Executive Summary

western
COPPER AND GOLD

Executive Summary

The proposed Casino Access Road will connect Western Copper and Gold Corporation's Casino property with the existing Yukon road system. As road construction has the potential to produce metal leaching / acid rock drainage (ML / ARD), Lorax Environmental Services Ltd. has completed a risk assessment in order to assess the ML / ARD potential along the proposed road alignment. This allows for areas of higher ML / ARD potential to be determined, in order to highlight areas where further work may be needed.

The risk assessment indicates that the majority of the road is low risk for ML / ARD; however, there are 16 sections of road over 38.25 km of the total 133 km long alignment that are deemed to have moderate-low risk or greater. These sections are generally in the final 50 km of the road alignment: from kilometer station 86+500 to 98+300 and 108+030 to 124+430. There are three exceptions to this, kilometer station 1+290 to 5+960, 13+420 to 18+400 and 78+420 to 79+010 also have an overall risk that is considered moderate-low or greater.

These sections were found to have a high enough ML / ARD risk potential that further work in these areas is recommended. This should include further sampling along these 16 sections of road, ideally by drilling in areas where bedrock will be disturbed. As fish sampling has not taken place in the westernmost sections, over a distance of roughly 50 km of the proposed road alignment, further characterization of the streams along this section of the road alignment will allow for an improved understanding of the risk to aquatic ecosystems in this area, and may reduce the potential risk of some of the road sections in this area. Additional rock and surficial material sampling will also be necessary once quarry locations are finalized in order to ensure that the material will not cause ML / ARD.

The risk assessment was completed by defining a stressor (ML / ARD), a pathway (surface water runoff) and a receptor (the aquatic ecosystems). The road was divided into sections based on the geology, the major watersheds, the type of cut and the stream crossings in order to keep the stressor, pathway and receptor consistent. The stressor rating was defined by the geology and the cut volume along sections of road. Each of the bedrock units was assigned a rock type rating, which was modified by the type of surficial material. The cut volume was used to determine the amount of disturbance, as areas of higher disturbance have a greater ML / ARD risk. The pathway was defined by the drainage area of the catchment up-gradient from the road, to determine an approximation for surface water volume. This term was modified using the cut volume

to determine a pathway ratio, which was used to determine the pathway rating. The receptor rating takes both the sensitivity of the species present and the flow regime in the aquatic ecosystem directly downstream of the road.

Each of these terms is given a risk rating. These ratings are multiplied to determine the overall risk for each road section. Sections of road with an overall risk rating of greater than 100 are considered moderate-low risk or greater and are highlighted for further work. Sections with an overall risk rating less than 100 are considered to have sufficiently low risk and no further consideration of these sections is required.

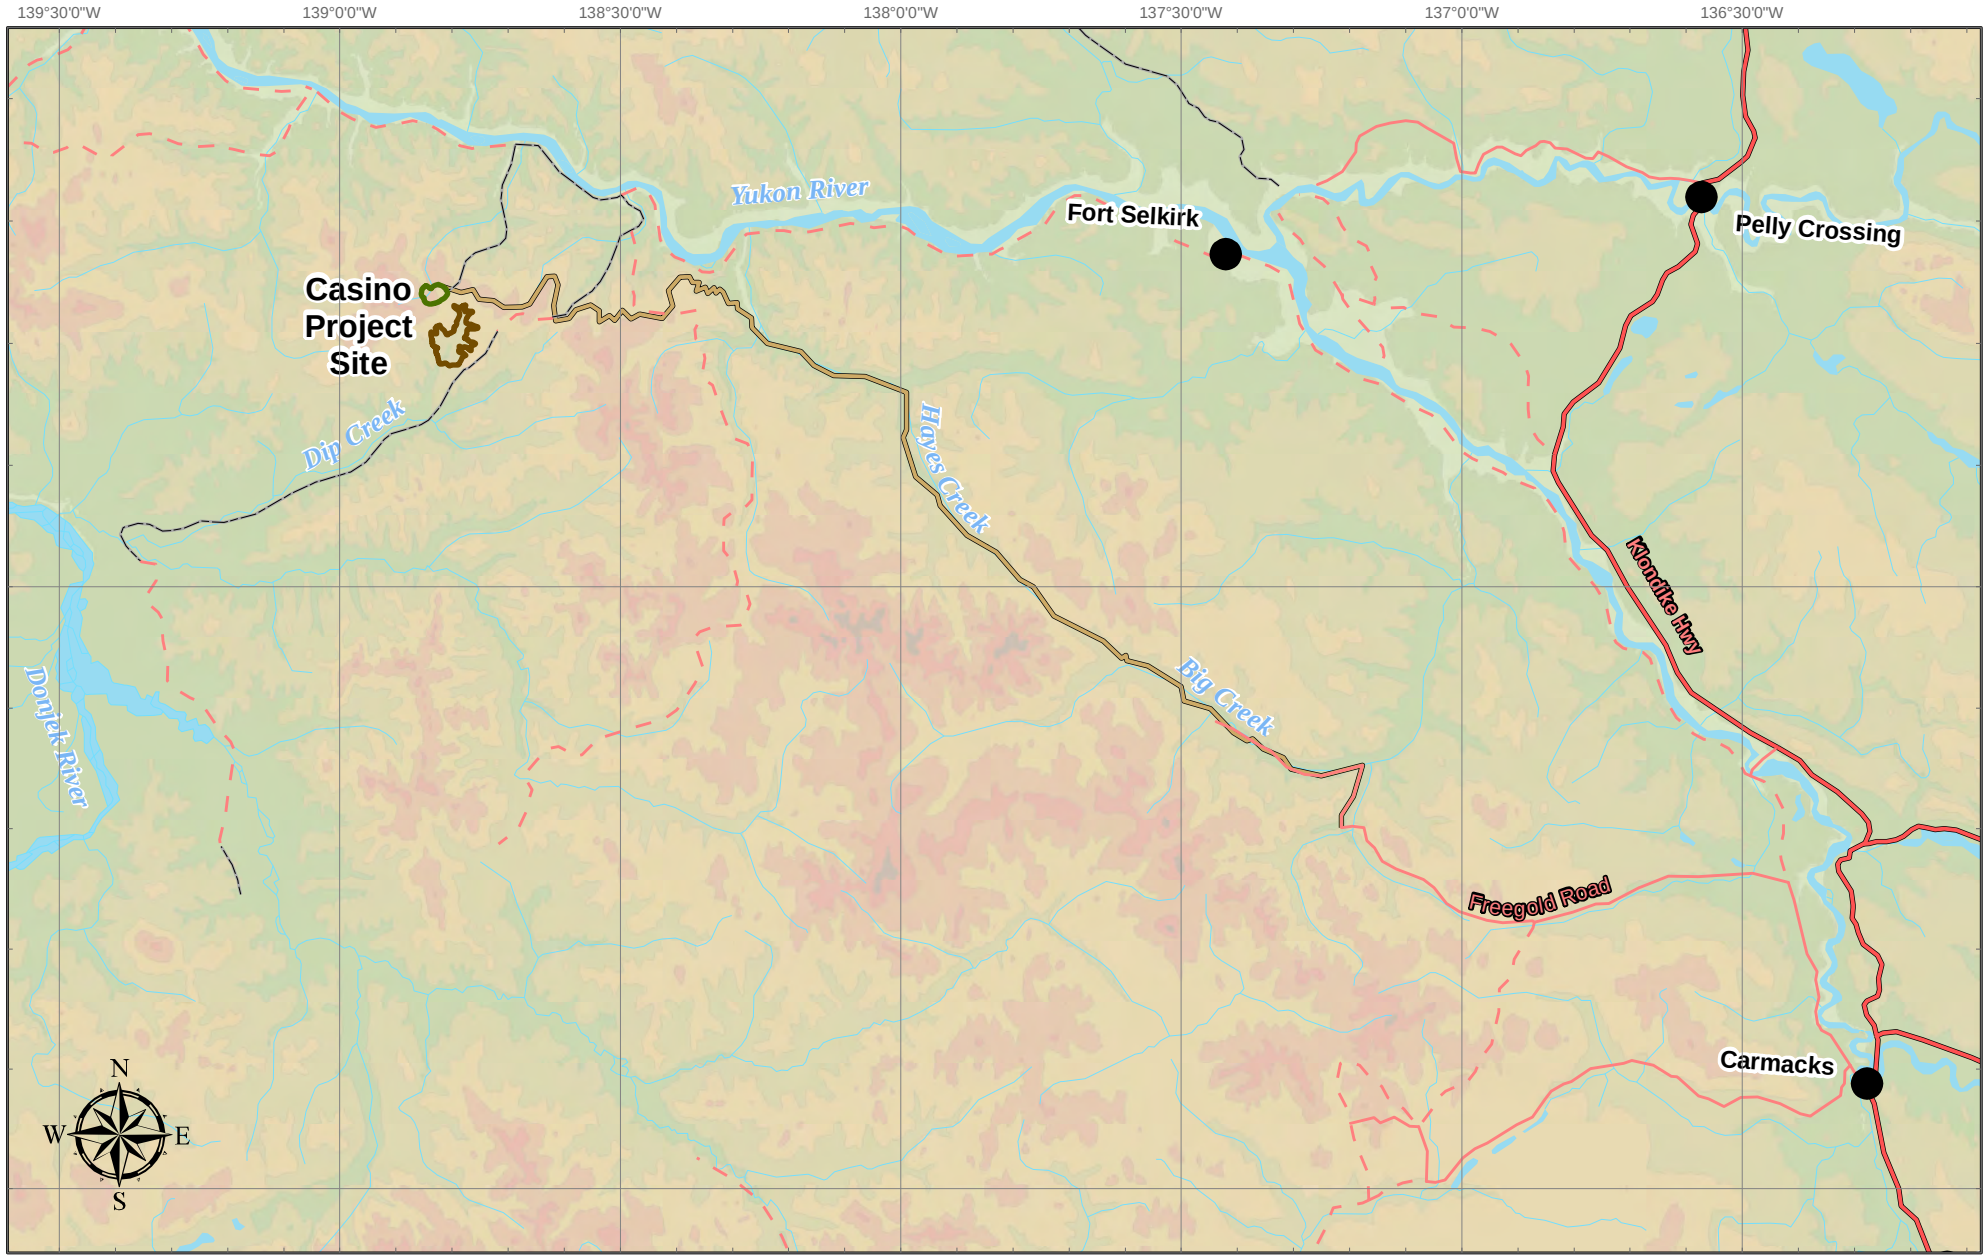
1. Introduction

1. Introduction



Western Copper and Gold Corporation retained Lorax Environmental Services Ltd. (Lorax) to undertake a preliminary assessment of the risk of potential metal leaching / acid rock drainage (ML / ARD) associated with the construction of a new road required for the further development of the Casino property in the Yukon. The proposed road is required to provide access between the Casino mineral deposit and the port of Skagway, Alaska via the Freegold Road and the Klondike Highway (M3 Engineering, 2011; see Figure 1-1).

This study is based on readily available information supplemented by an initial round of geochemical sampling and analysis. The analysis is considered adequate to indicate areas where the risk associated with ML / ARD is low, and areas where the potential risk or level of uncertainty are higher, and additional work may be warranted.

1.1 Study Objectives

The specific objectives of this study are to:

- Provide a general and preliminary indication of the level of risk associated with ML / ARD along the road alignment;
- Undertake the most robust analysis possible given the information available;
- Describe the methodology and results of the study in a way that is procedurally transparent, intuitive and easy to understand, reproducible, and appropriate given the information available to base the assessment on; and
- Provide the basis for more detailed investigation, where warranted.

Casino 2010 Project

TITLE: Proposed Casino Access Road Location

PROJECT #: J862-3

FIGURE: 1-1

P:\J862 (Casino)\Road\Drafting\MXDs\LocationMap of Proposed RoadV4.mxd

1.2 Project Description

Western Copper and Gold Corporation is developing its Casino property, which hosts a gold-copper-molybdenum porphyry. The property is located approximately 300 km northwest of Whitehorse, Yukon. An access road is proposed as an extension of the existing Freegold Road, a gravel road which originates at the Klondike Highway at Carmacks, and extends northwest for a distance of roughly 70 km, currently terminating at Freegold Ventures Limited mineral tenures (M3 Engineering, 2011; see Figure 1-1). The Freegold Road is currently maintained by the Yukon government. The proposed extension of the road to the Casino property will be maintained primarily by Western Copper and Gold (M3 Engineering, 2011).

The proposed road would be approximately 133 km long and reach the Casino mineral exploration camp. Current access to the site is by air, by barge or winter routes from either Burwash Landing or Carmacks (M3 Engineering, 2011; see Figure 1-1). The proposed road would provide a year-round access route for delivering supplies to the mine site and for transporting copper concentrate from the mine to the port of Skagway during operations.

The proposed route can be divided into eastern, central and western sections:

> The Eastern Section: From the Freegold Road the road descends through the Bow and Seymour drainages, reaching Big Creek approximately 40 km upstream of its confluence with the Yukon River, at an elevation of approximately 700m above sea level (asl). The road then ascends the Big Creek valley running alongside the river, and then ascends to the height of land that separates the Big Creek drainage from the Hayes Creek drainage, at an elevation of approximately 1100 m asl. The eastern section is approximately 43 km in length.
>
> The Central Section: The central section descends through the Hayes Creek Valley and runs along the creek for approximately 44 km to an elevation of 500 m asl. After this point, Hayes Creek continues northward to its confluence with the Yukon River, while the road would continue westward, towards a ridge to the northwest up to a watershed divide at approximately 1000 m asl. The central section is 53 km long.
>
> The Western Section: The western section continues westward along the ridge from an elevation of approximately 1000 m asl to 1300 m asl. It passes through three main watersheds: Mascot Creek, Idaho/Isaac/Sunshine Creeks and Casino Creek, before joining an existing road on the Casino property. This section is approximately 37 km in length.

Surficial material in the Eastern and Central Sections is mainly colluvium, with some fluvial material (alluvium) (Summit, 2011). The route traverses through colluvium and exposed bedrock through the Western Section.

1.3 Risk Assessment Overview

The basic approach for this risk assessment is to evaluate the risk associated with a specific stressor (ML / ARD), entering a pathway (surface water runoff and flow in watercourses that the road crosses) that could impact specific receptors (aquatic ecosystems at and immediately downstream of the road crossing).

There have been several examples where road construction has lead to the development of ML / ARD in Canada and the United States. The potential for the development of ML / ARD is dependent on the geology and the amount of disturbance. For example, bedrock with high sulphide content and low calcium carbonate content will have a greater ML / ARD potential than rock that contains little or no sulphide. In addition, the ML / ARD risk will vary depending on the type of material. ML / ARD is greatest for bedrock, followed by colluvium, followed by alluvium. Unconsolidated colluvial and alluvial deposits have been exposed to the elements and have often undergone extensive weathering and oxidation that has already depleted any acid generating sulphide minerals that may have been present in the parent bedrock from which the colluvium or alluvium was derived. This is particularly true of alluvial deposits that have been exposed. A second variable that contributes to ML / ARD impact is the volume of material that is disturbed with ML / ARD potential. Increasing the amount of disturbance increases the ML / ARD potential.

This study does not consider the potential effects of other stressors that may be associated with road construction, such as erosion, or the release of hydrocarbons or other contaminants from any other source. Nor does this study consider the cumulative effects of potential ML / ARD with other stressors.

The pathway as defined in this study considers surface water runoff generated up-gradient of a given section of road that mixes with runoff from exposed material from the road and transports any contaminants derived from ML / ARD to a downstream receptor. Other potential pathways through which ML / ARD could affect the receiving environment, such as through groundwater, for example, are assumed to ultimately report to the same surface water pathway in this assessment.

The receptors defined in this study are based on an initial consideration of aquatic ecosystems at and downstream of each section of road. The details of this consideration are described in more detail below.

Following this introduction, Chapter 2 provides an overview of the study approach and methodology. Chapter 3 discusses the rating system used in the risk assessment. Chapter 4 discusses the results of the risk assessment, highlighting areas with a higher risk. Recommendations are presented in Chapter 5.

2. Methodology

2. Methodology

Western Copper and Gold Corporation is undertaking work in preparation for detailed mine planning and permitting for its Casino property. It is anticipated that development of the mine will require approvals pursuant to the Yukon Environmental and Socioeconomic Assessment Act (YESAA), potentially the Canadian Environmental Assessment Act (CEAA), the Yukon Water Act, and other relevant legislation and regulations. It is anticipated that assessment of the potential for ML / ARD will be required for every aspect of the Project, including construction of the new access road, in support of permit applications. As the first step in addressing this requirement, the work summarized here is intended to identify areas that will require excavation and placement of native soil and rock ('cut' and 'fill') that represent a higher risk with respect to potential ML / ARD, and therefore may warrant some further investigation.

2.1 ML / ARD Approach

Based on MEM & MOE (1998) and MEND (2009), it is generally recognized that ML / ARD programs follow three main steps:

1. Determine the lithology or material type of the material that will be disturbed.
2. Determine the ML / ARD potential of this material. This may include static and/or kinetic testing.
3. Create mitigation and monitoring plans based on the ML / ARD potential to minimize impacts to the environment.

This study addresses the first step, by providing a description of the geology along the proposed road alignment. The second and third steps are addressed at a preliminary level. For the second step, static tests were conducted for an initial round of sampling completed along the proposed road alignment. The third step was initiated by identifying areas of lower risk where mitigation and monitoring may not be warranted, and areas where the risk is higher or uncertainty greater, which may warrant additional investigation, mitigation and/or monitoring.

In the absence of specific regulations and guidance for the Yukon, the approach for this study has taken MEM & MOE (1998), Price & Errington (1998), MEND (2009) and MOT (2004) guidelines for ML / ARD sampling into account, as well as the general methodology for ML / ARD studies along road routes proposed by Gusek *et al.* (2008), from the lithological determination stage to the monitoring stage. These include:

- Policy for Metal Leaching and Acid Rock Drainage at Minesites in British Columbia (MEM & MOE, 1998);
- Guidelines for Metal Leaching and Acid Rock Drainage at Minesites in British Columbia (Price & Errington, 1998);
- Policy for ARD Testing at Quarry and Rock Cut Sites (MOT, 2004);
- Prediction Manual for Drainage Chemistry from Sulphidic Geologic Materials (MEND, 2009); and
- A New Guidance Document for Mitigating Impacts from Acid-Producing Rock Formations in Tennessee Road Construction Projects (Gusek *et al.*, 2008).

2.2 Information Sources

In order to assess the ML / ARD potential along the proposed road alignment, relevant information was obtained from the following sources:

- Yukon Geological Survey Bedrock Geology base map (Gordey and Makepeace, 1999)
- Geological Descriptions of units along the proposed road alignment (Carlson, 1987; Payne *et al.*, 1987)
- Proposed Casino Road Alignment and Surficial Material polygons from Summit Environmental Consultants (2011)
- Geochemical results from sampling completed by Lorax personnel along the proposed road route and geochemical results from work completed for the Casino deposit
- Cut and Fill information from Associated Engineering (2011)
- Drainage Areas calculated based on topography
- Fish Presence and Stream data (Summit, 2011; supplemented by 2011 work by EDI (Kearns, pers. comm., 2011)

2.3 Risk Assessment Framework

The general risk assessment framework proposed by Pollard *et al.* (1995) was adopted. The stressor, pathway and receptors were characterized as follows:

- Stressor: the stressor that was the focus of this study was metal leaching / acid rock drainage (ML / ARD). The information available included the bedrock geology and surficial material along the road alignment, the results of an initial

round of static tests on rock, colluvium and alluvium samples, and preliminary estimates of the excavated volume of rock and soil.

- Pathway: Surface water drainage provides the main pathway through which any products of ML / ARD may interact with excavated ('cut') or permanent disposal ('fill') of soil and rock, and then be conveyed into the receiving environment. Information available included the size of catchments and the location of watercourses. A very general characterization of flow volumes was available for the purpose of this assessment.
- Receptor: The receptor of interest is the aquatic ecosystems in the watercourses in the vicinity of the proposed road. Information available was based on the results of preliminary studies in the major watercourses, some opportunistic efforts to characterize species presence by electrofishing, and information in the public domain.

This level of analysis corresponds with a preliminary quantitative ecological risk assessment (ERA) as defined by CCME (1996), as field data is combined with information from the literature. This is the second stage of assessment outlined in the CCME document. It is an intermediate step between a screening assessment, which relies solely on data in the literature, and a detailed quantitative ERA, which primarily uses field data. These three levels vary from simply describing the situation (screening assessment) to creating predictions on the outcomes (detailed quantitative ERA). In a risk assessment, each category must be defined qualitatively and, in quantitative risk assessments, it will also be assigned a numerical value representing the level of risk (Pollard *et al.*, 1995).

3. Analysis and Risk Ratings

3. Analysis and Risk Ratings

The analysis for this study was undertaken as a series of five major steps, as follows:

1. Dividing the proposed road alignment into sections that are homogenous with respect to the geology, type of cut (soil or rock), and aquatic receiving environment;
2. Assigning a risk rating for ML / ARD potential that considers both geological characteristics as well as the level of disturbance (*i.e*. the volume of cut and fill);
3. Assigning a rating for the pathway reflecting the amount of dilution that can be anticipated;
4. Assigning a rating for the aquatic receiving environment reflecting its importance and sensitivity (*i.e.* likely presence of fish species of commercial or recreational importance, and/or species at risk); and
5. Using the assigned ratings to determine an overall risk rating for each section of road, which is appropriate to serve as the basis for recommendations.

Each of these principal steps in the analysis and associated risk considerations and assumptions are described in the sections below.

3.1 Road Sections

For the purposes of this assessment, the road was divided into discrete sections to ensure that the stressor, pathway and receptor were generally consistent. The divisions were based on:

- Changes in geology
- Major watershed divides
- Changes in type of cut (soil or rock)
- The road route crossing a stream

The procedure is as follows:

1. The geological boundaries along the road were determined and used to subdivide the road based on data obtained from the Yukon Geological Survey (YGS) website;

2. The divides between the "soil cut" and "rock cut" zones were determined based on information provided as part of the preliminary road design (Associated Engineering, 2011) and were used to further subdivide the road;
3. The major watershed divides were determined based on topographical and watercourse mapping obtained from Canadian Digital Elevation Data and the National Hydro Network (www.GeoBase.ca), and were used to further subdivide the road; and
4. The locations where the road crosses a major stream were determined, and used to further subdivide the road.

Using this procedure, the proposed road alignment is divided into 81 sections, each of which is homogenous with respect to underlying geology, the nature of material that will be disturbed (bedrock, colluvium or alluvium), and the drainage basin through which they traverse. The shortest road section is 40m, while the longest is 9,040m.

The up-gradient catchment area for each road section was then defined (see Section 3.4 for further discussion). An overview of the road route and the bedrock geology is provided in Figure 3-1. The road sections, and associated road section catchments, are show in Figure 3-2a to 3-2c.

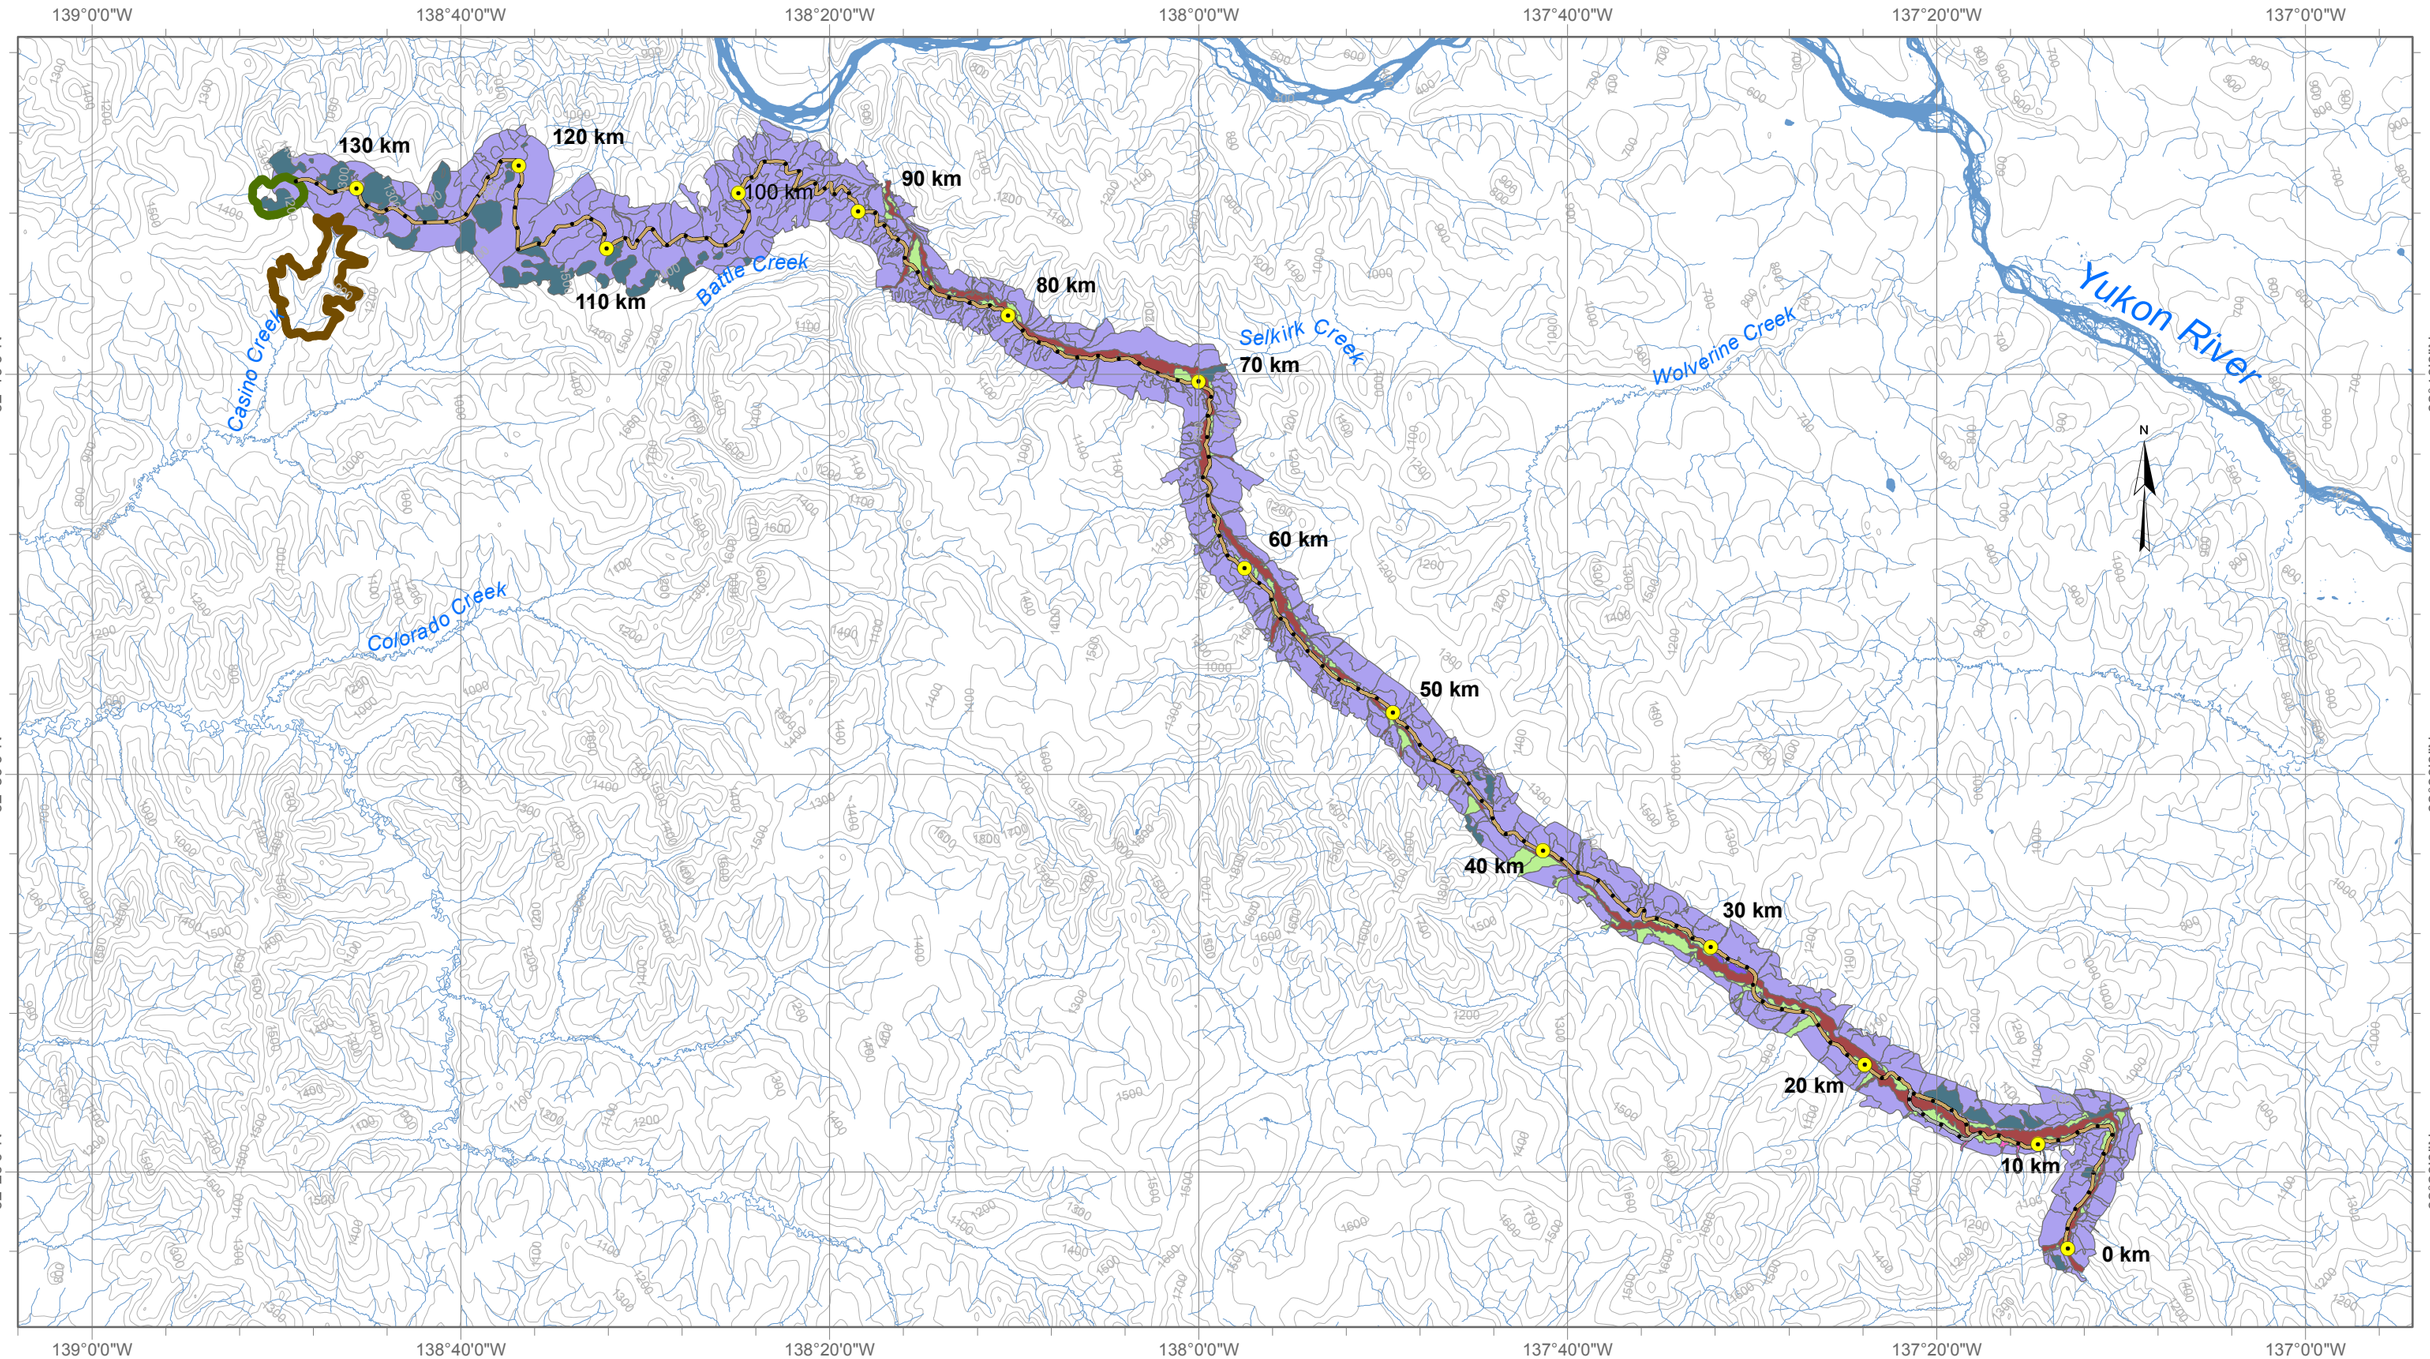
3.2 Stressor Rating



The stressor rating was calculated based on the designated risk posed by each geologic unit, and a risk rating assigned corresponding with the volume of material anticipated to be disturbed. The overall geology rating and the cut rating were multiplied to determine the stressor rating for each section of road

Each geologic unit was given a risk rating based on the expected mineral assemblage with each lithologic / stratigraphic unit and the available geochemical data. The cut volume is also included as part of the stressor risk as it is a measure of disturbance along each section of the proposed road. Areas of greater disturbance have a higher ML / ARD risk, as a greater area is exposed.

3.2.1 Geology

The development of ML / ARD from road construction is primarily controlled by the mineral composition of the construction material. The most critical mineral relationship is the relative amounts of sulphide and carbonate minerals (*i.e.*, the dominant acid-generating and acid neutralizing minerals). Determination of the likely mineral assemblages, specifically the sulphide abundance, that are typically associated with the predominant lithologies in a stratigraphic unit provides a method to qualitatively assess ML / ARD potential.

For the current study, the bedrock geology has been assessed from the geological map created from data from the Yukon Geological Survey website (Figure 3-1). More detailed descriptions of the geological units were reviewed from Carlson (1987) and Payne *et al.* (1987). The surficial material has been assessed from geology terrain maps from Summit Environmental Consultants (2011). An overview of the general surficial geology (bedrock, colluvium or alluvium) along the proposed road alignment is provided in Figure 3-3.

TITLE: Casino Road With Surficial Geology

PROJECT #: J862-3 FIGURE: 3-3

P:\J862 (Casino)\Road\Drafting\MXDs\Figures for report\Silvano\Casino Road with Surficial Geology.mxd

The proposed road route crosses seven geological units. The Whitehorse Suite (mKW) is divided into three subunits so nine rock types are considered in all. These units are:

1. Nasina Unit (DMN3, DMN5)
2. Pelly Gneiss Suite (DMgPW)
3. Long Lake Suite (EJyL)
4. Whitehorse Suite - Diorite (mKdW)
5. Whitehorse Suite – Granodiorite (mKgW)
6. Whitehorse Suite – Granodiorite to quartz monzonite (mKqW)
7. Mount Nansen Unit (mKN)
8. Carmacks Unit (uKC1)
9. Prospector Mountain Suite (LKfP, LKqP)

Table 3-1 provides a summary of each of the units. The Nasina Unit (DMN) includes both DMN3 and DMN5. Due to a lack of information on the lithological description of the subunits, they were combined as DMN for the purposes of this study. However, both units are shown on the bedrock geology maps. The Prospector Mountain Suite (LKP) includes the stock (LKqP) and the dykes (LKfP). In addition to these bedrock units, the proposed route will cross areas covered by colluvium and fluvial material.

A ML / ARD risk value from 1 to 5 was assigned to each unit, with 1 being the lowest risk and 5 being the highest risk. A brief rationale for the ML / ARD risk rating for each unit is provided in Table 3-1. This provides the rock type rating. It is typically based on the presence or absence of carbonates and pyrite, taking any available geochemistry data into account, as described below. The 1 to 5 scoring method of characterization was deemed appropriate to reflect the range and variation in the level of risk that could potentially result from the rock and soil types present. A simpler system, such as a low-moderate-high rating system would not have fully captured the ability to differentiate the ML / ARD risk associated with these rock types given the information available.

The Nasina Unit (DMN) and Whitehorse Suite Granodiorite to Quartz Monzonite (mKqw) were rated as having the highest ML / ARD potential of the rock types that occur along the road, 4 out of 5. The Pelly Gneiss Suite (DMgPW), Whitehorse Suite “Casino Granodiorite” (MKgW) and Prospector Mountain Suite (LKP) were rated as having moderate ML / ARD potential, (3 out of 5), and the Long Lake Unit (EJyL), Whitehorse Suite Diorite (mKdW), and Carmacks Unit (mKN) were rated low (2 out of 5).

Table 3-1:
Summary of Geology and Geology Risk

Map Code	Unit (YGS name)	Name (original document)	Rock Type (based on Carlson, 1987 and Payne *et al.*, 1987)	Alteration and pyrite/calcite presence from petrographic description in Carlson (1987)	ARD risk	Reasoning for ARD risk
DMN (DMN3 / DMN5)	Nasina	Yukon Metamorphic Complex (Payne *et al.*, 1987) / Wolverine Creek Metamorphic Suite (Johnston, 1995)	Meta-sedimentary quartzite and quartz-mica schist. The composition varies in the amount of mica. Generally banded. General composition: quartz (50-80%), mica (20-50%), feldspar (1-5%) and opaques (0-5%).	sericitic alteration, no mention of any pyrite or calcite	4	Unit includes variable lithologies which increases the potential variability and risk. Includes gneiss and schists, which may have elevated S content in the parent rock.
DMgPW	Pelly Gneiss Suite	Wolverine Creek Metamorphic Suite (Johnston, 1995) / Simpson Allochthonous Assemblage - Selwyn Gneiss (Tempelman-Kluit, 1984)	Meta-igneous schist and gneiss. Amount of metamorphism varies. Plagioclase is the dominant mineral (60-75%), with lesser K-feldspar, quartz, hornblende and biotite.	plagioclase to sericite alteration common, occasionally epidote and calcite alteration, pyrite: none to 0.3% calcite: none to 4%	3	Sulphide minerals reported, but sericitic alteration often includes carbonates. Some subunits include limestone.
EJyL	Long Lake Suite	Big Creek Syenite (Tempelman-Kluit, 1984)	Syenitic granitic rocks, monzonite to granodiorite and hornblendite. General composition of syenite: K-feldspar (30-50%), hornblende (20-75%), plagioclase (10-30%), quartz (0-20%) and minor sphene and apatite.	sericitic alteration, no mention of any pyrite or calcite	2	Presence of mafic silicate minerals which provide buffering capacity for low levels of acidity and sericitic alteration which may include carbonate minerals.
mKdW	Whitehorse Suite	Dawson Range Batholith (Johnston, 1995)	Diorite. General composition: plagioclase (50-60%), mafic minerals (25-30%), quartz (15%) and minor K-feldspar.		2	Phyllic alteration of hypogene samples in the Casino deposit typically contain > 1% carbonate content. Lower sulphide content is expected in this unit outside the deposit. Contains mafic minerals that can buffer low levels of acidity.

