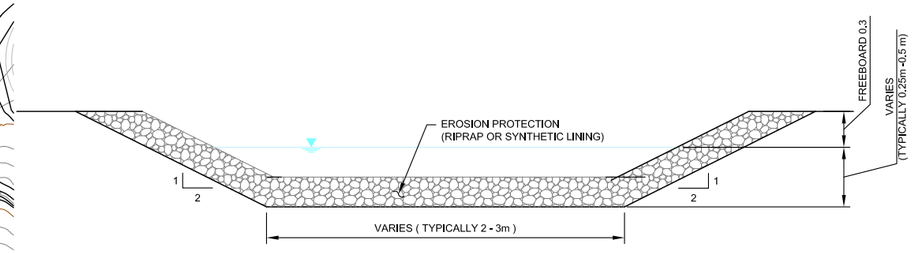
Under typical operating conditions the Events Pond will be operated as a dry pond to ensure that the maximum pond capacity is available for storage of excess HLF surface runoff from storm events. During a storm event leachate and runoff exceeding the HLF in-heap storage capacity will flow into the Events Pond via the HLF spillway to be stored in the Events Pond. This water will then be transferred back to the HLF in-heap storage as required. During storm events greater than 1 in

200 year 24-hour, water volumes exceeding the Events Pond storage capacity will be conveyed to the TMF pond via the Events Pond Spillway.

5.5 DIVERSION AND RUNOFF COLLECTION



The surface water management system for the site, as presented on Figure 5.8, consists of a series of ditches constructed around the perimeter of the HLF to intercept overland surface runoff around the HLF pad and to convey flows to the TMF. The ditches are designed to meet the following design criteria:



- Conveys the 1 in 100 24-hour duration storm event
- Minimum freeboard = 0.3 m
- Minimum ditch grade = 0.01 m/m
- Side slopes = 2H:1V, and
- Channel shape = trapezoidal.

Lining and protection of the ditch channels from erosion and scouring is required for all permanent ditches due to the steep ditch grades associated with the natural topography and the anticipated high runoff flowrates. The alignments of the HLF diversion ditches are shown on Figure 5.8. Diversion ditch requirements and dimensions are provided in Table 5.2. At start-up, (Year -3), a temporary ditch (Ditch C) approximately six metres wide will be constructed which will divert surface runoff from the upper portion of the final HLF pad footprint. This temporary ditch will be decommissioned in Year 3 when the footprint of the HLF extends beyond El 1264 m.

Table 5.2 Diversion Ditch Requirements

Ditch Name:	Length (m)	Water Depth: 100 yr event (m)	Total Ditch Width (m)	Velocity (m/s)	Flow capacity (m3/s)

5.6 OPERATIONAL WATER SUPPLY

Operation of the HLF requires a water supply with an approximate average flowrate of 104 m^3/h. In order to meet this demand two water sources will be used during the life of the HLF facility, a purpose built fresh water supply pond from Year -3 through Year -1, and the TMF from Year 1 through Year 15. To meet the HLF water demand prior to construction and commissioning of the TMF construction of an embankment and associated collection ditch system is proposed as shown on Figure 1.2. The earthfill embankment, which will be located in a northern reach of the final TMF footprint, will be approximately 21 metres high and have a storage capacity of approximately 460,000 m3 of water (six months' supply for the HLF operations) and requires a catchment area of approximately 430 ha. Water collection for storage behind the embankment will be undertaken through a diversion ditch system.

In Year 1, once the TMF embankment is constructed and commissioned, HLF water will be sourced from the water stored in the TMF. Alternatively, water may also be sourced from the Mill make-up water pipeline from the Yukon River which will be constructed for the start of Mill operations in Year 1.

5.7 WATER BALANCE

An operational average monthly water balance analysis was undertaken for the HLF. The intent of the modelling was to estimate the magnitude and extent of any water surplus or deficit conditions in the HLF based on annual average climatic conditions. The modelling timeline was for 19 years of HLF operations (covering 3 pre-production years and 16 years of mill operations, consistent with the project mine production schedule). The model incorporates the following major project components:

- Open Pit
- Heap Leach Pad
- Ore Stockpile
- Fresh Water Supply Pond (Makeup Water supply Years -3 to -1 only), and
- Events Pond Storage (50,000 m^3 Years -3 to -1 only).

The findings of the water balance were that the HLF will operate in a water deficit. The deficit is most pronounced in the early years and diminishes later in operations as water stored within the ore is released from the earlier leaching stages. The total make up required by the HLF is 4.3 million m^3 over the life of the facility. The HLF water requirement ranges from 50,000 m^3 to 670,000 m^3 annually, and during the final years the Site is in surplus.

The water balance was based on assumed moisture content values for the stacked ore. The model is sensitive to these values and they should be reviewed and confirmed for future design studies.

Details of the HLF water balance are included in Appendix A.

5.8 STABILITY ASSESSMENT

Analyses have been carried out to examine the stability of the HLF to a final ore heap elevation of 1,408 m. The stability analyses were carried out using the limit equilibrium computer program SLOPE/W. In this program a systematic search is performed to obtain the minimum factor of safety from a number of potential slip surfaces. Factors of safety were calculated using the rigorous Morgenstern-Price method of analysis.

Analyses have been performed to investigate the stability of the final heap leach pad under both static and seismic conditions. A typical cross-section of the heap leach pad used in the analyses is shown on Figure 5.9 The minimum acceptable factor of safety for the heap leach pad under static conditions is 1.3 for short-term operating conditions and 1.5 for long-term (post-closure) of the HLF. The consequences of failure of the HLF during an earthquake event are likely to be minimal and restricted to some displacement of the heap leach pad slopes. There would be negligible impact on the integrity of the HLF and little, if any, impact on other Mine site facilities. However, for design of the HLF a conservative design earthquake corresponding to the 1 in 500 year return period event has been adopted, consistent with the Operating Basis Earthquake (OBE) defined for the TMF. The corresponding mean peak ground acceleration is 0.08g. A design earthquake magnitude of 8.0 has been selected based on a review of regional tectonics, potential seismic source zones in the region and historical seismicity. The seismic stability assessment of the heap leach pad has included estimation of seismically induced deformations of the pad from the design earthquake.

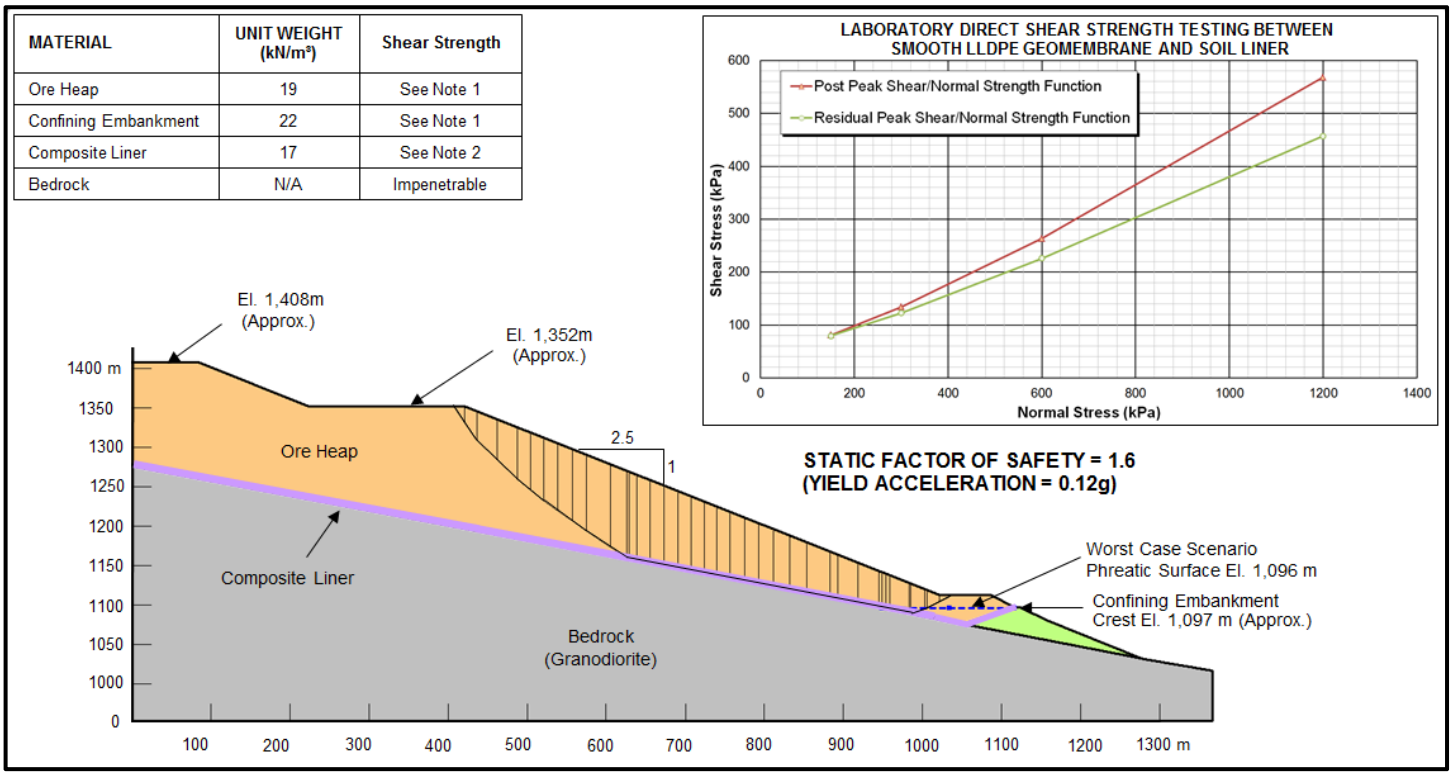

Figure 5.9 Heap Leach Facility: Leach Pad Stability Assessment

NOTES:

1. A relationship for friction angle and effective stress was developed for the ore heap and confining embankment material, based on LEPS (1970).
2. The liner interface with the lowest shear strength and therefore controlling the heap stability is the interface between the smooth LLDPE geomembrane and soil liner direct shear strength test results for LLDPE geomembrane and soil liner are shown on this figure. Post peak shear/normal strength function was used for static analyses. Residual shear/normal strength function was used for seismic analyses.

5.8.1 Material Parameters and Assumptions

The following parameters and assumptions were incorporated into the stability analyses:

- Unit weights for the heap leach pad and foundation materials were based on typical values for similar materials. Adopted values are included on Figure 5.9
- The shear strength for the ore heap and rockfill material in the confining embankment has been defined using a conservative (lower bound) strength function that defines the variation of shear strength with normal stress. This strength function is based on published information on the shear strength properties of granular rockfill materials (Leps, 1970).
- A phreatic surface within the lower portion of the leach pad was modelled with a constant head at elevation 1,096 m to represent maximum potential solution storage during shut-down. No water or phreatic surface was modelled in the upper portion of the leach pad. This is a reasonable assumption since adequate drainage will be provided at the base of the heap to minimize the build-up of pore water pressures within the heap.
- There are no excess pore pressures generated by thawing of foundation materials. It is assumed that appropriate foundation preparation and/or excavation have been conducted in any areas with frozen soil.

The stability of the heap leach pad is controlled by the interface shear strength between the various components of the liner system (overliner, geomembrane liners, soil liner, leak detection/bedding sand layers and geotextile), as shown on Figure 5.6. It is anticipated that the liner interface with the lowest shear strength and therefore controlling heap stability is the interface between the Smooth LLDPE geomembrane and Soil Liner.

The interface shear strength between the Smooth LLDPE geomembrane and soil liner has been defined using the results of laboratory direct shear strength testing. Direct shear strength testing was conducted using a suitable sample of smooth LLDPE geomembrane material and a composite sample of low permeability residual soil, provided by test pit samples and representing potential borrow material for the soil liner. The soil sample was prepared to the anticipated compaction specifications for the soil liner material (95% Standard Proctor density). Laboratory test results (stress-strain plots) were used to define relationships between interface shear strength and normal confining stress for peak, post-peak (15mm strain) and residual (> 60mm strain) strength conditions. The post-peak relationship was used for static stability conditions, as it is recognized that some relative displacement between the layers may occur during construction or operation of the pad. The residual strength value was used for seismic loading conditions from the design earthquake. The adopted relationships between interface shear strength and normal confining stress for the post-peak and residual strengths are included on Figure 5.9

5.8.2 Results of Stability Analyses

Results of the stability analyses indicate that the leach pad is stable with a minimum static factor of safety of 1.6. The potential slip surface and calculated static factor of safety is shown on Figure 5.9.

Stability of the HLF during earthquake loading has been assessed by performing a pseudo-static analysis, whereby a horizontal force (seismic coefficient) is applied to the heap to simulate earthquake loading to determine the critical acceleration required to reduce the factor of safety to 1.0. Deformation is predicted to occur if the critical acceleration is lower than the predicted average maximum ground acceleration along the potential slope surface from the design earthquake.

Potential deformations under earthquake loading have been estimated using the semi-empirical simplified methods of Newmark (1965), Makdisi-Seed (1977) and Bray (2007). These methods estimate displacement of the potential sliding mass based on the average maximum ground acceleration and the yield acceleration. The yield acceleration corresponds to the seismic coefficient required to initiate movement of the sliding mass. The yield acceleration was determined by iterative stability analyses. For the final heap leach pad configuration, the estimated yield acceleration is 0.12g. To account for the possible amplification of ground accelerations as seismic waves propagate through the heap leach pad, an amplification factor of 1.5 was assumed, resulting in an estimated average maximum acceleration of 0.12g. Predicted heap leach pad deformations calculated for the design earthquake are negligible, if any, and would not impact operations at the HLF.

The stability of the HLF is sensitive to the interface shear strengths associated with the liner system. It is recommended that laboratory shear strength tests for each of the liner interfaces within the composite liner systems are tested for detailed design studies, once all material sources have been confirmed.

6 – CONSTRUCTION AND OPERATIONS

6.1 STAGED CONSTRUCTION

The proposed heap leach pad will be developed in five stages. This will minimize initial capital costs while allowing monitoring to maximize the efficiency and recovery during leaching. The general operational strategy will involve placing the ore in successive lifts followed by irrigation with leach solutions. The lifts will be placed by conveyor and spread with dozers. The ore will then be placed in strips parallel to the confining embankment and loaded upslope to ensure on-going stability and to prevent trafficking over the liner. Proposed bench lifts of eight metres will be constructed at bench face angles of approximately 1.4H:1V. Berm widths of nine metres will be left at the toe of each lift resulting in an overall slope of 2.5H:1V. On-going pad development` will involve extending the composite liner upslope to allow for continued lift placement.

6.2 LIFT PLACEMENT AND LEACHING

Leachate solution will be collected by a series of drainage pipes within the coarse drainage layer at the base of the pad. The drain pipes will connect to main leachate collector pipes for transport to the vertical riser pipe within the potential ponding area.

The sequence of lift placement and leaching will likely be as follows:

- Place 38 mm minus overliner material on the surface of the geomembrane liner to provide liner protection and base drainage.
- Place eight metre lift of ore, as required, by moveable ore transport conveyors or haul trucks. Spread with dozers to establish an evenly graded surface for leaching.
- Layout irrigation lines for drip leaching. Sprinkler leaching may also be possible during summer months as part of a rotational, cell-type leach operation.
- Cover irrigation lines with ore having a thickness greater than the depth-of-freeze in the fall to prevent freezing during winter operations.
- Leach the lift of ore above the irrigation lines prior to loading with the next eight metre lift.

6.3 BORROW MATERIALS

Borrow materials will be required for the construction of the leach pad foundation, confining embankment and events pond. Random fill may also be required for foundation earthworks prior to soil liner placement. Borrow for overliner material may be obtained by screening ore at the crusher plant. Rockfill for embankment construction may be obtained from local rock excavation, remote quarry sources or suitable non-reactive (leah cap) mine waste rock, if available.

Materials for the soil liner and random fill may be obtained from borrow areas along south-facing slopes, upslope and east or west of the HLF. Additional test pits and laboratory testwork will be required in these areas to confirm the suitability, availability and quantity of borrow materials for earthworks construction. The borrow areas will be developed by dozing and ripping material down-slope to refusal. Finer grained residual silty sands near surface will be stockpiled for use as soil liner material. Coarser grained material at depth will be utilized as random fill in the construction of the confining embankment and the events pond dam. The material may also be used as general backfill over bedrock for the leach pad foundation. Ripping or blasting in rock may provide rockfill for the shell zones of the confining embankment and events pond, as required.

6.4 COLD WEATHER CONSIDERATIONS

As detailed in Section 2.2.2 the Casino Project area's mean minimum monthly temperature in January is -17 °C, extreme temperature events however produce temperatures significantly colder. In order to enable year-round operation of the HLF the Site's winter conditions (snowfall and cold temperatures) were considered during the preparation of the design.

As noted in Section 3.2, ore stacking will be conducted 300 days/year and leaching 365 days/year. Seasonal stacking of the ore reduces the risks and challenges of stacking during winter e.g. heavy snowfall and reduced day light hours. Challenges of leaching during winter include reduced leaching efficiency, freezing solution and leachate lines and freezing ponds. In order to overcome the risk of freezing ponds during winter, all leachate collection will be conducted within the heap leach pad behind the confining embankment within the ore voids rather than in an external free-surface pond. The events pond was designed as a dry-pond to ensure that freezing and associated ice-damage to the pond liner does not occur. Winterization of the leachate and solution lines will also be required and may include heat tracing and insulation. Winter operations for the HLF will also likely be modified during extreme cold events to include 'ripping' the frozen ore stacks to promote improved infiltration through the ore bed.

7 – INSTRUMENTATION AND MONITORING

Instrumentation and monitoring will be carried out on an on-going basis to ensure the safe and effective operation of the HLF. Recommendations for instrumentation and monitoring are summarized below:

Instrumentation

Geotechnical instrumentation will be installed to monitor the performance of the HLF during the construction stage and throughout the life of the facility. The purpose of the instrumentation will be to provide data to assess the stability of the heap leach pad and to evaluate the effectiveness and performance of the overliner and foundation drains.

The following instrumentation is recommended for installation at the HLF:

- Piezometers will be installed to allow measurement of phreatic levels and pore water pressures within the HLF and foundations. Vibrating wire piezometers will be installed in the following locations:
  - The leach pad and events pond embankment fill materials and foundation
  - The leach pad and events pond foundation drains; and
  - The overliner.

Monitoring

Preliminary recommendations for monitoring are summarized below:

- Surface water quality sampling at selected locations downstream of the HLF.
- Installation of monitoring wells around the facility to monitor groundwater quality during operations and at closure. These wells would be installed prior to development to obtain baseline information for comparative assessment.
- Installation of an LDRS to monitor and recover any leakage through the liner systems within the heap leach pad area and events pond.
- Slope movement monuments and survey control points installed and monitored to ensure the integrity and stability of the ore heap.
- The installation of flow monitoring devices in diversion ditches and creeks to confirm design flows.
- Review of thermistor data to confirm the thermal regime at the site.

Details of the instrumentation and monitoring plan will be developed in conjunction with the appropriate regulatory authorities.

8 – CLOSURE AND RECLAMATION

Reclamation will be carried out to minimize potential impacts to the surrounding environment. Preliminary recommendations for closure and reclamation are summarized below:

- Grading, covering and revegetation of final heap slopes to provide adequate drainage and erosion protection from surface runoff. This may be carried out during operations as the final slope of the heap is developed.
- Rinsing and drain-down of the ore and cyanide destruction at the end of HLF operations.
- Removal of geosynthetic liners from the overflow spillway and the events pond, as required.
- Decommissioning of the pregnant solution recovery system.
- Removal of pregnant solution and events pond pumps and pipeworks.

A preliminary closure and reclamation plan has been prepared by Others, and will continue to be developed in conjunction with the appropriate regulatory authorities.

9 – ESTIMATED QUANTITIES AND CAPITAL COST INFORMATION

Preliminary cost items and estimated quantities have been developed for the proposed leach pad, events pond and solution recovery components of the facility for pre-production and 157.5 million tonne configuration. The cost items and associated quantities have been summarized in Table 9.1. Appropriate unit rates and the capital cost estimate will be compiled by Others.

Initial capital costs will likely include the foundation works, embankment construction and ancillary works required for the leach pad, confining embankment, events pond and solution recovery systems. On-going capital costs will need to include for staged expansion of the leach pad up the slope.

Other costs associated with the HLF include operational costs and capital costs for leaching services.

NOTES:
1. A TOTAL DEPTH OF 2.5 m HAS BEEN ASSUMED FOR 'STRIPPING AND REMOVAL OF UNSUITABLE MATERIALS' UNDER THE HLF PAD CONFINING, EVENTS POND AND FRESH WATER SUPPLY POND EMBANKMENTS.
2. THE LLDPE LINER THICKNESS MAY BE REVISED AFTER ADDITIONAL LABORATORY TESTING.

10 – SUMMARY AND RECOMMENDATIONS

A Feasibility design for the HLF has been carried out for the Casino Project. The proposed leach pad is located on a uniform southeast-facing slope south of the deposit area. Preparation of layouts and sections of the various project components including the leach pad, confining embankment, liner systems and events pond have been completed. The leach pad will provide safe containment and storage for up to 157.5 million tonnes of leach ore and pregnant solution. There is capacity for additional leach ore placement, if required.

The following is a summary list of the main advantages for the proposed HLF:

- The leach pad is located near the deposit area thus minimizing haul and/or ore transport conveyor distances.
- Nearby potential borrow sources on well drained slopes east or west of the HLF may provide relatively short haul distances for leach pad foundation and embankment construction.
- Generally a shallow depth of bedrock throughout much of the HLF area, resulting in reduced foundation excavation requirements.

Design features include the following:

- Pumping of pregnant solution to a gold extraction plant, located southwest of the plant site.
- Excavation of overburden materials to competent bedrock, to eliminate potential settlement and instability resulting from thawing ice-rich overburden. These materials will require containment and sediment control upon thawing.
- Utilize suitable overburden (residual and colluvial soils) and weathered bedrock along well drained, non-frozen, south-facing slopes in the leach pad area as potential borrow for soil liner and embankment construction.
- A single composite liner system comprising an 80 mil (2 mm) smooth LLDPE geomembrane, compacted soil liner and leachate detection and recovery system to maximize leachate collection and minimize seepage losses will be constructed over the upper portion of the heap leach pad.
- A double composite liner system comprising of an 80 mil and a 60 mil (1.5 mm) smooth LLDPE geomembrane liner, a compacted soil liner and geotextile will be constructed over the lower portion of the leach pad and will include a leachate detection and recovery system for intercepting and collecting any leakage through the inner liner.
- A double composite liner system comprising of an 60 mil and a 60 mil (1.5 mm) smooth HDPE geomembrane liner, a compacted soil liner and geonet drainage layer will be constructed over the events pond.A one metre overliner layer comprising 38 mm minus crushed ore over the composite liner to protect the geomembrane and to provide free drainage at the base of the heap. A network of perforated, corrugated polyethylene tubing, or similar, to maximize leachate solution recovery.
- Pregnant solution recovery by means of a submersible pump and pipeline.
- An events pond to provide temporary storage of overflow from the potential ponding area and storm runoff over the leach pad.
- Diversion ditches around the facility to intercept and divert surface runoff.

The heap leach pad will be developed in five stages by loading in successive lifts upslope from the confining embankment. Bench lift heights of approximately eight metres will be constructed at repose bench face angles of 1.4H:1V. Benches approximately nine metres wide will be left at the toe

of each lift to establish a final overall slope angle of approximately 2.5H:1V. This will provide stability of the heap and allow for on-going reclamation during operations.

The following is a list of recommendations for additional site investigations, testwork and design studies required to carry the project through to final design and construction:

Geotechnical Investigations and Testwork:

- Additional test pits /drill holes to prove up suitability, availability and quantity of borrow materials for earthworks construction.
- Laboratory testing of potential borrow materials for pad foundation (overliner and low permeability soil layer) and embankment construction (including particle size distribution, Atterberg limits, specific gravity, moisture-density relationship, permeability and shear strength tests).
- Laboratory direct shear testing of liner interfaces, to determine the interface shear strength relationships for heap stability assessment. It is recommended that the shear strength tests are carried out for each of the liner interfaces within the composite liner systems, once all material sources have been confirmed.
- Ore testing (including particle size distribution, specific gravity, permeability under load, load-percolation, and direct shear/triaxial shear strength tests).

Design Studies and Analyses:

- Leach testing (by Others) to determine optimal ore densities, leaching rates and resulting in-heap moisture contents.
- Detailed water balance analyses, based on results of hydrology and leach testing, to estimate solution storage area water volumes, peak storm flows for ditch design, and to confirm sizing of pump and pipework systems.
- Heap stability assessment based on results of laboratory shear strength and liner interface strength testing.
- Seepage analyses to predict seepage flow patterns and solution losses for the design of the LDRS.
- Detailed design of all civil and mechanical works, including sumps, intakes, outlets, pumps, pipe systems etc.
- Advanced studies on the staging configuration of the heap leach pad.

WATER BALANCE

(Pages A-1 to A-7)

APPENDIX A

WESTERN COPPER CORPORATION
CASINO COPPER-GOLD PROJECT

OPERATIONAL AVERAGE MONTHLY WATER BALANCE MODEL

A.1. GENERAL

An operational average monthly water balance analysis was undertaken for the Heap Leach Facility (HLF) at the Casino Copper-Gold project site using Excel and annual average precipitation. The intent of the modelling was to estimate the magnitude and extent of any water surplus or deficit conditions in the HLF based on annual average climatic conditions. The modelling timeline included three pre-production years (Year -3 to Year -1), and 16 years of operation (Year 1 to 16). The model is shown schematically on Figure D.1 and incorporates the following major project components:

- Open Pit
- Heap Leach Pad
- Ore Stockpile
- Fresh Water Supply Pond (Makeup Water supply Years -3 to -1 only)
- Events Pond Storage (50,000 m^3 Years -3 to -1 only)

The model assumptions and parameters are discussed in the following sections the design inputs are summarized in Table D.1.

Table A.1 Heap Leach Facility Design Water Balance Inputs

Heap Leach Facility Stacking and Leaching		
Stacking Days	300	M3 Design Criteria
Leaching Cycle (days)	60	M3 Design Criteria
Leaching Days per Year	365	M3 Design Criteria
Leachate application Rate (m^3/hr/m2)	0.012	M3 Design Criteria
Leachate Maximum Flow (m^3/hr)	1,312	M3 Design Criteria
Maximum Leaching area	109,000	
Dry Density of Heap (t/m^3)	1.75	M3 Design Criteria
Moisture Contents by Mass		
Initial Moisture Content	2%	M3 Design Criteria
Leaching Moisture Content	12%	M3 Design Criteria
Residual Moisture Content	10%	M3 Design Criteria

A.2. MODEL ASSUMPTIONS

A.2.1 Average Hydrometeorological Conditions

The base case monthly operational water balance model was developed using average estimated values for precipitation and runoff. Complete details of the derivation of the climate and hydrology inputs for the project site are outlined in the Updated Hydrometeorology Report (Knight Piésold, 2012a). The values used for modelling are summarized in Table D.2.

The available runoff from the undisturbed catchment areas within the HLF catchment were modelled on the basis of the long-term runoff estimates for Casino Creek at hydrology station W4, as summarized in Table D.2. Natural runoff values however, are not applicable for mine disturbed areas because altering the ground cover changes the runoff. Therefore, the water (runoff/infiltration) generated from the mine affected areas was estimated based on rainfall and snowmelt. The available precipitation is summarized in Table D.2 and the runoff coefficients are given in Table D.3.

Table A.2 Average Hydrometeorological Inputs

Parameter	Monthly Value (mm)												Annual
	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	(mm)
Precipitation	32	24	19	17	37	62	91	67	47	38	43	33	**510**
Rainfall	0	0	0	8	37	62	91	67	47	18	0	0	**330**
Snowfall	32	24	19	9	0	0	0	0	0	20	43	33	**180**
Sublimation	5	5	5	5	0	0	0	0	0	5	5	5	**40**
Snowmelt	0	0	0	25	115	0	0	0	0	0	0	0	**140**
Available Precipitation	0	0	0	33	152	62	91	67	47	18	0	0	**470**
Lake Evaporation	0	0	0	0	49	69	75	66	41	0	0	0	**300**
Available Runoff	0.5	0.3	0.3	3	45	25	33	31	27	15	2	1	**183**

NOTES:

1. THE PRECIPITATION VALUES WERE ESTIMATED FOR ELEVATION 1200 m.
2. THE MONTHLY RUNOFF VALUES ARE SUMMARIZED FOR LOWER CASINO CREEK AT HYDROLOGY STATION W4.
3. MEAN ANNUAL RUNOFF (MAUR)

A.2.2 Heap Leach Facility

The ore will be stacked on a composite geotextile liner in eight meter lifts. Ore will be stacked on the heap 300 days per year and leaching will occur year round in 2 month cycles. The HLF inputs are detailed below:

- HLF Stacking is modelled at a steady rate over ten months each year. The annual stacking rate in Year –3 is 6.6 Mt per year, and increases to 9.1 Mt per year in Years -2 to 14, in Year 15 the rate drops to 4.9 Mt per year.
- HLF leaching is modelled as two month blocks. The leaching process will consist of applying leaching solution to the stacked ore thereby raising the moisture content of the ore from its initial level to the optimum level as shown on Table D.1. The hydration process is assumed to take place within the first month of the leaching cycle and in months where drawdown of the heap occurs (see below) the drawdown is recycled onto the heap. The first leaching cycle in the model occurs during freshet of Year -3. Approximately 30 k m^3 of makeup water will need to be supplied from external sources to fully hydrate the first block of ore.
- The heap pad has been designed to direct all infiltration to the solution sump at the base of the heap, as such available runoff from the active heap pad and composite liner catchments has been modelled as 98% recovered. Evaporation of moisture from the heap surface has been modelled as 50% of the lake evaporation.
- Drawdown occurs when solution is no longer applied to the ore and the moisture content of the leach block drops from the leaching moisture content to the residual moisture content. Solution will continue to flow through the lower heap layers, when actively leaching the upper ore lifts, therefore the model assumes that drawdown will occur once the active leaching process has been completed for that slice of the heap footprint. The tonnage of ore that is available to release drawdown water has been calculated on an annual basis and this has been applied uniformly over the year.
- The HLF Events Pond has been designed to attenuate the 1 in 100 year storm event on the full HLF footprint. During years -3 to -1 the undeveloped portion of the heap pad catchment is diverted. As a result approximately 50,000 m^3 of storm capacity id available to store excess runoff from the heap pad for recycling until the Tailings Management Facility (TMF) is constructed. The model draws water from the HLF Events Pond first and it is completely pumped out at the start of each new leaching cycle. Evaporation from this pond has not been calculated as the losses would be small and the surface area is to variable to accurately calculate on a monthly basis. The HLF Events pond is modelled as constructed prior to freshet Year -3. In years 1 through 16 excess runoff is assumed to be routed to the TMF.
- A fresh water supply pond is required to supply water to the HLF in years -3 to -1 prior to construction of the Yukon Water Supply Pipeline. The Fresh Water Supply Pond will be constructed prior to Year -3, and is able supply all makeup water requirements to the HLF in Years -3 to -1, with the exception of the first leaching block as noted above. Starting in Year 1 the Fresh Water Supply Pond and its associated catchments are incorporated in the TMF water balance. Evaporation has not been considered from this pond as the pond is at its maximum volume and spilling in all months when evaporation would occur and therefore all loses would be replaced by inflows.
- Water Storage within the heap has been modelled as zero. It has been assumed that the storage available in the pore spaces at the pump vertical riser will amount to approximately 1 day of pumping and will have a negligible effect on a monthly time step model. As there is no in heap storage, in months that inflows exceed the leaching requirements of the HLF all excess water is discharged and

routed to the TMF. Conversely in months where leaching requirements exceed inflows, makeup water is added to the HLF. As stated above, water supply is modelled to come from the Events and Fresh Water Supply ponds in Years -3 to -1. In Years 1 to 16 the makeup water is modelled as coming from an alternative water source (either the pipeline or TMF supernatant pond).

A.2.3 Ore Stockpile

The production rate of leachable ore from the Open Pit is highly variable from one year to the next, while leaching operations are limited by the available equipment to a certain range of annual production rates. The ore stockpile attenuates the variability of the Open Pit production, in years when an excess of ore is produced all excess is placed in the stockpile, in years when Open Pit production is lower than the design HLF stacking rate the remaining ore demand is sourced from the stockpile. The model inputs for the ore stockpile are detailed below:

- The initial water content of the ore is shown on Table D.1.
- Runoff infiltration and evaporation are calculated in the same way as infiltration and evaporation from the HLF. 98% of runoff is captured and evaporation from the heap is 50% of lake evaporation.
- The cumulative mass of water in the heap is tracked and is modelled to not exceed the residual moisture content shown in Table D1.
- Ore supplied from the stockpile has a higher water content than that of the Open Pit production due to hydration while stockpiled and the water required to fully hydrate stockpile ore to the leaching moisture content is calculated separately from the water required to hydrate Open Pit ore.

A.2.4 Catchment Areas

The HLF catchment areas and corresponding runoff coefficients used in the eater balance are summarized in table D.5

Table A.3 Facility Catchment Areas

Facility	Catchment Area (km^2)						Runoff coefficient
	Year -3	Year -1	Year 3	Year 11	Year 13	Year 15	
HLF Ore Stack	0.45	0.8	0.8	1.5	1.5	1.5	0.98
Undisturbed area in HLF catchment	0.35	0.0	0.7	0.007	0.0	0.0	-
Ore Stockpile	0	0.28	0.55	0.55	0.28	0	0.98
Events Pond	0.06	0.06	0.06	0.06	0.06	0.06	0.98
Freshwater Supply Pond	5.8	5.8	-	-	-	-	-

NOTES:

1. HLF = HEAP LEACH FACILITY.
2. THE ESTIMATED RUNOFF FOR ALL FACILITY FOOTPRINTS WITH THE EXCEPTION OF UNDISTURBED AREAS AND SOIL STOCKPILES IS CALCULATED BY MULTIPLYING THE MONTHLY AVAILABLE PRECIPITATION VALUE BY THE RUNOFF COEFFICIENT.
3. UNDISTURBED AND SOIL STOCKPILE RUNOFF IS ESTIMATED BASED ON THE MONTHLY AVAILABLE RUNOFF VALUES, WHICH IS A DIRECT INPUT TO THE MODEL.

A.3. RESULTS AND RECOMMENDATIONS

A.3.1 Model Results

The model results are summarized in Table D.4 below. It can be seen from this table that the makeup water requirements are highest at the start of the operation and discharge is lowest. By the end of the HLF production life the makeup water requirements have diminished to less than the discharge requirements.

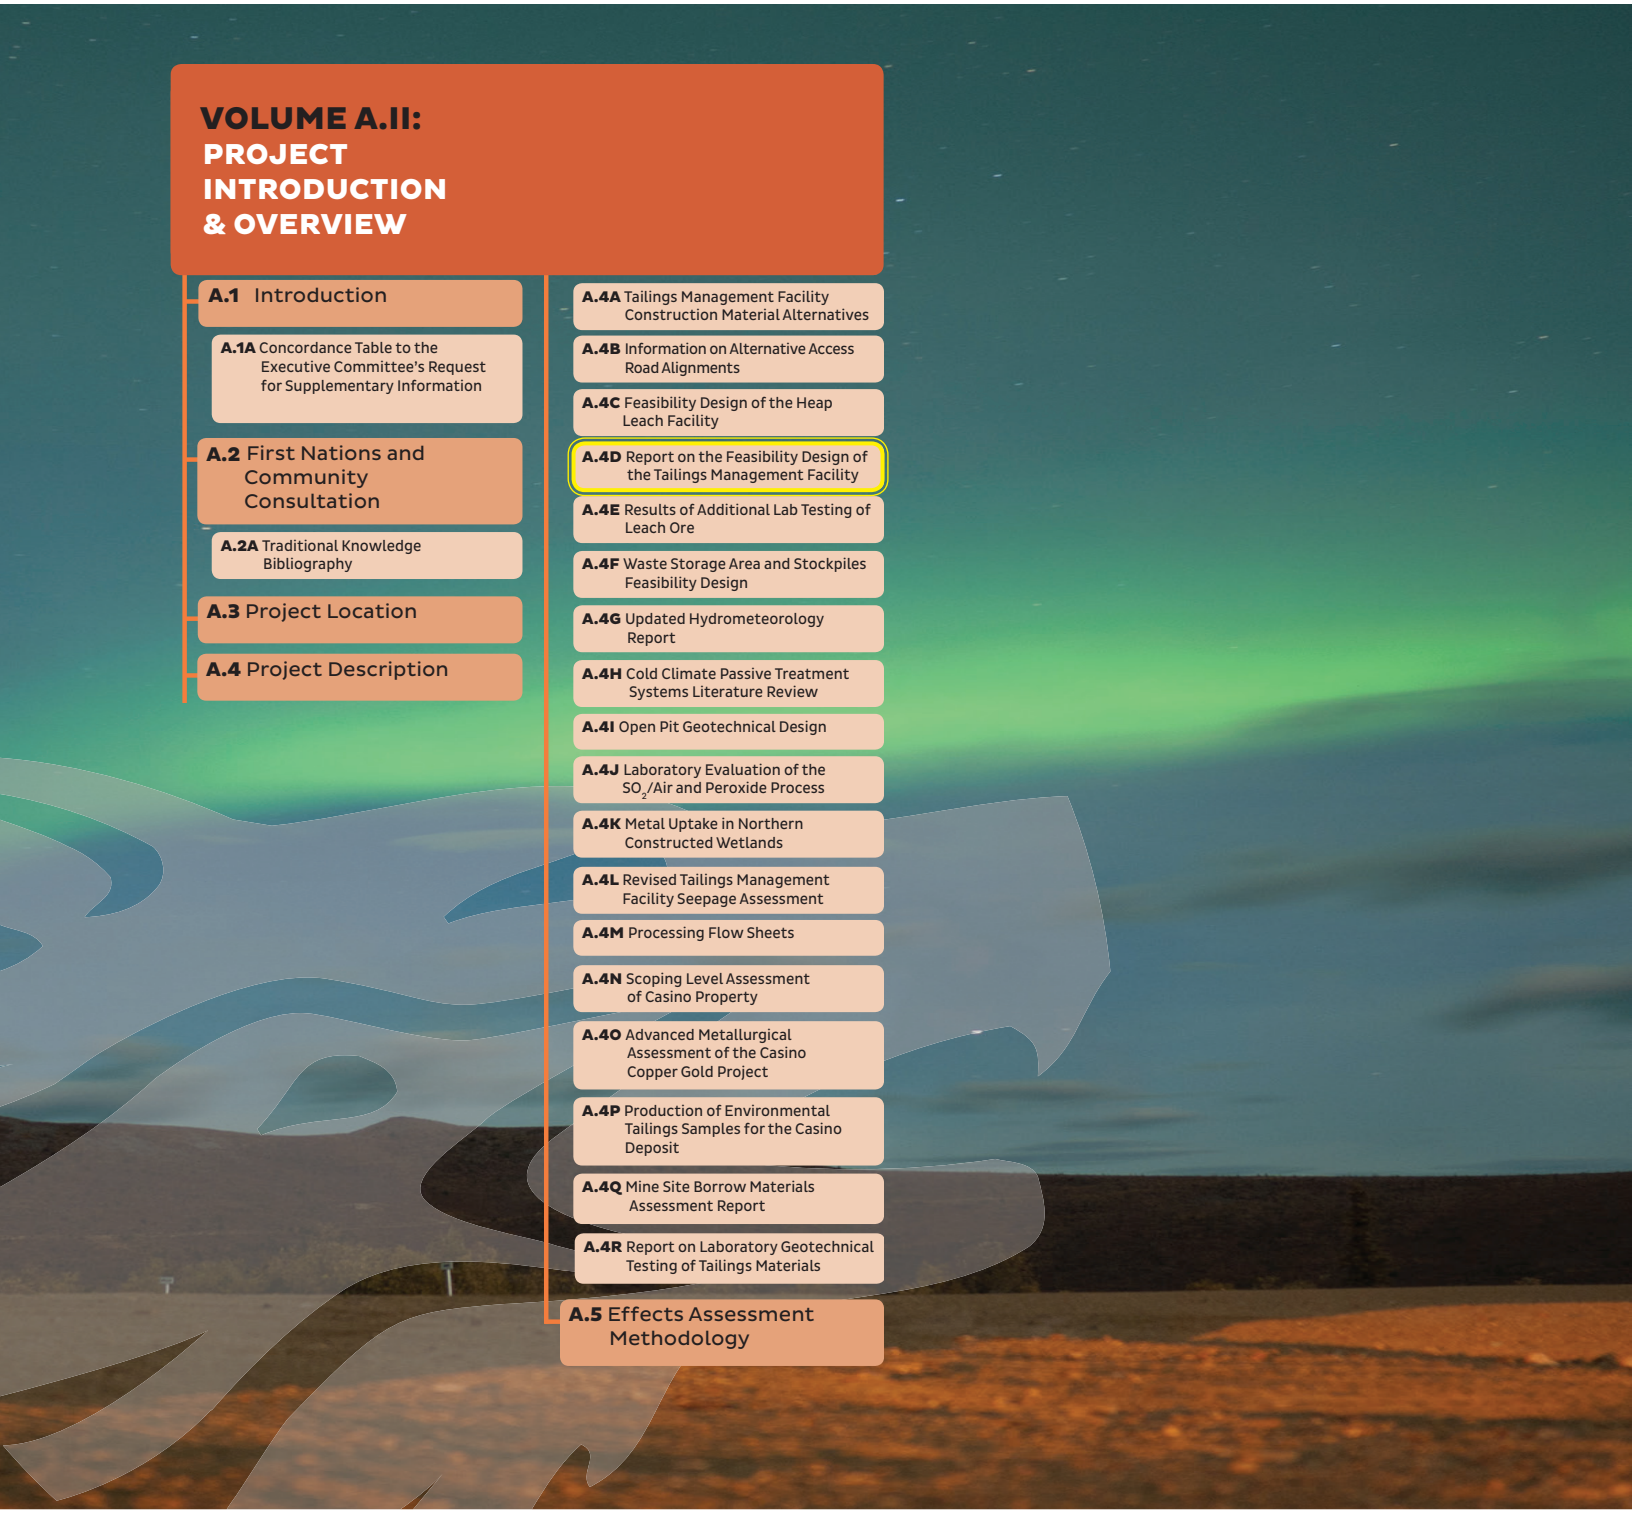
Table A.4 Annual Make up and Discharge Requirements

Mine Year	Makeup Water (m^3)	Discharge (m^3)
-3	522,000	0
-2	669,000	0
-1	666,000	0
1	666,000	167,000
2	666,000	167,000
3	596,000	234,000
4	579,000	237,000
5	450,000	263,000
6	418,000	269,000
7	571,000	282,000
8	581,000	280,000
9	581,000	280,000
10	290,000	688,000
11	357,000	318,000
12	299,000	329,000
13	273,000	340,000
14	210,000	372,000
15	58,000	479,000
16	0	269,000
Sub-total Years -3 to -1	1,857,000	0
Sub-total Years 1 to 16	6,595,000	4,974,000
Total	8,452,000	4,974,000

NOTES:

1. YEARS -3 TO -1 - MAKEUP WATER IS SOURCED FROM THE FRESH WATER SUPPLY POND.
2. YEARS 1 TO 15 - MAKEUP WATER IS SOURCED FROM THE YUKON WATER SUPPLY PIPELINE

A.3.2 Recommendations



The first leaching cycle in Year -3 was modelled as an equal portion of the annual tonnage, this will require an input of approximately 32 k m^3 of water to fully hydrate the ore. If the first block is reduced in size to approximately 80% there is sufficient water to fully hydrate. The remaining 20% from the first cycle can be distributed over the remaining months so that the annual target is met. The model has been calculated such that freshet flow occur at the beginning of a leaching cycle this allows close to 100% recycle of the runoff to hydrate a new block of ore. If this is not possible on an operational basis then there will be an increase in both the makeup and discharge requirements shown above.

Knight Piésold
CONSULTING

EXECUTIVE SUMMARY

The Casino Copper-Gold Project is a large copper-gold deposit located in the Dawson Range Mountains of the Yukon Territory, approximately 300 km northwest of Whitehorse. The deposit will be mined using open pit methods with a nominal mill throughput of approximately 125,000 tonnes/day of ore over a 22 year operating life. Knight Piésold Ltd. has been engaged to prepare a Feasibility design of the Tailings Management Facility (TMF) to accommodate all tailings and potentially reactive mine waste rock and overburden materials. The total mined ore reporting to the mill is approximately 965 million tonnes. Approximately 157.5 Mt of additional mined ore will be processed at a Heap Leach Facility (HLF) located south of the open pit.

The TMF will be used for safe, secure and environmentally secure disposal of mine tailings and all potentially acid generating and metal leaching waste rock and overburden. The TMF is located within Casino Creek valley. The embankments that confine the TMF are the Main Embankment to the south and the West Saddle Embankment to the west. The embankments have been designed in accordance to the Canadian Dam Association (CDA) “Dam Safety Guidelines” (2007).

Since the completion of the revised Pre-Feasibility design in 2011, additional geotechnical site investigations and laboratory testing have been completed in 2011 and 2012 to obtain additional geotechnical and hydrogeological information in the area of the TMF embankments. The information collected has been reviewed and incorporated into this Feasibility design. The findings of previous site investigation programs at the site in 1993, 1994, 2010 and 2011 were also used to support the Feasibility design.

The TMF has been sized to provide sufficient capacity to store approximately 956 million tonnes of tailings (including cyclone sand tailings used as embankment fill) and co-disposal of up to 658 million tonnes of potentially reactive waste rock and overburden materials. Potentially reactive waste rock and overburden will be hauled to the TMF for co-disposal with tailings and submergence by tailings and the supernatant pond. A Waste Storage Area (WSA) will be developed in the northern section of the TMF impoundment area.

Approximately 80% of the total tailings will be geochemically innocuous NAG material, following the removal of the pyrite component. These tailings will be used for the production of cyclone sand for construction of the Main Embankment. It is assumed that the NAG tailings will be passed through the cyclone plant for approximately nine months of each year. Cyclone operations will likely not be possible for a portion of the year due to freezing temperatures in the winter months. In addition to cyclone sand the cyclone plant will produce a high volume low solids content stream, containing the fines fraction of the tailings (cyclone overflow). This material will be discharged into the TMF. The discharge of bulk NAG tailings and cyclone overflow will be from valved offtakes located along the Main Embankment and from the West Saddle Embankment.

Approximately 20% of the total tailings will be PAG tailings which are delivered to the TMF in a separate pipeline. The PAG tailings deposit will be developed in a separate central region of the TMF by discharging the tailings from the north-western side of the TMF, close to the WSA. Deposition in this area will keep the PAG tailings remote from the confining embankments. This will minimise seepage from the PAG tailings and ensure that they remain in a subaqueous state.

The TMF embankments will be constructed as water-retaining zoned structures with a low permeability core zone and appropriate filter and transition zones to prevent downstream migration of fines. The core zone will include a seepage cut-off into competent rock in the foundation. The Main Embankment Starter dam is designed to store runoff as a source for mill start-up water and accommodate tailings and potentially reactive waste rock and overburden production for approximately one year of initial operations. The embankment shell zones for the Starter dam will be constructed with random fill comprising suitable rockfill from local borrow sources, supplemented by available non-reactive (leach cap) waste rock material from pre-production stripping. Cyclone sand production in Year 1 of operations will be used to extend the downstream shell of the Main Embankment, allowing the dam crest and core zone to be raised after about 1 year. Ongoing raises will comprise centreline raises with a vertical low permeability core zone and adjacent downstream filter zones. Cyclone sand will be produced from bulk NAG tailings at the Cyclone Plant and discharged into the cyclone sand shell zones (upstream and downstream of the core zone) where it will be spread in cells and compacted using bulldozers. Bulk tailings that bypass the Cyclone Plant and cyclone overflow (fines) produced during cycloning operations will be discharged into the impoundment. The final Main Embankment will be approximately 286 meters high at the deepest section of Casino Creek valley.

The West Saddle Embankment will be constructed at the south-western corner of the TMF and is required at the start of operations to provide a pipeline corridor at a suitable grade for tailings delivery to the cyclone sand plant and TMF. The embankment will comprise an earth-rockfill dam, constructed from local borrow materials to a maximum height of approximately 21 metres.

The TMF will be used to assist with site water management. The supernatant pond within the TMF will provide a large water storage capacity that will be used to both store water for later use and to attenuate inflows. The TMF supernatant pond will provide a water source for milling operations. The supply of reclaim water to the mill will be by a reclaim barge equipped with a pumping system and a reclaim water pipeline to connect the barge and mill.

A revised seepage assessment for the TMF has also been completed and the results incorporated into the Feasibility design. A detailed monthly operational water balance model has been developed for the TMF to assess the various flows to and from the facility, to predict the variation in supernatant pond volume during operations and to estimate makeup water requirements. The water balance includes consideration of Heap Leach Facility operations, cyclone sand operations, tailings consolidation and the co-disposal of potentially reactive waste materials within the TMF. The water balance indicates that the mine site will likely be in a deficit condition over the operating life of the TMF, except for the last 1 to 2 years.

A spillway and downstream channel will be required at closure to facilitate control and discharge of excess water accumulation within the TMF and to provide safe passage of storm water volumes from the TMF. The water balance model developed for the TMF indicates that there will be a water surplus at closure. The closure spillway will be located close to the right abutment of the West Saddle Embankment to provide long term protection against overtopping of the TMF during the post closure years.

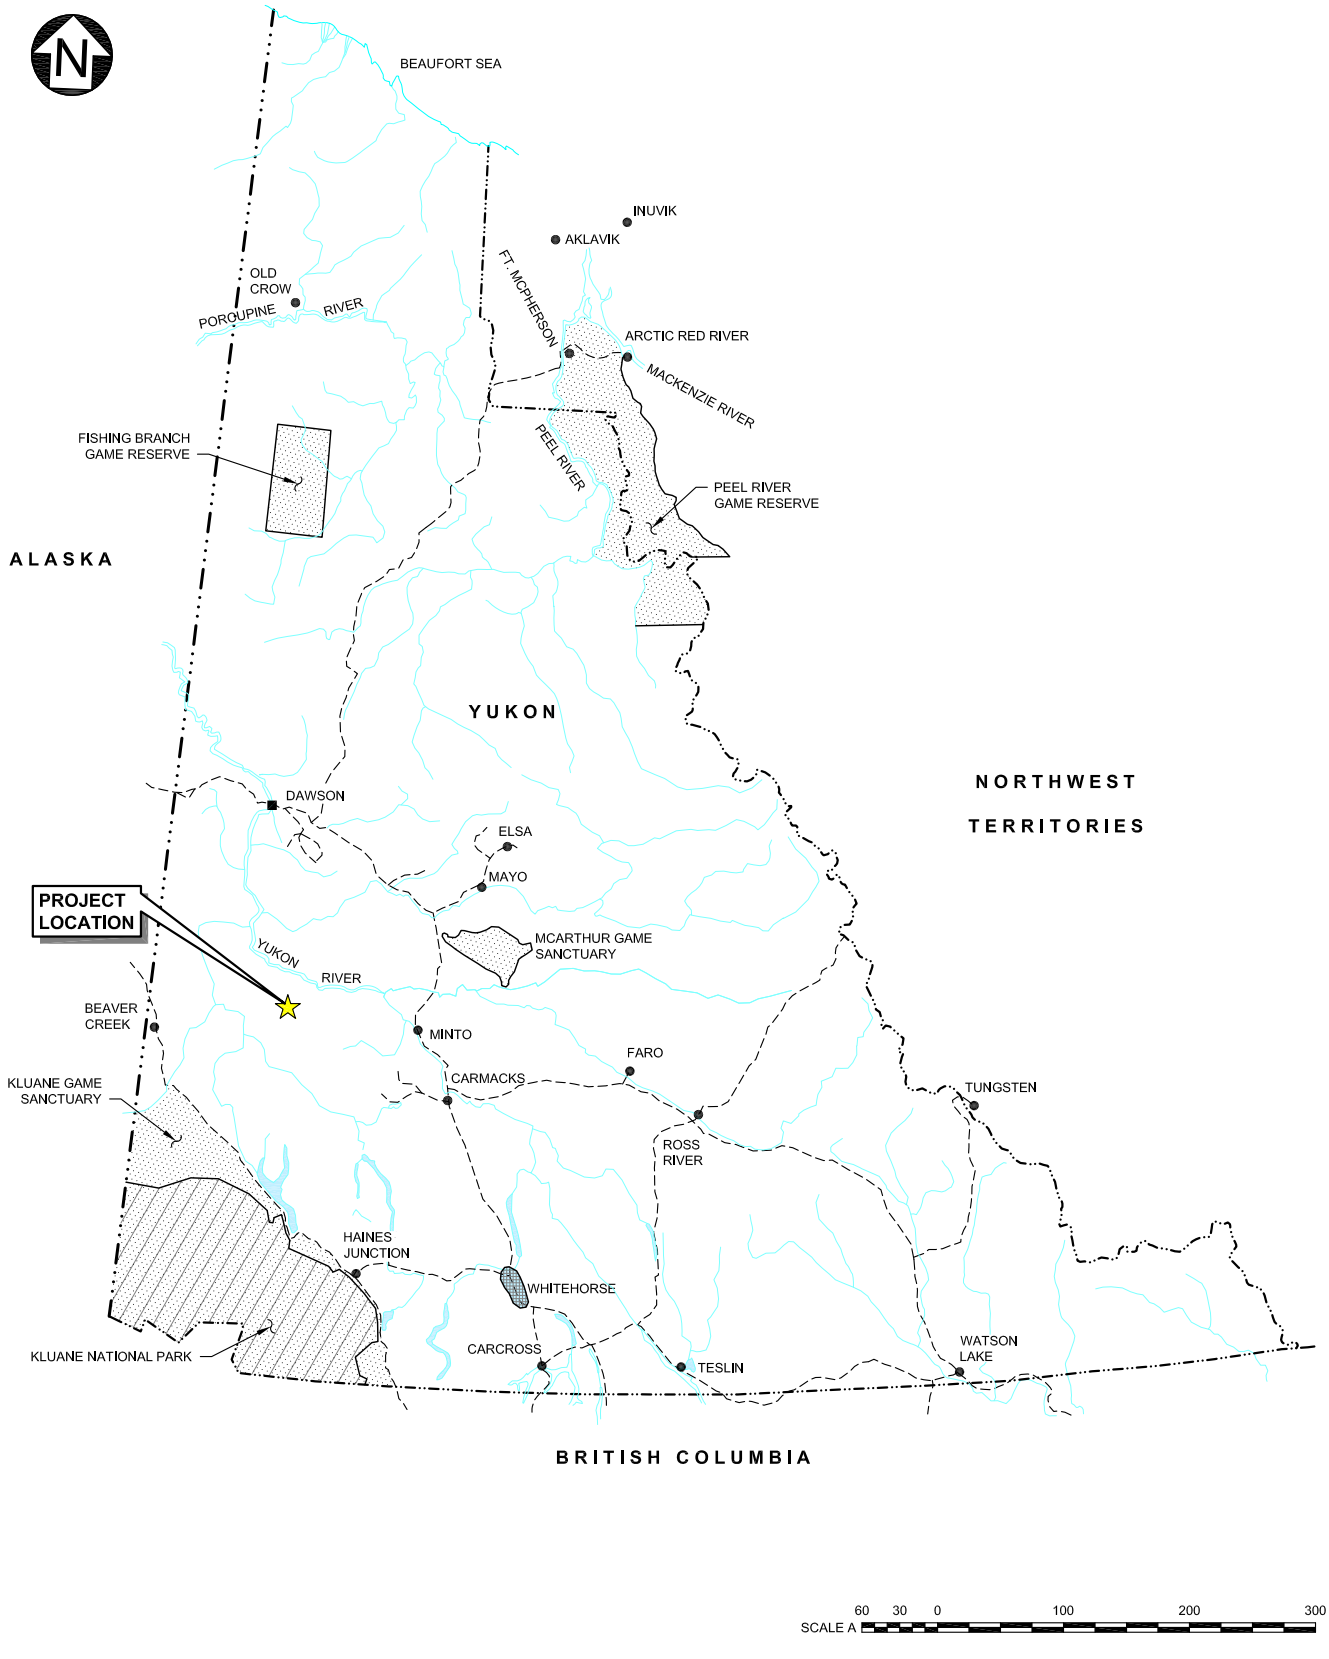
1 – INTRODUCTION

1.1 PROJECT DESCRIPTION

The Casino Copper-Gold Project is a venture by Casino Mining Corporation (CMC) to develop an open pit copper-gold-molybdenum mine in the Yukon Territory. The project is located in the Dawson Range Mountains of the Klondike Plateau approximately 300 km northwest of Whitehorse, Yukon, Canada, as shown on Figure 1.1. This area is somewhat unique in that the region was not glaciated during the Wisconsin Advance. The deposit is hosted by the Prospector Mountain Suite, a suite of igneous intrusive rocks with an intense hydrothermal alteration overprint. The deposit will be mined using open pit methods with a nominal mill throughput of approximately 125,000 tonnes/day (tpd) of ore over a 22 year operating life.



A general layout of the project site is shown on Figure 1.2. The proposed components of the project facilities include an open pit up to 600 meters deep containing a mineable reserve of approximately 965 million tonnes of mill ore. The Tailings Management Facility (TMF) has been sized to provide sufficient capacity to store approximately 956 million tonnes of tailings (including cyclone sand tailings used as embankment fill) and co-disposal of up to 658 million tonnes of potentially reactive waste rock and overburden materials.

Approximately 157.5 Mt of additional mined ore will be processed at a Heap Leach Facility (HLF) located south of the open pit. Details of the Feasibility design of the HLF are presented in Knight Piésold Ltd. (KPL) report “Feasibility Design of the Heap Leach Facility” (Ref. No. VA101-325/8-9, December, 2012). HLF operations will commence during pre-production stripping of the open pit.

Since the completion of the revised Pre-Feasibility design in 2011, additional geotechnical site investigations and laboratory testing have been completed at the TMF, HLF, plant site, ore stockpile areas and open pit. The information collected has been reviewed and incorporated into the applicable project design components. A revised seepage assessment for the TMF has also been completed in 2012. The results of the seepage assessment have been incorporated into the Feasibility design. A detailed operational water balance model has been developed for the TMF and includes consideration of HLF operations, cyclone sand operations and the co-disposal of potentially reactive waste rock within the TMF.

Approximately 80% of the total tailings will be Non-Acid Generating (NAG) material, following the removal of the pyrite component. The NAG tailings will be passed through a cyclone station to produce suitable cycloned sand for embankment construction. The quantity of cyclone sand used in embankment construction is approximately 221 million tonnes. It is estimated that 50% of the NAG tailings can be recovered as cyclone sand when the cyclone station is operating. This amounts to approximately 7.2 to 7.5 million m^3 (12 to 12.5 million tonnes) of cyclone sand fill material produced annually, except for Years 1 and 22. Approximately 20% of the total tailings will be Potentially Acid Generating (PAG) tailings which are delivered to a central region of the TMF in a separate pipeline.

Any non-reactive waste rock and overburden materials produced from mining activities can be used in embankment construction. It is anticipated that approximately 2 to 3 million tonnes of non-reactive leach cap material will be available during pre-production and will be used to provide some of the fill requirements for the Stage IA (starter) embankment.

1.2 PREVIOUS STUDIES

Knight Piésold Ltd. (KPL) was retained in 1993 by Pacific Sentinel Gold Corp. to prepare a scoping level study of the open pit, heap leach facility, mine tailings and waste rock management options for the proposed Casino open pit mine development. A number of engineering and environmental reports have been submitted by KPL and Hallam Knight Piésold since the beginning of the project. A list of the reports to date is included in Appendix A.

Several geotechnical site investigation programs were conducted by KPL in the Casino Project area from 1993 to 1994. Preliminary surficial geotechnical investigations were carried out at the site over the period of June 4 to October 1, 1993. The investigations were carried out as part of the Placer Lease Agreement Program to provide a preliminary overview of the surficial materials and foundation conditions for the various potential mine site components (including the open pit, plant site, heap leach facility, waste rock storage and potential tailings impoundment sites). The site investigation program included the excavation of geotechnical trenches for visual description and characterization of surficial materials, and for the collection of representative samples for laboratory testing. The laboratory testwork was carried out on site by KPL and included particle size analyses, natural moisture contents, Atterberg limits (plasticity), compaction tests and permeability tests. The results of the investigations are included in the KPL report "Report on Preliminary Surficial Geotechnical Investigations" (Ref. No. 1831/1, March, 1994).

Geotechnical and hydrogeological investigations conducted in 1994 resulted in fifteen drillholes throughout the Casino Project area. The investigation program also included the excavation of test pits for visual inspection and characterization of surficial materials. Representative rock core and test pit samples were collected for laboratory testwork. The laboratory testwork included particle size analyses, natural moisture contents, Atterberg limits, and compaction tests. In situ packer and falling head permeability tests and shut-in pressure tests were conducted within the drillholes and groundwater monitoring wells and thermistors were installed. Point load testing was conducted on site by KPL for select rock core samples. The results of the investigations are included in KPL report "Data Compilation Report on 1994 Geotechnical and Hydrogeotechnical Investigations" (Ref. No. 1832/2, February 22, 1995).

Alternative waste management sites were short listed for consideration during these previous studies. Preliminary studies identified Site No. 2 as the preferred option, and a scoping level conceptual design of the tailings facility was completed, and presented in the KPL letter report "230 Million Tonne Tailings Storage Facility Study" (Ref. No. 5/2115, September 14, 1995).

Initial scoping studies for a mine production rate of 100,000 tpd were completed in January 2008. This included a preliminary mine waste management alternatives assessment, comprising the following:

- Evaluation of potential TMF options, taking into consideration the recommendations of the previous studies on the conceptual layout for a 230 million tonne tailings storage facility completed by KPL in September 1995
- Determination of storage and embankment volume requirements for each potential TMF
- Consideration of the incorporation of potentially reactive waste rock within the tailings impoundment for flooded co-disposal with the tailings, and
- Selection of the most appropriate TMF option, considering a number of factors.

The TMF options were assessed using a number of criteria including:

- Ability to meet storage capacity requirements
- Minimal footprint and catchment area
- Water management, and
- Minimal infrastructure requirements, including consideration of tailings and reclaim pipelines, ease of road construction, embankment fill volume and construction requirements and location relative to the plant site and open pit.

Consideration was given to minimizing the overall project footprint, placing mine site facilities within one catchment, reducing the contributing catchment areas (simplifying site water management) and mitigating environmental impact.

This study also included a preliminary review and assessment of the potential use of dewatered (thickened/paste) tailings for surface disposal and an initial review of operating considerations for tailings and reclaim systems in freezing conditions. The results of the study were presented in the KPL letter report "Mine Waste Management Assessment" (Ref. No. VA07-01593, January 18, 2008).

The conceptual design for the selected TMF (Option 2) was used as a basis for development of the Pre-Feasibility level design completed in May 2008 and presented in KPL report "Report on the Pre-Feasibility Design of the Tailings Management Facility" (Ref. No. VA101-325/1, May 30, 2008).

Pre-Feasibility design studies completed in 2008 for the TMF utilized Non-Acid Generating (NAG) mine waste rock for embankment construction. However, subsequent geochemical characterization of the mine waste indicated that almost all of the mine waste material may have acid generating or metal (copper) leaching potential, and therefore not suitable for embankment construction. Consequently, a study was carried out to evaluate alternative embankment construction options and alternative tailings disposal technologies for the TMF. The findings of the study indicated that the use of cyclone sand for embankment construction is the preferred option and provides the most efficient and cost effective design concept for the TMF.

Consequently a revised Pre-feasibility design for the TMF completed in early 2011 incorporated the use of cycloned sand in embankment construction. A site investigation program was carried out between May and August of 2010 to obtain geotechnical and hydrogeological information in the TMF embankment area. This information was used to support the revised Pre-Feasibility Study. Geotechnical conditions were also investigated at the current locations of the Plant Site and Open Pit to assess the geotechnical factors affecting design. The results of the investigations are included in KPL report "2010 Geotechnical Site Investigation Data Report" (Ref. No. VA101-325/3-4, November 2, 2010).

1.3 FEASIBILITY DESIGN SCOPE OF WORK

This report presents the Feasibility design of the TMF. Specific design items which are addressed in the report include:

- Review of site characteristics including hydrometeorology, regional geology, hydrogeology and seismicity.
- Tailings physical characteristics.
- Review and evaluation of the results of previous geotechnical investigations carried out at the project site.

- Development of a suitable TMF layout and operating strategy.
- Evaluation of the TMF foundations and preliminary identification of potential borrow sources for construction materials.
- Development of a filling schedule for the TMF to determine initial and on-going staged embankment construction requirements.
- Design of TMF embankments, including static and seismic stability assessment.
- Development of a monthly operational water balance for the TMF to provide a running total of the inputs and outputs from the facility and water availability for reclaim.
- Examination of surface drainage and diversion requirements.
- Seepage analyses and consideration of seepage recovery and control systems.
- Consideration of the operating requirements for the tailings delivery, cyclone sand production and water reclaim systems.
- Preliminary consideration for TMF closure and reclamation requirements, including a closure spillway, and
- Estimation of TMF construction quantities (costing to be carried out by Others).

Additional site investigations to support the Feasibility design of the TMF and other project facilities (including the Waste Storage Area (WSA), stockpile areas and HLF) have been carried out in 2011 and 2012. A primary focus of the 2011 and 2012 site investigation programs was to confirm foundation conditions (including permeability of overburden and rock), refine the characterisation of geotechnical and hydrogeological conditions and to delineate and characterize the low permeability soil materials required for construction of the TMF and HLF. Thermistors were installed in the TMF and HLF areas to provide additional information on the subsurface thermal regime.

A summary of the geotechnical information provided by the site investigations is included in Section 4.0. Details and findings of the 2011 and 2012 site investigation programs for the waste management facilities are provided in KPL reports “2011 Geotechnical Site Investigation Data Report – Waste Management Facilities” (Ref. No., VA101-325/8-5, December, 2012), and “2012 Geotechnical Site Investigation Data Report” (Ref. No., VA101-325/8-14, December, 2012).

2 – TAILINGS CHARACTERISTICS

2.1 GENERAL

The tailings from the Casino Project operation will be produced from the conventional milling of copper and gold ore. The anticipated tailings stream from the mill will be at a typical solids throughput of approximately 45 to 46 million tonnes per year (approximately 34.5 million tonnes in Year 1 and 22.9 million tonnes in Year 22 of operations). The tailings will be transported from the mill at a thickened slurry solids content of about 55 percent by weight.

The tailings stream will be split into a PAG stream (20% by mass) and NAG tailings (80% by mass). Bulk NAG tailings will be passed through a cyclone station for approximately nine months of the year. The sand fraction (underflow) will be recovered and made available for embankment construction. The cyclone overflow (fine tailings) will report to the TMF for disposal. Bulk tailings will also report to the TMF when cycloning operations are suspended (assumed to be for approximately three months of the year) when freezing climatic conditions likely preclude sand placement in the embankments, and when the cyclone station is unavailable due to maintenance or downtime.

2.2 PHYSICAL CHARACTERISTICS

A laboratory testing program has been conducted in 2012 to determine the geotechnical characteristics of the Casino tailings materials. A tailings sample representing Non Acid Generating (NAG) Whole Tailings was provided by Casino Mining Corporation for testing. This sample was used to generate representative samples of tailings Cyclone Overflow (fine tailings) and Cyclone Underflow (sand) materials. A sample of Potentially Acid Generating (PAG) tailings was not available for testing at this time.

The test program included index testing to enable geotechnical classification of each of the materials. The Whole Tailings material can generally be described as non-plastic sand and silt with trace clay. The particle size distribution of the Whole Tailings sample comprises approximately 58% fine sand, 35% silt and 7% clay. The Cyclone Overflow sample was generated to a target particle size distribution with approximately 75% fines (silt and clay fractions). Similarly, the Cyclone Underflow sample was generated for a target particle size distribution with a maximum of 15% fines.

The specific gravity of the tailings solids was determined to be 2.70 for the Whole Tailings sample, 2.71 for the Cyclone Overflow sample, and 2.80 for the Cyclone Underflow sample.

A particle size distribution and specific gravity value for the PAG tailings material was provided by Casino Mining Corporation (based on test results conducted for laboratory metallurgical testing). The particle size distribution for the PAG tailings is included on Figure 2.1. The specific gravity of solids for the PAG tailings sample is 3.0. It is recommended that laboratory testing is also carried out on a representative sample of PAG tailings for future design studies.

Slurry settling (undrained and drained), air drying, consolidation and permeability tests were conducted to determine the characteristics of the Whole Tailings and Cyclone Overflow following deposition and for a range of conditions (representative of expected field conditions). Compaction, strength and permeability tests were carried out on the Cyclone Underflow sample to provide

information on the characteristics of the material as sand fill material over a range of stress conditions.

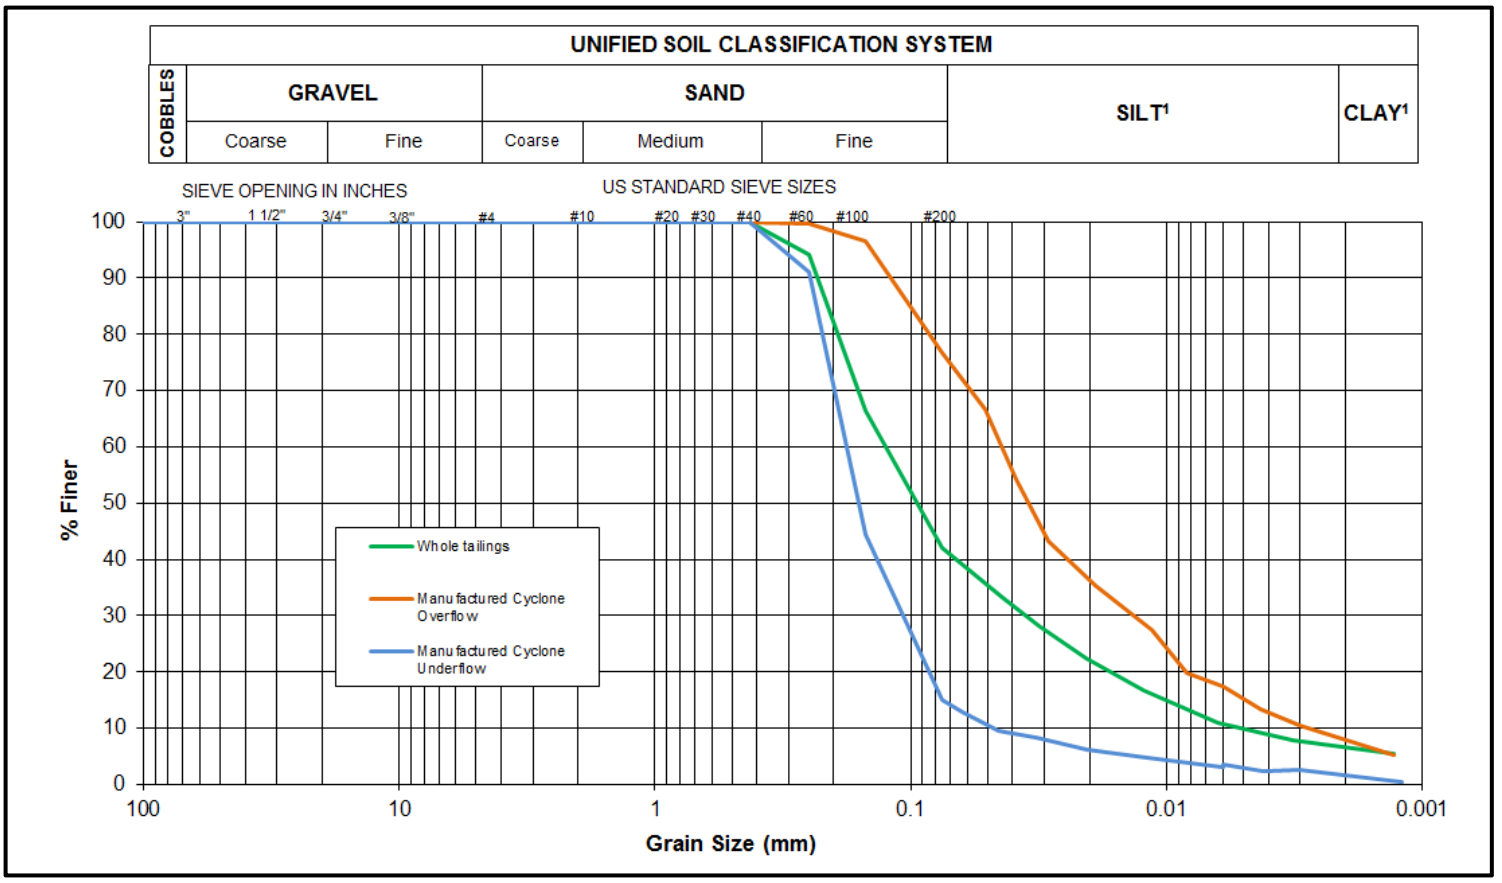

Figure 2.1 Particle Size Distribution for Tailings Samples

NOTES:

1. Silt and clay limits from the US Department of Agriculture definition. The Unified Soil Classification System defines all particles with diameters <0.075 mm as fines with silt and clay defined only by plasticity.

The methodology and complete results of the laboratory testwork are included in KPL report "Report on Laboratory Geotechnical Testing of Tailings Materials" (Ref. No. VA101-325/8-1, December, 2012). A summary of the laboratory testing and results is provided below.

2.2.1 Whole Tailings and Cyclone Overflow

The following is a list of the geotechnical tests conducted on the Whole Tailings and Cyclone Overflow samples:

- Undrained Settling
- Drained Settling (with Falling Head permeability measurement)
- Air drying
- Slurry Consolidometer Test (with permeability measurement), and
- Low Stress Slurry Consolidation (Burette) Test.

The slurry settling (sedimentation) tests provide an estimate of the density to which the tailings slurry will settle in a sub-aqueous environment, under undrained and drained conditions. These tests provide an estimate of expected tailings density in a storage facility after settling and before any significant consolidation or air drying occurs. The air drying test provides the geotechnical characteristics of the tailings for expected conditions on exposed beaches following deposition. The effect of air drying on moisture loss and tailings density is determined by this test.

The slurry consolidometer test is used to determine the consolidation, compressibility and permeability characteristics of the tailings over a wide range of confining pressures (typically corresponding to expected conditions in the field). These parameters are used to determine the amount and rate of consolidation, seepage rates, settlement and density increase for the tailings. The slurry consolidation cylinder test provides a measure of the consolidation characteristics of the tailings at very low effective stresses (representing freshly deposited tailings immediately following settling).

The following points summarize the pertinent findings of the tailings tests:

- For an initial slurry solids content of 55% the settled dry density of the Whole Tailings is approximately 1.0 tonnes/m^3 for undrained settling conditions and 1.09 tonnes/m^3 for drained settling conditions.
- For an initial slurry solids content of about 25% the settled dry density of the Cyclone Overflow is approximately 0.8 tonnes/m^3 for undrained settling conditions, and 0.95 tonnes/m^3 for drained settling conditions.
- Air drying of the tailings materials produces a significant increase in dry density over those from the undrained and drained settling tests. For the Whole Tailings with an initial slurry solids content of 55% a dry density of approximately 1.35 tonnes/m^3 is achieved under air drying conditions. For the Cyclone Overflow with an initial slurry solids content of 25% a dry density of 1.29 tonnes/m^3 is achieved.
- Relationships between coefficient of consolidation, void ratio and vertical coefficient of permeability to effective stress have been developed for the Whole Tailings and Cyclone Overflow material. The coefficients of consolidation generally increase with increasing effective stress, with calculated coefficients of consolidation for the Whole Tailings ranging from 100 m^2/year at very low stresses to over 1000 m^2/year at high stresses. Calculated coefficients of consolidation for the Cyclone Overflow range from 25 m^2/year at very low stresses to over 1000 m^2/year at high stresses.
- The dry density of the Whole Tailings and Cyclone Overflow increases with increasing effective stress (due to consolidation), with a value of approximately 1.6 tonne/m^3 achieved under effective stress conditions greater than about 500 kPa.
- Measured vertical permeability values for the Whole Tailings and Cyclone Overflow decrease with increasing effective stress. The permeability of the Whole Tailings ranges from approximately 1 x 10^{-4} cm/sec at low stresses (representing unconsolidated or fresher tailings near surface) to about 1 x 10^{-6} cm/sec at high stresses, corresponding to a reduction in void ratio (representing more consolidated or deeper tailings within the deposit). Similarly, the permeability of the Cyclone Overflow ranges from approximately 5 x 10^{-5} cm/sec at low stresses to about 1 x 10^{-6} cm/sec at high stresses.

2.2.2 Cyclone Underflow (Cyclone Sand)

The following is a list of the geotechnical tests conducted on the Cyclone Underflow sample:

- Compaction (Proctor) Test
- Tri-axial Shear Strength, and
- Flexible Wall Permeability.

The compaction test provides information on the expected density of the cyclone sand following placement as compacted sand fill for embankment construction. The optimum moisture content of the Cyclone Underflow sample was determined to be 16.7% and the maximum dry density was 1,559 kg/m^3.

The shear strength test provides information on the strength of the compacted sand over a range of confining stresses, and is used for embankment stability assessment. Similarly, the permeability test provides information on the expected permeability of the cyclone sand fill over a range of confining stresses. The permeability characteristics of the cyclone sand are an important consideration in the design of free-draining cyclone sand embankment dams. The shear strength and permeability tests were carried out over a large range of confining stresses to examine the influence of high confining stresses (corresponding to a large dam height) on the strength and permeability values.

The shear strength of the cyclone sand is defined by an average effective friction angle of 36 degrees and zero cohesion. The potential strength characteristics of the cyclone sand over a large stress range was examined by comparison of the laboratory test data to published information on the non-linear strength characteristics of similar granular materials (angular sands). This information suggests that the effective friction angle of the cyclone sand may be greater than 36 degrees at low confining stresses but potentially lower at very high stresses. However, the laboratory test results for the Cyclone Underflow sample suggest that there is no apparent loss of strength at the higher stresses, over the stress range tested (up to about 3000 kPa).

Permeability values determined for the Cyclone Underflow show a general trend of reducing permeability with increasing confining stress. This decrease is the result of the decrease in material density and potentially from the generation of finer particles due to particle crushing. However, the results do not appear to indicate a dramatic decrease in permeability at high stresses, which would be indicative of significant particle crushing and changes to the fines content of the material. The permeability of the Cyclone Underflow ranges from approximately 2×10^{-3} cm/sec at lower stresses to about 5×10^{-4} cm/sec at high stresses (approximately 3000 kPa). Extrapolation of these results suggests that the permeability of the Cyclone Underflow will remain greater than 1×10^{-4} cm/sec at very high stresses of about 4000 to 5000 kPa.

2.3 GEOCHEMICAL CHARACTERISTICS

Detailed laboratory testing and chemical analysis of the tailings (solids and process solutions) has been conducted by Others to determine their geochemical characteristics under saturated and unsaturated conditions. CMC has indicated that approximately 20% of the total tailings will comprise potentially acid generating material.

The PAG tailings are assumed to require complete subaqueous disposal in the TMF, to maintain the tailings deposit in a saturated state and inhibit their oxidation and potential reactivity.

The NAG tailings stream (80% of the tailings total) is assumed to be suitable for production of cyclone sand fill material for embankment construction.

3 – SITE CHARACTERISTICS

3.1 PHYSIOGRAPHIC SETTING

The project is located in the Dawson Range Mountains of the Klondike Plateau. The area is somewhat unique in that the region was not glaciated during the Wisconsin Advance. The characteristic terrain features are smooth, rolling topography, with moderate to deeply incised valleys. Major drainage channels extend below 1,000 m elevation. Most of the terrain lies between 1,000 m and 1,500 m elevation.

The tailings basin area is sited within the Casino Creek valley. The valley bottoms throughout the project area, with impeded drainage, have prominent permafrost features such as peat plateaus, palsas, hummocky tussock fields and polygons.

3.2 HYDROMETEOROLOGY

3.2.1 General

The climate at the Casino Project area is characterized by long, cold, dry winters and short, warm, wet summers, with conditions varying according to altitude and aspect. Streamflow in the region is typically highest in May due to melting of the winter snowpack. Annual peak instantaneous flows commonly occur in this freshet period on larger rivers, but on smaller streams they may also occur in summer or early autumn due to intense rain or rain on snow events. Flows decrease throughout the winter and minimum flows typically occur in March or April.