Map Code	Unit (YGS name)	Name (original document)	Rock Type (based on Carlson, 1987 and Payne *et al.*, 1987)	Alteration and pyrite/calcite presence from petrographic description in Carlson (1987)	ARD risk	Reasoning for ARD risk
mKgW	Whitehorse Suite	Casino granodiorite (Tempelman-Kluit, 1984) / Dawson Range Batholith (Johnston, 1995) / Dawson Range Suite (Payne, 1987) / Hornblende granodiorite (Tempelman-Kluit, 1984)	Granodiorite. General composition: plagioclase (50-60%), quartz (15-20%), K-feldspar (15-20%), biotite & hornblende (15%).	plagioclase altered to sericite, biotite altered to chlorite, no mention of pyrite or calcite	3	Lower levels of mafic silicate minerals from granodiorite than diorite.
mKqW	Whitehorse Suite	Coffee Creek Granite (Tempelman-Kluit, 1984) / Dawson Range Batholith (Johnston, 1995)	Granodiorite to quartz monzonite. General composition: quartz (25-35%), plagioclase (20-40%), K-feldspar (25-40%), biotite (5-10%), hornblende (<5%), minor pyrite, apatite, sphene and zircon.	plagioclase altered to sericite and clay, no mention of pyrite or calcite	4	Lower levels of mafic silicate minerals in quartz monzonite. Carbonate content would likely be restricted in this more silicate rich rock type, particularly in clay altered zones.
mKN	Mount Nansen	Mount Nansen Group (Tempelman-Kluit, 1984)	Volcanic flows and subvolcanic intrusions. The main rock type is an andesite typically with a fine grained matrix and visible plagioclase, hornblende, clinopyroxene and biotite. Phenocrysts are dominantly plagioclase and make up 35-55% of the rock. Groundmass is plagioclase, quartz, K-feldspar, chlorite and opaques.	sericite and clay alteration, some calcite, chlorite and epidote alteration pyrite: none to minor calcite: none to minor	2	Calcite content in mafic flows typically more abundant than sulphide content.

Map Code	Unit (YGS name)	Name (original document)	Rock Type (based on Carlson, 1987 and Payne *et al.*, 1987)	Alteration and pyrite/calcite presence from petrographic description in Carlson (1987)	ARD risk	Reasoning for ARD risk
uKC1	Carmacks	Carmacks Suite (Payne, 1987) / Carmacks Group (Johnston, 1995)	A volcanic sequence with a lower rhyolite to rhyodacite subunit, a middle andesite subunit and an upper basalt subunit.	plagioclase alters to clay or sericite, clinopyroxene alters to ankerite or calcite, pyrite: not mentioned, calcite: none, one sample has 7-8% ankerite, another sample has 2-3% calcite	2	Carbonate is typically reported in this unit. Basalt containing mafic silicate minerals capable of buffering low levels of acid production.
LKP (LKfP / LKqP)	Prospector Mountain Suite	Prospector Mountain Plutonic Suite (Johnston, 1995)	Quartz-rich monzonite stock (LKqP) with porphyritic latite and quartz-rich latite dykes (LKfP).		3	Limited mafic silicate content. Unit likely has variable ARD risk. In the Casino deposit typically contains carbonate but has elevated S content, which makes this unit PAG.
Surficial material			**Description**			
Colluvium			Clay to cobble sized fragments from past mass movements.		Bedrock rating -1	Moderate but variable risk dependent on the parent rock type.
Fluvial			Clay to cobble sized fragments. Includes both present river banks and old floodplains.		1	Low risk due to high degree of physical and chemical weathering.

The rock type rating was reduced for colluvium and alluvium. The risk factor for colluvium is lower than that of the parent rock type (the rating was reduced by 1, from 3 out of 5 in the case of the Pelly Gneiss Suite, to 2 out of 5 for colluvium derived from it, for example) as colluvium has been exposed to the elements for a longer period of time and will, therefore, be more weathered with the acid generating minerals depleted. This rationale depends on the assumption that the colluvium has not been transported a great distance so the parent rock type is the same as that of the underlying bedrock. The risk rating for alluvium is low (1) based on the same principle of advanced weathering and associated oxidation. In cases where both colluvium and alluvium are present in a particular section of road, the more conservative risk factor for colluvium is used.

Based on preliminary road design (Associated Engineering, 2011) the road will require excavation of soil (alluvium and colluvium) only, through the Eastern and Central section, from station 0-316 to station 86+120. In contrast, excavations are entirely in bedrock in the Western Section from station 86+120 (from roughly the western boundary of the Hayes Creek drainage basin) to station 132+410, where the new access road will join with the existing road on the Casino property.

3.2.2 Geochemical Analytical Results

In determining the ML / ARD risk described above, geochemical results were taken into consideration. Geochemical data is available both from data obtained as part of previous work at the Casino deposit itself, and preliminary sampling completed along the route for this 2011 study.

The geochemical testing from work completed in the Casino deposit was part of other Lorax studies and is not presented here. However, as the geological units encountered in the proposed pit also have restricted occurrence along the road alignment, the results were considered in determining the ML / ARD risk for the road assessment. However, the Casino ore deposit is unique in that it is a highly mineralized zone that would contain higher sulphide content than occurrences of the same stratigraphic units along the road alignment. The data includes mineral assemblages and static test results.

In June 2011, sixty samples were collected along the proposed route in support of this study. In total, thirty-nine bedrock samples, fifteen colluvium samples and six alluvium samples were collected (Appendix I). All samples were 1-5 kg, to allow for sufficient sample volume to complete all testing, as outlined in MEND (2009).

In order to obtain a preliminary characterization of the material along the proposed road route, an effort was made to collect samples from the main bedrock units and along a good distribution along the proposed road route. Where possible, samples were collected

in areas where a large amount of disturbance is expected, including areas of high cut and fill for colluvium and bedrock and at river crossings in the case of fluvial material. In some cases this was not possible, as permafrost prevented sediment sampling in several areas. This made it difficult to sample colluvium, as only areas without permafrost could be sampled, such as old cuts and areas with heavier vegetation. When quarry sites are finalized, further sampling may be required, based on the MEND (2009) sampling guidelines for tonnes of material disturbed.

The 2011 samples from along the road alignment were sent to SGS-CEMI in Burnaby, B.C for static testing. All samples were analyzed for rinse and paste pH, Acid-Base Accounting tests and Metals by Aqua Regia Digestion with ICP-MS Finish. The median values for ABA results for the different units are included in Table 3-2.

Table 3-2:
Summary of ABA results from the samples collected along the proposed road route (values presented are medians)

Median	Rinse pH	CaNP	C(T) %	S(T) %	Modified NP	NPR NP/AP	n
Rock Type							
DMN	9.12	11.7	0.15	0.02	11.4	18.2	3
DMgPW	9.07	4.17	0.06	0.01	8.30	27.7	4
mKW	7.25	0.83	0.06	0.01	5.90	18.5	28
mKN	9.14	118	1.49	0.01	72.6	242	1
uKC1	8.71	14.2	0.18	0.01	41.8	139	3
Surficial Material							
Colluvium	6.72	0.83	0.19	0.02	5.60	12.7	15
Alluvium	6.71	0.83	0.28	0.01	9.45	31.5	6

Note: DMN – Nasina, DMgPW – Pelly Gneiss Suite, mKW – Whitehorse Suite, mKN – Mount Nansen, uKC1 – Carmacks

Based on the geochemistry results, all samples were determined to be low risk due to low sulphur values (Table 3-2 and Appendix II-A). In general, the concentration of metals found in the rock samples is below three times the continental crustal abundance (Appendix II-B).

One notable exception is the concentration of arsenic measured in colluvium and alluvium samples (Appendix II-B). Although elevated concentrations of a parameter in the solid-phase may identify potential parameters of concern it does not necessarily mean that the parameter will be a source of metal leaching. Notwithstanding, the potential for arsenic leaching from these unconsolidated materials will be evaluated in Phase II testing.

The geology rating was not based solely on the data collected from sampling along the road, as the rock samples collected along the proposed road route were all collected from

the surface of outcrops and would have been exposed to more weathering relative to samples at a greater depth. Although all the samples have low ML / ARD risk, rock cuts will be made during road construction that may expose "fresher" material which hasn't been weathered, and potentially has a greater ML / ARD potential. Drilling along the proposed route in order to collect unweathered samples was not deemed necessary at this stage. Using a combination of the geologic description, the road sampling geochemistry, and the data from core samples from near the Casino deposit, allowed for a ML / ARD risk rating to be assigned with precision reasonable level of confidence for the purpose of this preliminary risk assessment.

3.2.3 Cut Volume

In general, the potential for ML / ARD increases in proportion with the amount of soil or rock that is disturbed, as the surface area of material exposed to air and water increases, and there is an increasing probability of higher variability in lithology. It is for this reason that the guidelines require more samples for a greater area or volume (Price & Errington, 1998; MEND, 2009).

This factor was included in the risk assessment by categorizing the total disturbance within a given road section (with uniform bedrock geology and confined to a given catchment area as explained above). Preliminary estimates of cut and fill volumes are available for the entire road alignment.

The cut volumes were provided for each 20m section of road. These values were added together to generate a total estimate for each of the 81 road sections which have been defined for the purposes of this risk assessment (See Table 4-1 and Appendix III). It was assumed that all of the cut volume would be placed ('filled') within the same road section, and if additional fill is required within any section, it was assumed that it will be sourced from a quarry with low ML / ARD potential. Consequently, fill volume is not directly included in the analysis.

A value between 1 and 5 was assigned for the cut volume based on guidelines from MEND (2009) and MEM & MOE (1998). The analysis takes swell factors and average densities into consideration. The soil cut volume (noted as excavated m^3 or em^3 in the table below) was calculated by multiplying the mass of disturbed material (the estimate provided as part of the preliminary road design in metric tonnes) by a swell factor of 1.05, and then dividing by an average soil density of 1350 kg/m^3 (1.35 g/cm^3). The soil density is based on Yu *et al.* (1993). Rock cut volume was calculated by multiplying the mass of disturbed material (given in tonnes) by a swell factor of 1.35, and then dividing by an average rock specific gravity of 2.7 (*i.e.* 2.7 tonnes per m^3) (www.edumine.com). The rating system is summarized in the table below.

Table 3-3:
Cut Volume Rating System

Mass of Disturbed Material (tonnes)	Soil Cut Volume (em^3)[a]	Rock Cut Volume (em^3)[b]	Cut Volume Rating	Rationale
0	0	0	0	No risk, as there is no disturbed material
< 1,000	< 780	< 500	1	Based on the minimum mass for which ML / ARD prediction is required (MEM & MOE, 1998)
1,000-10,000	780 - 7800	500 - 5000	2	
10,000-100,000	7800 - 78000	5000 - 50000	3	Based on the MEND (2009) mass for requiring 3 samples (10,000 tonnes)
100,000-1,000,000	78000 - 780000	50000 - 500000	4	Based on the MEND (2009) mass for requiring 8 samples (100,000 tonnes)
> 1,000,000	> 780000	> 500000	5	Based on the MEND (2009) mass for requiring 26 samples (1,000,000 tonnes)

[a] Soil cut volume was calculated based on an average soil density of 1.35 g/cm^3 (Yu *et al.*, 1993) and a swell factor of 1.05
[b] Rock cut volume was calculated based on an average rock specific gravity of 2.7 (www.edumine.com) and a swell factor of 1.35

3.3 Pathway Rating

It was assumed that the main pathway by which ML / ARD products would be exposed to receptors is via surface water drainage. The catchment area up-gradient of a given road section, as far as the nearest height of land, is the area over which precipitation will collect and interact with any ML / ARD products, whether through overland ('sheet') flow or water flowing in a watercourse to which drainage from the road is discharged (whether free-flowing or through constructed road ditches).

The surface area of up-gradient catchments (in hectares) was used as a proxy for surface water volume, based on the assumption that precipitation does not vary significantly along the road alignment. This was considered to be a reasonable assumption, given that the road traverses semi-arid terrain, across the northeast-facing slopes of the Dawson Range in the rain shadow of the St. Elias Mountains. There is some variation in elevation, which could cause some variability in the amount of precipitation across the road alignment, but this is considered to be a minor variable in the context of this analysis.

The volume of water interacting with any potential ML / ARD products establishes the pathway, but would also dilute metal concentrations and reduce acidity. Consequently, it was assumed that the worst case scenario would be a large cut volume with a small up-gradient catchment area. The best case scenario would be a small cut volume with a large up-gradient catchment area.

With these considerations in mind, the pathway rating was determined based on a ratio of the total cut in a section of road (in em^3) to the drainage area (in hectares). While this

provides a general indication of the affect of various pathways along the road alignment, it is imprecise. Consequently, it was deemed appropriate to assign a pathway rating, from 0 to 4, based on the order of magnitude of the ratio. Areas with a very low cut volume relative to the size of the up-gradient catchment area have a very low ratio, less than one in several cases. Areas with a very large cut volume relative to the up-gradient catchment area have a very high ratio. The highest ratio is 5973, and there are 20 sections of the road where the ratio is 101 or higher, equivalent to a pathway rating of 3 or higher.

This rating system is shown in the table below, along with the range in ratios, and number of road sections included in each pathway rating (Table 3-4). The ratio, and corresponding 'pathway rating', for each of the 81 road sections is included as Table 4-1.

Table 3-4:
Pathway Rating System

Pathway Ratio	Pathway Rating	No. of Road Sections	Range: Lowest and Highest Ratio
0	0	20	n/a
>0-10	1	17	0.0307 – 7.54
11-100	2	24	10.5 – 94.5
101-1000	3	15	133 - 781
1001-10000	4	5	1155 - 5973
TOTAL	**n/a**	**81**	**n/a**

The drainage area for each section was determined as the area upslope of the road to the height of land, as noted above, and these areas are shown in Figures 3-2a to 3-2c. In order to do this, Digital Elevation Model (DEM) data was downloaded at 1:50,000 scale (GeoBase.ca) and divided into watersheds using MapWindow GIS. The watersheds were subdivided into smaller areas manually in AutoCAD while following topography contours uphill to the height of land and then back down to the road. These subdivisions were based on changes in geology intersecting the road, watershed boundaries, streams intersecting the road and cut type (soil or rock).

This approach is considered adequate for an initial consideration of pathways in this preliminary risk assessment. While other pathways, including most notably groundwater, will ultimately influence the amount and concentration of potential ML / ARD products that may affect receptors, it is assumed for the purposes of this report that groundwater impacted by the stressor will report to the surface water pathway at a similar point as surface drainage from the road. The analysis summarized above helps to identify those areas where the inherent risk of ML / ARD due to bedrock geology, larger cut volumes, and relatively little dilution, coincide.

3.4 Receptor Rating

An important consideration is the importance of the aquatic ecosystems that may be affected by ML / ARD products through surface water drainage. These may range from benthic invertebrate communities excluding fish in the case of small, ephemeral headwater streams, to habitat that is critical for spawning and early life stages of important commercial species such as Chinook salmon, in the case of larger streams that are accessible to anadromous salmonids.

The importance and sensitivity of receptors has been evaluated based on the DFO Practitioners Guide to the Risk Management Framework (n.d.). This guide proposes that receptors be evaluated based on four primary considerations: (1) species sensitivity, (2) species' dependence on habitat, (3) species rarity, and (4) habitat resiliency. Species sensitivity is the sensitivity of the fish species present to changes in the environment. Species' dependence on habitat is how the habitat is used. For example, a section of stream that is only used for migration will have a lower value than a section of stream that is used for spawning. Rarity includes both species and habitat rarity. A rare species is defined as one that is listed as rare or endangered on the Species at Risk Public Registry. Rare habitat could be any type of habitat that is uncommon in the system and that is required for all or part of the year or for one or more life stages. Habitat resiliency can take both thermal regime and flow regime into account.

Of these four categories, only species sensitivity and habitat resiliency are included, as there was not sufficient information available with respect to the other two considerations. Species sensitivity and habitat resiliency were rated independently, as described below, and were added to derive an overall receptor rating.

The two factors that were used to characterize receptors (aquatic ecosystems) in the vicinity of the proposed road were incorporated to derive a receptor rating from 1 to 3. The rating system is summarized in the table below.

Table 3-5:
Receptor Rating System

Receptor Rating	Species Presence	Habitat Resiliency (Flow Regime)
1 - Low	Benthic Invertebrates and/or arctic grayling only	Ephemeral flow – stream only contains water after a rainstorm
2 - Moderate	Fish community including arctic grayling and slimy sculpin, overwintering habitat	Intermittent flow – stream only contains water seasonally
3 - High	Fish community including Chinook salmon, spawning and overwintering habitat	Permanent flow – stream contains water year-round

3.4.1 Species Sensitivity

Species sensitivity was rated based on the fish species present in the streams (Table 3-5). There are no species that are listed in the Species At Risk public registry found in the area around the proposed road. Salmon are the most sensitive species in the area; therefore, areas where they are known to be present are assigned a higher rating. A moderate rating is assigned to areas where slimy sculpin occur, as these fish remain in areas that provide overwintering habitat, and often coincide with other species including arctic grayling. A low risk rating is assigned to areas where only arctic grayling are present, as they use small ephemeral and intermittent streams as summer rearing habitat, or there are likely no fish present, based on no fish being caught during electrofishing surveys. In determining the receptor rating, an assumption was made that the furthest known upstream occurrence is the extent of the range and the particular species will not be found upstream of this point.

Data for fish presence was obtained from a recent report documenting the results of a preliminary habitat assessment (Summit, 2011), as well as the results of recent supplemental field work (Kearns, pers. comm., 2011). These information sources include what is known of fish presence in the streams that the road intersects from previous studies and field work completed in August 2010. These sources provide information on the section of road up to approximately station 90+000. Data for the Western Section of the road (the westernmost 40 km) is limited. Additional information on this section of road was provided by the Casino Project team, based on inspection of satellite imagery available for the area. In this way, it was determined that several of the Hayes Creek and Isaac Creek tributaries have potential for fish habitat, but the Sunshine Creek tributary is unlikely to support fish. However, uncertainty still remains for several sections of road. In these areas, the most conservative rating, corresponding to a more sensitive and/or diverse ecosystem was assigned.

3.4.2 Habitat Resiliency

Habitat resiliency was rated based on the flow regime (Table 3-5). The main stems of both Big Creek and Hayes Creek are considered to have permanent flow as they are both major streams in the area. Sections of the headwaters for both of these creeks are rated as ephemeral based on field photos provided by the Casino Project team. In areas where the flow regime is uncertain, a conservatively high rating of 3 was assigned, corresponding with permanent flow that could support fish populations year round. The thermal regime was not considered as it is assumed that all streams in the area are cold water streams and that thermal conditions are not a limiting factor.

3.4.3 Summary of Receptor Ratings

Based on the criteria outlined above, all 81 sections of the road were rated for Species Sensitivity and Habitat Resiliency. A summary of these ratings is provided in Table 3-6. These were added to determine the overall receptor rating. A summary of the receptor ratings is shown in Table 3-7. The majority of the road sections (72 of 81) have high receptor ratings (5 or 6).

Table 3-6:
Summary of Species Sensitivity and Habitat Resiliency Ratings

Rating	Species Sensitivity (Number of Sections)	Habitat Resiliency (Number of Sections)
1 (Low Importance or Sensitivity)	9	5
2	33	0
3	39	76
Total	**81**	**81**

Table 3-7:
Summary of Receptor Ratings

Receptor Rating	No of Road Sections (of 81)
1	0
2	5
3	0
4	4
5	33
6	39
Total	**81**

3.5 Overall Risk Rating System

Ratings were then assigned for each section of road to reflect available information about:

- The stressor: the risk associated with the ML / ARD potential of the underlying bedrock, together with the volume of soil or rock that is anticipated to be disturbed, based on the preliminary road design;
- The pathway: the amount of dilution that is expected, given the size of the up-gradient surface water catchment area;

- The receptors: the fish species anticipated to be present at, and immediately downstream, of the road, as well as the nature of the flow regime in each section (permanent flow, intermittent (*i.e*. seasonal) flow, or ephemeral flow (*i.e*. flow during storm events only).

A risk rating was derived for each section of the road, based on the following formula:

Stressor Risk (0 to 25) x Pathway (0 to 4) x Receptor Sensitivity (2 to 6)

The lowest possible outcome is 0 (0x0x2), while the highest possible outcome is 600 (25x4x6). The actual results of the analysis range from 0 to 288. These numerical results are equated with risk as shown in the following table (Table 3-8).

Table 3-8:
Risk Rating and Corresponding Risk Category

Overall Risk Rating	Risk Category
0-49	Very low risk
50-99	Low risk
100-149	Moderate-low risk
150-199	Moderate risk
>200	Moderate-high risk

4. Results

4. Results

All relevant values, ratings and results are presented in the Risk Assessment Matrix for each of the sections of road (Table 4-1).

A total of 16 road sections are considered to have moderate-low risk or greater (an overall risk rating of 100 or greater), representing a total road length of 38.25 km (or 29% of the 133 km total alignment). These road sections are summarized in Tables 4-2 and 4-3 and are discussed in greater detail below. The low risk sections have an overall risk less than 100 and cover 94.7 km (approximately 71%) of the proposed road alignment.

These 16 sections with moderate-low risk or greater are first presented in order from the Freegold Road to the Casino Property, for reference purposes. They are then described in more detail in order from the highest risk to the lowest, for the purpose of further describing the results, and for providing recommendations.

The 16 sections with moderate-low risk or greater are generally located in two main sections of road: (1) an 11.8 km section from 86+500 to 98+300, and (2) a 16.4 km section from 108+030 to 124+430. These sections are both in areas where rock cuts will be required (as opposed to excavating soil). In addition, there are three other road sections where the ML / ARD risk is considered to be moderate-low or greater: (3) 1+290 to 5+960, (4) 13+420 to 18+400, and (5) 78+420 to 79+010. The moderate-low risk and higher road sections are discussed in greater detail in sections 4.1-4.3.

The majority of the road (94.68 km) can be considered to have low risk for ML / ARD and no further work is recommended for these sections. These sections were determined to have little ML / ARD potential based on a low stressor, pathway or receptor rating, or a combination of the three. These sections have an overall risk of less than 100. The low risk sections are briefly addressed in section 4.5.

4.1 Moderate-High Risk (4) Sections

There are four sections with an overall risk rating greater than 200. These are all in the section of road where all the cut volume is in rock. There is uncertainty in both the species sensitivity and the habitat resiliency through this section, so the receptor rating may be reduced if it is found that the streams in this area do not support fish or are not permanent watercourses (these have been assigned conservatively high values, with a receptor rating of 6).

The section with the highest risk (288) is a 0.84 km section from 108+540 to 109+380. This section is through the Prospector Mountain Suite (LKqP), with an overall geology rating of 3. There is also a high volume cut rating (4) which results in a stressor rating of 12. The pathway rating is high as well (4), due to a high cut volume in the context of the small catchment area.

The remaining moderate-high risk sections have an overall risk rating of 216. The second (88+280 to 88+720) and third (95+460 to 95+650) sections are through the Whitehorse Suite granodiorite (mKgW). These sections have a moderate geology rating of 3, but the amount of cut is fairly high (3), as is the pathway rating (4).

The fourth section (112+460 to 115+640) with a moderate-high risk rating is through the Nasina quartzite and quartz-mica schist (DMN), which has a high risk rating (4). Both the cut rating and the pathway rating are moderate (3).

4.2 Moderate Risk (4) Sections

There are four moderate risk sections. These are within the rock cut section, where there is uncertainty in the receptor rating. As is the case with the sections in the moderate-high risk category, the receptor rating may be reduced based on the results from further fieldwork.

All of these sections are through the Whitehorse Suite granodiorite (mKgW), with an overall geology rating of 3. The road section from 115+640 to 124+430 has an overall risk rating of 180, with a high cut rating (4) and a moderate pathway rating (3). The species sensitivity rating is estimated conservatively as a 2, based on the assessment of satellite imagery of the area. It was concluded that the tributaries in this area are unlikely to support fish; however, fish sampling has not been completed in this area, and so a conservatively high rating was assigned to this section of road. The overall receptor rating for this section of road is 5.

The other three moderate risk sections listed in Table 4-1 have an overall risk rating of 162 with a moderate cut rating (3), a moderate pathway rating (3) and a conservatively high receptor rating (6).

4.3 Moderate-Low Risk (8) Sections

4.3.1 Rock Cut: 86+120 to 132+610

There are five sections within the rock cut section which have a moderate risk rating. The first three cross the Whitehorse Suite diorite (mKdW) and all have an overall risk rating of 144. These have a relatively low geology rating (2) but a moderate to high (3-4) cut rating. The pathway rating is also moderate to high (3-4), depending on the section. There is uncertainty in the fish species present in this area as well as uncertainty in the flow regime, which results in a conservatively high receptor risk rating (6). The section from 108+410 to 108+490 has an overall risk rating of 108 and crosses the Prospector Mountain suite (LKqP). It has a geology rating of 3 and a cut rating of 2. The pathway rating is moderate (3). The receptor rating is conservatively high, due to uncertainty. The final section (109+380 to 112+460) also has an overall risk rating of 108. It crosses the Whitehorse Suite granodiorite (mKgW) and has a moderate stressor rating of 9 (3x3). The pathway rating is low (2) as the drainage area is large relative to the cut volume. The receptor rating is high (6), again due to the uncertainty in the fish presence and the flow regime in the area.

4.3.2 Soil Cut: 0-316 to 86+120

There are three sections with a moderate-low risk rating in the first section of road where all the cut is predicted to be soil. These are (1) section 13+420 to 18+400, (2) from 78+420 to 79+010, and (3) from 1+290 to 5+960.

The highest rating (144) for these three sections is for the section from 13+420 to 18+400. This section is through the Whitehorse Suite granodiorite to quartz-monzonite (mKqW). The surficial geology air photos indicate that there is bedrock in this section, resulting in a high (4) overall geology rating. The cut rating is moderate (3), which results in a high (12) stressor rating. As this section of road runs along the main stem of Big Creek, the receptor rating is high (6). The overall rating is kept down by a relatively low pathway rating (2), as the cut volume is low relative to the up gradient catchment area.

Within this road section from approximately kilometre mark 12+800 to 17+000, there are two possible road route options. The route to the north of Big Creek, which includes the section discussed above, is currently considered the primary option. However, both

routes are shown on the maps (see Figures 3-1 and 3-2a). However, the secondary route will likely have a lower ML / ARD risk, based on the geology and the absence of bedrock at surface along this alignment. This option crosses the Long Lake Suite (EJyL) and the Carmacks unit (mKN). Both of these units have a low (2) ARD risk and this risk will be reduced further to 1 as colluvium and alluvium are the surficial materials in this area. The section of road from 17+000 to 18+400 is through the Whitehorse Suite granodiorite to quartz-monzonite (mKqW) and must be re-evaluated if this option is chosen to determine its overall risk, as the drainage area will be smaller, relative to the larger drainage area for the section through mKqW in the primary option. However, there is no bedrock in this area, so the geology rating would be reduced to 3.

The next highest risk section is in the Hayes Creek (valley bottom) drainage (78+420 to 79+010), with an overall risk rating of 135. It is through the Nasina quartzite and quartz-mica schist (DMN). This unit has a rock type rating of 4, which is modified to an overall geology rating of 3 as the surficial material in the area includes colluvium. The cut and pathway ratings are moderate (3) and the receptor rating is fairly high (5), due to the presence of slimy sculpin and Arctic grayling and the permanent flow in Hayes Creek.

The third section (1+290 to 5+960) is through the Pelly Gneiss suite (DMgPW). It has an overall risk rating of 108. The overall geology rating is fairly low (2), since the rock type rating is modified by colluvium being present. The cut rating is moderate (3), as is the pathway rating (3). The receptor rating is high (6), as Chinook salmon are present in Seymour Creek and flow is likely permanent.

4.4 Uncertainty

While the 16 road sections with moderate-low risk or greater are deemed to have a higher ML / ARD risk, including consideration of the surface water pathway and aquatic ecosystem receptors, there is a high degree of uncertainty in the results. This uncertainty can be reduced by obtaining additional information related to all three aspects of the risk assessment, and recommendations for additional work to achieve this objective are provided below. Further characterization will be required for the sections rated as having moderate-low risk or greater, in order to determine if there will be any ML / ARD issues during or following road construction.

4.5 Low Risk Sections

The low risk sections have an overall risk less than 100 and cover 94.7 km (approximately 71%) of the proposed road alignment. In general, these sections are in the first 87 km of the road where it's predicted to be all soil (and no rock) cut. The stressor rating is generally fairly low through this section as alluvium and colluvium

generally have a lower risk rating relative to bedrock. Furthermore, this section generally has lower cut volumes and lower pathway ratios relative to the rock cut section. The final section of the road route from 124+430 to 132+610 is considered low risk, due to moderate to low stressor and pathway ratings. No further work is recommended for these sections, as the overall risk is low enough to determine that ML / ARD will not be an issue during or following road construction.

5. Recommendations

5. Recommendations

The ML / ARD risk assessment of the proposed Casino access road identified 16 sections representing 38.25 km (29 %) of the road alignment with potential for ML / ARD issues. Thirteen of the 16 sections are located in two areas: 86+500 to 98+300 and 108+030 to 124+430. These sections are both within the rock cut area. The three remaining sections are 1+290 to 5+960, 13+420 to 18+400 and 78+420 to 79+010.

Further work is recommended for all of these road sections in order to fully assess the level of ML / ARD risk to aquatic ecosystems during and following road construction. In addition, the ML / ARD potential of the quarry locations must be assessed.

Further work should include:

1. Further characterization of the streams. Further work from 86+120 to the Casino property may reduce the receptor rating, and the overall risk, if it is determined that the streams in this area are not fish-bearing and/or do not have permanent flow. This may reduce the overall risk in some sections to less than 100 and decrease the area of further sampling along the proposed road.
2. Collecting bedrock or surficial material samples from along these 16 sections. In areas where there will be rock cut, the ideal sampling method would be by drilling, in order to fully characterize the weathering at different depths and to obtain “fresh” rock samples. For surficial material samples, sampling from below the organic layer would be sufficient. The number of samples collected should be based on the excavated volume of material, as per the MEND (2009) guidelines. These samples should be submitted for the same suite of static tests which were completed on the initial 60 samples. In addition, the arsenic leaching potential of colluvial and alluvial materials should be evaluated by conducting shake flask extractions on a sub-set of representative samples. This will allow for a more complete characterization of the ML / ARD potential of the rock or surficial material along the higher risk sections of road and it will determine if mitigation strategies are required.
3. Finalizing the proposed road alignment between 12+800 and 17+000, in order to assess the ML / ARD risk along this section and to determine which option has a lower ML / ARD risk.
4. Finalizing quarry locations. Quarry locations should take the overall geology risk rating into account. The three bedrock units with the lowest ML / ARD risk rating (2) are the Long Lake Suite (EJyL), the Whitehorse Suite diorite (mKdW)

and the Carmacks volcanics (uKC1). Where possible, bedrock quarries should be located in these units. If granular quarries are required, alluvial material has a lower risk rating relative to colluvium, and colluvium lower than bedrock. However, based on the results of the risk assessment, excavation of colluvium generally has a low risk when the excavated volume remains relatively low (less than about 10,000 m^3) or the bedrock geology rating is 3 or lower. This would result in an overall geology rating of 2. Based on this, areas should be avoided where the colluvial parent material is from the Nasina unit (DMN) or the Whitehorse Suite granodiorite to quartz monzonite (mKqW).

5. Sampling quarry locations, once they are finalized. The number of samples should be based on the MEND (2009) and the MOT (2004) guidelines. This will ensure that the material to be used as fill will have a low ML / ARD risk

In the event that further testing determines that certain areas are potentially acid producing, there are several possible mitigation measures that may be employed to minimize the development of ML / ARD along the proposed road alignment. Ideally, material with high acid generating potential will be avoided during road construction, in favour of selecting an alignment and construction materials that have a low acid generating potential.

In cases where this is not possible, the two main options are (1) mixing potentially acid generating material with acid consuming material and (2) placing the material away from important aquatic ecosystems. The first option allows for neutral pH to be maintained in runoff, which will result in a lower concentration of metals and other geochemical parameters. The second option requires placing any potentially acid producing material in a location where the pathway rating is low (*e.g.* in an area where there is little or no connection between the stressor and the receptor), reducing the concentrations of ML / ARD products in the aquatic environment. Both of these options will minimize the impact on the aquatic ecosystem.

ML / ARD monitoring should continue during the construction phase for any areas which are determined to be potentially acid generating. This should include sampling and static testing of geotechnical drill core or blasted rock from these sections of road. Prior to receiving the testing results, any material which may have acid generating potential should be placed in a location away from streams, to minimize impact to aquatic ecosystems. The results of this secondary testing will determine how the material must ultimately be handled.

Note:

AP = Acid potential in tonnes CaCO3 equivalent per 1000 tonnes of material. AP is determined from sulphide sulphur content.

NP = Neutralization potential in tonnes CaCO3 equivalent per 1000 tonnes of material. Acid addition based on TIC content.

NET NP = Modified NP - AP

Carbonate NP is calculated from TIC originating from carbonates and is expressed in kg CaCO3/tonne.

Sulphate Sulphur determined by 25% HCL with S by ICP Finish

Sulphide Sulphur determined by Sobek 1:7 Nitric Acid with Gravimetric Finish

Insoluble S is acid insoluble S (Total S - (Sulphate S + Sulphide S)).

Rinse pH on the -2 mm fraction.

APPENDIX IIB: METALS BY AQUA REGIA WITH ICP-MS FINISH

Appendix II-B: Metals by Aqua Regia with ICP-MS Finish

APPENDIX A.7K: Casino Mine Site Borrow Sites ML/ARD Potential

MEMORANDUM

To:	**Casino Copper Corp.**	**Date: July 22, 2014**
From:	**Jennifer Owen, Bruce Mattson**	**Project #: J862-6**
Subject:	**Casino Mine Site Borrow Sites ML/ARD Potential**	

1. Introduction

A review of the available geochemical results for borrow material samples was completed to characterize the Metal Leaching and Acid Rock Drainage (ML/ARD) potential of the borrow material in the Casino Mine area. The relevant borrow material data included acid-base accounting (ABA) results and Metals by Aqua Regia Digestion results for 49 samples. Additionally, shake flask extraction (SFE) tests were completed on the 7 borrow material samples from the Open Pit area. A brief description of the test pit samples and a discussion of the geochemical results for these samples are provided below.

The results indicate that the borrow material from the majority of locations has a very low ML/ARD potential as the majority of samples have total sulphur values < 0.1% and little or no sulphide-sulphur mineralization. However, there is very little carbonate content and portions of the borrow material from the areas underlying the low grade stockpiles, the heap leach facility and the main power plant, may initially have mildly acidic paste pH values (PpH < 5). Organic acidity rather than sulphide acidity appears to be responsible for the depressed pH from these samples as demonstrated by the organic carbon content. These materials will not be a source of ARD.

There is moderate ML/ARD potential for the borrow material from the Open Pit area as some samples had total sulphur values greater than 0.1% and all samples show a lack of carbonate content available to provide neutralization potential. Although sulphide mineralization is lacking in the Open Pit borrow material samples, mildly acidic runoff could be generated from the dissolution of jarosite, similar to what has been documented in CAP waste rock, as some of the samples had mildly acidic paste pH values (PpH < 5). Shake flask extraction results indicate that Cu leaching may occur from borrow material from the Open Pit area.

2. Description of the Samples

The test pit samples are from the following areas at the Casino Property (Figure 1):

- The Open Pit,
- The Low Grade Ore Stockpiles,
- The Gold Ore Stockpile,
- The Heap Leach Facility,

- The Main Power Plant site,
- The Tailings Management Facility (TMF),
- The airstrip borrow area, and
- The barge landing access road borrow areas.

The results and conclusions presented in this memo are associated with borrow materials found above the bedrock layer. The samples were generally collected from test pits at depths ranging from 0.3 m to 4 m below surface, although 3 of the 7 samples collected from the open pit area were collected from between 7.5 m and 20 m below surface (Appendix A). The greater depth of the overburden at the Casino site is due to a lack of glaciation in the area.

The test pit samples generally range from silt to gravel and generally contain a trace of clay. In addition to the test pit samples, weathered granodiorite samples were collected near the TMF, the main power plant site, and the airstrip borrow area and one sample of blasted rock was collected at one of the barge landing access road borrow areas.

3. Geochemical Results

The geochemical risk of the borrow materials is determined from the paste pH (PpH) and total sulphur (S_{TOT}) content of the samples rather than from a calculation of the net potential ratio (NPR), which is the standard method for sulphide-bearing waste rock at mining projects. The direct assessment of paste pH and total sulphur is more appropriate for weathered overburden that may contain low amounts of residual acidity associated with metastable oxidation products such as jarosite. The ABA criteria used to identify materials with ML/ARD potential are:

- PpH < 5.0 and
- S_{TOT} > 0.1 %S.

3.1 Open Pit

Four of the 7 test pit samples from the Open Pit area had paste pH values less than 5 (Table 1 and Appendix B.1). This result indicates that this material may produce mildly acidic runoff immediately after excavation. Two of the samples with low paste pH also had relatively high total sulphur content (1.04% and 0.1%), indicating that there is some longer term acid generating potential from borrow material from the Open Pit area. There were two additional samples with total sulphur values greater than 0.1%, although the paste pH was greater than 5. Although the sulphur is in the form of sulphate rather than sulphide in the Open Pit borrow material samples, mildly acidic runoff could be generated from the dissolution of the sulphate-mineral jarosite, similar to what has been documented in CAP waste rock. In addition, due to some enrichment of metals relative to average continental crustal abundance (*e.g.* Cu, Mo), there may be some metal leaching from borrow material from the Open Pit area (Table 2 and Appendix B.2). Based on these results, borrow material from the Open Pit area is considered to have moderate ML/ARD risk.

3.1.1 Shake Flask Extractions

Metal contents measured in SFE provide a measure of the mass of readily soluble metals which will be immediately available for leaching upon exposure to infiltrating water. SFE tests were conducted on the samples from the Open Pit area since 4 of the 7 samples had total sulphur contents greater than or equal to 0.1%. As discussed above, these higher sulphur values indicate a higher potential for ML/ARD.

In order to highlight the significance of various SFE results, the results are compared to Metal Mining Effluent Regulations (MMER, 2002) and Yukon Contaminated Sites Regulation, Schedule 3 (Yukon CSR, 2002) water quality standards for aquatic life (Table 3). Hardness dependent guidelines, including Cd, Cu, Ni and Pb, were calculated based on the mean water hardness of 111.4 mg $CaCO_3$/L measured at the water quality station on lower Casino Creek.

The only parameter to exceed MMER guidelines in the SFE tests is dissolved Cu in one sample (TP12-PIT-05). This sample had a lower solid phase Cu concentration relative to several of the other borrow samples from the open pit, indicating that Cu release is likely due to its relatively low SFE pH. The Yukon CSR standard for Cu (0.05 mg/L) is exceeded in 5 of 7 samples (1.3 to 9.8 times above the guideline), indicating that Cu is the main parameter of concern for metal leaching from the borrow material. Additional parameters which exceed the Yukon CSR standards include Cd (2 samples) and Co (4 samples). These exceedances are generally marginal, the Cd values are 1.2 to 2.1 times the guideline and the Co values are 1.0 to 5.5 times the guideline.

3.2 Ore Stockpiles, Heap Leach Facility and Main Power Plant

The low grade ore stockpiles, gold ore stockpile, heap leach facility and main power plant site are located adjacent to the Open Pit. Seven of 19 samples have paste pH values less than 5, indicating that there may be some mildly acidic runoff following excavation (Table 1 and Appendix B.1). However, the total sulphur values for all of the borrow material samples collected in these areas remain low (range: <0.01 to 0.09%, median: 0.01%). The lower paste pH values are expected to be related to higher organic C values. The samples with paste pH less than 5 have organic C values between 0.46 and 3.16% (median: 1.23%), while the samples with a higher paste pH typically have lower organic C (range: 0.03% to 0.97%, median: 0.17%). These results indicate that the borrow material from these areas has a low ARD risk.

3.3 Tailings Management Facility

The samples from the TMF area were collected from the embankment area at the southern end of the TMF. These test pit samples typically have higher paste pH values relative to the samples collected closer to the Open Pit area. Only one of 14 samples had a paste pH value below pH 5 (Table 1 and Appendix B.1). In addition, total sulphur values remain low for all samples (range: <0.01 to 0.07%, median: 0.01%). Based on these results, these samples are classified as non-acid generating.

3.4 Airstrip and Barge Landing Access Road Borrow Areas

Four samples were collected from the airstrip borrow area, located south of the project area and 5 samples were collected from two locations along the proposed barge landing access road, to the north of the project area. The samples indicate that the borrow material in these areas are non-acid generating as the paste pH values are high (> PpH 7) and the total sulphur values are low (0.01% or lower) (Table 1 and Appendix B.1).

4. Recommendations

The geochemical results indicate that there is some potential for ML/ARD from the borrow material from the Open Pit area and low to no ML/ARD potential from the other areas. Based on these findings, it is expected that borrow with a low ML/ARD risk can be derived from all the borrow areas identified except within the proposed open pit limits. However, it is recommended that a ML/ARD Management Plan be developed for each area prior to the excavation of borrow material to confirm these preliminary findings. The ML/ARD Management Plans should include the following:

- An accounting of the quantity of material expected to be excavated from each site subdivided into the quantity of bedrock, weathered bedrock, alluvium and colluvium that would be removed at each site, in addition to the lithologic composition and stratigraphic affiliation if applicable.
- At least three test pit samples should be collected from each borrow site and submitted for geochemical analysis, including ABA and total metals analysis, prior to excavation. Increased sampling and sample planning should be conducted in proposed borrow areas within the open pit extents and immediately adjacent to the open pit where a higher degree of ML/ARD risk was identified.

This approach will ensure that all borrow material used for construction will have a low ML/ARD potential.

Note:

SAP = Acid potential in tonnes $CaCO_3$ equivalent per 1000 tonnes of material. AP is determined from the measured sulphide sulphur content.

Non-SO4 AP = Acid potential in tonnes $CaCO_3$ equivalent per 1000 tonnes of material. AP calculated from non-sulphate sulphur (total sulphur - sulphate sulphur).

NP = Neutralization potential in tonnes $CaCO_3$ equivalent per 1000 tonnes of material.

NET NP = NP – SAP

Carbonate NP is calculated from TIC originating from carbonates and is expressed in kg $CaCO_3$/tonne.

Sulphate Sulphur determined by 25% HCl Leach with S by ICP Finish

Sulphide Sulphur determined by 1:7 Nitric Acid Leach with S by ICP-MS Finish

Insoluble S is acid insoluble S (Total S - (Sulphate S + Sulphide S)).

Notes:
NP = none proposed
MMER = Metal Mining Effluent Regulations (MMER, 2002);
MMM = Maximum authorized monthly mean;
MCS = Maximum authorized concentration in a composite sample; and
MGS = Maximum authorized concentration in a grab sample.
Yukon CSR = Yukon Contaminated Sites Regulation, Schedule 3 - Generic Numerical Water Standards, Aquatic Life (Yukon CSR, 2002)
*Hardness dependent guidelines were calculated based on a mean water hardness of 111.4 mg $CaCO_3$/L for the water quality station on Lower Casino Creek
Light grey shading indicates an exceedance of the MMER MMM guideline
Medium grey shading indicates an exceedance of the MMER MCS guideline
Dark grey shading indicates an exceedance of the MMER MGS guideline
Blue shading indicates an exceedance of the maximum Yukon CSR standard

Appendix A: Overburden Sample Description

CASINO
COPPER AND GOLD

Sample ID	Depth (m)	Description	Soil Type	Comments
Open Pit				
38-3	15.24-16.76	Silty sand, trace gravel, trace cla	Colluvium	
38-4	18.29-19.81	Sand and silt, trace clay, trace grave	Residual soil	
39-1	7.62-7.80	Silty sand, fine to coarse	Colluvium	
TP12-PIT-01	0.80-1.00	Sand and gravel, some cobble	Residual soil to highly weathered bedroc	Collected above permafros
TP12-PIT-04	3.00-3.20	Silty sand, some grave	Residual soil to highly weathered bedroc	Collected above bedrock
TP12-PIT-05	3.80-4.00	Gravelly sand, some cobbles, trace silt, coarse graine	Residual soil to highly weathered bedroc	Collected above bedrock
TP12-PIT-06	1.60-1.80	Silty sand, some grave	Residual soil to highly weathered bedroc	Collected above permafros
Low Grade Stockpiles				
TP11-04	0.77-0.97	Silt and sand, trace clay, trace grave	Colluvium	Collected above permafros
TP11-NAG-02	1.20-1.40	Silty sand, some gravel, trace cla	Colluvium	Boulders left out of sample
TP11-NAG-06	3.20-3.40	Gravelly sand, some silt, trace cla	Granodiorite, completely weathered	Collected above bedrock
TP11-NAG-07	0.70-0.90	Sand and silt, some gravel, trace cla	Colluvium	Collected above permafros
TP11-NAG-08	0.60-0.80	Silty, gravelly sand, trace cla	Colluvium	
Gold Ore Stockpile				
TP13-48 BU-1	2.5-2.7	Gravelly sand, trace to some silt, some cobble	Residual soil	
Heap Leach Facility				
TP11-HLF-01	2.00-2.10	Silty sand, some gravel, trace cla	Colluvium	Collected above permafros
TP11-HLF-05	1.50-1.90	Gravelly sand, some sil	Colluvium	Collected above permafros
TP11-HLF-13	1.80-2.00	Gravelly sand, some silt, trace cla	Colluvium	Collected from a road cu
TP11-HLF-16	2.80-3.00	Gravel and sand, some silt, trace cla	Highly weathered bedrock	Collected above permafros
TP11-HLF-21	0.80-1.00	Silty sand, some gravel, trace cla	Colluvium	Collected above boulders
TP11-HLF-41	1.50-1.70	Gravelly sand, some silt, trace cla	Colluvium	
Main Power Plant				
TP11-06	0.84-1.04	Sandy silt, some gravel, trace cla	Colluvium	Collected above permafros
TP11-10	0.30-0.65	Sandy silt, some gravel, trace cla	Colluvium	Collected above large boulder
TP11-11	1.10-1.30	Sand and gravel, some silt, trace cla	Colluvium	Collected above permafros
TP11-18	1.20-1.40	Silty sand, trace clay, trace grave	Residual soil	Collected above permafros
TP11-20	1.25-1.45	Sandy silt, some gravel, trace cla	Residual soil	Collected above bedrock
TP13-03 BU-1	2.0-2.2	Sand, some gravel, trace silt and cla	Residual soil	Collected from an existing exposur
TP13-04 BU-1	2.8-3.0	Weathered granodiorite, coarse graine	Granodiorite, completely weathered	Collected from an existing exposur
Tailings Management Facility				
TP11-TMF-01	1.22-1.42	Gravel, some sand, some silt, trace cla	Colluvium	Collected above bedrock
TP11-TMF-05	2.10-2.30	Sand, some silt, trace gravel, trace cla	Residual Soil	Collected above bedrock/permafros
TP11-TMF-09	0.85-1.05	Silt, trace clay, trace sand	Alluvium - Floodplain Deposi	Collected above permafros
TP11-TMF-10	1.00-1.20	Gravel, some sand, some silt, trace cla	Colluvium	Collected above bedrock
TP11-TMF-12	0.90-1.10	Gravelly sand, some silt, trace cla	Residual Soil	Collected above permafros
TP11-TMF-13	1.35-1.55	Sandy gravel, trace silt, trace cla	Colluvium	Collected above weathered bedrock
TP11-TMF-34	0.80-1.00	Silt and sand, some gravel, trace cla	Colluvium	Collected above permafros
TP11-TMF-94	1.30-1.50	Sandy, silty gravel, trace cla	Colluvium	Collected above bedrock
TP11-TMF-99	0.50-0.70	Silty sand and gravel, trace cla	Colluvium	Collected above bedrock
TP11-TMF-100	1.00-1.20	Sand and gravel, some silt, trace cla	May be weathered bedrock	Collected above bedrock
TP13-14 BU-1	3.0-4.0	Gravelly sands and cobble	Alluvium - riverbed deposi	Collected from frozen ground
TP13-27 BU-1	2.6-2.8	Weathered granodiorite, sand to grave	Granodiorite, completely weathered	Collected above bedrock
TP13-28 BU-1	1.4-1.6	Gravel and sand, some silt, few cobble	Residual soil	Collected above weathered bedrock
TP13-33 BU-1	2.0-2.3	Gravelly sand, some cobbles, trace sil	Residual soil	Collected above permafros
Airstrip Borrow Area				
TP13-76 BU-1	1.0-1.2	Sand and gravel, trace sil	Residual soil	
TP13-76 BU-2	1.7-2.0	Weathered granodiorite, coarse graine	Granodiorite, completely weathered	
TP13-77 BU-1	2.0-2.2	Granodiorite, coarse grained	Dawson Range Batholith granodiorit	Collected bedrock
TP13-78 BU-1	1.0-1.2	Gravelly sand, trace sil	Residual soil	Collected above weathered granodiorit
Barge Landing Access Road				
TP13-01 BU-0	0.6-0.8	Sand, trace to some gravel, trace sil	Alluvium - creek deposi	Collected from an existing exposur
TP13-01 BU-1	1.2-1.4	Sand and gravel, many cobbles, no to trace si	Colluvium	Collected from an existing exposur
TP13-01 BU-2	2.5-2.7	Sand and gravel, many cobbles, no to trace si	Colluvium	Collected from an existing exposur
TP13-01 BU-3	1.0-1.2	Sand and gravel, many cobbles, no to trace si	Colluvium	Collected from an existing exposur
TP13-84 BU-1	n/a	Granodiorite, medium grained (blasted rock	Dawson Range Batholith granodiorit	Collected from existing blasting sit

Note:

AP = Acid potential in tonnes $CaCO_3$ equivalent per 1000 tonnes of material. SAP is determined from the measured sulphide sulphur content, Non-SO4 AP is determined from the non-SO_4 sulphur content.

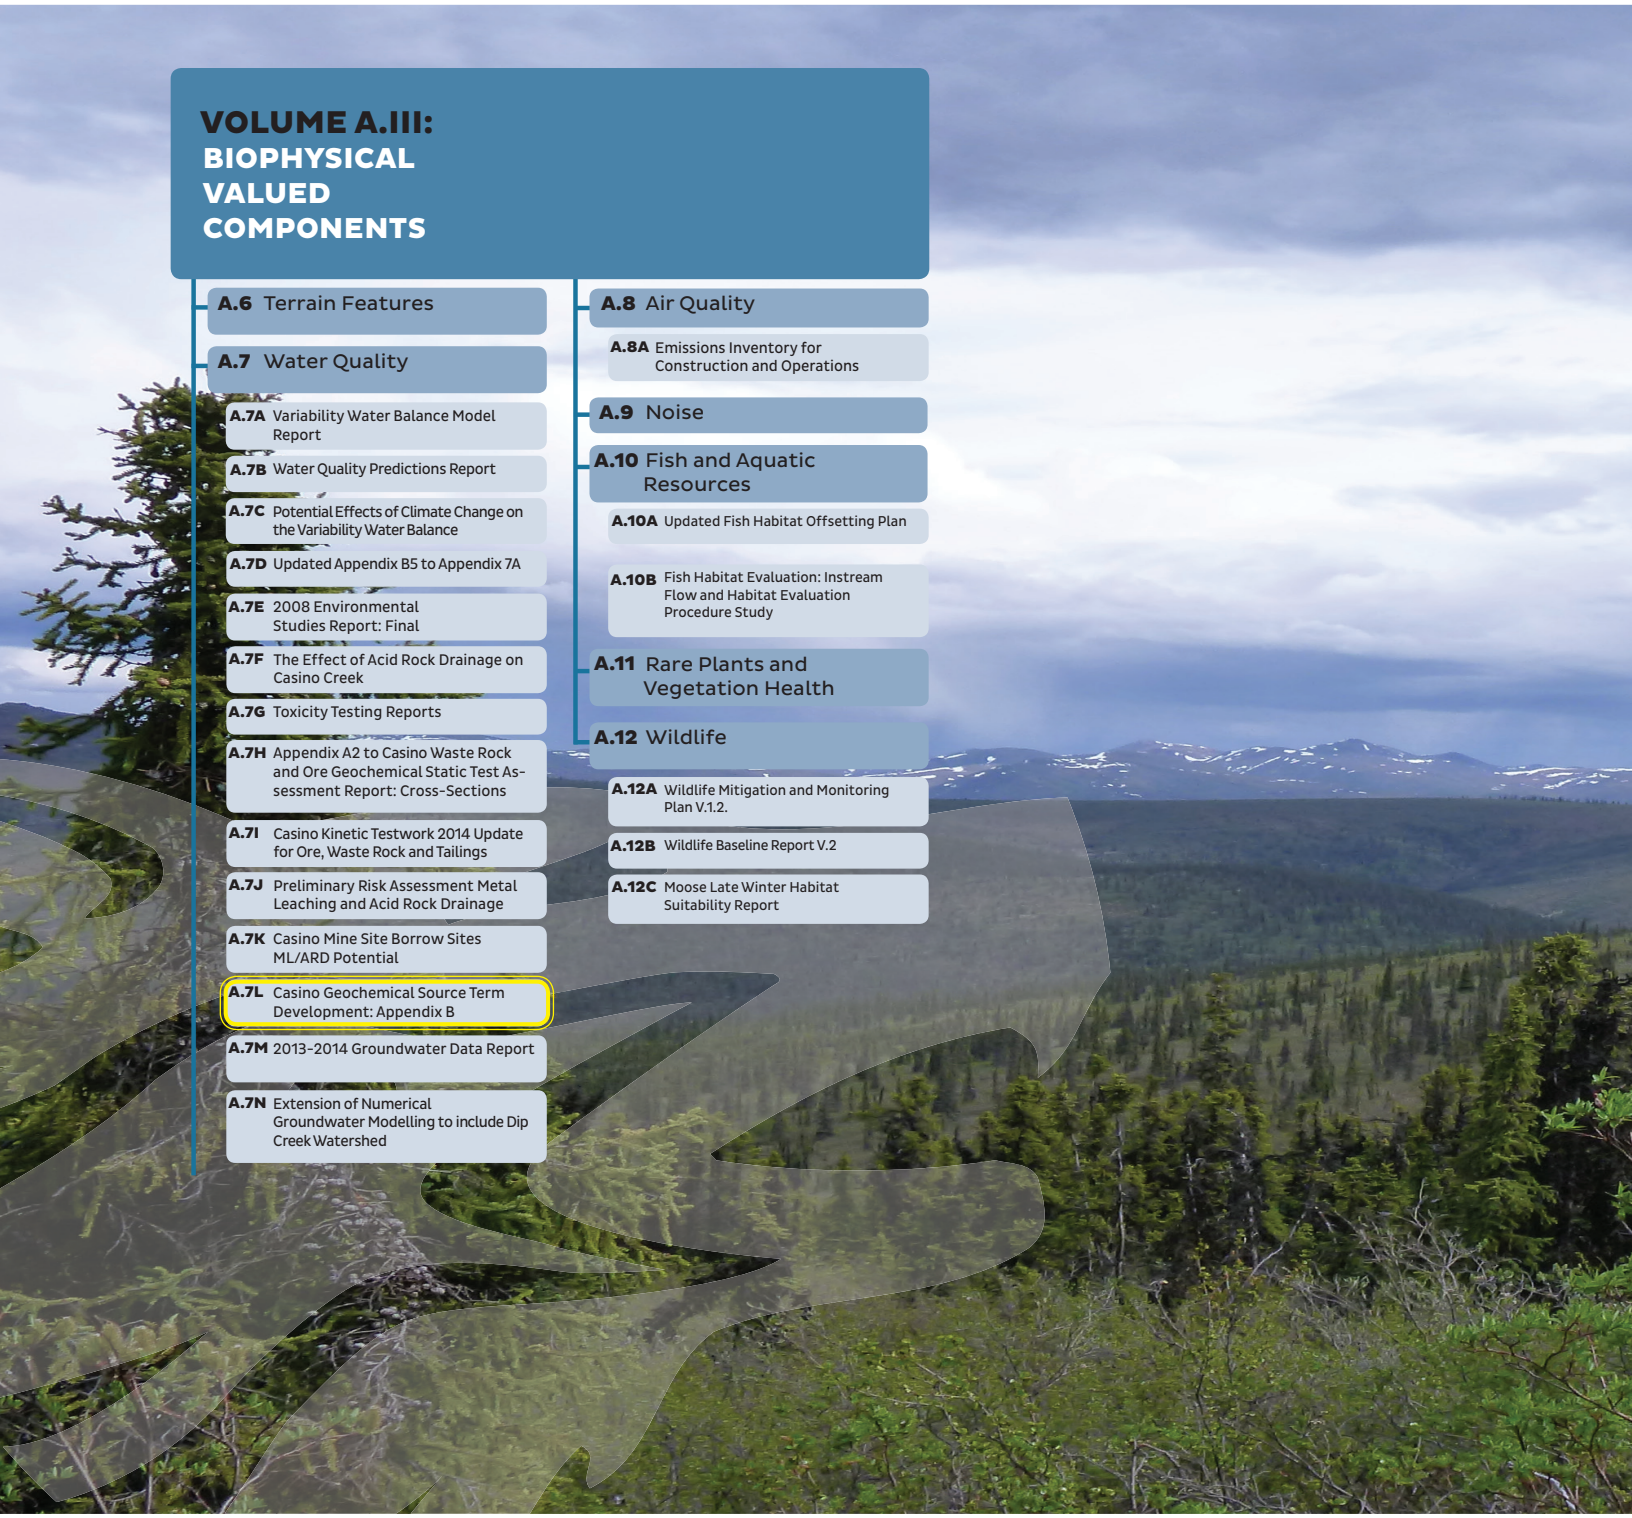
NP = Neutralization potential in tonnes $CaCO_3$ equivalent per 1000 tonnes of material.

NET NP = NP - SAP

Carbonate NP is calculated from TIC originating from carbonates and is expressed in kg $CaCO_3$/tonne.

Sulphate Sulphur determined by 25% HCL with Gravimetric Finish

Sulphide Sulphur determined by Sobek 1:7 Nitric Acid with S by ICP-MS Finish



Insoluble S is acid insoluble S (Total S - (Sulphate S + Sulphide S)).

For the 1994 samples, total S and sulphate S results were switched from the original result sheet because S(SO_4) was greater than S(T) for all samples.

Knight Piésold CONSULTING

EXECUTIVE SUMMARY

Knight Piésold Ltd. (KP) was contracted by Casino Mining Corporation (CMC) to perform a supplemental hydrogeological site investigation in the summer of 2013 to install monitoring wells and further advance baseline data collection. This data report documents the 2013 hydrogeological site investigation and presents baseline groundwater data collected across the site in 2013 and 2014.

The 2013 site investigation program included the drilling and installation of 11 monitoring wells at 6 locations. Overburden encountered during drilling generally consisted of silty sands and gravels of up to 7 m thick. The overburden deposits were interpreted to be colluvial deposits. Bedrock encountered during drilling included granodiorite and quartzite. Bedrock was weathered to at least 20 m below ground surface.

Monitoring well development, response testing, groundwater sampling and installation of pressure transducers for long-term water level monitoring were carried out in August 2013. A Waterra inertial pumping system was used to develop the monitoring wells where possible. Response testing was completed following monitoring well development. Hydraulic conductivity estimates from response testing ranged from less than $1x10^{-8}$ m/s to $2x10^{-4}$ m/s. Pressure transducers were installed in all monitoring wells and are programmed to record water level data every three hours.

Hydrogeology data were collected at the site during six site visits during 2013 and 2014, including continuous groundwater level and ground temperature monitoring, groundwater quality sampling, and re-development of select historic monitoring wells.

Water quality samples and *in situ* data were collected from 16 monitoring wells located throughout the project area in 2013 and 2014. Samples were collected three times per year targeting seasonal representation (spring, summer, and fall). The baseline groundwater quality datasets for all wells are provided in this report along with the assessment of the data quality for data collected since 2013.

1 – INTRODUCTION

1.1 PROJECT DESCRIPTION

Casino Mining Corporation (CMC) is proposing to develop the Casino Project (the Project), a proposed copper-gold-molybdenum mine, in Yukon Territory. The project is located in the Dawson Range Mountains of the Klondike Plateau approximately 300 km northwest of Whitehorse, as shown on Figure 1.1.

Knight Piésold Ltd. (KP) previously completed a baseline hydrogeology and groundwater quality study for the Project, detailed in the 2012 Baseline Hydrogeology Report (KP 2013). The report presented the understanding of the existing groundwater regime and summarized groundwater-related data collected during site investigations conducted from 1993 through 2012. Subsequent to the baseline report, KP was retained to carry out a 2013 hydrogeological site investigation to further advance baseline data collection in key areas of the Project and to continue baseline groundwater monitoring and collection of groundwater data in 2013 and 2014. The results of the 2013 site investigation and 2013 and 2014 data collection are presented in this report. This information will ultimately be used to support the understanding of the existing groundwater regime.

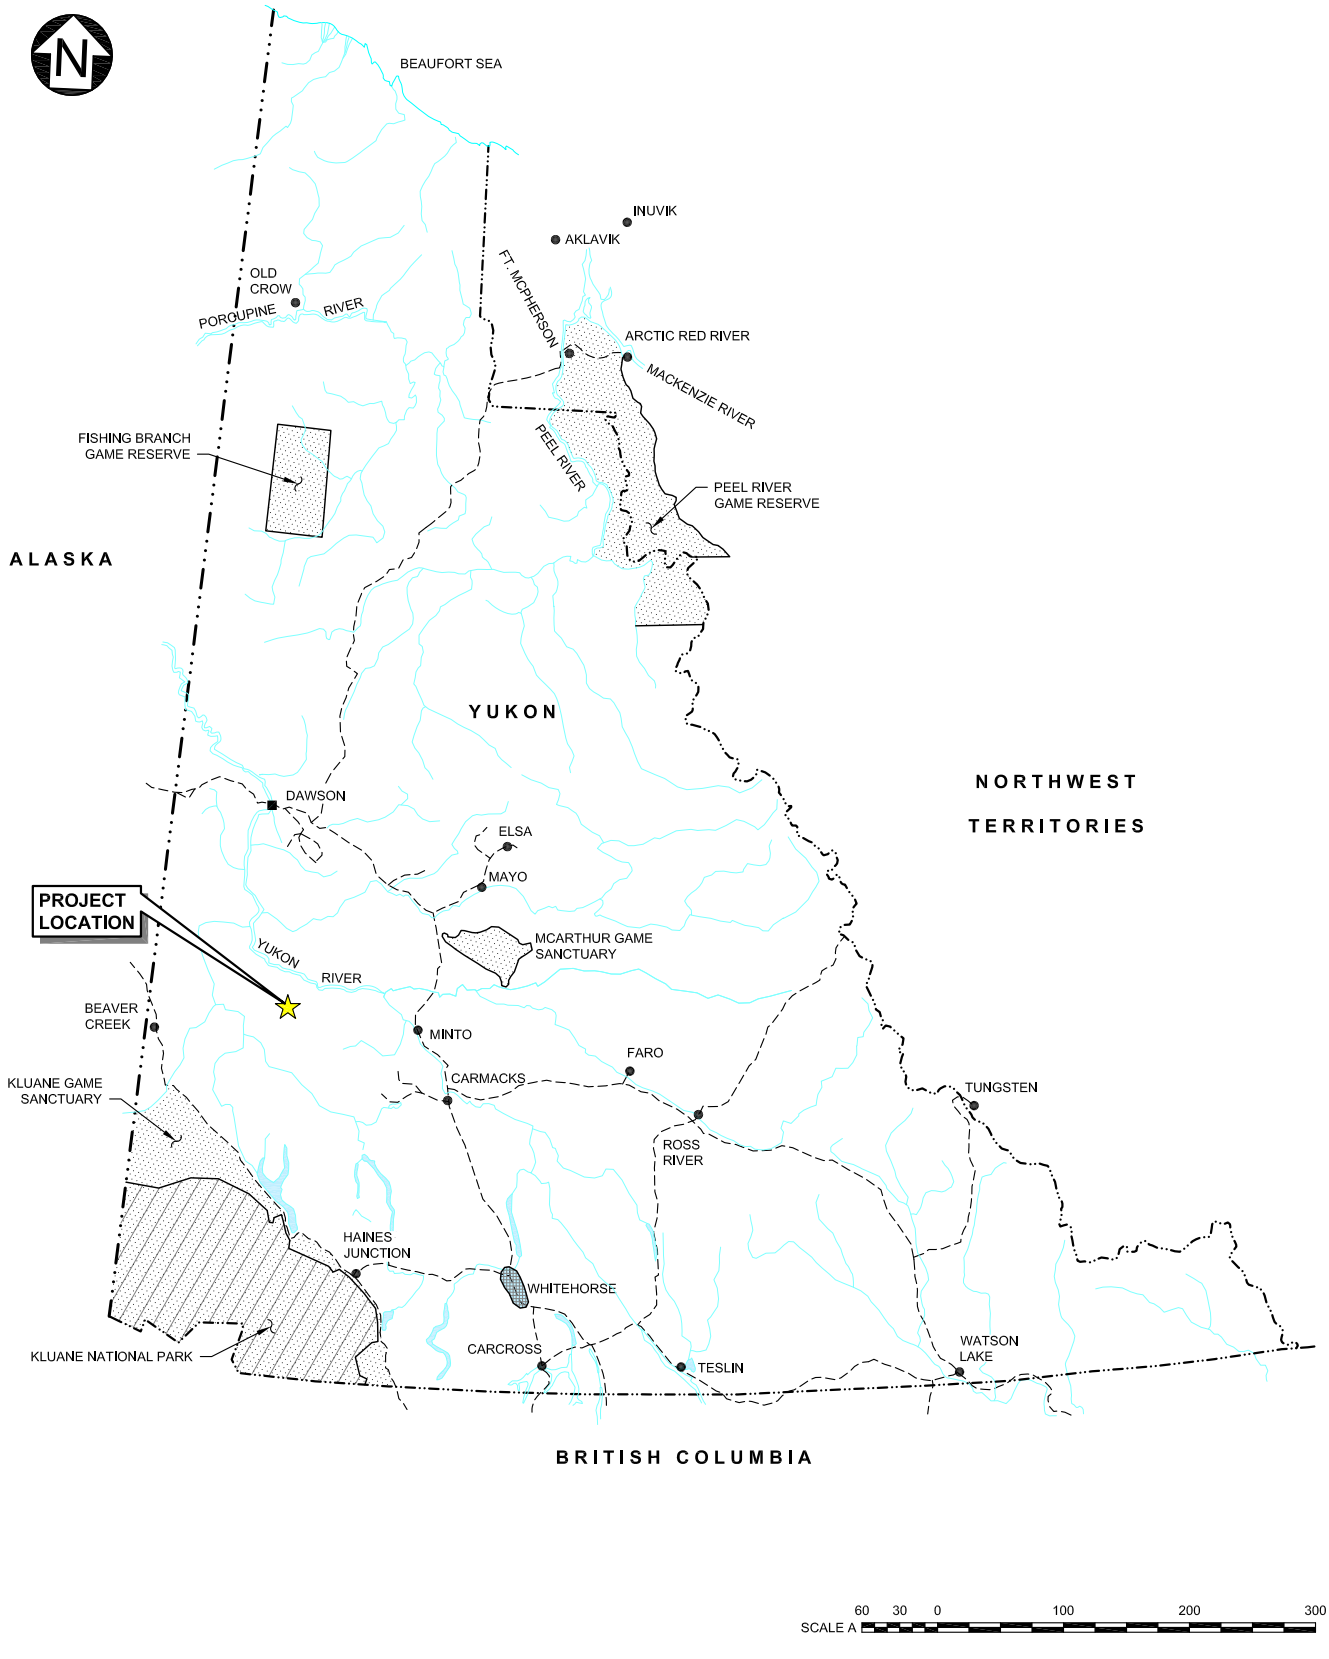
In addition to the 2013 site investigation and data collection work documented in this report, groundwater-related data was collected during a geotechnical site investigation in 2013 (KP 2014). A total of nine drillholes were advanced and two standpipes and two thermistors were installed during the geotechnical site investigation. Data collected from these installation sites are included in this report.

1.2 SCOPE OF REPORT

The objective of this data report is to describe the methodology and results of the 2013 hydrogeological site investigation and to present baseline groundwater data collected at the site in 2013 and 2014. Baseline groundwater data was collected during a total of six site visits in 2013 and 2014:

- June, August and September 2013, and
- May, July and September 2014.

The work described in this report includes:



2013 Hydrogeology Site Investigation:

- Supervising the drilling and installation of 11 monitoring wells at 6 locations,
- Developing the new monitoring wells,
- Response testing the new monitoring wells,
- Installing pressure transducers to collect long-term water level data at each location, and
- Groundwater sampling the new monitoring wells.

2013-2014 Data Collection Program (to October 2014):

- Collecting manual and continuous time-series water level data from monitoring wells, standpipe piezometers and vibrating wire piezometers (VWPs),
- Collecting ground temperature data from thermistor and VWP installations,
- Re-developing select monitoring wells installed prior to 2013, and
- Collecting groundwater samples at select monitoring wells.

Site investigation and groundwater monitoring methodology is presented in Section 2. Site investigation results and data collected during the site visits are presented in Section 3. Drillhole logs and monitoring well installation details are provided in Appendix A, response testing data are provided in Appendix B, water level data are provided in Appendix C, and ground temperature data are provided in Appendix D. Groundwater sampling methodology and results are presented in Appendices E through G.

2 – METHODS

2.1 DRILLING AND MONITORING WELL INSTALLATIONS

Kluane Drilling Ltd., based out of Whitehorse, Yukon was contracted to carry out drilling and installation of the groundwater monitoring wells at the Casino Project under the supervision of KP. A KD1000 diamond coring rig was used to complete the drilling.

Drillholes were completed using one of two drill rod and casing sizes based on the availability of drilling equipment:

- The first four drillholes (MW13-01D/S and MW13-02D/S) were advanced through overburden using 11.4 cm (4.5 inch) diameter HWT drill casing. Drilling continued without casing using 9.1 cm (3.6 inch) diameter HT drill rods once stable bedrock was encountered. Overburden and rock samples were recovered using an HQ core barrel.
- The remaining seven drillholes were completed using 14 cm (5.5 inch) PW casing to advance through the overburden and 11.4 cm (4.5 inch) HWT drill rod through bedrock. The larger diameter rods provided a greater annular space to accommodate monitoring well installation. Overburden and rock samples were recovered using an HT core barrel.

Rock core was collected in five foot lengths as drilling progressed and logged and photographed to characterize stratigraphy and identify potentially permeable zones. Observations recorded during drilling included input from the driller (e.g. drill chatter) and notes on zones of drilling fluid circulation losses. Water level measurements were taken during pauses in drilling to assess the depth to water or if permafrost was present. Additional notes related to the presence of permafrost included observations of ice in the drill core and indications that drill rods were sticking (freezing) to the drillhole walls.

All drillholes were flushed with water prior to monitoring well installation. All monitoring wells were constructed with the following materials in accordance with best practices:

- A 3 m (10 feet) long, 49 mm inner diameter (ID) (nominal 2 inch) threaded Schedule 40 or 80 machine slotted PVC screen (washed and bagged), 0.5 mm (0.020 inch) slot size, fitted with a threaded bottom cap,
- 3 m (10 feet) lengths of 49 mm ID (nominal 2 inch) threaded Schedule 40 or 80 PVC solids (washed and bagged) to approximately 0.5 m above ground surface,
- Filter sand (10/20) placed approximately 1.5 m (5 feet) below and above the screen,
- A 2 m (6 feet) seal of slow-release bentonite pellets above the filter sand,
- A cement/bentonite grout backfill prepared as approximately 30 liters (8 gallons) of water per 43 kg (94 lbs) portland cement and 2 kg (5 lbs) bentonite powder,
- A PVC monitoring well cap and a locking monitoring well surface protector, and
- A concrete surface pad approximately 1.5 m x 1.5 m to direct surface flow away from the monitoring well.

2.2 MONITORING WELL DEVELOPMENT

The objective of well development is to minimize near-well disturbances resulting from drilling so that collected data (response tests, groundwater levels and groundwater quality) are defensible and representative. To minimize these potential drilling effects, well developments aids with removing

drilling debris and fine-grained sediment from the vicinity of the screened zone. The following equipment was used to carry out the well development activities:

- A high capacity Waterra inertial pumping system activated by a Waterra Power Pump (Power Pump), and
- HDPE Waterra tubing (2.54 cm (1-inch)) fitted with a foot valve and surge block.

The water level in the monitoring well was recorded at the beginning of well development. The foot valve and surge block were fitted to the end of the Waterra tubing and lowered down the monitoring well to 1 m above the base of the well screen. Development began at this depth and the foot valve and surge block were raised in 1 m increments until the top of the screen was reached. Water level measurements were taken during development to monitor the rate of water level recovery and prevent the water level from dropping below the top of the well screen. Well development continued until there was an observable improvement in water quality based on recorded in-situ measurements (temperature, pH, electrical conductivity and turbidity) and qualitative observations (water clarity and sediment).

The above approach was modified for monitoring wells where the water level recovery was too slow to maintain the water level above the top of the screen during development. In these instances, the well development was limited to slightly agitating fines from within the well screen by plugging the discharge end of the Waterra tubing at surface. The pumping/surging action of the foot valve/surge block being operated manually moved water back and forth through the screen and filter pack without removing water from the monitoring well. If there was sufficient water in the monitoring well, the Waterra tubing was unblocked and the Power Pump was briefly operated to remove as much of the loosened sediment from the monitoring well without dewatering the screen. This modified approach is less efficient but provides a means to complete some development for monitoring wells with relatively slow water level recovery.

2.3 RESPONSE TESTING

The monitoring wells were response tested (slug tested) after water levels had stabilized following development. Slug tests are an efficient and inexpensive method to estimate a hydraulic conductivity in the immediate vicinity of a drillhole.

A 1.07 m length of 0.025 m outer diameter (OD) Schedule 80 PVC pipe capped and filled with 10/20 filter sand was used as a slug. The slug was secured to a 60 m tagline (manufactured by Solinst) so it could be quickly lowered into and retrieved from the monitoring well. A pressure transducer manufactured by Schlumberger Water Services (Diver model DI502-20m or DI505-50m) was used to record the water level response during testing. Manual water level measurements were taken during testing using a 100 m water level meter (manufactured by Solinst).

The response test data for the monitoring wells were analyzed using the Hvorslev (1951) method, which involves matching field data to a theoretical solution to produce an estimate of the formation hydraulic conductivity near the drillhole.

2.4 GROUNDWATER LEVELS

Water levels were measured manually after monitoring well installation and before and after monitoring well development and response testing. A pressure transducer was installed in each monitoring well suspended on stainless steel aircraft cable following well installation. The pressure

transducers are manufactured by Solinst and were programmed to record water level data every three hours. An atmospheric pressure transducer is located near the existing camp and records atmospheric pressure at hourly intervals. The barometric data were used to compensate the groundwater elevation time-series data for fluctuations in barometric pressure.

WellBuster™ monitoring well packers were installed in 2014 in some of the wells that are artesian or have shallow water tables. The intent of the well packers is to supress the water levels in the wells below the freezing elevation to enable sampling earlier in the year by keeping the well from freezing and to prevent damage to the wells that may result from expansion of frozen water in the PVC. WellBuster™ packers are specifically built for installation in water wells and are constructed of rubber seals and stainless steel.

2.5 INSTALLATION OF HEAT TRACE

Electric heat trace (3 watt, 120 volt) was installed in the new monitoring wells immediately following well completion to allow the monitoring well to be thawed for development and sampling work in the event the water column in the well froze due to permafrost. The heat trace was cut to length after installation so that it extended the entire depth of the monitoring well. A waterproof end splice was applied to the down-well end to guard against water intrusion and short-circuiting of the submerged heat trace. A 120 volt grounded plug was installed to the free end of the heat trace located at the well head. When activated, the heat trace was powered by 120 volt power supplied from a portable gasoline generator. Heat trace remains installed at all of the 2013 monitoring wells except MW13-02D/S and MW13-06D/S which have been unfrozen during all sampling events in 2013 and 2014.

The heat trace in MW13-01D and MW13-03S was upgraded to a higher wattage heat trace (10 watt, 120 volt) to increase heat output in order to promote thawing of the water column in the well prior to sampling and well development work.

2.6 GROUNDWATER QUALITY SAMPLING

KP adapted well purging and sampling procedures employed during the field program from the following documents:

- British Columbia Field Sampling Manual for Continuous Monitoring and the Collection of Air, Air-emission, Water, Wastewater, Soil, Sediment and Biological Samples (BC Ministry of Water, Land, and Air Protection, 2003).
- United States Environmental Protection Agency Low-Flow (Minimum Drawdown) Ground-Water Sampling Procedures (US EPA, 1996).

The purging and sampling methods employed were dictated by the conditions of each individual well. Two approaches were applied to the groundwater wells as the wells fell into two categories: wells that recharged very quickly and a minimum drawdown could be maintained while purging, and wells with slow to very slow recharge where minimum drawdown could not be maintained (despite very low pumping rates). Methods common to both procedures are described in the following section and methods for each well purging scenario are provided in the two following sections.

2.6.1 General Sampling Method

Both methods (minimum drawdown method and low recharge method) required the use of a submersible pump, which was placed approximately 1 m above the top of the screen, and both required a low pump rate during sampling and purging to minimize turbulence in the well. Target pumping rates ranged from 0.2 L/min to 0.5 L/min (higher rates may be achieved where turbidity does not increase and the water level is maintained).

In situ parameters were monitored during the well purging process using a flow-thru cell attachment on a calibrated multi-parameter probe. Final *in situ* parameters were recorded for the sampling event immediately prior to collecting the sample.

Samples for dissolved metals analysis were field filtered using a 0.45 µm in-line filter and samples for dissolved organic carbon analysis were field filtered using a syringe with a 0.45 µm syringe filter. Any required preservatives were added immediately after sample collection. Syringe filters were used for dissolved organic carbon analysis because the in-line filters contain activated carbon, which is known to contaminate samples with organic carbon; these filters are only certified for use for filtration of inorganic parameters.

2.6.2 Low-Flow Minimum Drawdown Purging and Sampling Method

The low-flow minimum drawdown method was used to purge and sample the wells where hydraulic conductivity was high enough to do so. The primary objective of this sampling method is to match the pumping rate with that of the natural groundwater flow-rate across the screened interval. This was achieved by adjusting the pumping rate such that the water level in the well was stable and relatively close to the static water level prior to pumping. With a stable water level, the water entering the pump must be from the screened interval below the pump intake and not from the stagnant overlying water column.

The key advantages of the low-flow groundwater quality sampling method are:

- Reduced stress on the surrounding aquifer,
- More representative samples due to reduced turbidity, and
- Reduced purge volume.

Well purging was considered complete and samples were collected when all of the following objectives were met during the purging process:

- Minimum purge volume was removed (volume in drawdown plus the volume below the pump intake),
- In situ parameters were stable (temperature, pH, specific conductance, turbidity, and dissolved oxygen), and
- The water level was confirmed to be stable or rising.

2.6.3 Low Hydraulic Conductivity Formation Purging and Sampling Method

This second approach was used where the groundwater recovery rate was slower than the lowest pump rate and the water level continued to drop during the purging process. The pump was placed above the top of the screen and the stagnant water above the pump was purged until the water level dropped to the pump intake. The water level in the well was then allowed to recover overnight or longer. The pump was left in place and was used to collect a sample once the water level had

recovered, unless the water in the tubing was likely to freeze overnight. If freezing temperatures were expected, the pump was removed from the well and the water sample was collected using a bailer or by re-deploying the pump down the well, once the well had recovered to a sufficient water level. In both cases, *in situ* parameters were recorded before and after sampling.

The key disadvantages of this second purge and sample approach are:

- Potentially less representative samples due to mixing of stagnant water with formation water,
- Greater stress on the surrounding formation,
- Greater purge volume, and
- Longer sampling time.