The climate and hydrology at the Casino Project site have been assessed based on both short-term site data and longer-term regional data. Climatic data were collected on-site at the Project climate station located in the upper Casino Creek sub-watershed at an elevation of 1200 m. The period of site record extends from 1993 to 1994 and from 2008 to 2011. Preliminary streamflow data were collected by Hallam Knight Piésold in 1993 and 1994. A new data streamflow collection program was initiated by AECOM in 2008, with the installation of ten streamflow gauging stations. As of 2012, nine streamflow gauging stations are considered to be in active operation and continue to be operated at present by Knight Piésold Ltd. (KPL). A summary of the hydrometeorological parameters is described below and the detailed analyses are presented in KPL report “Updated Hydrometeorology Report” (Ref. No. VA101-325/8-11, July 9, 2012).

3.2.2 Temperature

The mean annual temperature for the Casino Project area is estimated to be -3 °C, with minimum and maximum mean monthly temperatures of -17 °C and 12 °C occurring in January and July, respectively.

The mean monthly temperature values are presented in Table 3.1.

Table 3.1 Mean Monthly Temperature and Precipitation Values

Location	Parameter	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual
Casino Project Station (El. 1200 m)	Precipitation (mm)	32	24	19	17	37	62	91	67	47	38	43	33	**510**
	Temperature (°C)	-16.8	-14.0	-10.2	-1.9	5.0	10.0	11.6	9.2	3.8	-4.5	-12.1	-15.3	**-2.9**

3.2.3 Precipitation and Evaporation

The Mean Annual Precipitation (MAP) for the Casino Project area is estimated to be 510 mm, with 65% falling as rain and 35% falling as snow. The mean monthly values are presented in Table 3.1.

The annual potential evapotranspiration (PET) value for the Casino Project area is estimated to be 300 mm, based on measured temperatures at the Project site climate station, and long-term regional temperature records. Potential evapotranspiration values generally provide reasonable estimates of lake evaporation rates, and are assumed to be appropriate for estimating evaporation from lakes and ponds in the Project area.

3.2.4 Annual Snowfall and Snowmelt

Based on the estimated MAP of 510 mm and a rain/snow ratio of 0.65/0.35, the annual snowfall value for Casino was estimated to be 179 mm. This is generally consistent with the 141 mm mean annual maximum snowpack value (snow water equivalent, SWE), taking into account approximately 40 mm lost to sublimation, recorded in the Project area at the Casino Creek snow course station (09CD-SC01) operated by the Yukon Department of Environment (1977-2011), Water Resources Branch.

Based on the complete years of snowpack data, the average monthly snowmelt distribution for the Casino Project area was estimated to be approximately 20% in April and the remaining 80% in May, although there is considerable variation from year to year.

3.3 REGIONAL GEOLOGY

Regional geological information in the vicinity of the TMF is derived from the interpretation of KPL drillhole and test pit data within both the TMF and surrounding areas. Several geotechnical site investigation programs were conducted in the area of the TMF in 1993 and 1994 and in 2010, 2011 and 2012. Details and results of the site investigations and the foundation conditions defined for the TMF basin are presented in the following KPL reports:

- "Report on Preliminary Surficial Geotechnical Investigations" (Ref. No. 1831/1, March, 1994),
- "Data Compilation Report on 1994 Geotechnical/Hydrogeological Investigations" (Ref. No. 1832/2, February 22, 1995),
- "2010 Geotechnical Site Investigation Data Report" (Ref. No. VA101-325/3-4, November 2, 2010),
- "2011 Geotechnical Site Investigation Data Report – Waste Management Facilities" (Ref. No., VA101-325/8-5, December, 2012), and
- "2012 Geotechnical Site Investigation Data Report" (Ref. No., VA101-325/8-14, December, 2012).

The TMF is underlain by the following geotechnical units:

- Overburden
  - Topsoil
  - Silty SAND to GRAVEL with some cobbles, trace clay (residual soil and colluvial veneer) along valley ridges and upper slopes
  - SILT and SAND with some gravel and cobbles, trace clay (colluvial apron) and interbedded SAND and gravelly SAND with some cobbles (alluvium) along the lower slopes and valley bottom
- Weathered Bedrock, and
- Fresh Bedrock.

The bedrock primarily comprises Dawson Range Batholith Granodiorite throughout the TMF Main Embankment and impoundment area, and Yukon Metamorphic Group Gneiss and Quartzite in the West Saddle Embankment area. Dawson Range Batholith (Mid-Cretaceous) is the main country rock in the TMF area and is dominantly granodiorite in composition. Quartz monzonite and diorite are less abundant. Yukon Metamorphic Group (Paleozoic) is found at depth within drillholes 94-345, 94-346, DH10-01, DH10-02 and DH10-04. The Yukon Metamorphic group was also encountered in test pits near the west embankment. It consists primarily of mafic gneiss, with less abundant meta-diorite/amphibolite, quartz-rich and intermediate gneiss, and quartzite. The Yukon Group represents an older suite of metamorphic rocks which were intruded by the Dawson Range intrusives. Along slopes and ridges in Casino Creek valley the depth to bedrock varies from about 0.5 to 7.5 meters, with an average overburden thickness of between 2 and 3 metres. Depths to bedrock in the Casino Creek valley bottom vary from approximately 2 to 23 metres.

3.4 HYDROGEOLOGY

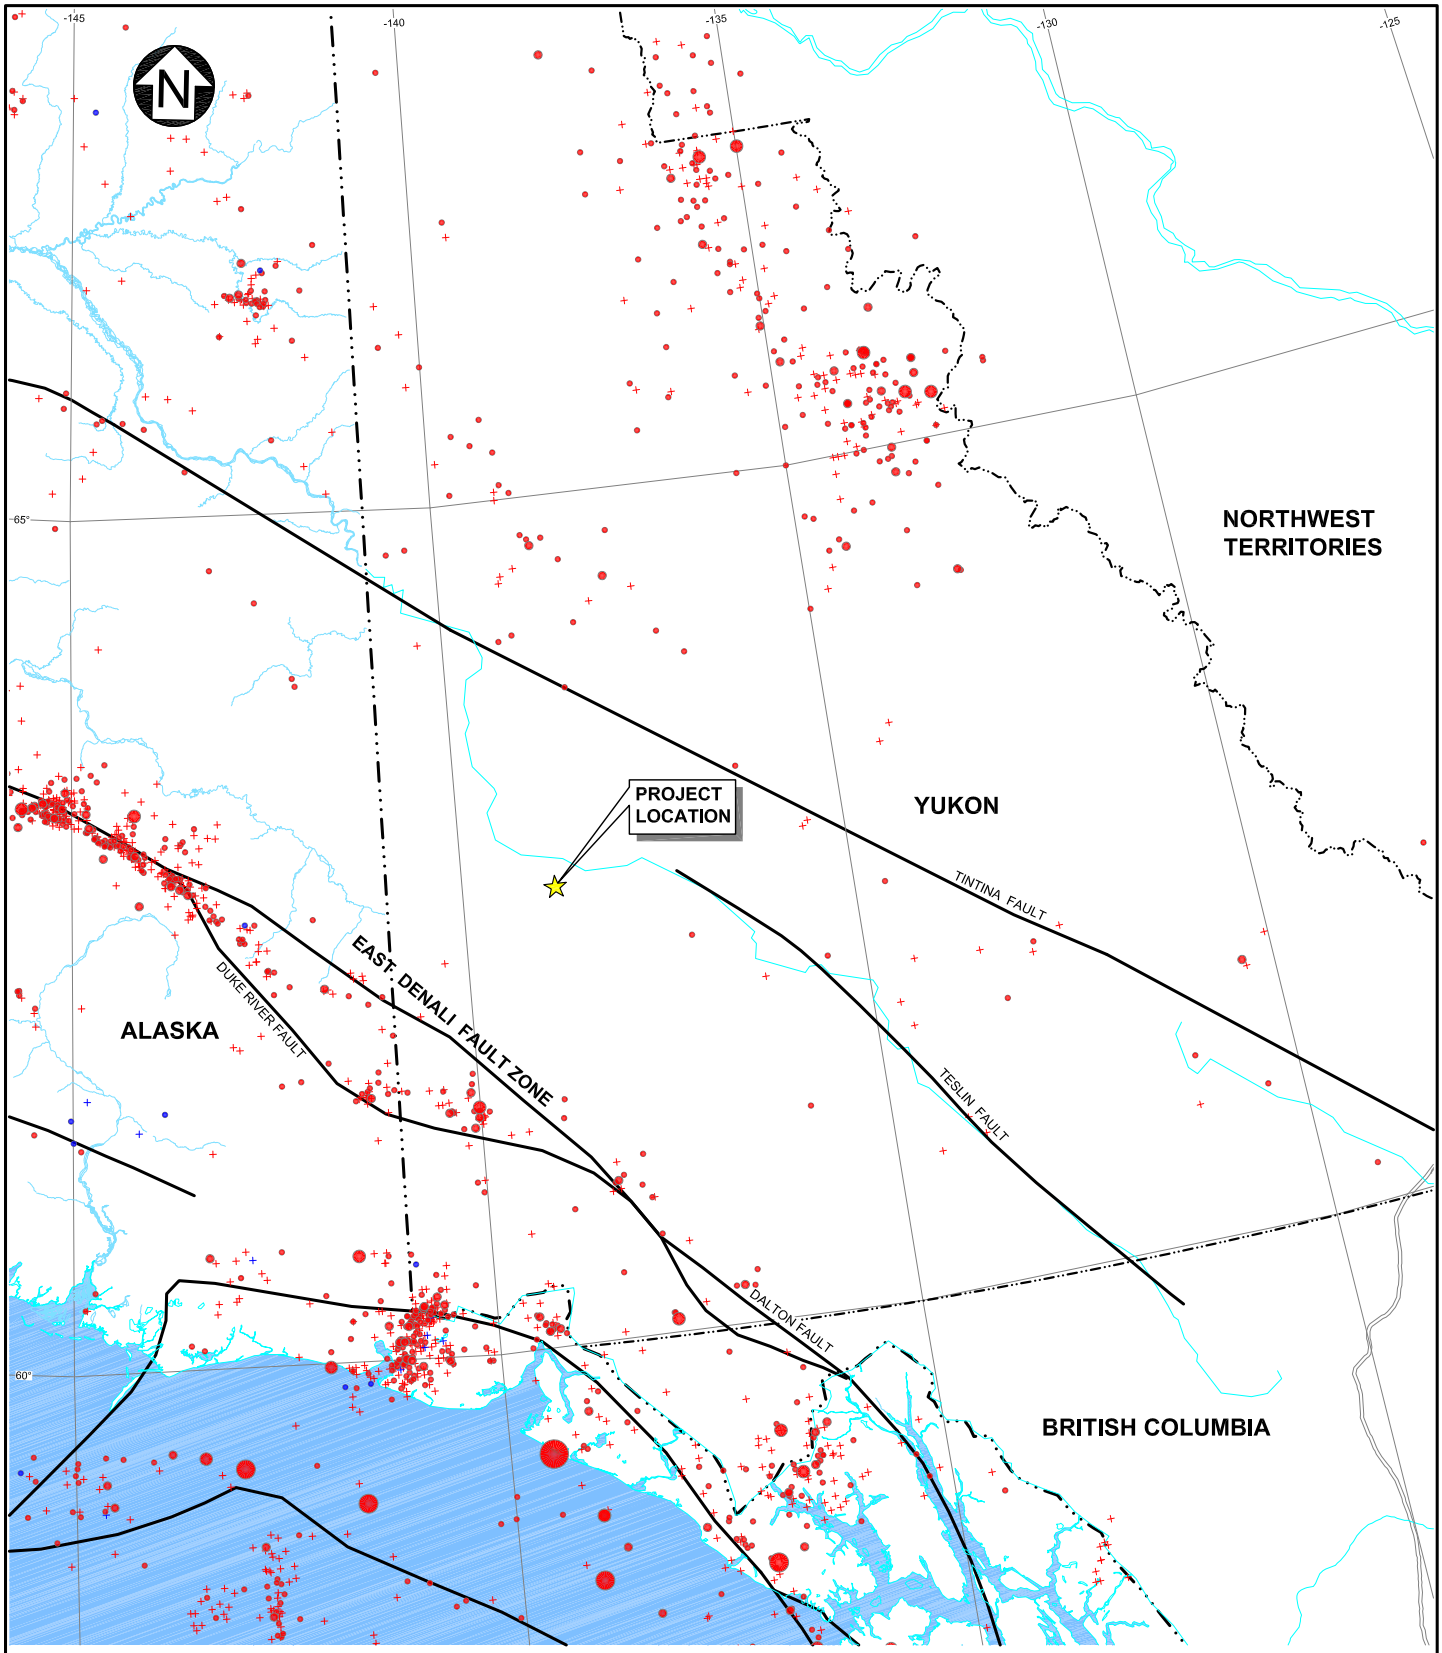
The interpreted baseline groundwater conditions are based on piezometric levels in standpipes throughout the study area, in addition to shut-in pressure tests performed during drilling in 1994. Permeability results are based on packer tests and falling head tests performed in the drillholes and piezometer standpipes in the different geotechnical units.

Estimates of in situ permeability values, along with supporting hydrogeologic observations are summarized as follows:

- In situ packer and falling head permeability tests were carried out in various drillholes within the TMF basin and Main and West Embankment areas during the 1994, 2010 and 2011 geotechnical/hydrogeological investigations. One packer test and two falling head tests were conducted in the overburden soils near the bottom of the Casino Creek valley in drillholes 94-345 and DH10-04. Permeabilities within the overburden soils ranged from 3×10^{-6} cm/s to 3×10^{-5} cm/s, with a geometric mean value of approximately 7×10^{-6} cm/s. These permeabilities are lower than expected possibly due to a high percentage of fines and/or frozen ground conditions in the vicinity of the tests.
- Permeabilities within Highly Fractured bedrock ranged from 2×10^{-3} cm/s to 2×10^{-7} cm/s, with a geometric mean value of approximately 5×10^{-5} cm/s.
- Permeabilities within Slightly to Moderately Fractured bedrock ranged from 6×10^{-4} cm/s to 2×10^{-7} cm/s, with a geometric mean value of approximately 1×10^{-5} cm/s.

- Permafrost has an important effect on hydrogeology. Saturated frozen soil and rock have a much lower permeability when frozen compared to a thawed or unfrozen state. In situ hydraulic conductivity test results showing very low hydraulic conductivities potentially indicate frozen soil or rock. Thermistors were installed during the 2011 and 2012 site investigations to provide a better understanding of the thermal regime in the subsurface. The permafrost conditions at the TMF site are discussed in detail in Section 4.0.

Well water level elevations in the TMF impoundment area within Casino Creek valley range from approximately 720 to 970 metres. The highest water levels are located at the West Saddle Embankment and the lowest at the Main Embankment, which indicates southeast moving groundwater flow from the West Saddle Embankment to the Main Embankment.



3.5 SEISMICITY

3.5.1 Regional Tectonics and Seismicity

A review of the regional tectonics and historical seismicity has been carried out to enable selection of appropriate design earthquake events for the TMF for use in seismic stability assessment.

The region of the southwest Yukon Territory and northwest British Columbia is one of the most seismically active areas in Canada. The seismic hazard in the region is also influenced by the seismically active region of southeast Alaska. The coastal region has experienced many large earthquakes, including events with magnitudes in the range of magnitude 7.0 to 8.0. In 1958 a magnitude 7.9 earthquake occurred along the Fairweather fault (the northern extension of the Queen Charlotte transform fault). The most significant inland zone of seismicity follows the Dalton and Duke River segments of the East Denali fault zone through the southwest Yukon. Farther inland there is only minor seismicity between the Denali and Tintina fault systems, including the region of the Casino Project site.

Figure 3.1 shows the regional tectonics and historical seismicity of the Yukon and surrounding regions and the location of the Casino project. Review of historical earthquake records and regional tectonics indicates that the Casino Project site is situated in a region of low seismicity.

SYMBOL SIZE PROPORTIONAL TO MAGNITUDE

3.5.2 Seismic Hazard Analysis

The seismic hazard for the Casino project has been defined using probabilistic methods of analysis. Design ground motion parameters have been determined for the project site using information provided by the probabilistic seismic hazard database of Natural Resources Canada (NRC) (http://earthquakescanada.nrcan.gc.ca/hazard-alea/zoning/haz-eng.php). The results are summarized in Table 3.2 in terms of earthquake return period, probability of exceedance (for a 22 year design operating life) and the corresponding peak ground acceleration (median and mean hazard values). For a return period of 500 years the corresponding median peak ground acceleration is 0.07g, indicating a low to moderate seismic hazard for the site.

Table 3.2 Summary of Probabilistic Seismic Hazard Analysis

Return Period (Years)	Probability of Exceedance[1] (%)	Peak Ground Acceleration (PGA)[2]	
		Median PGA[3,4] (g)	Estimate Mean PGA[5] (g)
100	20	0.04	0.05
500	4	0.07	0.08
1,000	2	0.08	0.10
2,500	1	0.11	0.13
5,000	0.4	0.14	0.17
10,000	0.2	0.18	0.22

NOTES:

1. Probability of exceedance calculated for a design life of 22 years:
   $q = 1-\exp(-L/T)$
   Where: q = probability of exceedance
   L = design life in years
   T = return period in years
2. Peak ground accelerations are for soft rock/very dense soil (Vs_{30} = 360 to 760 m/sec) .
3. Median peak accelerations for return period up to 2,500 years obtained from the seismic hazard database of Natural Resources Canada.
4. Median peak ground accelerations for return periods of 5,000 and 10,000 years obtained from site-specific analysis using EZ-FRISK.
5. Mean PGA values estimated as 1.2 x median values.

However, the NRC database only provides ground motion parameters up to a return period of approximately 2,500 years (corresponding to a 2% probability of exceedance in 50 years). Therefore, a probabilistic seismic hazard analysis was conducted to provide ground motion parameters beyond 2,500 years, specifically for return periods of 5,000 and 10,000 years.

The computer program EZ-FRISK (Risk Engineering, Inc., 2008) was used to develop a seismic hazard model for the Yukon and the surrounding regions. The seismic hazard analysis module available with EZ-FRISK includes a database provided by Risk Engineering Inc. of faults and areal seismic sources for the pertinent regions of western Canada. Seismic sources defined in the hazard model include the regions of the southern Yukon Territory, southeastern Alaska, and the Denali and Fairweather fault systems. The seismic hazard model was used to determine the relationship between peak ground acceleration and annual frequency of occurrence for the project site. Predicted values for the project site are included in Table 3.2 for return periods of 5,000 and 10,000 years. Predicted values for lower return periods were very similar to those provided by the NRC seismic hazard database.

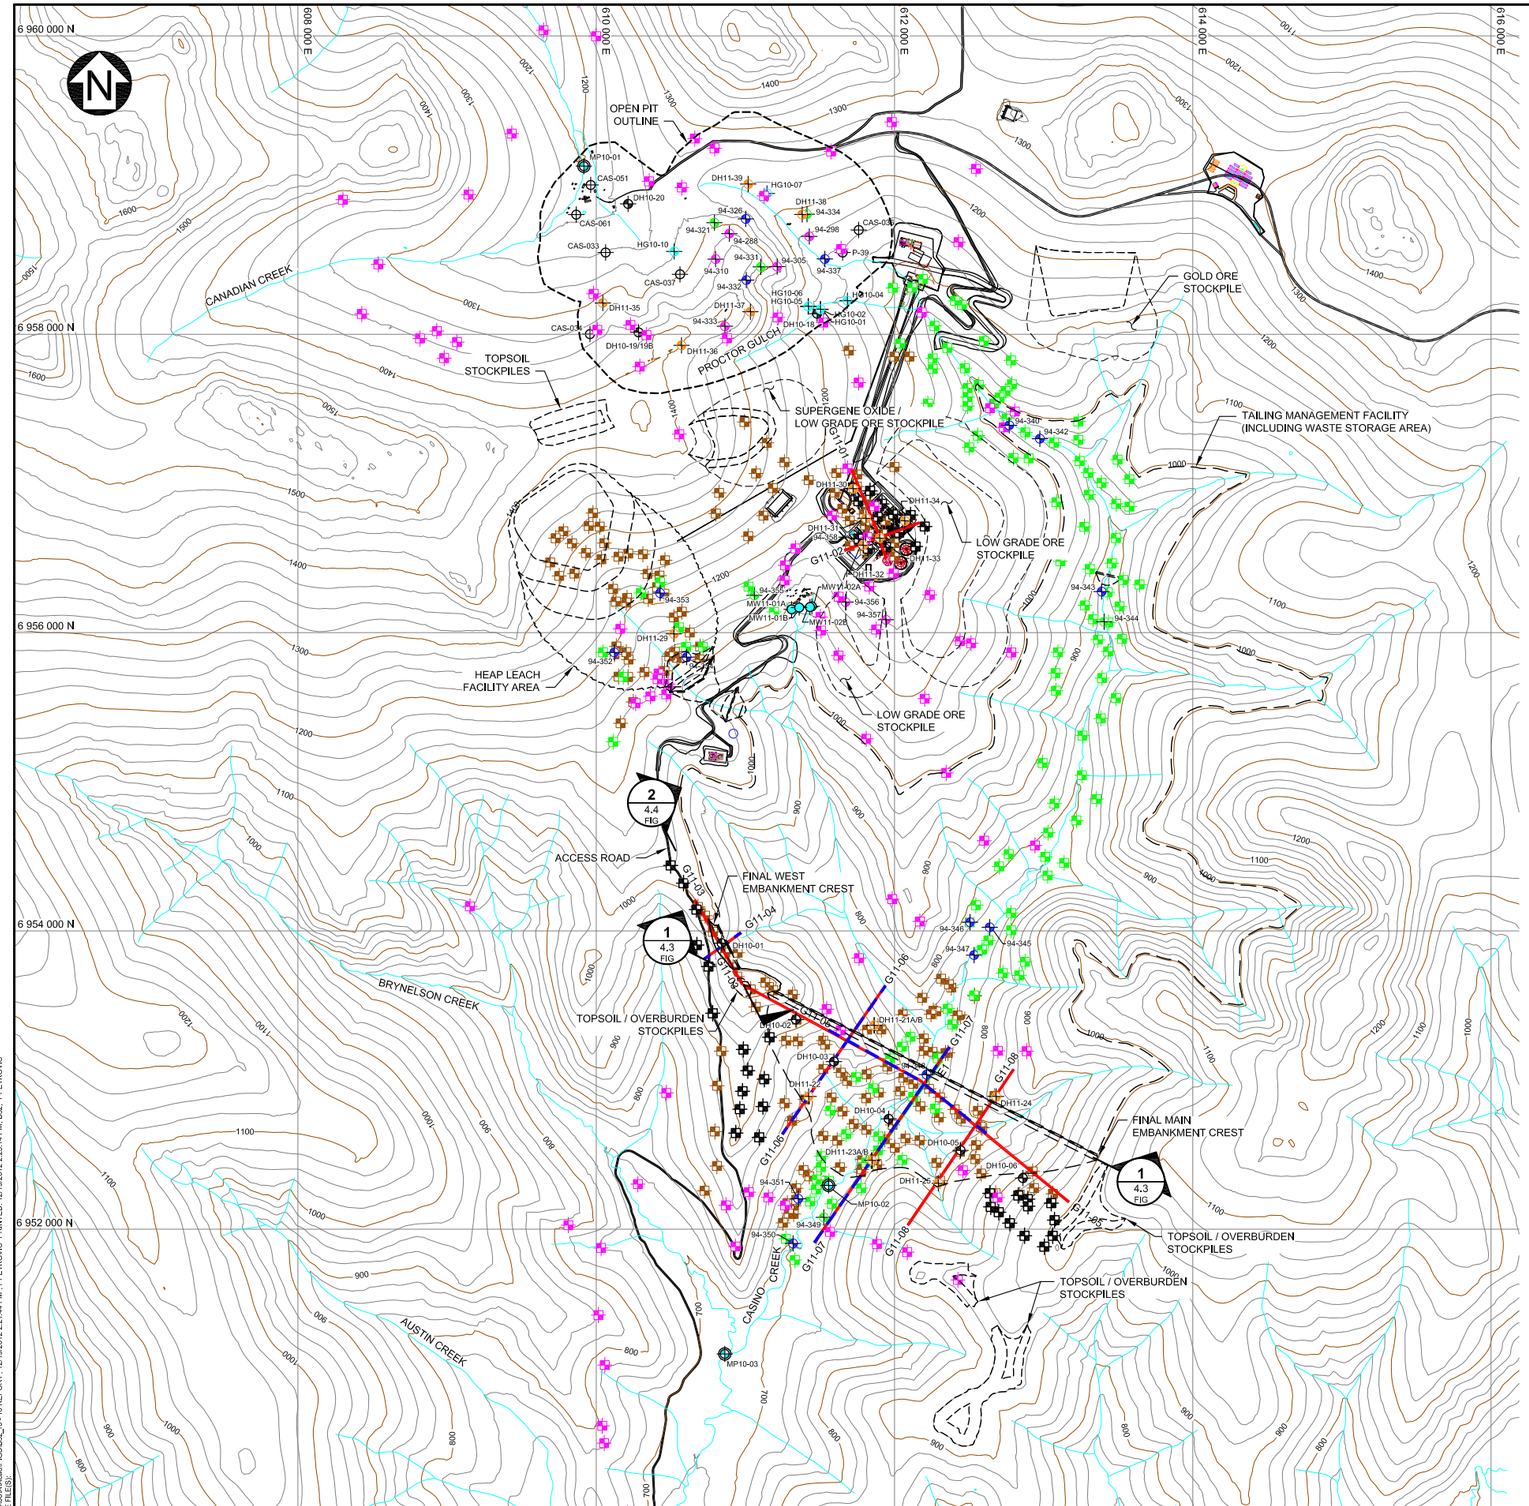
The seismic hazard for the project site is predominantly from shallow crustal earthquakes (magnitudes up to M7) in the region of the southern Yukon, but it is also influenced by the potential for larger magnitude earthquakes (approximately M7.5 to 8.0) occurring farther from the site on the East Denali fault zone.

Details of the probabilistic seismic hazard assessment are provided in Appendix B.

4 – SITE GEOTECHNICAL CONDITIONS

4.1 SITE INVESTIGATIONS

Geotechnical site investigation programs were conducted by KPL in the area of the TMF in 1993 and 1994 and more recently in 2010, 2011 and 2012. The programs included drillholes and test pits to investigate the geotechnical characteristics and foundation conditions. Geophysical surveys were carried out by Frontier Geosciences Inc. as part of the 2011 site investigations, and included seismic refraction surveys, Ground Penetrating Radar (GPR) surveys and an EM31 conductivity survey. The geotechnical data has been used to evaluate the tailings basin and embankment foundation conditions, and to evaluate the geological factors affecting design of the TMF.



The site investigations conducted in the area of the proposed TMF site included the following:

- Preliminary surficial geotechnical investigations were carried out in 1993 at the Casino project area. The investigations were carried out as part of the Placer Lease Agreement Program to provide a preliminary overview of the surficial materials and foundation conditions for the various potential mine-site components, including the Open Pit, Plant site, Heap Leach Pad, Waste Rock Storage and Tailings Impoundment sites. The exposed surficial materials were described and characterized, and representative samples were selected for laboratory testing. The laboratory testwork was carried out on site by KPL and included particle size analyses, natural moisture contents, Atterberg limits (plasticity), compaction tests and permeability tests. The results of the investigations are included in KPL report “Report on Preliminary Surficial Geotechnical Investigations” (Ref. No. 1831/1, March, 1994).
- Eleven drillholes were completed in 1994 near the proposed TMF embankment and impoundment areas. Groundwater monitoring wells were installed in nine of these drillholes, and thermistors were installed in two other holes. In situ packer, falling head permeability tests, and shut-in pressure tests were conducted within the drillholes. The investigation program also included the excavation of test pits for visual inspection and characterization of surficial materials. Representative test pit samples were collected for laboratory testing. The laboratory testwork included particle size analyses, natural moisture contents, Atterberg limits and compaction tests. The results of the investigations are included in KPL report “Data Compilation Report on 1994 Geotechnical and Hydrogeotechnical Investigations” (Ref. No. 1832/2, February 22, 1995).
- The 2010 Site Investigation program included six geotechnical drillholes, all near the crest of the proposed TMF Main Embankment. In situ packer and falling head permeability tests were conducted within the drillholes and piezometers. A test pit investigation was performed around the TMF embankment area to determine the suitability and availability of potential embankment construction materials. Representative test pit samples were collected for laboratory test work. The soil samples were subjected to particle size analysis, natural moisture content, Atterberg limit, specific gravity, flexible wall permeability, triaxial shear and compaction tests. Additionally, AECOM installed mini piezometer MP-02 downstream of the proposed TMF and a water level logger in drillhole 94-352 at the HLF area. The results of the investigations performed by KPL are included in KPL report “2010 Geotechnical Site Investigation Data Report” (Ref. No. VA101-325/3-4, November 2, 2010). The hydrogeological investigations by AECOM are summarized in

the report “Casino Project – Hydrogeological Technical Report – DRAFT” (Ref. No. 60146995-9, March 2011).

- A total of seven KPL geotechnical drillholes were completed in 2011 in the TMF area. Standpipe piezometers were installed in five of these drillholes, and thermistors were installed in two other holes. In situ packer and falling head permeability tests were conducted within the drillholes, as well as Standard Penetration Tests (SPT). More than 100 test pits were excavated for visual inspection and characterization of surficial materials. Laboratory testing on representative samples included particle size analyses, natural moisture content, organic content, Atterberg limit, specific gravity, flexible wall permeability, and compaction tests. Geophysical investigations comprised seismic refraction surveys along six sections, Ground Penetrating Radar (GPR) surveys along five sections, and an EM31 conductivity survey along one section across the TMF area. The results of the investigations are included in KPL report “2011 Geotechnical Site Investigation Data Report - Waste Management Facilities” (Ref. No. VA101-325/8-5, December 2012).
- Three drillholes were drilled in the TMF area during the 2012 site investigations. Thermistors were installed in all three drillholes. The investigation program also included the excavation of test pits for visual inspection and characterization of surficial materials, and to obtain representative test pit samples for laboratory testing. The laboratory testwork included particle size analyses, natural moisture content, organic content, soluble salts, Atterberg limit, flexible wall permeability, and compaction tests. The results of the investigations are included in KPL report “2012 Geotechnical Site Investigation Data Report” (Ref. No. VA101-325/8-14, December 2012).

Geological sections have been prepared with the site investigation results along the embankment crest. Figure 4.1 shows the locations of drillholes, test pits and geophysical survey lines from previous site investigations, and includes the locations of the geological sections. The site investigation plan for the 2012 site investigation is shown on Figure 4.2, and includes the outline of the colluvial apron under the embankment footprint. The geological section along the Main Embankment is shown on Figure 4.3 and the section along the West Saddle Embankment on Figure 4.4.

4.2 EMBANKMENT FOUNDATION

4.2.1 General

This section discusses in detail the geotechnical conditions encountered throughout the embankment area of the TMF in previous site investigation programs. Permafrost considerations and foundation preparation requirements are also discussed.

4.2.2 Geotechnical Conditions

Overburden

The results from site investigations show that overburden is generally shallow along the ridges and upper slopes of Casino Creek valley. The overburden depth in this area varies from 0.5 to 7.5 m, with an average thickness between 2 and 3 m. The overburden consists of residual soil and colluvial veneer, overlain by approximately 0.3 m of silty, mossy topsoil.

Residual soils are mainly present along ridges at higher elevations and along the upper parts of slopes. The residual soil is generally comprised of loose to compact silty sand and gravel with some cobbles and trace clay. The material is derived from in situ weathering of host bedrock. Weathering is dominated by frost action rather than chemical weathering, and as a result little clay is present. The material is locally silt-rich due to windblown loess enrichment. The residual soils coarsen with depth to fractured rock as the influence of frost action decreases.

The ridges and upper slopes are characterized by well drained colluvial and residual sandy soils, supporting stands of tall spruce and poplar. The colluvial veneer is locally overlying residual soils near the top of the slopes. The colluvial soils have been transported down-slope by gravity, causing variations in composition and intermixing of organic material. The colluvium is relatively thin along the upper part of particularly south facing slopes, and generally absent on ridges where residual soils predominate.

The colluvial veneer along the slopes of Casino Creek valley is comprised of a fine to medium grained sand with some silt, supporting coarse gravel and cobble sized broken rock fragments. The thickness and organic content generally increase down-slope. On north-facing slopes, the colluvial veneer is mostly frozen.

The depth to bedrock is considerably larger near the valley bottom, where slopes are gentler. The overburden thickness in the Casino Creek valley bottom varies from approximately 2 to 23 m. This material is classified as colluvial apron, which has a higher fines and organic content than the colluvial veneer. The colluvial apron is mostly frozen, with excess ice and massive ice layers, as recovered in DH11-23A. The colluvial apron is underlain by alluvium close to Casino Creek. The alluvium is coarse grained and comprised of interbedded sands and gravelly sands with cobbles. It is typically overlain by frozen, organic-rich colluvial apron, except near the creek where the alluvium is non-frozen and at surface. The alluvium is generally at surface in tributary valleys, and consists of highly saturated, ice rich, fine grained sands and clayey silts.

It is not always possible to differentiate residual soils from colluvial soils, as colluvial soils are essentially residual soils that have migrated down-slope. The gradations of residual and colluvial soils are often similar and range from sandy silt to gravel with many cobbles, depending on the

degree of weathering with depth, localized windblown silt enrichment and down-slope transportation processes.

Bedrock

Bedrock is considered "weathered" if weathering processes have considerably weakened the rock and penetrative discoloration has occurred. Geotechnical logging of drillholes revealed weathered bedrock (Granodiorite) up to 38 m thick. The average thickness of the weathered bedrock zone is approximately 17.5 m. The average RMR for weathered bedrock is approximately 40, indicating a rock mass quality of POOR to FAIR (Bieniawski, 1989).

Dawson Range Batholith Granodiorite was encountered in all 2011 and 2012 drillholes in the TMF Main Embankment area. The fresh bedrock is strong with an average unconfined compressive strength (UCS) field estimate of 70 MPa. The average RMR for fresh bedrock is approximately 60, and is considered FAIR to GOOD rock mass quality.

Drillholes from the 1994 and 2010 site investigations also indicate that Dawson Range Batholith Granodiorite is the primary lithology in the embankment area. The bedrock underlying the proposed West Embankment and the topographical knob between the West Embankment and the Main Embankment consist of Yukon Metamorphic Complex Gneiss and Quartzite. These lithologies were also encountered in the 2011 test pits near the proposed West Embankment. The 1994 drillholes that were drilled in the TMF impoundment area indicate the presence of Dawson Range Batholith Granodiorite, Yukon Metamorphic Complex Gneiss and Patton Porphyry.

Two narrow zones of low velocity within the competent bedrock were encountered in the seismic refraction data at chainage 40 NE on line G11-08 (on the east abutment of the Main Embankment) and at chainage 600 NE on line G11-06 (near drillhole DH10-03 on the west abutment). These low velocities are consistent with zones of highly fractured and weathered granodiorite, and likely indicate shear or fault zones in the bedrock. Confirmation and detailed mapping of these fault zones will require additional investigations.

4.2.3 Permafrost

Permafrost is discontinuous over the TMF embankment area, and is primarily present at the valley bottom, north-facing slopes and shaded areas. The ridges at higher elevations and upper slopes on the west abutment are southeast-facing, and are generally free of permafrost except for some local shaded areas.

Permafrost is common in the northwest-facing east abutment area, where test pits were terminated at shallow depths in frozen colluvium and residual soils. Permafrost occurs here as thin ice lenses in fine grained soils and as small ice wedges in broken rock.

Permafrost is abundant in the organic, silty colluvial apron of the Casino Creek and tributary valley bottoms. The overburden is generally saturated and frozen in these areas, with high ice contents. Massive ice layers were encountered in the colluvial apron in DH11-23A. The massive ice was also identified in the GPR data in more than half of the survey line length along the valley bottom. The GPR data also indicated ground ice close to tributaries leading to Casino Creek.

Alluvium lies at surface in very close proximity to Casino Creek, where it is not frozen due to the presence of a talik (permanently unfrozen ground). Permafrost is also absent in localized areas

along Casino valley as indicated by the presence of tall grasses and willows, and the absence of thick mosses. These areas are discontinuous and likely result from the historic shifting of the creek channel which acts to maintain a thawed region under the creek.

Thawing of ice-rich soils may lead to excessive settlements, and loss of strength. The ice-rich soils typically exhibit very low strengths when thawed, and flow even under very flat slopes. Two gelifluction lobes that were observed within the colluvial apron in the TMF embankment area are evidence of this potential for instability. Ice-rich soils also have the potential for long term creep displacements.

Disturbance or removal of the vegetative cover may result in the melting of permafrost and the development of unstable conditions. Frozen overburden and bedrock that are underlying part of the tailings impoundment and embankments are expected to thaw over time, as the tailings and water stored in the TMF will act as a heat source. It is therefore recommended that all ice-rich overburden encountered during construction be removed along the entire foundation of the TMF embankments. Ground ice is not expected to be significant in bedrock which will likely provide a stable foundation for the embankments. Preferential seepage paths may develop when ice filled discontinuities thaw. Bedrock may have to be steamed and grouted if this is the case.

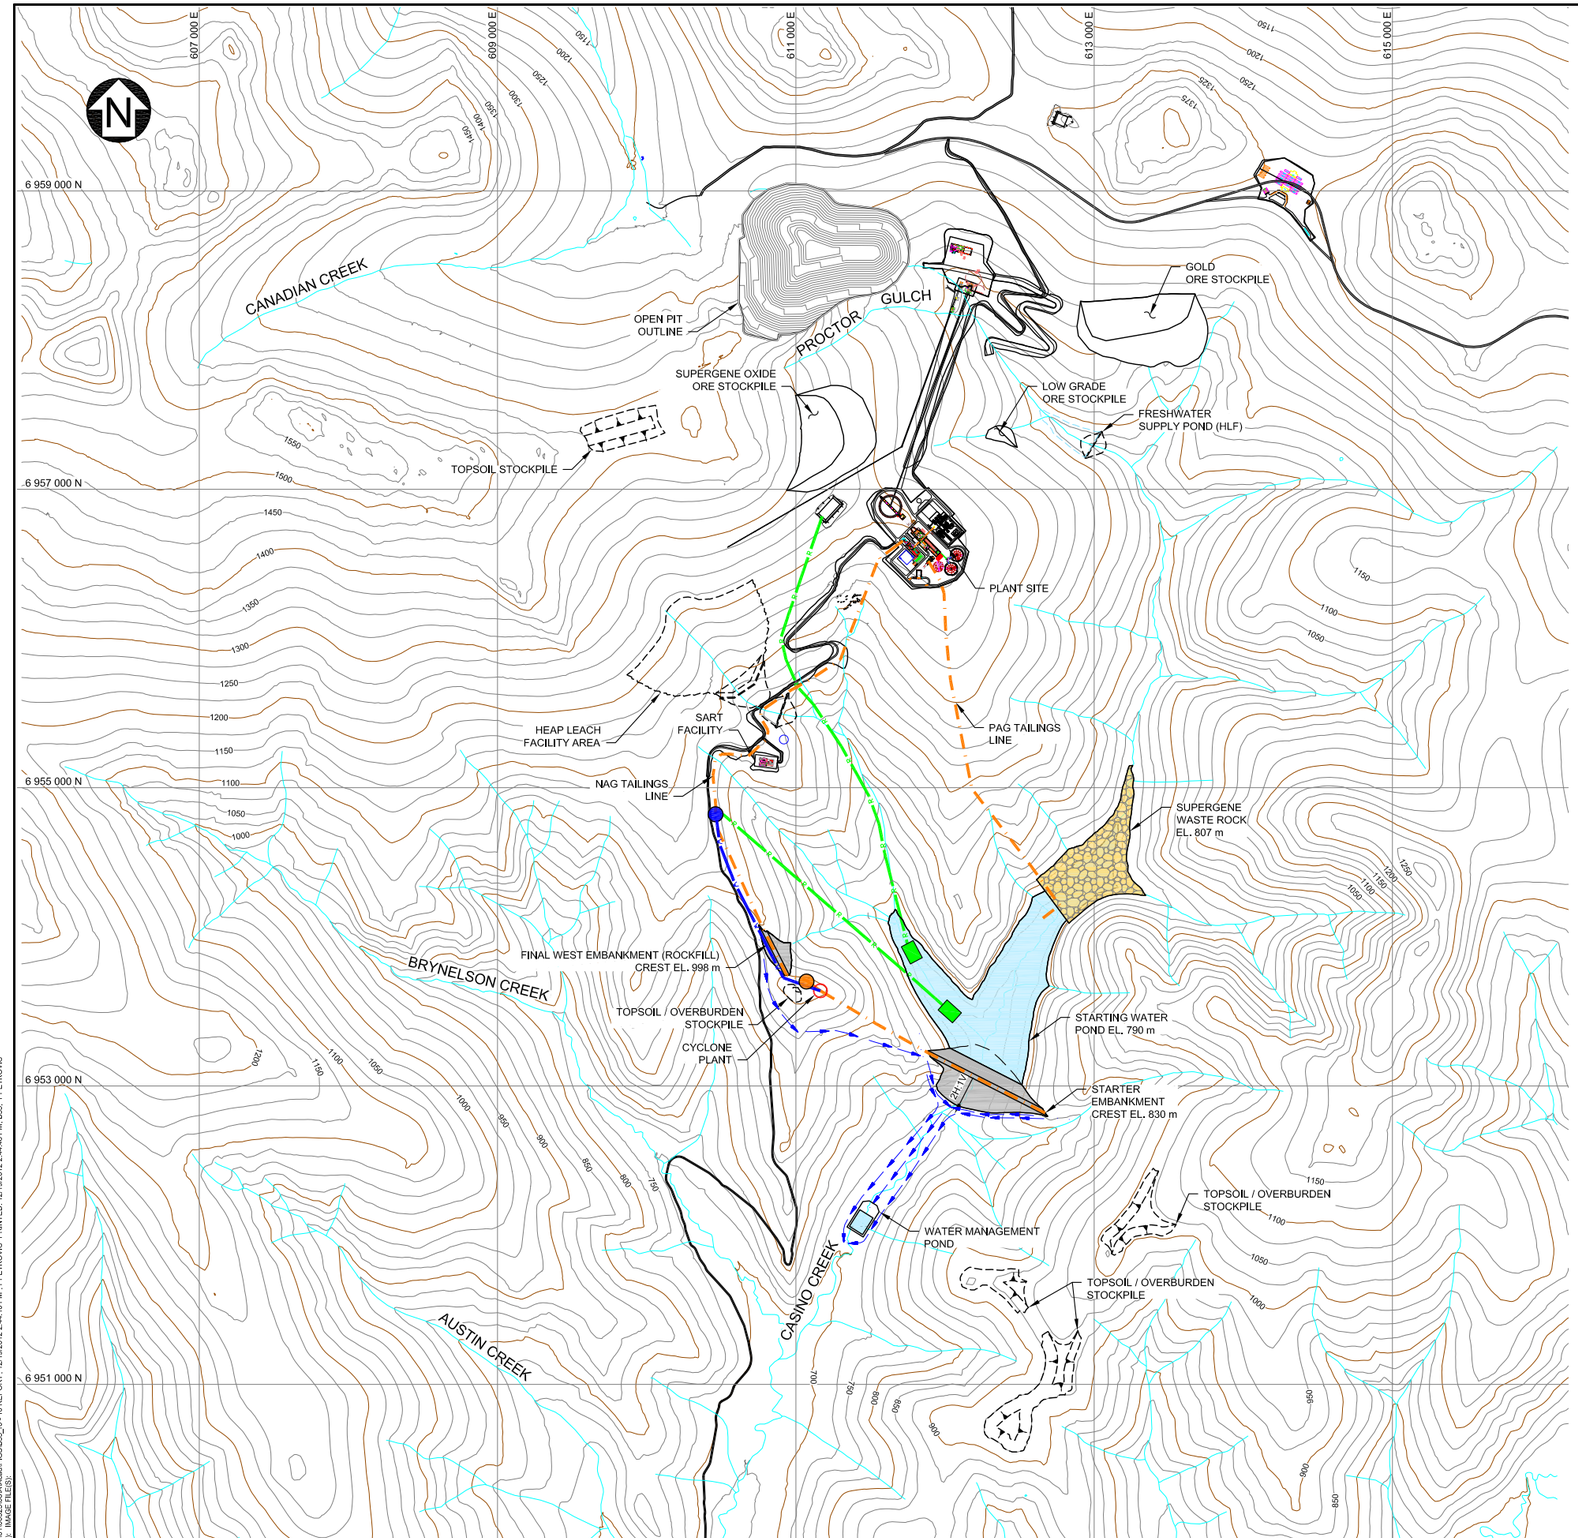
Thermistors were installed during the 2011 and 2012 site investigations to provide a better understanding of the thermal regime in the bedrock. Additional site investigations will be required to confirm the characteristics of the overburden and bedrock, and the extent of permafrost within the TMF embankment area. Thermal modelling may also be required to predict the effect of the proposed TMF on foundation conditions.

4.2.4 Foundation Preparation

Foundation preparation for the TMF embankments will involve the stripping of topsoil and vegetation and the removal of all talus boulders. The topsoil will be stockpiled for reclamation purposes. The underlying frozen soils will be excavated down to a competent, stable bedrock or non-frost susceptible overburden foundation. Ice-rich and frost-susceptible materials will be removed to spoil and are expected to be unsuitable for use as borrow in embankment construction. The quantity of spoil will be significant and may require special measures such as dams or berms to provide containment of the thaw-saturated materials. The ice-rich spoil material will be placed in the TMF impoundment to satisfy this requirement.

The embankment footprint area that covers colluvial apron or other ice-rich overburden will be excavated to competent foundation, absent of frost susceptible soil. The removed material will be replaced with core, filter or shell zone material, depending on the location relative to the embankment. The average thickness of the colluvial apron is expected to be approximately 10 metres based on the findings of the site investigations.

A low permeability cut-off is required beneath the core zone of the Main Embankment and West Saddle Embankment at locations where no colluvial apron or other ice rich soil is present, to provide an effective seepage control barrier. The seepage cut-off trench will extend through the foundation soils and key into competent bedrock, at an average depth of about three meters for both the Main and West Embankment.



5 – TAILINGS MANAGEMENT FACILITY DESIGN

5.1 GENERAL

The principal objectives of the Feasibility design for the Tailings Management Facility (TMF) are to ensure protection of the regional groundwater and surface waters both during operations and in the long-term (post-closure), and to achieve effective reclamation at mine closure. The Feasibility design of the TMF has taken into account the following requirements:

- Permanent, secure and total confinement of all solid waste materials within an engineered disposal facility.
- Control, collection and removal of free draining liquids from the tailings during operations for recycling as process water to the maximum practical extent.
- The use of cyclones to generate clean sand, from the bulk Non-Acid Generating (NAG) tailings, for embankment construction.
- The inclusion of monitoring features for all aspects of the facility to ensure performance goals are achieved and design criteria and assumptions are met.
- Staged development of the facility over the life of the project.

The overall project general arrangement of the TMF is shown on Figure 1.2. General arrangements illustrating the development at the end of pre-production (Year -1), at interim stages (Years 1, 4 and 10), and the final arrangement (Year 22) are shown on Figures 5.1 to 5.5, respectively. Typical sections showing the development of the TMF and WSA during mine operations (Years 1, 4, 10 and 22) are provided on Figure 5.6.

5.2 DESIGN BASIS AND ASSUMPTIONS

Mining of the open pit will yield approximately 965 million tonnes of ore (789 million tonnes of direct feed mill ore, 32 million tonnes of Supergene Oxide ore and 144 million tonnes of Low Grade ore). The mill will operate at a nominal mill throughput of approximately 125,000 tonnes per day of ore. The total estimated tonnage of tailings solids over the 22 year operating life of the mine is approximately 956 million tonnes, assuming an average one percent concentrate recovery during ore processing. Approximately 20% of the mill tailings will consist of PAG material and will be managed separately.

It is assumed that the NAG tailings (80% of the tailings total) will be passed through a cyclone station for approximately nine months of each year (on average) to produce suitable cycloned sand for embankment construction. Cyclone operations will likely not be possible for a portion of the year due to freezing temperatures in the winter. The cyclone sand plant is assumed to have 90% availability over the 9 month period. A required design criterion for the cyclone plant sand product is that the fines content (% passing a #200 sieve) must be 12% or less. The quantity of cyclone sand used in embankment construction is approximately 221 million tonnes. It is estimated that 50% of the NAG tailings can be recovered as cyclone sand when the cyclone station is operating. This amounts to approximately 7.2 to 7.5 million m^3 (12 to 12.5 million tonnes) of cyclone sand fill material produced annually, except for Years 1 and 22. For estimating cyclone sand fill requirements for embankment construction a conservative average in situ dry density of 1.65 tonne/m^3 was assumed for compacted fill. Typical values for compacted cyclone sand fill are in the range of 1.6 to 1.65 tonne/m^3.

A total of 658 million tonnes of mine waste materials will be mined from the open pit. The results of waste characterization studies completed by Others indicate that almost all of the waste rock is potentially reactive material (based on the mining schedule issued by CMC on November 1, 2012). This potentially reactive material made up of PAG and Metal Leaching (ML) waste rock and overburden will be stored subaqueously within the proposed TMF in a Waste Storage Area located in the upper (northern) region of the TMF basin.

The TMF has been sized to provide sufficient capacity to store approximately 956 Mt of tailings (including cyclone sand tailings used as embankment fill) and co-disposal of up to 658 million tonnes of potentially reactive waste rock and overburden materials. Approximately 221 million tonnes of NAG tailings will be used as cyclone sand fill for embankment construction. The remaining 735 million tonnes of tailings (544 million tonnes of bulk NAG tailings and NAG cyclone overflow, plus 191 million tonnes of PAG tailings) will report to the TMF as slurry for permanent storage.

For development of the TMF filling schedule, a tailings dry density of 1.2 t/m³ was assumed during the first three years of production, 1.3 t/m³ in Year 4 and 1.4 t/m³ for Years 5 to 22 (end of operations). These values were based on predicted average dry density values provided by tailings consolidation modelling incorporating the consolidation characteristics of the tailings (see Section 5.9). The average dry density is predicted to increase gradually to approximately 1.5 tonne/m^3 by the end of operations. However, a conservative lower value of 1.4 tonne/m^3 was adopted for determining the capacity requirements of the TMF. The depth-area-capacity relationship and filling schedule for the TMF are shown on Figures 5.7 and 5.8, respectively.

Each stage of TMF development has been sized to store tailings (based on the mine production schedule), together with potentially reactive waste rock from the open pit and a supernatant water

pond. Additional capacity is also provided for storm water storage for the inflow design flood event (see Section 5.3.1) and an allowance of two additional metres of embankment freeboard for wave run-up protection.

A summary of the design basis and operating criteria for the TMF is given in Table 5.1.

TABLE 5.1

CASINO MINING CORPORATION
CASINO COPPER-GOLD PROJECT

FEASIBILITY DESIGN OF THE TAILINGS MANAGEMENT FACILITY
SUMMARY OF DESIGN BASIS AND OPERATING CRITERIA

Print Dec/20/12 16:39:34

ITEM	DESIGN CRITERIA
1.0 GENERAL	
Site Coordinates	613,000 E 6,955,000 N (WGS84/NAD83) Zone 7
Climate	• Estimated Mean Annual Precipitation = 510 mm • Estimated Effective Runoff Coefficient = 0.4 • Estimated Mean Annual Temperature = -2.9 °C at 1200 m elevation. • Average Annual Lake Evaporation = 300 mm
Hazard Classification Consequence Category	• **HIGH**, as defined by the Canadian Dam Association (CDA) "Dam Safety Guidelines" (2007)
Design Flood	• Inflow Design Flood (IDF) up to and including Year 1 = 1,000 years event for 72 hour storm duration. • Inflow Design Flood (IDF) during operations = "one third between 1,000 years and the Probable Maximum Flood (PMF) event for 72 hour storm duration" • Inflow Design Flood (IDF) for closure = Probable Maximum Flood (PMF) event for 24 hour storm duration
Seismic Design[(2)]	• Operating Basis Earthquake (OBE) = 1/500 ◦ Mean maximum firm ground acceleration = 0.08 g, Magnitude = 8.0 • Maximum Design Earthquake (MDE) = 1/2,500 ◦ Mean maximum firm ground acceleration = 0.13 g, Magnitude = 8.0
2.0 PRODUCTION	
Mine Production	• Total Ore Milled = 965.2 Million tonnes (Mt) • Nominal Throughput = Approximately 125,000 tpd • Mine Life = 22 years • Average Stripping Ratio = 0.7 (Waste:Ore) • Concentrate = 1.0 %
Tailings	• Total tailings = 955.6 Mt • Bulk tailings specific gravity = 2.70 t/m^3 • Two tailings streams (55% solids by weight) ◦ 80% Non Acid Generating (NAG) tailings (764.5 Mt) ◦ 20% Potentially Acid Generating (PAG) tailings (191.1 Mt) • Tailings stored in impoundment = 734.3 Mt • NAG tailings specific gravity = 2.7 t/m^3 • PAG tailings specific gravity = 3.0 t/m^3 • 1.2 t/m^3 - in situ average dry density for Years 1, 2 and 3 • 1.3 t/m^3 - in situ average dry density for Year 4 • 1.4 t/m^3 - in situ average dry density for Years 5 to 22
Cyclone Sand	• Cycloning of NAG tailings only. • Approximately 50% of NAG tailings solids assumed to be produced by cyclone plant as sand fill suitable for embankment construction (based on expected tailings particle size distribution). • Cyclone sand production for average 9 months per year. • Cyclone sand production begins at start of Year 1. • Cyclone plant availability is 90%, during 9 months per year. • Cyclone sand material produced = 221.3 Mt • Cyclone sand product has no more than 12% fines (silt/clay fraction) • Compacted cyclone sand average dry density = 1.65 t/m^3 • Cyclone Overflow solids content = 24% • Cyclone Underflow solids content (undiluted) = 74% • Cyclone Underflow solids content (diluted for discharge) = 65%
Mine Waste Rock and Overburden	• Total waste material = 657.9 Mt (stored in TMF impoundment) • Total Hypogene waste material produced = 241.9 Mt • Total Supergene waste material produced (overburden, leach cap, supergene sulfide and supergene oxide) = 414.7 Mt • Total Unclassified waste material produced = 1.3 Mt • Waste material produced from Pre-Production to Year 19 • Subaqueous disposal within TMF • 2.0 t/m^3 - in situ average density (estimated) • Approximately 2 Mt of non reactive waste material available during pre-production.

Knight Piésold CONSULTING

TABLE 5.1

CASINO MINING CORPORATION
CASINO COPPER-GOLD PROJECT

FEASIBILITY DESIGN OF THE TAILINGS MANAGEMENT FACILITY
SUMMARY OF DESIGN BASIS AND OPERATING CRITERIA

3.0 WATER MANAGEMENT	
Site Water Management Priorities During Operations	• Maximum recycle to mill circuit. • Collect and recycle runoff from mine affected areas including open pit, plant site, heap leach facility, ore stockpiles, and tailings management facility. • Minimum TMF pond volume of 15 Mm^3 required (3 months of process water supply). • Project water supply (design by Others)
4.1 TAILINGS FACILITY EMBANKMENTS	
Embankment Crest Width	• 30 m
Design Freeboard	• Sufficient freeboard to accommodate Inflow Design Flood above maximum supernatant pond level at each stage plus 2 m allowance for wave run-up.
Construction Schedule	• Staged centreline construction ◦ Starter Embankment for 1 year of tailings storage and waste rock storage ◦ Final Embankment for 22 years of tailings and reactive waste rock storage
Construction Materials	• Overburden and/or non-reactive waste rock from open pit and borrow sources, and cyclone sand.
Water Management System & Monitoring Measures	• Embankment keyed into native overburden foundation • Seepage collection systems include: ◦ Embankment under-drains; ◦ Surface ditching system; ◦ Water management pond; and ◦ Groundwater monitoring wells (if required).
Stability Analyses	• The minimum acceptable factors of safety based on the CDA "Dam Safety Guidelines" (2007) are as follows: ◦ During construction 1.3 ◦ Long term (post closure) 1.5 ◦ Post-earthquake (full liquefaction of tailings assumed) 1.2
4.2 TAILINGS BASIN	
Geological and Geotechnical Conditions	• Previous data reports
Surface Soil Salvage and Stockpiles	• Topsoil from embankment foundation preparation will be stockpiled for reclamation. • Low grade ore stockpiled during operations ◦ Maximum size = 143.8 Mt • Supergene Oxide ore stockpiled during operations ◦ Maximum size = 32.4 Mt • Gold Ore stockpiled during operations (to Heap Leach Facility) ◦ Maximum size = 39.4 Mt
5.0 CLOSURE REQUIREMENTS	
General	• Saturated storage of potentially reactive mine waste rock and overburden. • Concurrent reclamation of disturbed areas conducted where possible. • TMF reclamation to include for revegetation of exposed embankments. • Remove all pipeworks, pump stations and surface structures. • Decommission and reclaim all non-essential access roads and diversion ditches. • Stockpiles topsoil and overburden required for reclamation of the tailings beach and downstream slope of the TMF embankment. • Closure spillway to pass 24 hr PMF event.

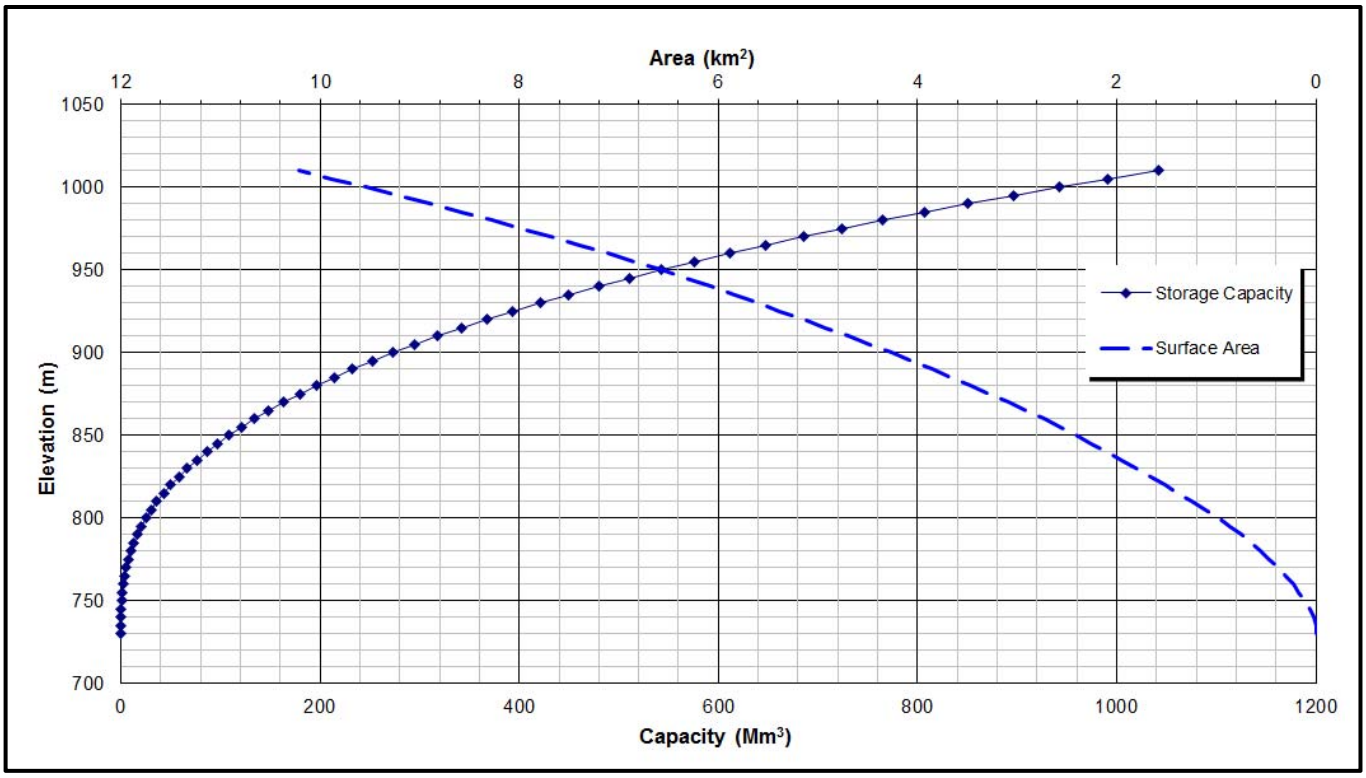

Figure 5.7 Tailings Management Facility – Depth-Area-Capacity Curves

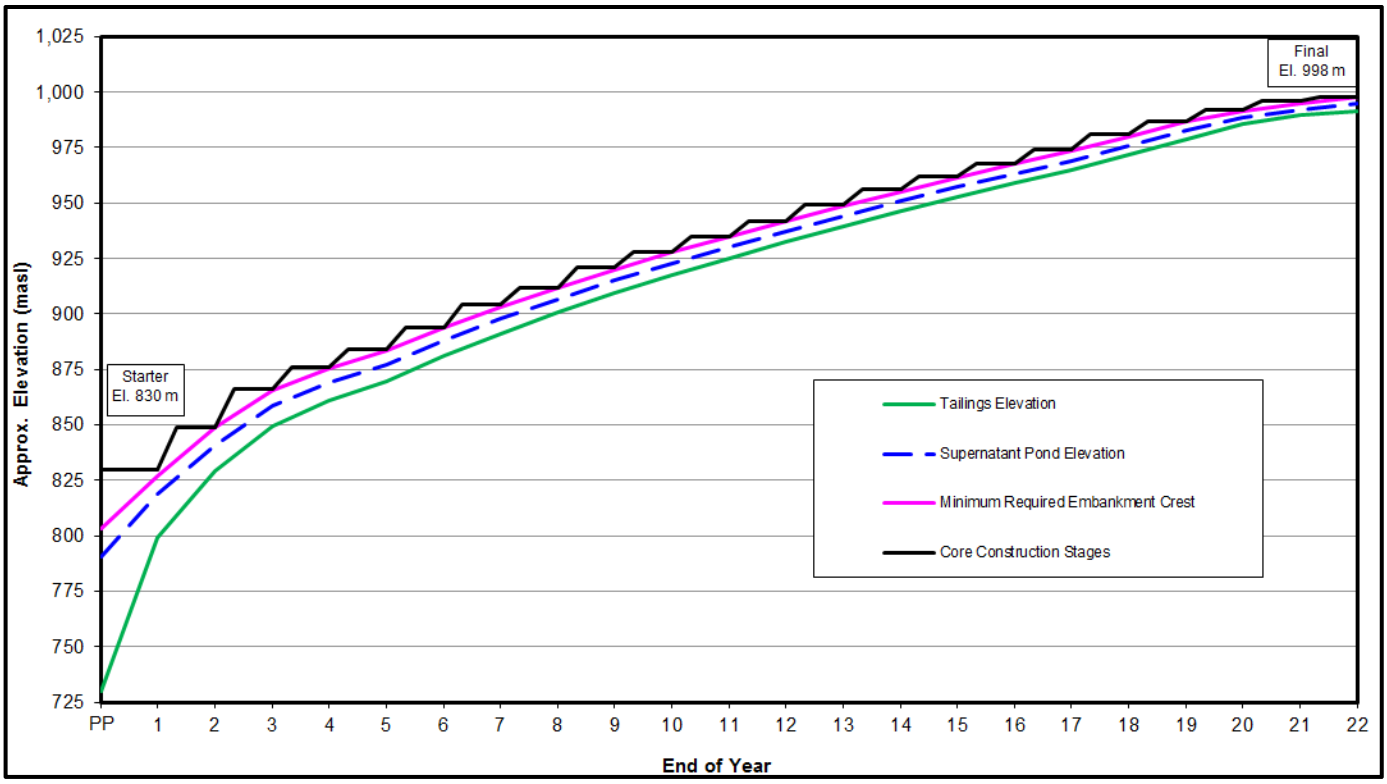

Figure 5.8 Tailings Management Facility – Production and Filling Schedule Curves

NOTES:

1. The filling schedule accounts for 734.3 Mt of tailings and 657.9 Mt of waste rock.
2. The average dry density of the tailings is assumed to be 1.2 t/m^3 in the first three years of production, 1.3 t/m^3 in Year 4 and 1.4 t/m^3 from Year 5 to end of mine life.
3. Compacted cycloned sand dry density assumed to be 1.65 t/m^3.
3. Nominal ore production is approximately 125,000 tpd.
4. Minimum required embankment crest includes freeboard to accommodate Inflow Design Flood (IDF) and two metres for wave run-up protection.
5. Tailings and waste rock modelled as a horizontal surface.
6. Waste rock average dry density assumed to be 2.0 t/m^3.
7. Core zone construction period assumed to be 4 months per year.

5.3 DAM CLASSIFICATION

A preliminary dam classification has been carried out to enable appropriate design earthquake and flood events to be determined for the TMF. The selection of appropriate design earthquake and flood events has been based on classification of the tailings dam using criteria provided by the Canadian Dam Association's (CDA) "Dam Safety Guidelines" (2007), shown in Table 5.2.

Table 5.2 Dam Classification

Dam Class	Population at Risk[1]	Incremental Losses		
		Loss of Life[2]	Environmental and Cultural Values	Infrastructure and Economics
Low	None	Zero	Minimal short-term loss No long-term loss	Low economic losses; area contains limited infrastructure or services
Significant	Temporary only	Unspecified	No significant loss or deterioration of fish or wildlife habitat Loss of marginal habitat only Restoration or compensation in kind highly possible	Losses to recreational facilities; seasonal workplaces, and infrequently used for transportation services
High	Permanent	10 or fewer	Significant loss or deterioration of *important* fish or wildlife habitat Restoration or compensation in kind highly possible	High economic losses affecting infrastructure, public transportation, and commercial facilities
Very High	Permanent	100 or fewer	Significant loss or deterioration of *critical* fish or wildlife habitat Restoration or compensation in kind possible but impractical	Very high economic losses affecting important infrastructure or services (e.g., highway, industrial facility, storage facilities for dangerous substances)
Extreme	Permanent	More than 100	Major loss of critical fish or wildlife habitat Restoration or compensation in kind impossible	Extreme losses affecting critical infrastructure or services (e.g., hospital, major industrial complex, major storage facilities for dangerous substances)

NOTES:

1. Definitions for population risk:
   None – There is no identifiable population at risk, so there is no possibility of loss of life other than through unforeseeable misadventure.
   Temporary – People are only temporarily in the dam-breach inundation zone (e.g. seasonal cottage use, passing through on transportation routes, participating in recreational activities).
   Permanent – The population at risk is ordinarily located in the dam-breach inundation zone (e.g. as permanent residents); three consequence classes (high, very high, extreme) are proposed to allow for more detailed estimates of potential loss of life (to assist in decision-making if the appropriate analysis is carried out).
2. Implications for loss of life:
   Unspecified – The appropriate level of safety required at a dam where people are temporarily at risk depends on the number of people, the exposure time, the nature of their activity, and other conditions. A higher class could be appropriate, depending on the requirements. However, the design flood requirement, for example, might not be higher if the temporary population is not likely to be present during the flood season.

Classification of a tailings dam is carried out by considering the potential incremental consequences of a failure. The incremental consequences of failure are defined by the CDA as *"the total damage from an event with dam failure minus the damage that would have resulted from the same event had*

the dam not failed." The consequences of failure considered include loss of life, environmental and cultural impacts and losses, and economic loss.

There is no permanent population at risk downstream of the TMF. The potential for loss of life from a dam failure is likely minor but cannot be discounted, particularly during operations when there will be work activities in the waste storage area and intermittently in areas downstream of the TMF. The economic consequences (including clean-up, repair and remedial works) would also be high.

The environmental impact on downstream watercourses has the potential to be significant if a failure resulted in the release of tailings and/or process water into Casino Creek. An uncontrolled release into Casino Creek may flow into Dip Creek and potentially to the Yukon River by way of the Klotassin, Donjek and White Rivers. Fish species present in Casino Creek include Arctic Grayling, Burbot, and Slimy Sculpin. In addition to these species, Round Whitefish have been observed, and Chinook Salmon are likely present in Dip Creek. The fish species present are all currently listed as 'Unthreatened' under the Species at Risk Act and are widespread in the region, as is rearing habitat. Based on the methodology presented by Eagen and Greenaway (2010, 2011) and the results of environmental baseline studies, the environmental consequences of a dam failure would be defined as HIGH, based on the classification criteria provided by the CDA Guidelines.

Consequently, a HIGH dam classification has been assigned to the TMF. This dam classification should be reviewed for future design studies and revised if appropriate.

5.3.1 Design Flood Event

Selection of an appropriate Inflow Design Flood (IDF) is required to carry out a safety assessment of the TMF and to determine storm storage requirements. The size of the IDF is dependent on the dam classification, as shown in Table 5.3. Based on the HIGH dam classification assigned to the TMF, an appropriate IDF is an event equal to "one third between 1,000 years and the Probable Maximum Flood (PMF)" event. For closure of the TMF the IDF has been defined as the PMF.

During operations there is no spillway to pass flood waters from the TMF. Therefore, the IDF has been defined using 72-hour 1:1,000 and PMF events. However, for the short-term Stage I TMF (pre-production and Year 1 of operations) the 72-hour 1:1,000 year event was adopted. This reduced IDF has been implemented in the TMF design so that it remains sufficiently large, but not so conservative that it would result in a Stage I embankment that is excessively oversized. A spillway will be constructed at the end of operations for closure water management. Accordingly, the IDF for closure has been defined as the PMF associated with the 24-hour maximum precipitation event.

The Hershfield (1977) method was used to estimate the probable maximum precipitation (PMP) and 1:1,000 year return period rainfall event values based on the 24-hour maximum precipitation data available in the Rainfall Frequency Atlas for Canada (RFAC) (Hogg and Carr, 1985). The 72-hour PMP and 1:1,000 year rainfall depths were estimated by scaling the 24-hour values by ratios of 1.6 and 1.3, respectively, based on measured depth-duration values developed by the National Oceanic and Atmospheric Administration (NOAA, 1999). The resulting 24-hour and 72-hour rainfall depths for the project area are summarized below:

- 24-hour 1:1,000 year rainfall depth = 66 mm
- 72-hour 1:1,000 year rainfall depth = 85 mm
- 24-hour PMP depth = 159 mm, and

- 72- hour PMP depth = 255 mm.

Potential snowmelt during an extreme rainfall event has to be taken into consideration when estimating the resulting flood event. The snowpack present during the IDF was assumed to be equivalent to a 1:100 year snowpack of 256 mm, based on fitting the annual average maximum snowpack (140 mm) and standard deviation (36.9 mm) to a Gumbel distribution. The derivation of the annual average snowpack and 24-hour rainfall depths are presented in KPL report "Updated Hydrometeorology Report" (Ref. No. VA101-325/8-11, July 9, 2012).

The potential snowmelt that could occur in conjunction with the 24-hour 1:1,000 year rainfall or PMP event was then estimated by applying a formula that considered how much snow would melt given a maximum daily temperature of 15 degrees Celsius and a wind speed of 8 m/s (Coulson, 1991). The highest potential snowmelt for the 24-hour rainfall events, assuming a clear catchment with no trees, is:

- 24-hour PMP snowmelt = 156 mm, and
- 24-hour 1:1,000 year snowmelt = 138 mm.

The additional snowmelt that would occur over the subsequent 24 hour periods for a 72-hour event was estimated based on the proportion of rain that is assumed to fall in the second and third 24-hour periods of a 72-hour event. For the 72-hour 1:1,000 year rainfall and PMP events, the total potential snowmelt was predicted to be 393 mm and 425 mm, respectively. However, the snowmelt is limited by the assumed available snowpack of 256 mm (equivalent to the 1:100 year snowpack); accordingly it was assumed that all of the available snowpack would melt during the IDF event. Furthermore, the IDF volume is typically applied to the maximum TMF pond volume in a given year, which generally occurs during the freshet months when the snowpack is melting. Since the maximum TMF pond volume already accounts for snowmelt of the average annual maximum snowpack (140 mm), this depth was then subtracted from estimated potential snowmelt of 256 mm, resulting in an estimated 116 mm of snowmelt contributing to the IDF storage volume requirements.

The resulting total potential runoff depth from a combined return period rainfall event and snowmelt for the 24-hour and 72-hour events are:

- 72-hour 1:1,000 year total runoff depth = 201 mm
- 24-hour PMP total runoff depth = 175 mm, and
- 72-hour PMP total runoff depth = 371 mm.

The total runoff depths were applied to the inflow catchment area of the TMF of 35 km^2. This results in an IDF flood volume of 7.0 million m^3 for the 72-hour 1,000 year event used for Stage I (Pre-production and Year 1), 9.0 million m^3 for the 72-hour one third value between the 1,000 year and PMF event used for the remainder of TMF operations, and 6.1 million m^3 for the 24-hour PMF event used for the TMF at closure, once the spillway is operational.

The design of the TMF embankments includes storm storage volume requirements for the IDF above the operating supernatant pond elevation, plus an additional two metres for wave run-up protection.

5.3.2 Design Earthquakes

Consistent with the current design philosophy for geotechnical structures such as dams, two levels of design earthquake have been considered: the Operating Basis Earthquake (OBE) for normal operations, and the Maximum Design Earthquake (MDE) for extreme conditions (ICOLD, 1995).

Values of Peak Ground Acceleration (PGA) and design earthquake magnitude have been determined for both the OBE and MDE.

The OBE is usually selected from the results of a probabilistic hazard evaluation. The hazard level selected for the OBE is often chosen as the earthquake with a 10% probability of exceedance in 50 years (with a corresponding return period of about 500 years). For design of the TMF, the OBE has been taken as the 1 in 500 year return period event. The probability of exceedance for this event is only 4% for a 22 year operating period. The corresponding median PGA for this event is 0.07g. However, for geotechnical structures it is recommended that the mean average PGA value be used for design (CDA Dam Safety Guidelines, 2007). The mean PGA is likely to be approximately 15 to 20 percent greater than the median value, giving an estimated value of 0.08g. A design earthquake magnitude of 8.0 has been selected for the OBE, based on a review of regional tectonics and historical seismicity. The TMF would be expected to function in a normal manner after the OBE.

An appropriate MDE for embankment design has been selected, based on the HIGH dam classification defined for the TMF and the criteria for design earthquakes provided by the Canadian Dam Association's (CDA) "Dam Safety Guidelines" (2007), and presented in Table 5.3. The CDA Guidelines require that a HIGH dam classification be designed for a probabilistically derived event (defined as the Earthquake Design Ground Motion) having an annual exceedance probability (AEP) of 1/2,500. Consequently, the MDE selected for the TMF is the 1 in 2,500 year earthquake. The median PGA is 0.11g for the 1 in 2,500 year earthquake. The corresponding mean average PGA used for design is estimated to be 0.13g. A design earthquake magnitude of 8.0 has been selected for the MDE, based on a review of regional tectonics and historical seismicity. Limited deformation of the tailings embankment is acceptable under seismic loading from the MDE, provided that the overall stability and integrity of the TMF is maintained and that there is no release of stored tailings or water (ICOLD, 1995).

To demonstrate the robustness of the embankment design to seismic loading the 1 in 10,000 year earthquake has also been considered. The mean PGA for the 1 in 10,000 year event is 0.22g.

Table 5.3 Suggested Design Flood and Earthquake Levels

Dam Class	Annual Exceedance Probability (AEP)	
	Inflow Design Flood (IDF)[1]	Earthquake Design Ground Motion (EDGM)[3]
Low	1/100	1/500
Significant	Between 1/100 and 1/1,000[4]	1/1,000
High	1/3 between 1/1,000 and Probable Maximum Flood[5]	1/2,500[6]
Very High	2/3 between 1/1,000 and Probable Maximum Flood[5]	1/5,000[6]
Extreme	Probable Maximum Flood (PMF)[6]	1/10,000

NOTES:

1. As defined in Table 5.2 – Dam Classification.
2. Extrapolation of flood statistics beyond 1/1,000 year flood (10^{-3} AEP) is discouraged.
3. AEP levels for EDGM are to be used for mean rather than median estimates for the hazard.
4. Selected on the basis of incremental flood analysis, exposure, and consequence of failure.
5. PMF has no associated AEP. The flood defined as "1/3 between 1/1,000 year and PMF" or "2/3 between 1/1,000 year and PMF" has no defined AEP.
6. The EDGM value must be adjusted to demonstrate conformance to societal norms of acceptable risk. Justification can be provided with the help of failure modes analysis focused on the particular modes that can contribute to failure initiated by a seismic event. If justification cannot be provided, the EDGM should be 1/10,000.

5.4 LAYOUT AND OPERATING STRATEGY

5.4.1 General

Tailings and potentially reactive waste rock and overburden will be deposited in an impoundment located in the Casino Creek valley southeast from the open pit. Specific overall features of the TMF are illustrated on Figures 5.1 to 5.6 and are listed below:

- Two earth-rockfill-cyclone sand, zoned embankments, referred to as the Main Embankment and West Saddle Embankment
- Cyclone sand plant
- Tailings distribution pipelines – bulk NAG tailings, PAG tailings, cyclone sand, cyclone overflow (fines)
- Two separate reclaim water systems – mill and cyclone plant
- Waste Storage Area – for potentially reactive waste rock and overburden
- Supernatant (surface water) pond, and
- Water Management system – seepage collection ditches and pond, and seepage recycle system.

5.4.2 Confining Embankments

The Main Embankment will be developed in stages throughout the life of the TMF using a combination of suitable non-reactive earth and rock fill borrow materials and cyclone sand.

The Main Embankment will be expanded in stages across the Casino Creek valley. The Stage IA (Starter) embankment is designed to store runoff as a source for mill start-up water and accommodate tailings and potentially reactive waste rock and overburden production for approximately one year of initial operations. Cyclone sand production in Year 1 of operations will be used to extend the downstream shell of the Main Embankment (Stage IB), allowing the dam crest

and core zone to be raised after about 1 year. Ongoing raises will comprise centreline raises with a vertical low permeability core zone and adjacent downstream filter zones. Cyclone sand will be produced from bulk NAG tailings at the Cyclone Plant and discharged into the cyclone sand shell zones (upstream and downstream of the core zone) where it will be spread in cells and compacted using bulldozers. Bulk tailings that bypass the Cyclone Plant and cyclone overflow (fines) produced during cycloning operations will be discharged into the impoundment.

The alignment of the Main Embankment has been revised since previous studies to take advantage of topographic features (based on the latest site topographic data). The alignment has been revised to minimize the size of the Stage I embankment, reduce seepage flows from the TMF and minimize the volume of colluvial apron material requiring excavation in the embankment footprint.

The West Saddle Embankment will be constructed at the south-western corner of the TMF (as shown on Figures 5.1 to 5.5), and is required at the start of operations to provide a pipeline corridor at a suitable grade for tailings delivery to the cyclone sand plant and the TMF. The embankment will be developed in pre-production years using suitable non-reactive earth and rockfill from local borrow sources.

5.4.3 Water Management

The Stage IA (Starter) Main Embankment will be constructed in pre-production years, with construction scheduled to provide enough time to impound sufficient surface water runoff for mill start-up. It is assumed that a start-up water pond of approximately 15 million m^3 is required, corresponding to about 3 months of mill water requirements. Mill process water for ongoing operations and water for cyclone plant operations will be reclaimed from the TMF supernatant pond.

A monthly operational mine site water balance, incorporating stochastic analysis for climate conditions, indicates that the TMF will be in a water deficit condition for the majority of the mine operating life. To satisfy mill requirements a make-up water supply system will be required, and has been design by Others.

Design provisions to minimize seepage losses from the TMF include the installation of a seepage cut-off beneath the Main Embankment and West Saddle Embankment, a low permeability blanket beneath the Stage I embankment, a seepage interception and recovery system and contingency measures for groundwater recovery and recycle.

Seepage water from the TMF will be collected by a Water Management System, which consists of an under-drain system and a surface ditch system which both discharge into a water management pond located downstream of the Main Embankment. Seepage collected in the pond will be pumped back into the TMF. The Water Management System has been designed to accommodate seepage through the TMF embankments, water recovered from cyclone sand embankment construction and surface runoff.

The water balance model developed for the TMF indicates that there will be a water surplus at closure. A spillway will be provided at closure to facilitate control and discharge of excess water accumulation within the TMF and to provide safe passage of storm water volumes from the TMF.