2.6.4 Alternative Groundwater Sampling Methods

In some cases, neither of the standard methods could be used to collect samples and alternative methods were used. Circumstances where alternative methods were applicable included the following:

- Blockages in the groundwater monitoring well: in some wells, frost or other factors have resulted in partial blockages in the PVC, inhibiting the use of a submersible pump.
- Low water levels in wells that are slow to recover: in some wells, there is not enough of a water column above the well screen to purge and sample.

Sampling methods for these circumstances included the use of bailers or HDPE tubing with a foot valve. These sampling methods are more aggressive than low-flow methods with a submersible pump and can result in higher turbidity and can result in mixing of stagnant well water with fresh water from the screened interval of the well. Analytical results for samples collected using these alternative methods can provide information about groundwater quality in the formation around the well, however, the resulting data may not be of the same quality as that resulting from the standard groundwater sampling methods. Data collected using the alternative methods are always interpreted with consideration to the method used.

2.6.5 Description of Groundwater Quality Monitoring Locations and Sampling Events

Water quality samples have been collected at the site from 29 groundwater quality monitoring wells strategically located in the vicinity of and down-gradient of key proposed project facilities. Monitoring well locations are grouped for analysis into three general areas, which are listed in Table 2.1: Open Pit area (eight wells), Casino Creek valley area (nine wells) and hillslope area (12 wells).

Samples were collected three times per year targeting seasonal representation (spring, summer, and fall). The timing of each sampling event was chosen such that the annual sample set would be representative of the seasonal variability of groundwater levels. Groundwater sampling events were intended to coincide with the lowest groundwater levels (prior to freshet), the highest groundwater levels (after freshet), and intermediate groundwater levels (autumn).

Over the course of the baseline data collection program some monitoring wells have been dropped from the sampling program as a result of damage such as blockages, likely due to winter ground freezing conditions. New monitoring wells were installed in 2013 and added to the sampling program. Samples were not collected from a monitoring well if it was frozen, which was more likely to occur in the spring and early summer.

2.6.6 Laboratory Analysis

Groundwater samples were submitted to ALS Environmental in Burnaby. The following parameters were analyzed:

- Physical Tests – Hardness, pH, specific conductivity, total dissolved solids (TDS), total suspended solids (TSS), and turbidity.
- Dissolved Anions – Alkalinity (bicarbonate, carbonate, and hydroxide), bromide, chloride, fluoride, and sulphate.
- Nutrients – Ammonium nitrogen, nitrate, nitrite, dissolved orthophosphate, and total and dissolved phosphate.
- Total and Dissolved Metals – metals and metalloids analyzed at low levels to meet the B.C. Water Quality Guidelines (BCWQG) and the Canadian Environmental Quality Guidelines (CEQG) criteria values (low-levels): Aluminum, antimony, arsenic, barium, beryllium, boron, cadmium, calcium, chromium, cobalt, copper, iron, lead, magnesium, manganese, molybdenum, nickel, selenium, silver, sodium, thallium, uranium, vanadium, and zinc.
- Total and Dissolved Mercury – ultra-low detection limits.
- Cyanide - Free, total, and weak acid dissociable (WAD).
- Organics – Total organic carbon (TOC) and dissolved organic carbon (DOC).

2.6.7 Relevant Guidelines

Baseline water quality analytical and *in situ* data from the groundwater samples were examined and compared to relevant guidelines with respect to the most sensitive receptors in the downstream environment which are aquatic life. While groundwater is not considered aquatic life habitat, the results of the groundwater quality baseline program for the Project have been compared to aquatic life guidelines because groundwater may contribute to the streamflow of creeks that do support aquatic life in the project area. The guidelines are reported in territorial and federal guidance documents and include the following:

- Yukon Contaminated Sites Regulation (YCSR) Schedule 3 - Generic Numerical Water Standards – Aquatic Life – The aquatic life standards were developed for groundwater assuming a minimum 1:10 dilution ratio for groundwater to surface water. Pursuant to section 145 of the Yukon Environment Act (O.I.C. 2002/171).
- Canadian Environmental Quality Guidelines - Water Quality Guidelines for the Protection of Aquatic Life (Freshwater) (CCME).

The guidelines are provided in Table F1 of Appendix F. Guidelines for some parameters are hardness or pH dependent. In these cases, the guideline was assessed based on the measured hardness or pH in each sample.

2.6.8 Quality Assurance/Quality Control, Data Management and Data Analysis

The QA/QC procedure aids with the collection of representative data that are scientifically defensible, repeatable, and well documented. KP implemented these procedures from 2011 to present. During the time when KP has been responsible for overseeing the groundwater quality data collection, these procedures have been facilitated at the project management level through organization and planning and the enforcement of both external and internal quality control. The following lists summarize the QA/QC procedures and practices that have been followed from 2011 to present, which are described in detail in Appendix E:

Internal Quality Control:

- Staffing the project with experienced/trained individuals,
- Providing representative, meaningful data through planning and efficient research,
- Use of standard protocols for sample collection, preservation, and documentation,
- Regular calibration and maintenance of all field equipment, and
- Collection of duplicate, blank, filter and travel blank samples for submission for analysis (approximately 10% of overall samples).

External Quality Control:

- Employment of fully accredited analytical laboratories for the analysis of all samples, and
- Determination of analytical precision and accuracy through the interpretation of the analysis reports for the blind duplicate, blank, filter and travel blank samples.

The quality of project data was assessed based on the performance of the data when compared to the pre-set data quality objectives (DQOs). DQOs provide a means of assessing the QA/QC data and determining whether the data in question are precise, accurate, representative, and complete. The results from QA/QC samples were reviewed to determine if sample contamination occurred, and these data were further used to determine if the contamination occurred during collection, handling, storage, or shipping. Upon receipt from the laboratory the data were uploaded into the FULCRUM data management system, along with copies of field notes, photos, Sample Receipt Confirmations, Microsoft Excel data, and Certificates of Analysis. The data were then routinely reviewed, based on the following considerations:

- Duplicate sample analytical results,
- Blank sample analytical results,
- Total and dissolved metals comparison,
- Ion balance,
- Data validation,
- Detection limits,
- Analytical precision, and
- Analytical accuracy.

The DQOs and the results of the QA/QC program are described in detail in Appendix E.

3 – RESULTS

3.1 2013 HYDROGEOLOGY SITE INVESTIGATION

3.1.1 Drilling and Monitoring Well Installations

Eleven monitoring wells were completed at six locations during the 2013 site investigation. Paired monitoring wells were installed at five locations to support estimation of vertical hydraulic gradients and maximize monitoring zones (BC MOE 2012). MW13-01D/S and MW13-02D/S were installed using HT drill rods and the overburden was cased using HWT size rods. The remaining seven drillholes were drilled using HWT drill rods and the overburden was cased using PW size rods. Based on availability of materials at the site, eight monitoring wells were constructed using Schedule 40 PVC (MW13-01S/D, MW13-02S/D, MW13-03S/D, and MW13-04S/D). The remaining three monitoring wells were constructed using Schedule 80 PVC. Monitoring well installation details are summarized in Table 3.1. Monitoring well locations are shown on Figure 3.1.

Drillhole depths varied from approximately 15 to 50 meters below ground surface (mbgs). Monitoring well screens were 3 m long and the top of monitoring well screen placement ranged from 10 m to 46 mbgs. In general, the most permeable zone observed during drilling was selected as the depth at which to place the screen, with subsurface lithology, fracture spacing and degree of weathering taken into account. Drillhole logs and monitoring well installation details are provided in Appendix A1. Geologic logs of drill core provided by CMC are included in Appendix A2.

The overburden encountered during drilling generally consisted of silty and gravelly sands. Overburden ranged in thickness from about 0.6 m to 7 m and was interpreted to be colluvium at all drillholes except MW13-02D/S. Sandy and gravelly material was recovered from the full depth of drillholes MW13-02D/S, advanced to a maximum depth of 30 mbgs. The origin of the material in drillholes MW13-02D/S was interpreted to be a fault zone; however, the deposit may be alluvial in origin given the proximity of these drillholes to Canadian Creek. Poor recovery of subsurface material for the entire length of both drillholes made logging and classification of the subsurface material difficult. Based on the recovered samples, subsurface material at drillholes MW13-02D/S was described as silty sand with cobbles and gravels with weathered and oxidized surfaces.

Bedrock encountered during drilling consisted of granodiorite and quartzite. Bedrock was described as weathered at the bottom of all drillholes except MW13-01D and MW13-03D, where bedrock at the bottom of the drillhole was described as competent. Fault zones up to 3 m thick were encountered in drillholes MW13-01S/D and a narrow shear interval (0.2 m) was encountered at the bottom of drillhole MW13-03D.

The following observations during drilling and monitoring well installation indicated that permafrost was present at MW13-01D/S, MW13-02D/S and MW13-03D/S:

- A 2 cm thick ice lens was observed in rock core sampled from approximately 10 mbgs in drillhole MW13-01D. The water column in both MW13-01D and MW13-01S froze before the 2013 drilling program was completed.
- Water level recovery measured during pauses while drilling at MW13-02D/S was negligible or slow at depths above 10 mbgs and was rapid below 10 mbgs. The base of permafrost at these drillholes was inferred to be 10 mbgs based on the change in water level recovery in the drillholes.

- The drill rods started to freeze to the walls of drillholes MW13-03D/S. The rods freezing complicated the installation of monitoring well MW13-03D.

No indications of permafrost were noted at drillholes MW13-04D/S, MW13-05, or MW13-06D/S during drilling and monitoring well installation. Ice was not observed in drill core retrieved from any drillhole locations other than MW13-01D.

3.1.2 Monitoring Well Development (2013 Monitoring Wells)

Eight of the eleven monitoring wells were developed using the methods described above. The column of water in monitoring wells MW13-01D/S froze within 20 days of installation and these wells could not be developed. Development of MW13-02S has been attempted over multiple site visits but has not been successfully completed due to an inflow of silt/sand through the well screen. Turbidity of water purged from MW13-02S remained above the recommended turbidity for groundwater sample collection.

Relatively high pH (above 9) was measured during well development at two locations, MW13-03D and MW13-04D, and likely indicates contamination from a bentonite or cement source. Slow groundwater recharge rates to these wells made development difficult. Efforts were made to purge as much water as possible from these monitoring wells to improve water quality, including purging the well completely dry. The pH remained above expected background levels at these wells.

Results of the monitoring well development are summarized in Table 3.2.

3.1.3 Response Testing

Response testing was carried out at nine of the eleven monitoring wells installed in 2013. Hydraulic conductivity values estimated from testing ranged from less than $1x10^{-8}$ m/s to $2x10^{-4}$ m/s. A response test was not conducted at monitoring well MW13-01S since the well is screened within permafrost or at MW13-02D since the well requires further development.

The water columns in monitoring wells MW13-01D and MW13-03S were thawed during the July 2014 site visit and a hydraulic conductivity was estimated using the water level recovery in the well following purging. Results of hydraulic conductivity testing at MW13-01D and MW13-03S were $<1x10^{-8}$ m/s and $2x10^{-8}$ m/s, respectively. The presence of frozen ground conditions are expected to reduce the hydraulic conductivity of the test interval and the results are not considered representative of formation conditions. Response test analyses at MW13-01D and MW13-03S are presented in Appendix C for qualitative purposes only and the hydraulic conductivity values are not included in Table 3.1.

Hydraulic conductivity values are summarized in Table 3.1 and response test analyses are presented in Appendix C.

3.2 2013 – 2014 DATA COLLECTION PROGRAM

Baseline hydrogeology data were collected during six site visits to the Project in 2013 and 2014. Data collected during these site visits are discussed in the sections that follow and include groundwater level monitoring, ground temperature monitoring, re-development of select historic monitoring wells and groundwater quality sampling.

3.2.1 Groundwater Levels

Manual water levels have been collected in monitoring wells and standpipe piezometers on site using a water level tape during all groundwater sampling events, after well installation/development and before and after response testing. Manual water levels measured at the 2013 monitoring wells soon after installation are presented in Table 3.1. All historic manual water level measurements at standpipes and monitoring wells across the site are presented in Appendix C1.

Pressure transducers were fitted in all 11 monitoring wells installed in 2013. Pressure transducers are also installed in seven additional monitoring wells across the project site and have been collecting water level data since 2010. Pressure transducers were removed from all wells in September 2012 by a third party consultant contracted to CMC and were re-installed in the monitoring wells in June 2013. Plots of long-term groundwater elevation data at the monitoring wells up to October 2014 are presented in Appendix C2. Transducer water level data collected at monitoring well MW13-06S is not included in Appendix C2 as the transducer was either unsaturated or suspect to be malfunctioning during the site visits. The transducer was replaced in September 2014.

Continuous water level data have been collected at six vibrating wire piezometers (VWPs) on site since 2009. A plot showing groundwater elevations calculated at the six VWPs is provided in Appendix C3.

3.2.2 Ground Temperature Data

Ground temperature data were collected from ten thermistor strings and six VWPs on site. In addition to the thermistor sites reported in the 2012 baseline report (KP 2013), two 10-node thermistor strings were installed as part of the 2013 geotechnical site investigation program (KP 2014). A summary of current thermistor installations is presented in Table 3.3 and includes details on permafrost presence and depth to the base of permafrost at each site. The depth of the active layer at thermistor locations, which is the uppermost layer of ground which freezes in the winter and thaws in the summer, is also included in Table 3.3. Plots of temperature versus time and temperature versus depth are presented in Appendix D1 for each thermistor string installation.

Temperature data were additionally recorded at temperature sensors at the six VWPs installed on site. Temperature data collected from the VWPs is presented in Appendix D2.

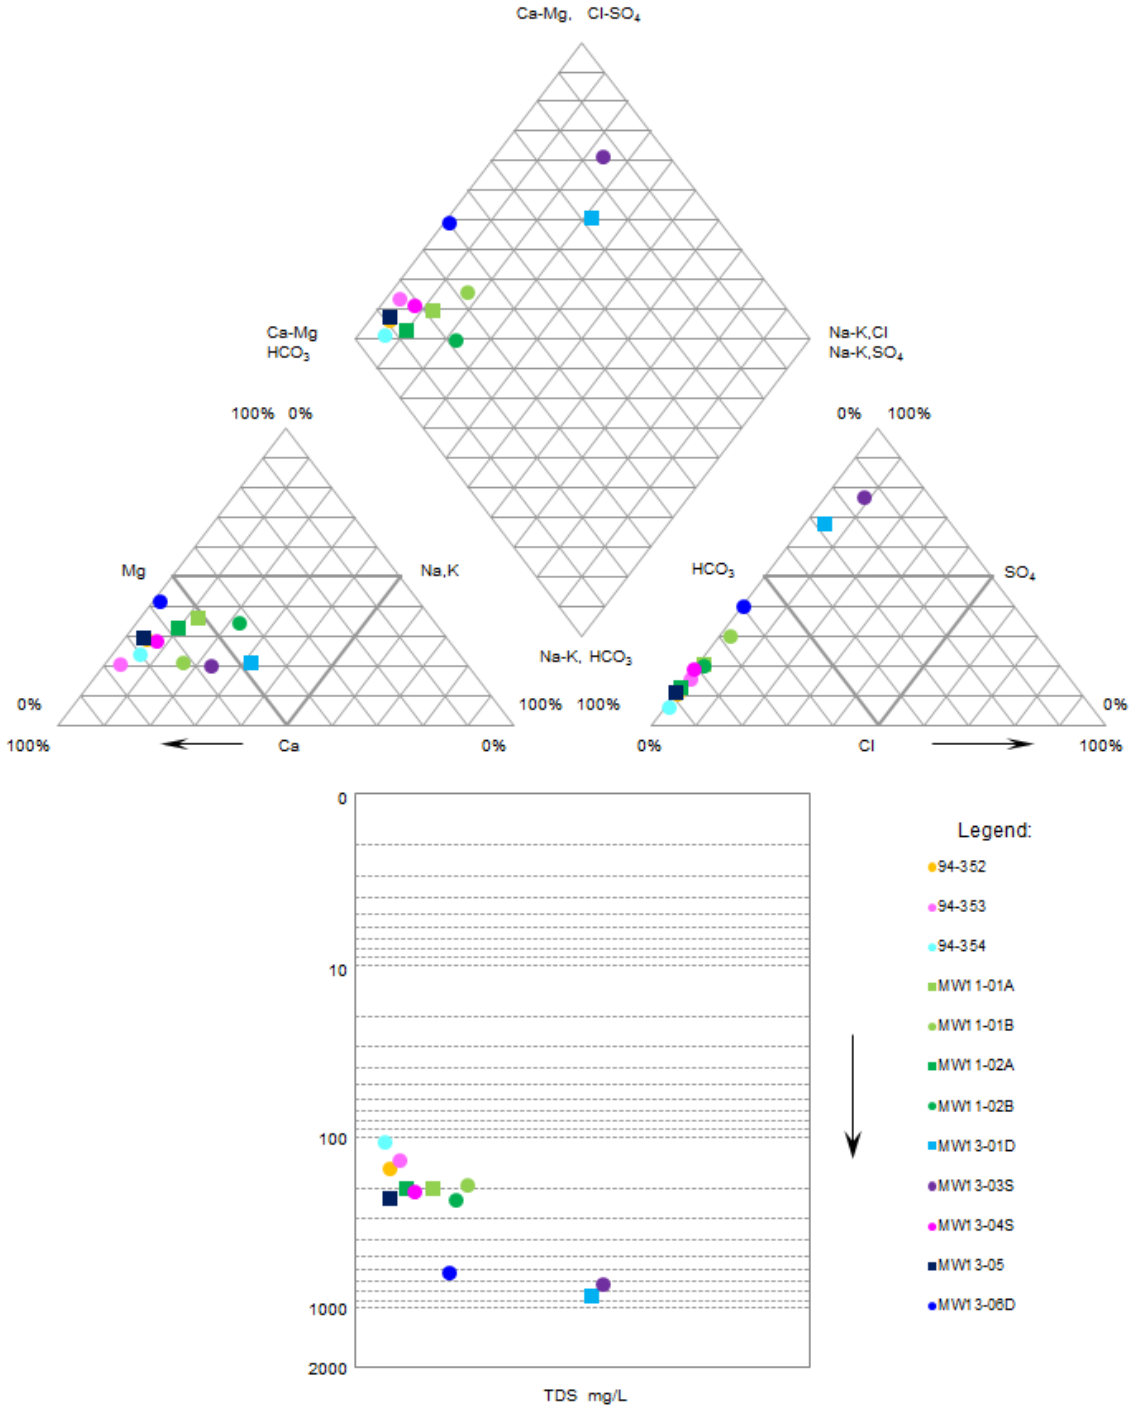
3.2.3 Monitoring Well Development (Monitoring Wells Installed Prior to 2013)

Groundwater samples have been collected by various consultants since the program began in 1993 and sampling and development methods have not always been clearly documented. It has been assumed that the groundwater sampling methods have been in accordance with the best practices for the time that they were sampled and likely ranged from hand or mechanical pump purging methods (three well volume) to low flow / minimum drawdowns (submersible pumps) methods. Turbidity is generally a good indicator of sample condition and higher turbidity samples tend to arise when pumping rates are greater than the natural flow through the screened interval of the well and sediments in the well are mobilized. Turbid conditions can also be an indicator that the wells were not sufficiently developed. The majority of the groundwater sample collected from monitoring wells prior to 2013 reported turbidity values below 50 NTU. Monitoring wells that reported groundwater sample turbidity values higher than 50 NTU even when sampled using the low flow submersible pumps were re-developed in the summer of 2013. Monitoring wells HG10-01, HG10-04, and MW11-02A were re-developed in June 2013 and MW11-02B was re-developed in September 2014. Results of the monitoring well development are presented on Table 3.2.

3.2.4 Groundwater Quality

Baseline analytical and *in situ* data have been compared to the relevant water quality guidelines for the Project. Data tables with guideline comparisons are provided in Appendix F. The data tables are inclusive of all data collected from 1994 to 2014; however, the QA/QC analysis (Appendix E) is limited to the data collected in 2013 and 2014. The QA/QC of preceding data are provided in the 2012 Baseline Hydrogeology Report (KP 2013). To remain consistent with the format of the previous report, data are presented by project area: Open Pit area, hillslope area, and Casino Creek valley area.



Piper diagrams were used to assist in characterizing groundwater quality in the project area and to compare major water types. A Piper diagram is a trilinear plot of the relative concentrations of the major dissolved ions in water, which provides a visual interpretation of the similarities and differences in the water throughout the project area. Piper diagrams were prepared for each of the three main project areas, using average analytical results for all samples collected from 1994 through 2014 from each monitoring site for major anion (bicarbonate, chloride, and sulphate) and cation (calcium, magnesium, sodium, and potassium) concentrations. These diagrams are provided on Figure 3.2 (Open Pit area), Figure 3.3 (hillslope area), and Figure 3.4 (Casino Creek Valley area). Piper diagrams showing individual samples for each well are provided in Appendix G.

NOTES:

1. DATA USED FOR THIS PLOT ARE AVERAGE VALUES.
2. PIPER DATA ARE PLOTTED IN PERCENT MILLI-EQUIVALENTS PER LITRE (%meq/L).
3. TOTAL ALKALINITY WAS USED FOR BICARBONATE VALUE, IF REQUIRED.

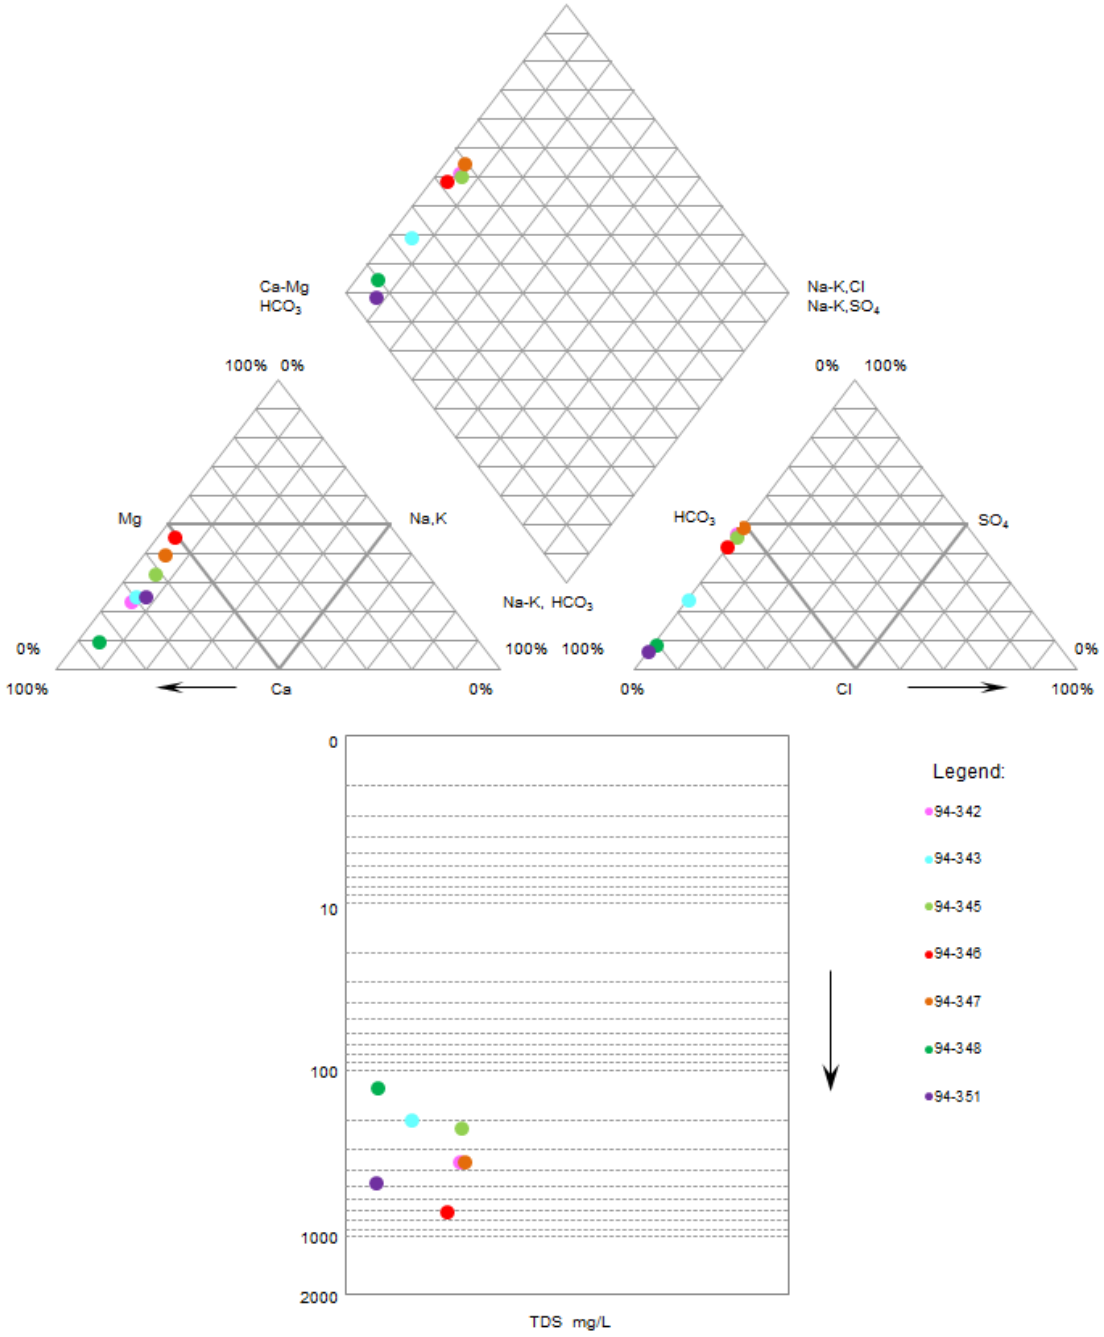


Figure 3.2 Trilinear Piper Diagram – Open Pit Area

NOTES:

1. DATA USED FOR THIS PLOT ARE AVERAGE VALUES.
2. PIPER DATA ARE PLOTTED IN PERCENT MILLI-EQUIVALENTS PER LITRE (%meq/L).
3. 94-352 DATA FOR 1994 AND 1995 WERE EXCLUDED.

Figure 3.3 Trilinear Piper Diagram – Hillslope Area

NOTES:

1. DATA USED FOR THIS PLOT ARE AVERAGE VALUES.
2. PIPER DATA ARE PLOTTED IN PERCENT MILLI-EQUIVALENTS PER LITRE (%meq/L).
3. GROUNDWATER CHEMISTRY DATA FOR SAMPLES COLLECTED PRIOR TO 2008 WERE EXCLUDED FOR THE CHARACTERIZATION OF 94-342 AND 94-345.

DRILLHOLE AND MONITORING WELL COMPLETION LOGS

(Pages A1-1 to A1-11)

Project:	**CASINO PROJECT**	Drill Hole No.	**MW13-01D**	**PAGE**	1 of 1
Contractor:	**Kluane Drilling Ltd.**	In Situ Sampler:	**N/A**	Date Started:	**5 Jun 13**
Location:	**Supergene Ox / Low Grade Ore Stockpile**	Total Depth:	**41.2 m**	Date Completed:	**6 Jun 13**
Coordinates:	**6,957,455 N, 611,804 E, UTM NAD83**	Elevation:	**1149 m**	Date Well Installed:	**6 Jun 13**
Drilling Rig:	**KD1000 Exploration**	"Inclination":	**-90°**	Logged by:	**KTD/CAS**
Drilling Method:	**Diamond Coring**	Hole size:	**0.091 m**	Reviewed by:	**CAS**

NOTES

Cased with HWT rods (0.114 m OD) to 7.62 mbgs.

Water level measured 27 June 2013, Frozen at 2.6 mbgs

2 cm ice lense observed at 10.2 mbgs

Stopped drilling to check water level at 29 m. Water level measured at 15.1 m and slowly rising.

GENERAL REMARKS:

COORDINATES WERE SURVEYED BY YUKON ENGINEERING SERVICES IN SEPT 2013.

REV. 1 - Issued with Report

ELVATION - (m)	DEPTH - (m)	GRAPHIC LOG	
			SILTY SAND, FROZEN (0 m to 1.2 m) Angular, fine to coarse grained, well graded, brown, wet
			SAND AND SILT, FROZEN (1.2 m to 4.6 m) Angular, fine to coarse grained, well graded, frozen (Residual Soil)
1145	5		**WEATHERED WRGD** (4.6 m to 9.1 m) Dawson Range Batholith - Granodiorite, coarse grained, mottled white and grey, strong to very strong, moderately to highly weathered, joint spacing close to moderately close oriented at 45° and 80° with orange oxide on joint surfaces.
1140	10		**FAULT ZONE** (9.1 m to 13.6 m) Fault zone, highly fractured to <10 cm pieces, clay altered with orange oxide staining
1135	15		**WEATHERED WRGD** (13.6 m to 15.2 m) Dawson Range Batholith - Granodiorite, coarse grained, mottled white and grey, strong to very strong, orange oxidation of joints, slight to moderate weathering, calcite and quartz infilled veins. **END OF HOLE - 15.2 m**

NOTES

Cased with HWT rods (0.114 m OD) to 4.57 mbgs

Water level measured June 27, 2013, Frozen at 2.4 mbgs

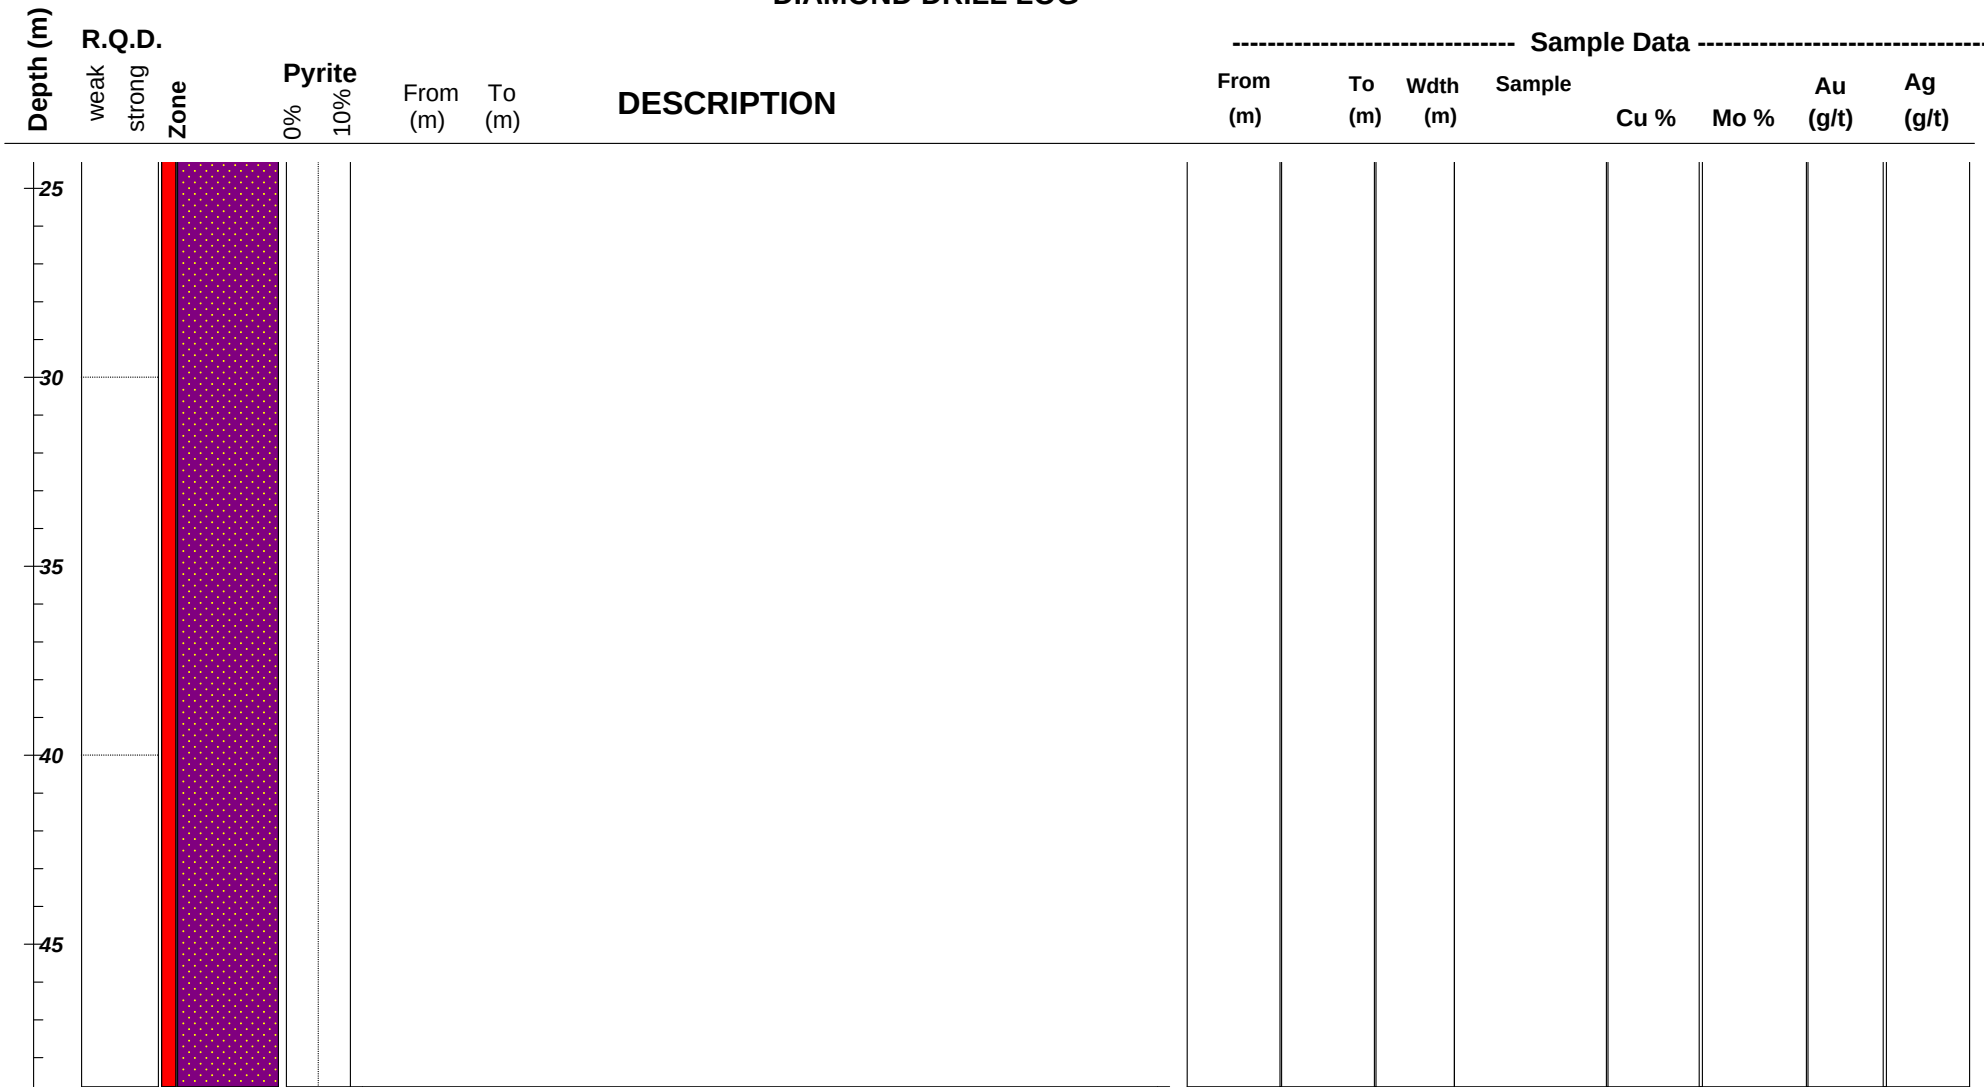
R.Q.D. weak strong | Zone | Pyrite 0% 10% | From (m) | To (m)

DESCRIPTION

0.00, 2.90 OVB: Overburden. Very little recovery, minor rounded pebbles.

2.90, 15.70 YMQT: Meta-sedimetary rock, Quartzite. Intensely weathered and fractured, bleached and limonite stained.



15.70, 48.77 YMQT: Meta-sedimentary rock, Quartzite. jBecomes more competent and less weathered. Blue-grey to white-grey, variably bedded, laminated meta-seds. Bedding variable, with folds, but at a high angle to core axis. Iron oxide on fractures decreases down hole. No sulphides.

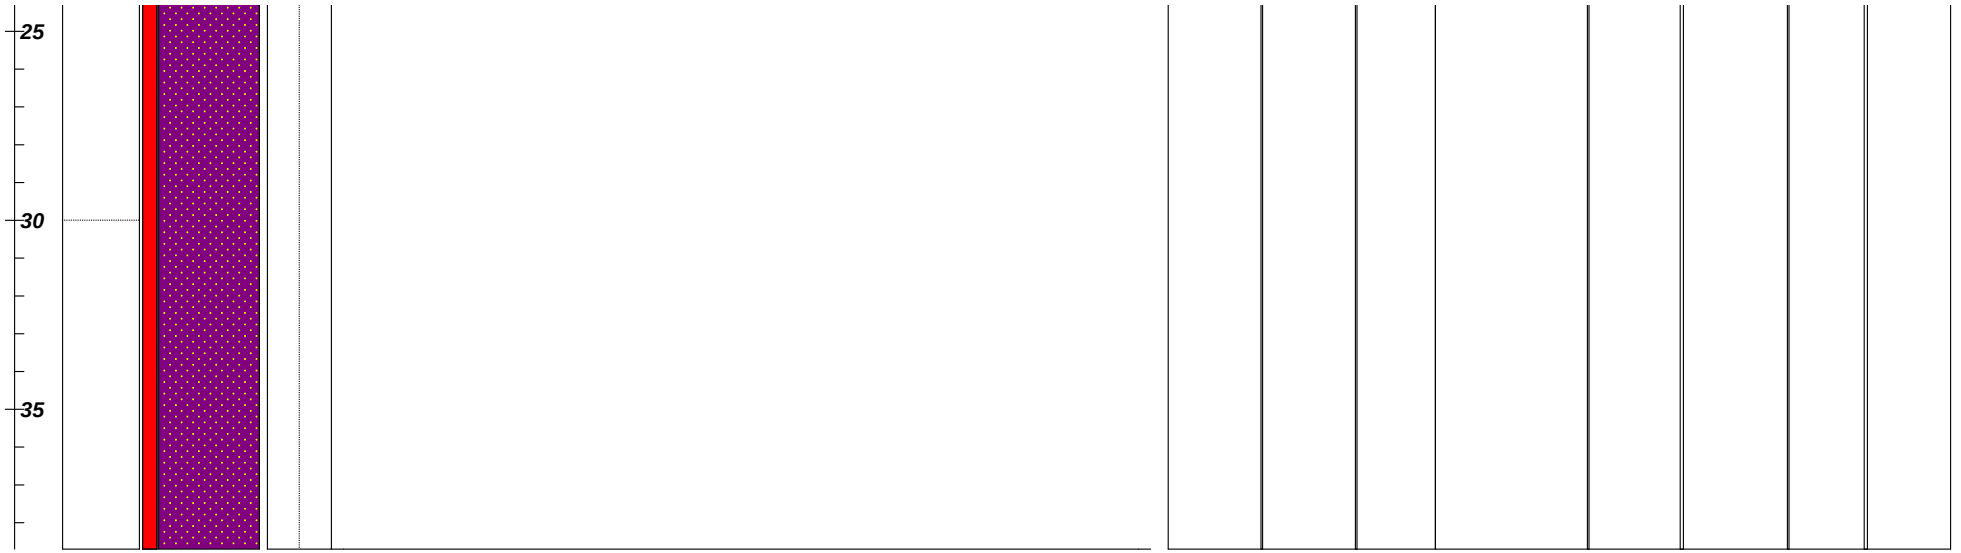
0.00, 2.75 OVB: Overburden - no recovery

2.75, 11.92 YMQT: Quartzite/silicified siltstone. Intensely fractured to pieces < 10 cm long. Slightly bleached and iron stained.



11.29, 38.70 YMQT: Quartzite/silicified siltstone. variably oxidized and iron stained. Folded and brecciated, obvious evidence of tectonism. Traces of pyrite deeper down hole towards the bottom. Becomes more competent and less iron oxide towards bottom.

Hydraulic Conductivity, K	<1E-8	**m/s**	H/H_o Intercept	1.00

TEST COMMENTS: The water column in the well was thawed in order to sample the well and the test analysis is based on water level recovery following sampling. The well was sampled 1.5 hour priors to conducting the slug test and a 3L slug of water was injected to the well at the test start time. Manually measured water level was 27m below the top of PVC at the test start time. The water level recovery over the monitored interval suggests that test results may be influenced by frozen conditions around the screen. Results are provided for qualitative purposes only in order to document the slow water level recovery.

Hydraulic Conductivity, K	2E-04 **m/s**	H/H_o Intercept	1.0

TEST COMMENTS: The water level response may be limited by filter pack surrounding the screen and the hydrauilc conductivity may be higher than estimated.

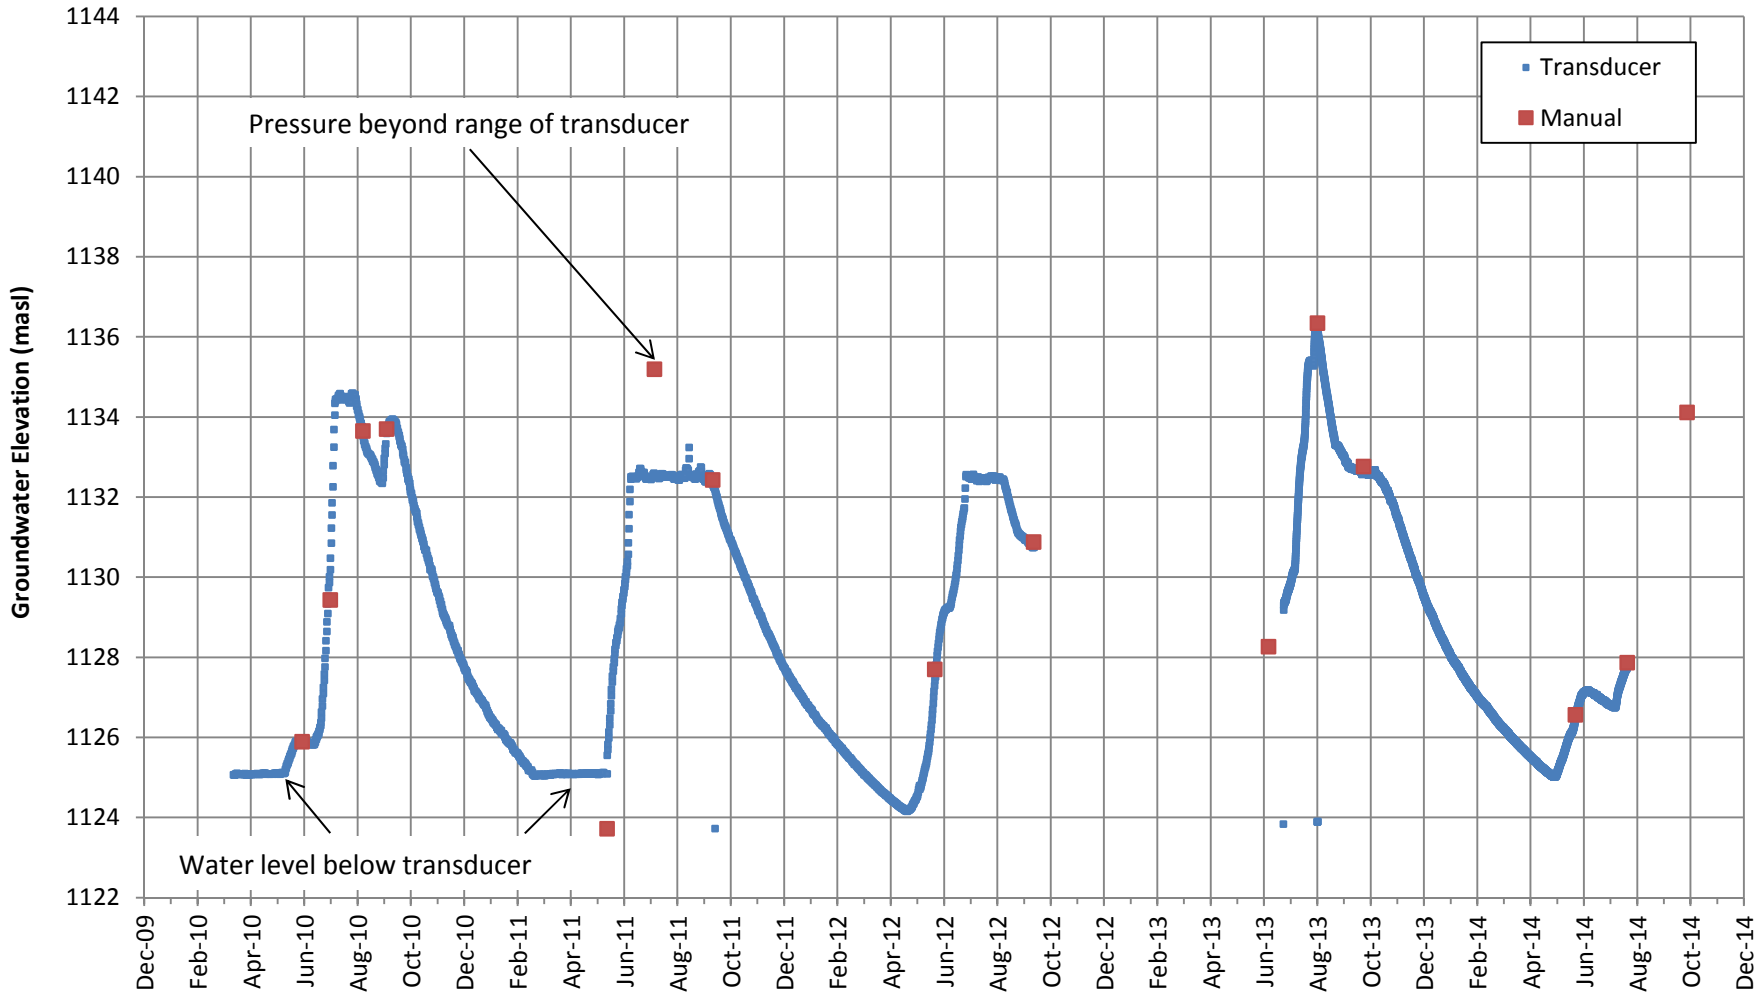
M:\2010\03\20117A\Data\Task 200 - 2011 Hydrogeology Addendum\1- Water level\Manual Water Level\[TABLE C1 - Measured GW levels and elevations.xlsx]C1- GW levels

NOTES:



1. 2011, 2012 AND 2013 LOCATIONS WERE SURVEYED BY YUKON ENGINEERING SERVICES IN SEPTEMBER 2013. COORDINATES PRESENTED IN UTM NAD83 ZONE 7.
2. ANGLED PIEZOMETER, DEPTHS ARE MEASURED ALONG HOLE.
3. mbPVC: METERS BELOW TOP OF PVC.
4. mbgs: METERS BELOW GROUND SURFACE.
5. DRY: DRY WELL.
6. F: FROZEN WELL.
7. atop: ABOVE TOP OF PIPE
8. OPEN BOREHOLE, DEPTH IS MEASURED FROM GROUND SURFACE.
9. B: BLOCKED.
10. WATER LEVEL MEASURED IMMEDIATELY AFTER WELL INSTALLATION AND MAY NOT REPRESENT STATIC WATER LEVEL CONDITIONS.
11. THE WELL MAY BE DAMAGED AND THE WATER LEVEL MAY NOT BE REPRESENTATIVE OF HYDROLOGIC CONDITIONS AT THE SCREEN DEPTH.
12. WATER LEVEL MEASUREMENT IS NOTICABLY DIFFERENT THAN PREVIOUS MEASUREMENTS.

APPENDIX C2

TIME-SERIES MEASUREMENTS FROM PRESSURE TRANSDUCERS

(Pages C2-1 to C2-14)

NOTES:

1. GROUND SURFACE ELEVATION IS 1142.8 m.
2. THE WELL IS SCREENED BETWEEN 1110.2 masl AND 1107.1 masl.
3. TRANSDUCER WAS INSTALLED AT 1125.3 masl UNTIL MAY 22, 2011 WHEN THE TRANSDUCER WAS LOWERED 2 m TO 1123.3 masl.
4. THE TRANSDUCER WAS REMOVED FROM THE WELL IN SEPTEMBER 2012 AND WAS REPLACED WITH A TRANSDUCER WITH A GREATER RANGE OF MEASUREMENT JUNE 2013 .
5. TRANSDUCER WAS TEMPORARILY REMOVED FROM THE WELL BETWEEN JULY AND OCTOBER 2014.

GROUNDWATER QUALITY – QUALITY ASSURANCE/QUALITY CONTROL

(Pages E-1 to E-16)

APPENDIX E – 2013 QUALITY ASSURANCE AND QUALITY CONTROL ANALYSIS

1 – OVERVIEW

The quality assurance and quality control (QA/QC) analysis within Appendix F includes review of data collected from June 2013 onwards. This appendix builds on the previous QA/QC reports generated for earlier data (Table E.1). As stated in the 2012 Baseline Hydrogeology Report (KP Ref. No. VA101-325/14-4), groundwater samples have been collected by various consultants and sub-consultants since the program began in 1993 and sampling methods have not been clearly documented. This report will detail the methods used to collect sample data from June 2013 onwards.

The quality of the data obtained for a project is assessed via adherence to a set of pre-defined data quality objectives (DQOs) for the project. DQOs provide a means of assessing whether the data in question are precise, accurate, representative, and complete. This 2013 QA/QC analysis covers three areas of operations: field data collection, laboratory analysis and office data management.

The results from QA/QC samples are reviewed to determine if sample contamination occurred. The data for any contaminated samples are then reviewed to determine if the contamination occurred during collection, handling, storage, shipping, or analysis.

The QA/QC Protocol and DQOs were compiled with reference to the following Canadian guidance documents:

- Guidance Document for the Sampling and Analysis of Metal Mining Effluents (Environment Canada, 2011).
- Canadian Council of Ministers of the Environment (CCME) Protocols Manual for Water Quality Sampling in Canada (CCME, 2011). This document is based on the Alberta and British Columbia sampling manuals (Alberta Environment, 2006; BC MWLAP, 2003).

Procedures for each area of operations are summarized in Section 2 and are described in detail within the internal manuals and during staff training to ensure the proper collection, analysis, and management of data that will meet the DQOs. A summary of the results obtained during the QA/QC analysis are provided in Section 3.

Table E.1 Historic Quality Assurance and Quality Control Reports

Data Range	Primary Consultant	Location of QA/QC Analysis
June 2012 – Current	Knight Piésold	Current Appendix
2011- June 2012	Knight Piésold	Appendix F1: 2012 Baseline Hydrogeology Report (KP Report VA101-325/14-4 Rev 1)
1993-2011	AECOM	Appendix G1: 2012 Baseline Hydrogeology Report (KP Report VA101-325/14-4 Rev 1)

2 – PROCEDURES

2.1 FIELD DATA COLLECTION QA/QC PROCEDURES

2.1.1 Equipment

Field water quality meters (YSI6820 or YSI6920) for measuring *in situ* parameters are rented from Pine Environmental, where they are maintained and calibrated between water sampling events. Each YSI is calibrated daily for dissolved oxygen and, in cases where water quality sampling events take more than two days, each YSI is recalibrated every three days for other *in situ* parameters using standard solutions specific to each parameter (i.e. pH, turbidity, conductivity, and ORP). The YSI is recalibrated more often if parameter readings are suspect (ex. pH values that are inconsistent with the rest of the data for a given monitoring well).

All equipment used in water quality sampling is rinsed or cleaned with a shop towel between sites. Each YSI is rinsed with distilled water or well water between sites for the collection of surface water samples. The YSI is stored overnight in a sheltered environment. Equipment used for processing samples (i.e gloves, filters, and syringes) is disposable and new packaged equipment is used at each site.

2.1.2 Field Procedures

Specific work instructions were provided in KP sampling manuals, which were based on the CCME Protocols Manual for Water Quality Sampling in Canada (CCME, 2011), as well as office presentations, and on-the-job training. All staff engaged in this work were required to read the sampling manuals prior to conducting any water or sediment quality work on-site. Staff were also required to work with more experienced personnel during their first site visit.

Field notes and *in situ* data were recorded on waterproof paper. At the end of each day, field personnel checked their field notes and sample labels to ensure that no samples were missing and that notes were complete. The laboratories provided protocols for sample labelling, preservation, and shipment. Bottles and preservatives were shipped with labels, chain of custody (COC) forms, and specific instructions. Water quality samples were labelled with their actual site name rather than an identification code since the samples are re-labelled by the lab prior to analysis.

2.1.3 QA/QC Samples

The repeatability and reliability of sample results was evaluated by submitting duplicate water samples, field blanks, and travel blanks for the same parameters for which the primary samples are analyzed. This allows for the detection and reduction of errors that may occur due to contamination of samples. The QA/QC samples conformed to standard sampling methods, outlined by the CCME and were labelled as QA/QC samples because the laboratory adds their own labels upon sample receipt (CCME, 2011). Details regarding each type of QA/QC sample are outlined below:

Duplicate Samples - The purpose of a duplicate sample is to estimate sampling and laboratory analytical precision. At least one duplicate sample is collected for every sampling event and the total number of duplicate samples is maintained at least 10% of the total number of samples. Duplicate samples are the same as their primary sample in collection and handling and are collected at the same time or a few minutes apart from their primary sample.

Field Blank Sample - The purpose of a field blank is to identify potential sources of contamination with preservatives, field filtration, sample handling or transportation, as well as any potential contamination from analytical procedures. Field blanks were prepared from distilled/deionized water provided by the laboratory. The distilled/deionized water was added to sample bottles using the same field techniques as other samples, including field filtration and field preservation. The DDW is filtered and preserved using the same methods as for sampling site groundwater.

Travel Blank Sample - The purpose of a travel blank is to identify potential sources of contamination associated with sample containers, shipping, storage, and analysis. These samples are prepared by the laboratory with distilled/deionized water and are never opened. Travel blanks travel with the sample bottles sent from the laboratory to the field site, and back to the laboratory.

2.2 EXTERNAL LABORATORY ANALYSIS QA/QC PROCEDURES

ALS Environmental (ALS) was retained for the analysis of the samples collected from the project site. ALS is an accredited laboratory for water quality analysis with rigorous internal QA/QC procedures. In the event of a failed internal QA/QC test, both laboratories re-run all analyses affected by the same factors as the failed internal QA/QC sample.

Sample integrity issues are highlighted on the sample receipt confirmation (SRC) reports that were provided to Knight Piésold Ltd. in a timely manner following receipt of samples at the laboratory. Where sample integrity issues were identified, the laboratories and Knight Piésold Ltd. followed up to provide corrective actions or clarity.

2.3 OFFICE DATA MANAGEMENT QA/QC PROCEDURES

The FULCRUM data management system is used to organize and store data received from ALS laboratories. In FULCRUM, data are transferred electronically into the database through the use of electronic data files.

Upon receipt of laboratory results, several data validation checks are conducted and any QA/QC issues are recorded in a tracking document. If the QA/QC results do not meet the DQOs, results associated with the QA/QC samples in question are flagged and further inspected. If the issue with the QA/QC sample is determined to potentially affect the validity of the sample results associated with it, data are rejected. Rejected results are not used in the statistical analysis of the data, but are presented in Appendix B with the rest of the data. Data are also rejected when the QA/QC issue indicates that the analytical result is not representative of the sample (ex. the blank sample is contaminated and the primary sample contains elevated concentrations of the same parameter that was observed in the blank sample). Data rejected due to potential contamination concerns are excluded from the final data tables and summary statistics. The validation checks used to determine whether data should be qualified are outlined below:

Hold time exceedances – hold time exceedances occur when the time period between the sample collection time and the sample analysis time is greater than the recommended maximum holding time. These time frames range from 0.25 hr to 6 months and represent the maximum length of time that should not be exceeded or sample degradation may occur. Reasons for hold time exceedances are determined and wherever possible revised to prevent future exceedances. The validity of the results is determined on a case by case basis. Where the holding time exceedance was significant and likely to have an effect on the quality of the result, the results were rejected.

Sample Blanks – results of blank samples are used to assess the potential sources of contamination associated with the sample containers, preservatives, and sample handling and transportation, as well as any potential contamination from the analytical procedures. For each batch of samples collected in the field, at least one field blank and one travel blank sample was analyzed. Blank sample results are flagged if any analyte exceeds the method detection limit (MDL). The sample blank data are assessed and any MDL exceedances are noted and investigated to determine the source of error. Field sampling and handling procedures may be modified to prevent similar errors from occurring in future sampling events. Blank sample results that exceed five times the MDL are considered invalid. In these cases, all site sample analyses associated with the blank sample in question are rejected unless the detected concentration in the blank is significantly (i.e. one order of magnitude) lower than the concentrations observed in the samples. Blank sample results that are greater than the MDL, but lower than five times the MDL may not always indicate potential contamination because of the uncertainty of results near the MDL. These values usually result in discussions with the lab about uncertainty. The decision matrix used to assess the QA/QC results are provided in Table E.2.

Table E.2 Decision Matrix for Flagged Blank Samples

Case	Travel Blank	Field Blank (unfiltered)	Field Blank (filtered)	Likely Cause	Actions Taken
1	>5xMDL	>5xMDL	>5xMDL	Contamination during transport, storage, or analysis of samples.	If the results were greater than 10% of the average of the results for samples collected on site, data were rejected.
2	>MDL	>MDL	>MDL	Some uncertainty associated with the MDL and the analysis.	Data were accepted, but the lab was consulted for a discussion on the uncertainty.
3	>5xMDL	-	-	Contamination at the laboratory or contamination of DDW	Discussions with laboratory on potential contamination of DDW. Results were accepted.
4	-	>5xMDL	-	Contamination due to sampling procedures or leaching from bottles.	See Case 1
5	-	-	>5xMDL	Contamination due to filters or filtering process.	See Case 1
6	>5xMDL	>5xMDL	-	Potential contamination of DDW, contamination from the bottles, or a combination of contamination sources.	See Case 1
7		>5xMDL	>5xMDL	Contamination due to sampling methods or contaminated DDW water.	See Case 1
8	>5xMDL		>5xMDL	Contamination from two sources.	See Case 1

Duplicate Samples – duplicate samples are used to estimate sampling and laboratory precision. Analytical results obtained for two samples collected from the same site at the same time are flagged if the relative percent difference (RPD) is greater than 20% and the measured concentrations are greater than five times the MDL. The RPD is the absolute difference in concentrations of the two duplicate samples divided by the average of the two values. Flagged results are further reviewed and to determine whether the high RPD is a result of naturally variable conditions or sampling error. If the latter case is suspected, efforts are made to prevent similar errors from occurring in the future and results associated with the result in question may be rejected. If the high RPD is most likely a result of natural variability in the water body from which the duplicate samples are collected, flagged data are noted as a point of discussion, but are not rejected.

Detection Limits – detection limits are examined on a regular basis to ensure that they coincide with guideline limits. If detection limits exceed the guideline limits, the laboratory is contacted and efforts are made to adjust the analytical procedures to achieve lower detection limits. Detection limits are often increased due to sample matrix interference and all efforts are made to adjust methodology, though results may not improve.

Dissolved and Total Metals Concentrations – dissolved and totals metal concentrations in all site samples are compared and flagged if the reported concentration of a dissolved metal was greater than reported concentration of the total metal. These sample results are further investigated and if the sample concentration exceeds five times the MDL and RPD between the total metal and the dissolved metal is greater than 30%.

2.3.1 Data Analysis

Data from FULCRUM was used for statistical calculations. Results that are below the MDL are set to equal the MDL for the statistical analysis. *In situ* and laboratory results are compared with previous results for the same sites and with expected data trends. Any data outliers are confirmed with the laboratory for validity. Results that do not fit within the realistic expected range are flagged and may be rejected if the likely cause of the discrepancy is determined to be a methodology error. For all analytes, annual statistics and monthly mean values are calculated. Several of the calculations are checked at random using a calculator to proof the Excel spreadsheet calculations.

3 – RESULTS

QA/QC results are used to verify data and identify any data that should be rejected. These results are divided into two categories: procedural results and results of the analysis of QA/QC samples. Procedural results included the analysis of field, laboratory, and office procedures that were part of the QA/QC process. Results of the analysis of the QA/QC samples are quantitative results that were used to identify specific data that did not meet the DQOs.

A total of 74 samples were collected since June 2013, including 11 blank samples and six duplicate samples; QA/QC samples represent 22% of the total. A summary of the samples collected is shown in Table E.3.

Table E.3 Summary of Samples Collected

Site ID	2013			2014			Total Samples
	Jun	Aug	Sep/Oct	May	Jul	Sep/Oct	
94-337	1	1	1	1	1	1	6
94-347	-	-	-	-	-	1	1
94-352	-	-	-	-	1	1	2
94-354	-	-	-	-	1	-	1
HG10-01	1	1	1	1	1	1	6
HG10-02	-	1	1	1	1	1	5
HG10-04	1	1	1	1	1	1	6
MW11-02A	1	1	1	1	1	1	6
MW11-02B	1	1	1	1	1	1	6
MW13-01D	-	-	-	-	1	-	1
MW13-02D	-	1	1	-	1	1	4
MW13-02S	-	1	1	-	1	-	3
MW13-03S	-	1	-	-	1	-	2
MW13-04S	-	1	1	1	1	1	5
MW13-05	-	1	1	1	1	1	5
MW13-06D	-	1	1	-	1	1	4

Camp Well	-	-	-	-	1	-	1
WR Well	-	-	-	-	1	-	1

NOTES:

1. SAMPLES SHOWN ON THIS TABLE INDICATE SAMPLING EVENTS AND DO NOT INCLUDE QA/QC SAMPLES.
2. ONE DUPLICATE AND ONE FIELD BLANK SAMPLE WERE COLLECTED FOR EACH OF THE SIX SITE VISITS.
2. A TOTAL OF FIVE TRAVEL BLANK SAMPLES WERE ANALYSED.

3.1 OPERATIONAL QA/QC RESULTS

Issues related to field, laboratory, or office procedures that could affect the validity of the data collected were flagged and evaluated in a QA/QC tracking document. If the issue was likely to affect the integrity of the data, the data was rejected.

3.1.1 Field Operations

3.1.1.1 Field Equipment

Field equipment was maintained either in the field or at Pine Environmental, where equipment was rented. In-situ probes were calibrated at Pine Environmental prior to shipping to site. Calibration records have been stored with the field notes. Dissolved oxygen was calibrated on site at the beginning of each sampling event and every time the atmospheric pressure or elevation of the sampling site changed significantly. Other parameters were recalibrated every three to five days, or when the probes detected readings that were unexpected and did not fit within the range of other samples collected from the same site. Probes were rinsed with distilled water or surface water between sampling sites. All other equipment used in sampling (ex. syringes, filters, gloves) was disposable and new equipment was used at each site.

3.1.1.2 Field Procedures

Site specific challenges, including permafrost, low water levels, damaged wells, and very low groundwater recharge rates, resulted in the need to use alternative groundwater sampling methods to collect samples from some wells. The quality of data collected using the alternative methods is not equal to that collected using the standard minimum drawdown or low recharge methods; however, these methods were used only when conditions made it impossible to collect groundwater samples using a submersible pump. The samples collected are not considered to be as representative of the baseline groundwater as the samples collected using the standard methods; however, the results may be used to support conclusions if specific considerations are made to the QA/QC analysis of such samples. The following samples, collected using alternative methods, should be flagged for potential QA/QC issues:

- MW13-03S (August 2013): this sample was collected several days after development and was not purged sufficiently for the standard methods due to low recharge. The water type of this sample is defined as containing more sulphate and less bicarbonate than other samples collected from the hillslope area.
- MW13-03S (July 2014): the well was frozen upon arrival and was thawed using hot tap water. The tap water was then purged using a foot valve and HDPE tubing until the water level was at the top of the screen. The water level was left to recover overnight before a sample was collected using a bailer. The water type of this sample is similar to that of other samples collected from the hillslope area, but is different from the other sample collected from the same well (August 2013). This July 2014 sample was collected using unconventional methods and is likely to represent a combination of groundwater and residual hot tap water. The sample was excluded from the dataset based on the metals analysis (see Section 3.2.3 – Metals Analysis).
- MW13-01D (July 2014): the well was frozen upon arrival and was thawed using hot tap water. The tap water was then purged using a foot valve and HDPE tubing until the water level was at the top of the screen. The water level recovered very slowly and a sample was collected a few

days later, after minimal recharge. The water type of this sample contains less bicarbonate and calcium and more sulphate than other samples collected from the hillslope area.

3.1.1.3 Monitoring Wells Excluded from Groundwater Quality Characterization Program

The pH of the water from monitoring wells MW13-04D and MW13-03D was high after well development and grout contamination is suspected. The low recharge rates of these wells poses a challenge for further well development; it is unlikely that further development could result in the clearing of the grout contamination. Data associated with samples collected from these wells have been excluded from the data set and samples are not proposed to be collected in future sampling events.

Permafrost conditions were observed in the vicinity of monitoring wells MW13-03S and MW13-01D and the wells were frozen when sampling was attempted in July 2014. The wells were thawed using hot tap water, which was purged prior to sampling; however, the low recharge conditions of these wells did not allow for sufficient purging. The sample quality for MW13-03S was poor and the July 2014 sample was rejected, as describe further in section 3.2.3 of this QA/QC summary. The sample quality for MW13-01D did not get flagged through the assessment of the DQOs, however, the sampling technique was similar to that used to collect the sample from monitoring well MW13-03S, and future sampling of both of these wells is not recommended.

3.1.2 Laboratory Operations

ALS has their own internal QA/QC methods for verifying data. Laboratory QA/QC results were reported for matrix spikes, method blanks, laboratory control samples, reference materials, and duplicates/replicates. ALS laboratory reports also provided details regarding sampling hold times.

3.1.2.1 Laboratory Qualifiers

Very few of the results reported by the laboratories were categorized as rejected. In most cases where data were flagged by the laboratory, the issue resulted in an adjustment of the MDL and did not result in the exclusion of results from the statistical analysis. Reasons for the MDL adjustment included the requirement of further dilution of samples prior to analysis, the detection of an analyte in the Method Blank, and sample matrix effects.

3.1.3 Office Data Management Operations

In the office, all *in situ* data and laboratory results from ALS laboratories were entered into FULCRUM. This task was completed by the field personnel who collected the samples and the entered data was checked regularly by other staff members. On the few occasions where an error in data entry was noted, the error was most commonly a unit conversion error. In these cases, the field personnel were informed of the non-conformance and the error was corrected.

3.2 QA/QC SAMPLE RESULTS

3.2.1 Blank Samples

Very few blank sample analyses were flagged. A summary of flagged blank sample results is shown in Table E.4 and all field blank and travel blank analytical results are shown in Table E.7 and Table

E.8, respectively. The flagged travel blank results indicate possible ammonia contamination at the laboratory or contamination of the DDI water. The latter is a more likely possibility, since laboratory contamination was checked with laboratory QA/QC protocols, which did not indicate contamination of ammonia. Dissolved organic carbon had a detectable concentration within the May 25, 2014 field blank. This detectable concentration is suspected to be as a result of the filtration device used for the dissolved samples, since the total samples are unaffected. The corrective action was to use a different filtering apparatus for future sampling.

Table E.4 Flagged Blank Results

Analyte (MDL)	Date	Blank Concentration (mg/L)	MDL (mg/L)	Holding Time	Type of Blank Sample
Ammonia	10-Jun-13	0.0121	0.005	28 days	Travel Blank
	26-Sep-13	0.0138	0.005		Travel Blank
	26-Sep-13	0.0238	0.005		Travel Blank
Dissolved Organic Carbon	25-May-14	0.01	0.5	28 days	Field Blank

NOTES:

1. THIS TABLE INCLUDES ONLY BLANK RESULTS WITH DETECTABLE CONCENTRATIONS.

3.2.2 Duplicate Samples

A summary of duplicate sample results for which the relative percent difference (RPD) between samples was greater than 20%, where one or both sample concentrations was greater than five times the MDL are listed in Table E.5. All duplicate analytical results from ALS Laboratories are shown in

Table E.9. A total of five duplicates were collected since June 2013. Each duplicate tested between 92 to 102 parameters. Over 450 individual samples were queried, and seven analytes reported RPDs in excess of 20%.

There are several possible reasons for duplicate sample RPDs exceeding 20%. Natural variability in groundwater quality data indicates the possibility that certain wells are not achieving a uniform steady state. Inconsistent sampling methods are another possibility.

All data associated with duplicate samples exceeding the acceptable RPD of 20% for analyses that were greater than five times the MDL were flagged and further examined. Two wells had more than one analyte that exceeded the acceptable RPD (HG10-04 and HG10-02). One sampling event (June 22, 2013) was responsible for three of the seven duplicates with elevated RPDs and a second sampling event (August 5, 2013) was responsible for two of the seven elevated duplicates. It is likely that the minimal variability shown in the duplicate data is both as a result of natural variability within groundwater, and inconsistencies in sampling methodology. Neither the site sample data nor the site data associated with the flagged duplicates were removed from the dataset used in the statistical analysis of results.

Table E.5 Flagged Groundwater Quality Duplicate Results

Site	Parameter	Date	Sample Concentrations		RPD (%)
			Sample	Duplicate	
HG10-04	Turbidity (NTU)	22-Jun-13	3.58	6.42	57%
	Total Aluminum (mg/L)	05-Aug-13	0.56	0.38	117%
	Total Lead (mg/L)	05-Aug-13	0.021	0.0054	117%
HG10-02	Sulphate (mg/L)	22-Jul-13	836	82.1	164%
	Total Zinc (mg/L)	22-Jul-13	0.087	0.05	54%
HG10-01	Turbidity (NTU)	23-May-13	2.32	8.53	115%
94-337	Total Lead (mg/L)	26-Sep-13	0.0037	0.0015	83%
MW13-04S	Lithium (Dissolved)	30-Sep-14	0.00623	0.00303	69%
	Manganese (Dissolved)		0.000537	0.000425	23%
	Molybdenum (Dissolved)		0.000841	0.00057	38%
	Potassium (Dissolved)		2.59	1.6	47%
	Sodium (Dissolved)		9.03	4.69	63%
	Manganese (Total)		0.000827	0.00109	27%

NOTES:

1. DUPLICATE SAMPLES WERE FLAGGED WHEN THE RPD WAS GREATER THAN 20% AND CONCENTRATIONS WERE GREATER THAN FIVE TIMES THE MDL.

3.2.3 Metals Analysis

Relative percent differences between total and dissolved metals concentrations were calculated for samples for which the dissolved concentrations of metals exceeded total concentrations of the same metals and one or both concentrations exceeded five times the MDL. Data were flagged when the RPD was greater than 20%. In cases where the flagged analytical result was different from the rest of the dataset (e.g., total concentration was lower and dissolved concentration was higher than the other data), both the total and dissolved data were rejected. A summary of the sample analyses that

were flagged is shown in Table E.6. Most of the flagged metals analyses were observed in the sample collected from MW13-03S in July, 2014 and are likely related to the unconventional methods used in sampling this well (see Section 3.1.1.2 – Field Procedures). Monitoring well MW13-03S is installed in a permafrost area and was frozen at the time of sampling. The ice inside the well was thawed using hot tap water, which was purged prior to sampling; however, the low recharge conditions of this well did not allow for sufficient purging. The sample likely represents a combination of tap water and groundwater. In addition, the sample was collected using a bailer because a low flow pump could not fit inside the well. The use of bailers can increase the turbidity in the well and stir sediments at the bottom. This could have resulted in a non-uniform sample, which would account for the discrepancies between total and dissolved metals. The data for the sample collected from MW13-03S in July, 2014 has been rejected for these two reasons.

Table E.6 Flagged Metals Analyses

Site	Date	Analyte	MDL	Dissolved	Total	RPD
94-352	30/09/2014	Zinc (Zn)	0.001	0.0139	0.0106	27%
94-352	30/07/2014	Zinc (Zn)	0.001	0.0185	0.0127	37%
MW13-03S	28/07/2014	Strontium (Sr)	0.0002	0.461	0.337	31%
MW13-03S	28/07/2014	Uranium (U)	0.00001	0.00869	0.00564	43%
MW13-03S	28/07/2014	Sodium (Na)	0.05	79	49.6	46%
MW13-03S	28/07/2014	Magnesium (Mg)	0.1	39.5	19.2	69%
MW13-03S	28/07/2014	Manganese (Mn)	0.00005	4.71	1.66	96%
MW13-03S	28/07/2014	Nickel (Ni)	0.0005	0.0252	0.00871	97%
MW13-03S	28/07/2014	Cobalt (Co)	0.0001	0.0162	0.00333	132%
MW13-03S	28/07/2014	Sulphur (S)	0.5	124	13.4	161%
MW13-03S	28/07/2014	Zinc (Zn)	0.001	0.527	0.0461	168%
MW13-04S	30/09/2014	Molybdenum (Mo)	0.00005	0.000841	0.000564	39%
MW13-04S	30/09/2014	Sodium (Na)	0.05	9.03	4.61	65%
MW13-04S	30/09/2014	Potassium (K)	0.1	2.59	1.31	66%

NOTES:

1. UNITS ARE mg/L UNLESS STATED OTHERWISE.
2. RESULTS ARE SHOWN FOR SAMPLES FOR WHICH A DISSOLVED METAL CONCENTRATION EXCEEDED THE TOTAL CONCENTRATION BY MORE THAN 20% AND THE CONCENTRATION EXCEEDED FIVE TIMES THE MDL.

M:\1\01\00325\17\A\Report\1-2013 Hydrogeology\Appendices\Appendix F - Groundwater Quality Data Tables\[Tables F1-F4 - Updated2014.xlsx]F1 - GUIDELINES AND STANDARDS

NOTES:

1. UNITS ARE IN mg/L UNLESS OTHERWISE STATED.
2. CCME - CANADIAN COUNCIL OF MINSTERS FOR THE ENVIRONMENT - CANADIAN ENVIRONMENTAL QUALITY GUIDELINES - WATER QUALITY GUIDELINE FOR THE PROTECTION OF AQUATIC LIFE (CEQG-PAL) - FRESHWATER.
3. YCSR - YUKON CONTAMINATED SITES REGULATION - GENERIC NUMERICAL WATER STANDARDS - SCHEDULE 3 - COLUMN 2 - YUKON ENVIRONMENT ACT (O.I.C. 2002/171).
4. YCSR AQUATIC LIFE STANDARDS ASSUME A MINIMUM 1:10 DILUTION IS AVAILABLE.
5. HARDNESS (H) DEPENDENT GUIDELINE LIMIT (DISSOLVED).
6. pH DEPENDENT GUIDELINE LIMIT (*IN SITU* VALUE PREFFERED).
7. TEMPERATURE DEPENDENT GUIDELINE LIMIT.
8. CHLORIDE (DISSOLVED) DEPENDENT GUIDELINE LIMIT.
9. Cr III (TRIVALENT CHROMIUM) GUIDELINES WERE ASSUMED FOR COMPARISON TO THE GROUNDWATER CHEMISTRY DATA.
10. STE - SHORT TERM EXPOSURE LIMIT.
11. LTE - LONG-TERM EXPOSURE LIMIT.
12. THIS SHADING INDICATES THAT THE VALUE EXCEEDS THE CCME LIMIT.
13. THIS SHADING INDICATES THAT THE VALUE EXCEEDS THE LIMITS OF THE YCSR.
14. THIS SHADING INDICATES THAT THE VALUE EXCEEDS BOTH THE CCME AND YCSR LIMITS.
15. ITALICIZED TEXT INDICATES SAMPLES THAT WERE COLLECTED IN 2013 AND 2014.

APPENDIX A.7N: Extension of Numerical Groundwater Modelling to include Dip Creek Watershed

February 20, 2015

File No.:VA101-00325/17
Cont. No.:VA15-01965

Ms. Mary Mioska
Senior Environmental Manager
Casino Mining Corporation
570 Granville Street, Suite 1800
Vancouver, British Columbia
Canada, V6C 3P1

Dear Mary,

Re: Extension of Numerical Groundwater Modelling to Include Dip Creek Watershed, Casino Project

1 – INTRODUCTION

Knight Piésold Ltd. (KP) was contracted in 2013 by Casino Mining Corporation (CMC) to develop a series of numerical groundwater models for the Casino Project (the Project) to assess baseline hydrogeological conditions and to evaluate potential effects of mine development on baseline hydrogeological conditions. Numerical model development and results of the modelling are presented in the Numerical Groundwater Modelling Report (KP 2013a). One of the primary objectives of the study was to delineate potential seepage pathways and estimate seepage flow rates from the proposed Tailings Management Facility (TMF). The area encompassed in the groundwater models included the Casino Creek watershed and the Canadian and Britannia Creek watersheds extending to their point of confluence. The completed models and study findings were submitted as Appendix 7E of the Casino Mine Project proposal to the Yukon Environmental and Socio-economic Assessment Board (YESAB) in January 2014.

Subsequent to submission of the proposal, Natural Resources Canada (NRCan) was invited by YESAB to provide comments on the adequacy of the information contained in the proposal. NRCan's comments were provided to CMC in a letter titled *Adequacy Review – Casino Mine Project (Project No. 2014-0002): NR Can Comments*. Comment 13 d) in NRCan's letter states that,

"The Proponent should provide:

Numerical groundwater flow modelling that extends into the Dip Creek watershed and eliminates the assumption of a no-flow boundary. Modelling should consider the potential for sub-permafrost groundwater flow across the topographic divide. Modelling the seepage from the TMF should consider three dimensional flow from the TMF in order to consider not only vertical flow through or beneath the dam but also horizontal flow around the dam and potentially into Dip Creek tributaries."

To assess the potential for TMF seepage to flow through the watershed divide between Casino and Dip Creek watersheds, the numerical groundwater models presented in KP (2013a) were extended to include a portion of Dip Creek watershed in the modelled domain. A seepage assessment was then completed using the revised models. The modelling work was updated with the following steps:

1. The calibrated Baseline Model was extended to include a portion of the Dip Creek watershed.
2. The goodness-of-fit between simulated and observed hydraulic head and baseflow targets in the revised baseline model was checked. Hydraulic head and baseflow results from the revised baseline model were also compared against the original Baseline Model.
3. A Year 22 Mine Effects model was developed in order to complete the seepage assessment. The Year 22 Mine Effects model was developed by telescopically refining the revised baseline model to a region surrounding the mine site that included the Dip Creek watershed. The Year 22 model was selected for the seepage assessment because it represents the last year of mine operations and is expected to have the

highest TMF Supernatant Pond elevation and tailings elevation. The Supernatant Pond will subsequently be drawn down after Year 22 to build a wetland on top of the TMF.

4. A MODPATH particle trace analysis was completed to assess the potential for TMF seepage to flow through the ridge between Casino and Dip Creek watersheds. The sensitivity of TMF seepage to travel through the ridge to Dip Creek watershed was assessed by varying the hydraulic conductivity value assigned to the upper bedrock unit.

Development of the revised baseline and Year 22 Mine Effects models and seepage assessment results are presented below.