5.4.4 Tailings Distribution

Three distinct tailings streams will discharge into the TMF:

- PAG tailings – 12 months of the year,
- Bulk NAG tailings – approximately three months of the year plus any periods when the cyclone plant is not operating, and
- Cyclone overflow (fine fraction of bulk NAG tailings) – approximately nine months of the year.

It is assumed that approximately 80% of the tailings will be geochemically innocuous NAG material, following the removal of the pyrite component. The discharge of bulk NAG tailings and cyclone overflow will be from valved offtakes located along the Main Embankment and from the West Saddle Embankment. The coarser fraction of the discharged tailings will settle rapidly, tending to accumulate closer to the discharge points and forming a beach slope. Finer tailings particles will travel farther and settle at a flatter slope beneath the supernatant pond. Deposition will be developed and managed, with the intent to maximize storage efficiency in the TMF and to maintain the deeper, cleaner locations of the supernatant pond in the vicinity of the reclaim barges. Schematic development plans for tailings discharge are included on Figures 5.2 to 5.5, for Years 1, 4, 10 and 22 of operations respectively.

Approximately 20% of the total tailings will be PAG tailings. The PAG tailings deposit will be developed in a separate central region of the TMF by discharging the tailings from the north-western side of the TMF, close to the WSA. The discharge point will be relocated frequently throughout operations to manage the deposition of the PAG tailings and to accommodate raises of the WSA. Deposition in this area will keep the PAG tailings between the WSA and NAG tailings deposit, remote from the confining embankments. This will minimise seepage from the PAG tailings and ensure that they remain in a subaqueous state.

Unsuitable colluvial apron material excavated from the footprint of the Main Embankment will be placed upstream within the TMF basin. This material can be placed in a location to provide a simple barrier between the initial zones of PAG and NAG tailings deposition. This will ensure PAG tailings deposited in the initial months of TMF operations will not flow towards the Main Embankment prior to establishment of a NAG tailings beach area.

A flat surface profile for deposited tailings solids has been assumed for capacity considerations. Detailed design studies should evaluate the potential impact of sloping sub-aerial and sub-aqueous beach areas. Consideration of tailings beach configurations may result in modifications to staged embankment heights and the tailings deposition strategy.

5.4.5 Waste Storage Area

Potentially reactive waste rock and overburden will be hauled to the TMF for co-disposal with tailings and submergence by tailings and the supernatant pond. The Waste Storage Area (WSA) will be developed in the northern section of the TMF impoundment area, upstream of the PAG tailings deposit. Development of the waste storage area has been designed in step with the mine production schedule presented in Table 5.4. It will be developed at the same or similar rate of rise as the tailings but will be several meters higher to provide a dry, stable placement surface. The ongoing maximum elevation of the WSA will be maintained at an elevation above the flood level of the supernatant pond (defined by the IDF event).

Waste rock delivery to the WSA is complete in Year 19. By the end of operations the WSA will be submerged below tailings (from the processing of Low Grade ore) and supernatant pond water,

ensuring long-term subaqueous containment for closure. The operational water balance developed for the TMF (see Section 6.0 and Appendix D) indicates that the WSA will be completely covered by the supernatant pond in Year 20, approximately one year following the end of waste rock deposition. Based on the present mine production schedule and development strategy, approximately three years of tailings deposition will occur after final placement of potentially reactive waste rock. This will result in a thin layer of tailings over the top of the WSA (approximately 3 metres thick). The depth of the final supernatant pond overlying the WSA and tailings is estimated to be approximately 4 metres deep.

Schematic development of the WSA during TMF operations is included on Figures 5.1 to 5.5, for Years -1 (pre-production), 1, 4, 10 and 22 of operations respectively.

In the case of a premature mine closure, a portion of the WSA may need to be excavated to an elevation below the natural pond elevation in the TMF. This would be required to ensure potentially reactive waste materials will be maintained in a saturated state with a sufficient minimum pond cover (2 metres).

Additional information on the development and operation of the WSA and a stability assessment are provided in the KPL report ““Waste Storage Area and Stockpiles Feasibility Design” (Ref. No. VA101-325/8-12, December, 2012).

5.5 CYCLONE SAND DESIGN CONSIDERATIONS

Numerous large cyclone sand embankments are utilized at mining operations in many regions of the world, including Anglo's Los Bronces mine, Southern Peru Copper's Quebrada Honda mine, and the Los Quillayes tailings impoundment operated by Minera Los Pelambres in Chile. Several large cyclone sand dams have been constructed to dam heights in the range of approximately 150 m to 200+ m and are often located in seismically active areas. The Los Quillayes tailings dam was constructed with cyclone sand to a maximum height of 198 m. The Mauro cyclone sand dam at the Los Pelambres mine was constructed to a height of 248 m in a region of high seismicity.

The particle size distribution of the Casino mill tailings is a key consideration for determining the suitability of the bulk NAG tailings to provide cyclone sand of suitable quality and in sufficient quantity. Coarser tailings are preferred, as a higher sand fraction or 'split' can be realized. Clean sand with sufficiently low fines content (% passing a #200 sieve) will be required for placement, in order to facilitate rapid drainage and subsequent compaction. The anticipated particle size distribution of the Casino tailings (see Section 2.2 and Figure 2.1) is well within the range of tailings particle size distributions that have been successfully cycloned at other tailings operations.

Experience from existing cyclone sand dams indicates that the sand fill should have an in situ permeability equal to or greater than 2×10^{-4} cm/s (Barrera, Valenzuela and Campana, 2011). This will ensure the rapid drainage of construction water (following cyclone sand placement), seepage water and direct precipitation. It is typical to present specifications limiting the fines content of the cyclone sand. For copper tailings a fines content in the range of 15 and 20 percent typically provides sufficient permeability for sand drainage. This criterion continues to be valid provided the sand grain size is not significantly changed by particle crushing, due to very large confining pressures imposed by dams of large height. Chilean experience for large copper cyclone sand tailings dams indicates that large confining pressures do not significantly affect the sand grain size. However, this may not be valid for tailings with a different mineralogy. Therefore, for large cyclone sand dams it is prudent to conduct permeability tests at large confining pressures to simulate the behavior of the material.

Permeability testing has been conducted on a laboratory generated sample of cyclone underflow (cyclone sand), as discussed in Section 2.2. The results of the permeability tests did not indicate any evidence of particle crushing and measured permeability values were greater than 2×10^{-4} cm/s, even at very high confining pressures.

From consideration of the large height and size of the Main Embankment it is recommended that the fines content of the cyclone sand be less than 15%, in order to maximize fill placement rates and to ensure adequate compaction, strength and drainage. A maximum fines content of 12% has been adopted for the Feasibility design. There may be an opportunity to increase the fines content a few percent to allow increased sand quantities, based on actual performance during operations and material characteristics (permeability and strength) of the cyclone sand. The potential to provide more sand fill material will allow increased operating flexibility related to construction activities.

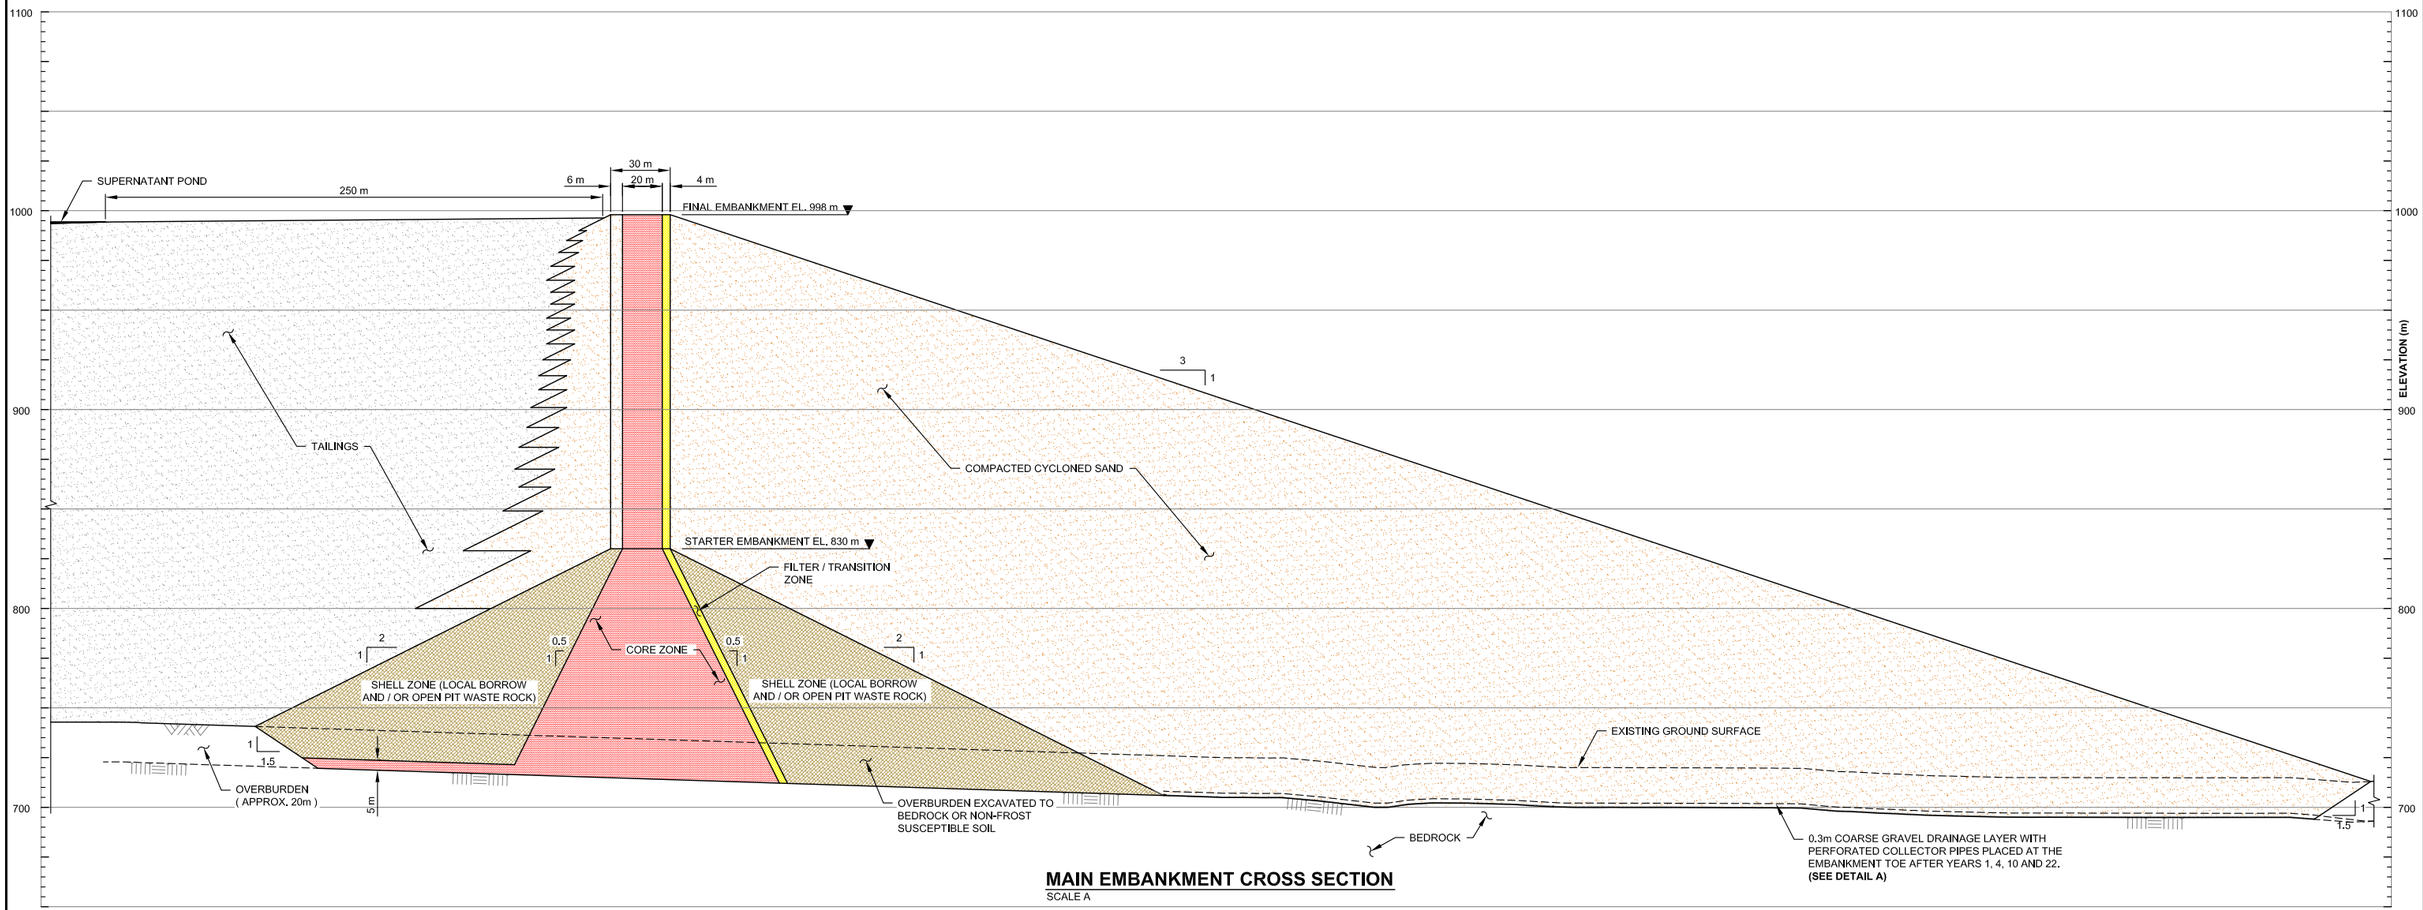
The large embankment height associated with the Main Embankment limits the sand placement options and likely necessitates construction using sand cells, where additional vibratory compaction will be required to ensure a sufficiently dense, high strength material. It is important to provide a cyclone sand fill material that is sufficiently dense to provide adequate strength for embankment stability (with consideration of the high confining stresses) and to ensure the material is not

susceptible to cyclic softening or flow liquefaction under seismic loading. A requirement of the cyclone sand placement will be to achieve a dry density of 95% Standard Proctor compaction.

It is recommended that future studies include examination of the influence of cyclone underflow solids content on the compaction characteristics of in situ cyclone sand fill. This will enable determination of the optimum solids content of the cyclone underflow to achieve good compaction of the sand fill.

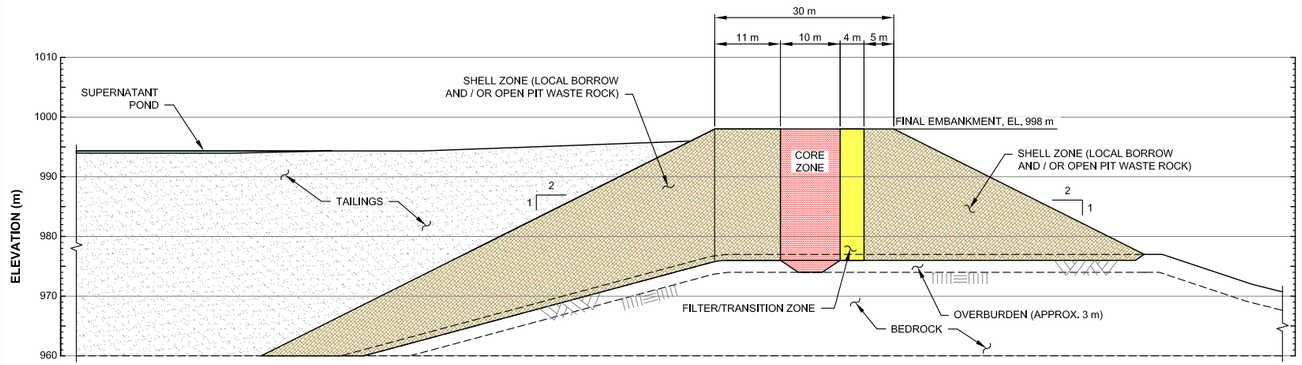
There is ample precedent in North America for tailings dam construction using cyclone sand, but this technique has not been used for large tailings dams in the Yukon. There is potential for cold winter conditions to reduce the construction period for cyclone sand placement, partly due to the potential for freezing and ice entrainment in the sand fill and partly because of snow drifting into sand cells. Examples of mine operations in British Columbia, where cyclone sand is used to construct the tailings dams, include the Kemess, Gibraltar and Highland Valley mines. To accommodate cold operating conditions in the winter months, the construction season at Gibraltar is typically from March to October. Longer cycloning operations for sand fill construction have apparently been possible at the Kemess mine, with operations possible at temperatures as low as -25°C. Dam construction typically runs 6 to 10 months of the year at Highland Valley. During the remainder of the year, tailings are used to construct an upstream beach between the dam and the tailings supernatant pond. For this Feasibility design the cyclone plant and cyclone sand placement activities are assumed to be operational for an average 9 months of the year (with a 90% sand plant availability to account for maintenance and other downtime).

5.6 EMBANKMENT CONSTRUCTION



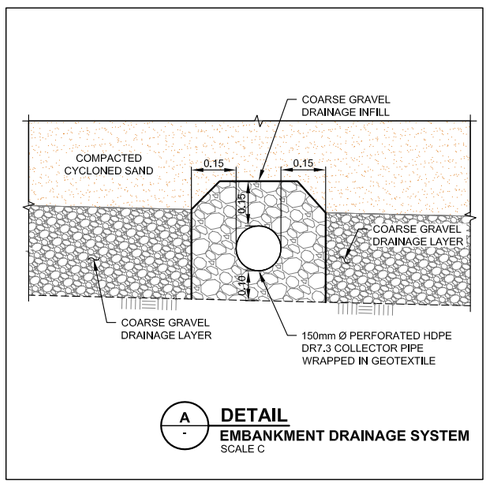
The embankments will be constructed as water-retaining zoned structures with a low permeability core zone and appropriate filter and transition zones to prevent downstream migration of fines. The core zone will include a seepage cut-off keyed into competent rock in the foundation.

5.6.1 Main Embankment



The Main Embankment required for the TMF has been designed to be constructed in several stages over the operating life of the mine. It will consist of an initial starter (Stage IA) embankment, an extension of the downstream shell during the first year of operations (Stage IB), and staged raises thereafter over the life of the project using the centreline method of construction. The filling schedule for the TMF is included on Figure 5.8. On-going raises of the embankment crest and core zone to support the staged expansion will be carried out annually, during the summer months of operations.

The Stage I embankment will comprise an approximately 105 metres high dam (crest to downstream toe) constructed to El. 830 m. A cofferdam will be required in order to drain and prepare the foundation prior to Stage I embankment construction in the pre-production years. The cofferdam will be constructed upstream of the Main Embankment footprint to capture upstream surface water flows and route it around the construction work area and back into Casino Creek in a surface pipeline. The embankment shell zones for the Stage IA (Starter) dam will be constructed with random fill comprising suitable rockfill from local borrow sources, supplemented by available non-reactive waste rock. Approximately 2 to 3 million tonnes of non-reactive waste rock (leach cap) material is available from initial open pit stripping operations.



The crest of the final embankment will reach an elevation of 998 m, providing storage capacity for 22 years of tailings and potentially reactive waste rock and overburden production. A typical section through the final Main Embankment is shown on Figure 5.9. The maximum height of the final embankment (crest to downstream toe) will be approximately 286 metres. Construction of each of the embankment stages will be scheduled to correspond with material availability for cyclone sand (produced from NAG tailings), local borrow sources and the tailings impoundment filling rate.

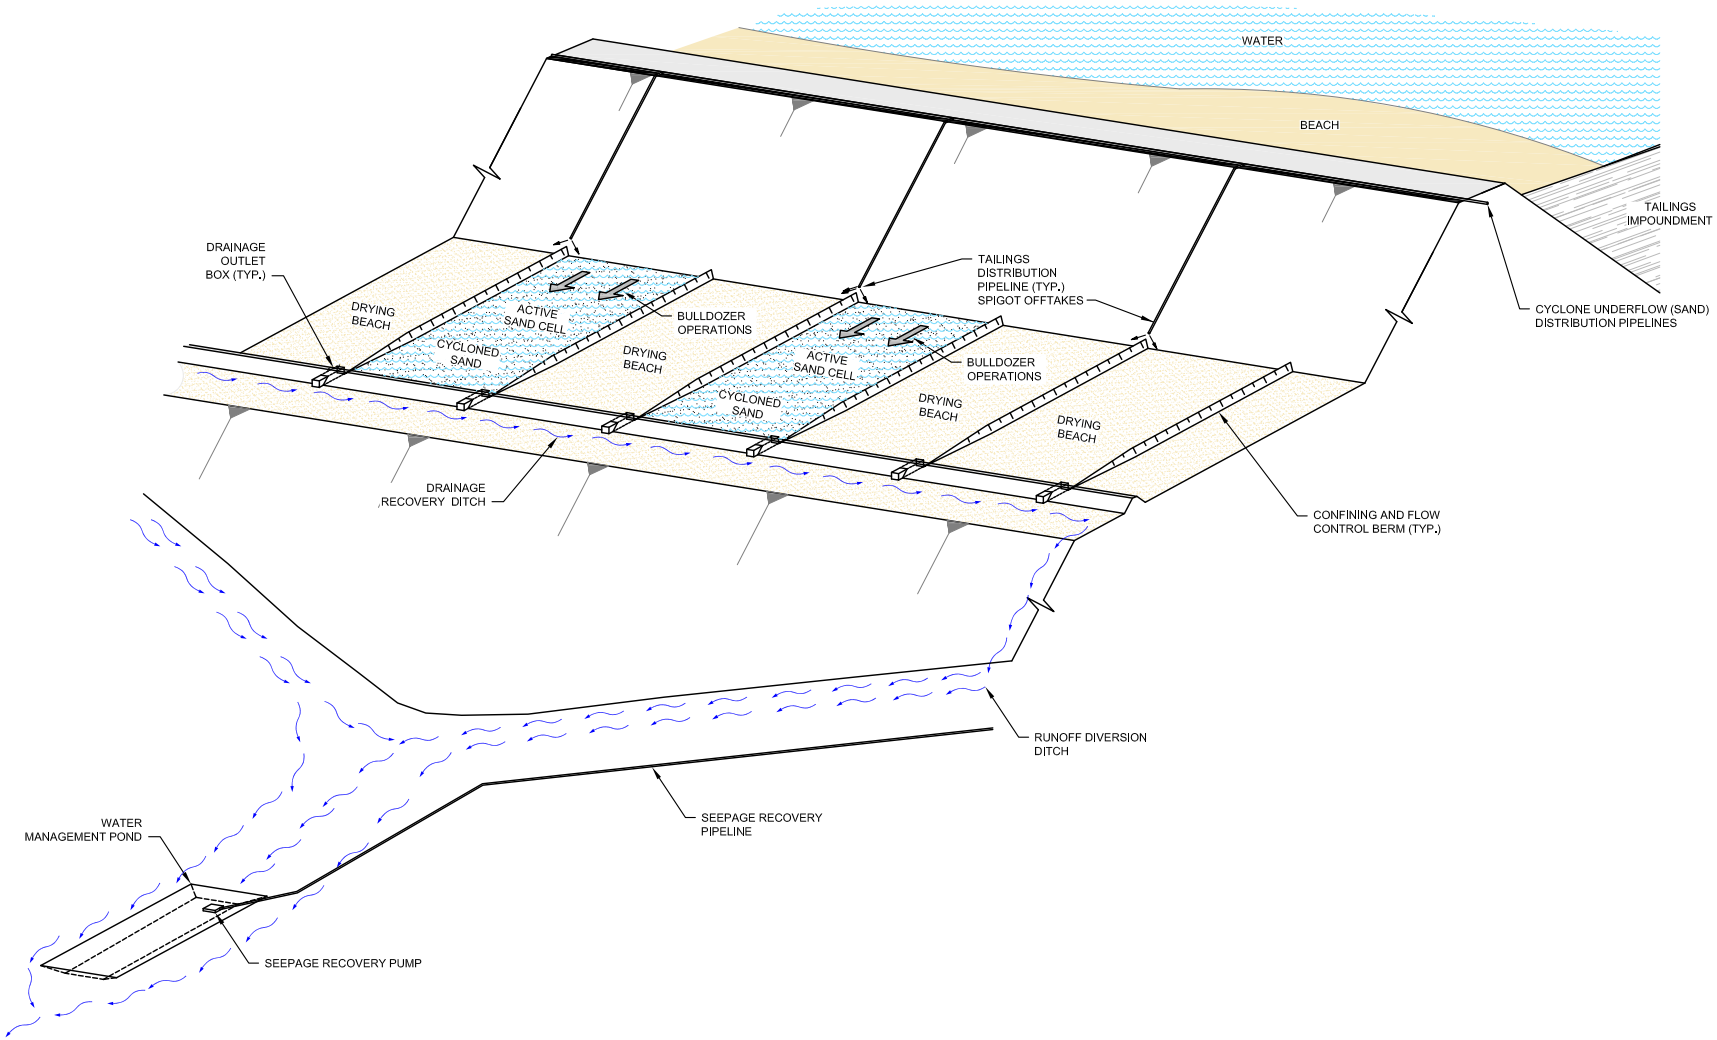
XREF FILES: IMAGE FILES):

For each stage of embankment construction the foundations will require clearing and stripping preparation for fill placement. An average stripping depth of one meter has been assumed within the embankment footprint. For the embankment footprint area that covers colluvial apron or other ice-rich overburden, all unsuitable material will be excavated to competent foundation, absent of frost susceptible soil. The average thickness of the colluvial apron is expected to be approximately 10 metres based on the findings of site investigations. The removed material will be replaced with core, filter or shell zone material, depending on the location relative to the embankment. A 5 metre thick low permeability upstream blanket is also included to reduce seepage from the TMF, as shown on Figure 5.9.

A low permeability cut-off is required beneath the core zone of the Main Embankment and West Saddle Embankment at locations where no colluvial apron or other ice rich soil is present, to provide an effective seepage control barrier. The seepage cut-off trench will extend through the foundation soils and key into competent bedrock, at an average depth of about three meters for both the Main and West Embankment.



Ongoing embankment stages will comprise centreline raises with a vertical low permeability core zone (20 metres wide) and adjacent downstream filter and transition zones. The development of sufficient tailings beach area will be required between the supernatant pond and the embankment to provide a stable upstream construction surface for the centreline embankment raises. The upstream and downstream shell zones will be constructed from compacted cyclone sand.

The embankment filter zone will prevent piping of the core zone material and will reduce pore pressures within the embankment. The transition zone will prevent the migration of fines from the dam core zone and filter zone into the pervious downstream shell zone (rockfill and cyclone sand). The filter and transitions zones will consist of suitable crushed and screened rock or local borrow materials.

Cyclone sand will be produced from bulk NAG tailings at the Cyclone Plant and discharged into the cyclone sand shell zones where it will be spread in cells and compacted using bulldozers. Cyclone sand slurry will be discharged into each construction cell to depths of 0.5 m to 2.0 m, and will be heavily track packed by dozers. Water expelled from the sand by the track packing will drain from the cells for collection in the downgradient water management pond at the toe of the embankment. The draining and track packing will provide compacted zones of cyclone sand that meet 95% Standard Proctor compaction density specification. The in situ density, moisture content, and fines content will be obtained from within 48 hours of sand placement. The embankment design relies on maintaining a free-draining downstream sand embankment for static and seismic stability.

Cell construction using narrow sand deposition panels will be required for raising the downstream shell of the Main Embankment. The panel method involves the construction and maintenance of long, narrow cells (typically approximately 100 m by 20 m) along the face of the embankment. A schematic of the panel construction sequence is shown on Figure 5.10.

REF NO. 10

FIGURE 5.10

REV 0

Cyclone sand production commencing in Year 1 of operations will be used to extend the downstream shell of the Main Embankment (Stage IB), allowing the dam crest and core zone to be raised after about one year. The availability of cyclone sand needs to be matched with the filling schedule for the TMF, to ensure adequate embankment heights are provided well in advance of the rising tailings surface. The Stage IA (Starter) embankment must be high enough to allow sufficient quantities of sand to be produced and placed to facilitate subsequent embankment raises.

It is estimated that approximately 7.2 to 7.5 million m^3 (12 to 12.5 million tonnes at an in situ dry density of 1.65 tonne/m^3) of cyclone sand fill material can be produced annually, except for Year 1, using the production values presented in Table 5.5. Approximately 5.6 million m^3 of cyclone sand can be produced in Year 1 as the mill ramps up to full production. This volume is less than the fill volume required for embankment construction in Year 1. The annual shortfall of embankment fill material will need to be made up with suitable fill material from a local borrow source or quarry. It is estimated that approximately 1.2 million m^3 of rockfill will be required to supplement the shortfall in cyclone sand production in Year 1. This rockfill can be preferentially placed in the bottom area of the downstream shell to further promote drainage of the cyclone sand. Additional filter and transition layers will be required between the cyclone sand and rockfill to prevent the migration of sands into the rockfill and to provide drainage for the transport of water released from the sand.

The current material balance indicates that sufficient cyclone sand material is available to meet embankment fill requirements for Years 2 to 22. Table 5.5 provides a detailed summary of embankment fill quantities for each of the zones by year.

The materials balance for construction requirements is sensitive to the factors assumed for cyclone sand production (including cold weather operations). Therefore, additional local borrow may be required for embankment construction in the event that cyclone sand production does not meet targets in any given year during operations.

The Stage IA Main Embankment requires approximately 9.3 million m³ of total fill material. The total fill requirement for the final Main Embankment (including the seepage cut-off) is 152 million m³.

The sequencing of sand cell construction in relation to the requirements for embankment crest raising will need to be carefully evaluated for detailed design studies.

Placement of additional rockfill against the downstream shell of the Main Embankment can be used to provide additional structural support, if required. However, stability assessment (see Section 5.10) indicates that the embankment satisfies operating and long-term (post-closure) stability requirements without downstream buttressing.

5.6.2 West Saddle Embankment

The West Saddle Embankment will comprise an earth-rockfill dam, constructed from local borrow materials. This embankment is not required for tailings and supernatant pond confinement until about Year 18 of operations. However, the embankment will be constructed for the start of operations to provide a pipeline corridor at a suitable grade for tailings delivery to the cyclone sand plant and the TMF. The embankment is required to a maximum height of approximately 21 m at El. 998 m.

Information collected during the site investigation programs in the West Embankment area indicated that the depth to bedrock throughout the area is likely to be less than three meters and the shallow overburden will likely comprise residual and colluvial soils.

The embankment includes a vertical low permeability core zone (10 metres wide) and adjacent downstream filter and transition zones. A cut-off trench will likely be required beneath the core of the dam to provide an effective seepage control barrier within the underlying permeable foundation soils. The seepage cut-off trench will extend through the permeable soils and key into competent rock, at an average depth of about three meters.

A typical section through the West Saddle Embankment is included on Figure 5.9.

The total fill required for construction of the West Saddle Embankment is approximately 0.36 million m^3.

5.6.3 Borrow Materials

Local borrow sources are required to provide the following materials for embankment construction:

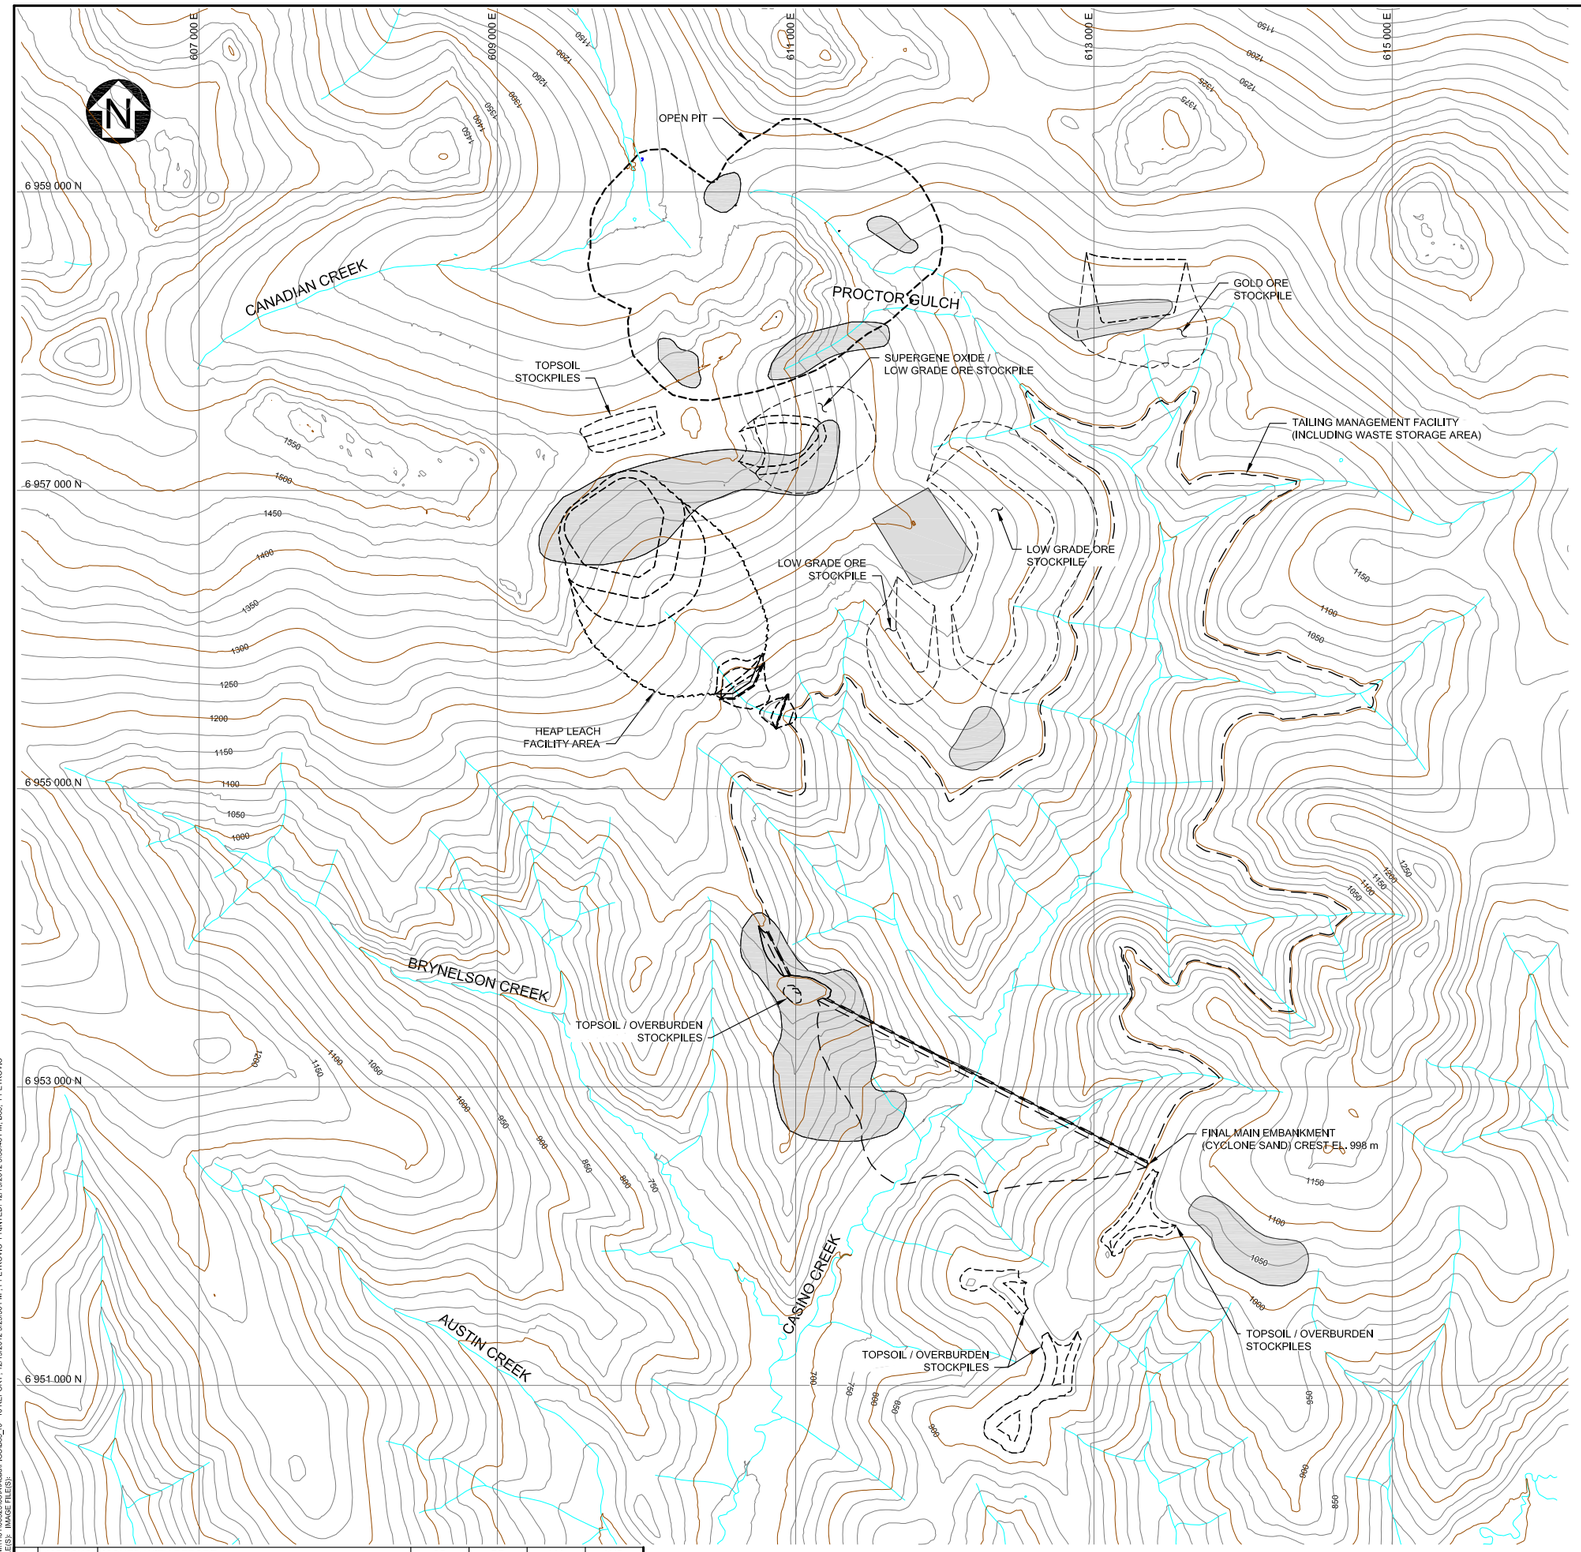
- Core zone – locally sourced low permeability overburden.
- Filter and transition zones – required gradation depends on the gradation of the core zone material. Local borrow is likely the main source for this material.
- Rockfill Shell Zones – partly sourced from non-reactive open pit waste, the remainder will be sourced from local borrow (quarries).

All embankment construction materials will need to be non-reactive. Rockfill is expected to be sourced relatively easily on site, including use of excavated material from preparation of the plant site foundations. The borrow sources for the filter and transition zones have not been identified at this stage as this depends on the gradation of the core zone material. An effort has been made to identify potential borrow sources for low permeability core zone material and the upstream blanket.

- Laboratory permeability test results on compacted residual and colluvial soil from 1993, 2010, 2011 and 2012 test pit samples indicate that permeabilities range from approximately 1×10^{-5} cm/s to 1×10^{-9} cm/s, depending on material gradation, moisture content, compactive effort and confining pressure. The more recent testing carried out in 2011 and 2012 indicates that permeability values in the range of approximately 1×10^{-6} cm/s to 1×10^{-5} cm/s are typically achievable for the finer grained soils (with more than 20% fines) present at the project site. The laboratory testing also suggests that the permeability will reduce at higher confining stresses, with a permeability decrease from 1×10^{-5} cm/s to 1×10^{-6} cm/s reported for an increase in confining stress from 200 kPa to 600 kPa. Confining stresses will exceed 600 kPa in the majority of the embankment core zone for the TMF Main Embankment (from about 30 metres below the dam crest). Therefore, it is expected that a permeability of about 1×10^{-6} cm/s, and

perhaps less, will be achieved in the majority of the core material. Additional testing is required to confirm the suitability of core materials.

The criteria that have been used to determine suitability of the material for use as low permeability core zone borrow material are:



- ≥ 20% fines. Material with ≥ 20% fines is expected to have a sufficiently low permeability for use as core zone material, based on available laboratory testing and experience with other projects.
- No organic content. Where the presence of organic material is indicated by laboratory testing or geotechnical logging, the material is considered unsuitable for use as core material. Organic material can oxidize over time, potentially causing settlements and leading to preferential seepage paths.
- Non frost susceptible. Ice rich soils are considered unsuitable as these are difficult to excavate when frozen. Thawing of ice rich soils will cause excess water to be released, which causes the soil to flow and makes it very difficult to handle and compact.

The residual soil and colluvial veneer materials identified at the site are potentially suitable core zone borrow materials. The colluvial apron in Casino Valley is typically organic-rich, saturated and frozen, and is not suitable for use as core zone construction material.

Residual soils are locally silt rich due to windblown loess enrichment. Residual soils at the site are mainly present along ridges at higher elevations and along the upper parts of some slopes. In the open pit and Gold Ore stockpile areas, residual soils are locally thick and clay-rich due to the presence of alteration zones and preferential weathering along shear and fault structures.

Colluvial veneer is found along valley slopes. The nature of colluvium, i.e. material that has been transported down slopes, causes local variations in the composition. The downslope migration also causes organic material to be included in the deposit at some locations. The organic content generally increases down-slope. On north facing slopes, the colluvial veneer is mostly frozen and not considered to be a suitable borrow source.

Several potential core zone borrow source areas have been identified at the project site and are shown on Figure 5.11.

FIGURE 5.11

SAVED: M:\101\00325\08\A\Acad\FIGS\BS5_rp - 10 REPORT, 12/19/2012 2:29:50 PM, PPETKOVIC PRINTED: 12/19/2012 3:30:48 PM, BS5, PPETKOVIC
XREF FILES: IMAGE FILES:

The main challenges to be considered in the sourcing of suitable core zone borrow materials are as follows:

- Colluvial veneer has a variable composition and has the potential of intermixed organics.
- The layer of suitable material is typically only between 1 and 2 meter thick, underlying an unsuitable (topsoil) layer of 0.3 m or more. This may lead to large spoil piles and disturbance areas.
- Topsoil overlying potential borrow sources should be carefully stripped in order to avoid contamination of the borrow materials with organic material.
- Permafrost and frost susceptible materials should be avoided.

Specific materials will be required at specific times from the borrow areas. For example, large quantities of free draining, possibly processed material will be required to construct the downstream filter and transition zones. This material will be prepared in advance and stockpiled near the work area. Alluvial soil deposits in the area may provide suitable free draining material for construction of the embankment filter and transition zones. Additional site investigations and laboratory testing will be required for future design studies to confirm the suitability of local borrow sources and provide sufficient material characterization to enable fill placement specifications to be defined (including lift thickness, particle size distribution and compaction requirements).

These investigations will also be required to confirm the extent and availability of sufficient suitable borrow materials for embankment core zone construction throughout the life of the facility. Future studies may also need to consider alternative core zone materials and options, if additional characterisation and delineation of borrow sources indicates a potential shortfall of suitable low permeability material.

Future studies should also confirm specific borrow sources for filter zone and quarried rockfill materials required for embankment construction.

5.7 TMF OPERATIONS UNDER FREEZING CONDITIONS

Numerous mines have operated or currently operate tailings facilities under severe winter (freezing) conditions. In many instances a frozen layer forms over the TMF supernatant pond, which is maintained and operated under the ice.

Design and operating considerations, developed from mine operating experiences under freezing conditions, which may be considered for winter operations at Casino, include the following:

- Shape the tailings impoundment surface (during summer tailings deposition) to provide a winter pond that can be maintained "localized" in one or specific areas of the facility.
- Concentrate winter tailings discharge from a single, relocateable, point. This will tend to channelize the flow and move it through and under the ice cover where the solid/liquid separation occurs. This prevents sheet tailings flow over the ice.
- Commence winter tailings discharge from a more remote location and retreat the deposition point closer to the source/pond/recovery point, in steps, as winter progresses.
- Store sufficient water in the tailings facility prior to freezing, to provide for all anticipated ice and pore water losses during winter (i.e. develop and maintain a good water/ice balance).
- The potential for dusting can be exacerbated during cold winter conditions as a 'freeze drying' process tends to destroy capillary tensions in partially saturated sand materials, making it more

susceptible to dusting. Appropriate provisions will be required to prevent dusting of cyclone sand fill. This may mean that the cyclone sand will need capping with erosion resistant fill material, particularly during the cold winter months, when it may be impractical to continue with active sand placement.

5.8 WATER MANAGEMENT SYSTEM

The Water Management System for the TMF has been designed to accommodate seepage through the TMF embankment, water recovered from the cyclone sand embankment construction and surface runoff from the 1 in 10 year 24-hour design storm event.

Seepage from the TMF will result from infiltration of ponded water directly through the embankment fill and the natural ground and from expulsion of pore water as the tailings mass consolidates. The seepage will largely be controlled by the low permeability core zone of the embankments, the seepage cut-off provided beneath the core of the dams, the upstream low permeability blanket provided for the Main Embankment and the tailings deposit.

Cyclone sand embankment construction will be undertaken for approximately nine months of the year and it is expected that there will be significant water recovery as a by-product of the construction process. The majority of water recovered will be collected as surface runoff, with a portion also collected as infiltration and drainage through the cyclone sands placed as embankment fill.

The 1 in 10 year 24-hour design storm event is anticipated to generate periodic high flow surface runoff events.

The Water Management System consists of an under-drain system and a surface ditch system which both discharge into a water management pond located downstream of the Main Embankment. The under drain system, which is installed beneath the Main Embankment, incorporates a 0.3 metre thick gravel drainage blanket with perforated collection pipes to convey collected water away from under the embankment (see Figure 5.9). The layout of the collection pipes has been designed with pipes installed at four phases during development, Year 1, Year 4, Year 10 and Year 22. The collection pipes will be spaced approximately every 230 metres as the footprint of the embankment increases with staged expansions. As the embankment height increases, it is expected that the perforated pipes will deform and likely collapse due to the embankment loading, however the majority of infiltration drainage from the cyclone sand operation is anticipated to be complete at this stage and any remaining drainage will still infiltrate through the gravel drainage blanket.

The surface ditch system has been configured as a dual-ditch design (two parallel ditches, one ‘clean’ and one ‘dirty’), with the upslope ditch (constructed along the toe of the embankment) collecting surface runoff from the embankment (generated by either precipitation or cyclone sand placement), and the downslope ditch diverting ‘clean’ surface runoff. The dual-ditch system was adopted to reduce the quantity of water that requires storage in the water management pond and pumping back to the TMF. Lining and scour protection of the ditching will be required to prevent erosion of the ditch channels. Similar to the underdrain system, the ditch system has been designed to be constructed with four development phases to accommodate staged embankment expansions. The ditch alignments through the four development phases are included on Figures 5.2 to 5.5.

The water management pond (see Figures 5.1 to 5.5) has been designed as a dry-pond and is sized to manage the 1 in 10 year 24-hour storm event. Any storm events greater than the 1 in 10 year will discharge through the pond discharge channel. A pump station to return the water stored in the pond back to the TMF will be controlled through level controls. Supplemental booster pump stations will be required as the TMF embankment height increases.

Groundwater will be monitored in wells situated downstream of the Main Embankment and West Saddle Embankment. If deemed necessary, groundwater recovery wells may be installed in the same locations, with water being pumped back to the TMF.

On-going water quality monitoring will be required to assess the effectiveness of the Water Management System. In the unlikely event that the Water Management System is found to not effectively collect and recover seepage, it will be necessary to install additional seepage control provisions.

5.9 TAILINGS CONSOLIDATION ANALYSES

On-going consolidation of the tailings deposit is an important consideration for the design and construction of the TMF during operations and after closure. Consolidation occurs continuously within the tailings deposit during deposition and will continue after completion of operations until all excess pore pressures have dissipated. Expulsion of pore fluids during consolidation produces settlement of the tailings surface and a corresponding increase in the average density of the deposit.

KPL have developed a one-dimensional finite difference computer model which predicts the magnitude and rate of tailings consolidation and the corresponding average density of the deposit. This model incorporates the consolidation characteristics of the tailings, the tailings deposition rate and large strain consolidation theory.

Analyses were performed to predict average tailings dry densities and consolidation seepage rates during operations and after closure of the TMF. The effect of co-disposal of waste rock within the TMF on the tailings rate of rise was accounted for in the analysis.

An average tailings dry density of approximately 1.2 tonne/m^3 was predicted during the initial three years of operations, increasing to 1.3 tonne/m^3 in Year 4. Thereafter, the average dry density is predicted to increase gradually to approximately 1.5 tonne/m^3 by the end of operations when tailings deposition ceases. The density of the deposit will increase once tailings deposition ceases at closure and self-weight consolidation continues, assisted by surface desiccation due to evaporation from exposed tailings beach areas. Following the end of operations the average dry density of the tailings deposit is predicted to increase to approximately 1.55 to 1.6 tonne/m^3 once fully consolidated conditions are achieved.

The large majority of consolidation seepage from the tailings deposit (typically about 80% to 90%) flows upwards and towards the supernatant pond. Most of the remaining consolidation seepage will likely flow toward the more free-draining tailings beach areas, confining embankments and Waste Storage Area. The low quantity of downward consolidation seepage is due to the increasing drainage path length during operations (between freshly deposited tailings and the base of the TMF) and the low permeability of deeper, more consolidated, tailings at the base of the facility.

The tailings will remain partially consolidated during operations and for a period of time after closure until all excess pore water pressures have dissipated. The actual time taken for complete consolidation will be dependent on the in situ consolidation characteristics of the tailings material.

The methodology, assumptions and results of the tailings consolidation analysis are included in the KPL document "Report on Revised Tailings Management Facility Seepage Assessment" (Ref. No. VA101-325/8-13, December, 2012).

5.10 SEEPAGE ANALYSES

Steady-state seepage analyses for the TMF were carried out to estimate the amount of seepage through the embankments and foundation materials. The analyses were completed using the finite element computer program SEEP/W. Seepage rates through the Main Embankment, West Saddle Embankment and tailings basin were examined.

The seepage rate through foundation materials and embankment fill zones is influenced by the following factors:

- Permeability of the embankment zones
- Permeability of the foundation materials
- The thickness and permeability of the tailings stored within the TMF
- Distribution of waste rock within the TMF
- Seepage gradients in the embankment and foundation zones, and
- The seepage area available (increases with time during operations).

The seepage flow rate will vary over the life of the TMF as it gradually fills with tailings, potentially reactive mine waste rock and supernatant water. During operation of the TMF the tailings deposit will increase in thickness and decrease in permeability due to on-going consolidation. The seepage analyses have been performed to predict seepage flows from the TMF for the embankments at various stages throughout operations (Year 1, Year 10 and Final).

The seepage analyses have been based on typical cross-sections through the TMF, as shown on Figures 5.6 and 5.9. Foundation conditions incorporated into the seepage analyses were based on information provided by the geotechnical site investigation programs (described in Section 4.0).

Material permeabilities were determined for each of the embankment fill zones, tailings deposit and foundation materials. All foundation permeability values are based on the results of in situ testing performed during the 1994, 2010 and 2011 geotechnical site investigation programs. The permeability of core zone and cyclone sand fill zones in the Main Embankment were based on the results of laboratory testing. Permeability values adopted for the tailings deposit were estimated using the results of laboratory testing and consolidation modelling.

Flow rates for seepage components passing through the TMF embankments and passing directly into the TMF foundation (from the tailings and Waste Storage Area) were estimated. The predicted total seepage rate from the TMF is approximately 5 l/sec for Year 1 (Stage I Embankment), increasing to about 20 l/sec by Year 10 and approximately 40 l/sec for the final embankment arrangement (El. 998 m). Approximately 70% of the total seepage is estimated to flow directly into original ground and about 30% through the Main Embankment and West Saddle Embankment. For the final TMF arrangement approximately 97 % of the total seepage through the embankments is estimated to flow through the Main Embankment and 3 % through the West Saddle Embankment.

Long-term (post-closure) seepage rates from the TMF are expected to be similar or less than the predicted values for the final embankment arrangement at the end of operations, but will be dependent on the reclamation and closure plan developed for the facility.

Details of the material permeabilities, modelling assumptions and results of the steady-state seepage analyses provided by the SEEP/W models are presented in the KPL report "Revised Tailings Management Facility Seepage Assessment" (Ref. No. VA101-325/8-13, December, 2012).

Water quality studies and environmental effects assessment are on-going and take into account the quantity and quality of seepage from the TMF, including any seepage that will not be recovered by the Water Management System. The findings of this assessment will dictate if additional seepage collection and recovery systems will be required, such as groundwater recovery wells.

5.11 EMBANKMENT STABILITY ANALYSES

Stability analyses were carried out to investigate the stability of the Main Embankment under both static and seismic loading conditions. These comprised checking the stability of the embankment arrangement for each of the following cases:

- Static conditions during operations and post-closure
- Earthquake loading from the Operating Basis Earthquake (OBE) and the Maximum Design Earthquake (MDE), and
- Post-earthquake conditions using residual (post-liquefaction) tailings strengths.

The stability analyses were based on a typical cross-section through the Main Embankment for the final TMF with a supernatant pond elevation of 995 m and an embankment crest elevation of 998 m.

The stability analyses were carried out using the limit equilibrium computer program SLOPE/W. In this program a systematic search is performed to obtain the minimum factor of safety from a number of potential slip surfaces. Factors of safety have been computed using the Morgenstern-Price method.

In accordance with international recommendations (ICOLD, 1995) and standard industry practice, the minimum acceptable factor of safety for the tailings embankment under static conditions is 1.3 for short-term operating conditions and 1.5 for long-term (post-closure) of the TMF. A factor of safety of less than 1.0 is acceptable under earthquake loading conditions provided that calculated embankment deformations resulting from seismic loading are not significant and that the post earthquake stability of the embankment maintains a factor of safety greater than 1.2, implying there is no flow slide potential. For the post earthquake case the tailings deposit was conservatively assumed to be fully liquefied, and an appropriate low residual strength was applied.

The results of the stability analyses satisfy the minimum requirements for factors of safety and indicate that the proposed design is adequate to maintain both short term (operational) and long term (post-closure) stability. The seismic analyses indicate that any embankment deformations during earthquake loading from the OBE or MDE would be minor, and would not have any significant impact on embankment freeboard or result in any loss of embankment integrity. The results also indicate that the embankment is not dependent on tailings strength to maintain overall stability and integrity.

Details of the embankment stability analyses, including the adopted material strength parameters are presented in Appendix C.

6 – SITE WATER MANAGEMENT

6.1 GENERAL

The main objective of the site water management plan is to effectively control all water that originates within the project area, or is brought into the project area, in an environmentally responsible manner. This includes optimizing the use of available water sources to supply the water requirements of the milling process and related mining activities, thereby reducing the demand for external make-up water. Water sources that will be controlled include surface water runoff, groundwater from the open pit, process water, tailings consolidation seepage, TMF seepage and bleed water from cyclone sand placement.

Freshwater is required to supplement process water requirements at start-up and to provide makeup water to the mill throughout operations. Freshwater for use during mill start-up will be supplied by constructing the starter (Stage IA) embankment in pre-production years concurrent with open pit stripping, with construction scheduled to provide enough time to capture sufficient surface water runoff for mill start-up. It is anticipated that approximately 3 months of mill water requirements will be available in the start-up water pond prior to commencement of mill operations. Provisions for makeup water to the mill have been included in the TMF water balance. The freshwater source is assumed to be the Yukon River and/or a groundwater well field.

A monthly water balance model was developed for the TMF to assess the various flows to and from the facility, to predict the variation in supernatant pond volume during operations and to estimate makeup water requirements. The determination of an accurate water balance for the operating facility is a key part of the TMF design process.

6.2 WATER BALANCE MODEL

A stochastic analysis was carried out on the base case monthly operational mine site water balance using the GoldSim© software package. The intent of the modelling is to estimate the magnitude and extent of any water surplus and/or deficit conditions in the TMF based on a range of possible climatic conditions. The modelling timeline includes two pre-production years (Year -2 and Year -1), and 22 years of operation (Years 1 to 22), based on the mine production schedule. The TMF pond is assumed to have a minimum pond volume of 15 million m^3 (approximately 3 months of slurry water requirements) in all months throughout operations. Therefore, a deficit condition is defined as when the TMF pond volume is at the minimum volume of 15 million m^3 and that the system (including the TMF, open pit, and contributing catchments) is not able to supply enough water to meet the mill process water requirements, thereby indicating the need for make-up water. Details of the water balance model including a schematic of the model and a summary table of input values are included in Appendix D.

The water balance indicates that the mine site will likely be in a deficit condition over the operating life of the TMF, except for the last 1 to 2 years. The maximum annual volume of makeup water required occurs in Year 3 for all climate scenarios. The 95th percentile wet and dry values are defined as having a 5% and 95% chance of being equalled or exceeded in any year, respectively. The range of monthly TMF pond volumes from Years -2 to 22, for the 95th percentile dry, median and 95th percentile wet scenarios is included in Appendix D.

It should be noted that the water balance results are very sensitive to the input values, which are best estimates based on currently available information, so changes to the inputs could result in substantial changes to the results.

7 – TAILINGS DISTRIBUTION AND RECLAIM WATER SYSTEMS

7.1 GENERAL

There will be two separate tailings slurry streams from the mill. The principal (rougher) stream (80%) will consist of bulk Non-Acid Generating (NAG) tailings. The minor stream (20%) will be Potentially Acid Generating (PAG) material that will be handled and stored separately and maintained under water. Both of these tailings streams will leave the mill at a solids content of approximately 55%. For approximately nine months of each year on average the NAG tailings will be passed through a cyclone plant to produce clean sand for embankment construction. The cyclone plant will also produce a high volume low solids content stream, containing the fines fraction of the tailings (cyclone overflow). This material will be discharged into the TMF at a solids content of approximately 24%. A flow diagram of the tailings handling process is shown on Figure 7.1.

Only clean (geochemically innocuous) bulk NAG tailings may be cycloned to produce sand fill material for embankment construction. No potentially reactive materials can be used for embankment construction. Management of the PAG tailings stream during system maintenance or breakdown needs to be coordinated, to ensure that any combined tailings that includes the PAG stream is not directed to the cyclone sand plant.

On this basis the design must consider four separate tailings streams:

- PAG tailings
- Bulk NAG tailings
- Cyclone sand (underflow), and
- Cyclone overflow.

The higher elevation of the mill relative to the TMF will enable gravity discharge for the tailings streams, including cyclone sand products for most, if not the entire project life.

Water will be reclaimed from the tailings supernatant pond by two floating, barge mounted, pump-stations. One reclaim barge reports to the process water settlement pond located above the mill terrace for mill water and the other to a dilution water head tank to provide gravity flow to the cyclone feed tank.

General locations for the tailings delivery lines, cyclone plant and reclaim system over the operating life of the TMF are included on Figure 5.1 for pre-production conditions (start of operations) and Figures 5.2 to 5.5 for operating years 1, 4, 10 and 22 (Final) respectively.

Summaries of the tailings distribution, cyclone sand production and reclaim water systems are provided in the following sections.

ORE

XREF FILE(S): IMAGE FILE(S):

7.2 PAG TAILINGS DISTRIBUTION

A single PAG tailings line will be laid heading approximately east from the mill, between low grade ore stockpiles, down to the TMF. Valved tees located at intervals in the line will enable subaqueous deposition of the PAG tailings into the TMF. This can be accomplished using a floating HDPE pipeline with submerged exit holes. The line will be moored to shore to allow its location to be managed. Floatation will be provided to ensure that the line remains at surface. Consideration will be given in future design studies to the possibility of the floating line freezing during winter conditions.

The design of the PAG tailings delivery system from the mill to the TMF has been designed by Others.

7.3 BULK NAG TAILINGS DISTRIBUTION

Bulk NAG tailings will be delivered to the southwest end of the TMF, either for the production of sand via the cyclone plant (for approximately nine months per year) or for direct deposition into the TMF.

The design of the NAG tailings delivery system from the mill to the tailings head tank (feeding the cyclone plant) has been designed by Others. The design of the tailings delivery systems from the tailings head tank onwards have been designed by Paterson and Cooke (details are provided in Appendix E).

The same pipe system used to deliver the cyclone overflow stream to the TMF can also be used for the undiluted Bulk NAG tailings stream when the cyclone station is by-passed (see Section 7.4.2). Tailings discharge into the TMF will be from a selected valved off-take along a pipeline on the embankment crest. Valves will be spaced at approximately 100 meter intervals. Normally only one off-take will be open to manage the tailings discharge. Discharge into the TMF will not be continuous from any one location in the pipeline. It will be rotated between off-takes as appropriate for tailings distribution within the TMF. This will ensure adequate beach development adjacent to the embankments and maximize the ability of the reclaim system to recover clean water.

Discharge from the line will be enabled at appropriately located tees, each provided with a downstream isolation valve and an off-take valve. The off-take will typically include a downstream section of pipeline to allow single point tailings out-flow to be delivered into the surface water pond or beach, with minimum erosion of the confining embankment face.

7.4 CYCLONE SAND PRODUCTION

The design of the Cyclone Sand Plant and delivery systems from the sand plant to the TMF have been designed by Paterson and Cooke of Vancouver, B.C. Details of the design of the cyclone sand plant, cyclone underflow (sand) distribution system, cyclone overflow (fines) distribution system (including the bulk NAG tailings by-pass system) and associated water systems are provided in the Paterson Cooke report “Casino Project Tailings Cyclone and Transport Study – Feasibility Study Report, December, 2012). This document is included as Appendix E.

A required design criterion for the cyclone plant sand product is that the fines content (% passing a #200 sieve) must be 12% or less. The current particle size distribution of the bulk NAG tailings (approximately 58% sand fraction) and information provided by cyclone suppliers indicates that single-stage cycloning will be sufficient to achieve a clean sand product with 12% fines or less and a

sand recovery of approximately 50% by weight from the bulk tailings stream. The cyclone feed will require water addition to reduce the cyclone feed solids content to 36%. The sand (cyclone underflow) product will be produced at approximately 74% solids by weight. This will require water addition and mixing to a solids content of approximately 65% for distribution to discharge points along the embankment crest.

7.4.1 Cyclone Sand Discharge to Main Embankment

Cyclone sand will be delivered through a piping system on the downstream side of the embankment.

The pipe system consists of four sections:

- 18" downhill pipe
- 18" horizontal pipe on the sand jacking header
- 14" downhill pipes – from jacking header, and
- 14" downhill pipe – jacking header bypass for high turn down throughput requirements.

The 18" cyclone sand pipeline initially follows the 15% site gradient down towards the dam. At the Main Embankment the pipeline continues on a jacking header. 14" take off valves are provided every 100 metres from the main pipeline for sand deposition. Each take-off valve is connected to a mobile 14" HDPE DR 11 pipe, running downhill on the embankment to sand deposition cells (approximately 100 m by 20 m in size). Each 14" individual branch pipe is capable of transporting the full sand plant production to fill a cell at a time.

7.4.2 Cyclone Overflow Discharge

In conjunction with the production of the cyclone sand, the cyclone plant produces a large volume of tailings fines (combined cyclone overflow), at a low solids content (approximately 24%). This material is discharged into the TMF from points upstream of the Main Embankment, generally over the same locations as the bulk NAG tailings.

This system handles the cyclone overflow stream as well as the undiluted Bulk NAG tailings stream when the cyclone station is by-passed.

The system consists of three sections:

- 36" HDPE DR 11 downhill pipe
- 32" CS Std Sch horizontal pipe on jacking header, and
- 16" HDPE DR 17 take-off pipes from the jacking header.

The cyclone overflow pipeline initially follows the 15% site gradient down to the Main Embankment. On the embankment the pipe is laid on a hydraulically raised jacking header, which is a separate structure from the sand jacking header. 16" take-offs with valves are placed every 100 metres. Each take-off valve is connected to a 16" HDPE DR 17 pipe running down from the jacking header onto the beach of the TMF.

7.5 RECLAIM WATER SYSTEM

Water will be reclaimed from the tailings supernatant pond by two floating, barge mounted, pump-stations. One reclaim barge reports to the process water settlement pond located above the mill terrace for mill water and the other to a dilution water head tank to provide gravity flow to the cyclone

feed tank. The floating pump-stations will be located in the general southwest corner of the TMF at the start of operations.

Additional pump-stations in series are currently envisaged for the mill reclaim system, due to the significant elevation difference between the initial supernatant pond in the TMF and the mill, coupled with the possibility of a shallow supernatant pond increasing the risk of barge grounding.

The design of the reclaim water system from the TMF to the mill and from the TMF to the dilution water head tank has been completed by Others.

Water reclaimed from the TMF consists of supernatant from the settled tailings, as well as run-off from precipitation, snowmelt and ice melt, from within the TMF catchment area. Dedicated pipelines will convey reclaimed water to the settlement pond located up-gradient of the mill and a water head tank up-gradient of the cyclone plant. The initial mill reclaim discharge pipeline will run approximately northwest and relatively directly to the mill head tank. The cyclone plant water line will run approximately west from the TMF.

Water reclaim from the surface water pond begins with two shallow draft, barge mounted, reclaim pump-stations, that float within the TMF. These will be installed at locations remote from the point of normal tailings discharge to ensure clean water recovery. A shallow draft maximizes the potential for year round recovery of water of acceptable clarity. Relocation of the barges is required to accommodate ongoing development of the TMF, changes in the elevation of the surface water pond and encroachment of the tailings discharge plume into the vicinity of the barge.

The barges will be fitted with vertical turbine pumps, including standby pumping capacity and all necessary control, check, drainage and isolation valves. One pump will normally be operated on the mill reclaim barge at all times during winter, to reduce the potential for water freezing in the reclaim pipeline. The cyclone reclaim system will be drained and the barge winterized appropriately.

8 – INSTRUMENTATION AND MONITORING

8.1 GENERAL

Geotechnical instrumentation will be installed in the tailings embankment and foundation during construction and over the life of the project. The instrumentation will be monitored during the construction and operation of the TMF to assess embankment performance and to identify any conditions different to those assumed during design and analysis. Amendments to the on-going designs and/or remediation work can be implemented to respond to the changed conditions, should the need arise.

Geotechnical instrumentation, comprising vibrating wire piezometers, thermistors, slope inclinometers and movement (survey) monuments will be installed at selected planes along the Main Embankment and West Saddle Embankment. Groundwater wells will be installed at suitable locations downstream of the embankment.

Monitoring of civil and mechanical operational components will be a daily/shift requirement, to ensure that systems are functioning correctly. Excess noise/wear/movement/leakage/spillage etc. may indicate problems with pipelines or valves. In particular, during winter operations, ice formation may impact reclaim barge stability and operation or result in blockage of pipelines.

8.2 INSTRUMENTATION

Vibrating wire type piezometers will be installed in the embankment fill, foundations and tailings deposit to measure pore water pressures during initial placement, throughout operations and post-closure. The piezometers will be distributed throughout the various foundation and fill zones to provide a spectrum of monitoring data. Thermistors may be required to determine the temperature profile to supplement piezometer data. The piezometer and thermistor leads will be appropriately routed to read-out panels for ease of monitoring.

Movement monuments will be installed on the embankment crest following the completion of selective embankment raises to monitor deflections along the slope and crest of the embankment. Periodic surveying of the monument locations will provide early warning of movements and possible acceleration of movement which often occurs prior to failure

Groundwater monitoring/recovery wells will be installed at appropriate locations along the downstream toe of the Main Embankment. The wells will be used to recover samples for water quality monitoring.

8.3 MONITORING PROGRAM

Monitoring should be done routinely both during construction and operations. Following initial installation of the geotechnical instrumentation, measurements should be taken and analyzed on a daily basis to monitor the response of the earthfill and foundation from fill loading.

The frequency of monitoring for piezometers and inclinometers may be decreased to bi-monthly readings once the effects of initial construction have dissipated. Surface movement monuments should be surveyed twice per year during operations. Water quality and flow monitoring of the seepage through the embankment and foundation shall be monitored monthly during operations.

Pipeline and pump-station flow, wear and pressure monitoring, pump-power consumption and vibration monitoring will be ongoing requirements. During winter, heating, insulation and de-icing measures must be checked on a shift by shift basis. For all pipelines, any components required for emergency use, such as drainage, must be scheduled for inspection.

8.4 INSPECTION AND REVIEW

In addition to the routine inspections carried out by mine personnel on a shift/daily/weekly and monthly basis, the TMF should be regularly audited by a suitably qualified Geotechnical Engineer to ensure it is operating in a safe and efficient manner. Such audits should be conducted annually. Additionally, a formal dam safety review should be conducted every 5 to 10 years, depending on the dam classification assigned to the TMF embankments. For a HIGH dam classification, the frequency suggested by the CDA “Dam Safety Guidelines” (2007) is seven years. The dam classification is reviewed during the dam safety review process and should also be routinely reviewed as part of the annual audit.

9 – CLOSURE AND RECLAMATION

9.1 GENERAL

The primary objective of the closure and reclamation initiatives will be to eventually return the TMF site to a self-sustaining facility with pre-mining usage and capability. The TMF will be required to maintain long-term stability, protect the downstream environment and manage surface water. Activities that will be carried out during operations and at closure to achieve these objectives are discussed in the following sections.

The closure plan for the project is being developed by Others.

9.2 DECOMMISSIONING AND CLOSURE

Upon mine closure, surface facilities will be removed in stages and full reclamation of the TMF will be initiated. General aspects of the closure plan include:

- Selective discharge of tailings around the facility during the final years of operations to establish a final tailings surface and water pond that will facilitate post closure surface water management and reclamation (including full coverage by the water pond to ensure all PAG tailings and reactive (PAG/ML) waste rock remain in a fully saturated state).
- Dismantling and removal of the tailings and reclaim delivery systems, cyclone plant and all pipelines, structures and equipment not required beyond mine closure.
- Removal of the seepage collection system at such time that suitable water quality for direct release is achieved.
- Construction of an overflow spillway and channel to allow surface water discharge downstream of the TMF.
- Removal and regrading of all access roads, ponds, ditches and borrow areas not required beyond mine closure.
- Long-term stabilization of all exposed erodible materials.
- During the closure phase of the project, suitable topsoil and seeding will be placed on the beach surface after tailings deposition ends to promote revegetation and minimise dusting potential.

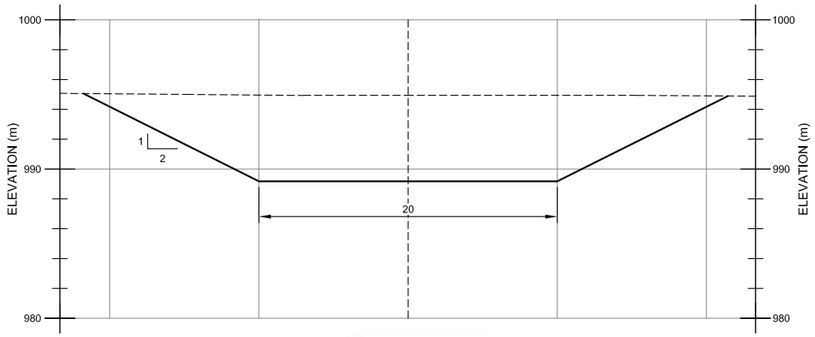
9.3 CLOSURE SPILLWAY

A spillway and downstream channel will be required at closure to facilitate control and discharge of excess water accumulation within the TMF and to provide safe passage of storm water volumes from the TMF. The water balance model developed for the TMF indicates that there will be a water surplus at closure.

The closure spillway will be located close to the west abutment of the West Saddle Embankment to provide long term protection against overtopping of the TMF during the post closure years. The spillway will be routed from the TMF to the south, ultimately terminating at a plunge pool prior to discharging to Brynelson Creek, as shown on Figure 9.1.

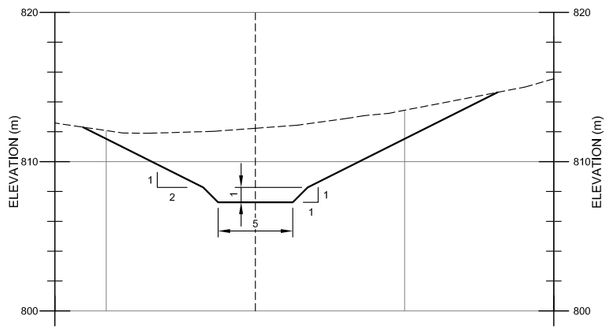
The spillway design flow (SDF) for the closure spillway was calculated by routing the Probable Maximum Flood (PMF) storm hydrograph through the TMF supernatant pond assuming the facility is at capacity at the time the storm occurs. Diversion ditches were assumed to have been damaged

and not functioning in this storm flood routing evaluation. The routing exercise determined the IDF hydrograph for the TMF to be 854 m^3/s. Modelling of the closure spillway indicated that a 20 meter wide spillway sill, with 2 horizontal to 1 vertical side slopes will result in a peak outflow (SDF) from the pond of approximately 45 m^3/s, with a peak water elevation of 1.1 m above the closure spillway invert.



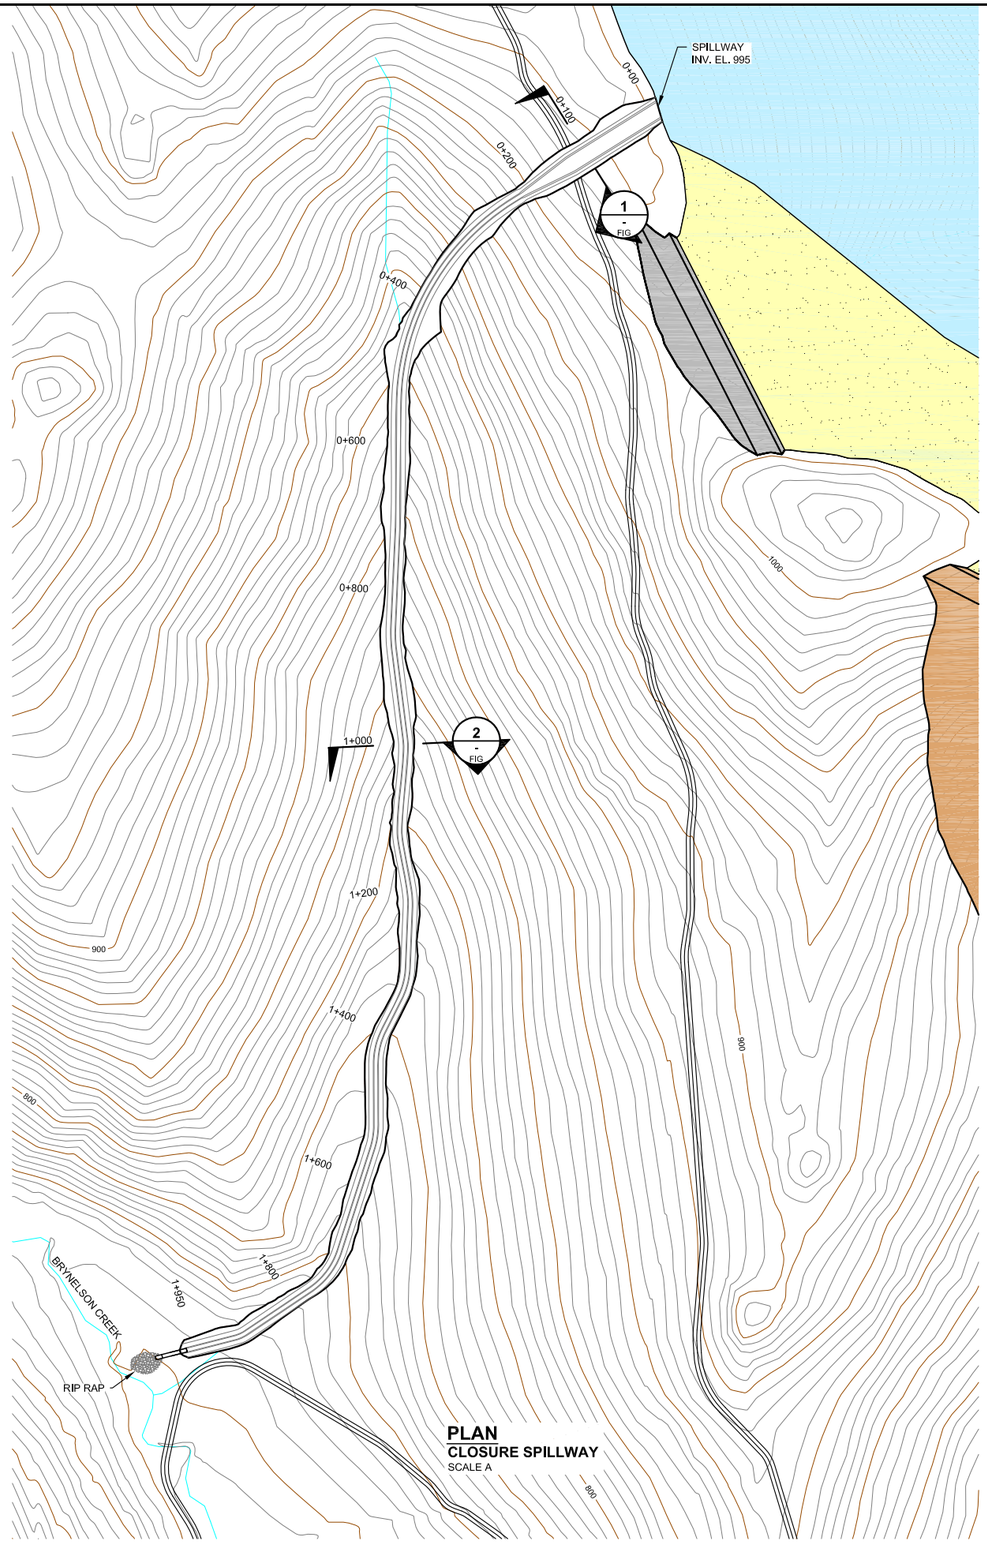
The spillway will be comprised of a 20 meter wide side sill, with 2 horizontal to 1 vertical side slopes, excavated in bedrock to an invert elevation of 3 m below the crest of the dam. The sill of the spillway will convey the SDF downstream to a discharge channel that will be aligned along an existing tributary for Brynelson Creek. This tributary will be modified to provide a channel having a minimum base width of 5 meters, and 1 (or greater) horizontal to 1 vertical side slopes. The spillway channel will ultimately terminate at an adequately sized and erosion protected plunge pool at the confluence of Brynelson Creek. Flow depths through the spillway channel have been calculated to range between 0.6 m in the steeper upper regions and 1 m in the shallower lower regions.

To satisfy post-closure water quality requirements and objectives a concrete “stop-log” system may be installed in the spillway structure to facilitate impounding of the supernatant pond. This allows downstream seepage water to be collected and returned to the pond during the winter months, and released during the summer months.



9.4 ON-GOING MONITORING REQUIREMENTS

The seepage collection ponds/sumps and recycle pumps will be retained until monitoring results indicate that any seepage from the TMF is of suitable quality for direct release to downstream waters. The groundwater monitoring wells and all other geotechnical instrumentation will be retained for use as long term monitoring devices.



Post-closure requirements will also include an annual inspection of the TMF and an on-going evaluation of water quality, flow rates and instrumentation records to confirm design assumptions for closure.

10 – SCHEDULE OF QUANTITIES

Quantity estimates for the materials and work items required for initial construction and for ongoing expansion and operation of the TMF are presented in Table 10.1.

Quantities have been estimated for the following components of the TMF:

- Topsoil/overburden stripping
- Foundation preparation within the embankment footprints (including excavation of unsuitable materials)
- Embankment fill placement, including seepage cut-off
- Seepage interception and collection system
- Instrumentation and monitoring, and
- Closure Spillway

The Feasibility level quantities were measured on the basis of the designs and dimensions shown on the relevant Figures of this report. These quantities have been developed to enable costing to be conducted to a level of accuracy of ± 15 percent. It is understood that the all initial and sustaining capital costs and operating costs will be carried out by Others.

The cost estimate will also need to include the following items:

- Hauling of all embankment fill materials to the embankment
- Hauling of topsoil/overburden materials to stockpiles
- Hauling of unsuitable foundation soils for disposal within TMF
- Hauling potentially reactive waste rock and overburden to the TMF, and
- Electrical power supply, instrumentation and control.

Equipment lists and quantities (material take-off lists) for the cyclone sand plant, cyclone underflow (sand) distribution system, cyclone overflow (fines) distribution system (including the bulk NAG tailings by-pass system) and associated water systems are provided in the Paterson Cooke report "Casino Project Tailings Cyclone and Transport Study – Feasibility Study Report, December, 2012). This document is included as Appendix E.

11 – RECOMMENDATIONS FOR FUTURE STUDIES

The following is a list of recommendations for additional geotechnical site investigations, laboratory testing and design studies required to carry the TMF design through to final design and construction:

Geotechnical Investigations and Laboratory Testwork

- Additional geotechnical drilling and test pits in the TMF area to investigate and confirm foundation conditions (specifically the extent of the colluvial apron), permafrost characteristics and depth to bedrock.
- Additional test pits and drilling to confirm suitability and quantity of borrow materials for embankment construction (specifically low permeability soils for embankment core zone).
- Additional laboratory index testing (including compaction tests) and strength and permeability tests on potential borrow materials for embankment construction.
- Laboratory testing to confirm the physical characteristics of the cyclone sand (material classification, strength and permeability tests). This should include strength and permeability tests at very high confining stresses, representative of the large height of the Main Embankment, and testing to examine the influence of cyclone sand fines content on available percentage of sand recovery and the impact on permeability.
- Examination of the influence of cyclone underflow solids content on the compaction characteristics of in situ cyclone sand fill.
- Laboratory testing to determine the physical characteristics of the PAG tailings (material classification, slurry settling, consolidation and permeability tests).

Large scale generation of a cyclone sand sample (using a laboratory cyclone device) is recommended to provide sufficient quantity of representative sand material for laboratory testing.

Design Studies and Analyses

- Review and updates to hydrometeorological and hydrology information, incorporating on-going site data collection.
- Review and confirmation of the thermal regime in the TMF foundation using site thermistor data. Thermal modelling may also be required to predict the effect of the TMF on foundation conditions.
- Confirmation of geochemical characterisation and potential reactivity of tailings and waste rock from on-going waste characterisation studies.
- Review and confirmation of TMF seepage predictions and seepage control measures and requirements
- Development of a tailings and waste rock deposition strategy to optimize material handling, and tailings discharge line and reclaim barge locations throughout operations.
- Consideration of alternative core zone materials and options if additional characterisation and delineation of borrow sources indicates a potential shortfall of suitable low permeability material.
- Assessment of the sequencing of sand cell construction in relation to embankment raising requirements to optimise material demand and placement strategies.
- Evaluation of the potential impact of sloping sub-aerial and sub-aqueous tailings beach areas. Consideration of tailings beach configurations may result in modifications to staged embankment heights and the tailings deposition strategy.

- Review and reassessment of trade-off study for embankment construction material options (cyclone sand versus local borrow material) based on the most current design requirements and cost estimate information.

APPENDIX B

SEISMIC HAZARD ASSESSMENT

(Pages B-1 to B-8)

APPENDIX B

CASINO MINING CORPORATION
CASINO COPPER-GOLD PROJECT

SEISMIC HAZARD ASSESSMENT

B.1 INTRODUCTION

A seismicity assessment has been carried out for the Casino Copper-Gold Project, including a review of the regional seismicity and a seismic hazard analysis. The results of the seismic hazard analysis are required to provide seismic design parameters for the design of the Tailings Management Facility and for other facilities at the project site, including the Heap Leach Facility and ore stockpiles. Design ground motion parameters provided by the seismic hazard analysis include peak ground acceleration, spectral acceleration (defining the uniform hazard spectrum) and design earthquake magnitude.

The findings of the seismicity review and the methodology and results of the seismic hazard analysis are presented in the following sections.

B.2 REGIONAL TECTONICS AND SEISMICITY

The region of the southwest Yukon Territory and northwest British Columbia is one of the most seismically active areas in Canada. The seismic hazard in the region is also influenced by the seismically active region of southeast Alaska. The coastal region has experienced many large earthquakes, including events with magnitudes in the range of magnitude 7.0 to 8.0. In 1958 a magnitude 7.9 earthquake occurred along the Fairweather fault (the northern extension of the Queen Charlotte transform fault). The most significant inland zone of seismicity follows the Dalton and Duke River segments of the Denali fault zone through the southwest Yukon. Farther inland there is only minor seismicity between the Denali and Tintina fault systems, including the region of the Casino Project site.

The southern coast of Alaska is a region of high seismicity and high seismic hazard, where earthquakes are generated by the Pacific (oceanic) plate subducting under the North American plate at an average rate of approximately 5 to 8 cm per year. Evidence shows that these tectonic plates are locking as they pass each other, building up tremendous pressure that can sometimes be released as large Magnitude 8 to 9+ earthquakes. These large interface subduction (thrust) earthquakes typically occur at shallow depths of 15 to 35 km. This seismic source region, known as the Alaska-Aleutian Megathrust, has been responsible for several of the largest earthquakes recorded globally, including the 1964 Prince William Sound Magnitude 9.2 (M9.2) earthquake. There is potential for future large interface subduction earthquakes (M8 to M9+) along the southern coast of Alaska. However, these earthquakes would occur at too great a distance from the Casino project to have any significant influence on the seismic hazard at the site, due to attenuation of ground motions over the large distance (over 400 km).

Figure B.1 shows the regional tectonics and historical seismicity of the Yukon and surrounding regions and the location of the Casino project.

B.3 SEISMIC HAZARD ANALYSIS

The seismic hazard for the Casino project has been defined using probabilistic methods of analysis. This method requires an examination of historical earthquake data and the regional tectonics to identify potential seismic sources and to determine the maximum earthquake magnitude for each seismic source. Appropriate relationships defining the attenuation of earthquake ground motion with distance are also required.

Design ground motion parameters have been determined for the project site using information provided by the probabilistic seismic hazard database of Natural Resources Canada (NRC) (http://earthquakescanada.nrcan.gc.ca/hazard-alea/zoning/haz-eng.php). The results are summarized in Table B.1 in terms of earthquake return period, probability of exceedance (for a 22 year design operating life) and the corresponding peak ground acceleration (median and mean hazard values). However, the NRC database only provides ground motion parameters up to a return period of approximately 2500 years (corresponding to a 2% probability of exceedance in 50 years). Higher return periods will need to be considered for dam design if the classification is defined as Very High or Extreme (based on the requirements of the Canadian Dam Safety Guidelines). Therefore, a probabilistic seismic hazard analysis has been conducted to provide ground motion parameters beyond 2500 years, specifically for return periods of 5000 and 10,000 years.

The methodology used to complete the site-specific probabilistic seismic hazard analysis and the results of the analysis are described in the following sections.

B.3.1 Ground Motion Attenuation

Appropriate attenuation models defining the relationship between earthquake magnitude, source to site distance and peak ground motion (acceleration) are required to carry out a probabilistic seismic hazard analysis. The ground motions experienced at the project site are dependent on the regional ground motion attenuation characteristics and the earthquake source mechanism.

For shallow crustal earthquakes a set of four ground motion attenuation models, known as the New Generation Attenuation (NGA) relations was used (Earthquake Spectra, 2008). These include the ground motion relationships of Abrahamson and Silva, Boore and Atkinson, Campbell and Bozorgnia and Chiou and Youngs. These ground motion attenuation relationships are applicable to shallow crustal earthquakes in western North American and similar tectonic regions of the world. The predicted peak ground accelerations for shallow crustal earthquakes are average values calculated using the four attenuation relationships (equal weighting).

The peak ground accelerations and spectral accelerations predicted using the attenuation relationships are for soft rock/very dense soil site conditions, assuming an average shear wave velocity in the upper 30 meters (defined as the Vs30 value) of 560 m/sec (range of 360 to 760 m/sec). This corresponds to Site Class C, as defined by the National Building Code of Canada (NBCC 2010).

B.3.2 Probabilistic Analysis

A probabilistic seismic hazard analysis is carried out to define a unique probability of occurrence for each possible level of ground acceleration experienced at a site. The methodology used for the probabilistic

analysis is based on that presented by Cornell (1968). The likelihood of occurrence of earthquakes within defined seismic source zones is determined by examining seismicity data. Using historical earthquake records for the region, magnitude-frequency recurrence relationships are established for potential earthquake source zones. The magnitude recurrence relationships are of the form derived by Gutenberg-Richter (1944):

$$\log(N) = a - b(M)$$

where, M = Earthquake magnitude
N =Annual frequency of occurrence for earthquakes exceeding magnitude M
(1/N = Return Period)

The computer program EZ-FRISK (Risk Engineering, Inc., 2008) was used to develop a seismic hazard model for the southern Yukon and the surrounding regions. The seismic hazard analysis module available with EZ-FRISK includes a database provided by Risk Engineering Inc. of faults and areal seismic sources for the pertinent regions of western Canada. Seismic sources defined in the hazard model include the regions of the southern Yukon Territory, southeastern Alaska, and the Denali and Fairweather fault systems. The project site is located within an areal seismic source that defines the seismicity in the southern Yukon. A maximum earthquake of Magnitude 7.0 was assigned to this source zone, which is characterized by shallow crustal earthquakes.

Magnitude-frequency recurrence relationships and the corresponding maximum earthquake magnitude for each seismic source are prepared by Risk Engineering from consideration of historical seismicity, fault characteristics and the regional tectonics, using information obtained from the Geological Survey of Canada and proprietary studies. For calculation of peak ground accelerations a minimum magnitude of 5.0 was used in the analysis for all seismic source zones. Earthquakes of lower magnitude are not considered to be a risk to engineered facilities. Appropriate ground motion attenuation relationships were assigned to each seismic source, as discussed in Section 2.1 above.

The seismic hazard model developed using EZ-FRISK was used to determine the relationship between peak ground acceleration and annual frequency of occurrence for the project site. Median hazard values of peak ground acceleration have been determined for return periods up to 10,000 years. Predicted values for the project site are included in Table B.1 for return periods of 5000 and 10,000 years. Predicted values for lower return periods were very similar to those provided by the NRC seismic hazard database.

The probabilistic seismic hazard analysis has also been used to calculate spectral acceleration values (5% damping). These have been used to develop site-specific uniform hazard spectra corresponding to return periods of 500, 2500 and 10,000 years. The uniform hazard spectra are shown on Figure B.2. Tabulated values of these uniform hazard spectra are provided in Table B.2.

Deaggregation of the probabilistic seismic hazard results has been carried out to provide the relative contributions of all potential seismic sources, and to more accurately define the characteristics of potential earthquakes contributing to the seismic hazard. The findings indicate that the seismic hazard for the

project site is predominantly from shallow crustal earthquakes associated with the southern Yukon region, but also from the Denali fault system.

A design earthquake magnitude of 8.0 has been selected, based on the review of regional tectonics and historical seismicity, and the findings of deaggregation off the probabilistic seismic hazard.

APPENDIX C

EMBANKMENT STABILITY ANALYSES

(Pages C-1 to C-7)

APPENDIX C

CASINO MINING CORPORATION
CASINO COPPER-GOLD PROJECT

EMBANKMENT STABILITY ANALYSES

C.1 GENERAL

Embankment stability analyses were carried out to investigate the stability of the Main Embankment under both static and seismic loading conditions. These comprised checking the stability of the embankment arrangement for each of the following cases:

- Static conditions during operations and post-closure;
- Earthquake loading from the Operating Basis Earthquake (OBE) and the Maximum Design Earthquake (MDE); and
- Post-earthquake conditions using residual (post-liquefaction) tailings strengths.

The stability analyses were based on the maximum cross-section through the Main Embankment for the final TMF with a supernatant pond elevation of 995 m and an embankment crest elevation of 998 m.

The stability analyses were carried out using the limit equilibrium computer program SLOPE/W. In this program a systematic search is performed to obtain the minimum factor of safety from a number of potential slip surfaces. Factors of safety have been computed using the Morgenstern-Price method.

In accordance with international recommendations (ICOLD, 1995) and standard industry practice, the minimum acceptable factor of safety for the tailings embankment under static conditions is 1.3 for short-term operating conditions and 1.5 for long-term (steady-state and post-closure) of the TMF. A factor of safety of less than 1.0 is acceptable under earthquake loading conditions provided that calculated embankment deformations resulting from seismic loading are not significant and that the post earthquake stability of the embankment maintains a factor of safety greater than 1.2, implying there is no flow slide potential. The TMF would be expected to function in a normal manner after the OBE. Limited deformation of the tailings embankment is acceptable under seismic loading from the MDE, provided that the overall stability and integrity of the TMF is maintained and that there is no release of stored tailings or water (ICOLD, 1995). Some remediation of the embankment may be required following the MDE.

The seismic stability assessment of the TMF has included estimation of seismically induced deformations of the dam from the OBE and MDE events. The OBE has been defined as the 1 in 500 year earthquake with a mean Peak Ground Acceleration (PGA) of 0.08g and design earthquake magnitude of 8.0. The MDE corresponds to the 1 in 2,500 year earthquake with a mean PGA of 0.13g and design earthquake magnitude of 8.0. To demonstrate the robustness of the embankment design to seismic loading the 1 in 10,000 year earthquake has also been considered. The PGA for the 1 in 10,000 year event is 0.22g.

The design PGA values are for very dense soils and soft (weathered) rock ground conditions. This is consistent with the foundation conditions beneath the Main Embankment. To account for the potential

amplification of ground motions as seismic waves propagate through the foundation soils and embankment, an amplification factor of 1.5 has been assumed to estimate the average PGA along a potential slip surface through the embankment. This amplification factor is based on consideration of the expected embankment foundation conditions and fill materials (density and stiffness). This results in an estimated average PGA within the embankment of 0.13g for the OBE, 0.2g for the MDE and 0.32g for the 1 in 10,000 year earthquake.

C.2 MATERIAL PARAMETERS AND ASSUMPTIONS

The following parameters and assumptions were incorporated into the stability analyses:

- Bulk unit weights for the Stage 1 embankment materials, low permeability core zone, and foundation materials were based on typical values for similar materials and the results of laboratory testing. The unit weights are listed in Figure C.1.
- A bulk unit weight of 18 kN/m^3 was used for the cyclone sand embankment fill, based on the results of compaction and triaxial testing of a laboratory prepared sample (representing cyclone underflow) and report density values for existing large cyclone sand dams.
- An undrained shear strength was adopted to represent the tailings material strength for the static, seismic and post-earthquake cases, as described by the following relation:

  Su/p' = 0.20 (static and seismic loading)

  Su/p' = 0.10 (post liquefaction residual strength)

  where, Su = undrained shear strength

  p' = effective vertical stress;
- An average effective friction angle of 35 degrees was adopted for the sand-gravel foundation soils based on laboratory test results conducted in 2010;
- Effective strength parameters for the embankment core zone material and low permeability upstream blanket were estimated based on typical values for similar materials. An average effective friction angle of 33 degrees was used;
- The shear strength for rockfill (Stage 1 dam shell zones) was defined using a conservative strength function that defines the variation with shear strength with normal stress. This strength function is based on published information on the shear strength properties of rockfill (Leps, 1970);
- Cyclone sand fill is assumed to remain well drained (unsaturated and therefore not potentially liquefiable);
- A strength function for angular sand (Leps, 1970), similar to that for rockfill, was adopted for the cyclone sand embankment fill, based on the results of shear strength testing of a laboratory prepared sample. The results of the testing are shown on Figure C.2. Details of the shear strength testing and results are provided in the KPL document ""Report on Laboratory Geotechnical Testing of Tailings Materials" (Ref. No. VA101-325/8-1, December, 2012); and
- The predicted phreatic surface from TMF seepage modelling (see Section 5.10) was used in the stability analysis for the Main Embankment.

The stability model developed for the Main Embankment is shown on Figure C.1.

C.3 RESULTS OF STABILITY ANALYSES

The potential slip surface through the final Main Embankment (Crest El. 998 m) is shown on Figure C.1.

For static stability conditions, the minimum factor of safety calculated is 2.2. This exceeds the minimum factor of safety for short-term operating conditions and for long-term (post-closure) conditions.

Embankment stability during earthquake loading has been assessed by performing a pseudo-static analysis, whereby a horizontal force (seismic coefficient) is applied to the embankment to simulate earthquake loading to determine the critical acceleration required to reduce the factor of safety to 1.0. Deformation of the embankment is predicted to occur if the critical acceleration is lower than the predicted average PGA along the potential slip surface from the design earthquake.

Potential deformations under earthquake loading have been estimated using the simplified methods of Newmark (1965) and Makdisi-Seed (1977). These two methods estimate displacement of the potential sliding mass based on the average maximum ground acceleration and the yield acceleration. The yield acceleration corresponds to the seismic coefficient required to initiate movement of the sliding mass. The yield acceleration was determined by iterative stability analyses. For the Main Embankment, the estimated yield acceleration is approximately 0.3g. Predicted embankment deformations from the OBE and MDE are negligible, as the calculated yield acceleration exceeds the estimated average PGA for these events. Calculated average embankment displacements are also minor (approximately 0.01 m) for the 1 in 10,000 year earthquake.

The more recently published method of Bray (2007) was also used to predict seismically induced slide displacement of the embankment. In addition to the yield acceleration, this method considers the predominant period of response (T_s) of the embankment under seismic loading and the corresponding spectral ground acceleration (Sa). The predominant period is related to the stiffness characteristics of the embankment fill and to the height of the embankment. Spectral acceleration values were provided by the uniform hazard spectrum defined for each design earthquake event. The uniform hazard spectra for the 1 in 500 (OBE), 1 in 2,500 (MDE) and 1 in 10,000 year earthquakes were defined from the results of a site specific probabilistic seismic hazard analysis (see Section 3.5) and are provided on Figure C.3. Maximum displacements of approximately 0.02 m and 0.01 m were predicted for the 1 in 10,000 year earthquake and MDE respectively, based on the stiffness of the embankment fill and predominant period of the embankment under seismic loading (estimated to be in the range of about 1.5 seconds). Predicted embankment displacement for the OBE is negligible (< 0.01 m). The predominant period of the embankment is long due to the embankment height (maximum of approximately 286 m). Spectral accelerations from the design earthquakes are lower in the longer period range. This results in the predicted displacement being lower than would typically be calculated for a lower height dam with the same yield acceleration.

Some deformation of the embankment is expected to result from settlement of the fill materials during earthquake shaking. Potential settlement of the embankment crest has been estimated using the empirical relationship provided by Swaisgood (2003). This relationship was developed from an extensive review of case histories of embankment dam behaviour due to earthquake loading. Required inputs to the relationship are the earthquake magnitude, the peak ground acceleration on rock at the site, the depth

to rock (overburden thickness) and the embankment height. The predicted maximum crest settlements for the Main Embankment section are approximately 0.2 m for the OBE, 0.25 m for the MDE and less than 0.4 m for the 1 in 10,000 year earthquake.

Maximum embankment deformations and settlements calculated for the design earthquakes are less than 0.5 m and do not have a significant impact on the available embankment freeboard (minimum of 3.0 m) or result in any loss of embankment integrity. Predicted embankment deformations from the OBE are negligible and would not impact on-going operations at the TMF.

The post earthquake condition that conservatively assumes complete liquefaction of the tailings deposit was also analysed, using a post-liquefaction residual tailings strength. The calculated factor of safety is the same as the static factor of safety as the critical potential slip surface does not pass through the liquefied tailings deposit. This indicates that the embankment is not dependent on tailings strength for downstream stability and is not susceptible to a flow slide or large deformations resulting from earthquake-induced liquefaction of the tailings deposit.

The stability of the Main Embankment can be increased further by placement of non-reactive waste rock, or suitable borrow material against the downstream face of the dam. However, this is not a requirement in providing appropriate embankment stability and minimum factors of safety, based on the strength parameters adopted for this study.

The on-going increase in tailings strength and reduction in pore water pressures as the tailings consolidate will only improve the overall stability and integrity of the embankment after closure.

APPENDIX D

OPERATIONAL MONTHLY STOCHASTIC WATER BALANCE MODEL

(Pages D-1 to D-4)

APPENDIX D

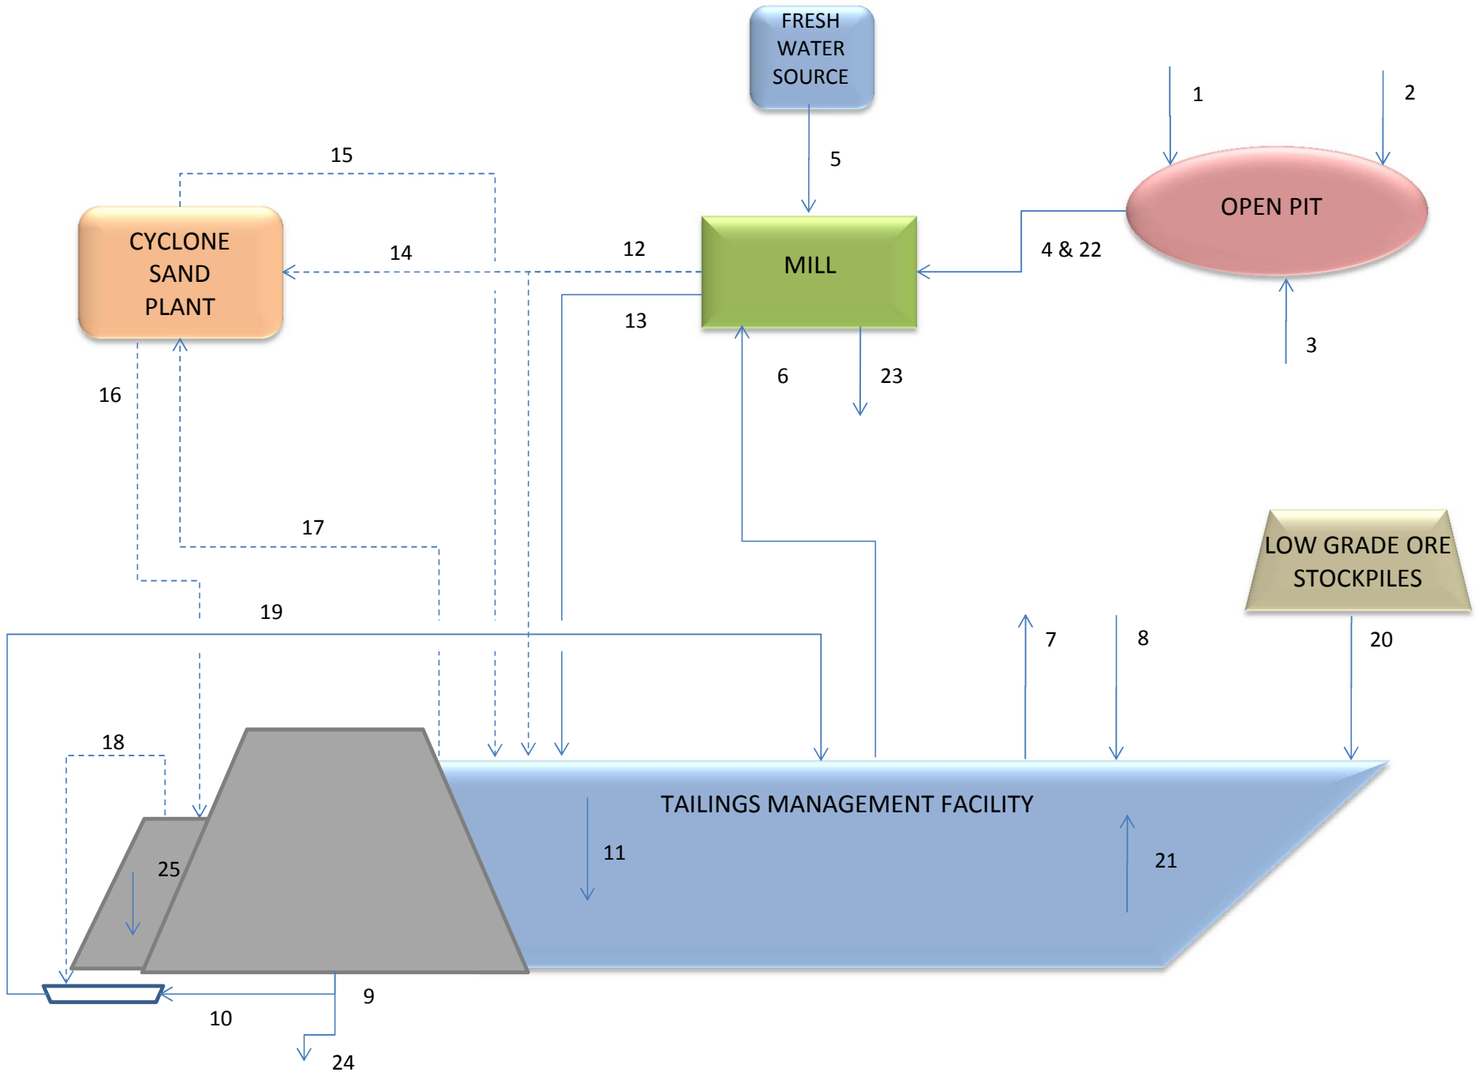
CASINO MINING CORPORATION
CASINO COPPER-GOLD PROJECT

OPERATIONAL MONTHLY STOCHASTIC WATER BALANCE MODEL

D.1 GENERAL

A stochastic analysis was carried out on the base case monthly operational mine site water balance using the GoldSim© software package. The intent of the modelling was to estimate the magnitude and extent of any water surplus and/or deficit conditions in the Tailings Management Facility (TMF), based on a range of possible climatic conditions. The modelling timeline included two pre-production years (Year -2 and Year -1), and 22 years of operation (Year 1 to 22) at a nominal rate of 125,000 dry metric tonnes per day. The model is shown schematically on Figure D.1 and incorporates the following major project components:

- Open Pit
- Mill Site
- Tailings Management Facility (TMF)
- Cyclone Sand Plant, and
- Low Grade Ore Stockpiles.



The model assumptions and parameters are discussed in the following sections and summarized in Table D.1.

D.2 MODEL ASSUMPTIONS

D.2.1 Average Hydrometeorological Conditions

The base case monthly operational water balance model was developed using average estimated values for runoff and precipitation. The mean annual unit runoff (MAUR) for undisturbed basins in the project area was estimated to be approximately 183 mm and the mean annual precipitation was estimated to be 510 mm. The annual average long-term potential evapotranspiration for the project site was estimated to be 300 mm. The mean monthly values for precipitation, runoff, and lake evaporation are summarized in Table D.2. Complete details of the derivation of the climate and hydrology inputs for the project site are outlined in the Hydrometeorology Report (Knight Piésold, 2012a).

The available runoff from the undisturbed catchment areas and ore stockpiles (within the TMF catchment) were modelled on the basis of the long-term runoff estimates for Casino Creek at hydrology station W4, as summarized in Table D.2. Natural runoff values are not directly applicable for mine disturbed areas because of the substantial changes in runoff caused by altering the ground cover. Therefore, the water (runoff/infiltration) generated from the mine affected areas and open water (TMF supernatant pond) was estimated on the basis of rainfall and snowmelt estimates. The available precipitation is summarized in Table D.2 and the runoff coefficients are given in Table D.5.

Number	Description

2. THE MONTHLY RUNOFF VALUES ARE SUMMARIZED FOR LOWER CASINO CREEK AT HYDROLOGY STATION W4.

D.2.2 Stochastic Inputs

The potential variability of surface water runoff was addressed with a stochastic version of the water balance model that uses Monte Carlo simulation techniques. Monthly runoff parameters were modelled as probability distributions rather than mean values. The year-to-year variability of monthly runoff was quantified using coefficient of variation (C_v) values that were derived using the long-term regional stream flow record for the Water Survey of Canada (WSC) station at Big Creek (station ID 09AH003). The monthly C_v values for runoff, along with the monthly mean and corresponding standard deviation values are listed in Table D.3. The monthly mean and standard deviation values were used to develop the monthly probability distributions required for a Monte Carlo simulation. The Monte Carlo simulations were run with 10,000 iterations enabling nearly every conceivable combination of wet, dry and average months and years of runoff to be considered. Each iteration resulted in distributions of possible results for each month in each year, from which probabilities of occurrence were assessed.

Table D.3 Stochastic Monthly Inputs

	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Mean Runoff (mm)	0.5	0.3	0.3	3	45	25	33	31	27	15	2	1

Coefficient of Variation (C_v)	1.0	0.9	0.9	2.0	0.7	0.5	0.6	0.6	0.6	0.5	0.6	0.9

NOTES:
1. COEFFICIENT OF VARIATION = STANDARD DEVIATION / MEAN

D.2.3 Tailings

The TMF design is based on the assumption that approximately 80% of the tailings will be Non-Acid Generating material (NAG) following pyrite separation and removal. The remaining 20% of the tailings comprises Potentially Acid Generating (PAG) tailings that will be discharged by a separate pipeline and contained within the central region of the TMF, remote from the embankments.

D.2.4 Cyclone Sand Plant

The NAG tailings (80% of total tailings by weight) will be used to produce cyclone sand for embankment fill, over a period of approximately 9 months each year (typically from about February to November). Cycloning operations are assumed to be suspended or significantly reduced during the coldest winter months (in particular December and January). Cyclone sand production can reduce during the last few years of TMF operations, when the demand for sand fill for embankment construction reduces.

The NAG tailings will be directed to the cyclone sand plant as a slurry at 55% solids by weight. The cyclone underflow (sand fraction) will be discharged from the sand plant as a slurry at 65% solids (by weight) to construction cells along the upstream and downstream shells of the TMF embankment. The cyclone overflow material (fine fraction) will be discharged directly to the TMF impoundment as slurry at approximately 25% solids by weight. Water will be recovered from the sand cells to the extent possible and pumped back to the TMF pond. Residual moisture draining from the fill in the sand construction cells will be collected in the downstream seepage collection system and pumped back to the TMF pond. Water required for operation of the sand plant will be supplied from the TMF pond. The sand plant is assumed to operate for 90% of the time during the period when it is active. Bulk NAG tailings will be

directed to the TMF impoundment when the sand plant is not in operation. The assumed months of sand plant operation during each year of the mine life are summarized in Table D.4.

Table D.4 Cyclone Sand Plant Operation

Year	Operating Months
1 to 17	9 months: February to October
18 to 20	4 months: May to September
21 to 22	3 months: June to August

D.2.5 Mill Water Requirements

Water requirements at the mill are calculated based on the specified mill production rate and the expected solids content (% by weight) of the tailings. The mine production rate used in the water balance model is approximately 125,000 tpd (less for Years 1 and 22). PAG) and Metal eaching (ML) waste rock will be placed into the TMF, starting in Year -1 (pre-production) and continuing until Year 19. The waste rock will be stored in the upper (northern) area of the TMF. The water balance indicates that the waste rock will become partially submerged by the TMF supernatant pond as of Year 1 and fully submerged by Year 20, approximately one year following the end of waste rock placement in the TMF.

The majority of the process water will be supplied by the TMF reclaim system and open pit dewatering. The mill requires 134 m^3/hr of fresh water in addition to the process water reclaimed from the TMF.

D.2.6 Open Pit Dewatering System

The water pumped from the open pit by the dewatering system includes pit wall runoff, undisturbed pit catchment runoff, and groundwater inflows. This water will be pumped to the mill for use as process water make-up.

D.2.7 Catchment Areas

The TMF catchment areas and corresponding runoff coefficients used in the water balance are summarized in Table D.5. The ore stockpile areas are included in the TMF undisturbed area, as summarized in Table D.5.

Table D.5 Facility Catchment Areas

Facility	Catchment Area (km^2)						Runoff coefficient
	Year 1	Year 5	Year 10	Year 15	Year 20	Year 23	
Open pit footprint	0.3	0.8	1.4	2.0	2.5	2.8	0.9
Undisturbed area in OP catchment	7.7	7.5	7.2	7.0	6.7	6.6	-
LG ore stockpile	0.1	0.6	1.2	1.7	2.2	0.0	0.8
HLF footprint	0.9	1.2	1.2	1.2	1.2	1.2	-
TMF beach	0.1	0.3	0.5	0.7	0.9	0.9	0.7
TMF pond	1.3	3.1	4.8	6.4	8.0	8.3	1.0
TMF undisturbed area	34	31	28	25	23	24	-

NOTES:
1. OP = OPEN PIT; HLF = HEAP LEACH FACILITY; LG = LOW GRADE; TMF = TAILINGS MANAGEMENT FACILITY
2. THE ESTIMATED RUNOFF FOR ALL FACILITY FOOTPRINTS WITH THE EXCEPTION OF UNDISTURBED AREAS AND SOIL STOCKPILES IS CALCULATED BY MULTIPLYING THE MONTHLY AVAILABLE PRECIPITATION VALUE BY THE RUNOFF COEFFICIENT.
3. UNDISTURBED AND SOIL STOCKPILE RUNOFF IS ESTIMATED BASED ON THE MONTHLY AVAILABLE RUNOFF VALUES, WHICH IS A DIRECT INPUT TO THE MODEL.

D.2.8 Heap Leach Facility

The Heap Leach Facility (HLF) will be constructed prior to mill operations (during Year -3) and will operate until approximately Year 15. For the purpose of the TMF water balance model, it was assumed that all water needed for the heap leach process is managed separately from the TMF water balance. Water supplied to the HLF will come from direct precipitation on the HLF footprint and recycled water from the HLF process, with make-up water sourced from a freshwater reservoir until Year 1. As of Year 1, the freshwater reservoir will be decommissioned and a pipeline from the Yukon River will supply the makeup water requirements from both for both the HLF and TMF. Details of the water balance model for the HLF are outlined in the Feasibility Design of the Heap Leach Facility report (Knight Piésold, 2012b).

D.2.9 Water Retained in Tailings and Waste Rock Voids

The amount of water retained in the tailings and potentially reactive waste rock (PAG and ML) voids is a function of the mine production schedule and the dry density and specific gravity of both the tailings and waste rock. The initial settled dry density values for the tailings and waste rock were assumed to be 1.1 t/m^3 and 2.0 t/m^3, respectively, as shown in Table D.1. Water released due to consolidation of the tailings mass was estimated based on tailings consolidation modelling. The resulting tailings consolidation water release rates are:

- 140 L/s in Year 1
- Increasing linearly each year up to a maximum of 400 L/s in Year 22

D.2.10 Reclaim Water

The volume of water available for reclaim to the mill was estimated using the TMF water balance.

The primary TMF inflows are:

- Water being pumped to the TMF from the mill as part of the tailings slurry
- Pit dewatering
- Direct precipitation on and runoff to the TMF, which includes runoff from the upslope catchments and ore stockpiles
- Tailings settling and consolidation seepage
- Cyclone sand cell water recovery, and
- Embankment seepage recycle.

The primary TMF outflows, excluding reclaim to the mill, are:

- Water retained in the tailings and waste rock voids
- Evaporation, and
- Seepage not intercepted by the embankment seepage collection and recycle system.

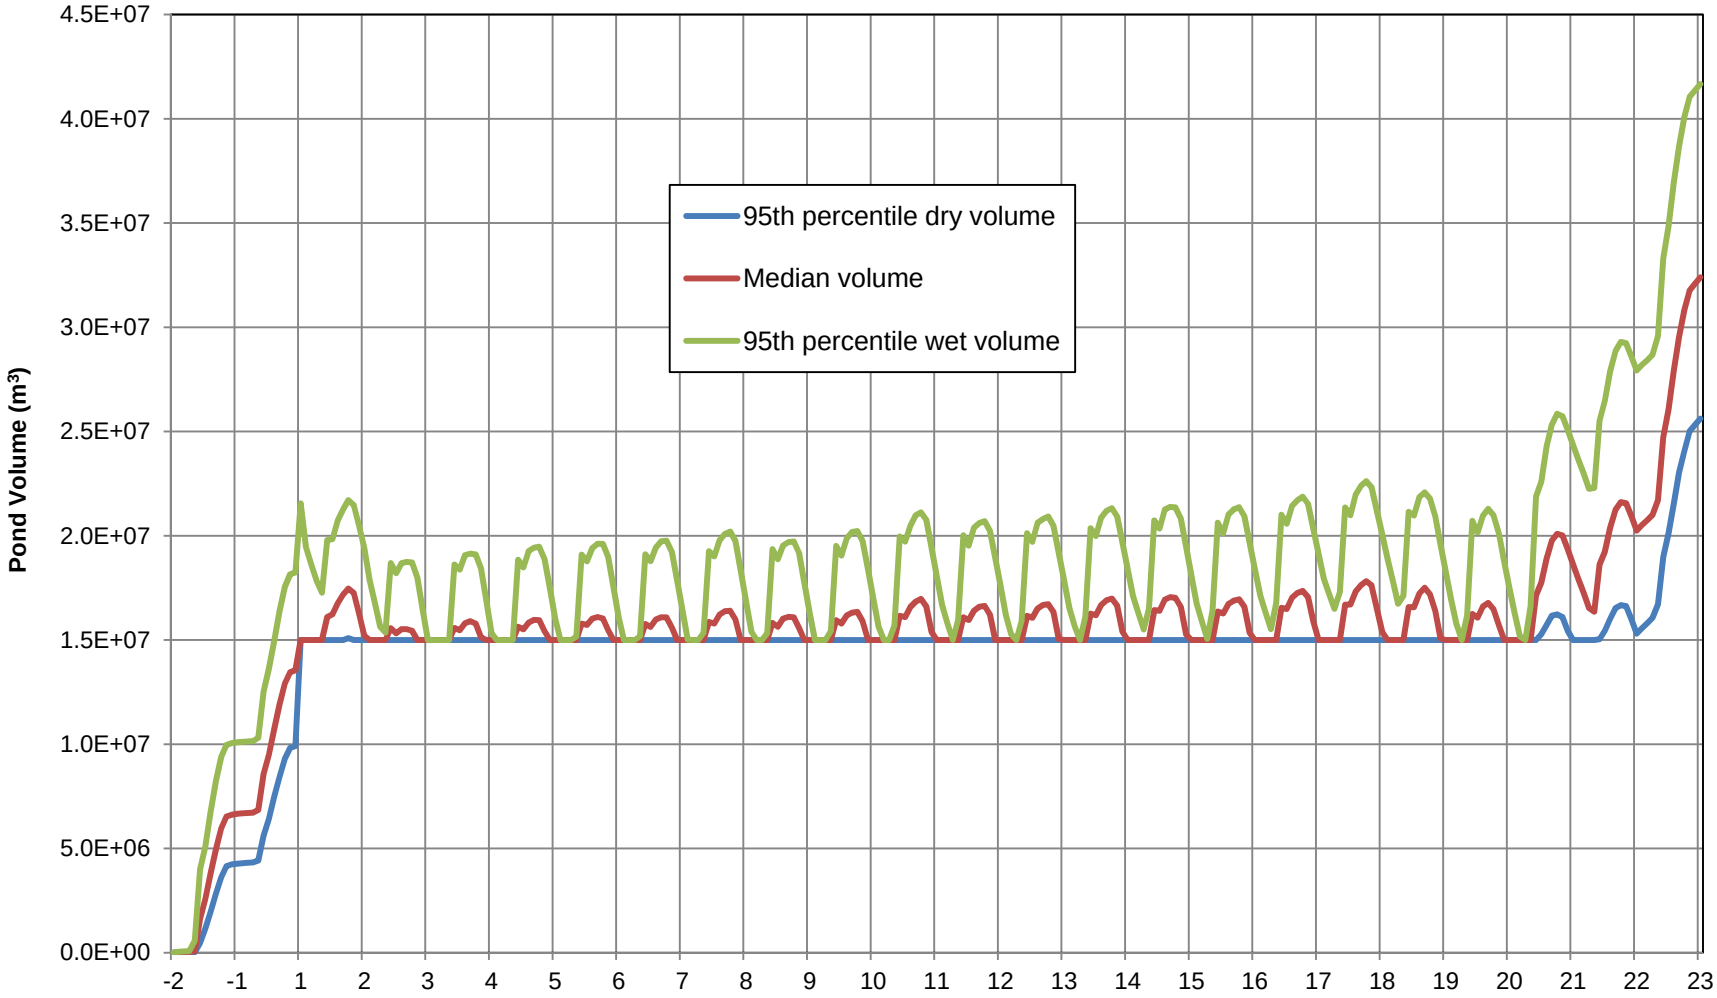
The water available for process use is assumed to be 100% of the difference between these inflows and outflows.

D.2.11 Fresh Water Requirements

The assumed total fresh water requirements at the project site are:

- Mill (operations) – 134 m^3/hr
- Potable water for the camp – 5 m^3/hr during operations

D.3 RESULTS



D.3.1 Model Results

The model results were used to determine the likelihood of having a surplus or deficit for the mine site, as illustrated on Figure D.2. The TMF pond is assumed to have a minimum pond volume of 15 million m^3 (approximately 3 months of slurry water requirements) in all months throughout operations. Therefore, a deficit condition is defined as when the TMF pond volume is at the minimum volume of 15 million m^3 and that the system (including the TMF, open pit, and contributing catchments) is not able to supply enough water to meet the mill process water requirements, thereby indicating the need for make-up water. Figure D.2 presents the range of possible cumulative pond volumes that in the TMF over the life of the mine, as defined by the 95th percentile wet and dry values (5% and 95% chance of being equalled or exceeded in any year, respectively). This range of volumes can also be thought of as the required active, or “live”, storage capacity of the TMF pond for a reasonably large range of anticipated climatic conditions. It was

assumed that a TMF start-up pond would be allowed to accumulate over two freshet seasons rather than one, thereby increasing the potential start-up water volume.

The TMF is able to accumulate a start-up pond volume of at least 15 million m^3 by the start of Year 1 for all climatic conditions. The stored water in the pond from Year 1 onward is slowly consumed by void spaces in the tailings and waste rock and the TMF pond volume is at the minimum of 15 million m^3 during some months in each year. During these months, the system operates in a deficit condition and requires additional makeup water, under the range of climatic conditions represented in the modelling. The process make-up water requirements from an outside source, for the range of modelled scenarios, are presented in Table D.6. The 5^{th} percentile and 95^{th} percentile scenarios shown correspond to the 95^{th} percentile wet and dry scenarios on Figure D.2, respectively. The maximum annual makeup water requirement occurs in Year 3. This is due to an increase in the volume of waste rock saturated by the TMF pond in that year, resulting in more water being lost to the waste rock voids.

It should be noted that the water balance results are very sensitive to the input values, which are best estimates based on the currently available information.

NOTES:

1. TMF MINIMUM POND VOLUME IS ASSUMED TO BE 15 MILLION m^3 (3 MONTHS PROCESS WATER REQUIREMENT).

EXECUTIVE SUMMARY

This document presents the feasibility study (FS) design for tailings cyclone and transport developed for Knight Piésold (KP) for the Casino mine project. The design has been prepared to a level appropriate for the development of capital costs to an accuracy of +15/-15%.

Paterson & Cooke (P&C) compiled aterial take-offs (MTOs) and power consumption estimates to support the development of the capital and operating cost estimates by others. The MTOs and power consumption estimates are presented in Appendix E and Appendix F respectively of this document.

Overall schematic of the proposed system is presented on the diagram.

Sand recovery in the cyclone plant is 50.2%, which was agreed with a cyclone vendor. The cyclone plant will be generating 2,138t/h (42,950tpd) or 11,75mln t/y of sand. This is based on:

- 120,000tpd run of mine (ROM)
- 1% of ROM as concentrate
- 80% of all tailings are NAG tailings feeding the cyclone plant
- 9 out 12 months of the cyclone plant operation
- 93% process plant availability
- 90% cyclone plant availability.

At a late stage of the study, a new production schedule was issued. The new throughput (46,249,000 tpy or 126,700tpd) is approximately 5% (5.6%) higher than the old throughput used by P&C (43,800,000 tpy or 120,000tpd). The new production rate is within the design factor of 15%. Consequently the cyclone plant design is capable of handling the new throughput.

High level summary for the system is presented in the following table.

TAILINGS CYCLONE AND TRANSPORT SYSTEM	
System overview	The thickened non-acid generating (NAG) tailings (nominal process values: 4,258 tph, 5,064 m^3/h, 55%m) flow by gravity from the mill to the cyclone plant. For approximately nine months of each year, the NAG tailings are processed in a single stage of cyclones to produce sand as cyclone underflow for the Tailings Storage Facility (TMF) embankment construction. The cyclone overflow material (fine tailings) is discharged directly into TMF on the upstream impoundment side of the dam. During the three winter months (and when the cyclone station is offline), the tailings bypass the cyclone plant and are deposited directly into TMF through the cyclone overflow pipeline. In order to feed the cyclones at optimum solids concentration for solids separation, dilution water is required at the cyclone plant. This dilution water is pumped directly from the TMF pond by barge and intermediate pumps (by others) to a water header tank located at the cyclone feed tank. Two jacking headers are provided; one for the cyclone underflow and the second for the cyclone overflow pipe line to match the piping lift rate with the rise rate of the dam crest. In the beginning of operation both sand and fines flow under gravity from the cyclone plant to the jacking header on the dam. Ten (10) ceramic orifices are required to slow down sand slurry in the downhill pipe. Orifices are gradually removed with the dam build up. As the dam further rises, centrifugal pumps are progressively added for pumping sand and fines to the dam.
Sand (Cyclone U/F) distribution	Year 1 to 5 – no pumps, gravity flow, pipe with ceramic orifices for energy dissipation Year 6 to 11 – 1 stage pumping Year 12 to 18 – 2 stage pumping Year 19 to 22 – 3 stage pumping.
Fines (Cyclone O/F) distribution	Year 1 to 12 – no pumps, gravity flow, no ceramic orifices Year 13 to 22 – 1 stage pumping.
Major equipment	Cyclones: Weir Cavex or similar One cyclone cluster with 10 operating plus 2 standby 800mm diameter cyclones Pumps Cyclone U/F: Warman 16x14 AHP or similar with 671kW motors and VFDs Operating/standby sets Pumps Cyclone O/F: Warman 650L or similar with 2000kW motors and VFDs Operating/standby set Orifices: 10pcs, cyclone U/F distribution in year 1 to 5 ID=254 mm (10”) on 18” pipe, 8m head loss per orifice
Pipelines	Cyclone U/F: 18” CS with ceramic liner for first 250m of pipe (slack flow conditions) 18” CS sch 80 for reminder pipe section (full pipe flow conditions) Cyclone O/F: 36” HDPE DR 11 for first 850m of pipe on the sloped section 32” CS std sch for jacking header section This pipe carries also the cyclone bypass during the three winter months in each year and during times when the cyclone plant is by-passed.
Key assumptions and considerations	▪ The mass balance was developed based on nominal process plant feed of 120,000 metric tons per day

TAILINGS CYCLONE AND TRANSPORT SYSTEM	
	▪ Design factors are +15/-10% from nominal plant feed ▪ Life of Mine (LOM) is 22 years ▪ NAG tailings solids concentration: 55%m ▪ The turn down requirement is 60% of nominal throughput ▪ Weather conditions, stringent sand quality and sand yield specifications necessitated the use of a central cyclone station instead of mobile cyclone rigs on the crest ▪ Due to high cost, cyclone plant is not considered to be relocated over LOM ▪ The cyclones are fed by gravity from an elevated feed tank to eliminate pumping ▪ The cyclone underflow pipes special protection (lined pipe, ceramic orifices) ▪ The slurry pipelines are not insulated and are to be drained to prevent freezing ▪ The high crest rise rate and high flow rates necessitates the use of jacking headers across the crest. ▪ Dam construction is by cell fill and mechanical compaction.
Risks and mitigation plans	▪ Lack of slurry rheology data. This was mitigated using conservative safety factors and historical data from similar copper operations. ▪ High pipeline wear in sloped sections (slack flow). This was resolved through the use of ceramic orifices to dissipate energy and reduce slack flow section lengths and ceramic lined pipes on remaining slack flow pipe section. ▪ Maximized plant availability; standby pumps provided, standby cells for sand deposition ▪ Sanding of the cyclone underflow pipeline. Mitigated through proper design and flush water availability along the whole sand pipe ▪ Large turn down ratio requirement to 60% of nominal plant throughput. This risk was eliminated through the use of a smaller diameter sand pipeline to the midslope ▪ Freezing of pipeline contest. Water pipelines are fitted with heat tracing and insulation. Slurry pipelines must be drained for shutdowns longer than two hours ▪ Valve malfunction due to freezing. Mitigated through insulation and heat tracing ▪ Pipeline failure. Drainage construction to ensure that all spillage are directed to the tailings pond.
Alternatives investigated	▪ Single versus two stage cycloning ▪ Various pipes materials for cyclone overflow and underflow to reduce wear ▪ Relocation of the cyclone plant over life of mine to higher elevation ▪ Location of the cyclone plant upstream of the saddle dam.
Future work	▪ Slurry testing is required to confirm hydraulic performance, particularly for cyclone underflow system ▪ Pipeline support analysis (including a seismic stress analysis)

1. INTRODUCTION

1.1 Background

The Knight Piésold (KP) from Vancouver office commissioned Paterson&Cooke (P&C) to prepare feasibility study (FS) level designs for Tailings Cyclone and Transport for the Casino Project. The designs have been prepared to a level appropriate for the development of capital and operating expenditure estimates to an accuracy of +15/-15%.

Paterson & Cooke compiled material take-offs (MTOs) and power consumption estimates to support the development of the capital and operating cost estimates by others. The MTOs and power consumption estimates are presented respectively in Appendix F and Appendix G of this document.

This report presents a technical description of the designed system.

1.2 Reference Documents

Document	Abbreviation
P&C Design Criteria Document, R01 Rev C, November 1, 2012.	P&C R01

1.3 Scope of Work

The design scope of work is shown in the table below.

Discipline	Description
Mechanical	The specification of mechanical equipment within the process battery limits is **included.**
Piping	The specification of piping within the process battery limits is **included.**
Tanks & Platework	The specification of tanks and plate work within the process battery limits is **included.**
Civil & Structural	Civil design (grading) for cyclone plant building and tanks benches is **included**. Jacking header structural design is **included**. *Note: P&C uses a sub-contractor in the compilation of the structural component MTOs.* Structural steel design and concrete for cyclone plant building and tanks is **excluded**.
HVAC, fire protection	Heating, ventilation and fire protection is **excluded**. Diesel or propane (non-electrical system) is used for cyclone plant heating.
Electrical	All electrical work within the process battery limits is **excluded.**

Discipline	Description
	Power consumption (kWh) for the cyclone plant and tailings distribution systems is **included**.
Control and instrumentation	Instrumentation requirements within the process battery limits are indicated on P&ID drawings. Higher level control (connection, programming) at the overall plant control system is **excluded.**
Costing	Costing is **excluded** for all items within the scope of work described above. The operating costing is **excluded.** Power consumption is **included**. Labor costing is **excluded**. *Note: P&C provided Material Take-Offs (MTOs) for the cost estimate.*
Services	Services (dilution water, clean water) outside battery limit are **excluded**.
Compressed Air	Compressed air system for cyclone plant operation is **included**.

The process battery limits are detailed in the table below:

Stream	Battery Limits
NAG Tailings Feed	At the inlet to the cyclone feed tank.
Cyclone U/F	At the discharge points on the tailing storage facility.
Cyclone O/F	At the discharge points on the tailing storage facility.
Dilution/Flush water (Reclaim water)	At the discharge of the reclaim water into the dilution water head tank. Reclaim water pumping and piping is the scope by others.

1.4 Appendices

Appendix	Description
A	Design Criteria
B	Paterson & Cooke Drawings
C	Hydraulic Grade Line Plots
D	Equipment List
E	Material Take-Offs
F	Power Consumption
G	Report for Structural Design of Jacking Headers
H	U/f Pipeline Material Selection – Value Engineering

1.5 Units

Metric units are used for this project. Pipes and valves sizes are reported in inches.

1.6 Abbreviations

The following abbreviations are used in this report:

amsl	above mean sea level
CS	carbon steel
FS	feasibility study
HDPE	high density polyethylene
KP	Knight Piésold
LOM	life of mine
m^3/h	cubic meters per hour
MTOs	material take-offs
NPV	net positive value
NAG	Non-acid generating (tailings)
O/F	overflow
P&C	Paterson & Cooke
PD	positive displacement
PSD	particle size distribution
RL	rubber lined
Sch	schedule
Std	standard
TMF	tailings storage facility
U/F	underflow
t/h	metric tons per hour
VFD	variable frequency drive
%m	solids percentage by mass.

2. CYCLONE FEED

2.1 Overview

Thickened NAG tailings from processing plant at solids concentration of 55%m report to the cyclone feed tank, which also receives pond reclaim water to dilute the slurry feed stream to an optimum solids concentration of 36%m for classification in the cyclones. Tailings after dilution flow under gravity from the tank to the cyclones for processing.

The baffles and valving arrangements around the cyclone feed tank allow bypassing of the cyclones and discharging of undiluted NAG tailings upstream of the dam through the cyclone O/F

distribution system. The tank has an emergency overflow into the emergency spillage pipeline to the nearest point of the TMF.

In case of upset condition in the concentrator, which could result in a turndown to 60% of nominal NAG tailings production, the tailings are diluted to 36%m at the process plant. As a result no dilution in the cyclone feed tank is required.

2.2 Key Assumptions and Consideration

The following considerations played a role in the design:

- The feed tank is elevated above the cyclone plant to allow feed the cyclones by static head from the cyclone feed tank therefore eliminating pumping of the high volume cyclone feed stream.

2.3 System Description and Operation

2.3.1 Cyclone Feed Tank

The tank is presented in Appendix A on P&C's Drawing #5277-1-304, "Cyclone Feed Tank General Arrangement". The tank elevation was established based on hydraulic calculations for the cyclone feed pipe, which operates under static head from the tank and the required cyclone feed pressure. Hydraulic performance of the system is presented in Appendix C on P&C's Drawing #5277-1-201, "Cyclone Feed Hydraulic Grade Line Plot".
The concrete tank has four compartments. The NAG tailing stream and dilution water report to the first compartment, where mixing, stilling and de-aeration occur. The diluted slurry flow over a baffle to feed the cyclone cluster through a rubber lined 38" carbon steel pipe. The overflow compartment has a total height of 6.0m, or 5.0m above the top of the feed pipe. As a result, 5 meter is available for level fluctuation for slurry feeding the cyclones.

Should the cyclones have to be bypassed, the 38" cyclone feed pipe can be isolated with a knife gate valve. The slurry level increases in the overflow compartment, until it reaches an overflow weir. Slurry overflows this weir to a bypass compartment piped through the cyclone plant to the cyclone overflow distribution system for deposition on the upstream side of the tailings dam. In addition, a 24" gate, flush with the cyclone feed tank bottom, provides a connection between the main and bypass tank compartments. The gate is opened during the bypass operation, allowing settling solids to report to the bypass, as the overflow weir is 6 m above the tank bottom.

The tank has also another overflow weir, 1 m above the first one, which takes all tank overflows and spillage in emergency situations to the fourth overflow compartment. The emergency

overflow feeds into the 42" emergency spillage line, which takes the spillage to the nearest location of the tailings pond.

2.3.2 Pipelines

The following piping is used for cyclones feed:

38" CS pipe std schedule with 6mm rubber lining, 100m long.

2.3.3 Valves

All slurry valves are knife gate slurry Clarkson KGD, KGA or equivalent. Valves 8" and above are fitted with air actuators.

2.4 Risks and Mitigation Plans

- All valves located outdoors are insulated and heat traced.
- The cyclone feed pipe is insulated. A drain valve, located within the cyclone plant, is provided to allow drainage of the cyclone feed line.
- Any spillage is carried to the tailings pond through a 42"emergency spillage pipe.

2.5 Alternatives Considered

P&C considered locating the feed tank at the same location as the cyclone plant, using a feed pump instead static head for feeding the cyclones. This option was discarded as more costly and complex.

2.6 Future Work

More detailed hydraulic calculations should be done for cyclone feed system, when slurry rheology data is available.

3. CYCLONE PLANT

3.1 Overview

The NAG tailings are diluted to 36%m before classification by single stage cycloning. Cyclone U/F (sand) is collected in the U/F tank and reports to the sand distribution system on the tailings dam. The cyclone O/F (fines) reports to the O/F tank and are further carried to the fines distribution system on the tailings dam.

The cyclone U/F solids concentration is around 74%m. This sand material is diluted to 65%m for ease of hydraulic transportation. As a result, dilution water is added the cyclone cluster U/F collection launder to control solids concentration for the sand. The water addition control valve is in control loop with a sand slurry density meter, located on a sample circulation loop.

Cyclone O/F is disposed through its piping to the dam as is.

During winter months (3 months/year) the sand construction activities cease. The cyclone section is by-passed entirely during that time. The undiluted whole stream NAG tailings report to the cyclone O/F tank and are discharged to the TMF through the same piping used for cyclone O/F distribution. The cyclone section is also by-passed during planned and unplanned non-availability of the cyclone section or lack of sand demand.

As the dam grows over LOM, slurry pumps for cyclone U/F and O/F are added, when required. The pumps are located in the cyclone plant building.

In addition, the cyclone plant is provided with a sand sampling system, gland water for slurry pumps, compressed air system and HVAC system.

3.2 Key Design Assumptions and Considerations

The following considerations played a role in the design:

- Early calculations showed that the sand quality and sand yield required for the sand construction can be achieved in a single cyclone stage. This reduces the capital and operating cost of a cyclone sand construction options significantly.
- A central cyclone station was chosen to ensure sand product quality and yield even during adverse weather conditions.
- The cyclone section is placed in a building to promote reliable and consistent cyclone control even during poor weather conditions, thus promoting an extended sand construction season.
- Due to the high cost of relocation of a complete building in a remote location the option of staged locations for the cyclone feed tank and cyclone plant was not considered.
- Sand recovery in the cyclone plant was verified with the cyclone vendor and is used throughout the design as 50.2%.
- Cyclone plant availability is assumed to be 90%.

3.3 System Description and Operation

3.3.1 Building

A pre-engineered building is provided for the cyclone plant.

The building is constructed in two phases. In the first phase the building is of LxWxH of 34x26x20m. In year 5, when the first set of sand pumps are added, the building to be expanded by 2 bays and the total length to be 46m.

The building contains the following features:

- A 15 metric ton overhead crane, sufficient for maintenance of the large slurry pumps
- A drive through maintenance bay within the building
- A 5% sloped floor to a sump to contain spillage
- Diesel (propane) heating, ventilation (out of P&C's scope, to be sized and selected by others)
- A leveled pad, filled with gravel, around the building for storage, trucks and maintenance equipment maneuvering.

It is anticipated that electrical rooms are in separate structures attached to the cyclone plant building (out of P&C's scope, to be sized and selected by others).

3.3.2 Cyclone Cluster

The relatively coarse grind makes possible the use of large diameter cyclones. The advantage of larger diameter cyclones is that a single cluster is sufficient which results in a smaller building. The cyclone cluster consists of twelve 800mm diameter Weir CAVEX cyclones. Ten cyclones are required to handle the design tailing tonnage of 4,258t/h. Two spare cyclones have been provided for maintenance and surge flows.

Through automatic control the cyclones can be switched into and out of operation. This and the ability to vary are the primary control parameters to ensure that a correct cyclone feed pressure are maintained.

The plant turn down to 60% of capacity is achieved by switching off cyclones to maintain the necessary feed pressure to the remaining operating cyclones.

3.3.3 Process Tanks

Cyclone U/F Tank.

Features	Description
Function	Collecting classified sand from cyclone U/F launder, 45deg sloped floor, feed tank for pumps
Material	Concrete
Location	Inside the cyclone plant building
Dimensions	LxWxH of 4.0x3.2x4.0m
Insulation	None
Retention time	40 seconds for nominal conditions.

Cyclone O/F Tank.

Features	Description
Function	Collecting fines from cyclone O/F launder, 45deg sloped floor, feed tank for pumps
Material	Concrete
Location	Inside the cyclone plant building
Dimensions	LxWxH of 6.2x5.5x5.0m
Insulation	None
Retention time	40 seconds for nominal conditions.

3.3.4 Slurry Process Pumps

During the initial years of operation, the elevation difference between the cyclone plant and the dam, there is enough static head to push by gravity cyclone U/F and O/F to the deposition points. Starting in year 5, due to dam development, pumps are gradually added to transfer sand and fines to the deposition points.

The pumps are described in the tables below:

Description	Cyclone U/F (sand)
Model	Warman 16x14AHP or similar heavy duty centrifugal pump with gland seal water
Duty point	2,236m^3/h @ 43m (flow sheet flow rate x 1.15)

Description	Cyclone U/F (sand)
Motor	671kW with VFD
Installation schedule	year 1 to 5 no pumps, gravity flow year 6 to 11 1 stage pumping year 12 to 18 2 stage pumping year 19 to 22 3 stage pumping
Standby	One operating train + standby train

Description	Cyclone O/F (fines) or thickened NAG tailings
Model	Warman 650L or similar heavy duty centrifugal pump with gland water
Duty point	8.748m^3/h @ 60m (flow sheet flow rate x 1.15)
Motor	2,000kW with VFD
Installation schedule	year 1 to 12 no pumps, gravity flow year 13 to 22 1 stage pumping
Standby	One operating pump + standby pump

3.3.5 Sand Sampling

The cyclones generate U/F with a solids concentration of 74%m. Dilution water is added at a controlled rate to keep target solids concentration of 65%m for deposition. A nuclear density meter installed on cyclone U/F sample circulation pipe is used to control the dilution water.

The sand sample pump draws sand slurry from the bottom of cyclone U/F tank and pump back to the top of the same tank. A density meter is installed on the 2" pump discharge piping. In addition, a sand sample port is available.

An air operated 1 ½" diaphragm pump is envisaged as sand sample pump.

3.3.6 Compressed Air System

Compressed air is used for instrumentation and the running of the sand sample pump. The air is dried in a desiccant air type dryer to prevent freezing of moisture in the compressed air system.

The compressed air package consists of:

- 11kW compressor providing 100m^3/h of air at 780kPa (110psig)
- Desiccant air dryer sized for 100m^3/h
- An air receiver.

3.3.7 Piping

The table below describes main pipes used in the cyclone plant:

Description	Pipe Size	Pipe Spec	Notes
Cyclone O/F to O/F tank	40”	CS std, 6mm RL	Partially filled pipe
Cyclone U/F to U/F tank	32”	CS std, 6mm RL	Partially filled pipe
Cyclone bypass (undiluted tailings)	32”	CS std, 6mm RL	Full pipe flow
Main spillage header from the cyclone plant	42”	HDPE DR 17	Partially filled pipe
Cyclone U/F to tailings dam	See section 4.0 of this document		
Cyclone O/F to tailings dam	See section 5.0 of this document		
Sand sample	2”	CS std sch, 6mm RL	-
Water distribution piping	See section 6.0 of this document		
Gland water piping	See section 6.0 of this document		
Compressed air piping	1” to 2” SS316 welded		

3.3.8 Valves

The following valves are used in the cyclone plant.

Slurry:

All slurry valves are knife gate slurry Clarkson KGD or KGA or equivalent. All valves 8” and above are air actuated.

Water:

See Section 6 of this document.

3.4 Risks and Mitigation Plans

- Spillage in the plant - 5% sloped floor, large sump and 42” spillage pipe to TMF
- Pipe plugging – flow velocities above deposition conditions, flushing water system available, wash stations
- Arctic conditions – heated building, dried compressed air
- Equipment failure – standby cyclones and pumps provided to keep the plant running
- Components wear – rubber lined piping, standby equipment, heavy duty pumps and valves.

4. CYCLONE U/F (SAND) DISTRIBUTION SYSTEM

4.1 Overview

Sand, at 65%m solids concentration, is to be deposited through a piping system on the downstream embankment side of the tailings dam. The system consists of four sections:

- A 18" downhill pipe
- A 18" horizontal pipe on the sand jacking header
- 14" downhill pipes – from jacking header
- 14" downhill pipe – jacking header bypass for high turn down throughput requirements.

The 18" sand pipeline initially follows the 15% site gradient down towards the dam. At the tailings dam the pipe continues on a jacking header. 14" take off valves every 100m from the main pipeline for deposition. Each take-off valve is connected to a mobile 14" HDPE DR 11 pipe, running downhill on the dam to 100 m by 20 m sand deposition cells. Each 14" individual branch pipe is capable of transporting the full sand plant production to fill a cell at a time.

4.2 Key Assumptions and Considerations

The following considerations played a role in the design:

- Slurry piping is not insulated. Only flush water pipe is insulated and heat traced.
- The cyclone U/F piping will experience high wear. P&C scaled wear rates for carbon steel piping from similar copper tailings applications and the summary is presented in the table below.

Description	Average slurry velocity, m/s	Estimate wear mm/1000h
Cyclone U/F in slack flow	11.0	9.16
Cyclone U/F in full pipe flow	3.7	1.5

4.3 System Description and Operation

The hydraulic performance for the sand distribution system for years 1, 3, 6, 12, 19 and 22 is shown in the Appendix C.

4.3.1 Downhill Pipeline

In the first years of operation, due to high elevation difference between the cyclone plant and the dam, the static head pushes the cyclone U/F to the deposition points. The upper section of the

pipe, with a slope of 15%, operates in slack flow (partially filled pipe) regime. For example, in the first year of the project the slack flow section is estimated to be on the first 600m of the sand pipe. In the following years, slack flow section is shortened, as backpressure builds up due to the dam growth. Eventually, by year 5, all extra head and associated slack flow disappears. Pumps are added to transfer sand to the deposition points.

Slack flow and associated high sand slurry velocities, up to 11m/s, creates very high wear in the sand piping. P&C estimates that 18" carbon steel pipe of Schedule 80 has to be rotated roughly every 100 days and replaced once a year. A value engineering trade off study for optimum pipe material selection was done. The full trade-off study is presented in the Appendix H.

The main findings from the trade-off study are presented in the table below:

Option for sand pipe material on the sloped section	**NPV**
Option 1: CS Sch 80 pipe, no orifices, no ceramic lining	$4,1mln
Option 2: CS Sch 80 pipe, orifices, no ceramic lining	$2.0mln
Option 3: no orifices, ceramic lined pipe	$1,3mln
Option 4: orifices, ceramic lined pipe	**$0.8mln**

P&C selected option 4, as it represents lowest cost for the project.

In the trade-off study P&C did not consider HDPE pipe, as CS outperforms HDPE for slurries with coarse particles.

Overall the recommended sand pipe configuration on the downhill section is as follows:

- Ceramic orifices.
  Orifices keep backpressure in the pipe to minimise the slack flow. Initially, 10 orifices are installed, one every 50m, on the downhill section of the pipe. Each orifice provides a head dissipation of 8m, which is equivalent of 55 m pipe on 15% slope. As the dam rises, one orifice should be removed from the system for every 8m of dam build up, to maintain the hydraulic performance of the system. All orifices are selected with openings of 254mm in 450mm (18") pipe and all of them should be removed from the pipe by year 5.
- Ceramic lined CS pipe.
  P&C recommends using ceramic lined CS pipe in the top section (250m) of the 15% sloped sand pipeline. This is the section, which by design has to be exposed to slack flow and high wear. This pipe section provides a safe margin preventing the sand slurry pipeline from backing up and overflowing to the cyclone plant. Pressure transmitters along the sloped pipe monitor the location of the transition between the slack flow and full bore flow. Once the sand pipe is backing up too close to the cyclone plant an orifice is removed from the pipe.

- CS pipe Sch 80
  The lower section of the sloped pipe is not exposed to slack flow and associated high wear. As a result a schedule 80 carbon steel pipe is sufficient. The same pipe schedule is used on the jacking header.

After year 5, when all orifices have been removed and sand pumps have to be installed progressively, the downhill pipe operates at full flow regime with velocity of around 4 m/s. Pipe wear is not be substantial, but of course should still be monitored. The pipe needs to be rotated to extend its life.

The downhill pipe on the ground is gradually lifted and placed on the expanding dam and jacking header.

4.3.2 Pipe on Jacking Header

A flexible slurry hose serves as transition piece between the downhill pipeline and pipeline on the jacking header. The sand pipeline on the jacking header is 18" CS Sch 80, non-insulated pipe. P&C evaluated using CS sch 40 pipe or ceramic lined pipe, but in both cases the NPV was higher than for CS Sch 80 pipe.

Overall, the sand pipe on the jacking header is provided with:

- 14" take-off valves, every 100m for individual deposition pipes
- 10" flush water connections with 10" water valves
- 18" shut-off valves to isolate sand pipe sections and be able to flush them with water
- Pressure gauges to monitor sand pipe performance
- 300# flanges to provide better pipe stiffness during jacking header lifting.

The pipe and jacking header is expanding over LOM, as the dam length grows.

The table below shows jacking header lengths for some typical years:

End of Year	Crest/Jacking Header Length (m)
Initial (-1)	868
1	868
3	1,450
5	1,610
7	1,832
12	2,061

End of Year	Crest/Jacking Header Length (m)
19	2,363
22	2,460

The sand pipeline on the jacking header is configured to run to the middle of the dam without any tees, further from the dam center, it branches to the two opposite directions of the dam ends. The take-off valves to the sand deposition cells are located after the main splitting tee. As a result, the sand pipe is longer, but because the system is symmetric, has more stable hydraulic performance. This scheme is indicated on P&ID #5277-2-103, "Cyclone Sand Distribution" in the Appendix A.

4.3.3 Downhill Piping off the Jacking Header

Sand deposition to individual cells is through pipes branching off the 18" main pipe on the jacking header. The branches are every 100 m with 14" knife gate valves hydraulically actuated. A manual pinch valve is located downstream of the knife gate valve to allow the adjustment of the flow.

Each 14" take-off pipe is capable of handling the full cyclone plant sand production. These pipes are laid at the same slope of the dam (3:1). Consequently the pipes are exposed to high wear. The pipes are constantly relocated, to suit sand deposition requirements. It is recommended that at all time, at least one pipe/cell set is kept available as standby to maintain a high system availability. After every sand placement campaign, the downhill pipe should be flushed with water.

4.3.4 Downhill Pipe – Jacking Header Bypass for Upset Conditions

In case of a concentrator upset condition, which could result in a throughput turn down to 60% of nominal NAG tailings production, the jacking header pipe cannot be used, as the horizontal pipe would plug because of low flow velocities. In such a case the sand tailings are diverted, before jacking header, to a 14" HDPE DR 11mid slope pipe. Solids deposition does not occur; as the pipe is continuously sloped, running downhill to the embankment's mid slope areas. This downhill pipe is capable of transporting the normal sand production to the mid slope, when the jacking header is down. This means that sand is conserved, even in upset conditions.

4.3.5 Structure for Sand Tailings Jacking Header

The jacking header is a structure on piles, which is hydraulically lifted as the dam rises. Lifting is achieved with hydraulic power packs, which are connected to hydraulic jacks located on each pair of piles. Jacking header piles is spaced every 15m.

The jacking header consists of:

- 12" carbon steel pipe piles on concrete foundation

- 18" sand pipe
- 12" flush water pipe
- Supporting structure
- 1m wide walkway with handrails
- Power cable tray
- Lights
- Hydraulic jacks, on each pair of piles, spaced every 15 m
- Take-off valves, every 100m typically.

5 mobile power packs provide lifting capacity for 5 hydraulic jacks (5 towers, or 60m of pipe) at any time. Each hydraulics pack has a lifting capacity up to 30 metric tons. The hydraulic power packs are moved and shared with the O/F jacking header.

As the dam expands the jacking header is expanded too; new piles (pipes) with support structure are added. Vertical pipes are extended by welding on of new sections. Materials for the header expansion are captured in MTOs.

The jacking header was designed by SMRC Structural Engineers, who were sub-contracted to P&C. More detailed description for the jacking header, drawings and MTOs are presented in the Appendix G.

4.4 Risks and Mitigation Plans

- Freezing of valves - all valves located outdoors are insulated and heat traced
- Plugging of the sand pipe – provision of a flush water pipe on the jacking header
- Freezing of the flush water pipe – provision of insulation and heat tracing
- Horizontal sand pipe plugging on the jacking header during process plant upset conditions (lower throughput) – provision of bypass piping, continuously sloping to prevent solids settling.

4.5 Alternatives Considered

Various pipe materials were considered for sand piping, see Appendix H for details.

4.6 Future Work

- More detailed hydraulic calculations.
- More detailed operation strategy should be evaluated, which may affect features of the pipeline.
- Weather enclosure may be considered for jacking header.

5. CYCLONE O/F (FINES) DISTRIBUTION SYSTEM

5.1 Overview

This system handles the cyclone O/F stream as well as the undiluted NAG tailings stream when the cyclone station is by-passed.

The system consists of three sections:

- A 36" HDPE DR 11 downhill pipe
- A 32" CS Std Sch horizontal pipe on jacking header
- 16" HDPE DR 17 take-off pipes from the jacking header.

The cyclone O/F pipeline initially follows the 15% site gradient down to the dam. On the tailings dam the pipe is laid on a hydraulically raised jacking header, which is a separate structure from the sand jacking header. 16" take-offs with valves are placed every 100m. Each take-off valve is connected to a 16" HDPE DR 17 pipe running down from the jacking header onto the beach of the impoundment of the tailings storage facility.

In case of a concentrator upset condition, which could result in a throughput turn down to 60% of nominal tailings production, this piping system can still handle the cyclone O/F. Fine solids are not as sensitive to settling, even at lower velocities. However, when the cyclones are bypassed, it is recommended that either the cyclone plant emergency spillage system is used to dump the undiluted NAG tailings at the nearest point of the tailings pond, or the NAG tailings are diluted in the overflow box to eliminate risk of plugging of 32" CS pipe on the horizontal jacking header with undiluted NAG tailings.

5.2 Key Assumptions and Considerations

The following considerations played a role in the design:

- The slurry piping is not insulated.
- P&C scaled wear rates for carbon steel piping from similar copper tailings applications and the summary is presented in the table below.

Description	Average slurry velocity, m/s	Estimated CS pipe wear mm/1000h of operation
Cyclone O/F in slack flow	12.6	N/A, thick wall HDPE pipe used on project

Description	Average slurry velocity, m/s	Estimated CS pipe wear mm/1000h of operation
Cyclone O/F in full pipe flow	4.2	0.01
Cyclone bypass in slack flow	11.0	N/A, Thick wall HDPE pipe used on project
Cyclone bypass in full pipe flow	2.8	0.1

5.3 System Description and Operation

Hydraulic performance for the system handling cyclone O/F for years 1, 13, and 22 are shown in the Appendix C.
Hydraulic performance for the system handling cyclone bypass for years 1, and 22 are also shown in the Appendix C.

5.3.1 Downhill Pipeline

In the first 12 years of operation, due to elevation difference between the cyclone plant and the dam, there is enough head for gravity flow. It is estimated that slack flow occurs on the first 750m of the downhill pipe in the first year of operation. Gradually, by year 13, all extra head and slack flow disappears, and at that point a pump is required to transfer fines and/or bypass to the deposition points.

Slack flow and associated high velocities, up to 10 to 12m/s, create high pipe wear of the pipe. The wear is not that substantial, as in the sand system however. 36" HDPE DR 11 pipe, which has wall thickness of 83mm, is recommended therefore for the downhill section. Thick wall combined with frequent pipe rotation is the most economical solution. The pipe wall thickness should be monitored however.

The downhill section of the pipeline gradually reduces and is replaced by expanding jacking header during LOM.

5.3.2 Pipe on Jacking Header

A flexible hose provides the transition between the downhill pipe section and pipe on the jacking header. The pipe on the jacking header is 32" carbon steel standard schedule and non-insulated. Low wear rates do not justify using thicker wall piping. HDPE cannot be used on the jacking header, as the carbon steel flanged piping provides the jacking heading rigidity. Flush water piping for the cyclone O/F system is not required.

The cyclone O/F pipe on the jacking header is be provided with:

- 16" take-off valves, every 100m for individual deposition pipes
- 32" shut-off valves on the main pipe to isolate sections and redirect the flow to the spigots
- Pressure gauges to monitor pipeline performance
- 300# flanges to ensure stiffness

The pipe and jacking header is expanded over LOMs as the dam grows.

The table below shows the jacking header lengths for some typical years.

End of Year	Dam/Jacking Header Length (m)
Initial (-1)	868
1	868
3	1,450
5	1,610
7	1,832
12	2,061
19	2,363
22	2,460

The piping on the cyclone O/F jacking header is routed as "run through" with the take-off valves and tees. The schematic is given on P&ID #5277-3-103, "Cyclone Overflow Distribution" in the Appendix A.

5.3.3 Deposition Piping off the Jacking Header

The cyclone O/F and cyclone bypass deposition is through 16" HDPE DR 17 pipes from the 32" pipe on the jacking header. Branching is every 100m with 16" hydraulically actuated knife gate isolation valves.

During normal operation 2 to 3 take off valves are open at a time. Each 16" take off valve/pipe set is capable of transporting 50% of cyclone O/F production or 50% of undiluted NAG tailings during the cyclone bypass.

5.3.4 Cyclone O/F Tailings Jacking Header

The jacking header is a structure on piles which is hydraulically lifted as the dam rises. Lifting is achieved with mobile hydraulic power packs which are connected to hydraulic jacks located on

each pair of piles. Jacking header piles are spaced every 15m. The cyclone O/F jacking header is a separate structure from the sand system jacking header.

The cyclone O/F jacking header consists of:

- 10" steel pipe piles on concrete foundation
- 32" CS overflow pipe
- A power cable tray
- Hydraulic jacks, spaced every 15m on each pair of piles
- Valves where required, every 100m typically.

No walkway is provided on the cyclone O/F jacking header. Access to the take off valves is through a manlift.

As the dam expands the jacking header is extended; new piles (pipes) with support structure are added. Vertical pipes are extended by welding. Materials for the header expansion are captured in MTOs.

The jacking header was designed by SMRC structural engineers, who were sub-contracted to P&C. More detailed description for the jacking header, drawings and MTOs are presented in the Appendix G.

5.4 Risks and Mitigation Plans

- All valves located outdoors are insulated and heat traced.

5.5 Alternatives Considered

Various pipe materials were considered for cyclone O/F piping.

5.6 Future Work

- More detailed hydraulic calculations.
- More detailed operation strategy should be evaluated, which may affect features of the pipeline.

6. WATER SYSTEMS

6.1 Overview

Water is used in the following applications:

- Dilution, to control the cyclone feed solids concentration for optimum cyclones performance.
- Dilution, to control solids concentration of the sand for deposition.
- Gland seal for process pumps, after year 6.
- Flushing for sanded pipes, housekeeping, etcetera.

Water supply is by others to the battery limits of P&C scope of work. The battery limit is defined as the top of the dilution water head tank. Distribution system downstream of this point is scope of this study.

Table below shows water system main features:

Main function	**Nominal/Maximum Water Flow (m^3/h)**	**Notes**
Dilution water for cyclone operation	4,088/4,699	• Feed by gravity from dilution water head tank • Dilution NAG tailings from 55%m to 36%m
Dilution water for sand slurry placed on the dam	400/460	• Feed by gravity from water buffer tank • Dilution sand from 74%m to 65%m
Gland water supply	7.2	• Gland water tank in the cyclone plant • PD gland water pumps • One gland water pump for each slurry pump
Flush water	525	• Feed by gravity from water buffer tank • Flow based on 2m/s in 12" delivery pipe
Total water demand @ battery limit	4,493/5,166[1]	

Note 1: Water for flushing is excluded from this number; storage tanks provide capacity for flushing.

6.2 Key Assumptions and Considerations

The following considerations played a role in the design:

- Available water quality is assumed to be as "reclaim water from a typical copper mine", that contains some fine particles.

6.3 System Description and Operation

6.3.1 Dilution Water for Cyclone Operation

It is necessary to dilute the plant NAG tailings from 55%m to 36%m, which is optimum solids concentration for the cycloning process. Water is supplied by gravity from the dilution water header tank to the cyclone feed tank. The water addition is controlled according to nuclear density measurement on the cyclone feed pipe.

Dilution Water Head Tank
The dilution water header tank is located around 1,300 m from the cyclone feed tank on a leveled pad at elevation of 1,035 meter above mean sea level. The tank location/elevation was established based on minimum elevation required to provide gravity flow from this tank to the cyclone feed tank.

Tank features are presented in the table below:

Description	**Water buffer tank**
Material	CS plate, 8 and 6mm
Location	Outdoor, P&C dwg #5277-0-301, "Cyclone Feed and Plant, Site Plan"
Dimensions	DxH 12.5x12.5m
Insulation	50mm polyurethane
Volume	1,530m^3
Retention time	20min for nominal conditions.

6.3.2 Dilution Water for Sand

The cyclone U/F is generated at a solids concentration of 74%m. This stream has to be diluted to 65%m, which is required solids concentration for sand deposition on the dam. Dilution water for the sand deposition is supplied by gravity from the water buffer tank. The water addition is controlled according to the nuclear density measurement on the sand sampling loop.