2 – BASELINE NUMERICAL MODEL

2.1 OVERVIEW

The Baseline Model presented in KP (2013a) was extended to include a portion of the Dip Creek Watershed in the model domain. The model grid, parameter values, and boundary conditions assigned to the area of the original Baseline Model remained unchanged in the revised baseline model. Boundary conditions and model parameters assigned to the model area extended into the Dip Creek Watershed are discussed below. The revised model domain is presented on Figure 2.1.

2.2 BASELINE MODEL GEOMETRY AND GRID

The revised baseline model encompasses an area of 224 km^2 with the Casino Project site located at its center as shown on Figure 2.1. The model domain extends north to include the Canadian and Britannia Creek watersheds to their point of confluence. The model domain extends south to include the confluence of Casino Creek with Dip Creek and east to include the eastern portion of the Dip Creek watershed.

The model grid was modified to include an additional two rows at the southern end of the model for a total of 153 rows and 122 columns. These two additional rows were added in order to extend the model domain south to the confluence of Dip and Casino Creeks. Vertical discretization of the revised baseline model remained unchanged from KP (2013a) and included four model layers that increased in thickness with depth. Cell size similarly remained unchanged and was 100 m by 100 m within the mine site and expanded to 200 m by 200 m at the edges of the model. The revised baseline model domain contained a total of a total of 73,932 cells, approximately 45,000 of which were active. The revised baseline model finite-difference grid is shown on Figure 2.1.

2.3 HYDRAULIC CONDUCTIVITY

Hydraulic conductivity zones assigned to bedrock layers in the original model area were extended laterally into the Dip Creek watershed. Alluvial deposits were assigned to the modelled Dip Creek watershed area according to surficial geologic mapping completed for the project (KP 2012). Alluvial deposits were assigned to model layer 1 and were assigned a hydraulic conductivity value of $1x10^{-5}$ m/s to match the alluvial zones in Casino, Canadian and Britannia Creek valleys. Plan and section views of the hydraulic conductivity zones for the revised model are presented on Figure 2.2. Hydraulic conductivity values assigned to the baseline model are presented in Table 3.1 in KP (2013a).

2.4 BOUNDARY CONDITIONS

The following boundary conditions were assigned in the model area extension into Dip Creek watershed:

1. No-flow boundaries along the model perimeter
2. Constant head boundaries to represent stream stage where a stream crossed the model boundary
3. Drain cells to represent creeks, and
4. Meteoric recharge.

Boundary conditions assigned to the revised baseline model domain are shown in Figure 2.1. Each boundary type assigned within the Dip Creek watershed model area is discussed in the subsections that follow. Further detail on boundary conditions assigned to the original baseline model domain is provided in KP (2013a).

2.4.1 No-Flow Boundary Conditions

The eastern boundary of the model was defined as a topographic ridge that separates two tributary sub-catchments to Dip Creek. The ridge was represented as a no-flow boundary based on the assumption that relatively steep topography at the site will cause groundwater divides to be the same as surface water divides, therefore groundwater flow across the ridge is not expected.

2.4.2 Constant Head Boundary Conditions

Constant head boundary conditions were specified along the channel alignment of Dip Creek and define the southeastern perimeter of the model as shown on Figure 2.1. Constant head cells were assigned an elevation equal to 1 meter below the ground surface of a given grid cell.

2.4.3 Drain Boundary Conditions

Drain boundary cells were used to represent five tributaries of Dip Creek within the extended model domain. Drain cells were assigned to stream channels in Layer 1 and drain stages were set as 1 meter below the ground surface of each grid cell. The rate of groundwater flux across a drain is dependent on a streambed conductance coefficient which is often a calibrated model parameter. Since streamflow measurements within the Dip Creek watershed were unavailable to use in calibration, Dip Creek tributaries were assigned conductance coefficients of approximately 10 m^2/day in order to be consistent with calibrated conductance values assigned in the original baseline model.

2.4.4 Meteoric Recharge

Recharge was specified to the extended model domain using the same methodology as the original baseline model domain presented in KP (2013a). Two groundwater recharge zones were defined based on inferred regions of permafrost and non-permafrost as presented in the 2012 Baseline Hydrogeology Report (KP 2013b). Regions of the model surface characterized as permafrost zones were assumed to have zero groundwater recharge. Non-permafrost regions were assigned a recharge rate of 124 mm/yr, which was the recharge value that provided the best fit between simulated and observed hydraulic heads and baseflows during calibration of the original baseline model. The spatial distribution of the two groundwater recharge zones applied to the baseline model is illustrated on Figure 2.3.

2.5 MODEL CALIBRATION

The baseline model was not re-calibrated and all parameter values assigned to the revised baseline model remained the same as values assigned in the original baseline model. Calibration of the extended model domain was not conducted since hydraulic head and baseflow measurements were unavailable to serve as calibration targets within this new area of the model.

The goodness-of-fit fit between simulated and observed hydraulic heads and baseflows at calibration targets was checked following construction of the revised model. Comparison of model simulated and observed hydraulic heads at the 17 calibration target locations in the revised baseline model is provided in Table 2.1. Comparison of simulated and observed baseflows at the six calibration target locations is provided in Table 2.2. Differences in simulated hydraulic heads and baseflows between the original and revised model were negligible and are discussed further in Section 2.6.

2.6 BASELINE MODEL RESULTS

A water table contour map for the revised baseline model is presented in Figure 2.5. The simulated water table generally mimics the surface topography with groundwater elevations ranging from 1,450 masl in the high

elevation region to the west of the mine site to 645 masl and 500 masl at the downstream extents of Casino Creek and Canadian/Britannia Creeks, respectively. Well-defined groundwater flow divides exist between the Casino and Canadian/Britannia Creek watersheds and along the ridgeline between Casino and Dip Creek watersheds where the newly added model domain meets the original model domain. Groundwater elevations along the ridgeline between Casino and Dip Creeks range from approximately 1,225 masl at the upper most extent to approximately 975 masl across from the eastern extent of the TMF Embankment.

Extending the modelled area to include a portion of Dip Creek watershed had a very minor effect on simulated hydraulic heads along the watershed divide between Casino and Canadian/Britannia Creek. Visual comparison between simulated hydraulic heads in the revised and original baseline models indicate that simulated water levels in the revised model along this watershed divide near and east of the deposit decreased slightly (as observed at the 1,150 m contour). Simulated hydraulic heads at calibration targets represented by monitoring wells HG10-04 and 94-337 located in within the proposed Open Pit near the divide decreased slightly from the original model (by approximately 0.1 meters and 0.2 meters, respectively; Table 2.1). Simulated water levels at monitoring well 94-350 and 94-351 locations in the lower reaches of Casino Creek watershed also decreased slightly (by approximately 0.2 meters and 0.7 meters, respectively). Simulated hydraulic heads remained unchanged from the original model at the other 13 calibration targets represented in the model. Simulated baseflow values at the six baseflow targets (hydrology stations) changed negligibly (<1 L/s) from values predicted using the original model in KP (2013a).

The revised baseline model simulates the same baseline groundwater flow system as that presented in KP (2013a). Where present, differences in simulated hydraulic heads and baseflows between the original and revised baseline models are minor. These differences are attributed to the change in boundary condition along the border to Dip Creek watershed as well as minor differences in the spatial distribution of properties that are assigned by importing GIS shapefiles, such as recharge.

3 – MINE EFFECTS (YEAR 22) NUMERICAL MODEL

3.1 OVERVIEW

The Year 22 Mine Effects model from KP (2013a) was updated in order to extend the model domain into the Dip Creek watershed. The model grid, hydraulic properties, boundary conditions, and representation of proposed mine facilities remained unchanged from the values and methodology presented in KP (2013a). Development and results of the Year 22 model are presented in the sections that follow.

3.2 YEAR 22 MINE EFFECTS MODEL DEVELOPMENT

The Year 22 Mine Effects model presented in KP (2013a) was initially developed by telescopically refining, or “cutting out”, a section of the Baseline Model domain centered on the mine site. This approach generates and assigns constant head boundary conditions along the perimeter of the telescopically refined model domain at locations where boundary conditions are not already assigned at perimeter cells. The constant head values are assigned to cells during the telescopic mesh refinement (TMR) based on the piezometric head distribution of the baseline model. This approach allows the Year 22 model to function independently of the regional Baseline Model. The boundary conditions, hydraulic properties and model grid were transferred directly from the regional Baseline Model to the telescopically refined Year 22 model.

The Year 22 Mine Effects model was updated as part of this work by re-generating the telescopically refined mesh using the revised baseline model as the parent model. The northern extent of the Year 22 model was refined during the TMR while the southern extent of the Year 22 model was the same as the revised baseline model. A constant head boundary condition was assigned along the northern model perimeter in all model layers as shown in Figure 3.1. As in the original model, the revised Year 22 model includes four additional layers added to the top of the model (Facilities Layers 1 through 4) to allow for the TMF to be specified in three-

dimensions. The model grid, layering and boundary conditions for the revised Year 22 model are presented in Figure 3.1.

Representation of major mine facilities in the revised Year 22 model was identical to the original Year 22 model presented in KP (2013a).

3.3 YEAR 22 MINE EFFECTS MODEL RESULTS

A simulated water table contour map from the revised Year 22 model is provided on Figure 3.2. Comparison of predicted water table contours in the Year 22 and baseline model indicate that groundwater elevations surrounding the TMF Supernatant Pond are predicted to increase adjacent to the TMF as supernatant water elevation in the TMF increases. Model results indicate the presence of a groundwater divide along the ridgeline separating Casino and Dip Creek watersheds. Groundwater to the northwest of the divide is expected to flow to the TMF or Casino Creek watersheds while groundwater to the southeast is expected to flow towards Dip Creek.

4 – TMF MODPATH SEEPAGE ASSESSMENT

4.1 MODPATH SEEPAGE ASSESSMENT

MODPATH particle tracking (Pollok 1994) was completed using the revised Year 22 model to delineate potential seepage pathways from the TMF. The main objective of the MODPATH simulation was to assess the potential for TMF seepage to travel through the ridgeline separating Casino and Dip Creek watersheds to the southeast of the TMF Embankment.

MODPATH particles were placed in all cells in the TMF Supernatant Pond and tailings beach (Facilities Layers 1 through 4) and particles were tracked forward indefinitely through the groundwater flow system to determine their discharge locations. MODPATH results are sensitive to specification of the “sink strength” input parameter, which defines the termination criterion for particle traces flowing through boundary cells. All MODPATH scenarios presented herein adopt a “stop at 50 percent strength” weak sink option to discontinue particle traces in boundary cells, meaning that the particle trace stops if the boundary condition removes 50 percent or more of the water in the cell. Conceptually this means that the model terminates a particle trace in a cell if >50% of the water in the cell is removed.

The MODPATH analysis using the revised baseline model indicates that seepage from the TMF is not expected to flow southeast through the ridgeline divide into the Dip Creek watershed. As in the original Year 22 model, the majority of seepage from the TMF is expected to flow southwest through the TMF Main Embankment or underlying foundation materials to discharge to the embankment drains or up-gradient of the TMF seepage collection pond. A small amount of unrecoverable seepage, approximately 7% of particle traces, is expected to discharge to Brynelson Creek and report to Casino Creek down-gradient of the seepage collection pond. The particle traces resulting from the TMF MODPATH simulation are presented in Figure 4.1.

4.2 SEEPAGE SENSITIVITY ANALYSIS

The sensitivity of simulated TMF seepage pathways to hydraulic conductivity was assessed by systematically varying the hydraulic conductivity value assigned to the weathered bedrock in Layers 1 through 5. For each sensitivity simulation, MODFLOW and MODPATH were re-run to generate a new set of particle traces defining predicted seepage pathways from the TMF. A predicted rate of seepage was calculated using the following steps for sensitivity scenarios with particle traces that travelled from the TMF to the Dip Creek watershed:

- A hydrostratigraphic unit (HSU) was defined in the TMF model area in Layers 1 through 4 outlining particle traces that were predicted to originate in the TMF and discharge to the Dip Creek watershed.
- The predicted rate of seepage to Dip Creek watershed was calculated using a water budget approach with the defined HSUs.
- The total foundation seepage rate for each sensitivity case was quantified using the HSUs defined in the original Year 22 model (KP 2013a) representing Non-PAG tailings, PAG tailings and waste rock in the TMF.

Results of the sensitivity analysis are presented on Figure 5.1. TMF seepage was not predicted to travel to Dip Creek watershed when the weathered bedrock was assigned a hydraulic conductivity value of $1x10^{-6}$ m/s or less. For hydraulic conductivity values greater than $1x10^{-6}$ m/s, simulated seepage rates to Dip Creek increased according to the trend shown on Figure 5.1. A hydraulic conductivity value of $2x10^{-6}$ m/s assigned to the weathered bedrock resulted in a seepage rate to Dip Creek watershed of less than 0.1 L/s or less than 0.1% of the total foundation seepage (52 L/s). Sensitivity simulations with the hydraulic conductivity value increased to $5x10^{-6}$ m/s and 1 $x10^{-5}$ m/s resulted in seepage rates to Dip Creek of 3.8 L/s and 12.1 L/s, respectively.

5 – CONCLUSIONS AND RECOMMENDATIONS

The Baseline and Year 22 groundwater models presented in KP (2013a) were revised to include a portion of the Dip Creek watershed within the active model domain. The objective of the model expansion was to assess the potential for seepage from the TMF through the ridge separating Casino and Dip Creeks to the southeast of the facility. MODPATH simulations completed for the TMF indicate that seepage is not expected to flow through the ridgeline divide into the Dip Creek watershed using the base case model.

The model parameters assigned to the Dip Creek watershed were not calibrated and assume that average hydrogeologic properties within this area are similar to those within the calibrated portion of the model. Based on results of the sensitivity assessment, seepage may travel to Dip Creek watershed if the bulk hydraulic conductivity of the weathered bedrock is higher than $1x10^{-6}$ m/s. This bulk hydraulic conductivity value is an order of magnitude higher than the calibrated hydraulic conductivity of the weathered bedrock unit in the base case baseline model. Available site data suggests that a hydraulic conductivity greater than $1x10^{-6}$ m/s is possible within localized zones across the Project but is considered high as a bulk hydraulic conductivity value. Based on bedrock geology mapping, geology in the ridge east of the proposed TMF Embankment consists of granodiorite (Ryan et al. 2013). Approximately 12% of the available 187 hydraulic conductivity tests conducted in the granodiorite unit across the site reported a hydraulic conductivity value of $2x10^{-6}$ m/s or higher (KP 2013b). The simulated water table depth within the east ridge was approximately 75 meters below ground surface (mbgs) using a hydraulic conductivity of $1x10^{-7}$ m/s. Water level data is not available along the ridge to compare against this estimated depth, but available baseline water levels from monitoring wells installed in 2013 along mid- to upper-slopes of the east side of the TMF valley (MW13-05 and MW13-06D/S) are approximately 30 to 40 mbgs. The simulated depth to water using the revised baseline model is approximately the same at MW13-05 and two times deeper than the measured water table at MW13-06D/S.

Please do not hesitate to contact the undersigned with any questions or comments.

A.8A EMISSIONS INVENTORY FOR CONSTRUCTION AND OPERATIONS

A.8A.1 CONSTRUCTION PHASE AIR EMISSIONS INVENTORY

The Casino project air emissions inventory was compiled from the feasibility study (M3 2013) and preliminary engineering design information provided in the Proposal for the Casino Project submitted by Casino Mining Corporation on January 3, 2014 to YESAB. The essential information was obtained from the following sections of the feasibility study:

- Mine production schedule;
- Mine major equipment fleet requirements;
- Project Schedule section 24.1.12; and
- Project Infrastructure Layouts.

Emissions of criteria air contaminants (CACs) associated with the construction were estimated for various types of combustion sources, including off road construction equipment (drills, dozers and graders, etc.), earth moving equipment (haul trucks, loaders and cranes, etc.), power generators, and motor vehicles. Air emissions of particulate matter were estimated for activities such as blasting, truck loading and unloading, drilling, processing, and hauling within the mine pit and along the Project haul roads, airport access road, explosive storage road and main access road. These emissions are named as fugitive emissions because they do not disperse into air from a specific point/area.

The emissions estimations were calculated by using emission factors which were developed by several regulatory agencies such as Environment Canada's Pits and Quarries Guidance (NPRI 2009), United States Environmental Protection Agency AP-42 (US EPA 1995), and Australian Mining Emission Estimation Technique Manuals (NPI 2008, NPI 2012). These emission factors are useful when there is no actual data collected such as stack measurements or manufacturer specifications and are therefore ideal for proposed industrial developments to estimate anticipated air emissions that could occur during the life time of the projects.

The temporary nature of construction differentiates it from operation phase emission sources because construction consists of a series of different operations, each with its own duration and potential for air emissions. Construction activities are expected to have a definable beginning and end and emissions are considerably variable over the different phases of the construction process. This is in contrast to the operations phase, where emissions are either relatively steady or follow a daily/hourly cycle.

Construction of the proposed mine is anticipated to be completed within 3 years and activity is expected to reach its maximum level during Project year -1 because the material movement and equipment use will be higher compared to other construction years. Earth moving and equipment use are considerably lower during construction years -2 and -3. Since a conceptual construction plan is not available, the air emissions were estimated by using an annual material movement summary and off road equipment requirements assuming that all activities would occur regularly within the proposed schedule and be relative to the amount of material movement. Direct mill feed is relatively low during year -1 therefore the majority of particulate matter emissions originated from unpaved roads. Top soil stockpiles were considered not vegetated during this period and are therefore considered sources of fugitive emissions during strong winds.

Table A.8A.1–1 summarizes the Project's mined material flow summary which was derived from the feasibility study.

Table A.8A.1-1 Construction Phase (year -1) Annual Material Movement

Mine Facility	Year - 1 (tonnes/year)	Truck Trips	One way Distance (km)	Annual Travel Distance (km)
To Waste Storage Area	5,262,000	14,496	9.648	279,712
Overburden	1,206,000	3,322		
Leach Cap	3,960,000	10,909		
Supergene Oxide And Unclassified	96,000	264		
To Supergene Oxide - Stockpile	9,950,000	27,410	4.105	225,040
To Gold Ore Stockpile	21,654,000	59,653	2.441	291,225
To Direct Mill Feed	4,510,000	12,424	3.550	88,220
Total Materials Moved	41,376,000	113,983		

Note: Leach Cap will be used for Embankment construction therefore included in road to Waste Storage Area

Open pit activities during construction are similar to those during the operations phase, and are based on blasting, drilling, loading and hauling activities. The blasting is assumed to take place once a day and ANFO will be used for explosive detonation. Table A.8A.1–2 summarizes the air emissions estimated for open pit activities and corresponding emission factors.

Table A.8A.1-2 Open Pit Particulate Matter Emissions during Construction

Mine Activity	Emission Factor	Units	Total Emissions (tonnes per blast)	Total Emissions (tonnes/year)
Blasting (AP-42 Table 11.9-2)				
Total Particulate Matter (TPM)	$= 0.00022 * Area^{1.5}$	kg/blast	0.22	80.3
PM_{10}	0.52 x TPM		0.1144	41.756
$PM_{2.5}$	0.03 x TPM		0.0066	2.409
# of blasts per day	1 per days, 7 per week			
Estimated area impacted per blast (m^2)	10,000	m^2		
Drilling (SCC 3-05-020-10)				
Total Particulate Matter (TPM)	8.46619×10^{-05}	(kg/Mg)		3.503
PM10	4.00428×10^{-05}	(kg/Mg)		1.657
PM2.5	6.06362×10^{-06}	(kg/Mg)		0.251
Haul Truck Loading(SCC 3-05-020-31)				
Total Particulate Matter (TPM)	0.000105714	(kg/Mg)		4.374
PM10	0.00005	(kg/Mg)		2.069
PM2.5	7.57143×10^{-06}	(kg/Mg)		0.313

Processing activities will start during year -1 with the commissioning of the sulphide ore flotation mill. Table A.8A.1–3 and Table A.8A.1–4 summarize the particulate matter emission estimates at these facilities.

Table A.8A.1-3 Particulate Emissions from the Primary Crusher Unit

Parameter	Reference	Emission Factor (kg/Mg)			Total Emissions Crusher 1 (tonnes/year)		
		Total Particulate Matter (TPM)	PM_{10}	$PM_{2.5}$	Total Particulate Matter (TPM)	PM_{10}	$PM_{2.5}$

Truck Unloading at Crusher Unit*	SCC 3-05-020-31	$2x10^{-05}$	$8 x10^{-06}$	$1 x10^{-06}$	0.008	0.004	0.001

*Mitigation Efficiency = 90%

Environment Canada Pits and Quarries Guidance, Crusher Emission Control Techniques, Enclosed Building Mitigation Efficiency

PM2.5 emission factor is not available therefore assumed to be same as PM10 as conservative approach, Project ore/waste considered as low-moisture because it is less than 4%

TPM and PM2.5 emission factors are not available for unloading therefore they were calculated by AP-42 general aerodynamic size distribution factors using PM10 EF.

Table A.8A.1-4 Oxide Ore Processing Facility Emissions

Mine Activity	Reference	Emission Factor (kg/Mg)			Total Emissions (tonnes/year)		
		Total Particulate Matter (TPM)	PM_{10}	$PM_{2.5}$	Total Particulate Matter (TPM)	PM_{10}	$PM_{2.5}$

Mitigation with Fabric Filter (AP-42 Table B.2.3) discharging from building

Site historical meteorological data indicate that the Project does not experience wind gusts very often. The wind speeds exceeded 5.4 metres/second hourly average for only 4.4% of the time from 2008 to 2012. Considering the gust speed and approximate silt contents, particulate matter emissions were estimated for each ore, waste, and topsoil stockpiles. Usually topsoil stockpiles are covered by grass however during the construction phase, it was assumed to be too early for vegetation growth and they are included in wind erosion estimations. Wind erosion emission estimates are summarized in Table A.8A.1–5.

Table A.8A.1-5 Wind Erosion Emissions

Mine Facility	Value (tonnes/year)		
	Total Particulate Matter (TPM)	PM_{10}	$PM_{2.5}$
Gold Ore Storage Area	1.64	0.82	0.33
Low Grade Supergene Oxide Pile	0.47	0.23	0.09
Supergene Oxide Ore Stockpile	1.87	0.94	0.37
Marginal Grade Ore pile	1.87	0.94	0.37

Mine Facility	Value (tonnes/year)		
Low Grade Supergene Sulphite	0.47	0.23	0.09
Waste Storage Area	0.29	0.14	0.03
Topsoil Piles	10.06	5.04	2.01
Topsoil Overburden Piles	13.00	6.50	2.60

Fugitive dust also occurs at stockpiles due to unloading and earth moving activities, and these emissions are summarized in Table A.8A.1–6 and Table A.8A.1–7.

Table A.8A.1-6 Earth Moving Air Emissions

Mine Facility	Value (tonnes/year)		
	Total Particulate Matter (TPM)	PM_{10}	$PM_{2.5}$
Gold Ore Stockpile Area	97.02	72.77	10.19
Supergene Oxide Ore Stockpile Area	164.36	123.27	17.26
Waste Storage Area	181.66	136.24	19.07

Emission factor is from USEPA AP-42 Table 11.9-2 Overburden Bulldozing
Silt content = 6.9 assumed for gold ore, moisture=3% feasibility study
Silt content = 6.9 assumed for supergene oxide ore, moisture=2% feasibility study
Silt content = 7.5 assumed for waste, moisture=2% feasibility study
Silt contents were used from AP-42 and moisture contents were taken from feasibility study

Table A.8A.1-7 Truck Loading/Unloading Emissions

Mine Facility	Reference	Emission Factor (kg/Mg)			Total Emissions (tonnes/year)		
		Total Particulate Matter (TPM)	PM_{10}	$PM_{2.5}$	Total Particulate Matter (TPM)	PM_{10}	$PM_{2.5}$
Gold Ore Stockpile	SCC-3-05-020-33	$1.06x10^{-04}$	$5.00x10^{-05}$	$7.57x10^{-06}$	2.29	1.08	0.16
Supergene Oxide Ore Stockpile	SCC-3-05-020-33	$1.06x10^{-04}$	$5.00x10^{-05}$	$7.57x10^{-06}$	1.05	0.50	0.08
Waste Storage Dump	SCC-3-05-020-33	$1.06x10^{-04}$	$5.00x10^{-05}$	$7.57x10^{-06}$	0.56	0.26	0.04

Note: Total Material dump at storage areas were derived from production schedule in feasibility study

Large unit construction activities are expected to have a beginning and an end and vary over the construction phase as activities change on a daily basis. Therefore, construction emissions are estimated area wide (e.g., power plant construction, concentrator area construction, crusher area construction, etc.) regardless of detailed construction activities. Since there is no conceptual plan for construction phase, general construction emission factors were used by assuming that each unit requiring erection would take around 90 days of heavy construction activity. This does not include mechanical and electrical installations which are negligible in terms of air emission estimates. Table A.8A.1–8 summarizes the estimated emissions for the largest unit construction activities.

Table A.8A.1-8 Other Construction Activities

Mine Facility	Value (tonnes/day)	Total Emissions (tonnes/year)*
Power Plant Construction =		
Total Particulate Matter (TPM)	0.404	36.31
PM_{10}	0.191	17.18
$PM_{2.5}$	0.029	2.60
Concentrator Construction =		
Total Particulate Matter (TPM)	0.269	24.21
PM_{10}	0.127	11.45
$PM_{2.5}$	0.019	1.73
Crusher Area =		
Total Particulate Matter (TPM)	0.022	2.02
PM_{10}	0.011	0.95
$PM_{2.5}$	0.002	0.14

Fugitive dust from haul roads is the largest and most contributor to particulate matter emissions during construction. AP-42 Section Unpaved Roads (US EPA 1995) was used as the main reference to calculate emissions during construction by using the following formula:

$$E = k\left(\frac{s}{12}\right)^{a}\left(\frac{W}{3}\right)^{b}$$

where:

- E is size specific emission factor (lb/VMT)
- s is surface material silt content (%)
- W is mean vehicle weight (tonnes)
- k (lb/VMT) is equal to 0.15 for $PM_{2.5}$, 1.5 for PM_{10} and 4.9 for TPM
- a is equal to 0.9 for $PM_{2.5}$ and PM_{10} and 0.7 for TPM
- b is equal to 0.45 for $PM_{2.5}$, PM_{10}, and TPM.

The truck trips were estimated by using the annual production schedule and the capacity of haul trucks. The summary of the unpaved road emissions are summarized in Table A.8A.1–9.

Table A.8A.1-9 Unpaved Road Emissions

Road Type	Average Weight (tonnes)	Daily Total Travelled Distance (km)	Total TPM (tonnes/year)	Total PM_{10} (tonnes/year)	Total $PM_{2.5}$ (tonnes/year)
Haul Road 1 To Waste Storage Area	443	766	184.4	48.8	4.9
Haul Road 2 To Supergene Oxide Stockpile	443	617	148.3	39.3	3.9

*Assumed that construction at Power Plant, Concentrator Building and Second Crusher could take 90 days

Air emission estimates from fuel combustion were based on the power rating, utilization factor for each piece of equipment and emission factors from the NONROAD2008 model (US EPA 2008) or USEPA AP-42 Emission Factors (US EPA 2005).

US EPA has developed the NONROAD2008 model to provide emissions factors for predicting accurate and reproducible non-road emissions inventories. NONROAD2008 provides emissions estimates based on fuel-use in a diverse collection of vehicles and equipment. NONROAD2008 provides emission factors for each equipment type and power rating such as haul trucks, graders, dozers, pumps, etc. It was assumed that the sulphur content of the diesel fuel was 0.0015% (15 mg/kg). This is consistent with the *Sulphur in Diesel Fuel Regulations* – Regular Sulphur Diesel Fuel - Type A fuel that is mainly limited to off-road applications (Environment Canada 2010).

The estimates from NONROAD2008 are conservative. The outputs have built-in adjustments for in-use operation versus new engine test results (*e.g.,* deterioration and transient operation). The air emissions were estimated for equipment provided in the feasibility study and time allocations were estimated by considering the available information in the feasibility study.

Other emission factors used in the air dispersion modelling assessment are provided in the US EPA's AP-42 document such as Chapter 3.4 Large Stationary Diesel and All Stationary Duel-Fuel Engines and Chapter 13.3 Explosives Detonation (US EPA 1995). Table A.8A.1–11 summarizes the Project's mined material flow chart.

Detailed blasting data were not available, therefore the ANFO use was estimated by using 0.25 times the powder factor and material extracted from the open pit in a year. It was assumed that blasting emissions would disperse in one hour which is the shortest modelling time interval for this study. The blasting was also assumed to occur once a day. Table A.8A.1–12 summarizes the blasting emission estimates.

Table A.8A.1-11 Mine Fleet and Percentage of Working Locations

Mine Fleet Equipment	Type	Operating Time (hr/day)	# of vehicles	Percentage of Working Locations (%)

[b] Assuming a powder factor of 0.250 Kg ANFO/tonnes with 41,376,000 tonnes extraction during year -1
[c] Assuming that blasting emissions will be released from 10,000 m^2 surface within one hour

The auxiliary power plant will be active during construction and is composed of three 6.7 MW large stationary diesel generators. An incinerator will be used for domestic refuse waste. An incinerator commonly used in the mining industry was assumed for this study. The emission rates are not available, therefore stack emissions were assumed to be equal to the Ontario Guideline A-7 emission limits (Ontario MOE 2010) as a conservative approach. The emissions rates for the auxiliary power plant and incinerator are summarized in Tables A.8A.1-13 and A.8A.1-14, respectively.

Table A.8A.1-13 Auxiliary Power Plant

A.8A.2 OPERATIONS PHASE AIR EMISSIONS INVENTORY

The air emissions inventory for the operations phase was generated from USEPA AP-42 document – Compilation of Air Pollutant Emission Factors, Volume 1 – Stationary Point and Area Sources, Environment Canada National Pollutants Inventory (NPRI) Pits and Quarries Guidance, and NONROAD2008a model. Supplemental emission factors were used from Australian Emission Estimation Technique Manual for Mining V 3.1 where there is insufficient data to estimate emissions.

The production schedule and mining equipment fleet activities formed the basis of year-by-year variations in the emissions model. As a conservative approach, the anticipated worst year was modelled for the operation phase.

Year 1, year 11 and year 12 were considered as the potential worst case air emissions as open pit depth is not very deep during year 1 and particulate matter might not be retained in the pit, waste amount and equipment use peak during year 11 and total material movement peaks during year 12. Due to the distance between the the waste storage area and the open pit, year 11 was chosen as the worst case year due to haulage distances and maximum equipment use during that year. Therefore, air emissions are predicted to be at their worst for all criteria air contaminants in year 11. Table A.8A.2–1 summarizes the Project's mined material flow summary derived from feasibility study.

Table A.8A.2-1 Material Movement Schedule Year 11

MINE FACILITY	Material Movement (tonnes/year)	Truck Trips	One way Distance (km)	Annual Travel Distance (km)
To Waste Storage Area	52,698,000	145,174	8.922	2,590,506
To Low Grade Ore - Hypogene Stockpile	1,642,000	4,523	6.082	55,025
To Low Grade Ore - Supergene Sulfide Stockpile	3,196,000	8,804	2.461	43,334
To Low Grade Ore - Supergene Oxide Stockpile	105,000	289	8.124	700
From Supergene Oxide - Stockpile	3,600,000	39,860	2.461	196,183
From Gold Ore Stockpile	7,862,000	87,050	0.894	155,680
To Direct Mill Feed	41,095,000	113,209	3.550	803,854
Total Materials Moved	**110,198,000**	**303,576**		

Note: Includes open pit activity and reclaim from stockpiles

Project emissions from mine fleet combustion sources were quantified based on information regarding the type, quantity and power rating provided in the feasibility study. The maximum operating time of equipment was estimated and air emissions from the diesel equipment were estimated by NONROAD2008a model based on the horsepower (hp) rating and utilization factor for each piece of equipment.

US EPA has developed the NONROAD2008 model (NONROAD) to provide emissions factors for predicting accurate and reproducible off road emissions inventories. The model provides emissions estimates based on fuel-use in a diverse collection of vehicles and equipment, classified categories.

The estimates from NONROAD are conservative. The model outputs have built in adjustments for in-use operation versus new engine test results (e.g., deterioration and transient operation). Given the inherent conservative estimations in NONORAD, the emission factors used for the Project air emissions inventory provide appropriate representation of a worst-case scenario.

Fugitive dust from haul roads is the largest source of particulate matter for the Project due to haul road distances from the open pit to ore stockpiles, crushers and waste storage area. Air emission factors for the crushers, waste rock dump area, ore stockpile, truck dump, process units (screen, mill, secondary crushing, etc.) are primarily derived from AP-42 emission factors. Some emission factors exist for only TPM or PM10 therefore other particulate matter emission factors could not be directly estimated. In these circumstances AP-42's generic aerodynamic particle size distribution was used to estimate other particulate matter emission factors. Overall, ore/waste moisture content was considered as dry because AP-42 considers materials below 4% as dry therefore low moisture emission factors were used for the assessment.

Precipitation normals were assumed to be the natural mitigation for particulate matter. The climate normals (1981-2010) were reviewed from Environment Canada's Burwash and Whitehorse meteorological stations and percentage of wet days were estimated as 68.2% and 67.9%, respectively (Table A.8A.2–2). As a conservative approach, the station with less precipitation (Whitehorse) was used as a natural mitigation factor (Table A.8A.2–2). The wet day estimation method was used from NPRI's pits and quarries guidance.

Table A.8A.2-2 Regional Data for Natural Mitigation Wet Day Estimation

	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Year	% of Wet Days

Regular open pit activities are based on blasting, drilling, loading and hauling. Blasting was assumed to take place once a day using ANFO for explosive detonation. Table A.8A.2–3 show the air emission estimated for open pit activities and the corresponding emission factors used.

Table A.8A.2-3 Open Pit Particulate Matter Emissions

Open Pit Activity	Emission Factor	Unit	Total Emissions (tonnes per blast)	Total Emissions (tonnes/year)
Blasting (AP-42 Table 11.9-2)				
Total Particulate Matter (TPM)	$= 0.00022 * Area^{1.5}$	kg/blast	0.22	80.3
PM_{10}	0.52 x TPM	kg/blast	0.1144	41.7

# of blasts	1 per day	blasts/day		
Area impacted per blast (m2)	10000	m^2		

Open Pit Activity	Emission Factor	Unit	Total Emissions (tonnes per blast)	Total Emissions (tonnes/year)
Drilling (SCC 3-05-020-10 and aerodynamic size distribution)				
Total Particulate Matter (TPM)	$8.46619x10^{-05}$	(kg/Mg)		8.4
PM_{10}	$4.00428x10^{-05}$	(kg/Mg)		3.9
$PM_{2.5}$	$6.06362x10^{-06}$	(kg/Mg)		0.6
Haul Truck Loading(SCC 3-05-020-31)				
Total Particulate Matter (TPM)	0.000105714	(kg/Mg)		10.4
PM_{10}	0.00005	(kg/Mg)		4.9
$PM_{2.5}$	$7.57143x10^{-06}$	(kg/Mg)		0.7

There are two primary crushers at site in an enclosed building as indicated in the feasibility study, the crushers units also include unloading emission sources. The estimated emissions from the crusher units are summarized in Table A.8A.2–4.

Table A.8A.2-4 Emissions from the Primary Crusher Units

Parameter	Emission Factor (kg/Mg)		Total Emissions Crusher 1 (tonnes/year)	Total Emissions Crusher 2 (tonnes/year)
Crusher	SCC 3-03-024-01	SCC 3-03-024-05		
	Low-moisture ore	High-moisture ore		
Total Particulate Matter (TPM)	0.2	0.01	893.9	155.1
PM_{10}	0.02	0.004	89.4	15.5
$PM_{2.5}$	0.02	$7.16x10^{-04}$	89.4	15.5
Crusher Mitigation Efficiency =	90%			
Environment Canada Pits and Quarries Guidance, Crusher Emission Control Techniques, Enclosed Building Mitigation Efficiency PM2.5 emission factor is not available therefore assumed to be same as PM10 as conservative approach, Project ore/waste considered as low-moisture because it is less than 4% therefore SC-3-03-024-05 was not used for estimations.				
Truck Unloading at Crusher Unit	SCC 3-05-020-31			
Total Particulate Matter (TPM)	$2.x10^{-05}$		0.076	0.062
PM_{10}	$8.x10^{-06}$		0.036	0.029
$PM_{2.5}$	$1.x10^{-06}$		0.005	0.004
Mitigation Efficiency =	90%			
Environment Canada Pits and Quarries Guidance, Crusher Emission Control Techniques, Enclosed Building Mitigation Efficiency. TPM and $PM_{2.5}$ emission factors are not available therefore they were calculated by generic aerodynamic size distribution factors using PM_{10} EF.				

Processing at the Project consists of two processing facilities, one for sulphide ore and one for oxide ore. The sulphide ore processing facility will produce mineral concentrates of copper and molybdenum using conventional flotation technology. The copper concentrate will be dewatered and transported as a filtered cake by highway trucks. The molybdenum concentrate will be dewatered and packaged in super sacks for transport. The feasibility study indicates that the unit will operate in a closed circuit, therefore secondary crushing, mill and cyclone emissions are within the process building and not released to atmosphere.

The oxide ore processing facility will produce gold and silver Doré bars via heap leach and carbon adsorption technology. Copper contained in the oxide ore will be recovered as a copper sulphide precipitate using SART technology. This facility includes conveyor drop off, secondary crushing and screening emission.

Table A.8A.2–5 and Table A.8A.2–6 summarize the emission estimations from the processing facilities.

Table A.8A.2-5 Sulphide Ore Processing Facility Emissions

Mine Facility	Reference	Emission Factor (kg/Mg)			Total Emissions (tonnes/year)

Site historical meteorological data indicate that the Project site does not experience wind gusts very often. The wind speeds exceed 5.4 metres/second hourly average for only 4.4% of the time from 2008 to 2012. However, the erosion related particulate emission were estimated and used in the model for exposed stockpiles and tailings beach. Table A.8A.2–7 summarizes the erosion emission estimations.

Table A.8A.2-7 Wind Erosion Emissions

Mine Facility	Emission Factor (tonnes/year)		
	Total Particulate Matter (TPM)	PM_{10}	$PM_{2.5}$
Gold Ore Stockpile (4ha)	1.87	0.94	0.37
Low Grade Supergene Stockpile (4ha)	1.87	0.94	0.37
Supergene Oxide Ore Stockpile (4ha)	1.87	0.94	0.37
Low Grade Hypogene Ore Stockpile (4 ha)	1.87	0.94	0.37
Low Grade Supergene Oxide Stockpile (1 ha)	0.47	0.23	0.09
Waste Storage (4 ha)	0.09	0.04	0.01
Tailings Beach (18 ha)	13.4	6.7	2.7

Earth moving activities such as bulldozing generate dust to move unloaded material at stockpile areas. Since ore/waste moisture content is low, the earth moving activities is included in the emissions inventory (Table A.8A.2–8). The air emissions predicted for loading/unloading activities are summarized in Table A.8A.2–9.