6.3.3 Flush Water System

This system provides water for housekeeping, flushing plugged slurry pipes, sand jacking header, washing tanks, pumps etcetera. Water is supplied from the water buffer tank. The water pressure is boosted to 500kPa (75psig) by a flush water pump. The tank is located next to the cyclone feed tank. The pump is located in the cyclone plant building.
Tank features are presented in the table below:

Description	Water buffer tank
Material	CS plat, 6mm
Location	Outdoor, P&C dwg #5277-0-301, "Cyclone Feed and Plant, Site Plan"
Dimensions	DxH, 6.1x9.0m
Insulation	50mm polyurethane
Volume	263m^3
Retention time	20min for full capacity of flushing pump.

Flush water pump description is presented in the table below:

Description	Flush water pump
Model	8x10 centrifugal pump with mechanical seal
Duty point	525m^3/h @ 40m
Motor	80kW, no VFD
Installation schedule	year 1
Location	Inside the cyclone plant building
Standby	No standby required.

6.3.4 Gland Water System

The process slurry pumps require clean gland seal water. The gland water system is installed in year 6, along with installation of the first pair of slurry pumps. Each process slurry pump is paired with a dedicated gland seal water pump. In this configuration, the system availability is maximized. Water for the gland seal water service comes from the dilution water system.

The system consists of:

- Filters
  The water is filtered to remove particles larger than 25 microns from dilution water feeding gland water system. The filters are two stage, double basket type with differential pressure transmitters to switch over between dirty and clean filter.
- Gland water tank
  The gland water tank has the following features:

Description	Water buffer tank
Material	CS plate, 6mm
Location	In the cyclone plant building
Dimensions	DxH 3.5x9.6m
Insulation	None
Volume	$92m^3$
Retention time	12h for supplying gland water for all operating slurry pumps (4 in total).

- Gland water pumps

Gland water pump description is presented in the table below:

Feature	Description
Type	Positive displacement, plunger type (similar are used in pressure washers), FMC or equivalent
Duty point	$1.8m^3/h$ @ 2,100kPa ($213mH_20$)
Motor	5kW fixed speed
Installation schedule	year 1 to 5 no pumps year 6 to 11 2 pumps year 12 to 13 4 pumps year 12 to 18 6 pumps year 19 to 22 8 pumps.

6.3.5 Piping

The following piping is required for the water system:

Description	Pipe Size	Pipe Specification	Length (m)	Notes
Dilution water for cyclone feed	36”	HDPE DR 11	1,300	By gravity
Dilution water for cyclone U/f (Sand)	8”	HDPER DR 11	100	By gravity
Gland seal water	1”	CS	~50m in total	Pressure
Flush water	Vary, 12” and	CS	Vary, following	Pressure

Description	Pipe Size	Pipe Specification	Length (m)	Notes
	down		jacking header over LOM	

6.3.6 Valves

The following valves are used for water:

2" and below: manual ball valves

3" to 8": manual butterfly valves

10" and above air actuated butterfly valves.

6.4 Risks and Mitigation Plans

- All valves located outdoors are insulated and heat traced.
- The 12" flush water pipe for the sand distribution system is insulated and heat traced.

6.5 Alternatives Considered

None.

6.6 Future Work

Overall more detailed design for all water systems.

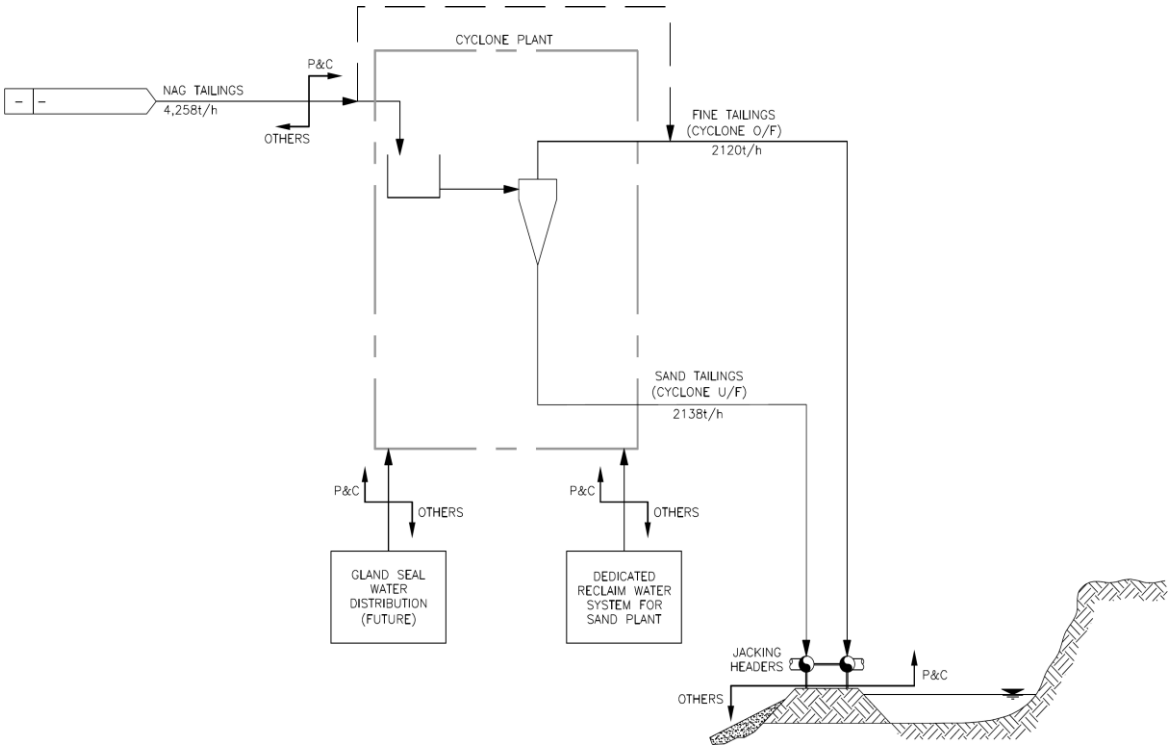
μ_{mf}	carrier fluid viscosity
amsl	above mean sea level
cP	centipoise

2. GENERAL

2.1 Process Description

The tailings from the process are split into two dedicated streams: potentially acid generating (PAG) stream (20% by distribution) and non-acid generating (NAG) stream (80% by distribution). This design criteria document applies only to the NAG tailings.



Rev C

Rev C

The NAG tailings from the milling process will be delivered from the mill to the Cyclone Plant. For approximately nine months of each year, the NAG tailings will be processed in one stage of cyclones to produce sand for the Tailings Management Facility (TMF) embankment construction. The cyclone overflow material (fine tailings) will be discharged directly into TMF impoundment on upstream side of the dam. During the three winter months (and when the cyclone station is offline), the tailings will bypass the Cyclone Plant and be deposited directly into TMF impoundment through the combined cyclone overflow pipeline. In order to feed the cyclones at optimum solids concentration for solids separation, dilution water is required at the Cyclone Plant.

Jacking headers are required for the cyclone underflow and the combined cyclone overflow pipelines to match the piping lift rate with the rise rate of the dam crest.

Rev 0

2.2 Study Level

The design is prepared at the feasibility study level of ±15% accuracy.

2.3 System List

System Name	System Description
Cyclone plant	Consists of cyclone feed box(es), cyclone feed pump(s), 1 stage cyclones, feed conditioning, water dilution system and interconnecting piping
Sand tailings	Consists of collection box, pump(s) and sand distribution pipelines
Fine tailings	Consists of collection box, fine tailings distribution piping and cyclones bypass arrangement.

Rev C

2.4 Process Battery Limits

The process battery limits are detailed in the table below:

Stream	Battery Limits
NAG Tailings Feed	At the inlet to the cyclone station feed box
Cyclone U/F	At the discharge point on the tailings storage facility
Cyclone O/F	At the discharge point on the tailings storage facility
Process water	Top of the dilution water head tank (Process water may be required for flushing, gland seal water or control aspects, such as dilution)

NAG tailings production	118,800*0.8=95,040t/d 95,040/0.93/24=4,258t/h	KP-06
NAG tailings concentration	Nominal 55%m Maximum 60%m Minimum 50%m	KP-06, KP-08

Rev C

Item	Value / Description	Source / Comments
Design factor	+15%, -10% 60% of nominal tonnage expected occasionally	KP-08
TR tailings tonnage	Nominal 4,258 t/h @ 55%m Maximum (+15%) 4,258*1.15=4,896 t/h @ 55%m Minimum (-10%) 4,258*0.90=3,832 t/h @ 55%m	KP-06, KP-08

4.3 Cyclone Plant

4.3.1 Cyclone Station Feed

Rev C

Item	Value / Description	Source / Comments
Cyclone station capacity	100% of NAG tailings production, 9 months of each year	KP-01
Design Factor	+15%, -10% 40% of nominal tonnage expected occasionally	KP-06, KP-08
Cyclone station feed rate	Normal 95,040t/d or 4,258 t/h at 55%m Maximum (+15%) 4,896 t/h at 55%m Minimum (-10%) 3,832 t/h at 55%m	KP-06, KP-08
Cyclone station location	Cyclone station in a heated building (by others), at a location to be determined by P&C. Cyclone Plant relocation during LOM will be minimized.	P&C design
Cyclone station availability	90% during 9 month period	KP-09
Solids density	2,695 kg/m^3	KP-02
Liquid density	1,000 kg/m^3 (water)	Assumption

4.3.2 Cyclone Station

Item	Value / Description	Source / Comments
Cyclone type	Conventional	P&C design
Feed concentration	36% (diluted from 55% as supplied by process plant)	P&C design
Dilution water source	Reclaim water provided by others	P&C design
Cyclone feed pressure requirement	72.4 kPa	P&C design

Item	Value / Description	Source / Comments
Feed mix box retention time	40 seconds	P&C design
O/F box retention time	40 seconds, cyclone O/F piped directly to TMF	P&C design
U/F box retention time	40 seconds	P&C design
Number of spare cyclones	2	P&C design

4.3.3 Dilution Water Head Tank

Item	Value / Description	Source / Comments
Tank bottom elevation	1035m asl	P&C design
Tank height	12.5m	P&C design
Tank diameter	12.5m	P&C design
Tank retention Time	20 minutes	P&C design

4.4 Cyclone Overflow

Item	Value / Description	Source / Comments
Medium description	Cyclone overflow	
Design concentration	23.7%m	P&C design
Pipeline route	As defined in P&C corridor drawings	KP-03 and KP-04
Pipeline design factor for friction losses	10% above calculated to cover minor losses and slurry model accuracy	P&C assumption

4.5 Sand (Cyclone Underflow)

Item	Value / Description	Source / Comments
Medium description	Cyclone underflow	

Cyclone plant sand recovery	50.2%	P&C design and KP-10
Cyclone sand production	Nominal 4,258t/d*0.502=2,138t/d 2,138t/d*0.93*0.9*(9/12)*24*365=11.76mln t/year	P&C calculation
Cyclone sand (U/F) quality	12% passing 74 µm	KP-10
Cyclone U/F solids mass concentration (before dilution)	74%	P&C simulation
Solids mass concentration after dilution for dam construction	65%	KP-09
Pipeline route	As defined on site corridor drawings	KP-03 and KP-04
Design factor for friction losses	15% above calculated to cover minor losses and slurry model accuracy	P&C assumption

Pond Elevation Below Crest	11m in year 1 5 to 6m in years 3 to 13 4 to 3m in years 14 to 22				KP-12

Rev C
General update of the table

7. IMPOUNDMENT

The NAG whole tailings, sand plant by-pass and combined cyclone overflow use the same pipeline and jacking header across the dam crest.

7.1.1 Non-Reactive Tailings Disposal (Sand Plant Bypass)

Item	Value / Description	Source / Comments
Operation	Continuous for 3 months per year, 24 hours per day, 100% of NAG flotation tailings during winter months, also when cyclone station is by-passed	KP-01
Discharge	Take off valves at 100 m spacing. One take off valve open at any time. Each take off valve/pipe branch set sized to carry 100% of full cyclone u/f.	P&C assumption
Availability	90%, matching sand plant availability	P&C assumption

Rev C

7.1.2 Combined Cyclone Overflow Disposal

Item	Value / Description	Source / Comments
Operation	Continuous for 9 months per year, 24hours per day, 100% of combined cyclone overflow	KP-01
Discharge	Take off valves every 100 m spacing. 2 to 3 valves open at any time. Each take off valve/pipe branch set sized to carry 50% of full cyclone O/f or bypass.	P&C assumption
Availability	90%, matching sand plant availability	P&C assumption

Rev C

8. MECHANICAL

Item	Value / Description	Source / Comments
Equipment size/types	Only equipment proven on similar operation will be considered	P&C assumption

8.1 Pumps

Item	Value / Description	Source / Comments
Standby	All pumps to be in operating/standby sets to maximize sand plant availability	P&C assumption

Item	Value / Description	Source / Comments
Centrifugal slurry pump lining material	High-head pumps: metal lining Low-head, low-duty slurry pumps: rubber lining	P&C assumption
Centrifugal slurry pump – seal arrangement	All slurry pumps equipped with gland flush seal arrangement	P&C assumption
Centrifugal slurry pump efficiency	Pump efficiency: from pump curve and duty point Variable frequency direct gearbox drive efficiency: 95%	P&C assumption
Centrifugal slurry pump – maximum impeller tip speed	Class 2 slurry with rubber lining: 28 m/s Class 2 slurry with metal lining: 38 m/s Class 3 slurry with rubber lining: 33 m/s Class 3 slurry with metal lining: 26 m/s	P&C assumption, ANSI/HI 12.1 -12. 6 slurry design code

8.2 Jacking Headers

Item	Value / Description	Source / Comments
Header type	Hydraulically operated 1 header for cyclone overflow and/or NAG whole stream tailings 1 header for sand stream	Industry standard
Average rate of rise	8 m per year	KP-02
Jack load	Sand tailings (cyclone u/f): 269kN (27 tonnes) Fine tailings (cyclone o/f): 169kN (19 tonnes)	P&C design
Wind load	Not available	

Rev C

9. PIPING

9.1.1 Steel piping

Steel piping used for all main pipelines.

Item	Value / Description	Source / Comments
Dimensional standard	ASME B31.10	P&C assumption
Steel grade	ASTM A53, API 5L X42 or higher	P&C assumption
Flange/couplings	Victaulic type preferred	P&C assumption

Item	Value / Description	Source / Comments
Internal lining	6 mm rubber lining within cyclone plant	P&C assumption
External coating	Painted, epoxy coating to provide life for pipes ~23 years	P&C assumption
Corrosion / wear allowance	2.1mm/1000h for NAG bulk tailings in slack flow 0.1mm/1000h for NAG bulk tailings in full pipe flow 0.1mm/1000h for cyclone O/F in slack flow 0.01mm/1000h for cyclone O/F in full pipe flow 9.1mm/1000h for cyclone U/F in slack flow 1.5mm/1000h for cyclone U/F in full pipe flow	P&C assumption
Support system	Above ground on sleepers, plinths	P&C assumption

Rev C

Rev C

Rev C

Rev C

9.1.2 High Density Polyethylene Piping

Rev C

HDPE piping used for cyclone o/f on the ground and branch piping off jacking header to deposition points.

Item	Value / Description	Source / Comments
Dimensional standard	ASTM F714	P&C assumption
Material grade	PE4710	P&C assumption
Flange/couplings	Victaulic style 995 or similar	P&C assumption

10. CIVIL

By others.

11. STRUCTURAL

By others.

12. ELECTRICAL AND INSTRUMENTATION

By others.

13. DESIGN CODES AND STANDARDS

Item	Value / Description	Source / Comments
Pipeline design	ANSI/ASME Code for Pressure Piping B31.11 Slurry	Industry standard

Item	Value / Description	Source / Comments
	Transportation Piping Systems	
Cyclone plant piping	ANSI/ASME Process Plant Piping B31.3	Industry standard
Slurry pumps	ANSI/HI 12.1-12.6 2011	Industry standard

14. COSTING

Costing will be done by others. P&C will provide MTOs to support a cost estimate of ±15% accuracy level.

15. KEY DESIGN ISSUES AND DECISIONS

None.

16. UNAGESOLVED ISSUES

16.1 None.

DESIGNED	MJ	12-OCT-12	DRAWING NUMBER 5277-2-206		REV 0
DRAWN	TF	12-OCT-12			

Tom Figas - P:\3 - Projects\KPV-5277 (Casino Project Tailing Cyclone and Transport)\Drawings\P&C Dwgs\Tailings Cyclone\HGL\5277-2-206.dwg - 12/11/2012 7:52 AM

NOTE
1. FOR SIMPLICITY HGL SLOPE FOR CS(STD) PIPE SHOWN. HDPE PIPE IS USED ONLY ON SLACK FLOW SECTION OF PIPE AND WILL BE REPLACED WITH CS PIPE AS THE LENGTH OF DAM PROGRESSES.

	CYCLONE STATION DISCHARGE	DISCHARGE POINT
PIPELINE ELEVATION (m)	998	835.5
PIPE NOMINAL DIAMETER / WALL THK	36"HDPE/83mm, 32"CS / 9.53mm	
PIPE SPECIFICATION / MATERIAL GRADE	ASME B36.10 / A106 Gr.B	
LINING TYPE / THICKNESS	N/A	
PIPE INTERNAL DIAMETER	738mm, 794mm	
PIPE PRESSURE RATING	1 466 kPa, 5 057 kPa	
FLANGE SPECIFICATION / MATERIAL	ASME B16.5 / ASTM A105	
FLANGE SIZE / PRESSURE RATING	36"/CLASS 150, 32" / CLASS 300	
MAX ALLOWABLE WORKING PRESSURE	1 466 kPa	

PRELIMINARY

Casino Jacking Header
Summary

1. General

The proposed project will consist of two jacking headers that will support slurry piping for discharge onto a tailings embankment. The fines tailings header consists of a 32" (813 mm) pipe that will span between jacking frames. The sand tailings header consists of 3 pipes with a walkway platform. Each header will be approximately 870 meters long and be supported by steel piling. The project is located in the Dawson Mountains of the province of Yukon in Canada. The feasibility study analyzed start up conditions only and did not consider subsequent yearly operations.

The following present the findings of our study.

2. General Arrangement

The electrical cable tray for both headers was placed above the piping instead of below it. This will avoid possible water leakage from the piping coming in contact with the electrical conduits.

Platforms were provided to operate piping valves and egress ladders down to the embankment were provided at the sand tailings header at 100 meters on center.

3. Steel Framing

At the sand tailings header, heavy steel wide flange members were used to support the piping at the walkway platform instead of prefabricated steel trusses. While the weight of the wide flange beam will be comparable to that of a prefabricated truss, using a wide flange beam will simplify the framing and connection details.

A Teflon bearing pad is recommended to accommodate thermal movement at the fines tailing header. Because of the long length of both headers, significant thermal growth will be encountered and appropriate engineering details will need to be provided to accommodate loads and movement from thermal changes.

4. Foundation

The jacking structures will be founded initially on concrete footings located at the crest of an embankment dam. It has been reported that footings near the edge of the dam can rotate causing maintenance problems with future pipe pile raises. Providing additional compaction and careful construction observation during the installation of the footings and embankment should prevent rotation of the footings in the future.

At the startup of the header operations the pipe piles will be founded on concrete footings. As tailings are deposited the mechanism for resisting structural loads will change. Lateral loads will change from being resisted by the concrete footings to being resisted by compacted tailings.

Stronger piles may be needed initially during this transition phase until the sufficient tailings are built up around the piles. It is possible that the size of the piles can be reduced for future raises, but further analysis is required.

Preliminary Structural Load List
Casino Jacking Header

1. General

The proposed jacking structures will be required to withstand the loads listed below including anticipated jacking loads.

2. Design Loads

The following describes the structural loads considered in the preliminary design of the jacking header. These loads include the following types of loads.

1. Dead Loads
2. Live Loads
3. Snow Loads
4. Wind Loads
5. Seismic Loads
6. Jacking Loads
7. Geotechnical Information

2.1 Dead loads

Dead loads acting on the structure or a portion thereof shall consist of the weight of all permanent construction, including platforms, ladders, piping, lights and all fixed equipment.

2.2 Live Loads

Live loads shall consist of uniform surface loads or equivalent point loads developed to represent loading effects due to the movement of materials, equipment or personnel on a temporary basis. Loads will be identified as live loads when the item imposing the load is not permanent or rigidly fixed to the structure. The platform of the jacking header shall be designed for a minimum live load of 4.8 kPa (100 psf). A weight of 0.22 kN/m (15 plf) along the length of the header shall be used for electrical conduits. The weights of lights will be covered by a weight of 0.07 kN/m (5 plf) along the edge of the walkway platform at the sand tailings header.

2.3 Snow Loads

A snow load of 2.26 kPa (47 psf) will be used on the horizontal surfaces of the header for snow loads. It is our understanding that the slurry header will not be operational during the winter months. Therefore, possible ice loads from the buildup of frozen slurry were not considered.

2.4 Wind Loads

Wind loads shall be 1.78 kPa (37.2 psf) on flat areas such as steel framing members and 1.23 kPa (25.6 psf) on round areas such as the steel piling and the elevated pipes.

2.5 Seismic Loads

The following parameters shall be used in the design.

Sa (0.2 sec) = 0.544g
Sa (0.5 sec) = 0.336g
Sa (1.0 sec) = 0.168g
Sa (2.0 sec) = 0.094g
PGA = 0.250g

Soil Conditions – A stiff soil was assumed for use in the seismic design.

2.6 Jacking Loads

The slurry header will need to be raised periodically as slurry is deposited. Raises will be performed by hydraulic jacks. Jacking loads will be calculated to size jacks and structural steel members.

The jacking loads for the two headers were analyzed. During jacking it was assumed that the slurry piping was full and that there was a live load on any access platforms or walkways of 15psf. The following jacking loads were determined. The loads do not include a safety factor.

Fines Tailings Jacking Structure – 169 kN (19 tons).

Sand Tailings Jacking Structure – 269 kN (27 tons)

2.7 Geotechnical Information

The following geotechnical information was used in the feasibility study.

1. Soil will consist of hydraulic fill sand with 12% fines.
2. Net allowable bearing pressure = 143.6 kN/m^2 (3000 psf)
3. Modulus of subgrade reaction = 27.13 MN/m^3 (100 pci)

3. Materials

3.1 Structural Concrete

The minimum ultimate compressive strength of structural concrete shall be 31.0 MPa (4500 psi) at 28 days.

3.2 Reinforcement

Reinforcing steel bars shall be grade 60. All bars shall conform to the specifications for deformed billet bars for concrete reinforcement (ASTM A615).

3.3 Structural Steel

All structural steel shall be ASTM A992, Grade 50 unless otherwise specified. Structural steel pipe shall be ASTM A53, grade B.

4. Unit Weights

The following unit weights will be used.

1. Unit weight of concrete shall be assumed equal to 2403 kg/m^3 (150 lbs/ft^3) for design purposes.
2. Unit weight of water shall be assumed equal to 1000 kg/m^3 (62.4 lbs/ft^3).
3. The weight of the slurry shall be assumed to equal 1602 kg/m^3 (100 lbs/ft^3).

MATERIAL TAKE OFF (MTO)

Casino Project
Tailings Jacking Structure
Summary of Modifications Per Year

Increase in Header Length Per Year (1)

Years	Length of Header	Length of Header	Increase in Header Length			
	Calculated	Adjusted for 15 Meter Bays	Number of Added Bays	Added Length	Running Total	
			Each Bay has a Length of 15 Meters	Added Bays x 15 Meters

Year 22	162	326	11			

Footnotes:
1. The Length of the Jacking Structures will Increase During Depostion of Tailings
2. Depostion of Tailings Will Require That Piles Be Added to The Top of the Constructed Piles to Allow For Vertical Raises of The Jacking Structure
3. As tailings are deposited, the length of the jacking structure will increase.
   The elevation of the piles in the new expanded sections will be on a different elevation than the rest of the jacking structure.
   A makeup length of pile will be required so that the top of all of the piles are on the same elevation.
   This will allow future raises for all piles to be the same.

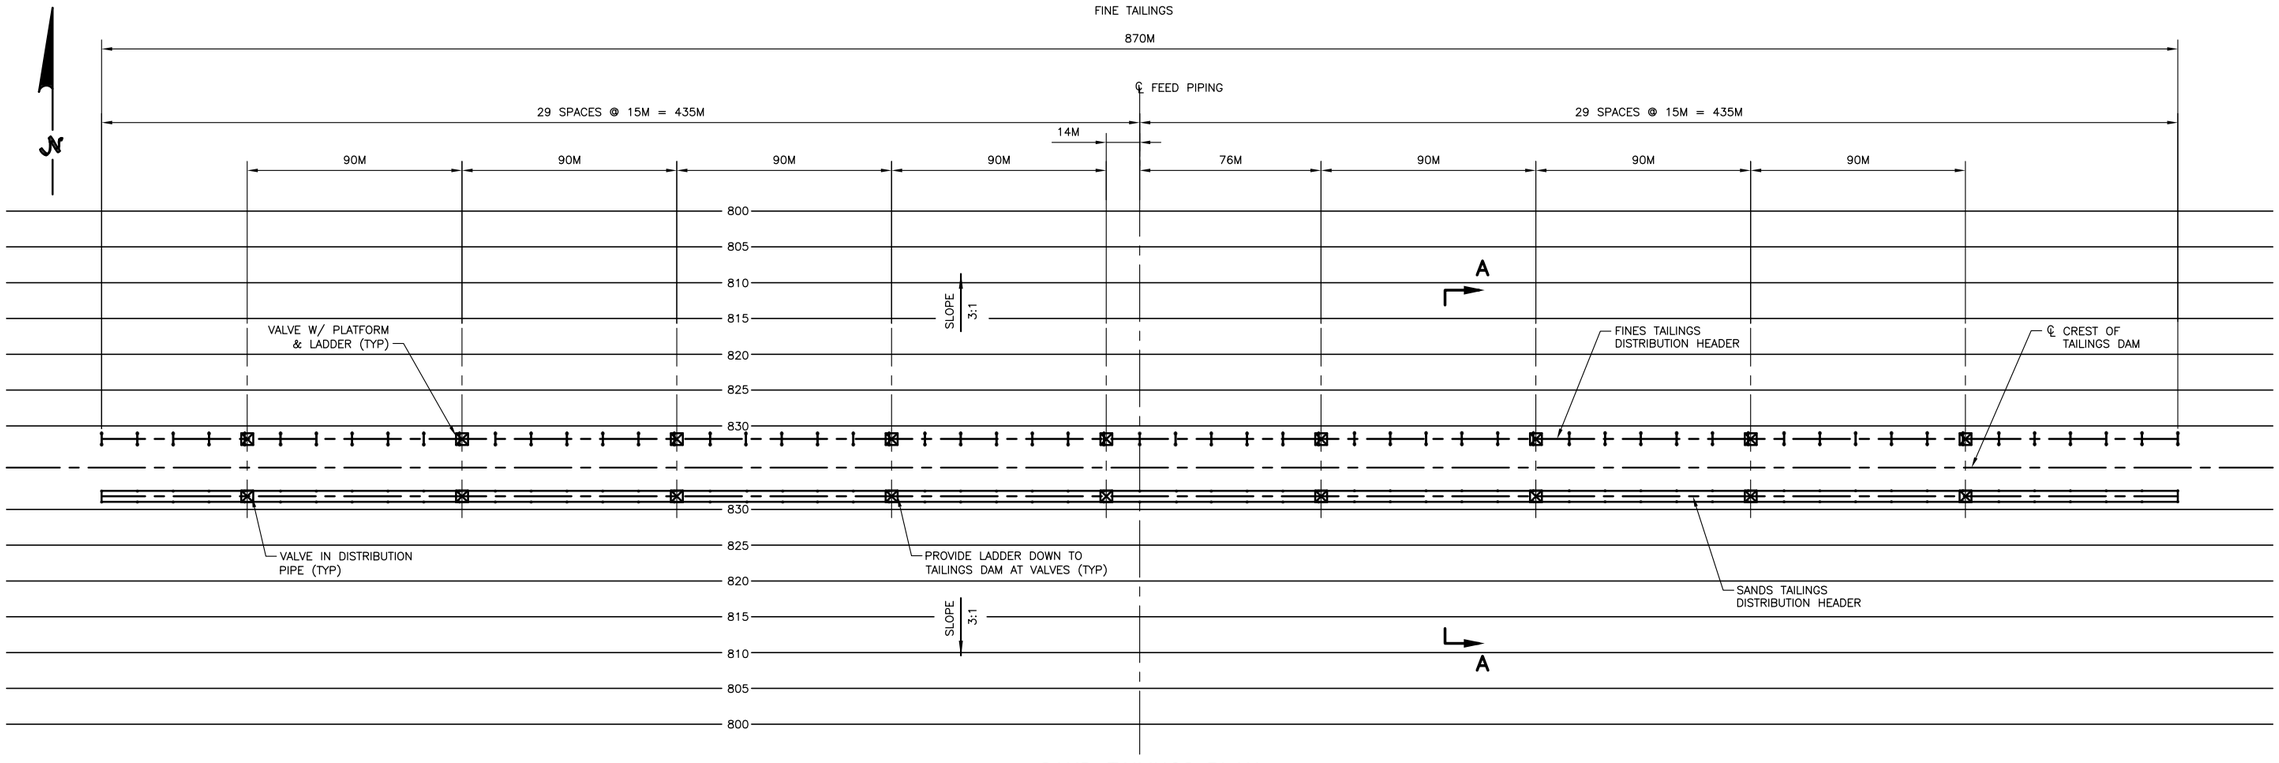
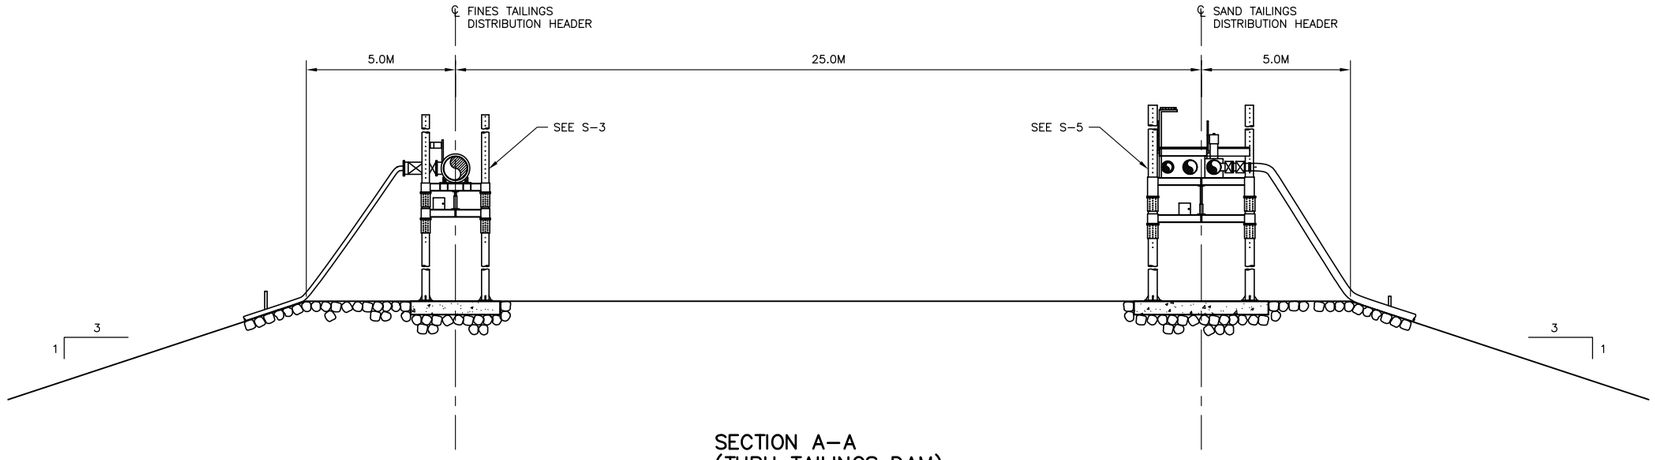
HSS - Hollow Structural Section

Wide flange, channel shapes and other rolled members shall meet ASTM A992. These members shall have a minimum yield strength, Fy = 50 ksi (350 MPa).



Angles and plate members shall meet ASTM A 36. These members shall have a minimum yield strength, Fy = 36 ksi (250 MPa).

Hollow Steel Sections shall meet the ASTM A500, grade B. These members shall have a minimum yield strength, Fy = 42 ksi (290 MPa).



Pipe Sections shall have a minimum yield strength, Fy = 35 ksi (240 Mpa)

The steel shall meet the supplemental requirements of a Charpy V-Notch Impact Test.
The minimum energy used in the Impact test shall be 25 ft lb @ 10 degrees F or 34 joules @ -12degrees C.

Dear Sanne

U/F PIPELINE MATERIAL SELECTION, VALUE ENGINEERING

1. INTRODUCTION

This report outlines the result of a value engineering study for selecting optimal cyclone underflow pipeline configuration and materials.

The cyclone underflow pipeline delivers cyclone sand to the tailings embankment. The pipeline is located on a steep slope and is routed from cyclone plant to the jacking structure. Due to the substantial elevation difference between the jacking structure and the cyclone plant, up to 600m pipeline upper section will be operating under slack flow.

Velocity in the slack flow section is estimated to be around 10-11m/s. These high velocities will cause the pipeline to wear quickly. This section of pipeline needs to be replaced often. P&C identified the cost of pipeline maintenance and replacement to be significant especially in the northern climate.

To reduce pipeline maintenance and replacement cost, P&C propose two technologies which will remedy the problem:

(i) Ceramic orifice plate places along the pipeline to increase pipeline back pressure and limit the slack flow to a short section of pipeline
(ii) Ceramic lined pipe to combat pipeline wear due to high slack flow velocities.

1.1 Document Distribution, Revision and Approval History

Rev	Date	Distribution/ Revisions	Prepared	Reviewed	Client
A	1st Oct 2012	Issued for Review	MJ	YK	-

2. ASSUMPTION

P&C's wear database is used to estimate wear rates based on collected data of various mine sites. The collected data is scaled based on similar applications and particle characteristics. Using particle energy scaling method a wear rate of 9.165mm/1000hr was determined.

The following table summarizes the basis of design used for the value engineering. Due to substantial wear carbon steel (CS) sch 80 pipeline is used for the slack flow section. The pipe is allowed to wear down to 5mm and can be rotated twice before it has to be replaced.

Item	Value / Description	Source / Comments
Pipe size for slack flow section	18" CS sch 80	P&C selection
Pipe outside diameter	0.4572 m	Pipe standard
Pipe thickness	23.83 mm	Pipe standard
Min wear thickness	5 mm	P&C assumption
No. pipe rotation	2	P&C assumption
No. times pipe replaced	1.6 x per year	Calculated from 9.165mm/1000hr
Pipe rotation per year (9 months)	3.2 x per year	Calculated from 9.165mm/1000hr
Days between rotations	90 days	Calculated from 9.165mm/1000hr
18" sch 80 pipe material cost	$ 710.00 /m	P&C assumption
18" sch 80 installation cost	$ 290.00 /m	P&C assumption
18" sch 80 pipe rotation cost	$ 355.00 /m	P&C assumption
18" sch 10 installation cost	$ 167.00 /m	P&C assumption
18" sch 10 pipe rotation cost	$ 205.00 /m	P&C assumption
18" sch 10 w/ceramic liner Cost	$ 2185.00 /m	Vendor pricing
Ceramic choke	$ 21450 Each	Vendor pricing
Ceramic choke maintenance cost	10% of CAPEX	P&C assumption
Discount rate	8%	KP

For the purposed of this value engineering exercise only cost associated with the pipe section operating under slack flow will be analyzed. Pressurized pipe or pipe operating under full pipe flow will not be operating at high velocities and are subject to normal wear and using ceramic liners or chokes is not required.

3. OPTION NO. 1: NO ORIFICES, NO CERAMIC LINING

Option one is the primary basis for evaluating other options. In this option CS schedule 80 pipe is installed on the slack flow section. The pipe is allowed to wear down to 5mm after which it is

rotated and eventually replaced with a new pipe. Section of pipe is under slack flow will be up to year five of operation. The cost of installation, rotation and replacement are significant.

Table I shows the estimated CAPEX and OPEX for the 600m sch 80 pipe. The length of the pipe decreases with each subsequent year as result of rising dam elevation. The pipeline will no longer operate under slack flow after year 5. The NPV value is estimated to be $ 4,131,040.

Table I: OPEX and CAPEX for option No. 1

Year	Replaced Pipe Length	Pipe Installation Cost	Pipe Material Cost	Pipe Rotation Cost	Cost of Chokes	Total Cost
Year 0	600.0 m	$ 278,206	$ 681,125	$ 681,125	-	$ 1,640,457
Year 1	480.0 m	$ 222,565	$ 544,900	$ 544,900	-	$ 1,312,366
Year 2	360.0 m	$ 166,924	$ 408,675	$ 408,675	-	$ 984,274
Year 3	240.0 m	$ 111,282	$ 272,450	$ 272,450	-	$ 656,183
Year 4	120.0 m	$ 55,641	$ 136,225	$ 136,225	-	$ 328,091
Option No. 1 NPV						$ 4,131,040

4. OPTION NO. 2: ORIFICES INSTALLED, NO CERAMIC LINING

In option 2, the slack flow is controlled by placing ceramic orifices along the pipeline. These orifices are evenly place along the pipeline and are removed periodically in subsequent years. This allows slack flow to be limited to 250m of pipeline without backing up the flow which will cause the underflow collection box to over flow. It is estimated that the 10 chokes will be installed at year 0. Each choke will drop the head by 8 meters for a total of 80 meter of energy dissipation.

Table II shows the estimated CAPEX and OPEX for the 250m sch 80 pipe. The length of the pipe decreases with each subsequent year as result of rising dam elevation. The pipeline no longer operates under gravity flow after at five. All chocks will be removed at year five. The NPV value is estimated to be $ 1,985,660.

Table II: OPEX and CAPEX for option No. 2

Year	Replaced Pipe Length	Pipe Installation Cost	Pipe Material Cost	Pipe Rotation Cost	Cost of Chokes	Total Cost
Year 0	250.0 m	$ 115,919	$ 283,802	$ 283,802	$ 214,500	$ 898,024
Year 1	200.0 m	$ 92,735	$ 227,042	$ 227,042	$ 21,450	$ 568,269
Year 2	150.0 m	$ 69,552	$ 170,281	$ 170,281	$ 21,450	$ 431,564
Year 3	100.0 m	$ 46,368	$ 113,521	$ 113,521	$ 21,450	$ 294,860
Year 4	50.0 m	$ 23,184	$ 56,760	$ 56,760	$ 21,450	$ 158,155
Option No. 2 NPV						$ 1,985,660

5. OPTION NO. 3: NO ORIFICES, CERAMIC LINED PIPE INSTALLED

Option 3 utilizes ceramic lined pipe which are wear resistant in up to 30m/s slurry velocity. It is assumed that this pipe will last the life of the project without any replacement of rotation. In this option choke are not used and the slack flow and ceramic pipe length are estimated to be 600m.

Table III shows the estimated CAPEX and OPEX for the 600m CS 18 inch schedule 10 pipe lined with 6mm of IMATECH IMCM Ceramic Reinforced Polymer Composite. The NPV value is estimated to be $ 1,306,667.

Table III: OPEX and CAPEX for option No. 3

Year	Replaced Pipe Length	Pipe Installation Cost	Pipe Material Cost	Pipe Rotation Cost	Cost of Chokes	Total Cost
Year 0	600.0 m	$ 100,200	$ 1,311,000	-	-	$ 1,411,200
Year 1	-	-	-	-	-	-

Year 3	-	-	-	-	-	-
Year 4	-	-	-	-	-	-
Option No. 3 NPV						$ 1,306,667

6. OPTION NO. 4: ORIFICES INSTALLED, CERAMIC LINED PIPE INSTALLED

In option four both technologies are utilized. Slack flow is controlled by placing ceramic orifices along the pipeline. These orifices limit the pipeline wear to 250 meter section of pipe. 18 inch CS schedule 10 Pipe lined with 6mm of IMATECH IMCM Ceramic Reinforced Polymer Composite is used for the 250 meter pipe section operating at high slack flow velocities.
Table IV shows the estimated CAPEX and OPEX for the 250m pipe section. The NPV value is estimated to be $ 808,838.

Table IV: OPEX and CAPEX for option No. 4

Year	Replaced Pipe Length	Pipe Installation Cost	Pipe Material Cost	Pipe Rotation Cost	Cost of Chokes	Total Cost
Year 0	250.0 m	$ 41,750	$ 546,250	-	$ 214,500	$ 802,500
Year 1	-	-	-	-	$ 21,450	$ 21,450
Year 2	-	-	-	-	$ 21,450	$ 21,450
Year 3	-	-	-	-	$ 21,450	$ 21,450
Year 4	-	-	-	-	$ 21,450	$ 21,450
Option No. 4 NPV						$ 808,838

7. RECOMMENDATION

Figure 1 shows the net present value (NPV) for the four options.

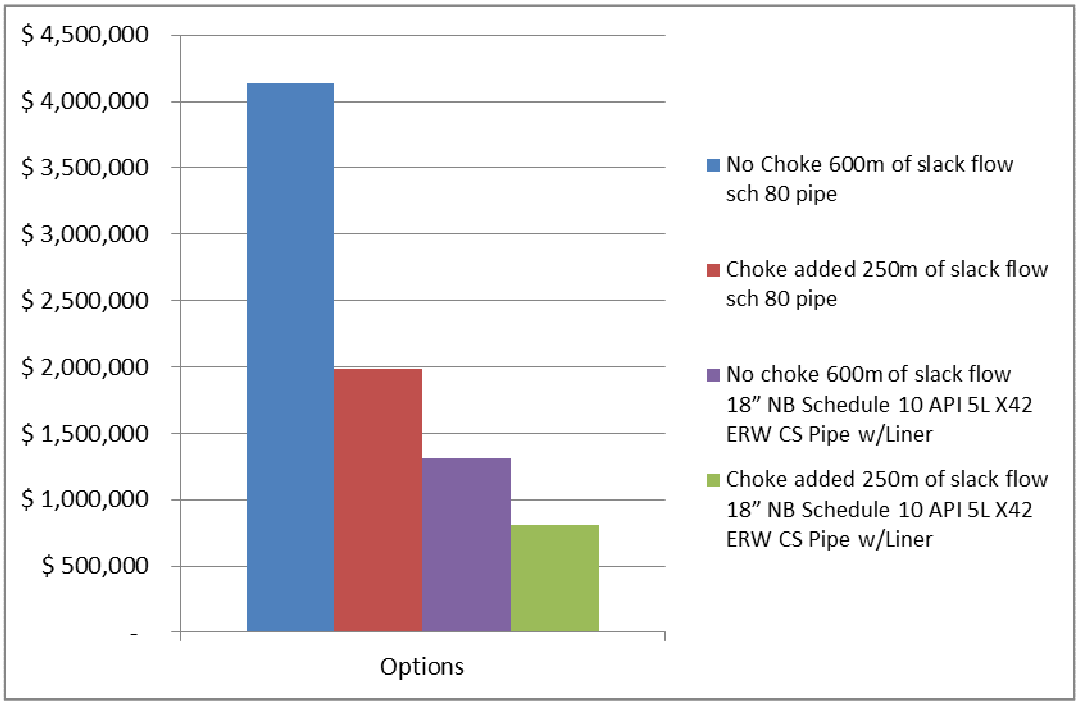

Figure 1 – NPV Compression between the Options

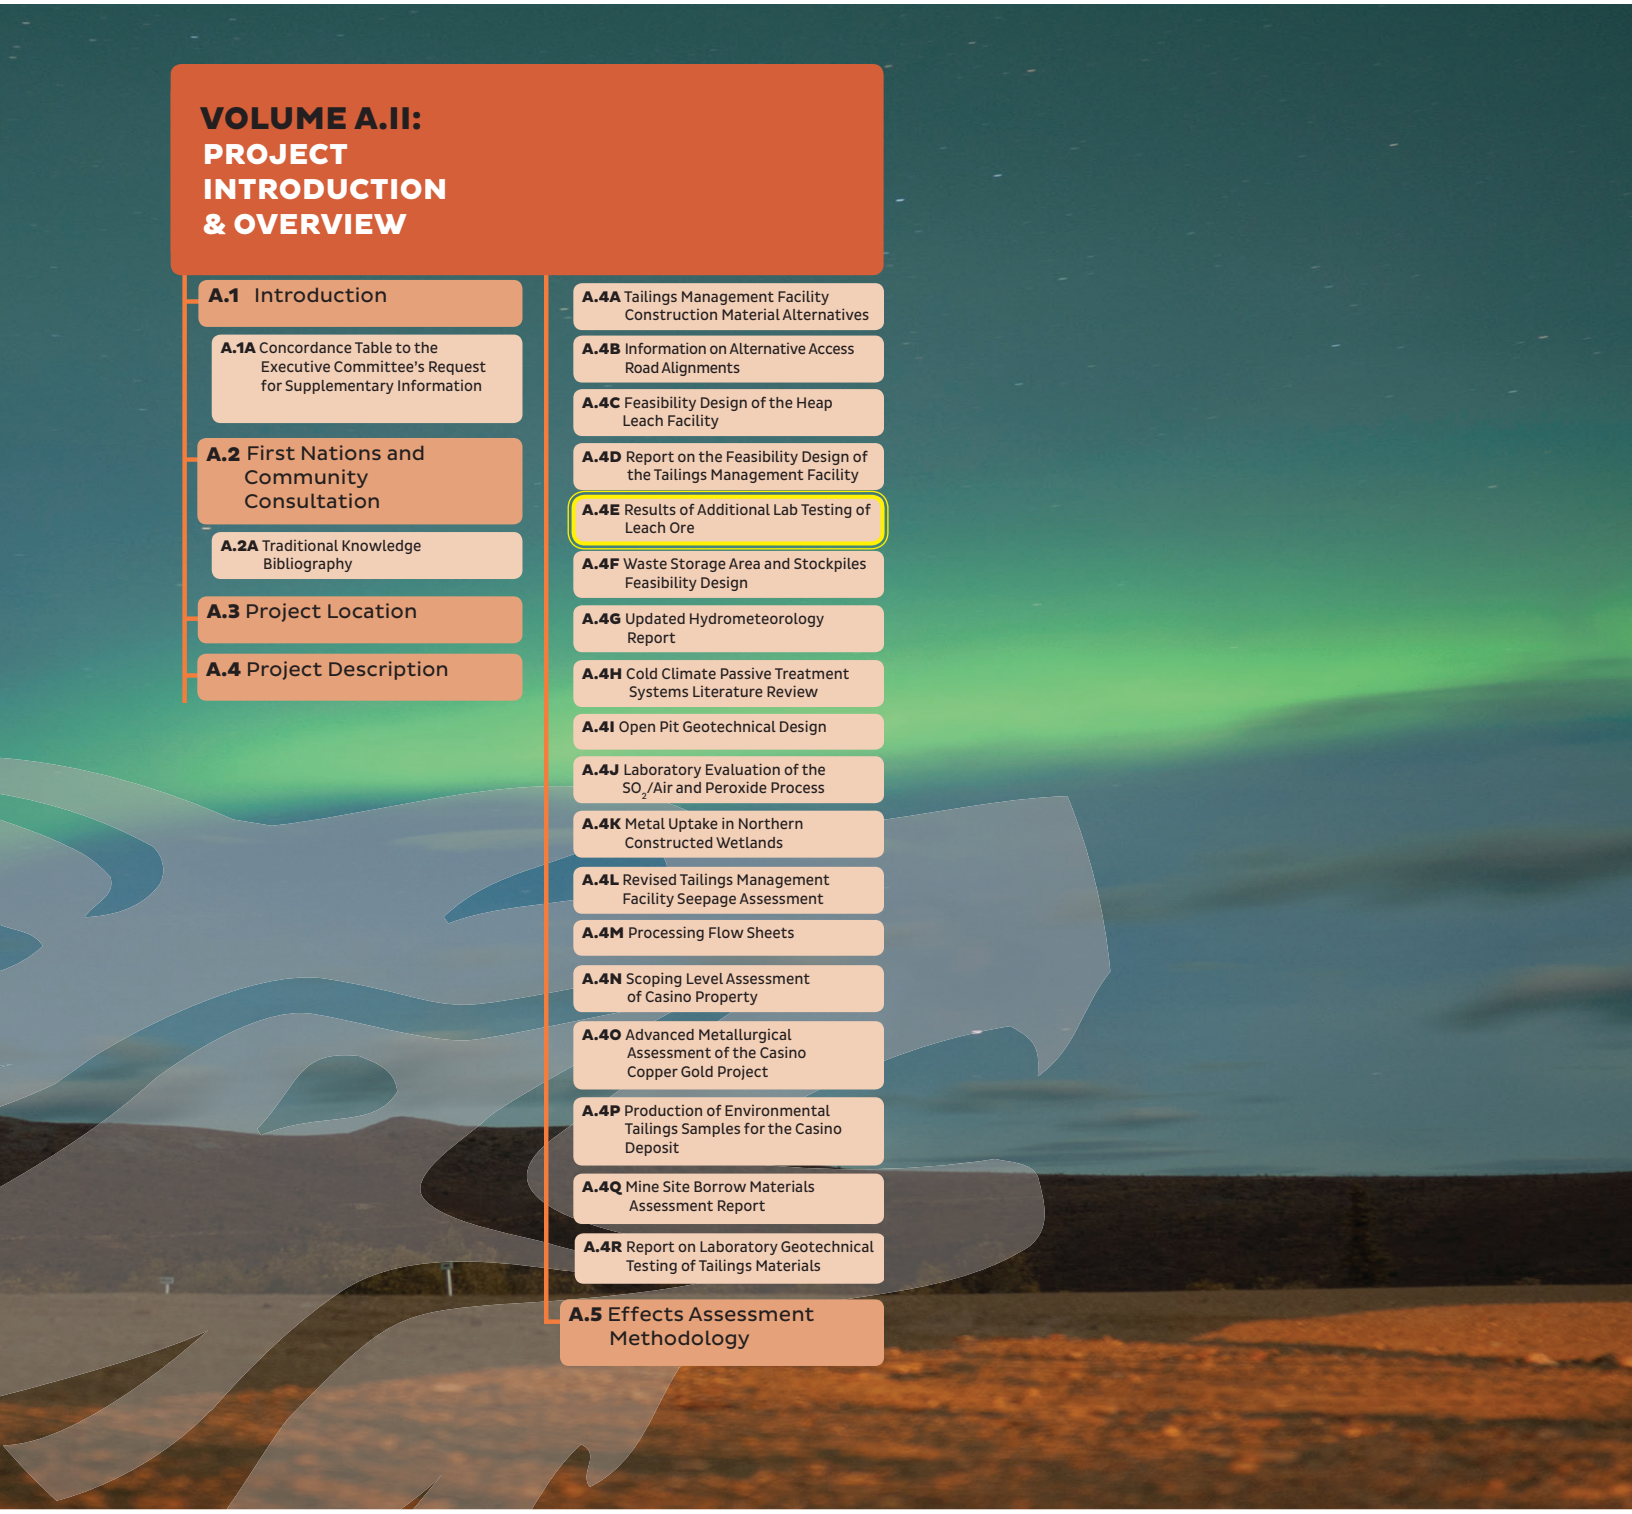
P&C recommends Option #4 – chokes and ceramic lined pipe. This option represents lowest NPV for the project.



In this option, using 10 chokes will allow control and limit the slack flow only to first 250 meters of sand pipeline. P&C also recommend installing ceramic lined pipe on the 250 meters exposed to slack flow to further reduce maintenance cost and pipeline downtime.

Yours sincerely

1.0 INTRODUCTION

In October 2008, drill core samples from el Casino Project were received at METCON Research (METCON). These samples were air dried and prepared for a preliminary column leach study conducted at the METCON facility in Tucson, Arizona. The scope of the metallurgical study conducted included;

- Sample Preparation
- Head Assay Screen Analysis
- Bottle Roll Testing
- One Open Cycle Column Leach Test

The main objective of the column leach study was to determine the amenability of this composite sample to gold and silver extraction by heap leach type of leaching process. A secondary objective was to produce pregnant solutions and residues to be evaluated in an environmental impact study. The first 15 days of pregnant solution and the final leach residue were sent to a different laboratory per client's request.

The testing procedures utilized in the Casino project column leach test program are standard leach procedures and are common and acceptable in industrial practice. The metallurgical study was directed by Francisco A. Garcia and supervised by METCON personnel.

2.0 SUMMARY

A bottle roll test and one open cycle column leach test were conducted on a composite identified as Gold Composite No. 2. The primary objective of this test program was to generate gold and silver extraction, cyanide and calcium oxide consumption data on composite sample from the Casino Project. The data developed and metallurgical results obtained on this study are summarized in the following paragraphs.

2.1 Sample Preparation and Head Assay

On 30 October, 2009, approximately 137 kilograms of drill core samples were received at METCON facilities from EL Casino project. The drill core samples received were weighted and classified according to the identification on samples. Log in data was sent to the client to verify weights and samples identification. Table 1 summarizes the log in samples received.

Table 1
Summary of Samples Received at METCON

Sample ID	Interval (m)		Weight (kg)
	From	To	
HOLE: CAS-002	4.20	24.38	42.40
HOLE: CAS-003	1.40	24.38	37.00
HOLE: CAS-009	16.76	37.70	14.32
HOLE: CAS-011	23.00	44.00	38.84
HOLE: CAS-019	21.05	27.05	4.54
		Total	**137.10**

All samples received were screened to obtain as received particle size distribution (PSD). Each screen fraction was weighed and kept segregated in plastic bags previously identified with METCON project number, screen size and weight. Table 2 summarizes the as received particle size distribution of all samples combine.

Table 2
Summary of As Received Particle Size Distribution on Gold Composite No.2

NOMINAL OPENINGS			Sample Weights (kg)	Weight Distribution (%)	Retained (%)	Passing (%)

Two test charges of approximately 45 kilograms were split for column testing and head screen assay based on the above particle size distribution. The screen fractions from the head sample test charge was stage crushed to 100 percent minus 1.7 mm and approximately 1,000 grams were split from each screen fraction, pulverized to 100 percent minus 150 microns and approximately 150 grams were split and submitted for gold assay by fire assay/AA finish and silver by Geochem method. The gold, silver and copper analyses on the head sample are summarized in Table 4 below.

Table 4
Summary of Head Screen Assay Analysis

CALCULATED ASSAY						0.41			2.9			0.053		
COMPOSITE ASSAY (Pulv.)						0.48			3.0			0.053		

The following comments relate to calculated gold, silver and copper analyses conducted on the head composite sample.

- Gold content in the head was 0.41 g/t and approximately 65 percent of the gold contained in the head sample reported to the 1 inch screen fraction.

- Silver content was low with 2.5 g/t and approximately 65 percent of this silver contained in the sample reported to the 1 inch fraction.

2.2 Bottle Roll Test

A minus 10 mesh composite sample was reconstituted based on the final PSD for bottle roll testing. The bottle roll testing was conducted under the following leaching conditions.

- Leach cycle of 48 hours.
- Test charge of 500 grams.
- 33 percent solids.
- 1 g/l of free sodium cyanide in solution.
- pH range of 10.5 to 11.
- Sampling at 3, 6, 24 hours.
- Pregnant solutions submitted for Au, Ag, Cu, pH, free calcium Oxide and sodium cyanide.

The following table summarizes the results obtained in the bottle roll leach test conducted on the gold Composite No. 2.

Table 5
Ambient 48 hr. Bottle Roll Leach Tests

Leach Test No.	NaCN Consumption (kg/tonne)	CaO Consumption (kg/tonne)	Leach Time (hr)	CUMULATIVE EXTRACTION				
				Au %	Ag %	Cu %	Au (g/t)	Ag (g/t)
BR-01	0.71	2.64	**48**	82.35	16.97	54.09	0.32	0.51

The following comments relate to bottle roll testing conducted on gold composite sample No. 2.

- Gold extraction of approximately 82 percent was achieved on the Gold Composite No. 2.

- A low Silver extraction of approximately 17 percent was obtained after 48 hours of leach cycle.

- A low cyanide consumption of 0.71 kg/tonne was observed.

- A high calcium oxide consumption of 2.64 kg/tonne was observed.

- The metallurgical developed on the bottle roll test are included in this report.

2.3 Open Cycle Column Leach Test

One 45 kilograms open cycle column leach tests was conducted at a crush size of approximately 100 percent passing 1.5 inches, Test charge for column test was reconstituted from individual screen fractions in accordance with the particle size distribution and loaded into 6 inch in diameter by 3 meter tall PVC columns. Prior to loading the columns, the calcium oxide consumed (kg/t) in 48 hour bottle roll was added to each test charge. The leaching parameters used in this column leach test are summarized below:

- Approximately 2.64 kg/tonne of calcium oxide was blended into test charge.
- The initial feed solution was prepared by adding reagent grade calcium oxide to Tucson tap water to obtain a solution pH of 11.00 followed by the addition of 1 gram of sodium cyanide per liter of solution. The column was irrigated at a flow rate of 12 liters per hour per square meter.
- Column test was conducted under open cycle type of leaching regime.
- Leach Cycle of 38 days.
- First 15 days of pregnant solution were sent to a Laboratory per client's request.
- All solution samples were assayed for gold, silver, copper, pH and free sodium cyanide and calcium oxide.
- Leach residue was shipped to a different laboratory per client's request.
- Metals extractions obtained in the column leach test are labeled as "Indicated Extraction" since the leached residue sample was not assayed.

The metallurgical data developed after 38 days of leaching are attached to this report. The following table summarizes the metallurgical results obtained in column leach test CL-01.

Table 6
Summary of Column Leach Test Conducted on Gold Composite No. 2

Test No.	Leach Day	Head Assay Screen (g/t)			Indicated Extraction (%)			Reagent Consumption (kg/t)	
		Au (g/t)	Ag (g/t)	Cu (g/t)	Au	Ag	Cu	NaCN	CaO
CL-01	38	0.41	2.9	526	50.45	17.90	18.75	0.40	3.59

The following comments relate to the column leach test conducted on the gold composite No.2.

- Indicated gold extraction of approximately 50 percent was obtained on this column test after 38 days of leach cycle.
- Indicated silver extraction of approximately 18 percent of the total silver contained in the head.
- Indicated copper extraction of approximately 19 percent of the total copper contained in the head.
- Low sodium cyanide consumption of 0.41 kg/t was observed in this composite sample.
- A high calcium oxide consumption of 2.9 kg/t was obtained after 38 days of leach cycle bottle roll test.

3.0 CONCLUSIONS AND RECOMMENDATIONS

The following conclusions and recommendations are based on the metallurgical data developed under open cycle cyanide column leach testing conducted on gold Composite Sample No. 2.

- Indicated gold extraction of approximately 50 percent was obtained on gold Composite Sample No. 2 after 38 days of leach cycle.
- Indicated silver extraction of approximately 18 percent was obtained.
- Indicated copper extraction of approximately 19 percent was obtained.
- Low sodium cyanide consumption of 0.41 kg/t was observed on this composite sample.
- High calcium oxide consumption of 2.9 kg/t was obtained in the bottle roll test.

CONSULTING

EXECUTIVE SUMMARY

This report presents the details and findings of a laboratory testing program to determine the geotechnical characteristics of leach ore for the Casino Project. A total of seven samples of leach ore material were provided by Casino Mining Corporation for laboratory testing at the Knight Piésold (KP) laboratory in Denver, Colorado. The samples were processed to gradations representative for the current design crushing process, and one sample was subjected to a leach column and unsaturated column test, prior to shipment to the KP laboratory.

The laboratory program included index tests, saturated hydraulic conductivity tests, and load-percolation tests. Specialized testing to determine the Soil-Water Characteristics Curve (SWCC) was undertaken on three samples at the Daniel B. Stephens and Associates (DBS) laboratory in Albuquerque, New Mexico.

Samples MET-11, MET-17, MET-19 and MET-20, as well as the leached ore sample CL-01, have similar particle size distributions. These samples comprise 85 to 90% gravel, 7 to 12% sand, 4% or less silt, and approximately 1% clay. Sample MET-02 is finer grained with approximately 73% gravel, 22% sand, 3% silt and 1% clay. Sample MET-05 is the finest leach ore material comprising roughly equal amounts of gravel and sand (48 and 45% respectively), 6% silt and 1% clay.

The ore samples are generally competent and exhibit little degradation under loading, although some particle breakage was observed for sample MET-02, which may reduce the hydraulic conductivity. The saturated hydraulic conductivity for the leached sample (CL-01) is lower than other samples with a similar particle size distribution. This may indicate that the leaching process does have some effect on hydraulic conductivity.

However, all test results indicate saturated hydraulic conductivities that are higher than the current design irrigation rate for ore leaching (12 l/hr/m^2, which is equivalent to 3.3×10^{-4} cm/s). This indicates that the proposed heap leach ore will not fully saturate under the design irrigation rate, even at the highest tested normal stress of 2720 kPa, which is equivalent to an approximately 150 m high heap (the maximum design heap height). Sample MET-05 and MET-11 can sustain irrigation rates of at least 10 times the current design rate. Ponding of solution on top of the ore sample due to saturation was observed for sample MET-02 at 120 l/hr/m^2 at the highest normal stress.

The DBS laboratory results indicate saturated hydraulic conductivities that are typically about one order of magnitude lower than the KP results for similar sample density. This can likely be attributed to the difference in the sample preparation method.

The steady state gravimetric moisture contents from the load-percolation tests (5 to 10%) are lower than those predicted from the SWCC (11 to 22%) at the current design irrigation rate of 12 l/hr/m^2.

It is recommended to do additional testing to determine the effect of the leaching process on the different types of ore. It is also recommended that the actual leach solution be used instead of tap water for conducting additional permeability and percolation testing. Additional strength and hydraulic conductivity testing is recommended for samples that are most affected by the leaching process.

1 – INTRODUCTION

This report presents the details and findings of a laboratory testing program to determine the geotechnical characteristics of the leach ore for the Casino Project. A total of seven samples of leach ore material were provided by Casino Mining Corporation for laboratory testing at the Knight Piésold (KP) laboratory in Denver, Colorado. The laboratory program included index tests, saturated hydraulic conductivity tests, and load-percolation tests. The index testing was conducted to enable geotechnical classification of the materials. The saturated hydraulic conductivity tests were used to determine the compressibility and saturated hydraulic conductivity of the ore over a wide range of normal loads. The purpose of the load-percolation tests was to determine the behaviour of the material under unsaturated conditions. Results from these tests include the steady state moisture content under leach and the residual moisture content after draindown.

Specialized testing to determine the Soil-Water Characteristics Curve (SWCC) was undertaken on three samples at the Daniel B. Stephens and Associates (DBS) laboratory in Albuquerque, New Mexico. The SWCC relates the ore moisture content with the suction pressure, and defines the moisture holding potential of the ore.

The geotechnical and hydrological properties of the ore depend on the gradation of the material. The current leach ore crushing process has been specified in the feasibility study (M3 Engineering and Technology Corporation, 2013) as follows:

- The ore from run-of-mine (ROM) is reduced to minus 200 mm using a primary gyratory crusher
- The primary crusher discharge is reduced to minus 50 mm through screening and a secondary cone crusher, and
- The secondary crusher discharge passed through a secondary screen with an undersize of 80% passing 1.5” (38 mm).

Six leach ore samples (MET-02, 05, 11, 17, 19, and 20) were sampled in 2013 by excavator from different locations in the deposit area to represent the various types of leach ore. Samples MET-02 and MET-05 comprise Dawson Range Batholith Diorite and Granodiorite. Samples MET-11 and MET-17 consist of intrusive Breccia from the Proctor Mountain Suite, containing Granodiorite, Diorite and metamorphic fragments. The lithology of samples MET-19 and MET-20 is Patton Porphyry from the Proctor Mountain Suite. Details of the sampling are provided in Appendix A. ALS laboratories in Kamloops, B.C. processed the leach ore to gradations representative for the current design crushing process. Approximately 100 kg of each sample was sent to the KP laboratory.

One sample (CL-01) constitutes the residue from a leach column test. This sample is an oxide gold composite comprising varying lithologies. METCON Research (2012) prepared sample CL-01 from approximately 137 kg of drill core samples from select holes drilled in 2008 and 2009. These samples were air dried and crushed to 100 percent minus 37.5 mm (1.5 inch). A subsample of 45 kilograms was used for an open cycle column leach test using a 6 inch in diameter by 3 meter tall PVC column. Prior to loading the columns, approximately 2.64 kg/tonne of calcium oxide was blended into the test charge. The column test was conducted under an open cycle type of leaching regime, using a leach cycle of 38 days. The initial feed solution was prepared by adding reagent grade calcium oxide to Tucson tap water to obtain a solution pH of 11.00 followed by the addition of approximately 1 gram of sodium cyanide per liter of solution. The column was irrigated at a flow rate of 12 liters per hour per square meter, which is the current design solution application rate

(M3 Engineering and Technology Corporation, 2012). The residue after 38 days of leaching was sent to SGS Canada Inc. (SGS) in Burnaby B.C.

SGS conducted an unsaturated column test on the leach residue. Approximately 25 kg of sample was constituted in a 10 cm diameter acrylic column with a pervious base and bottom drain. The column was kept on continuous humid or dry air (as per client request) for six day intervals. One day prior to sampling the air was shut off and nanopure water trickle leached at approximately 1 mL/min. The quantity of nanopure water added was generally 300 to 500 mL providing sufficient leachate for geochemical analysis. After sampling, the bottom drain was closed and humid or dry air was applied until the next sampling day. The test comprised 14 sampling cycles, for a total duration of approximately 3 months. The remaining ore residue was sent to the KP laboratory for geotechnical and hydrological analysis.

2 – INDEX TESTS

2.1 GENERAL

Index testing was carried out on all seven leach ore samples. The Specific Gravity, Atterberg Limits (Plastic and Liquid Limits), and particle size distribution (screen and hydrometer) of the leach ore were determined. These tests provide a measure of the type and condition of the material, specifically the particle density, composition (size and distribution) and plasticity characteristics. Modified Proctor compaction tests were also completed to establish the relationship between moisture content and maximum dry density. The index properties can provide a relationship to material structural properties, including compressibility, hydraulic conductivity and strength.

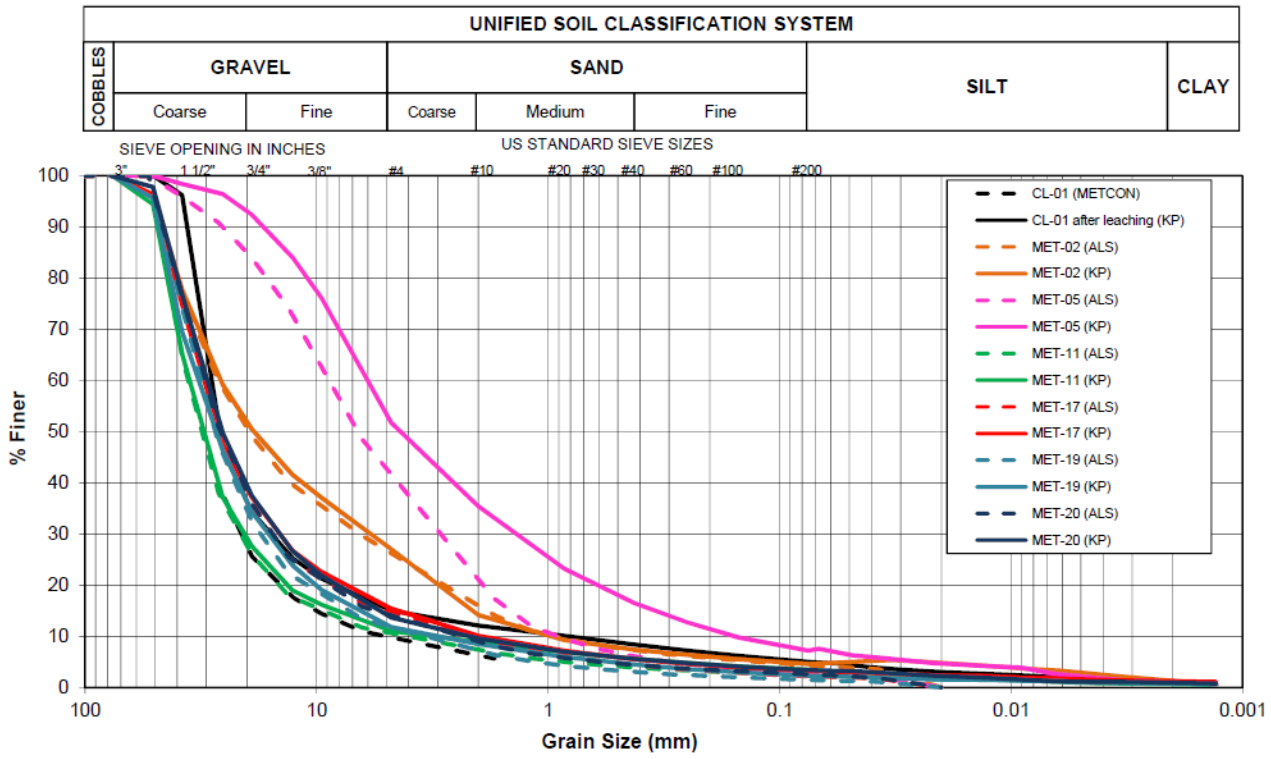
A summary of the leach ore index test results is presented in Table 2.1. Detailed results of the index tests are included in Appendix B.

Table 2.1 Summary of Leach Ore Index Tests

Sample ID	Specific Gravity	Atterberg Limits			Particle Size Distribution				Modified Proctor Compaction	
		LL	PL	PI	% Gravel	% Sand	% Silt	% Clay	Maximum Dry Density (tonne/m^3)	Optimum Moisture Content (%)
CL-01	2.66	NP	NP	NP	85.0	10.0	4.0	1.0	2.35	5.3
MET-02	2.73	22	21	1	73.0	22.4	3.3	1.3	2.32	5.4
MET-05	2.67	17	NP	NP	48.3	44.5	6.2	1.0	2.01	6.8
MET-11	2.69	19	18	1	89.0	7.5	2.8	0.7	2.46	3.1
MET-17	2.64	24	19	5	84.6	12.2	2.0	1.2	2.31	3.9
MET-19	2.75	NP	NP	NP	88.2	9.5	1.5	0.8	2.35	4.4
MET-20	2.65	NP	NP	NP	86.3	10.3	2.5	0.9	2.31	3.9

NOTES:

1. Laboratory analyses performed at Knight Piésold and Co. Soils Laboratory in Denver, CO.
2. Particle Size Distribution by percent of sample weight.
3. NP = Non Plastic, LL= Liquid Limit, PL = Plastic Limit, PI = Plasticity Index.
4. The weighted average is reported for specific gravity. See detailed lab results for specific gravities of the fractions smaller and greater than 4.75 mm.
5. Modified proctor includes an oversize correction as per ASTM D4718.



2.2 PARTICLE SIZE DISTRIBUTION

Mechanical sieve and hydrometer particle size analyses were carried out on each of the leach ore samples in accordance with ASTM standard D422 procedures. The hydrometer analysis was used to determine the silt and clay fraction particle sizes.

Samples MET-11, MET-17, MET-19 and MET-20, as well as the leached ore sample CL-01, have similar particle size distributions. These samples comprise 85 to 90% gravel, 7 to 12% sand, 4% or less silt, and approximately 1% clay. Sample MET-02 is finer grained with approximately 73% gravel, 22% sand, 3% silt and 1% clay. Sample MET-05 is the finest leach ore material comprising roughly equal amounts of gravel and sand (48 and 45% respectively), 6% silt and 1% clay.

The particle size distributions of the leach ore samples as received at the KP laboratory are presented on Figure 2.1, as well as gradations provided by ALS and METCON. The gradations of the samples that were not leached (MET-02 through MET-20) were determined by ALS after the crushing process. The particle size distribution for sample CL-01 was obtained by METCON after crushing, but before it was subjected to the leach and unsaturated column tests.

The particle size distributions from most samples as determined by KP are virtually identical to those provided by ALS, except for sample MET-05. The change in gradation for this sample is likely the result of degradation during transport and handling, which may indicate that this material is weaker and more prone to breakage than the other ore types. The particle size distribution of the leached sample (CL-01) as determined by KP is finer than that provided by METCON. The difference for this sample can be attributed to the fact that the METCON gradation was determined for the material before the leach and unsaturated column tests, whereas the KP gradation reflects the sample after these tests (in addition to any degradation due to transportation and material handling).

NOTES:

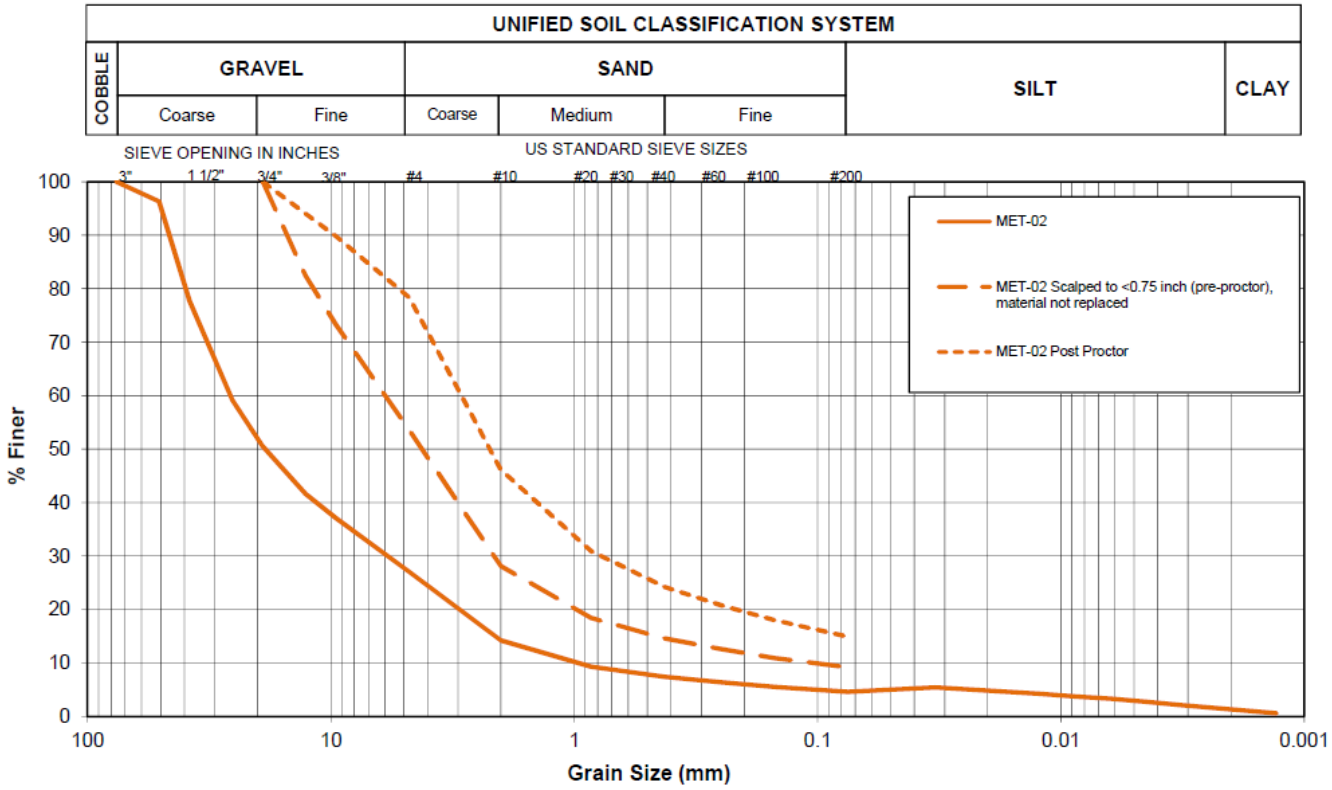
1. MET-02, MET-05, MET-11, MET-17, MET-19 and MET-20 data provided by ALS in Kamloops, B.C. after crushing, and by KP soil laboratory after transportation to Denver, CO. These samples were collected in 2013 and have not been subjected to leach column testing.
2. CL-01 data provided by METCON in Tucson, AZ. Gradation of the sample before it was subjected to leach column testing by METCON and unsaturated column testing by SGS.
3. CL-01 after leaching data provided by KP soil laboratory in Denver, CO. Gradation of the sample after it was subjected to leach column testing by METCON and unsaturated column testing by SGS.

Figure 2.1 Particle Size Distributions for Leach Ore Samples

2.3 SPECIFIC GRAVITY

The specific gravity of the leach ore material smaller than 4.75 mm (#4 sieve) was determined in accordance with ASTM standard D854. The coarse aggregate specific gravity for material retained on the #4 sieve was determined in accordance with ASTM standard C127. The weighted average of the specific gravity for each leach ore sample ranges from 2.64 to 2.75.

2.4 ATTERBERG LIMITS (PLASTICITY)



The Atterberg Limits (Plastic and Liquid Limits) of the leach ore samples were determined in accordance with the ASTM standard D4318 test procedure. The Atterberg Limits are only determined for the fraction of the sample smaller than 425 µm (No. 40 sieve). The material is non-plastic to slightly plastic, with a Plasticity Index (PI) of 5 or less.

2.5 MODIFIED PROCTOR (COMPACTION) TESTS

Modified Proctor compaction tests were completed in accordance with ASTM D1557, with oversize correction applied to each point as per ASTM D4718. The material was placed in a 6-inch mould and compacted at several moisture contents. The material greater than 3/4 inch is removed from each sample prior to testing.

The maximum dry density typically ranged from 2.31 to 2.46 t/m^3, except for the sample with the finest gradation (MET-05), which has a maximum dry density of 2.01 t/m^3. The optimum moisture content at which the maximum compaction is achieved varies from 3.1 to 6.8%.

The gradation of sample MET-02 was determined after Proctor testing to investigate the degradation of the material as a result of the compactive effort. The gradation before testing, after removal of the fraction greater than 3/4 inch, and after compaction testing is presented in Figure 2.2. The Proctor test resulted in significant degradation of the leach ore.

NOTES:

1. MET-02 data provided by KP soil laboratory in Denver, CO. This sample was collected in 2013 and has not been subjected to leach column testing.

Figure 2.2 Particle Size Distributions for MET-02 before and after Modified Proctor Test

3 – SATURATED HYDRAULIC CONDUCTIVITY TESTS

3.1 GENERAL

Saturated hydraulic conductivity tests were completed using rigid wall permeameters at both the KP and DBS laboratories. The purpose of the testing at the KP laboratory was to determine the saturated hydraulic conductivity over a range of normal loads. The saturated hydraulic conductivity tests were carried out in the DBS laboratory as part of the SWCC testing, and are discussed in Section 4.

The KP laboratory conducted saturated hydraulic conductivity tests on samples CL-01, MET-02, MET-05 and MET-11 using the constant head method. Sample CL-01 was selected as this sample was subjected to the leaching process during preceding test work. The other samples are considered to be representative of the fine, medium and coarse ore gradations. The tests were completed using an 8-inch rigid wall permeameter following USBR Procedure 5600 and 5605. Material greater than 1.5 inch was removed and replaced with finer gravel.

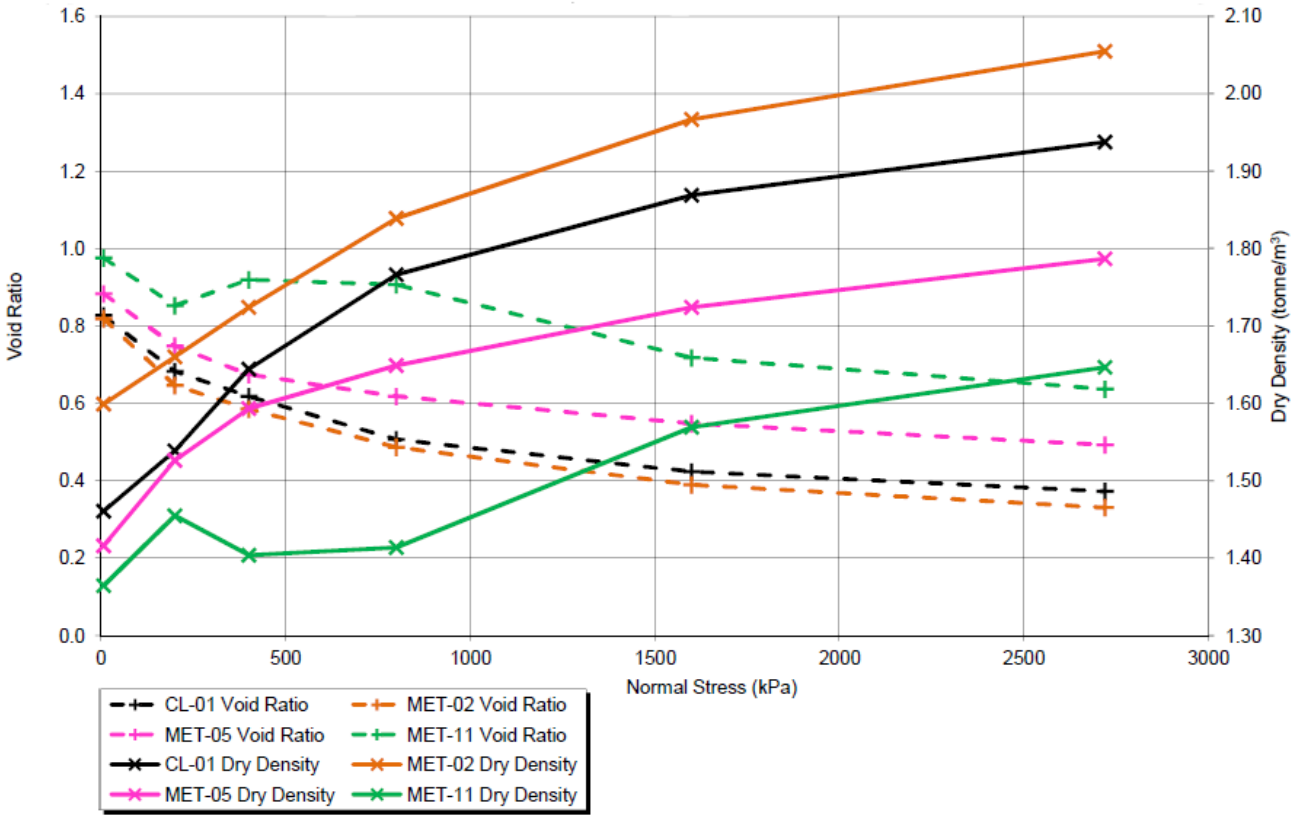
The material was placed loosely in the mould and tested at normal stresses of 200, 400, 800, 1600 and 2720 kPa.

Sieve analyses were completed on each sample material after the hydraulic conductivity tests to determine if the applied normal stress resulted in degradation of the leach ore (increase of fines content).

3.2 RESULTS AND INTERPRETATION

The results of the saturated hydraulic conductivity tests are summarized in Table 3.1. Detailed test results are included in Appendix C. The compaction of the sample as a result of the applied normal load is presented in Figure 3.1.

A correction is required for high permeability materials to account for head loss in the testing apparatus. A trial test without an ore sample was conducted to determine head loss in the apparatus, and the measured ore hydraulic conductivities were corrected for this head loss. Figure 3.2 shows the saturated hydraulic conductivity test results with and without head loss correction. The sample with the highest hydraulic conductivity (MET-11) requires the largest head loss correction. The results for pressures smaller than 1600 kPa are not reliable for this sample as the head losses in the apparatus exceed the applied heads.



The saturated hydraulic conductivity is presented as a function of the normal stress and dry density on Figure 3.2 and Figure 3.3, respectively. All samples have decreasing saturated hydraulic conductivity with increasing normal stress and density. An increase of normal stress from 200 kPa to 2720 kPa decreases the saturated hydraulic conductivity by less than one order of magnitude. This trend is not as evident for sample CL-01. An additional test was conducted on sample CL-01 at 2720 kPa to verify that the test results were not affected by issues such as incomplete saturation. The results of the additional test were similar to the initial test, confirming the validity of the results.

Table 3.1 Summary of Saturated Hydraulic Conductivity Test Results from KP Lab

Sample ID	Normal Stress (kPa)	Dry Density (tonne/m^3)	K_{sat} (cm/s)	$K_{sat,head\ corrected}$ (cm/s)
MET-02	200	1.66	3.4E-01	5.7E-01
MET-02	400	1.72	2.9E-01	4.5E-01
MET-02	800	1.84	9.0E-02	9.6E-02
MET-02	1600	1.97	6.4E-02	6.7E-02
MET-02	2720	2.05	4.7E-02	4.8E-02
MET-05	200	1.53	3.2E-01	5.0E-01
MET-05	400	1.59	1.4E-01	1.8E-01
MET-05	800	1.65	1.1E-01	1.3E-01
MET-05	1600	1.72	8.2E-02	9.2E-02
MET-05	2720	1.79	5.9E-02	6.3E-02
MET-11	200	1.45	1.2E+00	Invalid (2)
MET-11	400	1.40	1.2E+00	Invalid (2)
MET-11	800	1.41	1.2E+00	Invalid (2)
MET-11	1600	1.57	8.8E-01	1.5E+01
MET-11	2720	1.65	7.6E-01	4.4E+00
CL-01	200	1.54	2.2E-01	3.0E-01
CL-01	400	1.64	4.0E-01	7.7E-01
CL-01	800	1.77	2.1E-01	2.8E-01
CL-01	1600	1.87	1.4E-01	1.7E-01
CL-01	2720	1.94	1.7E-01	2.1E-01
CL-01 Re-test	2720	1.84	2.3E-01	3.2E-01

NOTES:

1. No oversize correction applied.
2. Results invalid as the head loss in the apparatus exceeds the applied head.
3. K_{sat} = saturated hydraulic conductivity, not corrected for head loss in testing apparatus.
4. $K_{sat,head\ corrected}$ = saturated hydraulic conductivity, corrected for head loss in testing apparatus.

NOTES:

1. Tested on fraction of material passing 1.5 inch.
2. All tests conducted by KP using an 8-inch rigid wall permeameter.

Figure 3.1 Void Ratio and Dry Density versus Normal Stress

The test results show that the coarsest sample (MET-11) has the largest saturated hydraulic conductivity. The particle size distribution of the leached sample (CL-01) is similar to MET-11. The saturated hydraulic conductivity, however, is considerably lower and closer to that of MET-02 and MET-05. This may indicate that the leaching process does have some effect on hydraulic conductivity.

The saturated hydraulic conductivity represents the maximum rate at which solution can flow through the ore. A solution application rate higher than the saturated hydraulic conductivity results in saturation of the ore and ponding at the surface. This will affect the leaching environment and may lead to stability issues. The solution application rate should be well below the saturated hydraulic conductivity of the ore to avoid saturated conditions.

The current design solution application rate for ore leaching (12 l/hr/m^2) is included on Figure 3.2 and Figure 3.3. All test results indicate saturated hydraulic conductivities that are higher than the design irrigation rate. This indicates that the proposed heap leach ore will not fully saturate under the design irrigation rate, even at the highest tested normal stress of 2720 kPa, which is equivalent to an approximately 150 m high heap (the maximum design heap height).

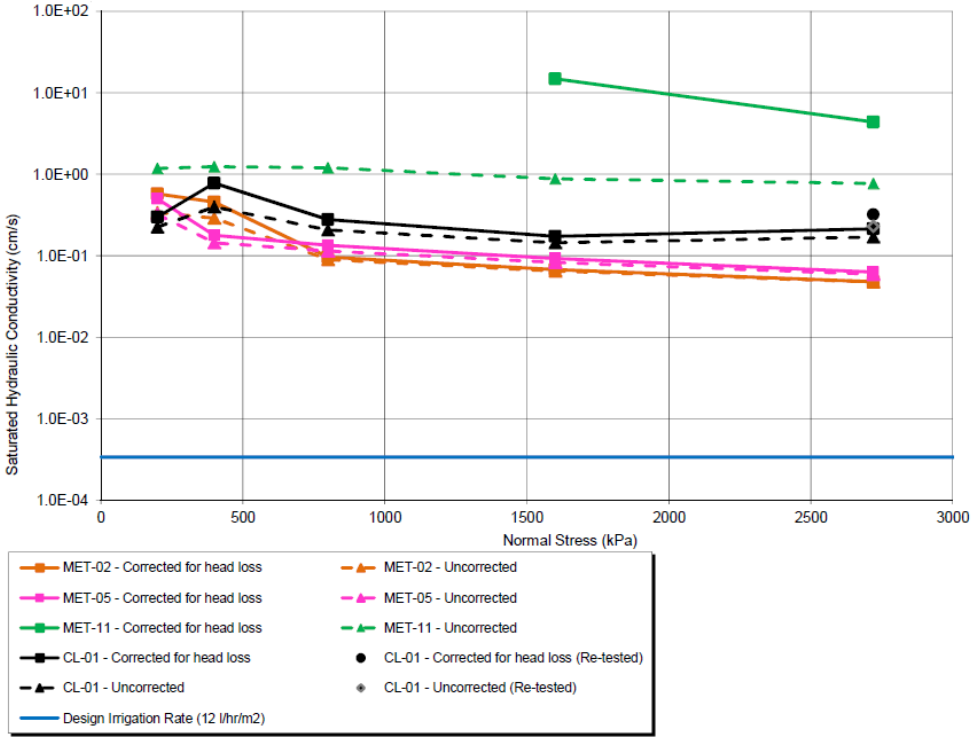


Figure 3.2 Saturated Hydraulic Conductivity versus Normal Stress

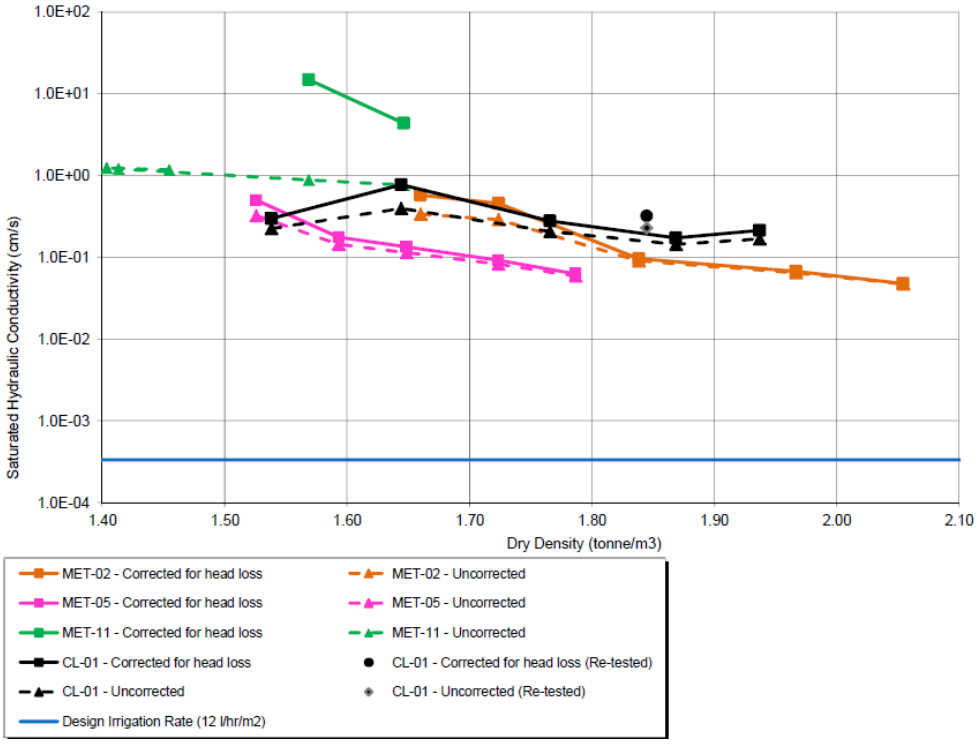

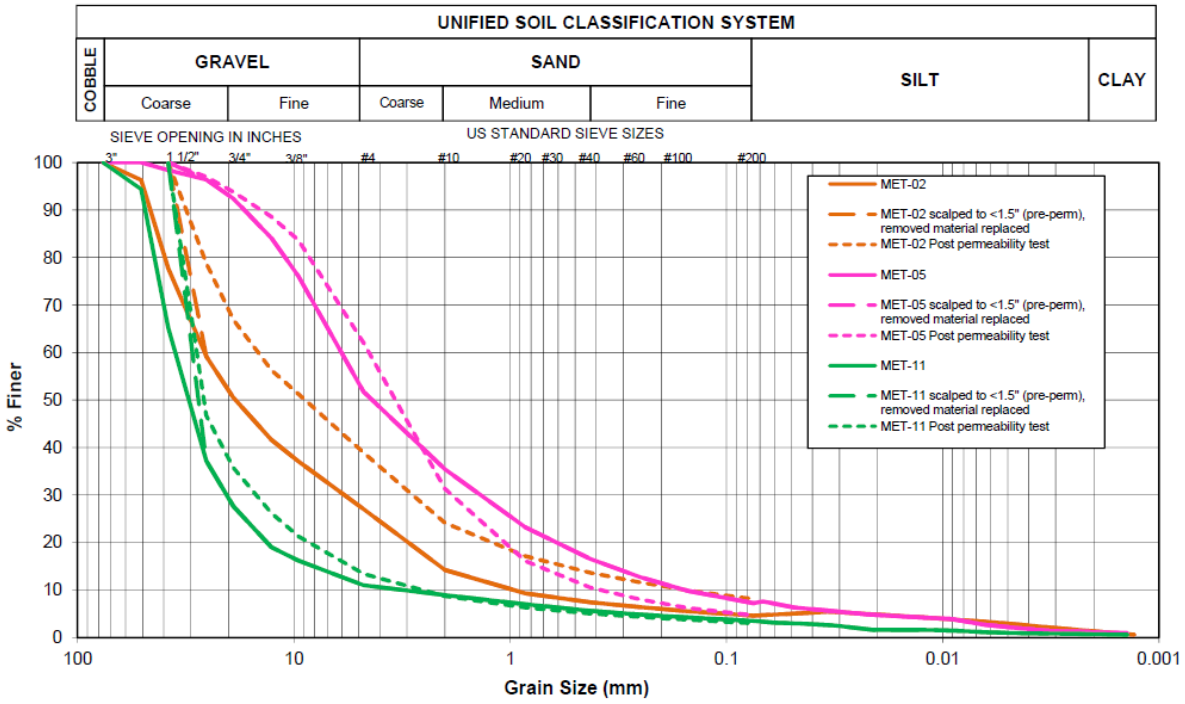

Figure 3.3 Saturated Hydraulic Conductivity versus Dry Density

Figure 3.4 displays the particle size distributions of samples MET-02, MET-05 and MET-11 before testing, after scalping off the material greater than 1.5 inch, and after hydraulic conductivity testing. Samples MET-05 and MET-11 have similar gradations before and after the hydraulic conductivity testing, indicating that there will be no significant degradation or particle breakage under heap leaching conditions. Sample MET-02 exhibits a larger change in gradation, which could indicate degradation and a reduced hydraulic conductivity.

NOTES:

1. MET-02, MET-05 and MET-11 data provided by KP soil laboratory in Denver, CO. These samples were collected in 2013 and have not been subjected to leach column testing.

Figure 3.4 Gradations Before and After Saturated Hydraulic Conductivity Tests

4 – SOIL-WATER CHARACTERISTIC CURVE TESTS

4.1 GENERAL

A soil-water characteristic curve (SWCC) relates the ore moisture content with the suction pressure, and defines the moisture holding potential of the ore. SWCCs are used to evaluate percolation and airflow studies within ore heaps.

Ore samples MET-02, MET-05 and MET-11 were tested by DBS to determine the SWCC. The remoulded samples were subjected to saturated hydraulic conductivity and moisture retention testing. The saturated hydraulic conductivity tests were conducted using the constant head method following ASTM D2434. The moisture retention testing included hanging column, pressure chamber, dewpoint potentiometer (all per ASTM D6836) and relative humidity chamber testing (Campbell and Gee, 1986). The interrelationship between moisture content, suction pressure, and hydraulic conductivity was derived by DBS using analytical equations (ASTM D6836; Van Genuchten, 1980).

The samples were tested in a 12-inch rigid wall permeameter. Material larger than 2 inch was removed and replaced with finer grained material. DBS remoulded and compacted the soil samples to match the densities achieved at 100 kPa and 2720 kPa normal stress from the KP laboratory testing, representing loose and dense samples. The densities that were targeted in the DBS laboratory included an oversize correction to account for the material greater than 1.5 inch that was removed in the KP laboratory testing. The target densities for the DBS samples (in tonne/m^3) are indicated in brackets in Table 4.1. Sample MET-05 (1.47 tonne/m^3) settled out during testing, leading to a higher density (1.62 tonne/m^3) than targeted.

4.2 RESULTS AND INTERPRETATION

The results of the saturated hydraulic conductivity tests are summarized in Table 4.1.

DBS presented saturated hydraulic conductivity results with and without a correction to compensate for the removal of material greater than 2 inch (Appendix D). The oversize correction uses the methodology published by Bouwer and Rice (1984). Their correction factors are based on testing of bi-modally graded materials containing uniform large rock fragments (boulders) and homogeneous fine earth fractions (pure sand). They found that an increase of the coarse fraction results in a more tortuous flowpatch, therefore reducing the hydraulic conductivity. However, research by Milczarek et al. (2006) on well graded material samples with varying amounts of gravel, show poor agreement with the published correction factors. They show that saturated hydraulic conductivity decreased with up to 30% gravel content but increased by orders of magnitude at higher gravel contents. They recommend that published correction factors not be used unless the sample is similar in gradation and bulk density to the soils tested by the published method. The tested leach ore materials have a coarse gradation with high gravel contents, which is different from the study by Bouwer and Rice. It is noted that the correction has little effect as the fraction greater than 2 inch is less than 6% by weight for all tested samples. Consequently no oversize correction is applied to the saturated hydraulic conductivity.

The DBS laboratory results indicate saturated hydraulic conductivities that are typically about one order of magnitude lower than the KP results for similar sample density. This can likely be attributed to the difference in the sample preparation method. The head loss in the testing apparatus is negligible for the hydraulic conductivities obtained by DBS, and therefore no head loss correction is

required. The DBS laboratory results indicate a decrease in hydraulic conductivity with increasing density, similar to the trend observed in the KP laboratory results. All test results show hydraulic saturated conductivities that are higher than the current design solution application rate of (12 l/hr/m^2, which is equivalent to 3.3 x 10^{-4} cm/s).

Table 4.1 Summary of Saturated Hydraulic Conductivity Test Results from DBS Lab

Sample ID	Normal Stress	Dry Density	K_{sat}
	(kPa)	(tonne/m^3)	(cm/s)
MET-02 (1.75)	Atmospheric	1.75	2.2E-02
MET-02 (2.00)	Atmospheric	2.00	2.0E-03
MET-05 (1.47)	Atmospheric	1.62	2.6E-02
MET-05 (1.79)	Atmospheric	1.79	1.6E-02
MET-11 (1.66)	Atmospheric	1.66	3.5E-02
MET-11 (1.94)	Atmospheric	1.94	1.9E-02

NOTES:
1. No oversize or head loss correction applied.
2. Sample MET-05 (1.47) settled out to a density of 1.62 tonne/m^3 during testing.
3. K_{sat} = saturated hydraulic conductivity, not corrected for head loss in testing apparatus.

The SWCC curves are presented on Figure 4.1 through Figure 4.3. The SWCC curves illustrate that hydraulic properties vary significantly with minor changes in grain size and moisture content. The particle size distribution in an actual ore heap is variable due to segregation from dumping and ore variability. The SWCC relationships will therefore vary more widely in practice than those obtained from the laboratory tests. The wide range in hydraulic properties may give rise to preferential flow paths, which are commonly seen in heap leach pads.

Figure 4.3 displays the hydraulic conductivity as a function of gravimetric moisture content. The design solution application rate is also included in the figure. The crushed ore samples are predicted to have gravimetric moisture contents ranging from 11 to 22% under steady state leaching conditions. However, the ore has a lower moisture content when it is crushed and placed on the heap. The gravimetric ore moisture content after placement is typically below 10%, which leads to a hydraulic conductivity that is lower than the irrigation rate. The solution will pool on top of the ore until the moisture content has increased (‘wet up’), and a hydraulic conductivity is reached that is compatible with the solution application rate.

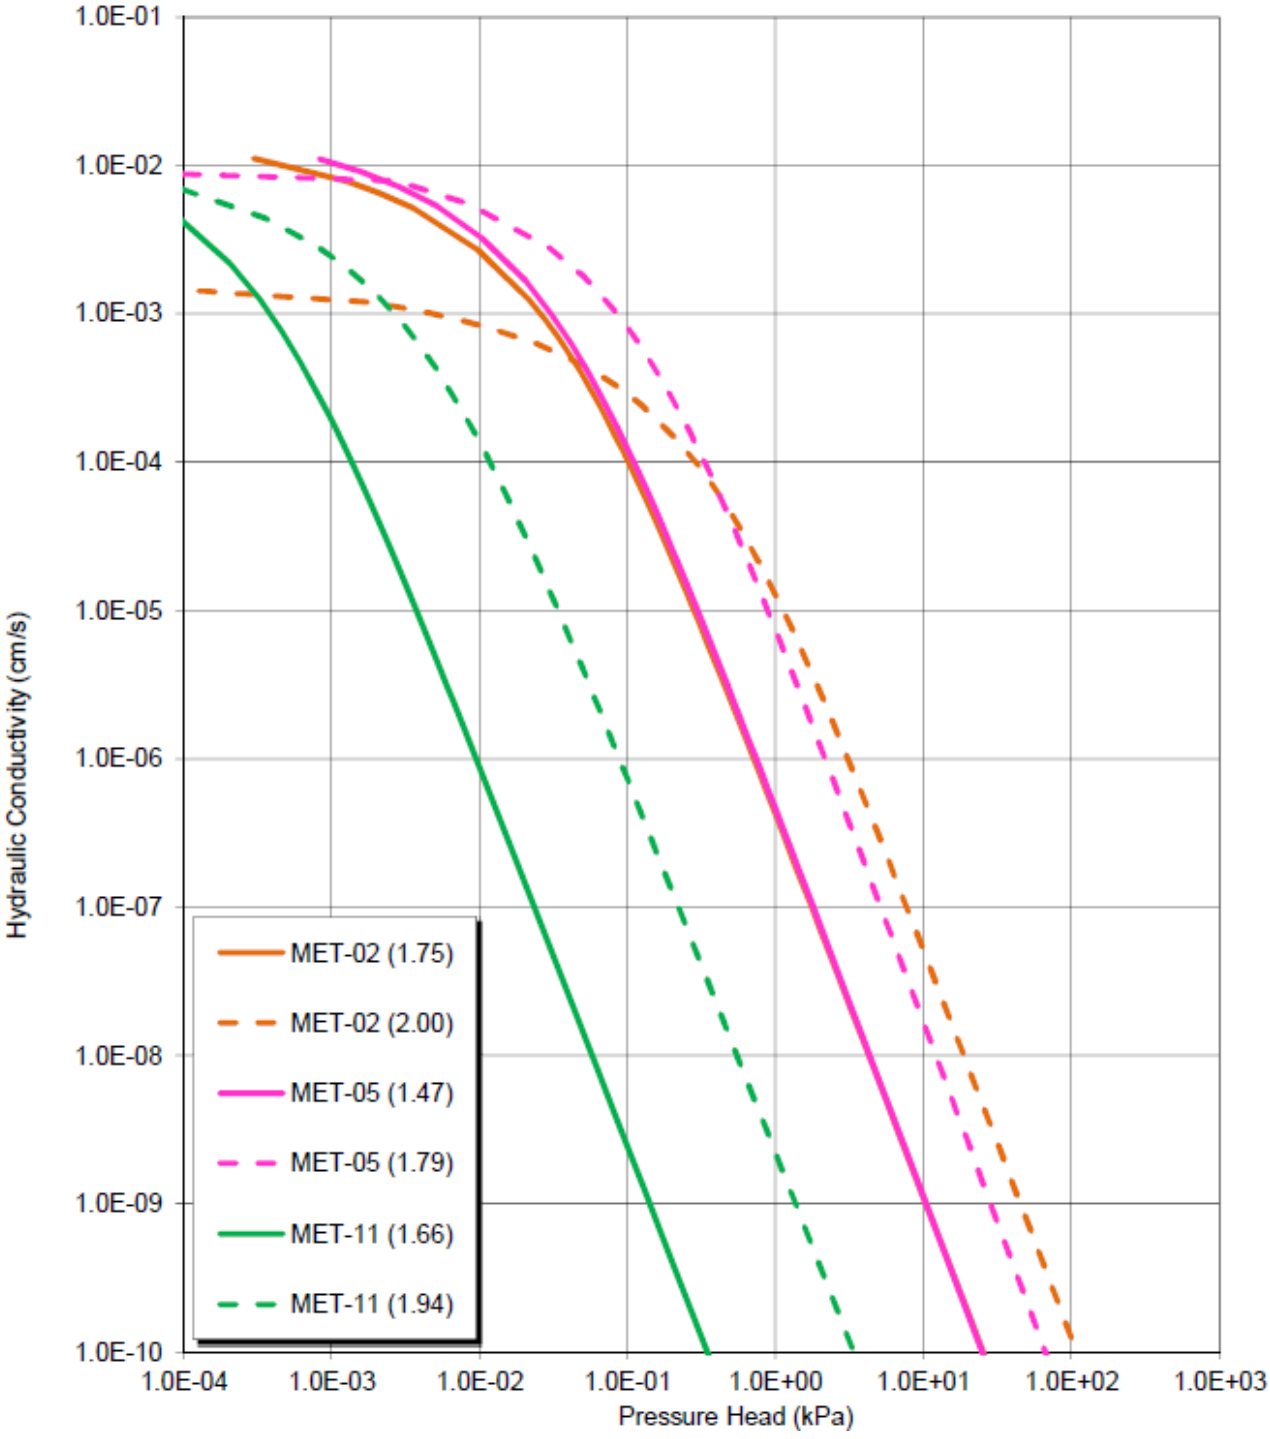

Figure 4.1 Hydraulic Conductivity versus Pressure Head

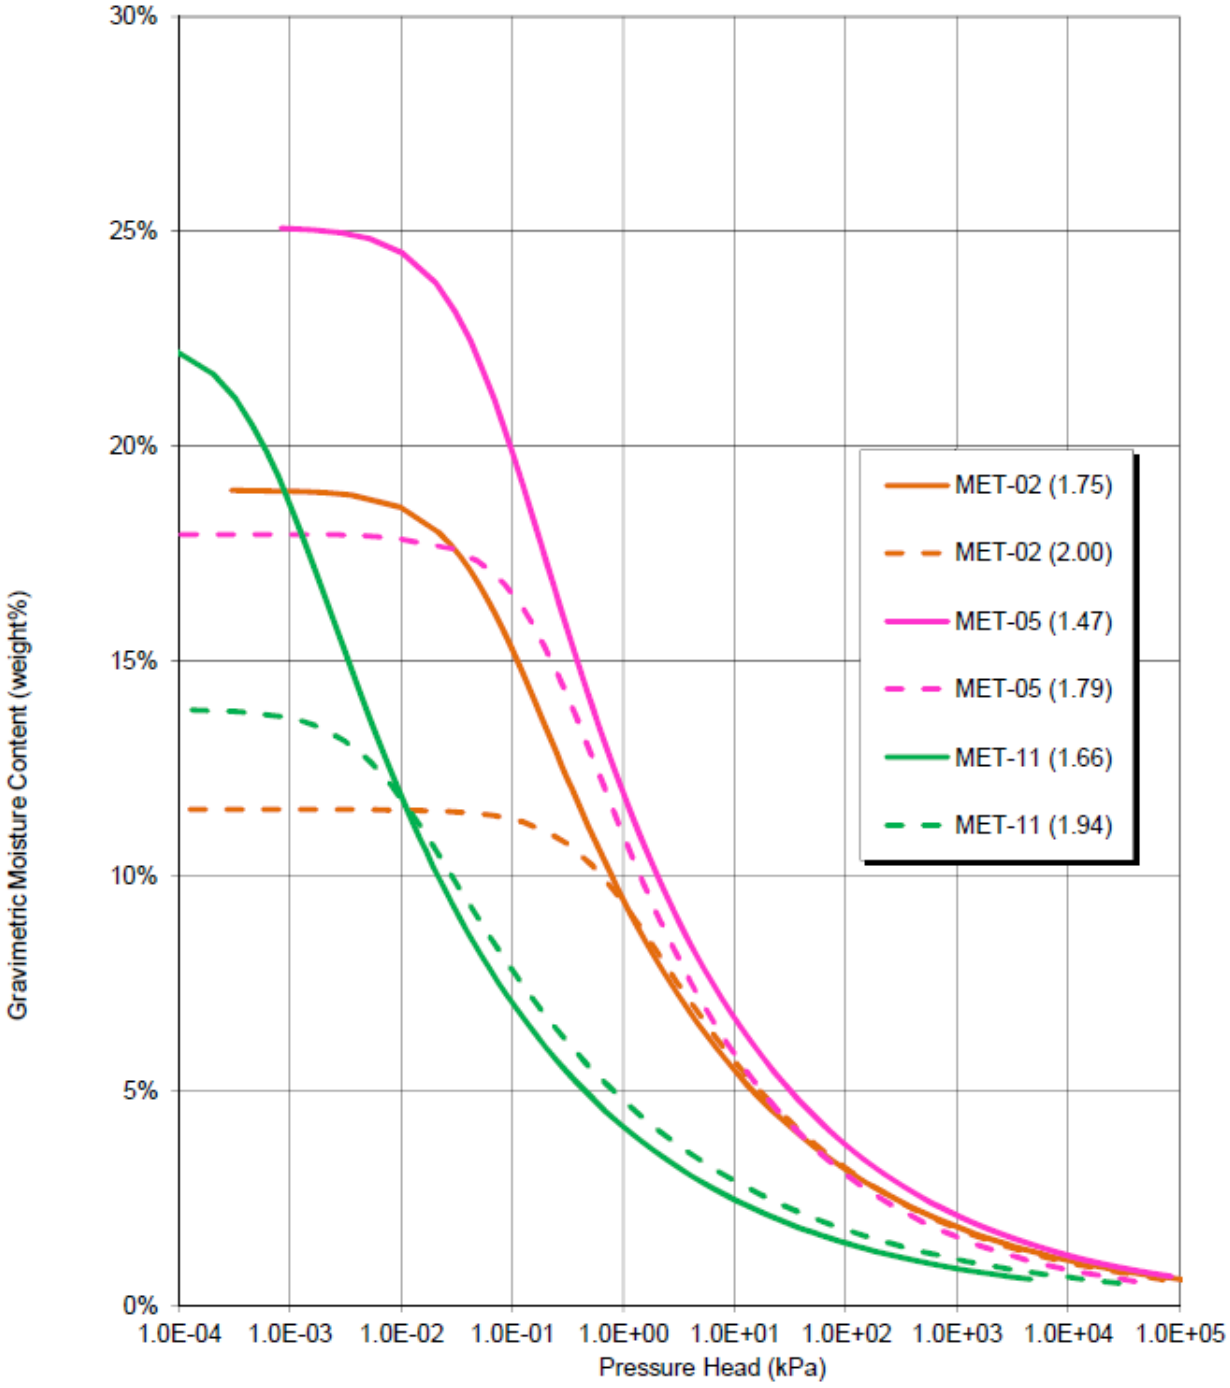

Figure 4.2 Gravimetric Moisture Content versus Pressure Head

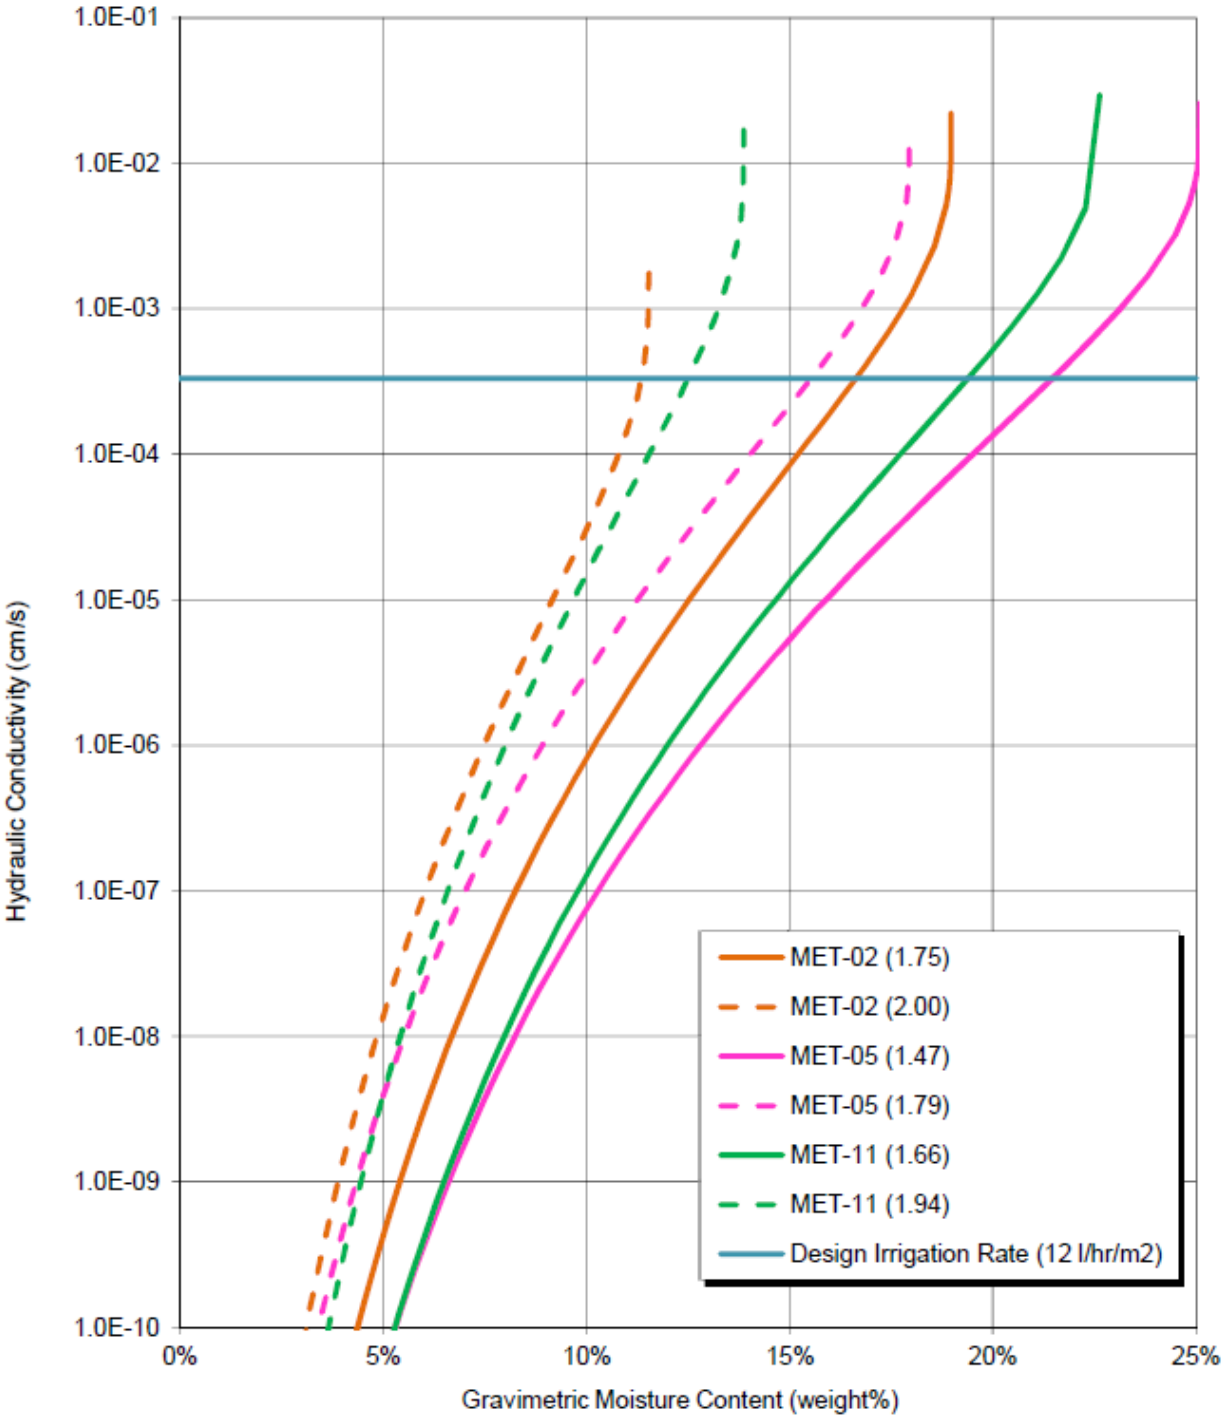

Figure 4.3 Hydraulic Conductivity versus Gravimetric Moisture Content

5 – LOAD-PERCOLATION TESTS

5.1 GENERAL

The purpose of the load-percolation tests is to determine the behaviour of the material under unsaturated conditions, and to determine what conditions (applied load and irrigation rate) are required to maintain unsaturated ore percolation. Results from these tests include the steady state moisture content under leach and the residual moisture content after draindown. These moisture content values are used in solution management (water balance) calculations.

Load-percolation tests were conducted by the KP laboratory on samples MET-02, MET-05, and MET-11. Material greater than 1.5 inch was removed from the samples and replaced with finer gravel. No standardized test procedure is available for the load-percolations test. A test procedure was developed based on a paper by Lupo (2012), as described below.

The load-percolation tests were conducted using the same 8-inch rigid-wall permeameter as used for the saturated hydraulic conductivity testing. The material was placed loosely in the test vessel, between porous plates and perforated load/bearing plates. The sample was loaded to a normal stress that was maintained throughout the test. Sample height was measured after loading to determine the bulk density and porosity of the ore.

Tap water was introduced at the top of the ore sample at a specified application rate and the effluent was collected at the bottom of the vessel. The inflow and outflow were measured during all stages of the test (including wetting, steady state and draindown) to determine when steady-state conditions were reached. The volume difference between the applied solution and effluent was used to estimate ore moisture content under leach and moisture up-take prior to leaching.

After steady-state conditions had been reached (i.e. inflow equals outflow), the sample was loaded to the next normal stress while maintaining the same irrigation rate. Irrigation continued until a new steady state developed. The sample was allowed to drain down by stopping the irrigation after loading stages as specified in Table 5.1. Measurement of the amount of effluent collected continued during draindown. The sample was removed from the apparatus after the draindown was completed (after approximately one day) and weighed to verify the moisture content. The sample was subjected to the next specified pressure or irrigation rate after determination of the draindown moisture content.

Table 5.1 Loading and Irrigation Schedule for Load-Percolation Tests

Normal Stress (kPa)	Irrigation Rate (litres/hour/m^2)
100	12

800	12
Draindown	
1600	12
2760	12
Draindown	
2760	120
Draindown	

5.2 RESULTS AND INTERPRETATION

The steady state and residual moisture contents for each sample are presented in Figure 5.1 through Figure 5.3. The test results are based on material smaller than 1.5 inch, and no oversize correction has been applied to the moisture contents. Detailed load-percolation test results are included in Appendix E.

The following observations were made:

- The steady state and residual moisture contents do not depend on normal stress.
- The steady state moisture content at 120 l/hr/m^2 is higher than that at 12 l/hr/m^2.
- The steady state moisture contents from the load-percolation tests (5 to 10%) are lower than those predicted from the SWCC (11 to 22%) at 12 l/hr/m^2.
- Ponding of solution on top of the ore sample was observed for sample MET-02 at 120 l/hr/m^2 at the highest normal stress (2760 kPa). Measurement of the degree of saturation confirmed that this sample was fully saturated. The test results indicate that saturation occurred between 3.3×10^{-4} and 3.3×10^{-3} cm/s, which is in agreement with the saturated hydraulic conductivity tests conducted at the DBS laboratory (2.0×10^{-3} cm/s). No ponding was observed for the other samples, which is also in agreement with the DBS laboratory results.
- All samples were unsaturated at the design irrigation rate (12 l/hr/m^2). Sample MET-05 and MET-11 can sustain irrigation rates of at least 10 times the current design rate.

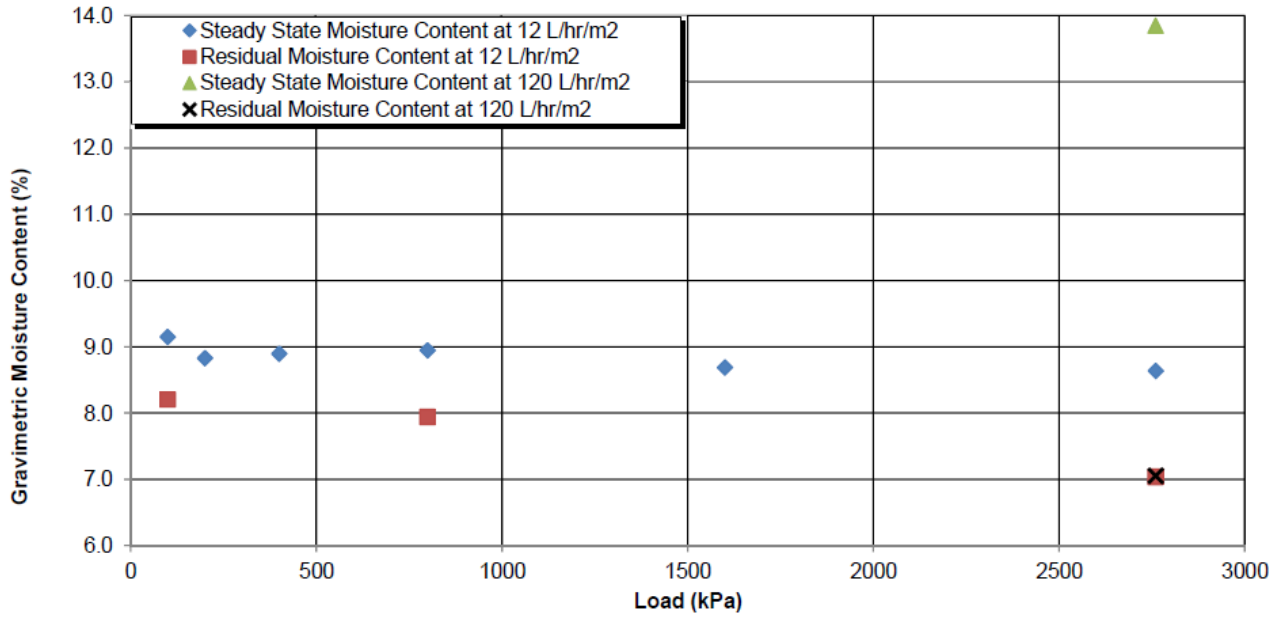

Figure 5.1 Load-Percolation Test Results for Sample MET-02

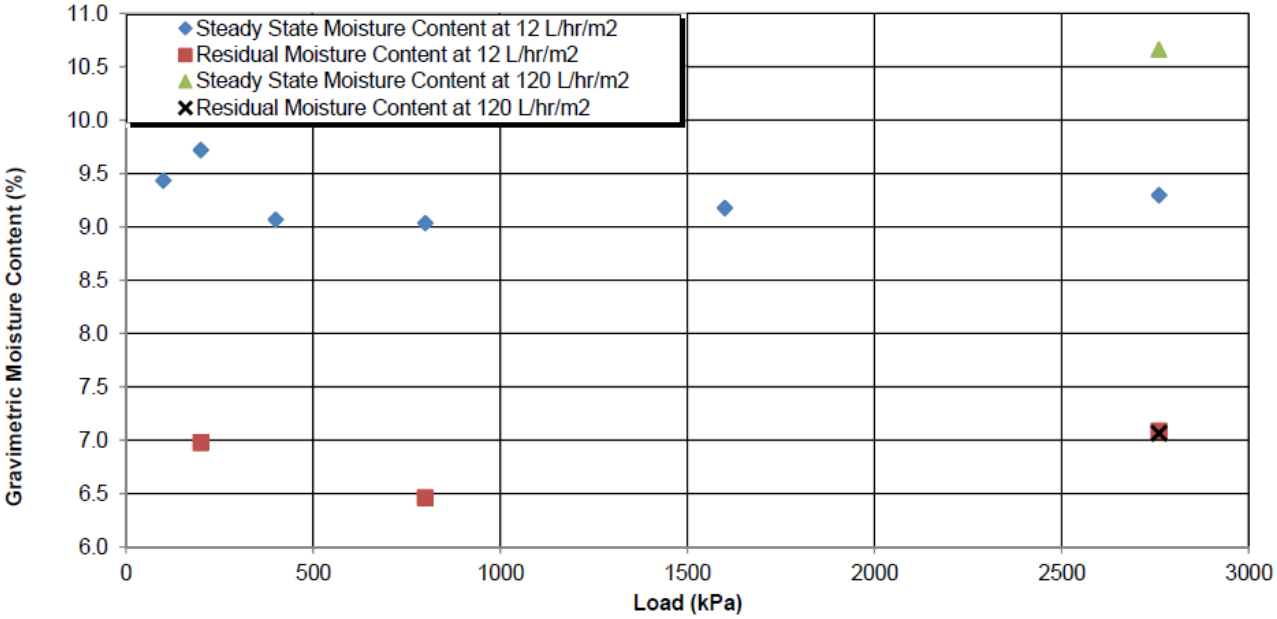

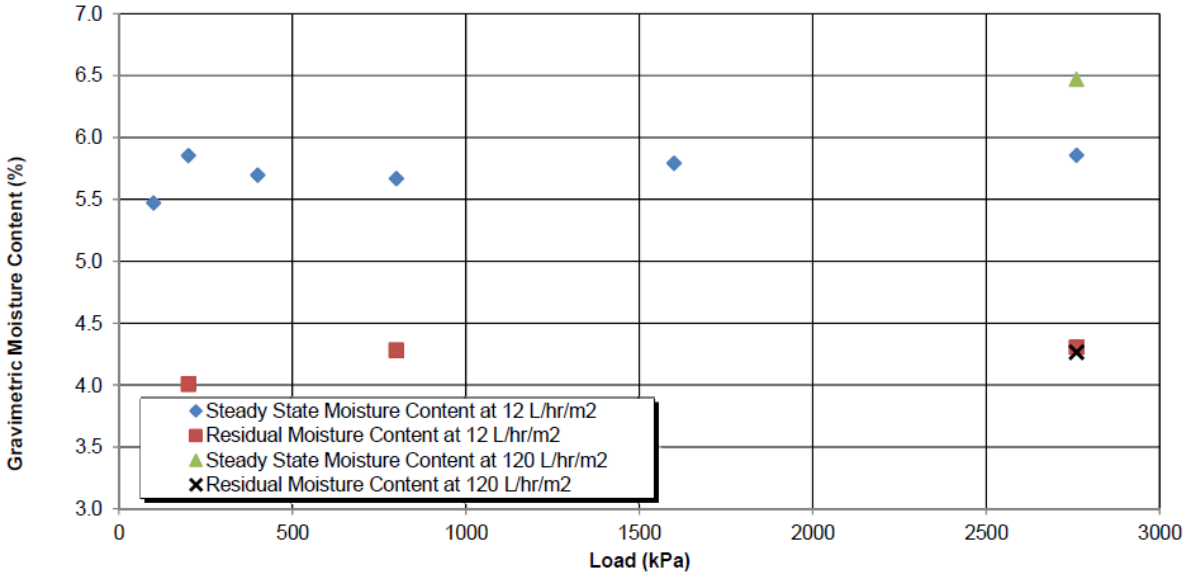

Figure 5.2 Load-Percolation Test Results for Sample MET-05

NOTES:

1. No oversize correction applied to the moisture contents.

Figure 5.3 Load-Percolation Test Results for Sample MET-11

6 – CONCLUSIONS

The ore samples are generally competent and exhibit little degradation under loading. Sample MET-05 displays most particle breakage as a result of material handling and transportation to the KP laboratory. Sample MET-02 exhibits the largest change in gradation before and after the hydraulic conductivity testing under load. This could indicate degradation and a reduced hydraulic conductivity for this ore under heap leaching conditions.

The test results show that the coarsest sample (MET-11) has the largest saturated hydraulic conductivity. The particle size distribution of the leached sample (CL-01) is similar to MET-11. The saturated hydraulic conductivity, however, is considerably lower and closer to that of MET-02 and MET-05. This may indicate that the leaching process does have some effect on hydraulic conductivity.

The results indicate a decrease in saturated hydraulic conductivity with increasing stress and density.

The DBS laboratory results indicate saturated hydraulic conductivities that are typically about one order of magnitude lower than the KPL results for similar sample density. This can likely be attributed to the difference in the sample preparation method.

The steady state gravimetric moisture contents from the load-percolation tests (5 to 10%) are lower than those predicted from the SWCC (11 to 22%) at the current design irrigation rate of 12 l/hr/m^2.

The steady state and residual moisture contents do not depend on normal stress. The steady state moisture content at 120 l/hr/m^2 is higher than that at 12 l/hr/m^2.

All test results indicate saturated hydraulic conductivities that are higher than the current design irrigation rate (12 l/hr/m^2, which is equivalent to 3.3×10^{-4} cm/s). This indicates that the proposed heap leach ore will not fully saturate under the design irrigation rate, even at the highest tested normal stress of 2720 kPa, which is equivalent to an approximately 150 m high heap (the maximum design heap height). Sample MET-05 and MET-11 can sustain irrigation rates of at least 10 times the current design rate. Ponding of solution on top of the ore sample due to saturation was observed for sample MET-02 at 120 l/hr/m^2 at the highest normal stress.

The SWCC curves illustrate that hydraulic properties vary significantly with minor changes in grain size and moisture content.

The crushed ore samples are predicted to have gravimetric moisture contents ranging from 11 to 22% under steady state leaching conditions based on the SWCC testing. However, the ore has a lower moisture content when it is crushed and placed on the heap. The gravimetric ore moisture content after placement is typically below 10%, which leads to a hydraulic conductivity that is lower than the irrigation rate. The solution will pool on top of the ore until the moisture content has increased (‘wet up’), and a hydraulic conductivity is reached that is compatible with the solution application rate.

The findings from the load-percolation tests are in agreement with the saturated hydraulic conductivity test results from the DBS laboratory.

7 – RECOMMENDATIONS

It is recommended to do additional testing to determine the effect of the leaching process on the different types of ore. It is also recommended that the actual leach solution be used instead of tap water for conducting additional permeability and percolation testing. Additional strength and hydraulic conductivity testing is recommended for samples that are most affected by the leaching process.

Memo

Attn: Paul West-Sells

From: Wm. W. Dunn July 8, 2013

Re: Casino Project Heap Leach -Metallurgical Samples 2013

- After some initial discussion between Paul West-Sells, Heather Brown & Scott Casselman, a list of potential sample sites was forwarded on June 27th; (see attached memo from Heather Brown dated July 8, 2013)
- The directions were to take samples ~0.5 meter below the bedrock/talus interface;
- The samples were to be as dry as possible and from intact bedrock;
- I located all of the site on June 28th but did not sample on June 29th due to heavy rain
- Sampled sites MET02, 11, 17, 19, & 30 on June 30th
- Sampled site MET05 on July 1st
- The samples were placed in 45 Gal drums with sealable lids;
- All drums were marked with the sample number & location
- The drums were shipped to Whitehorse via Alkan and stored in Alkan's covered storage area.
- The drums were relabeled with the final destination, Sample number and sample UTM co-ordinates on July 5th for pickup and haulage to ALS, Kamloops, BC on Monday July 8th
- See details below

NOTES:

1. No oversize correction applied.
2. Results invalid as the head loss in the apparatus exceeds the applied head.
3. K_{sat} = saturated hydraulic conductivity, not corrected for head loss in testing apparatus.
4. $K_{sat,head\ corrected}$ = saturated hydraulic conductivity, corrected for head loss in testing apparatus.
5. Head loss correction based on Trial 1.

Head Loss Correction

General Notes:
1) Tap water was used as permeant.
2) Flow conditions may vary depending on the particle distribution in the field.
3) Particles greater than 1.5" were removed and replaced with finer gravel prior to testing.
4) The sample was placed in the mold in a loose condition.
5) Audible breaking of rock noted during test.

General Notes:
1) Tap water was used as permeant.
2) Flow conditions may vary depending on the particle distribution in the field.
3) Particles greater than 1.5" were removed and replaced with finer gravel prior to testing.
4) The sample was placed in the mold in a loose condition.
5) Audible breaking of rock noted during test.

Re: DBS&A Laboratory Report for the Knight Piesold Casino, VA101-00325/16 Project

Dear Mr. Brinkman:

Enclosed is the report for the Knight Piesold Casino, VA101-00325/16 project samples. Please review this report and provide any comments as samples will be held for a maximum of 30 days. After 30 days samples will be returned or disposed of in an appropriate manner.

All testing results were evaluated subjectively for consistency and reasonableness, and the results appear to be reasonably representative of the material tested. However, DBS&A does not assume any responsibility for interpretations or analyses based on the data enclosed, nor can we guarantee that these data are fully representative of the undisturbed materials at the field site. We recommend that careful evaluation of these laboratory results be made for your particular application.

The testing utilized to generate the enclosed report employs methods that are standard for the industry. The results do not constitute a professional opinion by DBS&A, nor can the results affect any professional or expert opinions rendered with respect thereto by DBS&A. You have acknowledged that all the testing undertaken by us, and the report provided, constitutes mere test results using standardized methods, and cannot be used to disqualify DBS&A from rendering any professional or expert opinion, having waived any claim of conflict of interest by DBS&A.

We are pleased to provide this service to Knight Piesold and look forward to future laboratory testing on other projects. If you have any questions about the enclosed data, please do not hesitate to call.

Sincerely,

DANIEL B. STEPHENS & ASSOCIATES, INC.

Summaries

Summary of Tests Performed

Laboratory Sample Number	Initial Soil Properties[1]			Saturated Hydraulic Conductivity[2]			Moisture Characteristics[3]								Particle Size[4]			Specific Gravity[5]		Air Perm-eability	Atterberg Limits	Proctor Compaction
	G	VM	VD	CH	FH	FW	HC	PP	FP	DPP	RH	EP	WHC	K_{unsat}	DS	WS	H	F	C			
MET-02 (1.75) MR	X	X		X			X			X	X			X								
MET-02 (2.00) MR	X	X		X			X			X	X			X								
MET-05 (1.47) MR	X	X		X			X			X	X			X								
MET-05 (1.79) MR	X	X		X			X			X	X			X								
MET-11 (1.66) MR	X	X		X			X			X	X			X								
MET-11 (1.94) MR	X	X		X			X			X	X			X								

[1] G = Gravimetric Moisture Content, VM = Volume Measurement Method, VD = Volume Displacement Method

[2] CH = Constant Head Rigid Wall, FH = Falling Head Rigid Wall, FW = Falling Head Rising Tail Flexible Wall

[3] HC = Hanging Column, PP = Pressure Plate, FP = Filter Paper, DPP = Dew Point Potentiometer, RH = Relative Humidity Box, EP = Effective Porosity, WHC = Water Holding Capacity, Kunsat = Calculated Unsaturated Hydraulic Conductivity

[4] DS = Dry Sieve, WS = Wet Sieve, H = Hydrometer

[5] F = Fine (<4.75mm), C = Coarse (>4.75mm)

Notes

Sample Receipt:
Three samples were received on November 4, 2013, each in two full to 3/4 full 5-gallon buckets.

Testing Notes:
The samples were prepared by remolding the material passing the 2" sieve to target remold densities provided by the client. The target remold densities were based on permeability tests that were performed using material finer than 1.5". The target remold densities were corrected to account for the material larger than 1.5" and finer than 2", based on the client provided target densities (for material <1.5") and grain size distributions. The adjusted target remold densities are provided in the table below:

	-1.5"			-2"		
	-1.5" Target Density #1	-1.5" Target Density #2		Mass % of Material <2"/>1.5"	-2" Target Density #1	-2" Target Density #2
	g/cm^3	g/cm^3		%	g/cm^3	g/cm^3
MET-02	1.63	2.06		19.52	1.77	2.16
MET-05	1.47	1.79		1.60	1.48	1.80
MET-11	1.37	1.65		30.93	1.66	1.93

Samples MET-02 and MET-05 were remolded after moisture correcting the material to a gravimetric moisture content of ~3%, and sample MET-11 was remolded after moisture correcting the material to a gravimetric moisture content of ~1%. The actual initial remolded density of each sample was added to the sample ID (in g/cc).

The remolded samples were subjected to initial properties, saturated hydraulic conductivity, and the hanging column and pressure chamber portions of the moisture retention testing. Oversize correction calculations are presented for sample MET-11, since the fraction of material larger than 2" was greater than 5% of the bulk sample mass.

Remaining bulk sample material was used for the dewpoint potentiometer and relative humidity chamber portions of the moisture retention testing.

Volume changes (settling) occurred for the 'MET-05 (1.47)' sample during the hanging column and pressure chamber portions of the analysis. The reported volumetric moisture contents are adjusted for volume changes, when applicable. Due to the irregularities formed on the sample surfaces, volume measurements obtained after the initial reading should be considered estimates.

Total porosity calculations in this report are based on the use of an assumed specific gravity value of 2.65.

Summary of Sample Preparation/Volume Changes

	Target Remold Parameters[1]			Actual Remold Data				Volume Change Post Saturation[2]				Volume Change Post Drying Curve[3]			
Sample Number	Moist. Cont. (%, g/g)	Dry Bulk Density (g/cm^3)	Dry Bulk Density (pcf)	Moist. Cont. (%, g/g)	Dry Bulk Density (g/cm^3)	Dry Bulk Density (pcf)	% of Target Density (%)	Dry Bulk Density (g/cm^3)	Dry Bulk Density (pcf)	% Volume Change (%)	% of Initial Density (%)	Dry Bulk Density (g/cm^3)	Dry Bulk Density (pcf)	% Volume Change (%)	% of Initial Density (%)
MET-02 (1.75)	3.0	1.77	110.5	4.0	1.75	109.46	99.1%	1.75	109.46	---	100.0%	1.75	109.46	---	100.0%
MET-02 (2.00)	3.0	2.16	134.8	3.3	2.00	124.87	92.6%	2.00	124.87	---	100.0%	2.00	124.87	---	100.0%
MET-05 (1.47)	3.0	1.48	92.39	3.55	1.47	91.85	99.4%	1.62	101.28	-9.3%	110.3%	1.62	101.28	-9.3%	110.3%
MET-05 (1.79)	3.0	1.80	112.37	3.63	1.79	111.60	99.3%	1.79	111.60	---	100.0%	1.79	111.60	---	100.0%
MET-11 (1.66)	1.0	1.66	103.63	0.93	1.66	103.54	99.9%	1.66	103.54	---	100.0%	1.66	103.54	---	100.0%
MET-11 (1.94)	1.0	1.93	120.49	0.60	1.94	120.97	100.4%	1.94	120.97	---	100.0%	1.94	120.97	---	100.0%

[1]Target Remold Parameters: Provided by the client, and adjusted for material larger than 1.5" and finer than 2", based on the client provided grain size distributions. See 'Notes' page for additional information.

[2]Volume Change Post Saturation: Volume change measurements were obtained after saturated hydraulic conductivity testing.

[3]Volume Change Post Drying Curve: Volume change measurements were obtained throughout hanging column and pressure plate testing. The 'Volume Change Post Drying Curve' values represent the final sample dimensions after the last pressure plate point.

Notes:

"+" indicates sample swelling, "-" indicates sample settling, and "---" indicates no volume change occurred.

Summary of Initial Moisture Content, Dry Bulk Density Wet Bulk Density and Calculated Porosity

Volume Adjusted Data [1]

	Matric Potential (-cm water)	Adjusted Volume (cm^3)	% Volume Change [2] (%)	Adjusted Density (g/cm^3)	Adjusted Calculated Porosity (%)
Hanging column:	0.0	---	---	---	---
	7.5	---	---	---	---
	15.0	---	---	---	---
	50.0	---	---	---	---
	150.0	---	---	---	---

Comments:

[1] Applicable if the sample experienced volume changes during testing. 'Volume Adjusted' values represent each of the volume change measurements obtained after saturated hydraulic conductivity testing and throughout hanging column/pressure plate testing. "---" indicates no volume changes occurred.

[2] Represents percent volume change from original sample volume. A '+' denotes measured sample swelling, a '-' denotes measured sample settling, and '---' denotes no volume change occurred.

* Weight including tares

† Assumed density of water is 1.0 g/cm^3

‡‡ Volume adjustments are applicable at this matric potential (see comment #1). Changes in volume, if applicable, are estimated based on obtainable measurements of changes in sample length and diameter.

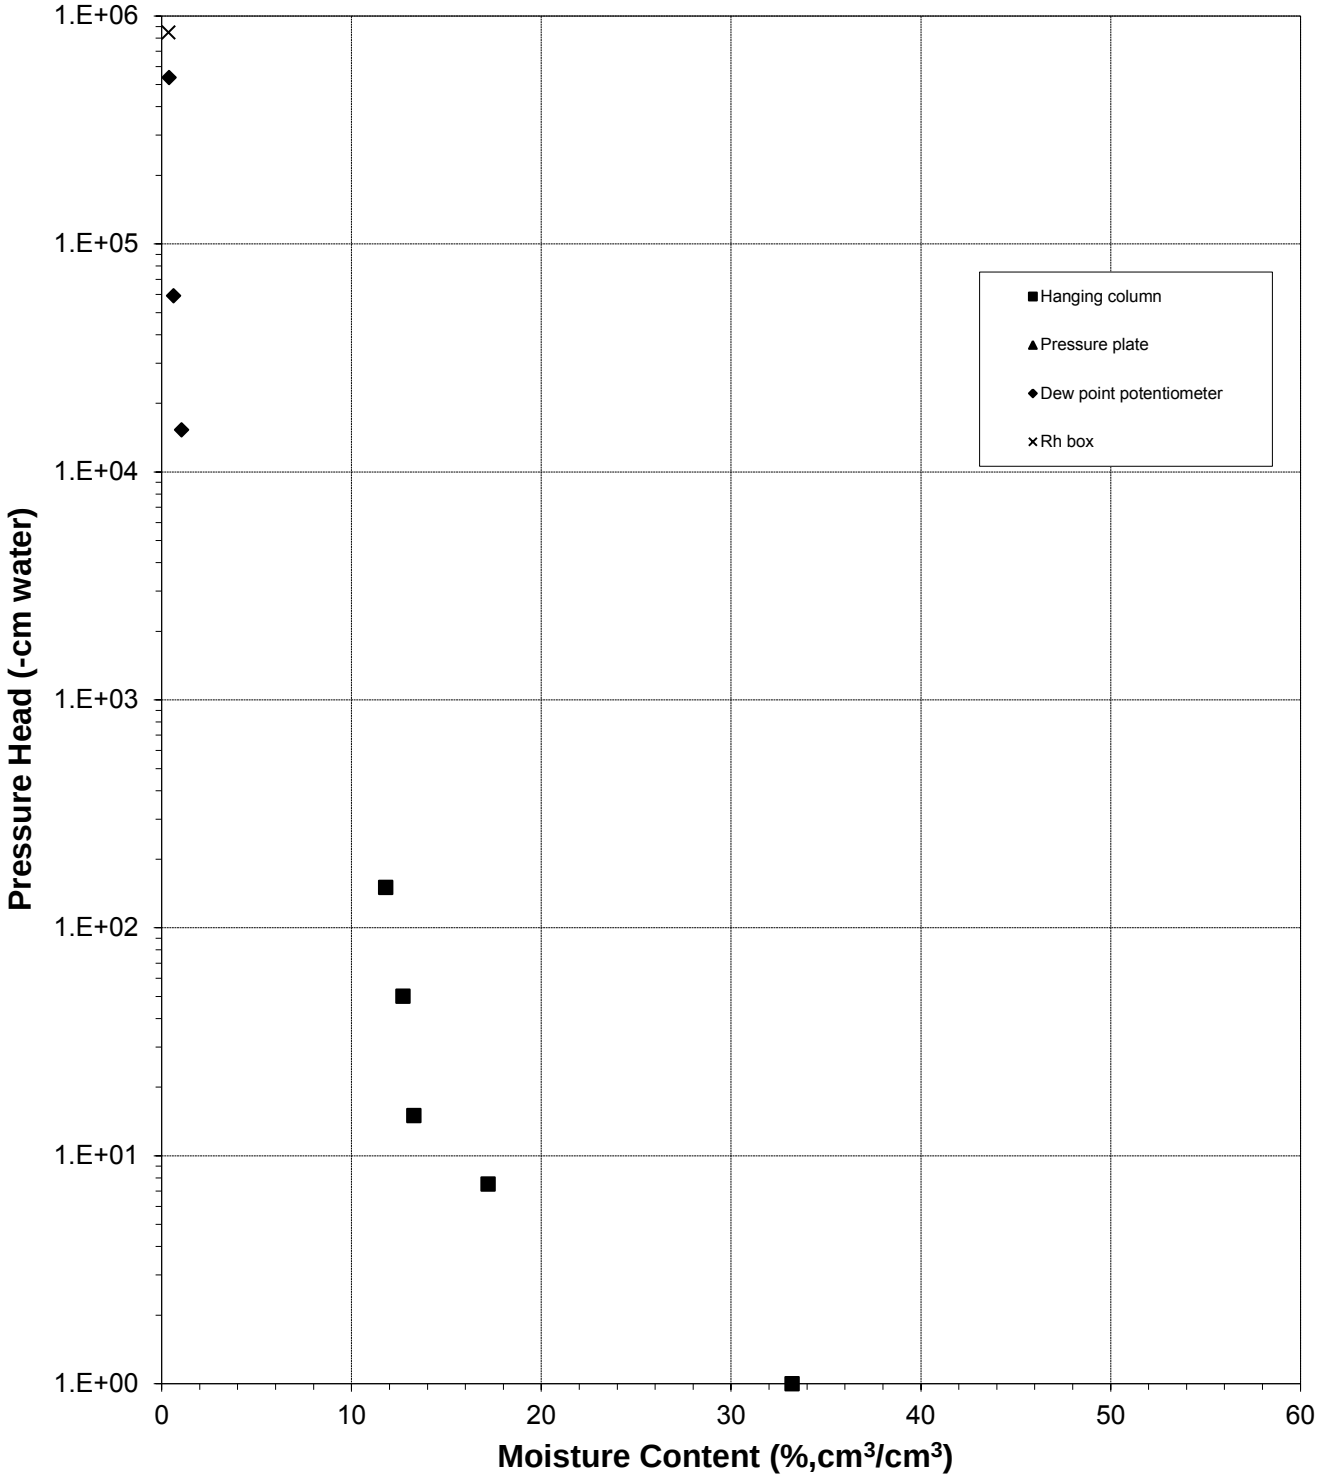
[2] Represents percent volume change from original sample volume. A '+' denotes measured sample swelling, a '-' denotes measured sample settling, and '---' denotes no volume change occurred.

* Weight including tares



† Adjusted for >2.00mm (#10 sieve) material not used in DPP/RH testing. Assumed moisture content of material >2.00mm is zero, and assumed density of water is 1.0 g/cm^3.

‡‡ Volume adjustments are applicable at this matric potential (see comment #1). Changes in volume, if applicable, are estimated based on obtainable measurements of changes in sample length and diameter.

1.0 INTRODUCTION

In October 2013, SGS E&S Engineering Solutions Inc. (SGS) submitted a proposal to Casino Mining Corporation for conducting a column leach study on lithology composite samples from the Casino Project. The metallurgical study was conducted at the SGS facility in Tucson, Arizona including the following scope of work:

- Sample Preparation and Head Sample Assays
- Cyanidation Bottle Roll Testing
- Cyanide Column Leach Testing
- Column Leach Test Residue Rinse Cycle Study

The main objective of the column leach study was to determine the amenability of the composite samples to gold and silver extractions by heap leach type of leaching process. The testing procedures utilized in this leach test program are standard leach procedures and are common and acceptable in industrial practice. The metallurgical study was conducted under the supervision of Rodrigo R. Carneiro, Director of Metallurgical Research.

2.0 SUMMARY

The column test program was conducted on three composite samples generated from the samples received from the Casino Project. The primary objective of this test program was to generate gold extraction, silver extraction, sodium cyanide and calcium oxide consumptions on the composite samples from the Casino Project. Cyanidation bottle roll tests were conducted at 100 percent minus 10 mesh sizes to evaluate the reagent consumption prior to the column leach testing.

The metallurgical data developed showed that approximately 62 percent and 83 percent of the gold contained in the head samples may be recovered by cyanide heap leach process. The data developed and metallurgical results obtained on this study are summarized in the following paragraphs.

2.1 Sample Preparation and Head Assays

Samples identified as MET-02, MET-05, MET-11, MET-17, MET-19 and MET-20 were received for metallurgical testing. See Appendix 1 for details on the samples received for metallurgical testing. Upon arrival the samples were logged in, blended to make three composite samples as listed below:

- Composite 1 (MET-02 / MET-05)
- Composite 2 (MET-11 / MET-17)
- Composite 3 (MET-19 / MET-20)

Each composite sample was processed using the standard operating procedures to prepare column test charges and samples for head screen assays. The head assay results obtained on the composite samples are summarized in the following table. Specific details on individual samples received for metallurgical testing, head sample preparation and assay results are discussed in Section 3.1 and Appendix 2. The following table summarizes the head assays on the composite samples.

Table 2.1
Summary of Head Assay Results

Sample ID	Au g/t	Ag g/t	Cu %	Fe %
Composite 1	0.27	0.85	0.01	1.65
Composite 2	0.54	2.70	0.05	2.24
Composite 3	0.63	2.77	0.07	5.12

The following comments relate to the head assay results developed on the three composite samples.

- Gold content ranged from approximately 0.27 g/t to 0.63 g/t. The highest gold content of 0.63 g/t was observed in Composite 3.

- Silver content ranged from approximately 0.85 g/t to 2.77 g/t. The highest silver content of 2.77 g/t was observed in Composite 3 sample.

- Low copper content was observed in all composite samples.

- Iron content ranged from approximately 1.65 percent to 5.12 percent. The highest iron content of 5.12 percent was observed in Composite 3.

2.2 Cyanidation Bottle Roll Testing on Composite Samples

Cyanidation bottle roll testing was conducted on each composite sample using a 1,000 gram test charge at 100 percent minus 10 mesh for 96 hours to evaluate cyanide and lime consumptions, and to determine lime dosage to be added to the test charge prior to the column loading.

The metallurgical data developed on the agitated cyanidation bottle roll testing on the composite samples are summarized in Table 2.2 below. Specific details relate to reagents additions, sampling schedule and mass balance are included in Section 3.2 and Appendix 3 in this report.

Table 2.2
Summary of Results
Bottle Roll Testing

Test No.	Sample ID	Assay Head			Calculated Head			% Extraction			Consumptions	
		Au (ppm)	Cu (ppm)	Ag (ppm)	Au (ppm)	Cu (ppm)	Ag (ppm)	Au (%)	Cu (%)	Ag (%)	NaCN (kg/t)	CaO (kg/t)
BR-01	Composite 1	0.270	72	0.8	0.255	147	0.9	80.40	11.52	20.71	0.293	2.701
BR-02	Composite 2	0.537	462	2.7	0.572	636	2.8	86.00	37.10	23.96	0.479	3.565
BR-03	Composite 3	0.627	729	2.8	0.642	854	3.0	82.86	7.45	29.58	0.130	4.180

The following comments relate to the metallurgical data obtained in the bottle roll tests on the three composite samples.

- Gold extraction ranged from approximately 80 percent to 86 percent. Composite 2 showed the highest gold extraction of 86.00 percent.

- Silver extraction ranged approximately from 21 percent to 30 percent. Composite 2 showed the highest silver extraction of 29.58 percent.

- Sodium cyanide consumption ranged from approximately 0.13 kg/t to 0.48 kg/t.

- Calcium oxide (lime) consumptions ranged from approximately 2.7 kg/t to 4.2 kg/t.

2.3 Open Cycle Column Leach Study

The open cycle column leach testing was conducted on the three composite samples prepared per instructions given by Casino Mining Corporation personnel. The column tests were conducted in 6 in x 10 ft PVC columns at the “as received” crush size. No crushing was conducted on the samples received for metallurgical testing.

Six column tests were conducted on three composite samples in duplicates and subjected to open cycle type of leach regime for 47 to 53 days followed by rinsing in open and closed cycle regimes for 44 to 79 days.

The feed solution containing approximately 700 mg/L of sodium cyanide and 300 mg/L of copper was used to leach the ore samples under open cycle type of leaching regime. Copper sulfate was added to feed solution to achieve the targeted concentration. The feed solution pH was maintained between 11 and 11.5 by adding reagent grade calcium oxide (CaO). The leaching parameters and test conditions are discussed in details in Section 3.3 in this report.

The summary of metallurgical results obtained from the column leach study on the composite samples after at least 104 days of leaching and rinsing cycles are presented in Table 2.3 below. Specific details relate to leaching conditions, solution assays, head and leach residue assays are included in Appendices 4 through 11 in this report.

Table 2.3
Summary of Locked Cycle Column Testing

Test No.	Sample ID.	Head Assay Screen (g/t)			Pregnant Solution pH	kl of Solution/t of Ore	Extraction (%)		Reagent Consumption (kg/t)	
		Au	Cu	Ag			Au	Ag	NaCN	CaO
		(g/t)	(g/t)	(g/t)						
CL-01	Composite 1	0.27	72.29	0.85	9.88	0.18	82.56	27.97	0.26	4.34
CL-02	Composite 1 Duplicate	0.27	72.27	0.85	9.85	0.19	81.90	27.78	0.20	4.18
CL-03	Composite 2	0.54	46.17	2.70	10.18	0.16	64.55	22.71	0.68	3.11
CL-04	Composite 2 Duplicate	0.54	46.19	2.70	10.23	0.16	62.31	16.63	0.44	3.10
CL-05	Composite 3	0.63	72.95	2.76	10.12	0.15	75.09	26.29	0.47	3.51
CL-06	Composite 3 Duplicate	0.63	72.95	2.77	10.39	0.15	73.28	26.01	0.19	3.38

The following comments relate to the column leach tests conducted on the three composite samples.

- Gold extraction on composite samples ranged from 62.31 percent to 82.56 percent. The highest gold extraction of approximately 83 percent was observed on the Composite 1 rinsed with re-circulating off solution.

- It seems that copper content in the feed solution did not have a significant impact on sodium cyanide consumption and gold extraction

- Silver extraction ranged from approximately 17 percent to 28 percent in all tests.

- Sodium cyanide consumption on the composite samples ranged from 0.19 kg/t to 0.68 kg/t.

- Calcium oxide (lime) consumption ranged from 3.10 kg/t to 4.34 kg/t.

- There is a good correlation of the gold and silver extractions between the duplicate column tests. See Appendices 4 through 10 for details on column leach mass balance and daily assays.

3.0 RESULTS AND DISCUSSIONS

The results of the head screen assays, agitated cyanidation bottle roll tests and column leach tests conducted on the composite samples tested are presented in the following paragraphs. Specific details related to leaching conditions and metallurgical data developed are included in Appendices 2 through 11 in this report.

3.1 Sample Preparation and Head Assay

In April 2014, six samples identified as MET-02, MET-05, MET-11, MET-17, MET-19 and MET-20 from the Casino Project were received for metallurgical testing. See Appendix 1 for samples received metallurgical testing. Upon arrival the samples were logged in and prepared according to the following steps:

- MET-02 and MET-05 samples were combined to generate Composite 1, MET-11 and MET-17 samples were combined to generate Composite 2 and MET-19 and MET-20 samples were combined to generate Composite 3.

- Each composite sample was air dried and screened using the 2 inch, 1-1/2 inch, 1 inch, 3/4 inch, 1/2 inch, 1/4 inch, 10 mesh and minus 10 mesh.

- Each screen fraction was weighed and the as received particle size distribution was calculated. Each screen fraction was kept segregated. See Appendix 2* for screen fraction weights and assay results.

- Two test charges of 89 kilograms for column testing and one test charge for head screen assays were reconstituted based on the “as received” particle size distribution.

- Each screen fraction from the head screen assays test charge was stage crushed to 100 percent minus 10 mesh. A sample of approximately 1,000 grams was split from each screen fraction, pulverized, and a portion of approximately 150 grams was split and submitted for gold, silver, copper, iron, cyanide soluble gold, cyanide soluble silver and cyanide soluble copper assays.

- A 1,000 gram sample was split from the minus 10 mesh fraction and submitted for wet/dry screen analysis using 14 mesh, 20 mesh, 28 mesh, 35 mesh, 48 mesh, 65 mesh, 100 mesh, 150 mesh, 200 mesh, 270 mesh and 400 mesh sieves.

- One pulverized composite of 1,000 grams was reconstituted from the pulverized fraction samples based on the “as received” particle size distribution, a portion was split and submitted for gold, silver, copper, iron, cyanide soluble gold, cyanide soluble silver and cyanide soluble copper assays.

- One 1,000 gram 100 percent minus 10 mesh test charge was prepared from the crushed (minus 10 mesh) head screen fraction samples based on the particle size distribution for agitated cyanide bottle roll testing.

Head screen assays on the composite samples for metallurgical testing are summarized in the following tables. Specific details relate to the screen fraction assays and size distributions are included in Appendix 2 in this report.

The following comments relate to the head assay results developed on the Composite1 sample.

- Gold content in screen fractions ranged from approximately 0.14 g/t to 0.57 g/t. The highest gold content of 0.57 g/t was observed in minus 10 mesh fraction. Calculated gold content for the overall sample is 0.27 g/t.

- Silver content in screen fractions ranged from approximately 0.5 g/t to 1.7 g/t. The highest silver content of 1.7 g/t was observed in minus 10 mesh fraction. Calculated silver content for the overall sample is 0.846 g/t.

- Low copper content was observed in all fractions. Calculated copper content for the overall sample was 0.007 percent.

- Iron content ranged from approximately 1.13 percent to 3.07 percent in the screen fractions. The highest iron content of 3.07 percent was observed in minus 10 mesh fraction. Calculated iron content for overall sample was 1.654 percent.

The following comments relate to the cyanide soluble gold, cyanide soluble silver and cyanide soluble copper on Composite 1.

- Calculated cyanide soluble gold content is approximately 0.279 g/t. This indicates that the gold contained in the sample is soluble in cyanide.
- Calculated cyanide soluble silver content is approximately 0.706 g/t. This indicates that the silver contained in the sample is soluble in cyanide.
- Calculated cyanide soluble copper is 0.004 percent, therefore approximately 57 percent of the copper contained in the sample is soluble in cyanide.

The following comments relate to the head assay results developed on Composite 2.

- Gold content in screen fractions ranged from approximately 0.43 g/t to 1.00 g/t. The highest gold content of 1.00 g/t was observed in minus 10 mesh fraction. Calculated gold content for the overall sample is 0.537 g/t.

- Silver content in screen fractions ranged from approximately 2.2 g/t to 4.3 g/t. The highest silver content of 4.3 g/t was observed in minus 10 mesh fraction. Calculated silver content for the overall sample is 2.7 g/t.

- Copper content in screen fractions ranged from approximately 0.03 percent to 0.1 percent. The highest copper content of 0.1 percent was observed in minus 10 mesh fraction. Calculated copper content for the overall sample is 0.046 percent.

- Iron content ranged from approximately 1.84 percent to 3.29 percent in the screen fractions. The highest iron content of 3.29 percent was observed in minus 10 mesh fraction. Calculated iron content for overall sample is 2.244 percent.

The following comments relate to the cyanide soluble gold, cyanide soluble silver and cyanide soluble copper in Composite 2.

- Calculated cyanide soluble gold content in the Composite 2 was approximately 0.504 g/t. This indicates that approximately 94 percent of the gold contained in the sample is soluble in cyanide.

- Calculated cyanide soluble silver content was approximately 2.246 g/t. This indicates approximately 83 percent of the silver contained in the sample is soluble in cyanide.

- Calculated cyanide soluble copper is 0.020 percent, therefore approximately 43 percent of the copper contained in the sample is soluble in cyanide.

COMPOSITE ASSAY (Pulverized)			**0.770**		**2.700**		**0.078**		**4.810**	

The following comments relate to the head assay results developed on Composite 3.

- Gold content in screen fractions ranged from approximately 0.49 g/t to 1.49 g/t. The highest gold content of 1.49 g/t was observed in minus 10 mesh fraction. Calculated gold content for overall sample is 0.627 g/t.

- Silver content in screen fractions ranged from approximately 2.2 g/t to 5.7 g/t. The highest silver content of 5.7 g/t was observed in minus 10 mesh fraction. Calculated silver content for overall sample is 0.846 g/t.

- Copper content in screen fractions ranged from approximately 0.06 percent to 0.11 percent. The highest copper content of 0.11 percent was observed in minus 10 mesh fraction. Calculated copper content for the overall sample is 0.073 percent.

- Iron content ranged from approximately 4.46 percent to 7.21 percent in the screen fractions. The highest iron content of 7.21 percent was observed in minus 10 mesh fraction. Calculated iron content for the overall sample is 5.122 percent.