Table A.8A.2-8 Earth Moving Air Emissions

Mine Facility	Emission Factor (tonnes/year)		
	Total Particulate Matter (TPM)	PM_{10}	$PM_{2.5}$
Gold Ore Stockpile	97.0	72.8	10.2
Low Grade Supergene Stockpile	164.4	123.3	17.3
Supergene Oxide Ore Stockpile	164.4	123.3	17.3

Note: Total Material dump at storage areas were derived from production schedule in feasibility study

Fugitive emissions from haul roads were estimated based on U.S. EPA emission factors for unpaved roads. Haul roads are predicted to generate the majority of particulate emissions. It was assumed that a dust control program (i.e. applying water to control dust emissions) would be applied and would control fugitive dust emissions from haul roads by approximately 75%, and natural mitigation (precipitation and snow cover) would also aid to suppress fugitive dust. The Whitehorse and Burwash weather stations (Table A.8A.2-2) were considered for natural mitigation data and Whitehorse was used in calculations (67.9%) as a conservative approach. Regular activity consists of ore/waste hauling, explosive transport, airport transportation and access road materials supply and concentrate transport. Table A.8A.2–10 summarizes the fugitive emissions predicted for haul roads and overall particulate matter emissions are summarized in Table A.8A.2–11. Similar to the construction phase emissions calculations for haul roads, fugitive dust was calculated using AP-42 Section Unpaved Roads (US EPA 1995):

$$E = k\left(\frac{s}{12}\right)^{a}\left(\frac{W}{3}\right)^{b}$$

where:

- E is size specific emission factor (lb/VMT)
- s is surface material silt content (%)
- W is mean vehicle weight (tonnes)
- k (lb/VMT) is equal to 0.15 for PM2.5, 1.5 for PM10 and 4.9 for TPM
- a is equal to 0.9 for PM2.5 and PM10 and 0.7 for TPM
- b is equal to 0.45 for PM2.5, PM10, and TPM.

Project emissions from mine fleet combustion sources were quantified based on information regarding the type, quantity and power rates of the equipment. Other large sources include the natural gas fired power plant and auxiliary power plant.

The mine fleet emissions were estimated using NONROAD2008a model, and the equipment type, function, and number of vehicles was obtained from the feasibility study (M3 2013). The allocations were estimated by professional judgement by considering material amounts moved during year 11. The mine fleet, models, number of vehicles and allocation used for modelling are summarized in Table A.8A.2–12 and resulting air emissions for the mine fleet are in Table A.8A.2–13.

Table A.8A.2-12 Mine Fleet and Percentage of Working Locations

Note: The list provided in feasibility study, power ratings and quantity provided in feasibility study (M3 2013).
Non-road model includes deterioration factors in the model.
Operating times estimated with professional judgement by considering material movement during year 11.

Detailed blasting data were not available, therefore the ANFO use was estimated by using 0.25 times the powder factor and material extracted from the open pit in a year. It was assumed that blasting emissions would disperse in one hour which is the shortest modelling time interval for this study. The blasting was also assumed to occur once a day. Table A.8A.2–14 summarizes the blasting emission estimations.

Table A.8A.2-14 Blasting Emissions

Species	Emission Factor [A] (kg/Mg ANFO)	Daily ANFO [B] (tonnes)	Daily Air Emissions (kg)	Emission Rate [c] ($g/s/m^2$)
CO	34	67.63	2299.33	1.18x10-03
NO_x	8	67.63	541.02	2.78x10-04
SO_2	1	67.63	67.63	3.48x10-05

[A] source: US EPA AP-42 Section 13.3
[B] Assuming a powder factor of 0.225 Kg ANFO/tonnes with 98736000 tonnes extraction during year 11
[c] Assuming that blasting emissions will be released from 10000 m^2 surface within one hour

During operations, power is provided by a natural gas fired power plant (two at 47 MW capacity each) with heat recovery steam generators, and supported by the auxiliary power plant, which is composed of three 6.7 MW generators. Combined gas plants show variable emissions characteristics depending on gas composition, heat recovery system, and changing power demand which changes air emission rates considerably. Since details such as design, fuel consumption, stack clusters, emission control techniques and heat recovery combination of this combined plant were not available, the emission rates were estimated by using power output ratings provided by Australia's emission estimation technique manual for combustion engines Combustion Engines version 3.0, Table 51. The emission factors are developed for uncontrolled natural gas turbines. It was assumed that gas turbines could provide 90% efficiency with an additional 5% preventive maintenance time. The resulting emissions predictions are summarized in Table A.8A.2–15 for the natural gas fired power plant. For the auxiliary power plant, emissions during operations are the same as during construction (Table A.8A.1-13)

Table A.8A.2-15 Natural Gas Power Plant Emission Rates

Parameter	Value	Unit	Reference
Stack Height	20	m	
Stack Diameter	3	m	
Stack Velocity at operating temperature	25.0	m/s	
Stack Gas Temp	312.15	°C	
Efficiency	90%		
Installed Power	2x47	MW	Nominal rates (kg/kWh)
NO_X	12.930	g/s	$4.95x10^{-04}$
CO	3.320	g/s	$1.27x10^{-04}$
SO_2	0.020	g/s	$7.86x10^{-07}$
TPM	$7.68x10^{-02}$	g/s	$2.94x10^{-06}$
PM_{10}	$7.68 x10^{-02}$	g/s	$2.94x10^{-06}$
$PM_{2.5}$	$7.68 x10^{-02}$	g/s	$2.94x10^{-06}$

Similarly to the construction phase, an incinerator will be used to manage domestic refuse waste. The incinerator emissions during operations were assumed to be the same as during construction, as summarized in Table A.8A.1-14.

Casino Project

Preliminary Fish Habitat Offsetting Plan

Prepared for

Casino Mining Corporation

December 5, 2014

PALMER ENVIRONMENTAL CONSULTING GROUP INC.

*470 Granville Street, Suite 630, Vancouver, BC V6C 1V5 **t** 604-629-9075*

December 5, 2014

Mary Mioska
Senior Environmental Manager
Casino Mining Corporation
1800 – 570 Granville Street
Vancouver, BC V6C 3P1

Dear Ms. Mioska,

Re: Casino Project, Preliminary Fish Habitat Offsetting Plan

Palmer Environmental Consulting Group Inc. is pleased to submit the attached Preliminary Fish Habitat Offsetting Plan for the Casino Project, in support of its Project Proposal to the Yukon Environmental and Socio-Economic Assessment Board.

This report has been updated in accordance with new fisheries protection provisions of the *Fisheries Act*. It describes how Casino Mining Corporation proposes to offset residual impacts to fish habitat in order to ensure the sustainability and ongoing productivity of Yukon fisheries. Following summaries of existing conditions and predicted impacts, it outlines the offsetting objectives and rationale, provides overviews of offsetting candidates, and describes how the proposed offsetting opportunities will restore, create or enhance fish habitat for long-term benefits in productivity.

If you or technical reviewers have any questions about this report, please feel free to contact Rick Palmer at 604-629-9075 or at rick@pecg.ca.

We appreciate the opportunity to work with you on this project.

Yours truly,

Palmer Environmental Consulting Group Inc.

R. Palmer

Rick Palmer, M.Sc. R.P.Bio.
President, Senior Fisheries Biologist

Executive Summary

Casino Mining Corporation proposes to develop the Casino Project, a copper-gold-molybdenum-silver mine in west-central Yukon, approximately 300 km northwest of Whitehorse. The project is within the traditional territories of the Selkirk First Nation and Little Salmon / Carmacks First Nation, with elements of proposed habitat offsetting extending into the traditional territory of Tr'ondëk Hwëch'in First Nation. The proposed mine consists of an open pit, processing facilities, a heap leach facility, a tailings management facility and an airstrip, with access provided from Carmacks along the upgraded and extended Freegold Road. The Casino Project will process 120,000 t/d or 43.8 million t/y of material over 22 years of production. Based on comprehensive baseline and risk studies, Casino Mining Corporation has minimized predicted impacts of the project on fish and fish habitat through re-design, refinement and mitigation measures.

This document presents the Casino Project Preliminary Fish Habitat Offsetting Plan to address predicted residual impacts on fish habitat, pursuant to the *Yukon Environmental and Socio-economic Assessment Act* and the federal *Fisheries Act*. It has been updated from the previous Preliminary Fish Habitat Compensation Plan (November 29, 2013), in accordance with recent changes to the *Fisheries Act*, based on new data and feedback from DFO, First Nations and their technical advisors.

The Casino Project is located wholly within the Yukon River watershed. The proposed mine and associated facilities are situated in the upper watersheds of Casino Creek and Canadian Creek (a tributary to Britannia Creek), with the proposed airstrip located in the adjacent Dip Creek watershed. Slimy sculpin and Arctic grayling are the dominant species within the high-elevation mine area, where cold water temperatures, high gradients and velocities, a lack of overwintering habitat, and locally poor water quality and benthic communities greatly limit productive capacity. Low numbers of burbot and round whitefish are present in the lower watersheds. Juvenile Chinook salmon have been captured in lower Britannia Creek, near its confluence with the Yukon River. Fish habitat in the Project area predominantly supports rearing activities of local species, with limited opportunities for spawning, and overwintering restricted to larger, downstream watercourses with sufficient base flows and deep pools. Similar species and habitat types dominate the watercourses crossed by the Freegold Road upgrade and extension, between the mine site and Carmacks. However, chum salmon and Chinook salmon spawning habitat have also been documented in some of the largest creeks and rivers within this area.

The main impacts of the Casino Project on fish habitat are anticipated in the upper Casino Creek watershed, in association with tailings management facility construction. More modest in-stream impacts are also expected along lower Casino Creek and Dip Creek, due to flow reductions; along a small, unnamed tributary to Dip Creek, which will be diverted around the new airstrip using natural channel design principles; along lower Canadian Creek, once surface runoff in its headwaters is allowed to drain into the open pit; along lower Britannia Creek, in association with the reinstatement of its historical, meandering channel as an element of habitat offsetting; and within the small footprint of a single bridge pier in the Nordenskiold River. Impacts to riparian habitat are predicted in correspondence with these sites of in-stream impact, as well as in association with the abutments and approaches to clear-span bridges along the Freegold upgrade and extension, and the airstrip access road.

Potential impacts of the Casino Project on in-stream fish habitat were assessed using a Physical Habitat Simulation, where a partial loss of flow is predicted, and a Habitat Evaluation Procedure, where a complete loss of flow is anticipated. Both methods have been widely used across North America as a reliable model for quantifying habitat loss, including for recent environmental assessments for similar projects in Canada, because they provide a means of quantifying biologically-relevant habitat loss (or gain) by taking into account the habitat preferences and requirements of a species at varying life stages. Impacts to riparian habitat were determined based on the predicted areas of disturbance or loss of vegetation within stream-side buffers that reflect the type of vegetation and the suitability and sensitivities of adjacent, in-stream habitats. The assessments predict a loss of 23,632 m^2 of 'usable' in-stream habitat and a loss of 538,705 m^2 of riparian habitat alongside fish-bearing watercourses.

In order to offset the residual impacts outlined above, Casino Mining Corporation and Palmer Environmental Consulting Group Inc., in conjunction with Selkirk, Little Salmon / Carmacks and Tr'ondëk Hwëch'in First Nations, have identified and developed preliminary designs for fish habitat offsetting opportunities that address known limitations to fisheries productivity in the affected watersheds. A systematic inventory of offsetting opportunities in the project area identified 22 candidate sites for restoring, creating or enhancing in-stream and riparian habitat. Four of these candidates, plus a complementary research project, have been recommended as preferred offsetting opportunities; another four candidates have been identified as contingency opportunities. Implementation of some combination of the proposed offsetting opportunities will ensure that the unavoidable residual serious harm to fish is counterbalanced with a 2:1 offset ratio (except a 1:1 offset ratio for impacts in the uppermost Casino Creek watershed, where fish use is rare) to improve the productivity of local commercial, recreational or Aboriginal fisheries, in accordance with the *Fisheries Act*.

The reinstatement of the historical channel of lower Britannia Creek, within 2 km of its confluence with Yukon River, would re-establish approximately 14,870 m^2 of pre-existing, high quality habitat that exhibits tortuous meanders, gravel and cobble substrates, deep pools separated by low-gradient riffles, undercut banks and functional in-stream large woody debris. Bank morphology and riparian habitat would be restored at five abandoned fords along lower Britannia Creek, where vehicle tracking has led to bank erosion and continued sedimentation downstream, resulting in no gain (0 m^2) of in-stream habitat but complete restoration of the riparian buffer. Stocking of whitefish in fishless Diamain Lake, near the Selkirk First Nation community of Pelly Crossing, provides the opportunity to create a new Aboriginal fishery supported by a large area of usable habitat. The localized excavation of dredge piles east of Dawson would connect four large ponds to the adjacent Klondike River, creating at least 9,120 m^2 of usable off-line pool habitat to support rearing and overwintering of juvenile Chinook salmon. As a complementary measure to habitat offsets, a research project equivalent to 10% (3,840 m^2) of the total offsetting amount is proposed to study Chinook salmon stock of origin in natal and non-natal streams.

Contingency habitat offsetting opportunities include extending and enhancing a slope-toe side channel that parallels lower Britannia Creek, in order to create approximately 1,210 m^2 of rearing and overwintering habitat for Arctic grayling and juvenile Chinook salmon; enlarging a groundwater-fed side channel along lower Britannia Creek, by approximately 1,830 m^2, to increase the availability of off-line rearing and overwintering habitat for Arctic grayling and juvenile Chinook salmon; extending a groundwater-fed side channel of the Klondike River into a gallery of pool habitats (approximately 2,680 m^2) to ensure juvenile Chinook salmon that rear in the side channel are also able to survive winter beneath a thick ice cover; and excavating an interconnected gallery of pools (approximately 4,820 m^2)

within an area of shallow groundwater seepage across a meander of the Klondike River, in order to increase access by juvenile Chinook salmon to off-line rearing and overwintering habitat.

This document outlines a strategy for safely implementing the proposed offsetting measures, including consideration of the timing and phasing of construction, the installation and maintenance of erosion and sediment control measures, and the need for construction and effectiveness monitoring. The total cost of the fish habitat offsetting plan will be estimated once the exact combination of proposed offsetting opportunities to be implemented is finalized in consultation with First Nations, Fisheries and Oceans Canada, and other stakeholders. Subsequent detailed, multi-disciplinary design, the implementation of offsetting works before or in conjunction with impacts, and an allowance for adaptive management will ensure the long-term effectiveness of the proposed offsetting measures.

Appendix A. Fish Habitat Offsetting Preliminary Design Drawings

1 Introduction

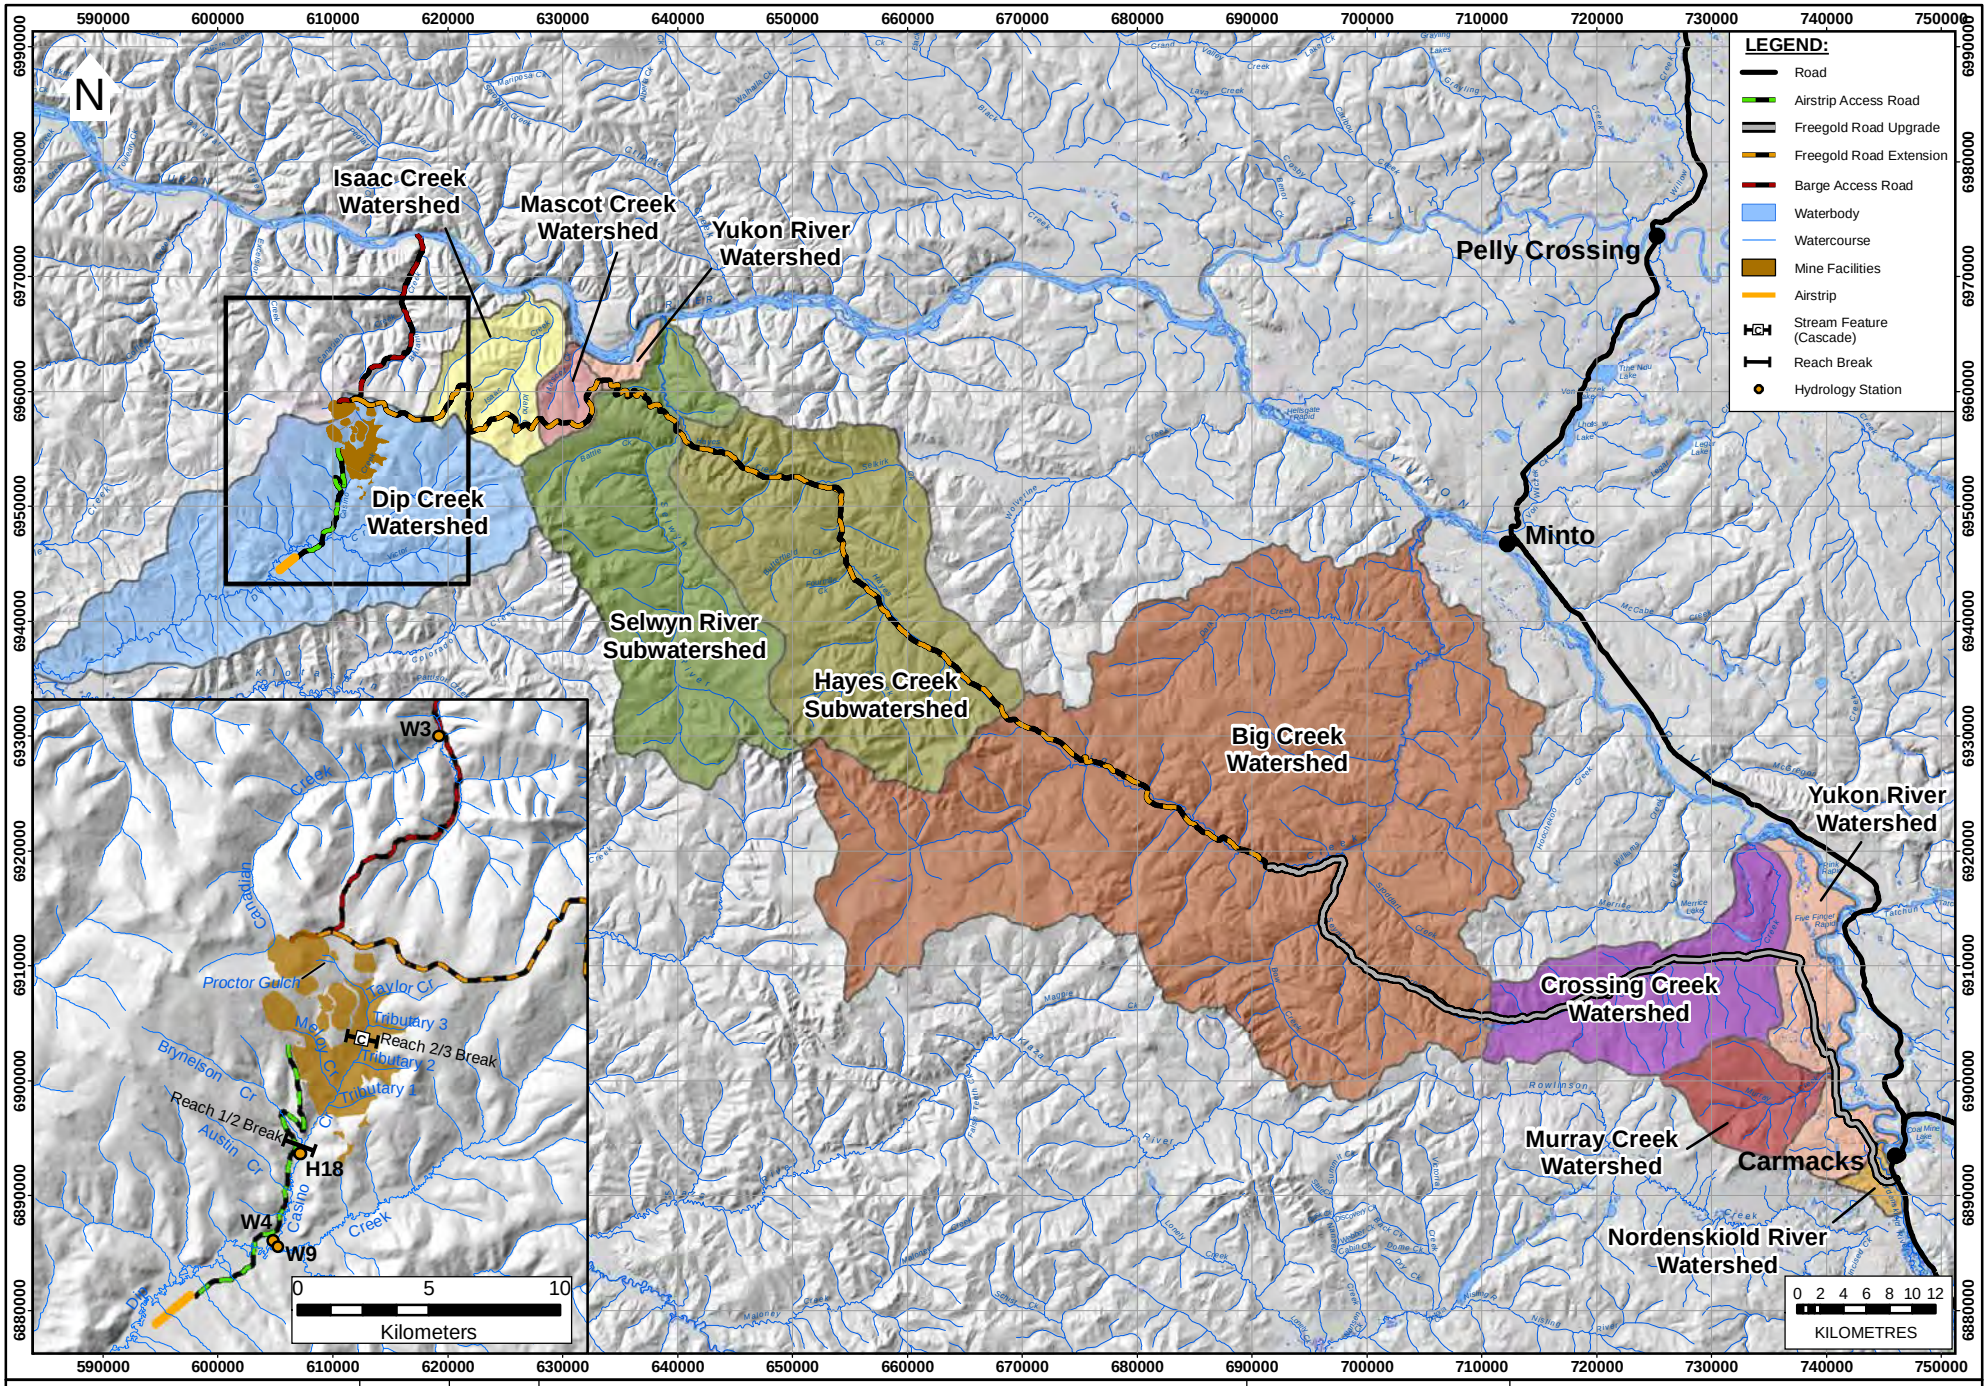
Casino Mining Corporation (CMC) proposes to develop the Casino Project ("the Project"), located in west central Yukon approximately 150 km northwest of Carmacks (**Figure 1-1**). The Project is a proposed open pit copper-gold-molybdenum-silver mine that is anticipated to process 120,000 t/d or 43.8 million t/y of material over 22 years of production. The Project is located on Crown land and is within the traditional territory of the Selkirk First Nation (SFN), with access proposed along an extension to the Freegold Road, which crosses the traditional territory of Little Salmon / Carmacks First Nation (LSCFN). Elements of proposed fish habitat offsetting are also within the traditional territory of Tr'ondëk Hwëch'in First Nation (THFN).

This document presents the Casino Project Preliminary Fish Habitat Offsetting Plan (FHOP) to address predicted impacts on fish habitat, as described in the "Fish and Aquatic Resources Effects Assessment" (Section 10) of the Project Proposal pursuant to the *Yukon Environmental and Socio-economic Assessment Act* (YESAA). The previous version of this document, the Casino Project Preliminary Fish Habitat Compensation Plan (Appendix 10C of the Project Proposal), was completed during a time of transition for the Canadian *Fisheries Act*, administered by Fisheries and Oceans Canada (DFO), and thus incorporated terminology and references relating to the older *Fisheries Act* provisions. In addition to the technical updates described in subsequent sections, this FHOP has been updated according to the new fisheries protection provisions, including amendments to Section 35 of the *Fisheries Act*. It also aligns with new guidelines provided by DFO's supporting documents, Fisheries Productivity Investment Policy: A Proponent's Guide to Offsetting (DFO, 2013a), and Fisheries Protection Policy Statement (DFO, 2013b). The new *Fisheries Act* is focused on avoiding "serious harm to fish", which is defined as "the death of fish or any permanent alteration to, or destruction of, fish habitat," where "fish" include any fish that are part of a commercial, recreational or Aboriginal (CRA) fishery, or fish that support such a fishery. To avoid contravening the *Fisheries Act*, proponents anticipating unavoidable serious harm to fish normally require an authorization under Section 35(2) of the *Fisheries Act*. In addition, proponents are required to submit an Offsetting Plan (DFO, 2013a) outlining how residual serious harm to fish will be counterbalanced in order to achieve DFO's overall goal of ensuring the sustainability and ongoing productivity of Canadian CRA fisheries.

CMC has completed comprehensive baseline and risk assessment studies to avoid and minimize predicted impacts of the Project on fish and fish habitat through re-design, refinement and mitigation measures. Offsetting measures and an authorization under Section 35(2) of the *Fisheries Act* will be required, however, where it is not possible to avoid all residual serious harm to fish. Accordingly, CMC understands that DFO will be identified by the Yukon Environmental and Socio-economic Board (YESAB) as a Decision Body under *YESAA*. The objective of the FHOP is to support DFO review of the Project Proposal, which will be submitted under *YESAA*. Detailed designs for fish habitat offsetting measures will be provided to DFO in association with CMC's subsequent request for *Fisheries Act* authorization.

1.1 Overview of Offsetting Approach

The objective of this FHOP is to outline the offsetting measures required to counterbalance unavoidable serious harm to fish resulting from the Project, with the goal of maintaining or improving the productivity of the CRA fishery, as outlined in DFO's *Fisheries Protection Policy Statement* (DFO, 2013b). A major focus of the new *Fisheries Act* is the integral role of fisheries management objectives in guiding impact assessments, and creating plans for offsetting. Thus, considerable efforts have been made to incorporate fisheries objectives from various partners and stakeholders in the region. Throughout the engagement process, fisheries partners have continually identified the high economic, cultural and ecological significance of Yukon River Chinook salmon (*Oncorhynchus tshawytscha*), which has had a major influence on the development of this FHOP. In addition to assessing their applicability to meeting fisheries objectives, all offsetting candidates were assessed relative to parameters that aimed to evaluate their potential for increasing fisheries productivity. These factors included the quality and rarity of the habitat types used in offsets, the distance between proposed impacts and offsetting sites, the risk of failure of offsetting measures, the potential for time lags and thus reduced fisheries productivity between project impacts and offsetting development, and the expected duration of offsetting benefits. The evaluation of all proposed offsetting candidates relative to these identified parameters is detailed in Section 4.



1.2 Casino Project Overview

1.2.1 Principal Mine Components and Infrastructure

This section provides an overview of eight principal mine components and associated infrastructure that have the potential to affect fish and fish habitat in the Project area (**Figures 1-1** and **1-2**):

- Open Pit;
- Ore stockpiles;
- Tailings Management Facility (TMF);
- Processing Facilities;
- Heap Leach Facility;
- Freegold Road Upgrade;
- Freegold Road Extension; and
- Airstrip and Airstrip Access Road.

Additional details on the mine components are presented in the "Project Description" in Section 4 of the Project Proposal.

CASINO PROJECT

MINE SITE OVERVIEW: MAXIMUM EXTENT

FIGURE 1-2

FHOP REPORT

PN 10011

Casino Mine Open Pit

The proposed Open Pit straddles the headwaters of Casino Creek and Canadian Creek and is anticipated to produce an average 120,000 t/d of ore over 22 years of full production (**Figure 1-2**). The Open Pit will occupy an area of approximately 300 ha and will extend to a maximum depth of approximately 600 m below existing grade (Knight Piésold Ltd., 2012a). The Open Pit will contain two designated mining zones, the Main Pit and the West Pit, which will be developed concurrently during the operations phase of the Project using standard drill and blast technology.

Ore Stockpiles

During mine operations, approximately 144 million tonnes of Low Grade ore and 32 million tonnes of Supergene Oxide (SOX) ore will be stored in temporary stockpiles. The SOX ore will be stockpiled at a location between the open pit and plant site during the pre-production years and in Year 1 of mill operations, and report to the mill during Years 4 to 12 together with direct feed mill ore. Mined Low Grade ore will be stockpiled up to Year 17 in locations generally east and south of the plant site, on valley slopes above the TMF (**Figure 1-2**). Low Grade ore mined after Year 12 can also be stockpiled at the same location used for the SOX ore south of the open pit. The stockpiled Low Grade ore will be milled during the last four years of mine operations (Years 19 to 22). Gold ore will be stored in a temporary stockpile near the crusher on the valley slope east of the open pit and at the northern end of the TMF. This stockpiled ore will report to the heap leach facility over a period of about 18 years, starting in the pre-production years (3 years prior to mill start-up) and continuing up to Year 15 of mill operations.

Tailings Management Facility (TMF)

The Project TMF is located southeast of the Open Pit within the valley formed by the headwaters of Casino Creek (**Figure 1-2**). At its full extent, the TMF will cover approximately 1,120 ha of land within the Casino Creek valley. The objective of the TMF is to protect groundwater and surface waters from potentially reactive waste rock from the Open Pit, acidic supergene waste and supernatant water pond. The TMF has been designed to retain 974 Mt of tailings together with 598 Mt of potentially reactive waste rock and overburden, as well as 9 Mt of acidic supergene waste (Knight Piésold Ltd., 2012b, 2013a). The two embankments of the TMF – the Main Embankment and West Saddle Embankment – will be developed in stages throughout the duration of the Project using a combination of suitable non-reactive overburden, cyclone sand and waste rock materials from the plant site, Open Pit and local borrow sources (Knight Piésold Ltd., 2012b). The final heights of the Main Embankment and West Saddle Embankment will be 286 m (998 m elevation at crest) and 21 m (998 m elevation at crest), respectively.

Processing Facilities

The Project consists of two ore processing facilities, one for sulphide ore (producing molybdenum and copper concentrates) and one for oxide ore (producing gold and silver dore bars and copper concentrate) (**Figure 1-2**). Sulphide ore processing involves primary crushing followed by conventional single-line semi-autogenous (SAG) mill circuit and conventional copper molybdenum floatation. Oxide ore processing involves a heap leach with a carbon adsorption facility to recover gold and silver and a Sulphidization, Acidification, Recycling and Thickening (SART) process to recover copper.

Heap Leach Facility

The proposed heap leach facility is located south of the open pit within the small tributary valley of Meloy Creek (**Figures 1-1 and 1-2**). This facility utilizes heap leach to process oxide 'gold' ore. The heap leach facility is anticipated to process approximately 157.5 million tonnes of oxide ore over the life of the Project.

Freegold Road Upgrade

Access to the proposed Casino mine site is currently limited to fixed-wing aircraft, helicopter and Yukon River barge, with some limited winter access for heavy equipment available along the old Casino Trail. To provide year-round access for heavy equipment, fuel and haulage trucks, CMC plans to construct a new all-weather resource road that connects the Casino mine site with the western limit of the existing Freegold Road, located approximately 85 km northwest of Carmacks (**Figure 1-1**). The existing Freegold Road will be upgraded to a two-lane (8.2 m-wide) gravel resource road that can accommodate the anticipated traffic from the Casino mine (hereinafter referred to as the "Freegold Road Upgrade"). Existing bridge and culvert crossings along the Freegold Road Upgrade section will be expanded to accommodate larger construction vehicles (Associated Engineering (AE), 2013). Bridge upgrades will be required over Crossing Creek and Bow Creek, and a new bridge will be constructed across the Nordenskiold River.

Freegold Road Extension

Beginning where the Freegold Road Upgrade section ends, CMC proposes to construct a new, all-weather, gravel road to the Casino mine site, referred to as the "Freegold Road Extension" (**Figure 1-1**). The Freegold Road Extension is a 120 km-long, two-lane gravel resource road designed to accommodate mine traffic. There are 18 major bridge crossings proposed along the extension, including crossings of Big Creek, Hayes Creek and Selwyn River, as well as several larger tributaries and side channels. Small, clear-span bridges are proposed across all other fish-bearing watercourses, with culverts only proposed for non-fish-bearing watercourse crossings, although the use of bridges or culverts will be dependent on geotechnical conditions at the crossing.

Airstrip and Airstrip Access Road

The existing Casino Airstrip will be replaced with a larger facility located in the Dip Creek valley, approximately 12 km southwest of the Casino mine site (**Figure 1-1**). The airstrip will be 2,000 m long and 30 m wide, with an 80 m grade width and a run out of 60 m at each end, and will be oriented northeast to southwest (AE, 2013). A new Airstrip Access Road will be constructed between the new Airstrip and the Casino mine site. This access road will be a 14 km-long, single-lane gravel road, with two major bridge crossings and several minor crossings.

1.2.2 Project Phasing and Scheduling

The Project phases are defined as Construction, Operations, Closure and Decommissioning, and Post-Closure (**Table 1-1**). The construction phase of the Project will begin once required permits and financing are in place. This phase is anticipated to be four years in duration. Completion of the Freegold Road Upgrade, Freegold Road Extension and Airstrip and Airstrip Access Road are priorities for early in the construction phase. Soil removal and pre-stripping of the Open Pit will occur during this phase. Construction of the TMF and Processing Facilities (including the heap leach facility) will also occur during the construction phase and will be fully operational by Year 1 of the operations phase.

Table 1-1. Casino Project Phases and Schedule

Project Phase	Period	Anticipated Schedule	Project Year
Construction	4 years	2016 - 2019	Year -4 to Year -1
Operations	22 years	2020 - 2042	Year 1 to Year 22
Closure and Decommissioning	3 years	2043 - 2045	Year 23 to Year 25
Post-Closure	5 years	2046- 2050	Year 26 to Year 30

Note: From the "Project Description" (Section 4 of the Project Proposal)

The operations phase of the Project will begin at the commencement of sulphide ore processing and is projected to last 22 years (**Table 1-1**). In Year 1, the Casino Project is projected to operate at 75% capacity, with production increasing to the nominal daily production capacity of 120,000 t/d for the remainder of this phase. Open pit mining and ore processing (including both heap leaching and sulphide ore processing) will gradually increase to meet the nominal daily production capacity. Waste rock and tailings management will be a key element of the operations phase.

The closure and decommissioning phase (hereinafter referred to simply as "closure") is projected to commence in Year 23 and last three years (**Table 1-1**). During the closure phase, the surface facilities will be removed and the Casino mine site will be fully reclaimed according to the reclamation objectives established in the "Closure and Reclamation Plan" (Section 4B of the Project Proposal).

Post-Closure phase activities include annual inspections and monitoring of the Project area over a five-year timeframe to evaluate the predicted results of reclamation and ensure that reclamation objectives have been met (**Table 1-1**).

1.3 Consultation

CMC is committed to communicating clearly and openly about the planning of the Project, and to soliciting and incorporating feedback received through its consultation process. Since conception of the Project, CMC has regularly consulted regulatory agencies, First Nations and local communities, Renewable

Resource Councils and the public through a combination of site field tours and community meetings and workshops. Valuable insight into fisheries protection and enhancement opportunities has been provided by SFN, LSCFN and THFN through field reconnaissance visits, community meetings and technical workshops. CMC has made changes to project design based on feedback received from First Nations and agencies such as DFO (as outlined below in Section 3.3). Several fisheries-related meetings and site visits have been conducted in 2014 to engage and consult with regulators, third party reviewers, and First Nations (**Table 1-2**).

Table 1-2. Summary of FHOP-related Meetings and Site Visits in 2014

Date	Meeting/Site Visit	Objective
27/28-Jan-14	SFN Water and Fish Technical Session	Briefing of what SFN and technical water/fisheries advisors will be reviewing, following submission of Project Proposal to YESAB on January 3, 2014, including an overview of habitat modelling and components of FHOP
01-Apr-14	Meeting with THFN	Introduction to Project, with an emphasis on fisheries considerations and offsetting planning
26-May-14	Meeting with SFN, Environment Canada and DFO	Feedback regarding updates to offset planning to address new *Fisheries Act* and additional offsets
30-May-14	Reconnaissance site visits with SFN	Reconnaissance flight and site visits to identify and discuss offsetting candidates within SFN traditional territory
19-Jun-14	Meeting with LSCFN	Consultation regarding proposed Freegold Road upgrades and extension through LSCFN traditional territory, with an emphasis on fisheries considerations and offsetting planning
15-Jul-14	Meeting with FHOP Advisory Group	Discussion about existing offsetting candidates and feedback regarding newly identified candidates within SFN traditional territory
16-Jul-14	Site visit with SFN and LSCFN representatives	Reconnaissance flight and site visits to provide overview of Project area and to identify and discuss offsetting candidates primarily within SFN traditional territory
23/24-Sep-14	Meeting and reconnaissance site visits with THFN	Update on FHOP development and expression of interest in considering offsetting opportunities in THFN traditional territory, followed by reconnaissance site visits
07-Oct-14	Field survey assistance by THFN representative	Preliminary field investigations of offsetting candidates identified in THFN traditional territory, with assistance from a THFN representative with valuable local knowledge
04-Nov-14	Meeting with FHOP Advisory Group	Presentation and discussion on planned FHOP updates, as an opportunity to solicit feedback on technical/feasibility issues associated with each offsetting candidate
18-Nov-14	Meeting with FHOP Advisory Group	Presentation and discussion on proposed research program on Chinook salmon, as a complementary measure to habitat offsets

SFN, LSCFN and THFN have provided considerable support in the identification, evaluation and preliminary design of fish habitat offsetting opportunities for the Project. SFN Lands and Environment Director, William Sydney, participated in an on-site tour on May 30, 2014 to discuss offsetting options, in addition to several community meetings. The SFN prioritized offsetting opportunities targeting Chinook salmon and identified the important traditional use of lower Britannia Creek, where considerable offsetting efforts are now proposed. In 2014, SFN helped CMC identify additional, off-site offsetting candidates within its traditional territory.

CMC and its consulting team engaged DFO early in its Project planning and continued regular consultation throughout Project design, recognizing the valuable input DFO is able to provide to CMC's project team, technical advisors and local communities regarding priorities for fish habitat protection and offsetting strategies. CMC has hosted several YESAA workshops, in which DFO staff participated, and led on-site field tours and information sharing sessions aimed at identifying critical habitats for protection and opportunities for habitat restoration and enhancement. DFO has been regularly updated on project changes and implications to fish and fish habitat, and has had the opportunity to provide feedback on conceptual offsetting strategies.

1.3.1 FHOP Advisory Group

Since the Project Proposal submission in January 2014, an FHOP technical advisory group ("FHOP Advisory Group") was established comprising Palmer Environmental Consulting Group Inc. (PECG), CMC and members from SFN, LSCFN and THFN. The FHOP Advisory Group consists of First Nations community members, fish biologists, habitat restoration specialists and a water resources engineer. Each participant has contributed important ideas and feedback at key stages of FHOP development, drawing on individual experiences and expertise. The insight has not only been incorporated into this updated FHOP, but it has also helped prioritize on-site and off-site opportunities for habitat offsetting. Strong support and excellent ideas for proposed research, as a complementary measure to habitat offsetting, have been provided by the FHOP Advisory Group.