COMPOSITE ASSAY (Pulverized)			**0.530**		**2.960**		**0.016**	

The following comments relate to the cyanide soluble gold, cyanide soluble silver and cyanide soluble copper in the Composite 3.

- Calculated cyanide soluble gold content is approximately 0.719 g/t. This indicates that the gold contained in the sample is soluble in cyanide.

- Calculated cyanide soluble silver content is approximately 2.845 g/t. This indicates that the silver contained in the sample is soluble in cyanide.

- Calculated cyanide soluble copper is 0.015 percent, therefore approximately 20 percent of the copper contained in the sample is soluble in cyanide.

3.2 Cyanidation Bottle Roll Testing on Composite Samples

Cyanidation bottle testing was conducted on a test charge of 1,000 grams at 100 percent minus 10 mesh for 96 hours with a pulp density of approximately 45 percent solids, using 760 mg/L of sodium cyanide, 300 mg/L of copper.

The pulp pH was maintained between 11.00 and 11.50 throughout the test duration. The objective of the bottle roll testing was to evaluate cyanide and lime consumptions on the composite samples tested, and determine lime dosage to be added to the test charge prior to the column loading.

The metallurgical data developed on the agitated cyanidation bottle roll testing on the composite samples are summarized in Table 3.2 below. Specific details relate to reagents additions, sampling schedule and mass balance are included in Appendix 3 in this report.

Table 3.2
Summary of Results
Bottle Roll Testing

Test No.	Sample ID	Assay Head			Calculated Head			% Extraction			Consumptions	
		Au (ppm)	Cu (ppm)	Ag (ppm)	Au (ppm)	Cu (ppm)	Ag (ppm)	Au (%)	Cu (%)	Ag (%)	NaCN (kg/t)	CaO (kg/t)
BR-01	**Composite 1**	0.270	72	0.8	0.255	147	0.9	80.40	11.52	20.71	0.293	2.701
BR-02	**Composite 2**	0.537	462	2.7	0.572	636	2.8	86.00	37.10	23.96	0.479	3.565
BR-03	**Composite 3**	0.627	729	2.8	0.642	854	3.0	82.86	7.45	29.58	0.130	4.180

The following comments relate to the metallurgical data obtained in the bottle roll tests on Composite 1, Composite 2 and Composite 3 samples.

- Gold extraction ranged from approximately 80 percent to 86 percent. Composite 2 showed the highest gold extraction of 86 percent.
- Silver extraction ranged approximately from 21 percent to 30 percent.
- Sodium cyanide consumption ranged from 0.13 kg/t to 0.48 kg/t.
- Calcium oxide consumptions ranged from 2.7 kg/t to 4.2 kg/t.

3.3 Open Cycle Column Leach Testing

The column tests were conducted inside 6 inches in diameter by 10 feet height PVC columns using 89 kg test charges prepared from the composite samples. Approximately 70 percent of the calcium oxide consumption obtained in the bottle roll testing was added to the test charges prior to the column loading. The following table summarizes composite samples identification, leach cycle, rinse cycle and drain cycle durations.

Table 3.3.1
Leach and Rinse Cycle Periods

Test No.	Sample ID.	Leach Cycle (Days)	Recirculation[1] (Days)	Open[2] Cycle Rinse (Days)	Drain Cycle (Days)	Total Cycle (Days)
CL-01	COMPOSITE 1	47	44	2	3	142
CL-02	COMPOSITE 1 Dupl.	47	-	79	3	208
CL-03	COMPOSITE 2	53	56	2	3	172
CL-04	COMPOSITE 2 Dupl.	53	-	73	3	202
CL-05	COMPOSITE 3	53	56	2	3	172
CL-06	COMPOSITE 3 Dupl.	53	-	73	3	202

Remarks: (1) Daily off solution was re-circulated back to the feed solution.
(2) Tucson tap water was used for open cycle rinse.

The six column tests were conducted on three composite samples in duplicates and subjected to open cycle type of leach regime for 47 to 53 days using the below test conditions followed by rinsing in open and closed cycle regimes for 44 to 79 days.

The following leaching parameters and test conditions were common to the column leach tests conducted on the three composite samples:

- Approximately 70 percent of the calcium oxide (lime) consumption determined on each composite sample in the 96 hour bottle roll testing was added to each test charge and blended prior to loading in the columns.

- The feed solutions were prepared by adding reagent grade calcium oxide to de-ionized water to obtain a solution pH of 11.00 to 11.50 range followed by the addition of 750 mg of sodium cyanide and 300 mg of copper as copper sulfate per liter of solution. The columns were irrigated at a flow rate of 9.78 liters per hour per square meter.

- Pregnant leach solution samples were collected on daily basis and submitted for WADCN, gold, silver and copper assays. Free sodium cyanide and calcium oxide were also determined on the daily pregnant solution samples.

- Column tests were subjected to open cycle type of leaching regime for 47 days on CL-01 and CL-02 and 53 days on CL-03 through CL-06 followed by rinsing in open and closed cycles.

- At the end of the leach cycle, CL-01, CL-03 and CL-05 were set under locked cycle rinse regime by re-circulating the daily off solutions back to the feed solution after obtaining 1 liter of solution sample for WADCN analysis. Re-circulating rinse cycle lasted for 44 to 56 days, or until run out of solutions.

- Tucson tap water was used for columns CL-02, CL-04 and CL-06 that were rinsed in open cycle for 73 to 79 days. Approximately 1 liter of the daily effluent solution was submitted for WAD CN analysis. Report for the WADCN analysis is included in Appendix 13 in this report.

- At week 2, 4, 6 & 8 during cyanide leach cycle and week 0.5, 2, 4, 6, 8 and 10 during rinse cycle, 6 samples from each column test were collected and submitted for environmental analysis. The environmental sample collection procedure provided by Lorax Environmental in included in Appendix 12 in this report.

- Per instructions received from Casino Mining Corporation, approximately 25 kilograms and 15 kilograms of wet leached residue samples were split and submitted to for geotechnical and environmental studies respectively.

- Remaining wet residue samples were oven dried at 110 degree Celsius for 48 hours to determine moisture content. The dry leach residue was weighed and screened on the same suite of screens used in the head sample preparation stage and the fractions were kept segregated.

- Each individual screen fraction from the leach residue screen analysis was crushed to 100 percent minus 10 mesh utilizing laboratory jaw and cone crushers.

- A 1000 grams test charge were split out and approximately 150 grams was split out from each screen fraction and submitted for total gold and total silver by fire assay followed by atomic absorption finish and copper, iron assays. Cyanide soluble gold, cyanide soluble silver and cyanide soluble copper contents were also determined for each fraction.

- A 1,000 gram pulverized composite was prepared by reconstituting individual pulverized screen fractions based on the residue particle size distribution. A portion was split and submitted for total gold and total silver by fire assay followed by AA finish and copper, iron, cyanide soluble gold, cyanide soluble silver and cyanide soluble copper assay.

- As QA/QC the assay results for the pulverized residue composite was compared to the calculated residue assays of the individual pulverized screen fractions. Mass balance was conducted using the calculated assay results to determine the overall gold, silver and copper extractions.

- Gold, silver and copper extractions by screen fractions were also calculated based on the screen fraction results of the head and residue samples.

The summary of metallurgical results obtained from the column leach study on composite samples after at least 104 days of leaching and rinsing are presented in Table 3.3.2 below. Specific details relate to leaching conditions, solution assays, head and leach residue assays are included in Appendices 3 through 8 in this report.

Table 3.3.2
Locked Cycle Column Testing

Remarks: (1) Metal Gold Content Extracted Plus Metal Content in Leach Residue Screen Fractions

The following comments relate to the open cycle column leach tests conducted on the three composite samples.

- Gold extraction on composite samples ranged from 62.31 percent to 82.56 percent. The highest gold extraction of approximately 83 percent was observed on the Composite 1 that the rinsed with re-circulating effluent solution.

- It seems that the copper content added to the feed solution did not have a significant impact on sodium cyanide consumption and gold extraction.

- Silver extraction ranged from approximately 17 percent to 28 percent.

- Sodium cyanide consumption on the composite samples ranged from 0.19 kg/t to 0.68 kg/t.

- Calcium oxide (lime) consumption ranged from 3.10 kg/t to 4.34 kg/t.

- There is a good correlation of the gold and silver extractions between the duplicate column tests.

3.4 Gold Extraction by Screen Fractions

Gold and silver extractions by fractions were calculated using the fraction weights, gold and silver assays of the head and leach residues screen fractions. The following table summarizes the gold extraction by screen fraction on the six column tests. Specific details relate to gold and silver extraction, and screen fraction degradation information are included in Appendices 4 through 9 in this report.

Table 3.4
Gold Extraction by Screen Fraction

Screen Fraction	Column Tests					
	CL-01	CL-02	CL-03	CL-04	CL-05	CL-06
2"	80.50	77.22	67.16	48.68	84.61	76.24
1-1/2"	63.32	81.75	36.87	55.54	76.17	70.84
1"	78.56	75.65	61.31	50.07	58.32	58.57
3/4"	83.21	77.14	58.24	51.19	67.09	79.20
1/2"	81.53	79.30	72.50	70.02	82.79	75.46
1/4"	88.83	77.07	86.19	80.50	87.43	84.82
10 mesh	85.57	67.19	85.08	82.64	87.01	83.92
-10 mesh	92.34	90.51	89.65	93.91	91.58	93.31
Overall Gold Extraction	**84.12**	**81.01**	**63.82**	**63.30**	**76.85**	**75.72**

The following comments relate to the gold extraction by screen fraction.

- Gold extractions ranged approximately from 37 percent to 94 percent in all fractions of the composites samples.

- In most column tests fractions finer than 1/4 inches showed more than 80 percent gold extraction.

- The minus 10 mesh fractions showed more than 90 percent gold extraction in all column tests.

- There is a good correlation between the gold extraction by screen fraction and gold extraction using the calculated head (see Table 3.3.2 above).

3.5 Column Rinse and Re-Circulation Stages

After conducting 47 to 53 days of open cycle type of leaching on CL-01, CL-03 and CL-05 tests, the three column tests were irrigated with the pregnant leach solutions collected from the last 7 days of the leach cycle. Daily effluent solutions from these columns were placed (re-circulated) in the feed solution reservoir after obtaining a daily one liter of sample for WADCN analysis. The objective of the effluent solution

re-circulation cycle was to observe natural degradation of the sodium cyanide contained in the leach solution.

The duplicate column tests, CL-02, CL-04 and CL-06, were rinsed with Tucson tap water after 47 to 53 days of open leach cycle and sampled on daily basis. One liter of daily effluent was collected and submitted for WADCN analysis.

Combined rinse solutions (60 liters) and combined pregnant solutions (60 liters) were shipped to ALS Laboratory in Vancouver for analysis per instructions received from personnel from Casino Mining Corporation.

3.6 Column Drain Down Data

Column drain down solutions volumes were recorded at the end of rinse cycle for 48 hours. Volumes were recorded every five minutes for the first one hour and every one hour for the next seven hours. Daily total drain solution volumes were also recorded and the cumulative drain down volumes were calculated and plotted in Appendix 10 in this report.

4.0 CONCLUSIONS AND RECOMMENDATIONS

The following conclusions and recommendations are based on the metallurgical data developed from the open cycle cyanide column leach testing and cyanide bottle roll testing conducted on three composite samples from the Casino Project.

4.1 COMPOSITE 1

The following comments relate to the column leach tests conducted on the Composite 1 sample .

- The composite sample contained approximately 0.27 g/t of gold and the gold contained in the sample is soluble cyanide soluble. After 47 days of leach and 46 to 82 days of rinse, approximately 82 percent of gold extraction was obtained in duplicate column tests.

- Silver content was at 0.85 g/t and approximately 83 percent of the silver contained in the sample is cyanide soluble. After 47 days of leach and 46 to 82 days of rinse cycles, approximately 28 percent of silver extraction was obtained.

- Sodium cyanide consumption ranged from 0.20 kg/t to 0.26 kg/t in the duplicate column tests.

- Calcium oxide (lime) consumption average approximately 4.26 kg/t for both column tests.

- Further column leach testing should be conducted at a crush size of 80 percent minus 3/8 inch to evaluate the impact on precious metal extraction.

4.2 COMPOSITE 2

The following comments relate to the column leach tests conducted on the Composite 2 sample.

- The composite sample contained approximately 0.54 g/t of gold and approximately 94 percent of the gold contained in the sample is soluble in cyanide. After 53 days of leach and 58 to 73 days of rinse, approximately 63 percent of gold extraction was obtained in duplicate column tests.

- Silver content was at 2.7 g/t and approximately 83 percent of the silver contained in the sample is soluble cyanide. After 53 days of leach and 58 to 73 days of rinse cycles, an average of approximately 20 percent of silver extraction was obtained in two columns.

- Sodium cyanide consumption was ranged from 0.44 kg/t to 0.68 kg/t in the duplicate column tests.

- Calcium oxide (lime) consumption averaged approximately 3.10 kg/t in both column tests.

- Further column leach testing should be conducted at a crush size of 80 percent minus 1/2 inch to evaluate the impact on precious metal extraction.

4.3 COMPOSITE 3

The following comments relate to the column leach tests conducted on the Composite 3 sample.

- The composite sample contained approximately 0.63 g/t of gold and the gold contained in the sample is soluble in cyanide. After 53 days of leach and 58 to 73 days of rinse, approximately 63 percent of gold extraction was obtained in duplicate column tests.

- Silver content was at 2.7 g/t and the silver contained in the sample is soluble in cyanide. After 53 days of leach and 58 to 73 days of rinse cycles, an average of approximately 26 percent of silver extraction was obtained in two columns.

- Sodium cyanide consumption was ranged from 0.19 kg/t to 0.47 kg/t in the duplicate column tests.

- Calcium oxide (lime) consumption averaged approximately 3.45 kg/t in both column tests.

- Further column leach testing should be conducted at a crush size of 80 percent minus 1/2 inch to evaluate the impact on precious metal extraction.

REMARKS:

(1) A 25 ml Aliquot Sample Was Removed For Assays, Lime and Cyanide Titration. 25 ml of Distilled Water Were Added To Keep A Constant Volume
(2) Pregnant Leach Solution Volume was calculated based on the weight difference of net weight of the bottle and solids weight.
(3) Includes Metals Content Removed In Aliquot Samples Volumes

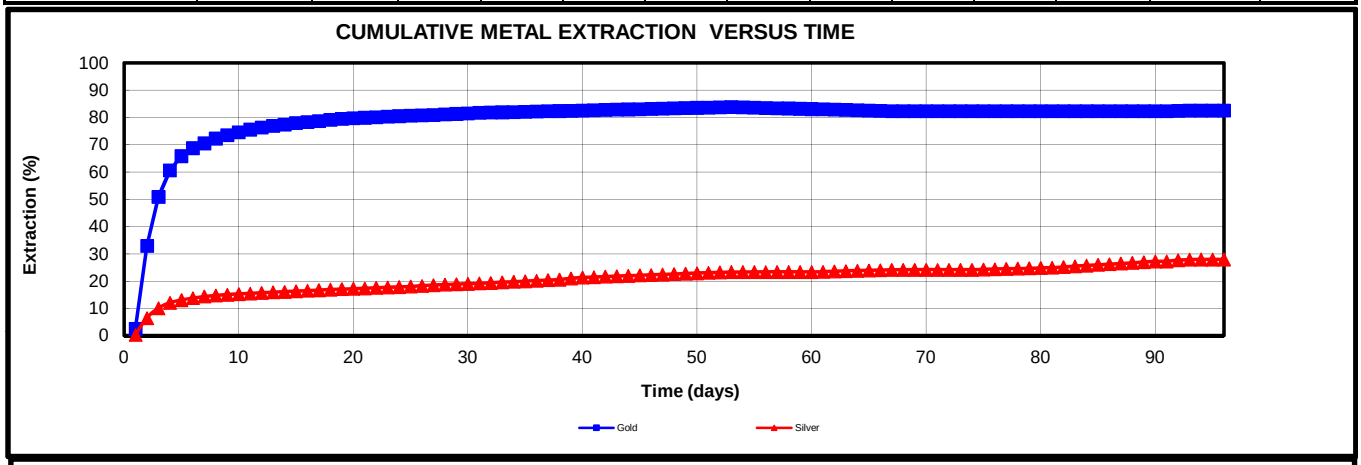
APPENDIX 4

Column Leach Test CL-01 on Composite 1

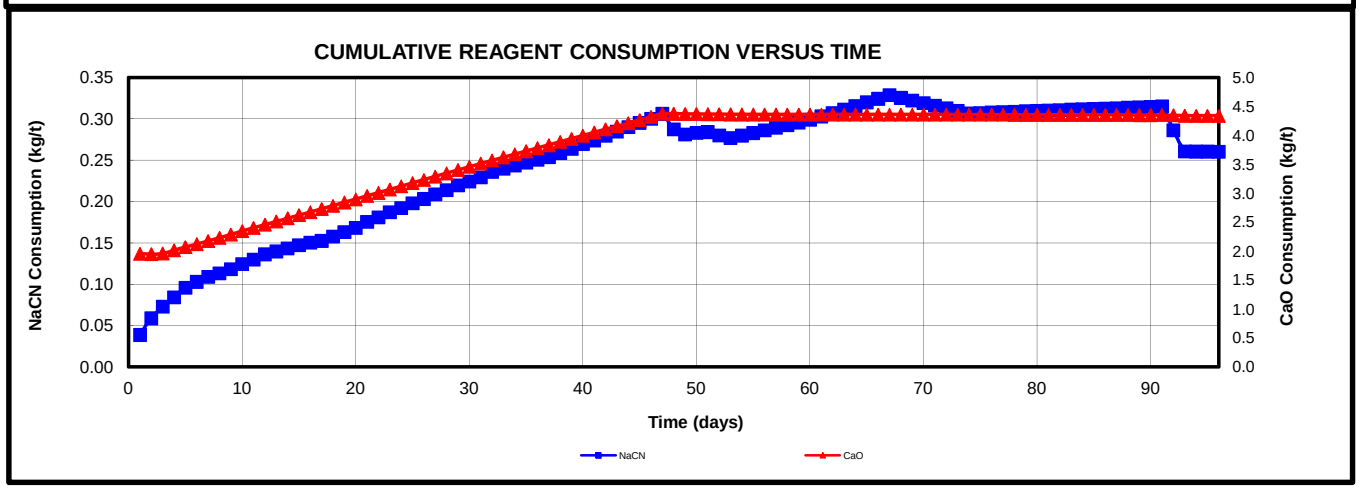
Summary of Results | **SGS Metcon** | Current Date: 09/26/14

SGS Metcon Project No.: M-709-03

Western Copper & Gold Corp. Casino Project



TEST No.: CL-01 | Crush Size: P100 minus 3 in.



SAMPLE : Composite 1 (Met-02/05) | Lime Addition: 1.95 kg Lime/tonne of ore

Objective: Gold and Silver Extraction vs Time

Cure Days:	0
Leach Days:	91
Rest Days:	0
Wash Days:	2
Drain Days:	3
Total Cycle Days:	96

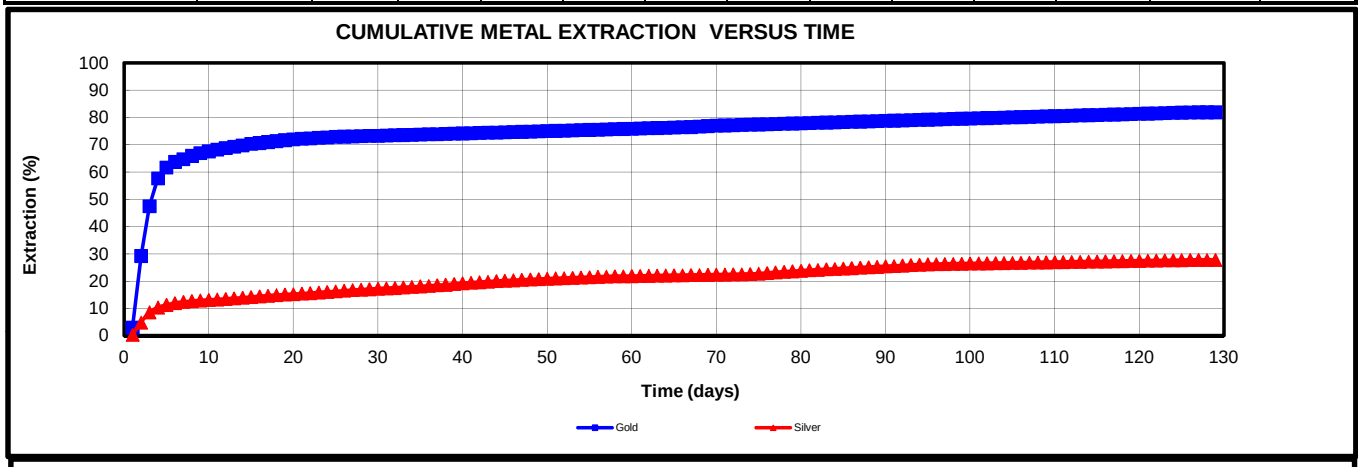
APPENDIX 5

Column Leach Test CL-02 on Composite 1 (Duplicate)

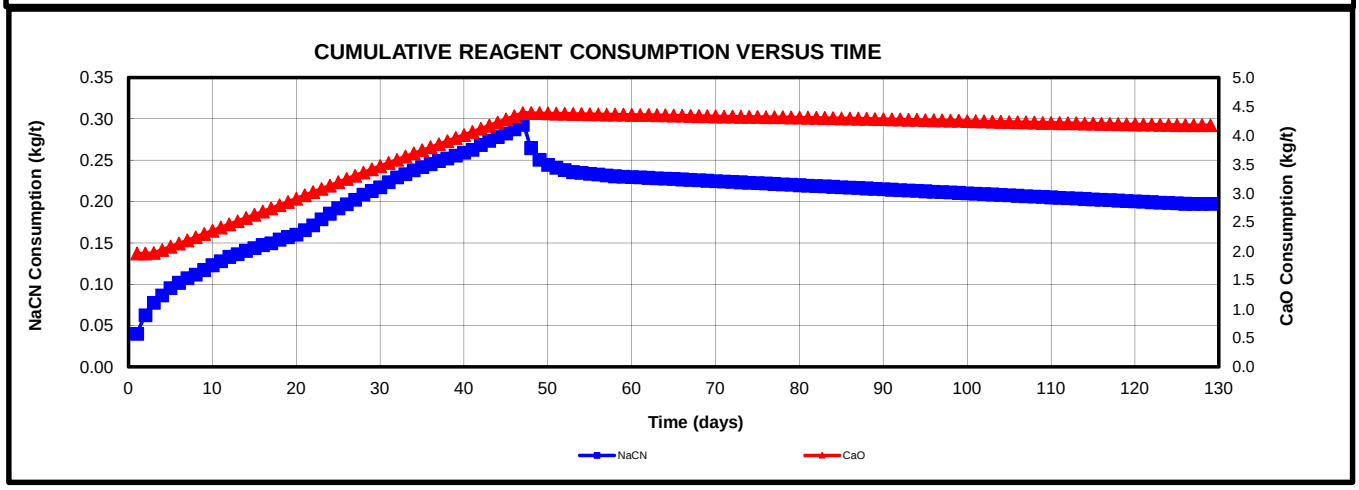
Summary of Results | **SGS Metcon** | Current Date: 09/26/14

SGS Metcon Project No.: M-709-03

Western Copper & Gold Corp. Casino Project



TEST No.: CL-02 | Crush Size: P100 minus 3 in.



SAMPLE : Composite 1 (Met-02/05) | Lime Addition: 1.95 kg Lime/tonne of ore

Objective: Gold and Silver Extraction vs Time

Cure Days:	0
Leach Days:	47
Rest Days:	0
Wash Days:	79
Drain Days:	3
Total Cycle Days:	129

PRODUCTS	Volume	Weight	Cumulative

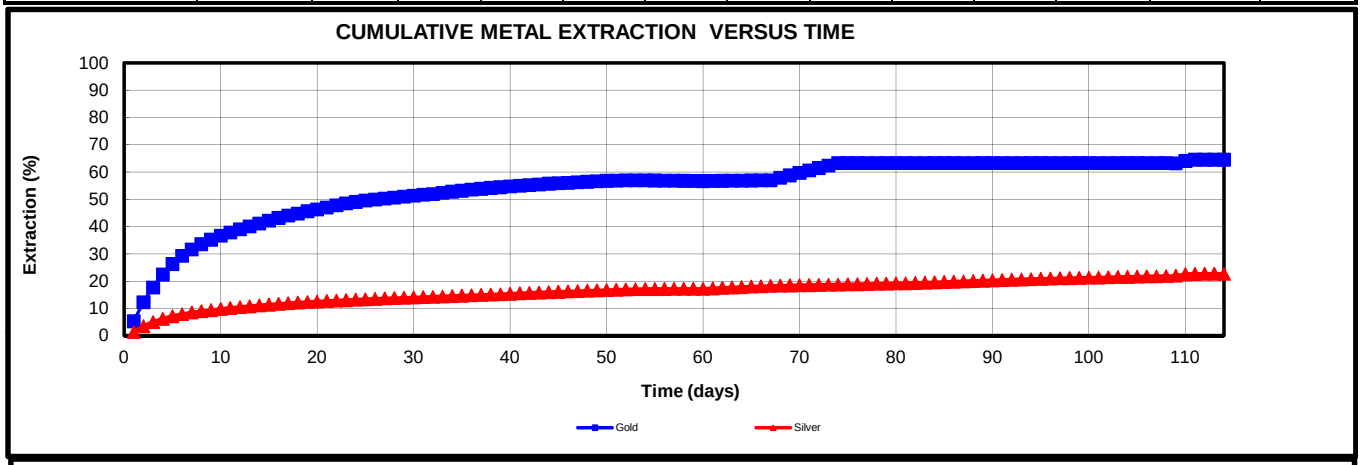
APPENDIX 6

Column Leach Test CL-03 on Composite 2

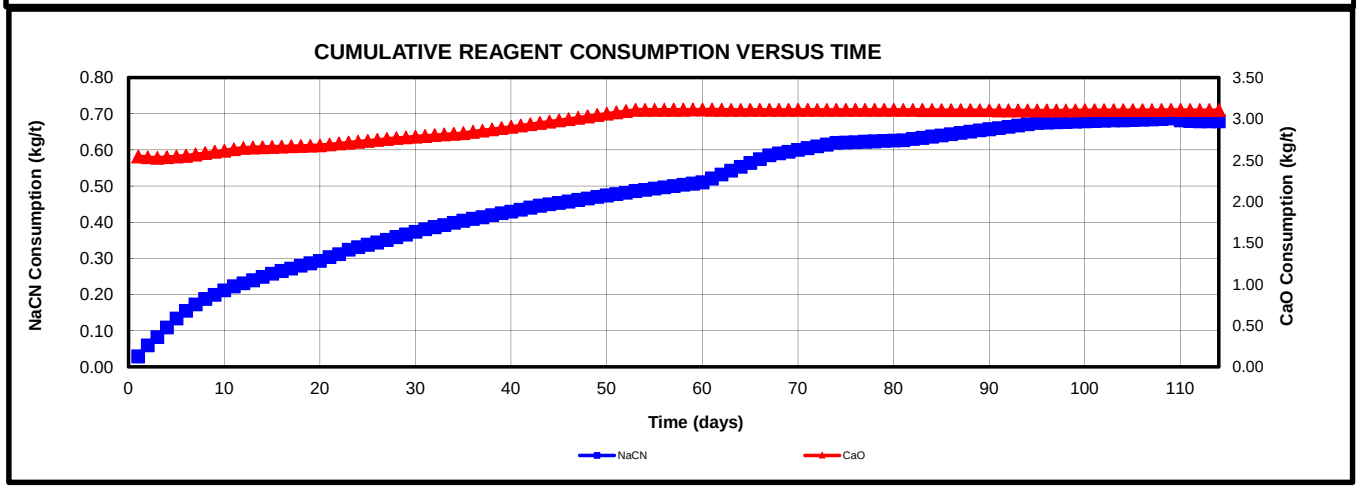
Summary of Results | **SGS Metcon** | Current Date: 09/26/14

SGS Metcon Project No.: M-709-03

Western Copper & Gold Corp. Casino Project



TEST No.: CL-03 | Crush Size: P100 minus 3 in.



SAMPLE : Composite 2 (Met-11/17) | Lime Addition: 2.54 kg Lime/tonne of ore

Objective: Gold and Silver Extraction vs Time

Cure Days:	0
Leach Days:	109
Rest Days:	0
Wash Days:	2
Drain Days:	3
Total Cycle Days:	114

PRODUCTS	Volume	Weight	Cumulative										
			Assay (g/t)			Contents (mg)			Indicated Extraction			Consumption

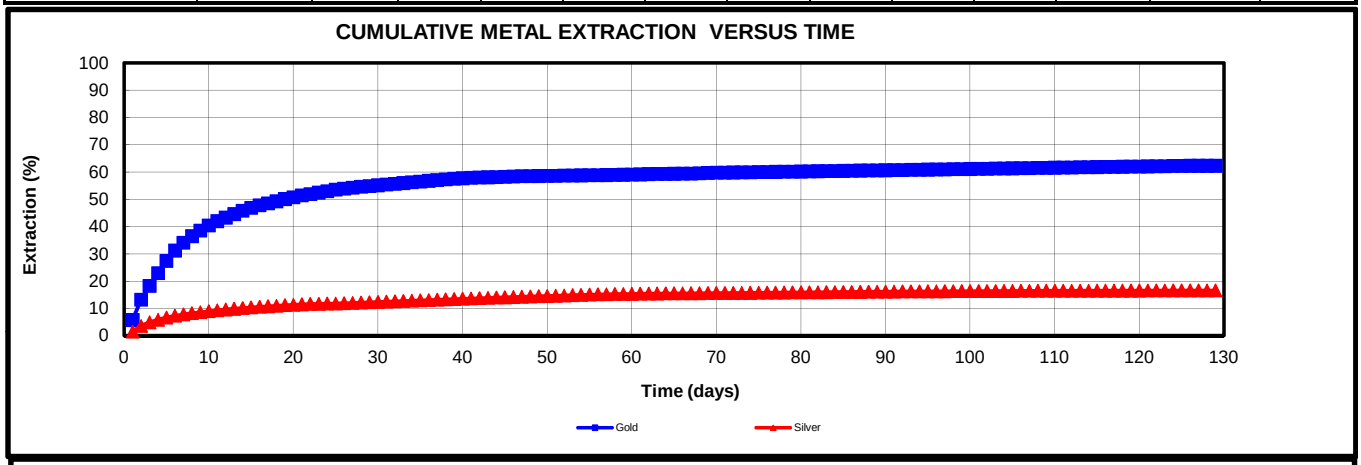
APPENDIX 7

Column Leach Test CL-04 on Composite 2 (Duplicate)

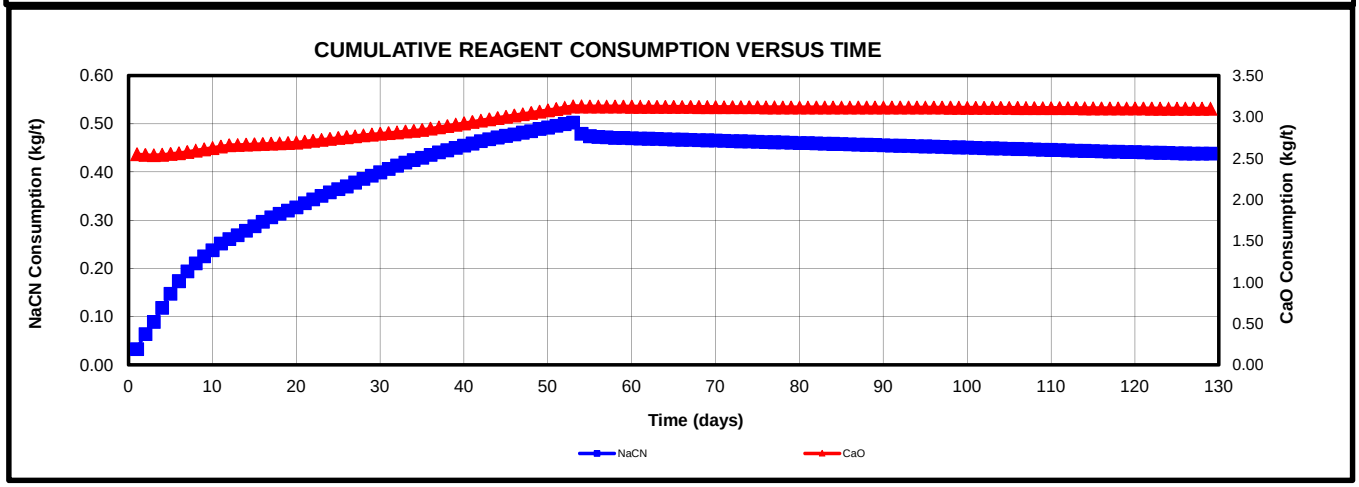
Summary of Results | **SGS Metcon** | Current Date: 09/26/14

SGS Metcon Project No.: M-709-03

Western Copper & Gold Corp. Casino Project



TEST No.: CL-04 | Crush Size: P100 minus 3 in.



SAMPLE : Composite 2 (Met-11/17) | Lime Addition: 2.55 kg Lime/tonne of ore

Objective: Gold and Silver Extraction vs Time

Cure Days:	0
Leach Days:	53
Rest Days:	0
Wash Days:	73
Drain Days:	3
Total Cycle Days:	129

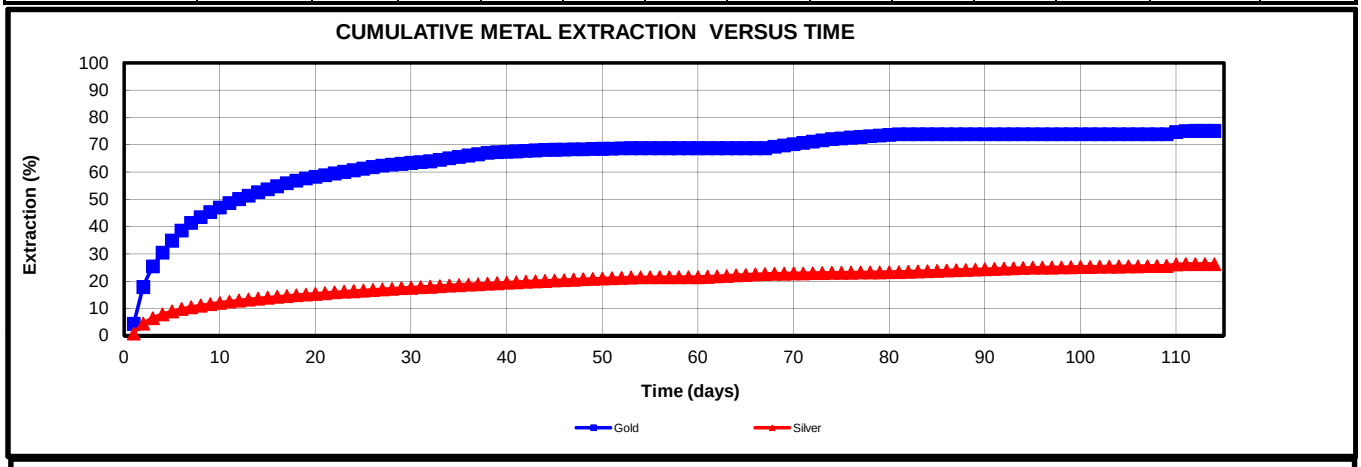
APPENDIX 8

Column Leach Test CL-05 on Composite 3

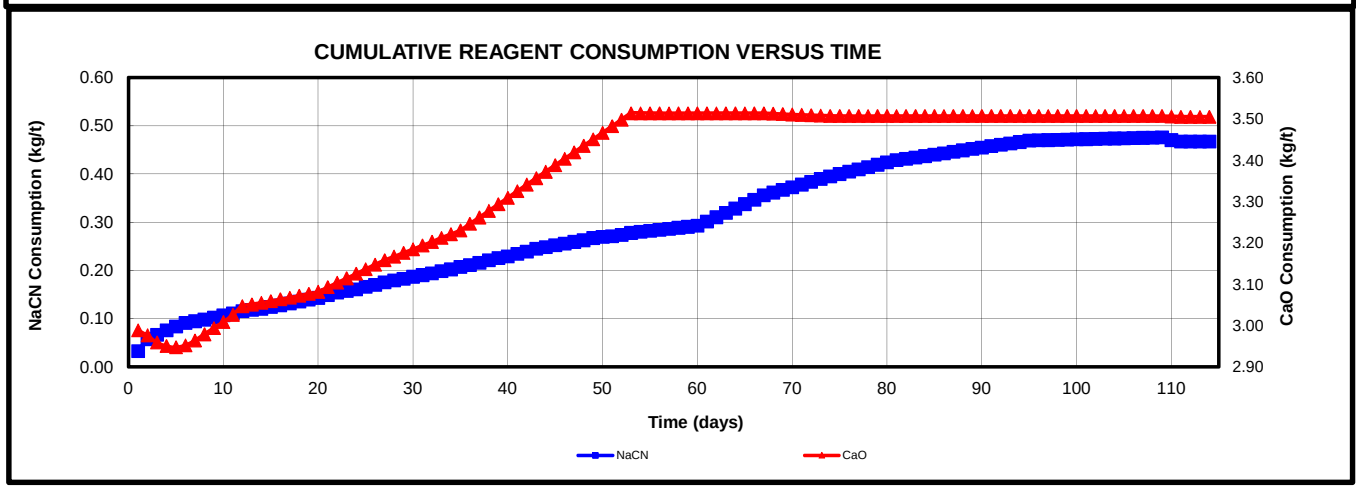
Summary of Results | **SGS Metcon** | Current Date: 09/26/14

SGS Metcon Project No.: M-709-03

Western Copper & Gold Corp. Casino Project



TEST No.: CL-05 | Crush Size: P100 minus 3 in.



SAMPLE : Composite 3 (Met-19/20) | Lime Addition: 2.98 kg Lime/tonne of ore

Objective: Gold and Silver Extraction vs Time

Cure Days:	0
Leach Days:	109
Rest Days:	0
Wash Days:	2
Drain Days:	3
Total Cycle Days:	114

PRODUCTS	Volume	Weight	Cumulative										
			Assay (g/t)			Contents (mg)			Indicated Extraction			Consumption

PHYSICAL CHARACTERISTICS SHEET

CLIENT	Western Copper & Gold Corp. SGS Metcon Project No.: M-709-03	**TEST CONDITIONS**	
		TEST START	05/01/14
PROJECT	Casino Project	**COLUMN SIZE**	6 in. Diameter X 10 ft Height
SAMPLE	Composite 3 (Met-19/20)	**CRUSH SIZE**	P100 minus 3 in.
		LEACH SOLUTION	750 ppm free NaCN, 300 ppm Cu
OBJECTIVE	Gold and Silver Extraction vs Time	**Lime Addition**	2.98 kg CaO/tonne of Ore
		CURE CYCLE	0 days
		FLOWRATE	9.78 lph/m2

FLOWRATE (lph/sq m)		9.78			
CURE STAGE (days)		0			
COLUMN DIAMETER (mm)		152.40			
ELEMENTS ANALYZED	Au	CNs Au	Ag	CNs Ag	Cu
HEAD ASSAYS (g per tonne)	0.63		2.76		72.95
LEACH RESIDUE ASSAYS (g per tonne)	0.15		2.80		648.16
SAMPLE PERCENT MOISTURE AS RECEIVED (Dry Basis)		0.00			
SAMPLE WEIGHT BEFORE AGGLOMERATION (kg)		88.90			
AGGLOMERATED SAMPLE WEIGHT (kg)		90.86			
INITIAL SAMPLE PERCENT MOISTURE (including agglomeration water)		2.20	(Dry Basis)		
INITIAL SAMPLE DRY WEIGHT (kg)		88.90			
INITIAL SAMPLE HEIGHT (m)		3.15			
INITIAL SAMPLE BULK DENSITY (kg/cu m)		1545	(Dry Basis)		
FINAL SAMPLE HEIGHT (m)		3.10			
RESIDUE WET WEIGHT (kg)		92.82			
RESIDUE DRY WEIGHT (kg)		88.90			
VOLUME DRAINED (l)		1.33			
SUBSIDENCE (%)		1.65			
MOISTURE UNDER LEACH (%)		5.91	(Dry Basis)		
MOISTURE RETAINED (%)		4.41	(Dry Basis)		
FINAL SAMPLE BULK DENSITY (kg/cu m)		1571	(Dry Basis)

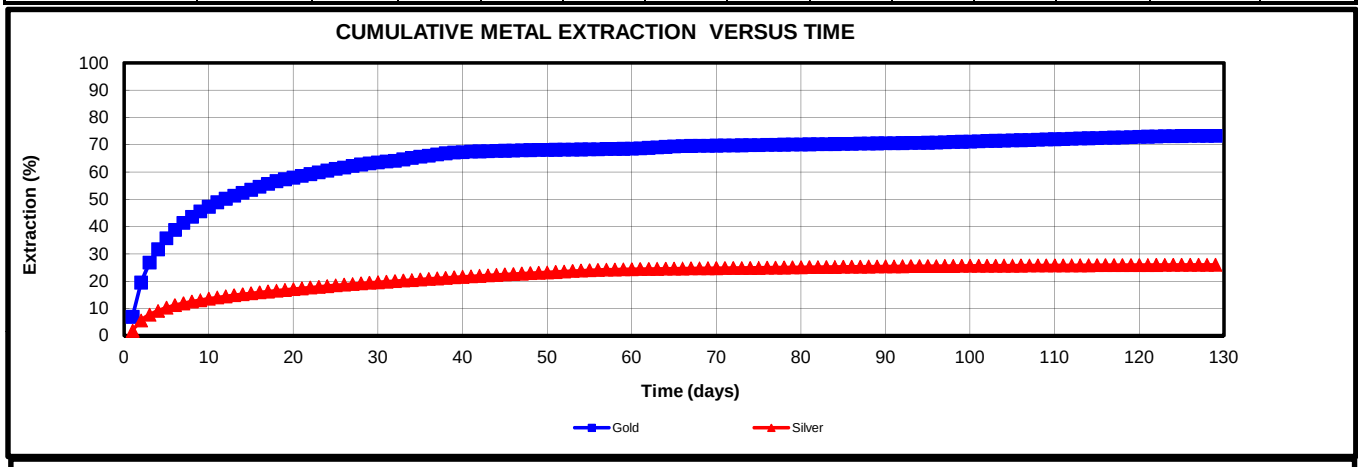
APPENDIX 9

Column Leach Test CL-06 on Composite 3 (Duplicate)

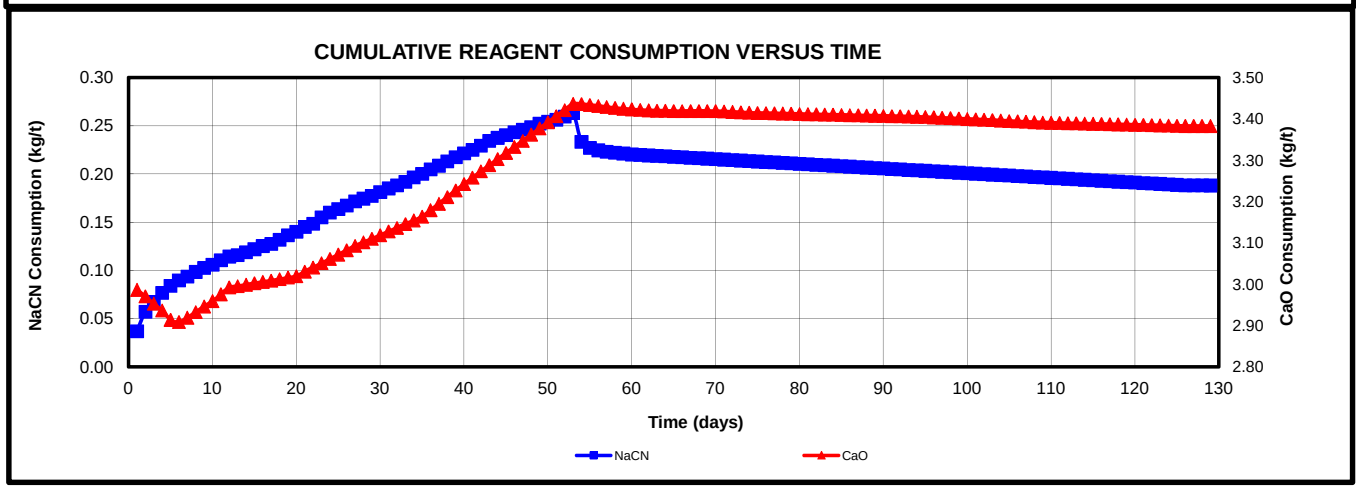
Summary of Results | **SGS Metcon** | Current Date: 09/26/14

SGS Metcon Project No.: M-709-03

Western Copper & Gold Corp. Casino Project



TEST No.: CL-06 | Crush Size: P100 minus 3 in.



SAMPLE : Composite 3 (Met-19/20) | Lime Addition: 2.981773 kg Lime/tonne of ore

Objective: Gold and Silver Extraction vs Time

Cure Days:	0
Leach Days:	53
Rest Days:	0
Wash Days:	73
Drain Days:	3
Total Cycle Days:	129

PRODUCTS	Volume	Weight	Cumulative

CLIENT	Western Copper & Gold Corp. SGS Metcon Project No.: M-709-03	**TEST CONDITIONS**	
		TEST START	05/01/14
PROJECT	Casino Project	**COLUMN SIZE**	6 in. Diameter X 10 ft Height
SAMPLE	Composite 3 (Met-19/20)	**CRUSH SIZE**	P100 minus 3 in.
		LEACH SOLUTION	750 ppm free NaCN, 300 ppm Cu
OBJECTIVE	Gold and Silver Extraction vs Time	**Lime Addition**	2.98 kg CaO/tonne of Ore
		CURE CYCLE	0 days
		FLOWRATE	9.78 lph/m2

FLOWRATE (lph/sq m)		9.78			
CURE STAGE (days)		0			
COLUMN DIAMETER (mm)		152.40			
ELEMENTS ANALYZED	Au	CNs Au	Ag	CNs Ag	Cu
HEAD ASSAYS (g per tonne)	0.63		2.77		72.95
LEACH RESIDUE ASSAYS (g per tonne)	0.15		2.45		701.45
SAMPLE PERCENT MOISTURE AS RECEIVED (Dry Basis)		0.00			
SAMPLE WEIGHT BEFORE AGGLOMERATION (kg)		88.88			
AGGLOMERATED SAMPLE WEIGHT (kg)		90.90			
INITIAL SAMPLE PERCENT MOISTURE (including agglomeration water)		2.27	(Dry Basis)		
INITIAL SAMPLE DRY WEIGHT (kg)		88.88			
INITIAL SAMPLE HEIGHT (m)		3.16			
INITIAL SAMPLE BULK DENSITY (kg/cu m)		1540	(Dry Basis)		
FINAL SAMPLE HEIGHT (m)		3.17			
RESIDUE WET WEIGHT (kg)		93.02			
RESIDUE DRY WEIGHT (kg)		88.88			
VOLUME DRAINED (l)		1.20			
SUBSIDENCE (%)		-0.08			
MOISTURE UNDER LEACH (%)		6.00	(Dry Basis)		
MOISTURE RETAINED (%)		4.66	(Dry Basis)		
FINAL SAMPLE BULK DENSITY (kg/cu m)		1539	(Dry Basis)

TECHNICAL MEMORANDUM

To:	**Paul West-Sells, Heather Brown (Western Copper Corp)**	**Date: May 16 2014**
From:	**John Dockrey, Bruce Mattson**	**Project #: J862-6**
Subject:	**Environmental Sample Procedure of Cyanide Leach Columns - 2014**	

This technical memorandum provides instruction for the collection of leachate samples from the Casino CN leach columns. The columns will be operated in two phases, active cyanide leaching and rinsing. Distinct sampling requirements during each of the operational phases are outlined below.

Sampling Dates

Samples of column leachate needs to be collected four times from each column over the course of the CN leach test and four times during rinsing/recycling. Timing of sample collection during CN leaching and rinsing is outlined in Table 2. Note that leachate samples must be collected from column drainage produced within 24 hours of sample collection. In addition to column leachate, samples of the tap water used as influent and blank samples prepared with DI water need to be taken on certain occasions. Tap water is sampled to characterize the solution that the column is being irrigated with, while a blank of DI water sample needs to be collected every sampling event for QAQC.

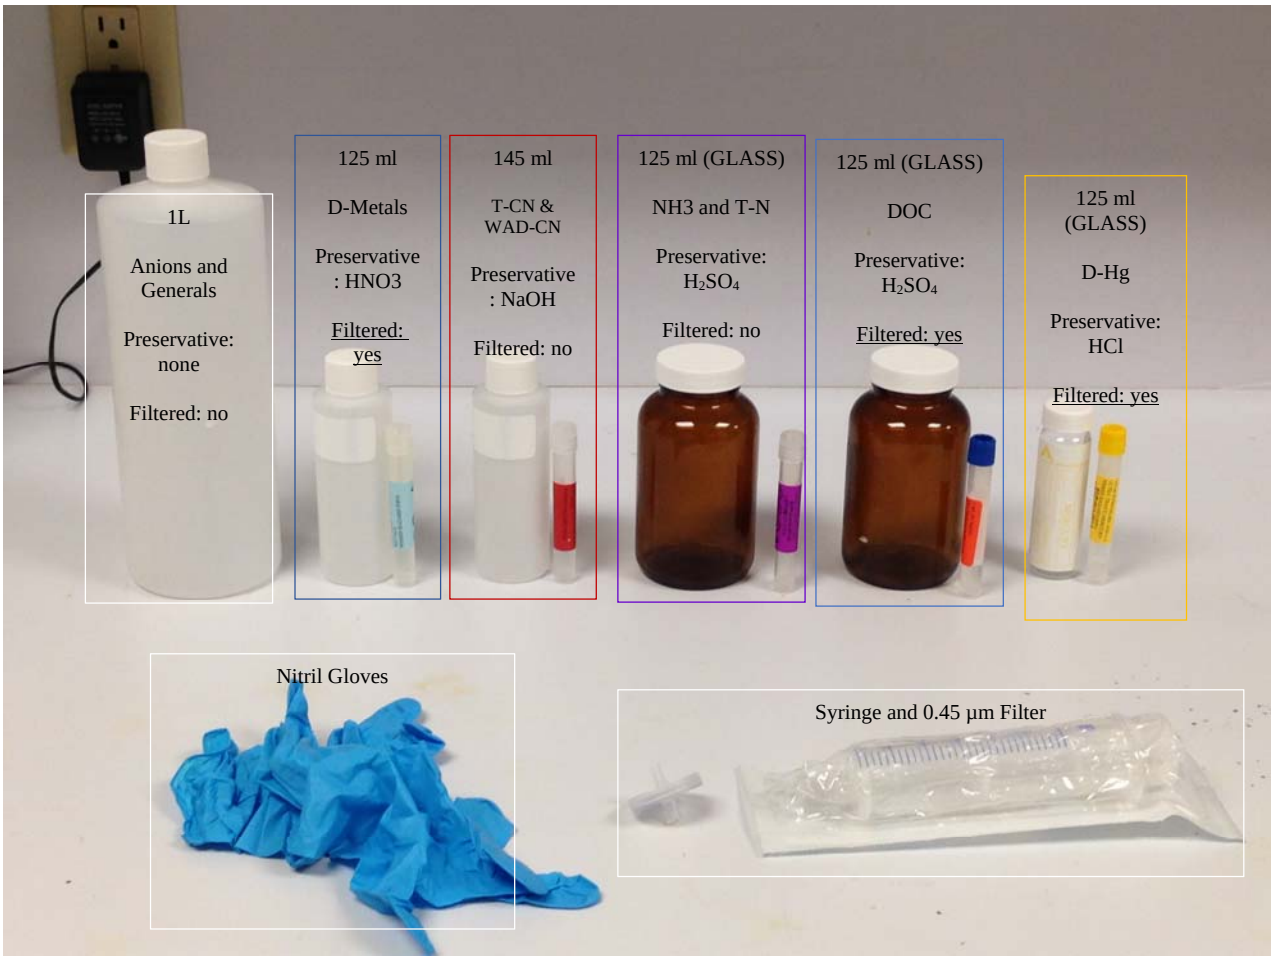
Table 1:
Environmental sampling schedule during CN leaching

Solution to be Sampled	Date
Tap Water	week 2 & 6
Blank (DI water)	week 2, 4, 6 & 8
Leachate Sample (x6 Columns)	week 2, 4, 6 & 8

Table 2:
Environmental sampling schedule during rinsing and cycling of detoxified solution

Solution to be Sampled	Date
Tap Water	week 0.5 & 6
Blank (DI water)	week 0.5, 2, 4 & 6
Leachate Sample (x6 columns)	week 0.5, 2, 4 & 6

Sampling Supplies



Sampling bottles, preservative, filters and syringes will be provided by ALS-Vancouver. Note that it is our understanding that at least 76 1L plastic bottles have already been delivered for the purposes of environmental sampling. ALS will provide the following supplies:

- 76 x 145 mL plastic bottles
- 76 x 125 ml plastic bottles
- 76 x 125 Glass bottles
- 76 x 250 ml plastic bottles
- 76 x HNO_3 preservative vials
- 76 x NaOH preservative vials
- 76 x H_2SO_4 preservatives for DOC
- 76 x H_2SO_4 preservative vials for NH_3 and T-Nitrogen
- Chain of custody forms
- Bottle labels
- 0.45 µm syringe filters
- Syringes

The following supplies will have to be sourced at site:

- Coolers and ice packs for sample shipment (Approximately 2 coolers per sampling event will be required).
- Nitril gloves
- DI water for blanks

Step 1: Prepare Bottles and Supplies

- Set out required bottles for each sample as illustrated in above photo and outlined in Table 3 below.
- Filter and syringe are provided along with bottles from ALS.
- Label each bottle with marker before proceeding to next step (analysis type and column ID).

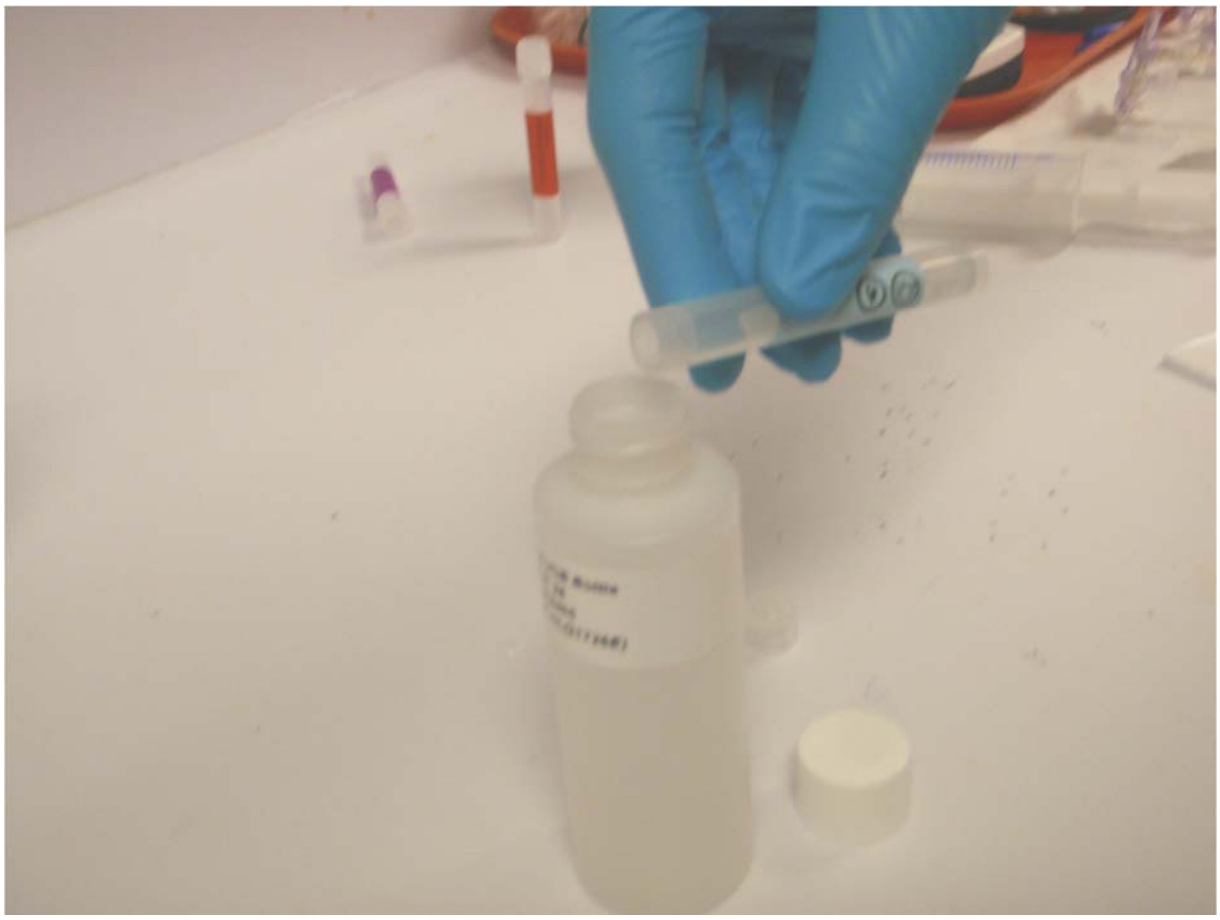
Table 3:
List of Bottle Volumes and Sampling Requirements

Bottle Volume	Analyze For	Filter	Preserve
1 L	Anions and Physical tests	none	none
145 ml	WAD-CN and T-CN	none	NaOH
125 ml	D-Metals	yes	HNO_3
50 ml (GLASS)	D-Hg	yes	HCl
125 ml (GLASS)	Ammonia and T-N	none	H_2SO_4
125 ml (GLASS)	DOC	yes	H_2SO_4

Step 2: Filter samples if required and fill bottles

Samples Requiring Filtration (D-metals and DOC)

- Pull sample into syringe
- Attach Filter
- Push sample through filter and fill entire volume of the bottle. Leave small headspace for preservative.

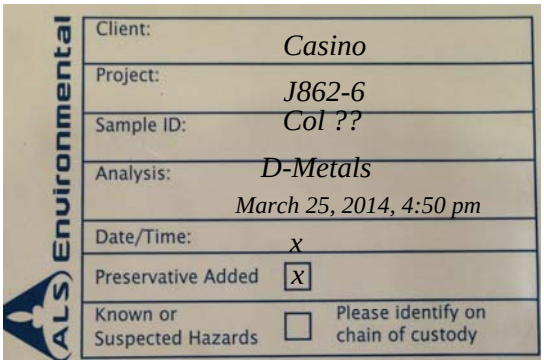


Note: DO NOT REUSE FILTERS OR SYRINGES

Note: SAMPLE MUST BE COLLECTED FROM LEACHATE PRODUCED WITHIN PAST 24 HOURS

Samples not requiring filtration (anions and physicals, T-CN &WAD-CN, T-N &NH3)

- Completely fill each of the sample bottles, leaving small volume for preservative if required.



Step 3: Add Preservative

- Pore entire volume of preservative from preservative vials provided by ALS into sample bottles as required.
- Required preservatives are outlined in Table 1.

Note: DO NOT ADD PRESERVATIVES BEFORE BOTTLES ARE FILLED WITH SAMPLE

Step 4: Fill out Labels and Label Bottles

- Fill out labels provided by ALS as per example provided above
- Label should indicate, column sampled, date sampled, requested analysis (*i.e.*, D- metals, T-CN & WAD-CN, *etc*.) whether sample was filtered, whether preservative added (yes for D-Metals, DOC *etc*.) and known or suspected as hazardous (yes due to potential for high CN > 100 mg/L).
- Stick labels to appropriate bottles.

Step 5: Pack Cooler and fill out chain of custody form (COC)

- Pack samples in cooler with ice and copy of COC form.
- Example COC form is provided on next page
- Ship cooler as priority to:

RE: M-709-03

Dear Natska Gantumur,

Turner Laboratories, Inc. received 70 sample(s) on 05/13/2014 for the analyses presented in the following report.

All results are intended to be considered in their entirety, and Turner Laboratories, Inc. is not responsible for use of less than the complete report. Results apply only to the samples analyzed. Samples will be disposed of 30 days after issue of our report unless special arrangements are made.

The pages that follow may contain sensitive, privileged or confidential information intended solely for the addressee named above. If you receive this message and are not the agent or employee of the addressee, this communication has been sent in error. Please do not disseminate or copy any of the attached and notify the sender immediately by telephone. Please also return the attached sheet(s) to the sender by mail.

Please call if you have any questions.

Respectfully submitted,

Turner Laboratories, Inc.

Client: SGS Metcon
Project: M-709-03
Work Order: 14E0453
Date Received: 05/13/2014

Case Narrative

Cyanide WAD: Quality control samples contaminated by samples with high concentrations. MSD unusable due to formation of precipitant during color development.

The Arizona Department of Health Services does not license laboratories for the determination of Cyanide WAD in a wastewater matrix.

B7	Target analyte detected in method blank at or above the method reporting limit. Concentration found in the sample was 10 times above the concentration found in the method blank.
L1	The associated LCS/LCSD recovery was above laboratory acceptance limits.
N1	See case narrative.

All soil, sludge, and solid matrix determinations are reported on a wet weight basis unless otherwise noted.

ND	Not Detected at or above the PQL
PQL	Practical Quantitation Limit
DF	Dilution Factor

RE: M-709-03

Dear Natska Gantumur,

Turner Laboratories, Inc. received 36 sample(s) on 05/19/2014 for the analyses presented in the following report.

All results are intended to be considered in their entirety, and Turner Laboratories, Inc. is not responsible for use of less than the complete report. Results apply only to the samples analyzed. Samples will be disposed of 30 days after issue of our report unless special arrangements are made.

The pages that follow may contain sensitive, privileged or confidential information intended solely for the addressee named above. If you receive this message and are not the agent or employee of the addressee, this communication has been sent in error. Please do not disseminate or copy any of the attached and notify the sender immediately by telephone. Please also return the attached sheet(s) to the sender by mail.

Please call if you have any questions.

Respectfully submitted,

Turner Laboratories, Inc.
ADHS License AZ0066

RE: M-709-03

Dear Natska Gantumur,

Turner Laboratories, Inc. received 58 sample(s) on 05/28/2014 for the analyses presented in the following report.

All results are intended to be considered in their entirety, and Turner Laboratories, Inc. is not responsible for use of less than the complete report. Results apply only to the samples analyzed. Samples will be disposed of 30 days after issue of our report unless special arrangements are made.

The pages that follow may contain sensitive, privileged or confidential information intended solely for the addressee named above. If you receive this message and are not the agent or employee of the addressee, this communication has been sent in error. Please do not disseminate or copy any of the attached and notify the sender immediately by telephone. Please also return the attached sheet(s) to the sender by mail.

Please call if you have any questions.

Respectfully submitted,

Turner Laboratories, Inc.
ADHS License AZ0066

Terri Garcia

RE: M-709-03

Dear Natska Gantumur,

Turner Laboratories, Inc. received 36 sample(s) on 06/03/2014 for the analyses presented in the following report.

All results are intended to be considered in their entirety, and Turner Laboratories, Inc. is not responsible for use of less than the complete report. Results apply only to the samples analyzed. Samples will be disposed of 30 days after issue of our report unless special arrangements are made.

The pages that follow may contain sensitive, privileged or confidential information intended solely for the addressee named above. If you receive this message and are not the agent or employee of the addressee, this communication has been sent in error. Please do not disseminate or copy any of the attached and notify the sender immediately by telephone. Please also return the attached sheet(s) to the sender by mail.

Please call if you have any questions.

Respectfully submitted,

Turner Laboratories, Inc.
ADHS License AZ0066

RE: M-709-03

Dear Natska Gantumur,

Turner Laboratories, Inc. received 42 sample(s) on 06/17/2014 for the analyses presented in the following report.

All results are intended to be considered in their entirety, and Turner Laboratories, Inc. is not responsible for use of less than the complete report. Results apply only to the samples analyzed. Samples will be disposed of 30 days after issue of our report unless special arrangements are made.

The pages that follow may contain sensitive, privileged or confidential information intended solely for the addressee named above. If you receive this message and are not the agent or employee of the addressee, this communication has been sent in error. Please do not disseminate or copy any of the attached and notify the sender immediately by telephone. Please also return the attached sheet(s) to the sender by mail.

Please call if you have any questions.

Respectfully submitted,

Turner Laboratories, Inc.
ADHS License AZ0066

Project: M-709-03
Work Order: 14F0604
Date Received: 06/17/2014

Case Narrative

M2 Matrix spike recovery was low; the associated LCS/LCSD was acceptable.

All soil, sludge, and solid matrix determinations are reported on a wet weight basis unless otherwise noted.

ND Not Detected at or above the PQL

PQL Practical Quantitation Limit

DF Dilution Factor

RE: M-709-03

Dear Natska Gantumur,

Turner Laboratories, Inc. received 51 sample(s) on 06/27/2014 for the analyses presented in the following report.

All results are intended to be considered in their entirety, and Turner Laboratories, Inc. is not responsible for use of less than the complete report. Results apply only to the samples analyzed. Samples will be disposed of 30 days after issue of our report unless special arrangements are made.

The pages that follow may contain sensitive, privileged or confidential information intended solely for the addressee named above. If you receive this message and are not the agent or employee of the addressee, this communication has been sent in error. Please do not disseminate or copy any of the attached and notify the sender immediately by telephone. Please also return the attached sheet(s) to the sender by mail.

Please call if you have any questions.

Respectfully submitted,

Turner Laboratories, Inc.
ADHS License AZ0066

Case Narrative

E4	Concentration estimated. Analyte was detected below laboratory Minimum Reporting Limit (MRL) but above MDL.
H1	Sample analysis was performed past holding time.

All soil, sludge, and solid matrix determinations are reported on a wet weight basis unless otherwise noted.

ND	Not Detected at or above the PQL
PQL	Practical Quantitation Limit
DF	Dilution Factor

RE: M-709-03

Dear Natska Gantumur,

Turner Laboratories, Inc. received 42 sample(s) on 07/11/2014 for the analyses presented in the following report.

All results are intended to be considered in their entirety, and Turner Laboratories, Inc. is not responsible for use of less than the complete report. Results apply only to the samples analyzed. Samples will be disposed of 30 days after issue of our report unless special arrangements are made.

The pages that follow may contain sensitive, privileged or confidential information intended solely for the addressee named above. If you receive this message and are not the agent or employee of the addressee, this communication has been sent in error. Please do not disseminate or copy any of the attached and notify the sender immediately by telephone. Please also return the attached sheet(s) to the sender by mail.

Please call if you have any questions.

Respectfully submitted,

Turner Laboratories, Inc.

Client: SGS Metcon
Project: M-709-03
Work Order: 14G0556
Date Received: 07/11/2014

Case Narrative

E4	Concentration estimated. Analyte was detected below laboratory Minimum Reporting Limit (MRL) but above MDL.
H1	Sample analysis was performed past holding time.

All soil, sludge, and solid matrix determinations are reported on a wet weight basis unless otherwise noted.

ND	Not Detected at or above the PQL
PQL	Practical Quantitation Limit
DF	Dilution Factor

Casino Mining Corporation – Casino Samples

Date 1 October 2014
To Heather Brown

Copies to Wolfgang Baum
From Kevin Ausburn
Filing "R:\Projects\2014 Projects\M-14085 Western Copper & Gold Casino Samples\Reports\M-14085 Final Report on Casino Samples.docx"
Subject Final Report on Casino Samples

Background and Objective

Casino Mining Corporation requested a baseline mineralogical analysis of select leach feed ores from their Casino gold-copper-molybdenum project. The objective of the mineralogical work was to provide:

1. An overall characterization of the gangue mineralogy.
2. Identify the cyanide consuming minerals.
3. Determine the concentration of clay minerals.
4. Identify the mode of occurrence of gold.
5. Check the ore samples for potential leach refractoriness and/or optimization factors.

Samples Received and Methods of Analysis

Three composite ore samples were received. A listing of the received samples, along with their assigned laboratory identifications, is presented in Table 1. Photographs of the received samples are presented in Figures A1 to A3 in the appendix of this report.

Table 1. Received Samples

Sample Description	OCPM Lab ID
Composite 02/05	M-14085-001
Composite 11/17	M-14085-002
Composite 19/20	M-14085-003

The samples were prepared for the following:

- Chemical analyses on the head samples including multi-element ICP, Total Carbon, Organic Carbon, Fire Assay Au/Ag, and Au Cyanide Shake-Leach Test.
  - The ambient cyanide shake-leach test was performed on 10 g of ore with a p95 of -106 micron. Leach time was 1 hours. The shake-leach test was performed at four different cyanide strengths (0.1, 3, 15, & 50 g/L CN). The procedure used for the shake leach testing is included in the appendix of this report.
- Gravity Separation via Vanning Plaque.
  - Material for the gravity separation was stage crushed to 100% passing 65 Tyler Mesh (-212 micron) and the slime portion (-25 microns) was screened off prior to the gravity separation.
- The gravity concentrate, gravity tails, and slimes fraction were all analyzed for Au & Ag via Fire Assay.
  - These gravity products were also measured by QEMSCAN in order to determine the copper deportment.
- Optical Microscopy. All feed samples (minus 10 mesh material) and the gravity concentrate were also examined via stereomicroscope and polarized light microscopy to check for any free gold, identify copper sulfides, other trace minerals and assess pertinent textural features.
- Quantitative X-Ray Diffraction (XRD) and Cation Exchange Capacity (CEC) analyses were performed on the head samples in order to determine the bulk mineralogy and swelling clay.

Discussion of Results

Chemical Analyses

The results of the cyanide soluble gold (CN Sol Au) shake leach test are presented in Table 2, while the remaining chemical analyses are presented in Table 3. The pertinent findings of the chemical analyses can be summarized as follows:

- The gold content in the three composites is low, ranging from 0.32 ppm to 0.6 ppm. Silver concentrations in the feeds are equally low (< 3 ppm).

- The cyanide soluble gold response for composite 11/17 & 19/20 was similar with gold extractions of >90% at 15g/L cyanide and almost 100% gold extraction at 50g/L cyanide. Approximately 60 % of the gold was readily soluble in cyanide in composite 02/05 at 3g/L cyanide; however, only minor additional extraction was achieved with the higher cyanide strengths. Figure 1 presents a graph of the gold extractions.

  - Note these extraction rates are based of shake leach test on pulverized material. It is recommended that bottle roll leach test and/or column leach test be performed in order to establish more realistic extraction rates.

- The copper concentration in the samples was low and ranged from 0.01 Wt. % to 0.09 Wt. %. The majority of the copper was non-acid soluble.

- The organic carbon concentration in the ore composites were <0.1 Wt. %.

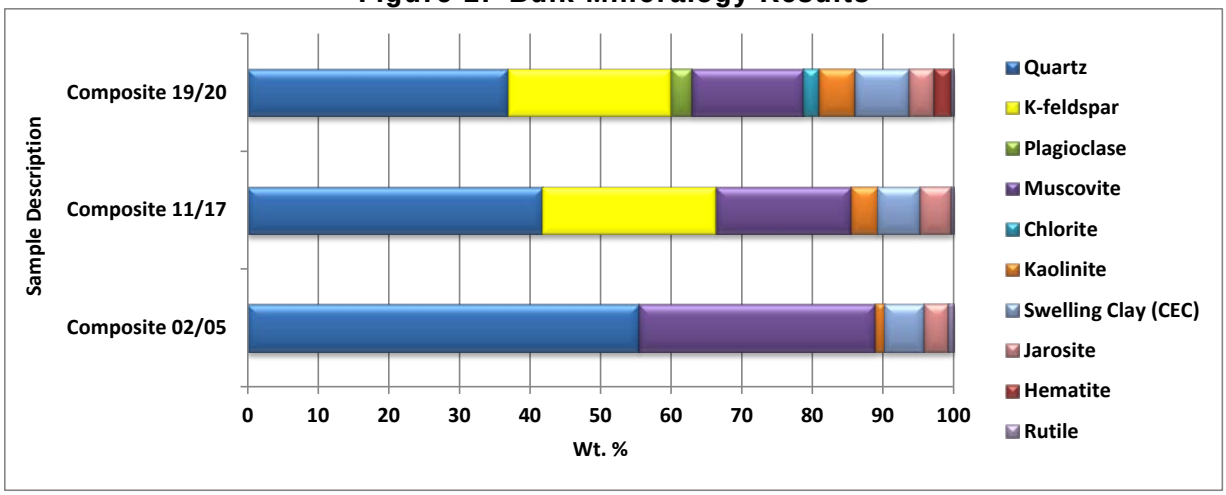
Bulk Mineralogy



The bulk mineralogy results (XRD/CEC) on the received samples are presented in Table 4 and graphically illustrated in Figure 2. The following summarizes the findings from the bulk mineralogy work:

- Composite 02/05 is a quartz-muscovite rock with minor amounts of clay, jarosite, and rutile. Composites 11/17 & 19/20 are both similar and are dominated by quartz, K-feldspar, and muscovite.
- The main difference between composite 11/17 & 19/20 is that the latter contains hematite.
- It is pointed out that all samples contain variable amounts of hydrous iron oxides (limonitic material, goethite-like phases). These compounds are notoriously poorly crystalline to amorphous which means the concentration reported by XRD may be low.

Table 4. Bulk Mineralogy Results

Sample Description	Composite 02/05	Composite 11/17	Composite 19/20
OCPM Lab ID	M-14085-001	M-14085-002	M-14085-003
Phase Name	Wt. %	Wt. %	Wt. %

Jarosite	3.5	4.4	3.5
Hematite	0.0	0.0	2.4
Rutile	0.7	0.4	0.4

Figure 2. Bulk Mineralogy Results

Optical Microscopy of Head Samples

The optical microscope examination of the -10 mesh petri dish head samples can be summarized as follows:

- The ore consists of a quartz-feldspar matrix with elevated amounts (5-10%) of hydrous iron oxides and/or admixed jarositic iron sulfates some of which are jarosite proper, goethite-like material and/or are tentatively classified as limonitic phases. Some of these hydrous iron oxidation products are finely disseminated stains, coatings, fracture fillings and/or more massive fragments.

- The gangue matrices of these composites have been subject to extensive alteration (ferruginous alteration, clay alteration and potassic alteration/sericitization). In addition, the composites received contain minor to moderate amounts of rutile, hematite and traces of magnetite.

- The earthy nature of the alteration will result in generation of -25 micron slimes during processing.

- The samples contain trace amounts of pyrite, chalcopyrite, chalcocite and covellite. These sulfide minerals are commonly encapsulated within Fe oxides/hydroxide minerals indicating that Fe oxides/hydroxides are an oxidation product of the sulfides. As such, any gold associated with the original sulfides would now be associated with the Fe oxide/hydroxides.

Photomicrographs illustrating the as-received material and showing pertinent features of the select minerals and textures are shown in Figures A1 to A12 in the appendix of this report.

Gravity Separation

The results of the gravity separation are shown in Table 5 and are summarized below:

- The results of the bench-scale gravity separation via vanning plaque indicated that (at a liberation size of 65 Tyler mesh and de-sliming at 500 Tyler mesh), 50 to 64% of the gold reported to the -500 mesh slimes.

- Slightly less than one third of the gold (22 to 27%) remained in the gravity tails fraction. This gold is most likely encapsulated in siliceous gangue.

- Recovery of gold into the gravity concentrate was negligible.

- It is pointed out that, due to the limitation of sample material and the very low gold concentrations, the gravity data and the gold distributions are considered “trend/drift data”. Follow-up and confirmatory gravity tests on larger samples are recommended using a gravity table.

Table 5. Gravity Separation Results

Sample Description	OCPM ID	Fraction	Weight grams	Weight Percentage	Au ppm	Au Distr. %	Ag ppm

Mode of Occurrence of Gold

Given the very low gold grades of the composites it is very difficult to mineralogically characterize the gold occurrence. As such, the following observations should be considered preliminary:

- Based on the results of the cyanide shake leach tests it is concluded that the majority of the low gold values present in the samples occur as native gold.
    - The optical microscope examination of the composite samples or their gravity concentrates did not show any evidence of native gold at the microscope's detection limit of +/- 1 micron. Although the shake leach cyanide extraction results are positive, it is cautioned that minor refractoriness of gold to leaching could be caused by submicroscopic gold in sulfides, native gold encapsulated in impervious iron oxide, hydroxide or jarosite matrices, and, of course, native gold encapsulated in quartz/feldspar minerals.
    - The encapsulation of gold within quartz and/or iron oxide/hydroxides is likely the reason that 30% of the gold in composite 02/05 was refractory in the cyanide shake leach tests.
- Although extremely high gold extractions were observed during the analytical shake-leach tests, it is cautioned that in a heap leach environment and considering the gangue minerals, cyanide consumers and clay content, oxide cap heap leaching will most likely achieve lower (~60-75%) gold extractions.
- The determination of the presence of submicroscopic gold in sulfides or other phases was beyond the scope of this analysis and would require detailed D-SIMS work.

Mode of Occurrence of Copper

The QEMSCAN measurements from the individual gravity products were used to calculate the copper deportment for each sample. The copper deportment is shown in Table 6 and summarized as follows:

- The majority of copper was not detected by the QEMSCAN measurements. Approximately 33% of the copper in composite 02/05 was detectable, while only ~8 percent was detectable in composites 11/17 & 19/20.
    - This indicates that the copper is present in low (<5 Wt. %) concentrations in phases.
- Chalcopyrite was the dominant copper mineral identified by QEMSCAN. Ultra-trace amounts of bornite & covellite were also detected.
- A Cu-bearing iron oxide phase was detected in composite 11/17 & 19/20. This phase has copper concentration >5 Wt. %.

Table 6. QEMSCAN Copper Deportment

OCPM ID	M-14085-001	M-14085-002	M-14085-003
Sample Description	Composite 02/05	Composite 11/17	Composite 19/20
Mineral / Element	Mass Cu%	Mass Cu%	Mass Cu%
Cu-bearing Iron Oxide	0.0000	0.0002	0.0032
Chalcopyrite	0.0032	0.0038	0.0033
Bornite	0.0001	0.0001	0.0001
Chalcocite	0.0000	0.0000	0.0001
Covellite	0.0000	0.0001	0.0000
Other Cu	0.0000	0.0002	0.0000
Total QEMSCAN Cu	0.0033	0.0044	0.0069
ICP Cu	0.0100	0.0560	0.0850
Dist.% measured by QS	33.34	7.79	8.06

Note: Confidence in the QEMSCAN measurements is typically only to the first decimal place (0.1 Wt. %). Due to the extremely low concentrations the reported phases are shown to the fourth decimal place; however, there is likely significant variance in the data.

Copper X-Ray maps were produced via Scanning Electron Microscope (SEM) equipped with Energy Dispersion Spectrometers (EDS) because the QEMSCAN measurements only accounted for minor amounts of the copper present in the samples. These X-Ray maps allow for a quick scan of the samples to locate any phases that contain copper >1 Wt. %. Based on these X-Ray maps it was apparent that the majority of iron oxides/hydroxides and iron sulfates all contain minor concentrations of copper. The X-Ray maps, along with selected X-Ray spectra, are presented in Figure A13 through A18 in the appendix.

While no quantitative micro-chemistry was performed on these copper-bearing iron phases it was apparent that their copper concentration varied based on their energy dispersion X-Ray spectra. Given their variable copper content and low copper concentration it is not feasible to try to determine the full copper deportment via QEMSCAN. However, it is concluded that the majority of copper not identified by QEMSCAN occurs within these iron oxides/hydroxide and iron sulfate phases. This agrees with the optical observation that the iron oxides/hydroxides & iron sulfate phases are replacement (oxidation) products of primary sulfides. As such, it is reasonable to conclude that there would be some copper contained within the alteration product if the original sulfide was copper-bearing.

Conclusions & Recommendations

Although the potential process detriments related to mineralogy may prove to be a minimal concern in the actual heap leach operation, they are pointed out hereinafter in order to enable rapid optimization – should leach problems be encountered. Further, it is noted that all conclusions and recommendations are strictly based on the three composite samples received. Potential variances inherent in other ore types or alteration suites cannot be assessed or extrapolated on the basis of these three samples.

- The ore samples received represent a quartz-K-feldspar-muscovite matrix. Heap leach detriments (permeability and wetting) could originate from elevated clay contents (i.e. feed material with >10% Total Clay). Further, ore feeds high in swelling clay (>10%) could conceivably contribute to agglomeration problems.

- QEMSCAN measurements only accounted for ~33% of the copper in composite 02/05 and only ~8 percent in composites 11/17 & 19/20.

    - Chalcopyrite was the dominant copper mineral detected by QEMSCAN.

    - Copper X-Ray maps showed that a significant amount of iron oxides/hydroxides & iron sulfate phases contain minor (<5 Wt. %) concentrations of copper. It is tentatively concluded that the majority of copper in these samples occurs within these iron oxides/hydroxides & iron sulfate phases.

    - Verification of the copper concentrations in non-copper sulfides (i.e. copper-bearing iron oxides/hydroxides, copper-bearing gangue, etc…) would require detailed microprobe and/or D-SIMS analyses.

- Since rock and alteration may introduce some variance in regard to hardness and abrasion, it is recommended that a robust mineralogical ore profiling be completed to assist in minimizing spikes in hardness and related metallurgical issues.

- The cyanide gold extraction rate was similar for composite 11/17 & 19/20 with >90% extraction being achieved with 15g/L CN strength. Composite 02/05 only achieved ~60% gold extraction with 15g/L CN strength.

    - These extraction results are based off lab shake leach tests and should only be used as relative values. Bottle roll leach test and/or column leach test should be performed in order to establish actual cyanide soluble gold extraction rates.

- No visible gold was observed in the received composites or in their gravity concentrates. Considering the lack of observed gold and the cyanide soluble results, it is speculated that the gold primarily occurs as sub-microscopic native gold.

    - Given the low grades of the material it is extremely difficult to mineralogically characterize the occurrence of gold. As such it is recommended that a true diagnostic leach test be performed in order to establish a reasonable deportation of gold. In addition, D-SIMS work could be considered in order to determine the gold occurrence.

- The predominant cyanide consumers are copper sulfides in concert with earthy iron oxidation products and clays. High amounts of jarositic and limonitic material admixed with clays may impact overall wettability of liberated/accessible gold. Further, these minerals may induce potential mineral preg robbing or –borrowing (note: finely disseminated goethite and jarosite, especially after crushing, may exhibit reactive/sorptive surface areas of 50 to 100 m^2 per gram[1]).

- Any ore samples (i.e. their leach residues) which exhibit substantially lower precious metals extractions should be subjected to a gold deportment analysis to assess the reason(s) for the lower extractive response (e.g. true locking in gangue, slimes coatings, or iron salt scaling).

- High(er) amounts of acidic minerals (such as jarosite or alunite) could contribute to pH changes in the heap which may hamper optimal cyanidation. Continuous monitoring of the gangue mineralogy is recommended.

- Due to the presence of various detrimental alteration minerals, the hydrometallurgical ore treatment may require the use of anti-scalants.

APPENDIX

SOP for Cyanide Soluble Shake Leach Procedure

1. Pulverize a rotary split aliquot of the sample to a p95 of -106 microns (i.e. assay pulp).
2. Weigh 10.000 ± 0.200 grams of sample material into a 50-mL centrifuge tube.
3. Under a fume hood, add 20.0 mL of sodium cyanide solution to the sample.
4. Swirl sample to homogenize and place it on the shaker table for an hour.
5. Centrifuge for three minutes.
6. Decant portion to 15 mL test tube.
7. Analyze on AA or ICP for gold.

Note: Sodium hydroxide used to maintain pH 12 in CN solution

EXECUTIVE SUMMARY

Hydrodynamic characterization of two Casino head samples was undertaken to define the physical and hydraulic response of the ore. The samples included Composites Met 02-05 and Met 11-17 which represent 1:1 blends of the individual samples Met 02 and Met 05; and Met 11 and Met 17, respectively.

The metallurgical data indicate average head grades of the metals of interest; Au (0.32 ppm & 0.50 ppm), Ag (1.0 ppm & 3.0 ppm), Cu (0.01% and 0.053%) for composites Met 02-05 and Met 11-17, respectively. These samples show high levels of Al (6.9% & 6.7%), Fe (2.3% & 2.6%), K (3.3% & 4.6%), and S (0.4% & 0.6%). Some trace elements are present; Ba (1,187 ppm & 1,614 ppm), Bi (3 ppm & 2 ppm), Mo (61 ppm & 181 ppm), Ti (1500 ppm & 972 ppm), Pb (20 ppm & 123 ppm), and Th (16 ppm & 17 ppm) which could have some influence in gold extraction. The grade by size data indicate that Au and Ag are not uniformly distributed along the PSD of these composites. Met 02-05 has most of its metal value (35%) on the size fractions smaller than 1.7 mm. In contrast, Met 11-17 has most of its metal value (>25%) on rock fragments larger than 25.4 mm.

The mineralogical characterization indicates that Au occurs primarily as sub-microscopic native gold. Potential cyanide consuming minerals include metal sulfides including copper, iron, arsenic and zinc; iron oxide-hydroxides such as Limonite and Jarosite which can also act as preg-robbing; and secondary alumino-silicates and swelling clays. Shake leach tests conducted by FL Smidth leads us to believe that: the increased recovery on composites Met 11-17 (and Met 19-20) at very high CN-concentrations results from the dissolution of sulfide minerals (sulfide encapsulation due to, but not exclusively, copper sulfides) which may be coating the Au minerals and dissolve at high CN concentrations. On the other hand, the ultimate Au recovery in Met 02-05 is likely associated to silica encapsulation.

A few key findings from the hydrodynamic characterization are as follows:

- Agglomeration of individual composites and blending produce improved hydrodynamic performance which increases the range of heap heights supported by these samples. For instance, 2:1 blend of Met 02-05 and Met 11-17 sample agglomerated to a Level 3 (L3) could support a heap height close to 140 m. The more competent composite Met 11-17 would support percolation leaching to heights up to 140 m even without agglomeration.
- The Casino head samples are competent and show limited compaction and loss of percolation capacity along a 140-m heap profile. Notwithstanding the strong nature of the Casino samples, it appears that the key considerations for the adequate leaching of the **non-agglomerated** Casino ore include:
    - The permeability for Composite Met 02-05 or a blend thereof as the heap height increases beyond 70 m, and
    - Effective solution-to-ore contact for Composite Met 11-17 if not blended.
- As a result of the very competent nature of the Met 11-17 and its low content of fines, the void space is dominated by macro-porosity. This macro-porosity provides, on the one hand, high solution percolation capacity, but in the other limits wettability of the ore. The large component of the macro-porosity translates into gravity-dominated flow where limited horizontal movement of solution occurs leading to inefficient wetting and hence limited metallurgical performance. Typically, this type of flow

condition combined with non-agglomerated ore leads to reduced metal extraction, inefficient reagent (cyanide and lime) utilization and protracted leach cycles. Blending with Met 02-05 will improve the wettability of composite Met 11-17.

- The results from the Hydrodynamic Column Tests (HCTs) confirm that composites Met 02-05 and Met 11-17 will effectively support percolation leaching during the initial stages of the operation as shown by the results of the Hydrodynamic Column Tests (HCTs) for a 32-m heap with a solution application rate of 10 L/h/m^2.
- According to the results from the HCTs, the best performing sample is Met 02-05 as it produces a good solution-to-ore contact which should promote efficient gold dissolution and recovery.
- Blending and agglomeration leads to improved hydrodynamic performance of these two composites which is expected to also improve their metallurgical performance.

As part of its characterization technology HGS has developed the Integrated Column Test (ICT), a procedure that allows simultaneous determination of hydrodynamic and metallurgical performance). Application of this procedure, at no cost to WCG, on the Casino samples shows that:

- Preliminary gold recoveries of about 70% for Composite Met 02-05 and 30% for Met 11-17.
- These results seem to be in good agreement with the conclusions arising from the available physical, hydrodynamic, metallurgical and mineralogical data.
- Based on the metallurgical data, gold recovery on composite Met 11-17 may be hindered due to coating by sulfide minerals (sulfide encapsulation due to, but not exclusively, copper sulfides) while ultimate recovery from Met 02-05 is likely associated to silica encapsulation.

The work conducted as part of this study and other available data show that:

1) There are significant physical, hydrodynamic, metallurgical and mineralogical differences between the two composites evaluated on this study.
2) Ore preparation practices (crushing, blending, and agglomeration) would have a significant impact on the metallurgical performance of the ore. Operational design should consider agglomeration, blending or both to improve the hydrodynamic properties of these composites.
3) For composite Met 02-05, the optimal solution application rate would be equal to or smaller than 10 L/h/m^2 to balance between reagent delivery and air-percolation capacity.
4) For composite Met 11-17, the optimal solution application rate would be equal to or smaller than 6 L/h/m^2 to balance between reagent delivery and solution-to-ore contact.
5) A 2:1 blend of Met 02-05 and Met 11-17 may perform better than the each of the individual composites. Agglomeration of this blend would allow leaching this material to the 140-m design height.
6) The distance between drip points should not be larger than 30 cm.
7) The irrigation for both of these composites should follow a ramp-up irrigation scheme (RUI).

A fact that needs to be considered in the interpretation of the results presented in this report is that all the samples tested to date represent fresh ore. A multi-lift heap is susceptible to weathering, slumping, differential settlement, and for oxide-gold to chemical-induced decrepitation to a lesser extent. All of these mechanisms negatively impact the hydrodynamic properties of the ore and increase the potential solution and metal inventory. Therefore, it is critical that hydrodynamic properties of the leached residue be determined to

optimize the design and operational conditions of the heap. Additional HCTs for process optimization are recommended at heap design heights once the mine operation starts and the ore has been exposed to at least three leaching cycles.

Section 4.0 of this document presents additional discussion of the results and recommendations aimed to improve the design and eventual performance of the heap leaching process of the Casino project.

1.0 TEST PROGRAM AND BASIC METALLURGICAL DATA

1.1 Characterization Program

WCG provided two different composite head samples, namely Composite Met 02-05 and Composite Met 11-17. It is understood that these composites represent a one-to-one blend of the individual samples by the same name (i.e., Met 02, Met 05, Met 11, and Met 17). A total of 89 kg already separated into eight size fractions was supplied by SGS/Metcon (Metcon). As indicated on the test matrix presented in Figure 2.1, each of the samples was subjected to the Stacking Test procedure under three different conditions:

- As-received dry ore mixed with 2.93 kg of pebble lime per ton of ore (kg/t) per Metcon results from their bottle role tests and the value used on the recent metallurgical columns;
- As-received dry ore mixed with powder lime at 2.93 kg/t per Metcon recipe used on the ongoing metallurgical columns;
- A sample mixed with 2.93 kg/t of powder lime and agglomerated with alkalinity amended tap water with a pH of 11.3.

The non-agglomerated samples represent a benchmark to assess the potential benefits from agglomeration. After these tests, it was recommended that for practical purposes the use of pebble lime be discontinued and any future work use only powder lime.

The characterization program consisted of:

a) Review of available particle size distribution (PSD) information,

b) Agglomeration trials to define the optimal moisture content for each PSD,

c) Review of metallurgical and mineralogical data,

d) Stacking Tests to determine the potential hydrodynamic behavior of the samples to select the most promising agglomeration conditions, and

e) Hydrodynamic Column Tests on three PSD to determine the potential operation conditions for these samples for a 32-m heap.

The following paragraphs provide a summary of the data reviewed as part of this study, testing methods and the most relevant results from the application of these tests to the Casino ore. The last section of this document presents a number of recommendations on the basis of these findings.

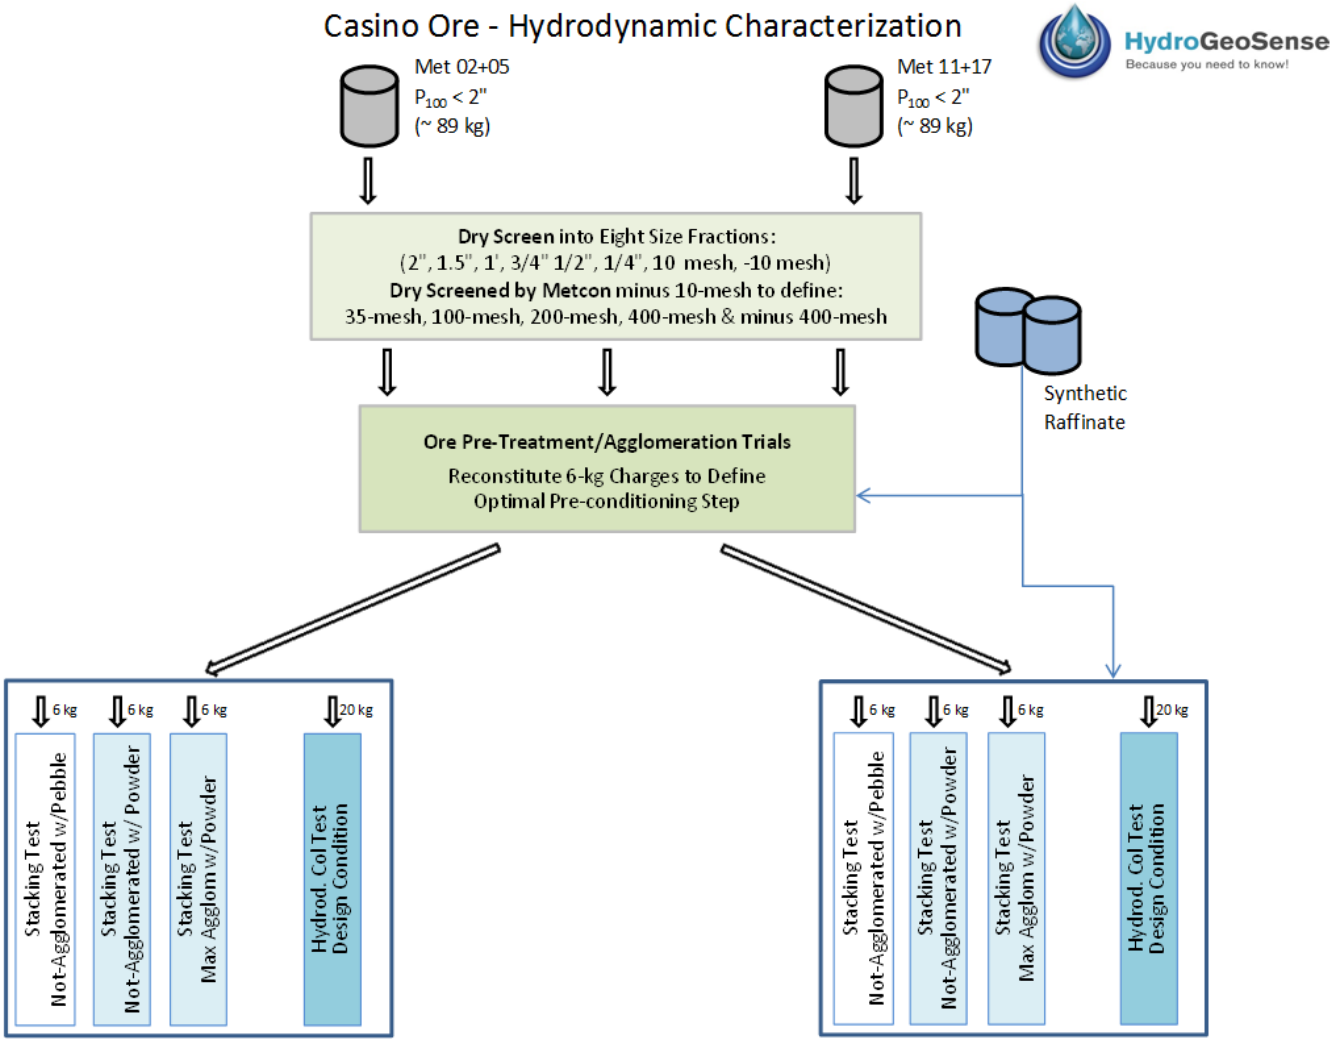

Figure 1.1 Casino – Final Test Matrix

1.2 Particle Size Distribution

The particle size distribution (PSD) for the head ore samples was determined by Metcon and is summarized in Figure 1.1. For comparison, HGS used the PSD of the individual ore samples determined by ALS Metallurgy to determine the PSD of the 1:1 composites also presented as in Figure 1.1. It is noted that none of the ALS' PSD showed particle sizes larger than 5.cm (2") while the two composites received from Metcon (M 02-05 and M 11-17) contained particle sizes larger than 5 cm. Overall, the PSD for the 1:1 composites determined from ALS' PSDs are similar to those reported by Metcon, indicating good consistency between the procedures used by these laboratories.

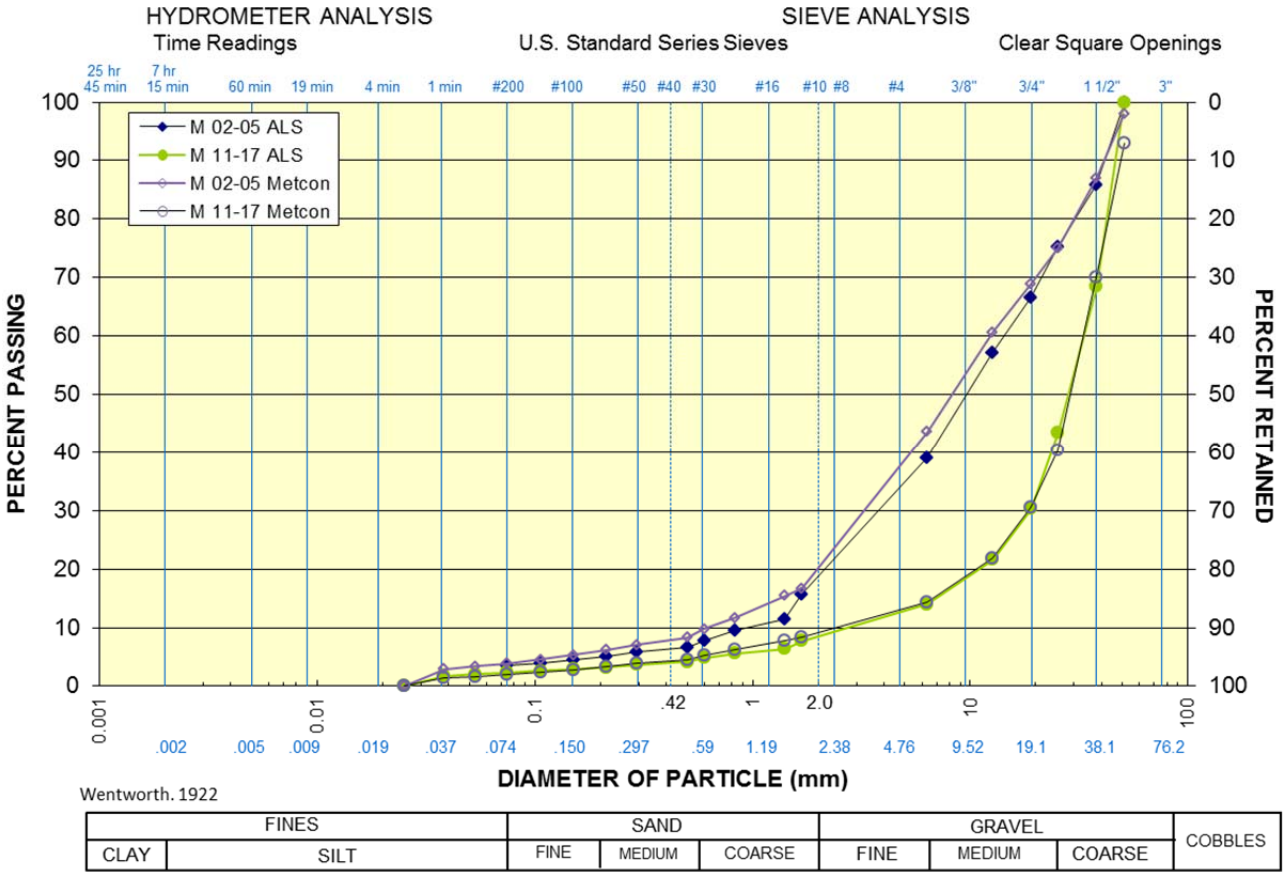

Figure 1.2 Particle size distribution TMC Fresh ore

From the PSD of each composite the P_{80} (the particle size larger than 80% of the rock fragments) and the main size fractions (gravel, sand and fines) can be determined (Table 1.1). These data show that:

- The **P_{80}** of M 02-05 is 30.6 mm while that for the M 11-17 composite is 43.6 mm.
- The fines:sand:gravel partition of the Casino ore is: 3.9:12.8:83.3 for the M 02-05 composite and 2.0:6.3:91.7 for the composite M 11-17. This partition of the main size fractions indicates that as long as the rock fragments are stable, these composites should be permeable to allow percolation through the heap of a significant height.
- However, it is noted that the large gravel content (more so for composite M 11-17) could promote solution channelization and low wetting efficiency.
- The Stacking and Hydrodynamic Column Tests described below provide additional insight in this potential issue.

Table 1.1 Particle size distribution from Metcon				
Sample ID	**P_{80} (mm)**	**Gravel (%)**	**Sand (%)**	**Fines (%)**
M 02-05	30.6	83.3	12.8	3.9
M 11-17	43.6	91.7	6.3	2.0

1.3 Ore Specific Gravity

The Casino samples were tested to determine the Specific Gravity (SG) of the solids on each of the main size fractions (gravel, sand and fines). An accurate determination of the porosity (void ratio) of the sample requires an accurate value of the SG. Difference in the SG on the main fractions indicates potential differences on the alteration type and extent of the rock mass. In the case of alteration differences between the size fractions, these data also provide a better estimate of the overall specific gravity of the sample. The average SG for the Casino is estimated at 2.660 for M 02-05 and 2.632 for M 11-17.

Table 1.2 Specific Gravity		
	Specific Gravity	
Fraction	**M 02-05**	**M 11-17**
Gravel	2.673	2.641
Sand	2.575	2.529
Fines	2.678	2.556
Overall	**2.660**	**2.632**

The difference in specific gravity of the gravel, sand, and the fines may be indicative of varying degrees of alteration among these fractions, and in this particular case, also between the two composites.

1.4 Head Assay Determination

In order to get an understanding of the relationship between the hydrodynamic behavior and the potential metallurgical performance of the Casino samples the data presented by ALS and Metcon are briefly summarized in this section.

ALS assayed each size fraction of samples M 02, M 05, M 11, and M 17 for total copper, iron, sulfur, and gold as well as for multi-element ICP analysis. Metcon performed head assays for gold and silver on the two composites delivered (M 02-05 and M 11-17) to HGS.

HGS recommended mineralogical characterization (QEMSCAN or Quantitative XRD and optical microscopy) of the Casino composites to better understand the mineral species responsible for the occurrence of the Au/Ag values. A one kilogram test charge was prepared for each of these composites (including M19-20) and submitted for mineralogical analysis to FL Smidth during the first week of August 2014. The results of this characterization are summarized below in section 1.4.3.

Table 1.3 summarizes the total copper, iron, sulfur, gold, and silver of the individual samples (Met 02, Met 05, Met 11, Met 17) based on the ICP analysis by ALS and composite samples (Met 02-05 and Met 11-17) determined by Metcon. These data show that:

- Sample Met 05 contains less copper, iron, gold and silver than any of the other individual samples summarized on Table 3.1. It is noted from the individual PSD of this sample that 95% of the rock fragments are smaller than 38.1 mm (1.5") while the average of the other (including Met 19 and 20) is only about 72% (Met 11 has only 63.3% of its mass smaller than 38.1 mm). This information suggests that Met 05 may represent a more altered zone of the deposit.

- M 11-17 has the highest Au and Ag content, although it also has the highest Cu content (530 ppm) of the two composites. Depending on the copper solubility, this higher Cu content might promote CN consumption and interfere with Au/Ag absorption.

- The calculated head assays from the ALS data are similar to those reported by Metcon for copper and gold but the calculated silver content is slightly larger than the values reported by Metcon. Overall, the agreement between these two independent evaluations is quite good.

Table 1.3 Summary of Head Assays

Lab	ALS					Metcon		
Sample ID	Cu (%)	Fe (%)	S (%)	Au (ppm)	Ag (ppm)	Cu (%)	Au (ppm)	Ag (ppm)
Met 02	0.018	3.2	0.64	0.52	1.59			
Met 05	0.002	1.4	0.18	0.20	0.52			
Met 11	0.022	3.2	0.94	0.42	4.62			
Met 17	0.083	2.1	0.31	0.64	2.15			
Met 02-05*	0.010	2.30	0.41	0.36	1.06	0.009	0.32	0.8
Met 11-17*	0.053	2.65	0.63	0.53	3.39	0.051	0.55	2.7

*Composite assays calculated from individual assays assuming a 1:1 mix

- The S content would indicate that the iron on the Casino sample occurs mostly as oxides rather than sulfide minerals. If this is correct, there would be some potential for the iron-oxides to encapsulate or coat the gold minerals and the reaction of sulfides minerals to consume oxygen and lower the pH.

1.4.1 ICP Elemental Analysis

ALS (2013) reports the results from a 48-element ICP scan on seven size fractions which provides a general indication of the geochemical composition of the samples. The results from ALS AR-ICP analysis were combined with the percent of each of the particle size fraction to determine the elemental composition for each of the samples and the two composites of interest for this evaluation. The resulting calculations are summarized in tabular form in Table 1.4 and graphically in Figure 1.2.

Inspection of the data summarized in Table 1.4 and Figure 1.2 indicates that:

- Only three elements are reported with concentration larger than 1% (10,000 ppm), namely: Al (ranging from 6.2% in Met 05 to 7.6% in Met 02), Fe (ranging from 1.4% in Met 05 to 3.2% in Met 02), and K (ranging from 3.0% in Met 05 to 5.1% in Met 17). All of these are highlighted in Table 1.4.
- Similarly, Calcium (ranging from 0.019% in Met 05 to 0.058% in Met 11) and Magnesium (ranging from 0.22% in Met 05 to 0.39% in Met 02) are also present. To the extent that these minerals are associated to Dolomite or Calcite they could reduce the alkalinity requirements of the leaching process.
- The concentrations of the metals of interest (in blue font in Table 1.3) are as follows: Ag (ranging from 0.5 ppm in Met 05 to 4.6 ppm in Met 02), and Cu (ranging from 0.01% in Met 05 to 0.08% in Met 02). As mentioned before, at the higher concentrations (>100 ppm) copper, if sufficiently soluble, has the potential to promote CN consumption and interfere with Au/Ag absorption.
- Several trace metals are reported to be present, namely; As, Ba, Cd, Pb, Rb, Ti, V and Zr although only Ba and Ti are reported to have concentrations of about or larger than 1,000 ppm.
- There is a good agreement between the Cu and S concentrations derived from the ICP analysis and the head assays reported above.
- Similarly, there is good agreement between the Cu and Ag grades estimated from the ICP with those reported by Metcon for both composites.
- Based on the results from the ICP characterization, it can be concluded that the chemical composition for composites M 02-05 and M 11-17 is quite similar with the exception of the concentrations of Ag, Cu, Mo, Sr, U and Zn (see Figure 1.2).

1.4.2 Mineral distribution as a function of particle size

Both ALS (2013) and Metcon (2014[1]) reported Au and Ag head grades as a function of particle size. The Au and Ag grade and the percent retained for each size fraction is summarized in Figure 1.3 and Table 1.5. These data show that:

- The overall trend depicted by these two sets of data for the Au and Ag head grades is consistent.
- The gold and silver content vary in proportion to each other. For Met 02-05 the average ratio of Au to Ag is about 0.33 while for Met 11-17 is about 0.19 which remain fairly constant over the various size fractions. As such, it would be expected that Met 02-05 would leach more efficiently than Met 11-17.
- For Met 02-05, the gold and silver content shows a consistent reduction from the coarsest to the 1.7 mm fraction and then a noticeable increase on the minus 1.7 mm fraction. This type of metal distribution requires good solution-to ore contact in order to efficiently leach the coarse fractions.
- For M 11-17, the gold and silver content is relatively constant over the size fraction although, similar to that observed for Met 02-05, it shows a noticeable increase (a factor of two) in the minus 1.7 mm fraction. Given the coarse nature of this composite, efficient leaching of the Au/Ag from both the coarse and fine fractions will require careful selection of the irrigation scheme.

-10 mesh	7.75	1.53	7.53	8.29	1.00	4.30

- According to the Metcon data, for Met 02-05 about 16% of the Au and about 16% of the Ag occurs in the size fractions larger than 25.4 mm (1") in size. For Met 11-17 about 29% of the Au and more than 25% of the Ag occur on these coarse fractions.
- Similarly, Metcon's data show that for Met 02-05 35% of the Au and about 34% of the Ag are present in the minus 1.7 mm fraction. For Met 11-17 these numbers are 15.4% and 13.2%, respectively. These data suggest that everything else being equal, Met 02-05 should leach better than Met 11-17.
- A comparison between the data generated by ALS with the assays determined by Metcon shows that these data sets produce similar results lending confidence to the head assay values.

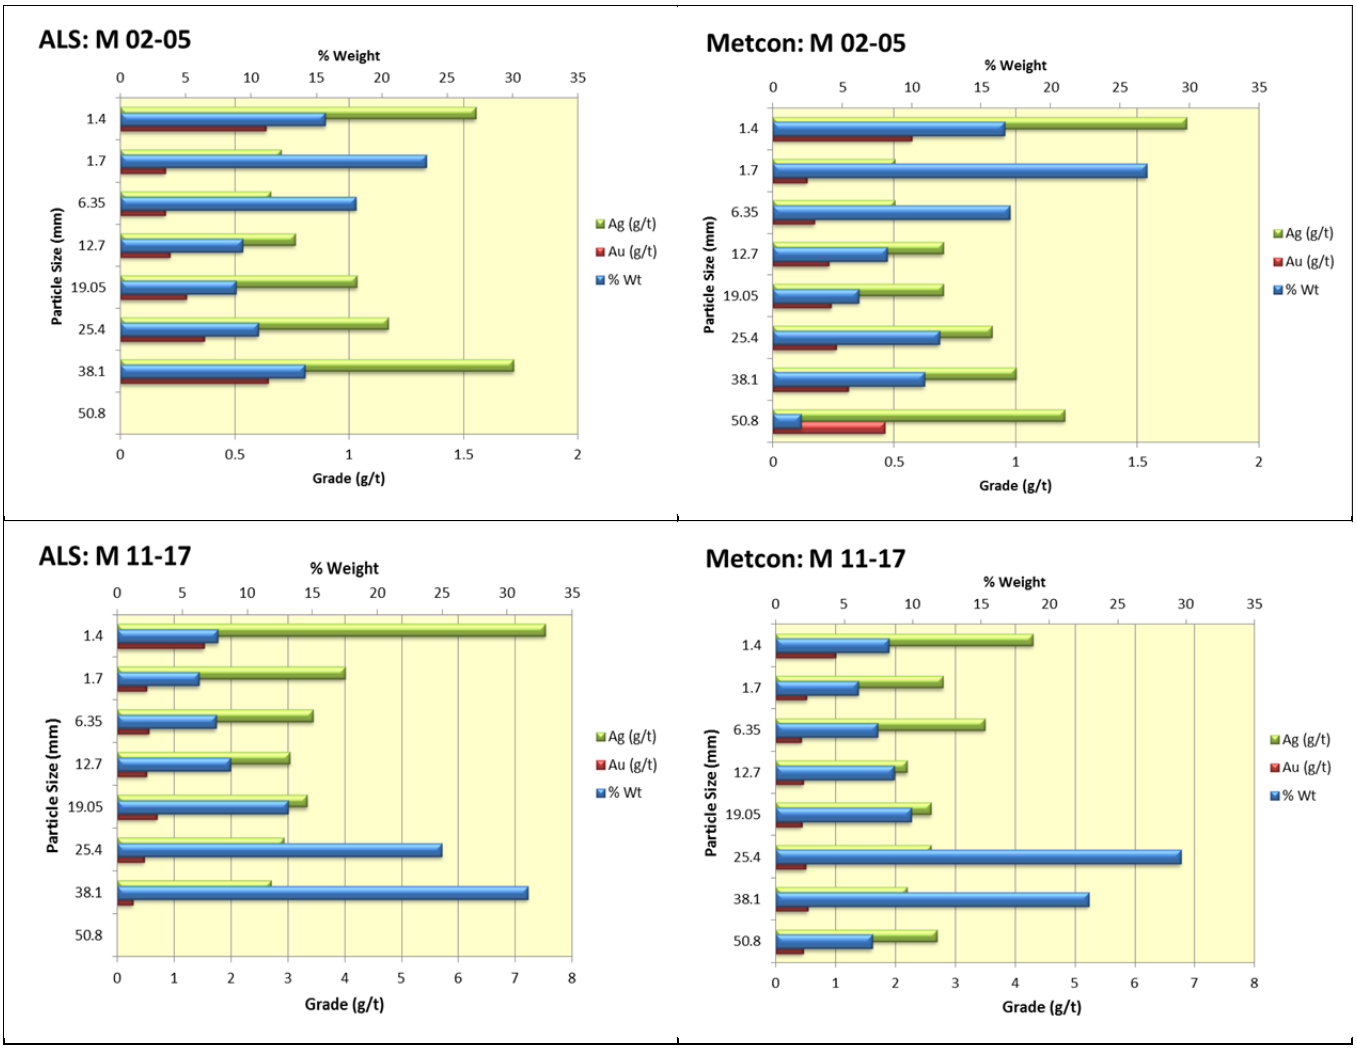

Figure 1.3 Gold and silver grade distributions by size fraction and percent retained

1.4.3 Mineralogical characterization

HGS recommended to WCG to undertake mineralogical characterization of the samples in an attempt to understand the mineral assemblage responsible for the mineralization. HGS coordinated with SGS personnel to deliver a one-kilogram split of each of the three Casino composites to FL Smidth to determine: the gangue mineralogy, abundance of clay minerals, potential cyanide consuming minerals, and mode of gold occurrence. In addition, WCG undertook QEMSCAN of the composites.

For completeness and to help with the interpretation of the data derived during this characterization effort, the following paragraphs provide a brief discussion of the findings by FLS for the two composites of interest, namely;

Met 02-05 and Met 11-17. For a complete analysis and discussion of the procedures used to generate these data the interested reader is refer to the FLS report (FLS, 2014)[2].

Gangue mineralogy

The bulk gangue mineralogy determined by FLS is summarized graphically in Figure 1.4. These data show:

- The gangue is composed predominantly by quartz ($Si0_2$) and alumino-silicate minerals; K-feldspar ($2KAlSi_3O_8$) and Muscovite ($KAl_2(AlSi_3)O_{10}(OH)_2$). Chlorite ($(Mg,Fe)_3(Si,Al)_4O_{10}(OH)_2 \bullet (Mg,Fe)_3(OH)_6$) is present in a minor amount in Met 19-20. These minerals make up about 88%, 85% and 81% of the gangue minerals in Met 02-05, Met 11-17 and Met 19-20, respectively.
- The quartz fraction is quite different from each of the composites, 55.5% for Met 02-05, 41.7% for Met 11-17 and 36.8% for Met 190-20.
- The secondary alumino-silicate minerals include Kaolinite ($Al_2Si_2O_5(OH)$), with some swelling clays representing 5.5%, 6.0% and 7.7% for Met 02-05, Met 11-17 and Met 19-20, respectively.
- Iron oxides include Jarosite ($KFe^{3+}{}_3(OH)_6(SO_4)_2$) and Hematite ($Fe_2O_3$). The presence of these minerals confirms the conclusion reached from the ICP data regarding iron in the Casino samples being indeed representative of oxide minerals.
- The concentrations of Ti identified by the ICP analysis are explained by the presence of Rutile (TiO_2) in all three composites.
- Met 11-17 and Met 19-20 are similar except for the presence of Plagioclase (a transition feldspar), Chlorite, and Hematite on the latter.

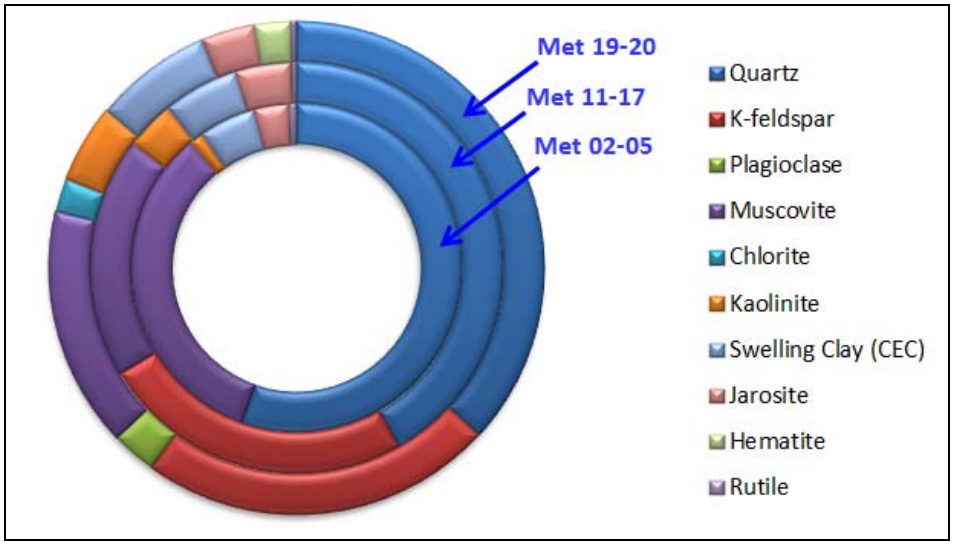

Figure 1.4 Casino – Bulk gangue mineralogy (After FLS, 2014)

[2] FLSmidth 2014. Draft Technical Report, M-14085 Western Copper & Gold Casino Samples.

Potential Cyanide Consuming Minerals

Based on the mineralogical characterization from FLS and other mineralogical data, the potential CN consuming minerals include:

- Metal sulfides including copper, iron, arsenic and zinc;
- Iron oxide-hydroxides such as Limonite and Jarosite which can also act as preg-robbing. Further, Jarosite as well as other acidic materials may also induce lower pH values which may promote CN destruction; and
- Secondary alumino-silicates and swelling clays to a minor extent.

Mode of Gold Occurrence and Potential Solubility

The FLS report indicates that:

- Given the low grades of the material it is extremely difficult to mineralogically characterize the occurrence of gold and further characterization was recommended by FLS.
- From the fact that no visible gold was observed in the received composites or in their gravity concentrates, and the results of the cyanide solubility, FLS conclude that the gold occurs primarily as sub-microscopic native gold.
- Shake leach tests at various concentrations of CN were used to determine the potential solubility of gold. These tests were conducted on 10 g with a P_{95} of minus 106 micron and show that:
    - Au recoveries increase with increased CN concentrations. A CN concentration of 3 g/L results in an average Au recovery of about 61% for all the three composites;
    - Increasing CN concentration produces additional Au recovery for composites Met 11-17 and Met 19-20 but not for composite Met 02-05. Even at a CN concentration of 50 g/L at which the other composites yielded an Au recovery greater than 97%, the recovery for the latter was only 75%.
    - It is our contention that the additional recovery on the first two composites results from the dissolution of sulfide minerals (sulfide encapsulation due to, but not exclusively, copper sulfides) which may be coating the Au minerals and dissolve in the presence of higher CN concentrations. On the other hand, the limited Au recovery in Met 02-05 is likely associated to silica encapsulation.

The available head grade for composites Met 02-05 and Met 11-17 for copper, Au and Ag are summarized in Table 1.6. These data show a good correspondence between these three data sets lending confidence in the sample preparation and analytical methods as well as on the values of the head assays.

Given the low Au grade on these composites, it would be important to understand the minerals responsible for the copper values. FL Smidth recommended and conducted QEMSCAN analysis to try to identify the copper minerals present on these samples. However, FLS indicated that given the low concentration of Cu (< 5%) and the accuracy of this method (0.1% by weight), only a small fraction of the Cu (33% for M 02-05 and ~8% for M11-17 and M 19-20) was detected which prevented full determination of Cu deportment. Notwithstanding these limitations, the QEMSCAN characterization shows that Chalcopyrite is the dominant Cu-sulfide and that

some Cu bearing Iron Oxides are present in M 11-17 and M 19-20 but not in M 02-05. The results from the FLS study reinforce our conclusion that Met 02-05 would metallurgically outperform the other two composites.

Table 1.6 Head Grades for Casino Composites

2.0 HYDRODYNAMIC CHARACTERIZATION

Over the years, the leaching community has bought into the false precept that as long as an ore is very permeable it is good for a leaching process and therefore standard geotechnical characterization is typically limited to the measurement of the saturated hydraulic conductivity. ROM ore and crushed ore devoid of fines are good illustrations of the falsehood of this assertion. In these materials, the leaching solution will indeed move quickly through the ore bed but it will do so with minimal solution-to-ore contact resulting in an inefficient leaching process. Solution bypass through the coarse fractions and pooling on the fines fractions is a common occurrence in ROM heaps which leads to inefficient metal recovery. As discussed in the following paragraphs, a leaching material must not only be permeable but should satisfy a number of other physical and hydraulic requirements.

Industrial experience worldwide shows that the lack of ore preparation standards, in general, and of agglomeration standards, in specific, results in significant variability from day to day and from operation to operation. Improved agglomeration significantly enhances hydrodynamic performance of the ore and hence the metallurgical performance of the process. With this in mind, HGS developed the following scale to qualify the condition of the ore delivered to a heap; a non-agglomerated sample is assigned a Level 0 (L0), while a sample that has been fully agglomerated is assigned a Level 5 (L5). Most crushed, agglomerated ore leaching operations are working with an intermediate agglomerated product with a quality below L3. Recent experience shows that attaining higher levels of agglomeration (L3 to L5) is feasible once the necessary conditions have been identified and operators have been properly trained[3]. It is important to recognize that low levels of agglomeration and ROM ore placement result in particle size segregation along the heap profile, which in turn promotes solution segregation (channeling), protracted leach cycles and overall poor leaching efficiency.

[3] Guzman, A., R.E. Scheffel and S. Flaherty 2006. *Geochemical Profiling of a sulfide leaching operation: A case study*. SME 2006 Spring Meeting. March 2006 St. Louis, Mo

Application of the above agglomeration scale helps explain the discrepancies often encountered amongst metallurgical tests as well as the difference between lab-scale tests and industrial leaching operations. We have concluded[4] that optimal agglomeration needs to satisfy the following specifications:

1.0 Bind all the dispersed fines to minimize their negative effect on the percolation and solution-retention capacity of the ore;

1.1 The percolation capacity of the ore should be at least 100 times larger than the typical application rate (10^{-4} cm/s) for a dynamic heap, and at least 1,000 times larger than this rate for a multi-lift heap.

1.2 The maximum solution retention capacity during irrigation should result in a liquid degree of saturation smaller than or equal to 75% for an oxide-leaching operation or 60% for a sulfide leaching operation.

1.3 Air conductivity should remain larger than 10^{-3} cm/s.

2.0 The resulting porous structure yields at the maximum lift/heap height a total porosity larger than 30% which is partitioned between macro- and micro-porosity of about 50:50 to facilitate bulk solution movement and intimate contact between solution and ore;

3.0 The porous structure is sufficiently resilient to withstand deformation and physical stress resulting from the design heap-height;

4.0 The agglomeration product is sufficiently resilient to chemical decrepitation;

5.0 The agglomeration product and resulting porous structure is able to withstand flooding without major loss of structural integrity; and

6.0 Produce an agglomeration product which promotes leaching bed homogeneity, uniform flow distribution and equal opportunity-leaching for all the size fractions.

All these specifications are more critical in the case of a multi-lift heap where the material will be exposed to the cumulative effect chemical decrepitation and compaction resulting from multiple leaching cycles. In general, alkaline leaching conditions (as those used in the leaching of Au and Ag) produce less decrepitation than that observed in acidic leaching conditions (as those used in the leaching of Cu, Zn and Ni) so the conditions specified on item 1) above may be relaxed slightly.

With these requirements in mind, two testing procedures (the Stacking Test and the Hydrodynamic Column Test) were developed based on experience from the hydrological sciences and observations in more than 50 leaching operations worldwide. **These test procedures provide the most complete characterization of the physical and hydrodynamic properties of an ore-for-leach available to the mining industry.**

[4] A. Guzman, S. Robertson and B. Calienes, Constitutive relationships for the representation of a heap leach process, in The **Heap Leach** Solutions 2013 Proceedings Vancouver, Canada, September 22-25, 2013.

Extensive experience with the application of these procedures to the leaching processes on a variety of minerals including crushed-agglomerated ore and ROM ore indicates that:

- Ore bulk density controls the hydrodynamic performance of the ore;
- Bulk density varies in a non-linear fashion along the heap profile and strongly depends on ore preparation practices (particle size distribution, crushing approach, agglomeration and additives, and stacking mode);
- Hydrodynamic performance controls operational conditions, metallurgical performance as well as geotechnical performance of the ore mass; and
- As such, it is critical to recognize that operational conditions for a given ore sample depend on ore preparation techniques, method of stacking and equally important, the bulk density of the ore.

In practical terms, a large difference between the Stacking Test results from Level 0 and Level 5 material indicates a strong sensitivity of the hydrodynamic properties of the ore and highlights the need for optimizing the agglomeration process. On the other hand, a relatively small gap between L0 and L5 STs suggests that the ore is robust enough and that a sub-optimal agglomeration product would not greatly impact the performance of the leaching process.

The following sections provide a brief overview of these procedures, test conditions, and the results from their application to the Casino head composites.

2.1 Testing Solution

Testing with a representative solution (density, viscosity, and bulk chemistry) is a key procedural practice that has been overlooked during the measurement of hydrodynamic properties in the context of the design of many heap leaching operations. This oversight typically results on erroneous conclusions regarding the hydraulic performance of the ore. With this in mind, the tests requiring solution were conducted as follows:

- Tap water with 0.13 g of lime per liter of water to obtain a pH close to 11.3 for the agglomerating solution and Stacking Tests.
- The HCTs used tap water with 0.10 g/L of lime, a pH of 11.2 plus 0.5 g/L of NaCN for the irrigating solution.

Saturated hydraulic conductivity tests were conducted using synthetic raffinate to make the results from these tests as representative as possible. The moisture content values represented in Table 2.1 represent the optimal moisture required to achieve an agglomeration level of L3 (the typical attainable at an industrial scale without much difficulty).

Hydraulic conductivity is directly proportional to the solution density and inversely proportional to the viscosity of the solution. The specific gravity (S.G.) of the synthetic raffinate was measured at 1.00. It is noted that all values of saturated hydraulic conductivity reported on this document have been normalized to a temperature of 20°C to account for the variation of solution viscosity as a function of temperature.

2.2 Stacking Tests

A Stacking Test[5] (ST) simulates the lithostatic load resulting from the weight of the ore as the height of the heap increases. A ST is performed by placing an ore sample into a test cell and mechanically increasing the confining load to simulate the effect of heap height on the bulk density of the ore. The load is increased in a stepwise fashion, allowing for height stabilization during each of the loading steps. The density and permeability of the ore are measured at each step and then the load is increased to simulate additional lithostatic loading. The maximum load for a stacking test is selected to represent either the maximum lift height in the case of a dynamic heap or the maximum heap height in the case of a permanent (multi-lift) heap[6]. A soft-ore produces a steep density profile indicative of a rapidly changing hydraulic conductivity profile while a competent ore produces relatively flat density and conductivity profiles. The stacking test is conducted under partially saturated conditions, containing only the moisture of agglomeration (or as-drained moisture in some cases), as opposed to fully saturated conditions typically employed in similar studies conducted by geotechnical practitioners. The results from a Stacking Test include:

- *Density profile* – defines the relationship between the ore density and heap height. This profile provides a direct measurement of the physical integrity of the ore sample under load and, as such, it quantifies the robustness of the pore structure resulting from the selected ore-preparation practice;
- *Hydraulic conductivity profile* – defines the relationship between the ore conductivity and heap height. These data represent a direct measurement of the integrity of the porous structure and its resilience under various heap heights and determines the effect of physical and chemical decrepitation (when using a leached sample) on the percolation capacity of the ore;
- *The minimum hydraulic conductivity of the sample* – By design, the results from a Stacking Test represent the bulk density, ore permeability and, at the end of the test, the saturated hydraulic conductivity of unit volume of ore located at the bottom of the heap. Therefore, the saturated hydraulic conductivity value at the end of the load-sequence indicates whether the heap is sufficiently permeable at its ultimate height to allow free drainage of the pregnant leach solution (PLS) to the collection system;
- *Preliminary estimates of total-, micro- and macro-porosity* – these preliminary estimates provide a direct indication of the capacity of the sample to support percolation leaching. Ample data from industrial operations indicate that a total porosity of at least 30% is required for proper solution and air percolation. In addition, a 50:50 portioning of the porosity into micro- and macro-components has been determined to provide a good balance between advection and diffusion controlled solution movement.

---

[5] A. Guzman and R.E. Scheffel, The Fundamentals of Physical Characterization of Ore for Leach, in International Symposium Hydrometallurgy (6th: 2008 Phoenix, AZ). Edited by C.A. Young et al., SME.

[6] A. Guzman, S. Robertson and B. Calienes, Constitutive relationships for the representation of a heap leach process, in The **Heap Leach** Solutions 2013 Proceedings Vancouver, Canada, September 22-25, 2013.

- *The maximum lift and heap height* – Data from the density and permeability profiles provide a direct measurement of the lift and heap height at which the leaching process will allow unimpeded percolation of solution.

As described above, two composites from the Casino ore body were subjected to the ST procedure under different conditions of agglomeration. To accommodate the coarser nature of Met 11-17, the STs were conducted on 8" diameter cells. The agglomerated samples were targeted to an optimal condition (L5), however, due to the high proportion of gravel size fragments agglomeration for Met 02-05 reached an intermediate level of agglomeration (L3) while the coarser composite Met 11-17 reached a low level of agglomeration (L2). In addition, to fulfilling the tests the test matrix (Figure 2.1), we also tested a 1:1 blend of Met 02-05 and Met 11-17 under a non-agglomerated condition and a 2:1 blend of these composites under a L# agglomeration level. A total of 8 STs were conducted as summarized in Table 2.1.

Figures 2.1a and 2.1b present a visual record of the samples used during this characterization; non-agglomerated (L0) and agglomerated (L2 and L3). As indicated by the contrast in porous structure between the L0 and L3 samples, despite the low level of fines on the Casino samples, it seems likely that agglomeration has a positive impact on the hydrodynamic performance of the ore – more so for sample Met 02-05 with smaller top size and larger amount of fines. Agglomeration of the 2:1 blend of M 02-05 and M 11-17 (Figure 2.1b) produces a significant improvement of the porous structure when compared with the agglomerated samples of either one of these composites (Figure 2.1a).

Table 2.1 presents the sample identification (ID) together with the conditions for each of the STs. The sample ID contains information about the Composite (M-02-05, M-11-17 or Blend of these two), type of lime mixed with the initial non-agglomerated sample (Peb for Pebble and Pow for Powder), and the level of agglomeration (L0, L2 or L3). Powder lime was used for the remaining tests (agglomerated samples, blended non-agglomerated sample and the samples used on the HCTs described below). Also included are the Specific Gravity, the moisture content, maximum test height, minimum and maximum bulk density, minimum and maximum air conductivity, and minimum saturated hydraulic conductivity.

As indicated in Table 2.1, a 1:1 blend of composites Met 02-05 and Met 11-17 was prepared and tested under non-agglomerated conditions to evaluate the potential benefit of mixing these two samples. An additional 2:1 blend of these samples was prepared and tested under a L3 agglomeration level to document the beneficial impact of agglomeration on the Casino composites.

The samples were initially tested to a maximum heap height of about 70 m for the initial, then to about 140 m to simulate the range of heap heights considered within the current heap design. As discussed below, the load sequence was selected to generate sufficient detail over the range of heap heights relevant to the current multi-lift heap. It is noted that the slope of all the density profiles generated to date seem to steepen once the simulated heap height increases beyond twenty meters.

By design a Stacking Test determines the effect of lithostatic load on the degree of compaction of a sample. These results are presented on and X-Y semi-log plot where the Y-axis represents the bulk density (dry mass of ore per unit volume) and the X-axis represents the lithostatic load expressed in terms of the associated heap height. The shape of the density profile is in general diagnostic of the physical competence (strength) of the ore

such that a "soft" or "weak" ore is characterized by a steep density profile while a competent, strong sample is described by a flatter density profile. It is noted, however, that the slope of the density profile is also affected by the initial porous structure of the sample such that the density profile of a fully agglomerated sample might be steeper than that from the corresponding non-agglomerated sample. Notwithstanding, this stepper density profile, the fully agglomerated samples invariably have a much higher percolation capacity than the non-agglomerated sample due to its more organized porous structure.

As such, interpretation of the results from a ST requires combined analysis of the density and conductivity profiles as well as the preliminary estimates of the total porosity and its partition into macro and micro. The following sections present a summary of the results in graphical form for the density and the conductivity profile as well as the partition of porosity into its micro- and macro-components to facilitate evaluation of the impact of the various testing conditions.

Appendix A at the end this document presents the laboratory report for each of the STs conducted as part of this investigation.

2.2.6 Discussion of Stacking Tests Results

The results from the STs for the Casino samples are presented in Figures 2.2 to 2.4. Inspection of these data shows that:

- The bulk density and conductivity of all the samples are a function of the heap height. As the heap height increases the density increases and the conductivity (percolation capacity) decreases in a non-linear fashion. The change in these properties is relatively minor over the range of heap heights evaluated on this study (h < 145 m) indicating that the Casino composites are mechanically competent.
- The type of lime used for alkalinity amendment has an effect on both the density and conductivity profiles. This is interesting in that the alkalinity dosage was identical (2.93 kg/t) on these samples and the only difference was the texture of the lime; pebble or powder.
- The results from the STs show that alkalinity amendment with pebble lime slightly increases the density and the conductivity of these two composites. Although, the industrial significance of these difference is minor because using pebble lime would not be practical, they highlight some very important technical details:

  - The texture of the fines (dispersed versus clumped in this particular case) has a measurable effect on the hydrodynamic response of a sample;
  - The shape and actual values of the density and conductivity profiles are able to identify changes as small as 0.3% in the pore structure; and
  - Designing optimal conditions by controlling the PSD, ore preparation practices (as shown below) and measuring the impact of these changes via the Stacking Tests are attainable.
- Agglomeration (although not optimal due to the level of fines present on the Casino samples used for this evaluation; < 4% minus 200-mesh) provides a noticeable improvement on both the density and conductivity profiles with respect to those of the non-agglomerated samples even for the very coarse composite (Met 11-17).
- The conductivity profiles (bottom frames on Figures 2.2 to 2.3) confirm the beneficial effect of agglomeration showing an increase in conductivity of one order of magnitude (a factor of 10) for both composites (Met 02-05 and Met 11-17).
- Similarly, blending and agglomeration (Figure 2.4) produce a significant improvement on both the density and conductivity profiles. **These results show that ore preparation practices are therefore critical for an improved performance of the process.**
- Blending and agglomeration of Met 02-05 and Met 11-17 produced an improved sample from the hydrodynamic point of view, namely:
  - The density profile of the blended samples fall between those from the two original composites showing the incremental benefit of blending alone (M02-05+M11-17 1:1 L-0) and blending and agglomeration (M02-05/M11-17 2:1 L-3). The density of the agglomerated sample is smaller than that of the blended, non-agglomerated sample.
  - The conductivity profile of the blended samples is higher than that from the original M02-05-Pow-L0 composite showing the incremental benefit of blending alone (M02-05+M11-17 1:1 L-0) and blending and agglomeration (M02-05/M11-17 2:1 L-3) which produce conductivity values larger than those measured for the original M11-17-Pow-L0 composite. The conductivity of the agglomerated sample is larger than that of the blended, non-agglomerated sample.
  - These data indicate that blending all these samples would be beneficial for both composites from the point of view of their hydrodynamic performance (increasing conductivity for Met 02-05 and reducing the negative effect of the high gravel content for Met 11-17). Agglomeration further increase the benefit of blending.
  - Depending of the location of these composites with respect to the mining plan, blending all of these samples may be advantageous for the metallurgical process.
- Overall, the heap height has a small effect on the conductivity of the ore. As part of the ST procedure, each sample is fully saturated with synthetic raffinate, allowed to drain under the influence of gravity, and then reloaded to the maximum heap height simulated during the tests (~140 m). This portion of the ST determines the physical stability of the ore and its potential compaction at residual liquid saturation (typically larger than the optimal moisture of agglomeration) as expected to occur during the life of the multi-lift heap. The maximum compaction during reload was observed for the agglomerated samples. However, even **these values are smaller than 4.8% indicating a competent ore whose porous**

structure is able to withstand flooded conditions and the full lithostatic stress at its residual saturation.

Industrial experience on several different ore types (oxide and sulfide minerals) suggests that:

- For a dynamic (on and off) heap, a minimum saturated hydraulic conductivity of 100 times the application rate is required. For the recommended application rate of 6 L/h/m^2 (1.67 x 10^{-4} cm/s), this requirement translates into a minimum saturated hydraulic conductivity of 600 L/h/m^2 (1.67 x10^{-2} cm/s). For a multiple-lift (permanent) heap, the minimum saturated hydraulic conductivity requirement is 1,000 times the application rate to account for potential decrepitation, slumping and compaction. This requirement translates into a minimum saturated hydraulic conductivity of 6,000 L/h/m^2 (1.67 x10^{-1} cm/s) for a permanent heap.
    - As indicated in Table 2.1, all the samples tested during this program satisfy the requirement for a dynamic heap but some samples fall short of the requirement for the permanent heap. Of the samples prepared with powder lime, the non-agglomerated Composite Met 11-17 has the smallest K_s value (7.7 x 10^{-2} cm/s - 46% of the required value) while the projected minimum K_s for Composite Met 02-05 (9.9 x 10^{-2} cm/s) would be about 60% of the required hydraulic conductivity.
    - The minimum K_s value for the blend of these composites is 1.4 x 10^{-1} cm/s, interestingly higher than that for each of the composites. This improvement is attributed in the one hand to contribution of the coarser material from Met 11-17 and the beneficial effect of the sand fraction from Met 02-05 which prevents the migration of fines from Met 11-17. The fines tend to migrate and deposit along the heap profile forming low permeability layers.
    - Agglomeration increases the minimum saturated hydraulic conductivity of Composite Met 11-17 by a factor of three to 2.0 x 10^{-1} cm/s (120% of the required Ks) and has a smaller, though still positive, effect on Composite Met 05-02 (1.0 x 10^{-1} cm/s; 60% of the required K_s).
    - Blending produces a saturated hydraulic conductivity which essentially meets the 1,000 larger than the application rate requirement (1.4 x10^{-1} cm/s for M02-05+M11-17 1:1 L0) while the blended and agglomerated sample slight improves on the hydraulic conductivity (1.5 x10^{-1} cm/s for M02-05+M11-17 2:1 L3).
- As the total porosity approaches a value of 30% the ability of the ore to support percolation leaching is diminished. In addition, an optimal partition of the pore space consists of 50% micro-pores and 50% macro-pores to provide a good balance between advection and diffusion controlled solution movement. Inspection of the preliminary estimates of porosity and its partition into micro- and macro-components summarized in Table 2.2 below and Figure 2.7 shows that for the samples prepared with powder lime:
    - The total porosity of the agglomerated samples is smaller than that of the non-agglomerated samples; 31% versus 29% for Met 02-05 and 41% versus 35% for Met 11-17.

- The partitioning of the pore space of the Met 02-05 samples is close to the optimal; a macro/micro ratio of 55/45 for the non-agglomerated sample and slightly improved (48/52) for the agglomerated sample.
- However, the partitioning of the pore space for the Met 11-17 samples is dominated by macro-porosity (80/20 for the non-agglomerated and 74/26 for the agglomerated sample. The smaller improvement on composite Met 11-17 is due to its low fines content (2.0%) and its high gravel component (91.7%).
- Interestingly, the blended composite has a slightly lower total porosity (30%) but a macro- to micro-porosity partition of 49/51which is very close to the optimal (50/50).
- Similarly, the agglomerated 2:1 blend of M 02-05 and M 11-17 produces a micro to macro partition of 50:50.

- **The large component of the macro-porosity of the Met 11-17 non-agglomerated composite would translate into gravity-dominated flow where limited horizontal movement of solution occurs leading to inefficient wetting and limited metallurgical performance.** This type of flow conditions leads to poor metal extraction, inefficient reagent utilization and protracted leach cycles.
- In other words, an ore sample can be too permeable to be efficiently leached and more so if the irrigation scheme is not properly designed and operated to counteract the gravity-dominated flow.
- Composite Met 02-05 when not agglomerated may be able to support a percolation leaching process in heap with heights up to 70 m. An L3 level of agglomeration improves the percolation of this sample such that a heap as tall as 100 m may be supported.
- Notwithstanding the potential complications resulting from flow channelization, composite Met 11-17 may support percolation leaching in a heap with heights up to 140 m.
- Blending would lead to improved hydrodynamic and metallurgical performance of these two composites. The ST data from the agglomerated 2:1 blend of M 02-05 and M 11-17 indicate that this sample could support a heap height close to 140 m.

Table 2.2 Preliminary Estimates of Porosity

Test ID	SG	Agglomeration		H_{Max}	Minimum Porosity			Fraction (%)	
	( )	Level	Moisture	(m)	Total	Macro	Micro	Macro	Micro
M-02-05-Peb-L0	2.660	L0	0.4%	70.6	0.31	0.16	0.15	50.6	49.4
M-02-05-Pow-L0	2.660	L0	0.4%	71.2	0.31	0.17	0.14	54.6	45.4
M-02-05-L3	2.660	L3	5.7%	129.2	0.29	0.14	0.15	47.6	52.4
M-11-17-Peb-L0	2.632	L0	0.3%	82.5	0.40	0.35	0.06	85.9	14.1
M-11-17-Pow-L0	2.632	L0	0.3%	120.3	0.41	0.33	0.08	80.0	20.0
M-11-17-L2	2.632	L2	2.4%	147.7	0.35	0.26	0.09	73.9	26.1
M02-05+M11-17 1:1-L0	2.645	L0	0.3%	138.1	0.30	0.14	0.15	48.6	51.4
M02-05/M11-17 2:1-L3	2.651	L3	5.5%	130.7	0.30	0.15	0.14	51.6	48.4

- An important fact that needs to be considered in the analysis and interpretation of the results of the Stacking Tests is that all the samples tested to date represent fresh ore. Leaching typically results in chemical-induced decrepitation (more so under acidic conditions than alkaline conditions) which in turn negatively impacts the hydrodynamic properties of the ore. **Given that the Casino heap leaching process is designed as a multi-lift operation, it would be important that hydrodynamic properties of the leached residue after a three to four leach cycles be determined to define the potential impact of decrepitation on the long term operation of the heap. Given the favorable response of the blended, agglomerated samples it is expected that this long term condition could be easily managed.**

2.3 Hydrodynamic Column Tests

The hydrodynamic column test procedure provides the most complete characterization of the physical and hydrodynamic properties of an ore-for-leach at given bulk density. A Hydrodynamic Column Test (HCT) is performed by placing an ore sample into a column and subjecting the sample to a confining pressure equivalent to desired lift or heap height. The diameter of the test cell is selected to minimize potential wall effects on the determination of hydrodynamic parameters of the ore sample. Once the sample has been placed onto the test cell, the irrigation rate is varied over several orders of magnitude to evaluate the corresponding degree of saturation and the resiliency of the porous structure as the ore becomes increasingly wet. Each irrigation rate period is extended until steady state flow conditions are developed at which point the corresponding degree of saturation is measured. The maximum solution application rate is determined by the value at which the surface of the column becomes saturated (flooded). Once the ore is flooded, a saturated hydraulic conductivity test is conducted to quantify the maximum flow capacity of the ore (K_s). The relationship between irrigation rate and degree of liquid saturation (solution retention) varies from sample to sample and is strongly influenced by the ore preparation practice.

The parameters obtained from a HCT include: a) saturated hydraulic conductivity, b) hydraulic conductivity as a function of solution content (hydraulic conductivity curve), c) the moisture retention curve (the relationship between degree of saturation and pore pressure), d) the air permeability as a function of solution content (air conductivity curve), e) the drain down curve, and f) total, macro-, micro- and residual-porosity. As such, **the HCT provides a complete characterization of the potential hydrodynamic response of an ore sample under a percolation leaching process.** A description of each of the parameters obtained from the HCT test is as follows:

a) *Saturated hydraulic conductivity* – defines the maximum capacity of the ore to allow percolation of leaching solution. A saturated hydraulic conductivity (K_s) greater than or equal to 10^{-2} cm/s is a necessary but not sufficient condition to ensure an adequate metallurgical performance of an ore under percolation leaching at an industrial scale. As indicated above, the actual criteria for an adequate K_s is different for a dynamic heap (initial K_s greater than 100 times the application rate) than for a multi-lift, permanent heap (initial K_s greater than 1,000 times the application rate);

b) *Moisture retention curve* – provides the degree of saturation (moisture content) of the sample as a function of capillary (pore) pressure and hence defines the energy state of the solution within the pore

space. This parameter is critical if numerical modeling of the flow process would be pursued but not critical from a practical point of view of design of the leaching process;

c) *Hydraulic conductivity curve* – indicates the degree of liquid saturation resulting from a steady-state solution application rate. This is the critical parameter in the design of the leaching/bio-oxidation process since the liquid saturation not only defines the ability of the ore to allow solution and air movement (from the air permeability curve described below) through an ore sample, but also determines the mechanical stability of the ore;

d) *Air permeability curve* – provides the air flow capacity of the ore as a function of degree of liquid saturation (solution application rate). This is a fundamental design parameter for forced or natural aeration system, which has not been traditionally considered;

e) *Drain down curve* – provides an idea of the rate of solution drainage due to the action of gravity. It represents a critical parameter necessary to estimate residual solution (and metal) inventory, required rest time before over-stacking (for a permanent heap) or removal of the leached residue (for a dynamic heap), as well as the potential discharge volume and rate during closure and post-closure conditions;

f) *Total-, micro-, macro-, and residual-porosity* – the total porosity indicates the pore space per unit volume of the sample. For a given ore sample, in general, and in an agglomerated ore in particular, the macro porosity is associated with the pore space between rock particles/agglomerates while the micro-porosity represents the pore space within rock particles/agglomerates themselves. The residual porosity is the fraction of the pore space which will remain saturated even after a prolonged drain down period. Optimal agglomeration process produces a 50:50 micro to macro partition and minimizes the residual porosity.

By design a sample subjected to HCT represents a unit volume of ore located at the bottom of the lift (heap) – the target bulk density is selected from the results of a Stacking Test on the same sample. This location experiences the most stringent conditions since it is exposed to the maximum lithostatic load and to the maximum degree of liquid saturation along the heap profile. If the hydraulic performance of this portion of the heap/lift is adequate, it is reasonable to conclude that the rest of the heap/lift profile will perform just as well or better.

The results from an HCT provide all the necessary information to understand movement of solution and air under a percolation leaching process. In other words, the HCT generates all the parameters required in the context of numerical representation (Computational Fluid Dynamics, CFD) of the leaching process. **From the more practical point of view, the HCT answers the key question for the design of a heap – the degree of saturation resulting from a given application rate.** Experience shows that for an oxide leach the maximum liquid saturation should be kept below 85% and ideally below 75% to accommodate the natural variability associated with the heap stacking process. Leaching of a sulphide ore typically requires that the degree of saturation remains below 60% to ensure that forced (or natural) aeration is properly supported. **As such, the operating degree of saturation is the critical design parameter as it controls solution-ore contact, aeration capacity of heap, and mechanical stability of the heap.**

From the point of view of the design of a leaching operation, hydrodynamic characterization provides a way to quantify the benefits from alternative ore preparation approaches (from mining methods, to crushing, to agglomeration and stacking) so these results can be used to select the most favorable ore preparation techniques and maximum bulk density for a given ore sample. In addition, this type of information can be used to select optimal operational conditions, including maximum lift height, maximum heap height, irrigation and aeration schemes and schedule as well as to determine the operation moisture content, drain-down moisture and maximum air intake among others.

As indicated by the Test Matrix (Figure 1.1) a HCT was conducted on each of the composites Met 02-05 and Met 11-17. The conditions for the HCTs were selected per WCG personnel to represent non-agglomerated ore. Table 2.3 summarizes the conditions used during the HCTs. The density of the samples, a critical variable which is in many cases overlooked on standard metallurgical column tests, was selected to represent a 32-m heap to ensure proper operation for the first several lifts.

Table 2.3 Hydrodynamic Column - Test matrix

Sample ID	Top Size (mm)	P_{80} (mm)	Bulk Density (t/m^3)	Agglomerate Level
Met 02-05	~50	30.6	1.770	L0
Met 11-17	~55	43.6	1.530	L0

One of the key pieces of information derived from a HCT is the hydraulic conductivity curve; the relationship between solution application rate and degree of liquid saturation (or saturation). In general, the shape of the hydraulic conductivity curve is influenced by the particle size distribution, ore conditioning/curing and moisture content, the blending ratio of the ore type, the type of solution used during the agglomeration process, the quality of agglomeration and the bulk density. All these parameters can be changed as part of the design of an operation so they constitute the **ore preparation practices**. As such, the shape of the curve is diagnostic of the effect of the ore preparation practices on the hydraulic response of an ore sample. The hydraulic conductivity curves derived for the Casino fresh ore samples are summarized in graphical form on the top frame of Figure 2.8.

A hydraulic conductivity curve can be read in two different ways:

1. To obtain the operational saturation associated to a given solution application rate (equivalent to the hydraulic conductivity); enter the plot along the y-axis, move horizontally to intercept the conductivity curve and then move downward to find the corresponding degree of saturation on the x-axis; or
2. To obtain the solution application rate (hydraulic conductivity) able to be sustained by a given degree of saturation enter the plot along the x-axis, move upward to intercept the curve and then horizontally to intercept the y-axis to find the corresponding solution application rate.

It is noted that in the context of the HCT and specifically for the hydraulic conductivity curve, because of the conditions imposed during this test, under steady-state flow conditions the solution application rate is closely

equivalent to the hydraulic conductivity of the ore. Hence, we refer to these variables interchangeably throughout the rest of this document.

In addition to defining the relationship between irrigation rate and degree of liquid saturation (moisture content), the HCT procedure allows for the simultaneous determination of the air conductivity of an ore sample. The air conductivity is a critical parameter in the design of an aeration system that is typically overlooked. The lower frame of Figure 2.8 presents a graphical summary of the measurements of air for the two Casino non-agglomerated composites. The lab reports included in Appendix B present the numerical results from these tests.

From the operational point of view, the results from the HCTs on these TMC samples indicate that near the bottom of a 32-m heap:

- For the application rate (10 L/h/m^2) used by Metcon on their recent metallurgical columns, the Casino samples would operate at a degree of saturation below 56% for Composite Met 02-05, and 23.2% for Composite Met 11-17.
- It is noted that the degree of saturation obtained for Met 11-17 is one of the lowest of all samples tested by HGS to date. This low operational degree of saturation arises from the fact that nearly 74% of the void space of this composite is macro-porosity.
- These results confirm the preliminary determination obtained from the STs; **from the hydraulic point of view the Casino samples, even when not agglomerated, would easily support percolation leaching of a 32-m heap (lift).**
- It is important to note that slumping during initial irrigation of the lifts, potential decrepitation during leaching and destruction of the pore structure due to increase overburden stress will necessarily increase the density and degree of saturation as depicted in Figure 2.8. **Based on the results from the STs presented above, it is expected that these effects would be relatively minor for heap heights below 70 m.**
- **It is recommended, however, that leached residue from the recent Metcon columns or from the first lift once the operation is started be tested under the ST procedure to assess the potential impact of one leach cycle on the density and conductivity profiles of these two composites. If these results show a significant difference from the tests on the head samples, HCTs should be conducted to better assess the impact of leaching on the hydrodynamic properties of the Casino ore and the potential changes to the current heap design.**

As described in the previous section, the total porosity and its partition into macro and micro components are important parameters for the design of a heap leach process. Experience shows that a 50:50 partition between micro and macro porosity produces optimal hydrodynamic performance. Table 2.4 below summarizes the estimated total porosity, macro-, micro- and micro-residual porosity derived from the analysis of the drain down curves derived from the HCTs. The sum of the micro-drainable porosity and the micro-residual yields the micro-porosity.

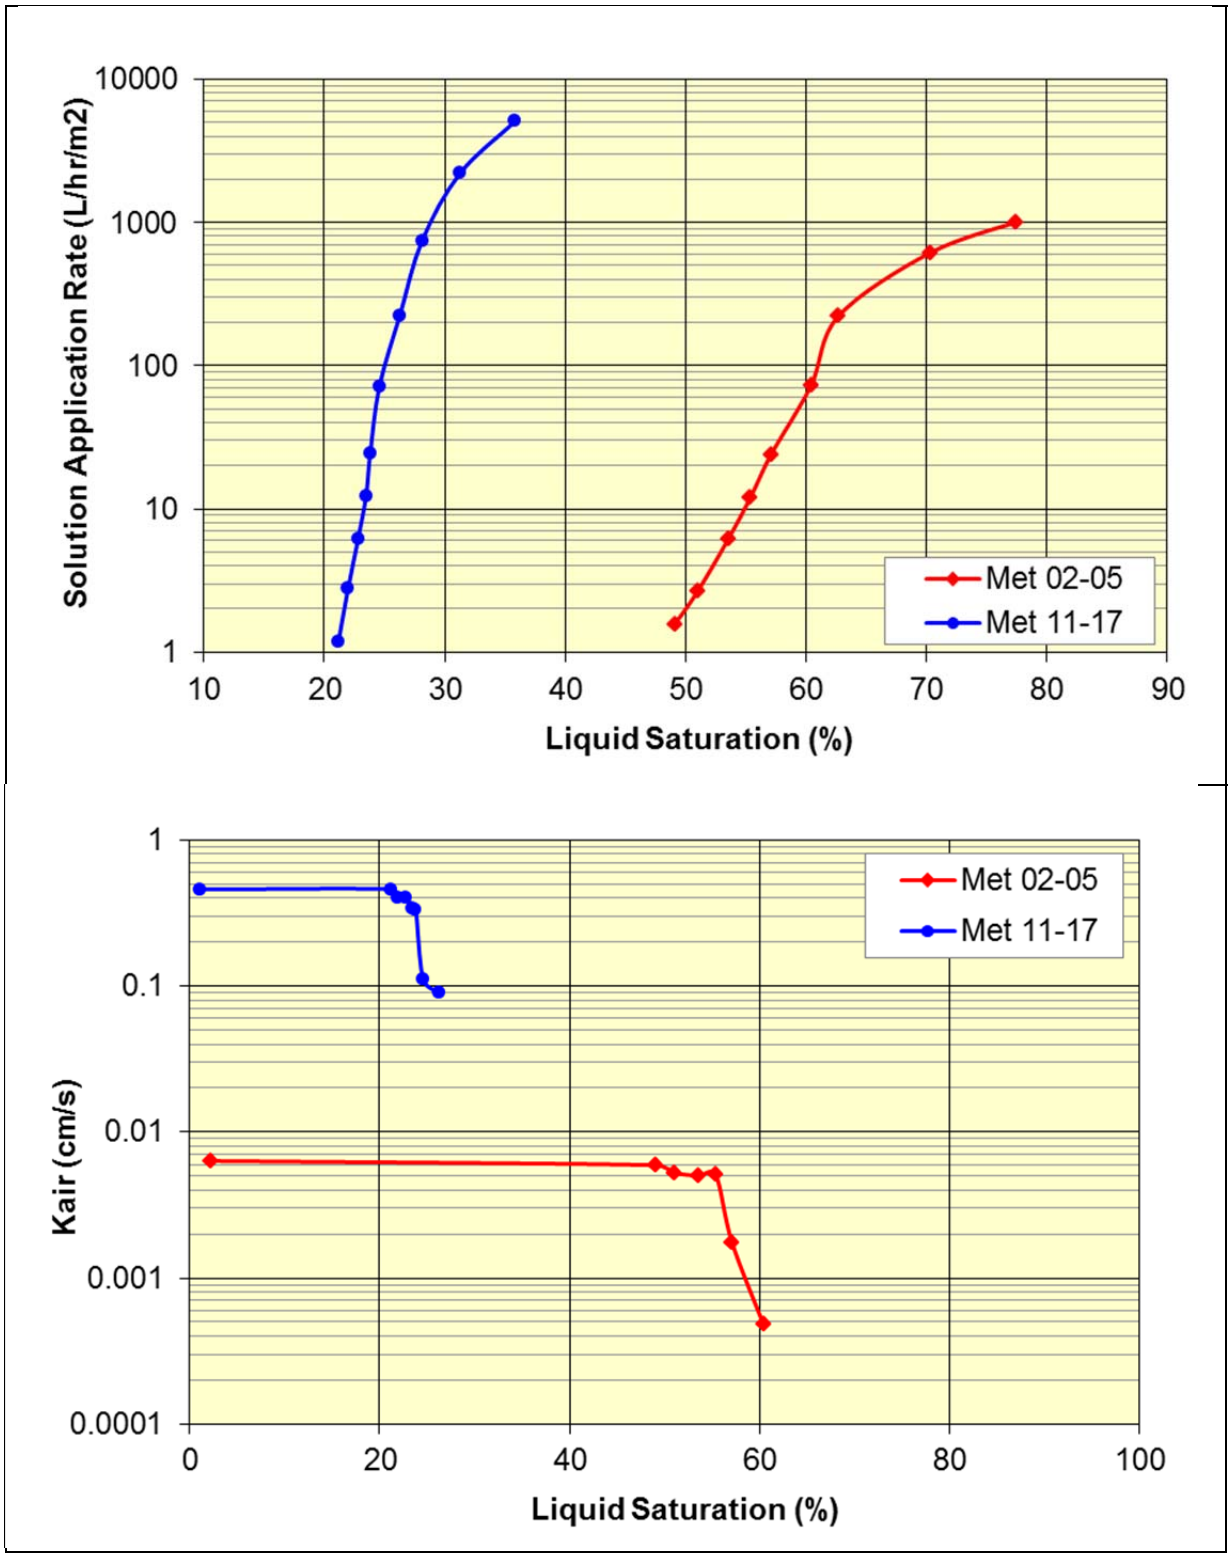

Figure 2.8 TMC – Conductivity Curves

Table 2.4 – Porosity Values					
Sample	Total	Drainable	Macro	Micro Drainable	Micro Residual
Met 02-05-L0	0.331	0.197	0.137	0.059	0.134
Met 11-17-L0	0.409	0.347	0.302	0.045	0.063

These data show that the Composite Met 02-05 has a macro-micro porosity partition of 42:58, while for the Composite Met 11-17 this partition is 74:26. These ratios suggest that Met 02-25 may be most suitable for the leaching process. It is important to note that the ST results on the 1:1 and 2:1 blend of these two composites resulted on improved hydrodynamic properties for both of the individual composites.

The air conductivity curve presented in the bottom frame of Figure 2.8 highlights a number of important aspects of two-phase flow associated to the porous structure in the context of natural and/or forced aeration:

- In general, air conductivity is a strong function of the PSD, degree of saturation and bulk density. In this particular case the spread on between the curves arises from the differences in the PSD of the samples.
- Typically, at low degree of liquid saturation (low moisture values) the air conductivity is nearly constant. The conductivity decreases slightly with increased saturation to the point when the degree of saturation reaches a threshold saturation value (S*) beyond which the conductivity drops rapidly.
- In this particular case, both composites follow this pattern but with significant different magnitudes – the initial air conductivity of Met 11-17 is almost 100 larger than that of Met 02-05.
- In general, the threshold saturation value at which air conductivity begins its rapid reduction is a function of the ore and the ore management practice (degree of agglomeration, top crush size, agglomeration additives, bulk density of the ore as placed, etc.). This saturation threshold corresponds to the moisture content at which the air-filled porosity starts to become discontinuous which greatly increases the resistance for air flow.
- It is important to note that this saturation threshold is, for most of the ore samples we have tested, far from full saturation (i.e., air flow is impaired much before all the pore space is occupied by solution). For most ores, the ability of a sample to allow air flow is, for all practical purposes, lost as the liquid saturation reaches a value of about 65%. For the Casino samples, the threshold saturation value for which the air permeability becomes smaller than that require to allow unimpeded air flow varies significantly for each of the composites:
    - For the Met 02-05, the air conductivity starts its rapid reduction at a saturation value of about S* = 55.4%;
    - For the Met 11-17, the saturation threshold occurs at about 22% despite the otherwise very permeable sample.
- Under natural aeration, air enters the heap through the top surface of the heap and its slopes. This air flow results from density differences due to thermal gradients between the heap and the atmosphere

and changes in atmospheric pressure. The force gradients resulting from these processes are small, so efficient aeration requires high air permeability values (> 10^{-3} cm/s).