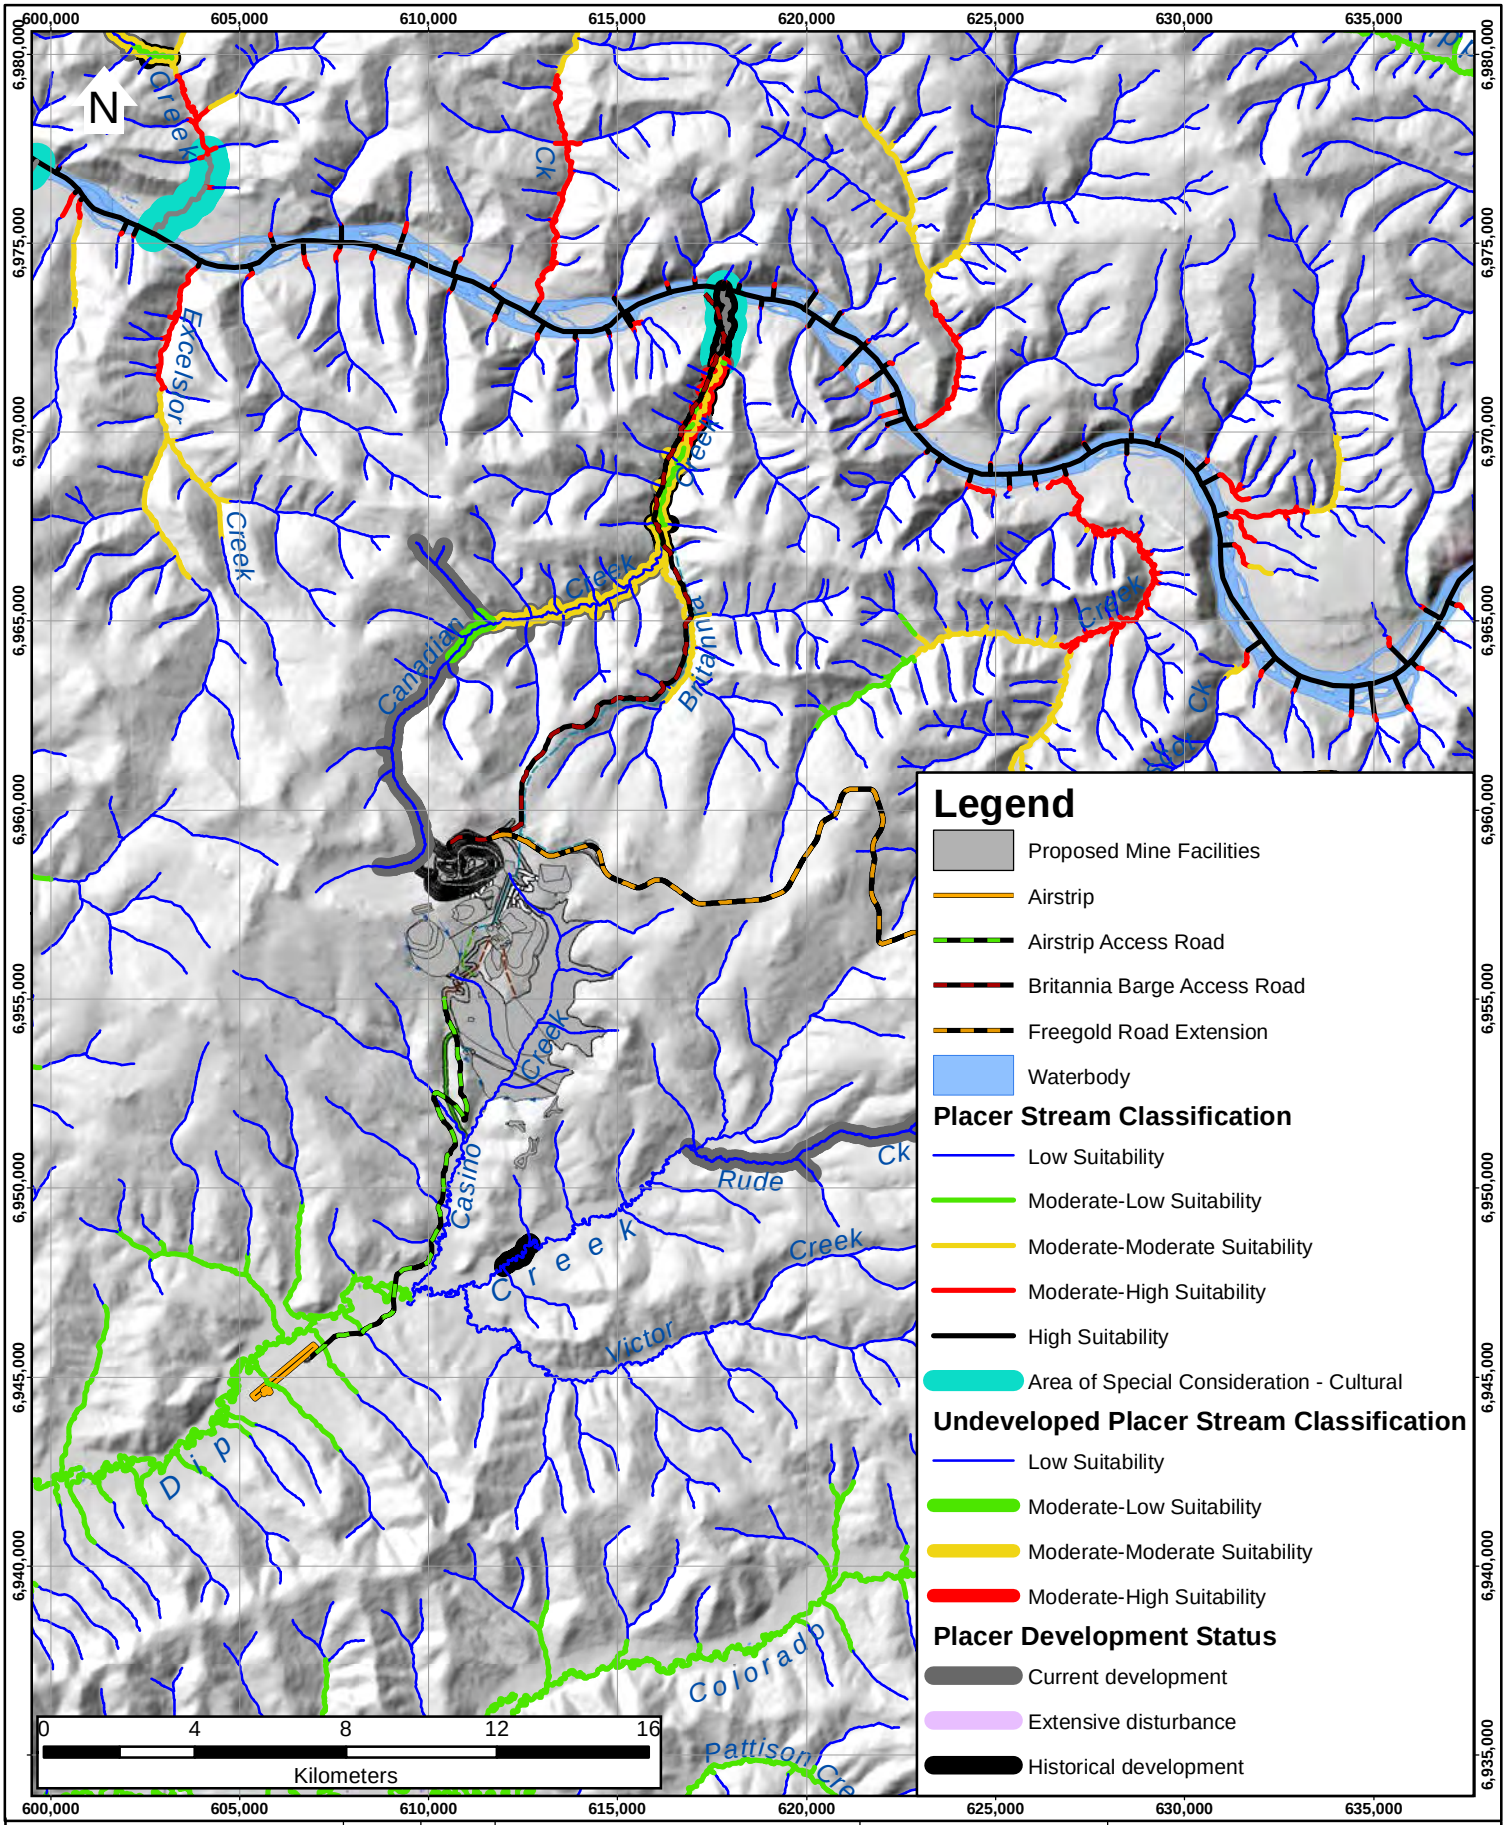
1.4 Report Organization

This document demonstrates how the FHOP will address DFO's requirement to ensure the sustainability and ongoing productivity of Canadian fisheries. Following this introduction (Section 1), it provides an overview of fish and fish habitat in the Project area (Section 2) and summarizes predicted habitat impacts (Section 3). Section 4 provides an overview of offsetting objectives and candidates, followed by a description and preliminary design drawing of each proposed offsetting opportunity (Section 5). Section 6 outlines the overall implementation strategy for the offsetting opportunities, and acknowledges uncertainties and next steps in offsetting planning and design.

2 Overview of Fish and Fish Habitat in the Project Area

Detailed descriptions of fish and fish habitat in the Project area are provided in the "Casino Project Fish and Aquatic Resources Baseline Report" for the mine area (Appendix 10A of the Project Proposal) and for the Freegold Road Extension, Freegold Road Upgrade and Casino Airstrip and Airstrip Access Road (Appendix 10B of the Project Proposal). A summary of the pertinent watersheds, general sampling methods, species distribution and habitat characteristics is provided below.

The Project, including the proposed mine area and its access roads, is wholly located within the Yukon River watershed (**Figure 1-1**). The proposed mine and associated facilities are situated in the upper watersheds of Casino Creek and Canadian Creek (a tributary to Britannia Creek), with the proposed Airstrip and its Access Road located in the adjacent Dip Creek watershed. The Freegold Road Upgrade and Extension cross several large and small watersheds between Carmacks and the mine site, including (from east to west) those of Nordenskiold River, Yukon River minor tributaries, Murray Creek, Crossing Creek, Big Creek, Hayes Creek, Selwyn River, Yukon River minor tributaries, Mascot Creek, Isaac Creek and Dip Creek. Fish and aquatic resource studies were conducted from 2008 to 2013 in the Project study area. Fish sampling and habitat assessment efforts were concentrated in the Casino and Canadian Creek watersheds, where potential near-field effects are anticipated. Backpack electrofishing and minnow trapping were the primary fish sampling methods used, and fish habitat assessments were conducted according to pre-established methods to characterize habitat quality including site-specific potential for supporting rearing, spawning and overwintering activities. In addition, multi-year Chinook spawning surveys were completed in the Britannia and Dip Creek watersheds. To further characterize local fisheries in the mine area, benthic invertebrate and periphyton studies were conducted in the Casino, Dip and Britannia Creek watersheds to assess the primary productivity, community characteristics and overall aquatic ecosystem health. Following initial reconnaissance completed in 2010 and 2011, fish and fish habitat assessments were completed at 61 locations along the Freegold Road Upgrade, 95 locations along the Freegold Road Extension and 12 locations along the Airstrip Access Road.



In the Casino, Britannia and Dip Creek watersheds encompassing the mine area, slimy sculpin (*Cottus cognatus)* and Arctic grayling (*Thymallus arcticus)* were the most dominant species captured, with low numbers of burbot (*Lota lota)* and round whitefish (*Prosopium cylindraceum)* also present in the lower watersheds. The greatest efforts were made to assess baseline conditions in upper Casino Creek (reaches 2 and 3, **Figure 1-1**), where most habitat loss is predicted, with an emphasis on characterizing habitat quality, fish abundance and life history usage. Cold water temperatures, high gradients and velocities, cascades (flow-dependent barriers) and poor water quality from natural and anthropogenic acid rock drainage in upper Casino Creek greatly limit its productive capacity. Despite four years of fish sampling in upper Casino Creek (Reach 3, **Figure 1-1**), only four Arctic grayling were ever captured (in 2013), during exceptionally clear and low-flow conditions (as outlined by PECG in Appendix 10A of the Project Proposal).

Fish abundance and species diversity generally increased downstream within the watersheds, particularly in close proximity to the Yukon River. Juvenile Chinook salmon were captured in lower Britannia Creek in 2009 and 2011, near its confluence with the Yukon River. The capture of only one juvenile Chinook salmon in Dip Creek (downstream of the confluence with Casino Creek), despite sampling from 2008 to 2013, indicates that Dip Creek may occasionally provide habitat for low abundances of juvenile Chinook salmon. Historically, juvenile Chinook salmon were also captured in the lowest 10 km of Dip Creek (DFO, 1994). No Chinook salmon spawning was observed in either the Britannia or Dip Creek watersheds despite multi-year surveying within the Chinook salmon spawning season.

Rearing habitat is the most common habitat type within all watersheds, with most sites providing moderate to good opportunities for juvenile rearing for all species present. In upper Casino Creek, however, moderately steep cascades limit rearing opportunities. There is minimal overwintering habitat in the mine area, except along portions of Dip Creek, due to a lack of deep pools and the widespread formation of anchor ice during the winter. The lack of young-of-the-year rearing in the majority of the Project area suggests that Arctic grayling spawning activities are correspondingly minimal.

The potential for spawning habitat throughout the Project area was mostly rated none to poor, consistent with the Yukon Mining Secretariat's designation of the watercourses as not supporting spawning activities or providing critical migratory corridors for spawning Chinook salmon. According to the Yukon Placer Stream Classification Model (Yukon Placer Secretariat, 2012), the entire Casino Creek watershed is classified as "low" suitability habitat, whereas most middle to lower reaches of Britannia Creek have been classified as "low-moderate" to "moderate" suitability (**Figure 2-1**). The lowermost reach of Britannia Creek has been designated as an "area of special consideration", subject to the most restrictive conditions for placer mining.

Within the watersheds crossed by the Freegold Road Extension and Upgrade, Chinook salmon, chum salmon (*Oncorhynchus keta*), Arctic grayling, slimy sculpin and round whitefish are known to be present. No aquatic species at risk exist within the Project study area. Fish abundance and diversity are greatest along large, meandering creeks and rivers (>third-order), where flow and groundwater discharge is sufficient to inhibit anchor ice formation, pool-riffle morphology is well developed, and bed material is dominated by gravel/cobble substrate (as outlined by PECG in Appendix 10B of the Project Proposal). Big Creek, Selwyn River and Nordenskiold River are known to be utilized by adult Chinook salmon for spawning habitat (DFO, 1985; Yukon River Panel, 2008a), and the tributaries of Seymour Creek, Bow Creek, Stoddart Creek, Hayes Creek and Dip Creek have all been shown to contain fry and juvenile Chinook (DFO, 1994; von Finster, 1998). Juvenile Chinook salmon have also been documented in the lower reaches of Britannia Creek, Isaac Creek, Mascot Creek, Crossing Creek and Murray Creek, near the confluence with the Yukon River (DFO, 1994; EDI Environmental Dynamics Inc. (EDI), 2011).

Along most first- and second-order tributaries crossed by the Freegold Road Extension and Upgrade, flows are generally intermittent and groundwater inputs are often insufficient to maintain ice-free conditions. Stream gradients along the tributaries at the crossing locations are generally less than 5%, but steepen dramatically immediately upstream. Bed material typically comprises cobbles to boulders, which in some cases become difficult for fish to negotiate during low-flow conditions. Pools are comparatively rare and, where present, relatively shallow. The lack of pool and overwintering habitat limits productivity in many small watercourses and suggests that many creeks in the study area may not provide critical habitat required for sustaining fish populations. Thawing permafrost in the summer months maintains cold water temperatures at many of the crossing locations, which also limits habitat productive capacity.

2.1 Contribution to Local Fisheries

The remoteness and inaccessibility of the Casino and Dip Creek watersheds probably limits any recreational or Aboriginal fishing in the mine site area. Also, watersheds draining directly into the Yukon River along the proposed road corridor, and north of the mine site, are generally remote waterways with limited access for fishing activities. However, watersheds in the Project area support important life history stages for subsistence, recreational and commercial species of Yukon River fish, including Arctic grayling and salmon.

Adult Chinook salmon are known to spawn in Big and Selwyn Creeks, which also provide important overwintering habitat for a variety of fish species. Historically, the Yukon River supported regionally significant CRA Chinook salmon fisheries, with recent population declines observed from 1998 onwards (Joint Technical Committee (JTC), 2013). Due to the noted run failures, there have been restrictive regulations applied on recent harvesting activities in order to help stocks recover, including complete fisheries closures over multiple years (JTC, 2013; Yukon Salmon Sub-Committee, 2014).

Yukon River fall chum salmon support both commercial and Aboriginal fisheries, with 63% and 37% of the catch occurring in the commercial and Aboriginal fisheries, respectively (Yukon River Panel, 2008b). Commercial fisheries for chum salmon are located in the Minto and Dawson areas (Appendix 19A of the Project Proposal).

There are no commercial fisheries for other fish species in the Project study area, however, recreational and Aboriginal fishing activities may occur along the nearby Yukon River and in adjacent accessible tributaries. Of note is the Arctic grayling fishery, as grayling is considered the most popular sport fish in the Yukon (Environment Yukon, 2010).

2.2 Habitat Requirements

Arctic grayling and slimy sculpin are the most dominant fish species in the Project area, followed by juvenile Chinook salmon. Arctic grayling primarily occupy areas with clear, slow-moving water, typically with velocities of 20 to 110 cm/s (Hubert et al., 1985; Vehanen et al., 2003; Stewart et al., 2007). As juveniles, Arctic grayling reside in shallow pools and side channels within the lower and middle reaches of small streams (Stewart et al., 2007). Adult Arctic grayling undergo seasonal migrations upstream, where

they occupy slow-moving shallows and deeper pools (Roberge et al., 2002; Stewart et al., 2007). The formation of anchor ice in shallow, lower-order tributaries within the Project area during the fall and winter forces Arctic grayling (and other species) to retreat downstream to higher-order creeks with deeper pools. Arctic grayling spawning occurs from April to mid-June around ice break-up, in streams with velocities of 30 to 80 cm/s, and over gravel substrates (Stewart et al., 2007).

The slimy sculpin is a bottom-dwelling species, residing under cobble or other in-stream habitat cover features. Slimy sculpins demonstrate very high site fidelity, generally remaining within a 50 m-radius home range throughout their lives (Gray et al., 2004). Thus, all life history stages, including overwintering and spawning, must be carried out within this limited home range. Spawning takes place in the spring when temperatures approach 5 to 10°C, in nests on the underside of rocks, submerged rocks or other available in-stream habitat (Roberge et al., 2002).

Juvenile Chinook salmon in Yukon rear in freshwater generally for 1 year before migrating to sea. During the winters in freshwater, overwintering habitat with adequate oxygen, flow and water quality is critical for juvenile survival. They generally occupy slow-moving pools and stream margins, and are often found around undercut banks and woody debris accumulations (Healey, 1991). The importance of small, non-natal streams within the Yukon River watershed as habitat for juvenile Chinook salmon has been previously documented, particularly where deeper pools and slow-moving water were available (Bradford et al., 2001). Chinook spawning in Yukon takes place in low gradient (<4-5%) streams that sustain sufficient overwinter incubation flows over gravel-cobble substrate from July to September (Healy, 1991).

2.3 Limitations to Fisheries Productivity in the Project Study Area

An understanding of the factors that limit fisheries productivity, where project impacts are predicted, enables proposed offsetting measures to be designed specifically to address these potential bottlenecks in production. Several important habitat limitations have been identified in the watersheds surrounding the mine site (where most project impacts are anticipated):

- **Lack of overwintering habitat** – Deep pools provide an important ecological function through their provision of overwintering habitat and low-velocity refuge for juvenile rearing. Within the study area, deep pools capable of providing overwintering and juvenile rearing habitat are uncommon. Winter air temperatures are too cold, and winter baseflows from groundwater are generally insufficient, to prevent the formation of anchor ice and full, frozen-to-bed conditions. Fish are forced to retreat downstream, and overwinter and rear in deep pools of larger creeks that remain unfrozen at depth, such as Dip Creek. This natural, lack of overwintering habitat is common throughout the headwater drainages encompassing the Project area.

- **Unsuitable spawning habitat** – Arctic grayling, the most widely distributed species in the study area, require particular sizes and areas of gravel substrates in which to spawn. Much of the substrate along upper Casino Creek has been derived from colluvial mass movements from the adjacent valley sides; it is comprised of angular cobbles and boulders and is generally unsuitable for spawning, which typically requires unembedded gravel with an approximate diameter of 2.5 cm (Stewart et al., 2007 and references therein). Although spring and summer flow conditions along portions of Casino Creek are amenable to spawning activity, the rarity of appropriate gravel substrates represents a natural limitation on productivity (recruitment back into the population).

  Chinook spawning requirements are even more stringent than Arctic grayling requirements as spawning occurs in the fall, and the eggs require flowing water with sufficient oxygen over the winter season. Many streams in the study area freeze to bottom during the winter, including Casino Creek where anchor ice formation has been documented. Incubating embryos and alevin survival are susceptible to both freezing temperatures and the formation of anchor ice, which can cause reduced flows or even complete de-watering (Bjornn and Reiser, 1991). According to the habitat suitability maps produced by the Yukon Placer Secretariat (2010a, 2010b, 2010c), watercourses within the project area do not support spawning activities or provide critical migratory corridors for spawning Chinook salmon.

- **Natural obstructions to fish passage** – Periodic obstructions or barriers to fish passage have been documented in both upper Casino and Canadian Creeks during baseline sampling. A barrier (20% gradient cascade) to fish passage was documented in upper Canadian Creek, more than 1 km downstream of the majority of predicted impacts in the watershed. Upper Casino Creek and its tributaries are predisposed to naturally forming obstructions to fish habitat, at least seasonally, due to their cobbley to bouldery substrates, moderately steep gradients and relatively low discharges. Casino Creek exhibits small cascades and step-pool morphology in its upper reaches. Some of the boulder-formed steps create vertical drops of 0.5 m or more across the full width of the channel. Over time, these bedforms evolve; a boulder cascade one year may collapse into a fish-passable riffle another year. The capture of very few Arctic grayling in upper Casino Creek, only once in four years of sampling, may relate to the natural formation and collapse of in-stream barriers (Appendix 10A of the Project Proposal). In the long-term, this process limits the quality and reliability of habitat.

3 Summary of Impact Assessment

The assessment of potential impacts of the proposed Project on fish habitat was completed using a combination of methods, depending on whether impacts were predicted to result in a partial loss of flow, complete loss of flow, or loss of riparian habitat. A *Physical Habitat Simulation* (PHABSIM) was used to predict the change in 'usable' in-stream habitat following a reduction of flow along lower Casino Creek (downstream of the TMF), Dip Creek (farther downstream of the TMF) and lower Canadian Creek (downstream of the open pit) (Section 3.1.1). A *Habitat Evaluation Procedure* (HEP) was used to quantify predicted impacts following a complete loss of flow along upper Casino Creek and its headwater tributaries, within and upstream of the TMF footprint; along lower Britannia Creek, in association with reinstatement of the historical, meandering channel as a form of habitat offsetting; and along an unnamed tributary of Dip Creek, which must be diverted around the proposed airstrip (Section 3.1.2). Both methods, originally developed by the U.S. Fish and Wildlife Service, have been widely used across North America as a reliable model for quantifying habitat loss. Recent environmental assessments for similar projects in Canada have successfully employed either PHABSIM or HEP (e.g., Mount Milligan, Kemess, Doris North). Detailed documentation of the comprehensive methods and results of the PHABSIM and HEP studies is provided by PECG and Normandeau Associates, Inc. (Normandeau) (2014) in the Project Proposal Supplementary Information Report (Appendix A.10B). Both PHABSIM and HEP are advantageous methods as they provide a means of quantifying biologically-relevant habitat loss, or gain, by taking into account the habitat preferences and requirements of a species at varying life stages. Further, the methods allow a standardized measurement of habitat loss, which facilitates an effective comparison with different potential offsetting opportunities, regardless of habitat type.

Predicted impacts to riparian habitat were quantified with consideration for the suitability and sensitivity of adjacent in-stream habitat (Section 3.1.3). Following the overview of habitat impact evaluation (Section 3.1), a summary is provided of predicted habitat impacts corresponding to each main component of the Project (Section 3.2). Section 3.3 highlights several ways in which Project design changes were made to avoid or significantly reduce potential impacts to habitat that might otherwise have occurred.

3.1 Habitat Impact Evaluation

3.1.1 Physical Habitat Simulation (PHABSIM)

Overview

PHABSIM is designed to characterize the amount of usable habitat available for a specific fish species at different ages and life history stages including rearing, spawning and overwintering. Measuring the area (m^2) of usable habitat is done by integrating habitat suitability indices (HSI curves) derived from scientific literature that define the range of age- and stage-specific optimal flows, depths and substrate types for a particular species, in this case Arctic grayling. Arctic grayling is one dominant species with widespread distribution in the Project area, and data for flow and habitat indices are available in the literature for this species. Thus, the usable habitat index is defined as a proportion of the total usable habitat (m^2/1000 m of stream length) at a specific flow. PHABSIM can be used further to predict habitat losses under

different flow scenarios, providing a range of potential responses over the Project life. Accordingly, it is possible to quantify the usable habitat index for each age and life history stage, both before and after development.

Methods and Results

Habitat type units were identified and mapped along Reach 1 of Casino Creek; along Dip Creek, from its confluence with Casino Creek downstream to its confluence with the next major tributary (beyond which effects would be undetectable); and along lower Canadian Creek (**Figure 1-1**, **Table 3-1**). Next, hydrology transect locations were chosen in different habitat type units on the basis of their relative abundance in the creek reach under investigation. Casino Creek was divided into two, 3.25 km-long sections, upper and lower, with ten transect sites in each section. Two groups of ten transects were selected in Dip Creek, starting just downstream of its confluence with Casino Creek. Twenty transects were originally selected in Canadian Creek, starting just upstream of the confluence with Britannia Creek. One transect was later removed as changes in the discharge rendered it inappropriate for the model.

Table 3-1. Descriptions of Habitat Types Characterized along Casino, Dip and Canadian Creeks

Habitat Type	Description
Pool	• Low velocity flow
	• Generally deep across the channel or scoured along one bank
	• Often contain eddies along one or both banks
	• Retains standing water as discharge approaches zero
Glide	• Shallow, uniform channel with smooth or laminar flow
	• Normally little or no exposed substrate
	• Typically do not have defined thalweg
	• May also occur in tailouts of pools or interspersed with runs
Run	• Generally deep, higher velocity flow
	• Can contain intermittent exposed boulders, bedrock or coarse substrate
	• Well-defined thalweg, often along one bank
Low Gradient Riffle	• Shallow and turbulent, white-water flow, exposed substrate at low flows
	• Usually composed of gravel/cobble substrate
	• Lacks any definitive thalweg
	• Generally act as controls for lower gradient habitat types
High Gradient Riffle	• Fast, high gradient (usually greater than 4%) habitat type
	• Substrate generally cobble or boulder dominated
	• May have interspersed steps and small pools at low flow
Cascade	• Steep, high gradient habitat type
	• May have interspersed pools at low flow
Other	• Includes any uncommon habitat type (e.g., falls, bedrock chutes, etc.)

Velocity, depth and water elevation measurements along each transect were recorded during one sampling event, and water surface elevations, along with one representative discharge measurement, were recorded during two more sampling events. Sampling events were conducted in order to obtain

three distinct flow regimes (Low, Mid, High) in the creek whenever possible. Bank elevations at each transect were also measured from the water level up to the estimated high water mark to facilitate a complete creek profile. The following substrate types were documented for aiding in the habitat suitability modeling:

- Organics/Silt/Mud
- Fines (<0.2 cm)
- Gravel (0.2 – 6.4 cm)
- Rubble (6.4 – 17.0 cm)
- Cobble (17.0 – 25.6 cm)
- Boulders (>25.6 cm)
- Bedrock

Habitat suitability indices for Arctic grayling were obtained from Hubert et al. (1985), a reference commonly used in habitat offsetting planning (e.g., Ruby Creek Molybdenum Project 2006, Adanac Moly Corporation). Although slimy sculpin is the most dominant fish species in Casino and Dip Creeks, the species was not used for in-stream flow modeling as it is a sedentary benthic species, and has no habitat suitability indices derived. Instead, Arctic grayling was chosen for modeling as it is also a dominant species in Casino and Dip Creeks, it has habitat suitability data available, and it has similar habitat requirements to one of the key species being targeted for offsetting: Chinook salmon.

Each hydrologic cross-section was subdivided into a minimum of 20 cells, with each cell conveying approximately 0 to 10% of the total flow. The area of each cell (m^2) was derived using water depth and a cross-section length interval at a specific flow. Each cross-section cell was designated a habitat score, depending on the measured habitat quality of the cell and how it compared with the habitat requirements for a specific Arctic grayling life stage (Hubert et al., 1985). The habitat score was multiplied with the total cell area to obtain the proportion of usable habitat in that cell. The usable habitat in each cross-section cell was combined to estimate the total usable habitat of the entire cross-section. The calculations were done for each Arctic grayling life stage separately, given their different habitat requirements.

Each cross-section represented a specific habitat type (e.g., run, pool, glide, riffle) found in Casino, Dip or Canadian Creek. The known proportion of each habitat type was used to extrapolate results from habitat usability calculations to the entire creek length. In Casino Creek, for example, Site 1-Transect 1 was recorded as a run. As runs in Reach 1 of Casino Creek comprised 36% of the total length, and a total of six run transects were measured, the representative contribution of Site 1-Transect 1 was 6% (0.36/6*100=6%). Thus, the calculated usable habitat at Site 1-Transect 1, for a specific flow, was used to represent 6% of the total length of Reach 1 of Casino Creek, or 0.39 km.

The usable habitat of a cross-section varies depending on the water stage. Thus, using the three sets of hydrologic measurements at each cross-section, the velocity and depth for Low, Mid and High flow conditions were calculated using the MANSQ channel conveyance method developed by Normandeau. Usable habitat for each Arctic grayling life stage was then calculated for a full range of potential flows, for example as shown below for Casino Creek (**Figure 3-1**).

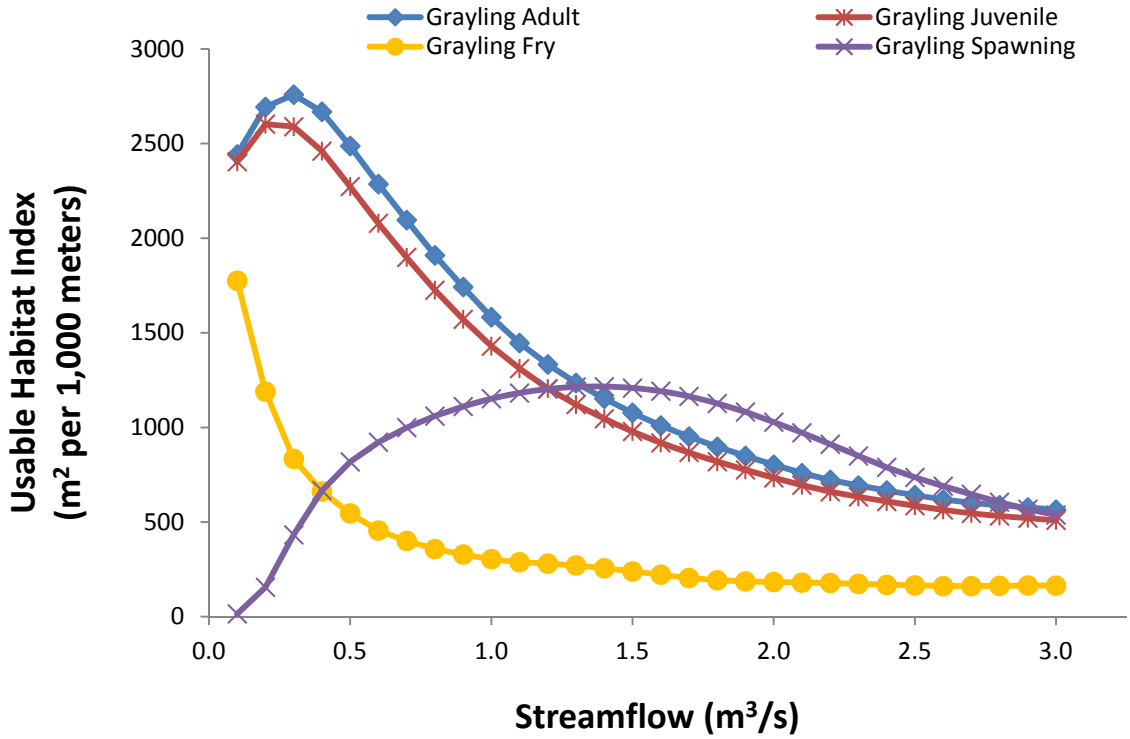

Figure 3-1. Habitat Index versus Flow for All Life Stages of Arctic Grayling in Casino Creek

As a basis for estimating the changes in usable habitat following project development, hydrological data from stream gauges recently installed in Casino, Dip and Canadian Creeks were combined with long-term flow records from nearby, permanent gauges (prorated according to watershed area) to generate long-term synthetic flow series (Knight Piésold, 2013b). To estimate the effect of each project phase on flows in Reach 1 of Casino Creek, flows from mid Casino Creek (H18) were subtracted from those in lower Casino Creek (W4). Baseline and project-phase flows were then entered into the in-stream flow model to estimate changes in usable habitat for each life stage during each project phase, averaged for the two flow stations (**Table 3-2**). As the net loss would still fluctuate depending on the time of year and thus flow chosen for the model, the amount of usable habitat available during 50% or more of the year was used in the final assessment.

In order to ensure all habitat impacts were represented in the predicted totals across all project phases, impacts to different life stages were added by project phase, and then the maximum phase-specific habitat loss was selected for the final impact value (residual serious harm to fisheries) for each affected area (**Table 3-3**). Adult and juvenile Arctic grayling usable habitat losses were not considered additive, because their HSI curves are almost identical, and it would be redundant to include both losses.

Table 3-2. Habitat Index Value (m^2/1000 m) for Arctic Grayling Life Stages at Selected Habitat Duration Percentages under Baseline and Project Phases for Casino Creek (H18 and W4 Average)

*Based on PECG and Normandeau (2014); bolded values are used in final habitat loss calculations (as shown below in **Table 3-8**)*

[a] Represents the most conservative estimate of impact from Artic Grayling Adult Rearing and Arctic Grayling Juvenile Rearing values

[b] Represents the sum of all adverse impacts to usable habitat that occur in any one Project phase, excluding net gains

A long-term synthetic flow series for Dip Creek, downstream of Casino Creek, was generated by Knight Piésold (2013b) based on the sum of flows at gauges W4 (Casino Creek, near mouth) and W9 (Dip Creek, immediately upstream of the confluence with Casino Creek) (**Figure 1-1**). Baseline and project-phase flows were then entered into the in-stream flow model for Dip Creek to assess predicted changes in usable habitat (**Table 3-4**). The final habitat loss values are provided in **Table 3-3**.

The long-term synthetic flow series for Canadian Creek was generated by Knight Piésold (2013b) based on flow records from the gauge in lower Canadian Creek (W3). Baseline and project-phase flows were then entered into the in-stream flow model for Canadian Creek to assess predicted changes in usable habitat (**Table 3-5**). The habitat loss values are provided in **Table 3-3**.

Note: From PECG and Normandeau (2014)

Results from PHABSIM for Reach 1 of Casino Creek demonstrate that the usable habitat area for most life history stages will increase during the construction and operational phases of the project, with the exception of spawning habitat (**Table 3-6**). A small additional increase in usable habitat is noted for adult, juvenile and fry rearing during the closure phase. The increases in habitat can be mainly attributed to the lower flows predicted following TMF construction, which will facilitate a larger area of the creek being usable for Arctic grayling during both adult and juvenile rearing, with a higher net change in usable habitat predicted for the latter. As higher velocities are optimal for spawning, estimated reductions in flow are predicted to reduce the volume of usable habitat for this life stage during construction (3,155 m^2, or 78.3%), operation (3,157 m^2, or 78.4%) and closure (320 m^2, or 7.9%). As there is no evidence for spawning activities in Casino Creek, the net loss of spawning habitat is likely to have minimal impact on Arctic grayling production. However, the reduction in spawning habitat is noted as a conservative measure and included in the total calculation for habitat loss. During the post-closure phase, the largest habitat losses in lower Casino Creek are predicted for adult rearing (1,083 m^2, or 7.2%) and juvenile rearing (1,038 m^2, or 7.6%), followed by fry rearing (360 m^2, or 11.8%). A small increase in spawning habitat is predicted.

In Dip Creek, the amount of usable habitat is predicted to increase for adult and juvenile Arctic grayling during the construction, operation and closure phases of the project, reflecting slight reductions in velocity in association with reduced flow contributions from Casino Creek (**Table 3-6**). During the post-closure phase, small reductions in usable habitat of 1,001 m^2 (2.7%) and 847 m^2 (2.6%) are predicted for adult and juvenile rearing habitat, respectively, due to periodic increased discharges from the reclaimed TMF upstream. Fry rearing habitat is predicted to decrease by 164 m^2 (3.2%) during construction and operations, but by only 13 m^2 (0.3%) during closure. Spawning habitat is predicted to decrease by only 147 m^2 (1.9%) during construction and operations, and by only 90 m^2 (1.1%) during closure. Fry and spawning life stages are expected to return to baseline values during the post-closure phase.

In Canadian Creek, small increases in usable habitat are predicted for Arctic grayling adults, juveniles and fry during the operation phase of the project (**Table 3-6**). Spawning habitat is expected to decrease by 52 m^2 (2.5%) during operations. During closure and post-closure phases, a 59 m^2 (0.6%) decrease in adult rearing habitat is expected, while a slight increase in juvenile rearing and fry habitat is predicted. Usable spawning habitat is predicted to be reduced by 240 m^2 (11.4%).

3.1.2 Habitat Evaluation Procedure (HEP)

Overview

HEP is based on the rationale that the most limited but important habitat characteristic in a waterbody is restricting and therefore regulating fisheries capacity. The total amount of habitat lost calculated using stream measurements is then adjusted to the predicted area of habitat being used, which varies depending on the estimated magnitude of limitation.

Methods and Results

Habitat in reaches 2 and 3 of Casino Creek, which would be impacted by the construction of the TMF, was mapped over its entire 7.5 km length by habitat unit type and length (**Table 3-1**). The TMF's footprint also necessitated habitat mapping along Meloy Creek, lower Taylor Creek downstream of a natural fish barrier (vertical drop along a steep gradient), and three unnamed eastern tributaries of Casino Creek. Habitat mapping was completed along an unnamed tributary to Dip Creek, which would be abandoned when flow is diverted around the proposed airstrip (Section 3.3.3), and along the lower reach of Britannia Creek, in order to represent loss following the proposed reinstatement of the historical meandering channel in association with habitat offsetting (Section 5.1.1).

Within each habitat unit, several parameters were measured including mean depth, mean width, substrate, cover type and percentage, and maximum pool depth. In areas deemed suitable for Arctic grayling spawning, additional information was collected including the percentage of spawning substrate (e.g., gravel and rubble), the percentage of fine substrate (<0.2 cm diameter), area (m^2) of spawning habitat available, and estimated velocity.

Habitat data were analyzed to determine habitat features that may be limiting Arctic grayling productive capacity. From this analysis, five habitat variables were chosen as being potentially limiting: % spawning substrate, % fines in spawning areas, % total fines, overwintering habitat, and % pools and backwaters. Using habitat suitability indices (Hubert et al., 1985), a score was assigned to each habitat variable ranging from 0 to 1, with 1 representing the most optimal conditions for Arctic grayling and indicating that 100% of the available habitat is usable, and 0 indicating that no habitat is usable.

Results of all completed HEP studies in the Project area are summarized below in **Table 3-7**. HSI results were derived in Casino Creek and its small tributaries, Britannia Creek, and the unnamed tributary of Dip Creek from the lack of appropriate pool habitat, which is required for Arctic grayling rearing. It is also likely the greatest constraint to their production in these watersheds. The Meloy Creek HSI score of 0.0 reflects both the lack of available pool habitat in the creek and the predominance of fine sediment substrates.

Table 3-7. Results of HEP Studies Quantifying Predicted Habitat Loss

Watercourse Segment (project impact in parentheses)	Total Available Habitat (m^2)	HIS Score Applied	Net Habitat Loss[a] (m^2)
Casino Creek – Reach 2 (TMF footprint and influence)	19,499	0.26	5,070
Casino Creek – Reach 3 (TMF footprint)	19,653	0.26	5,110
Taylor Creek (below natural fish barrier) (TMF footprint)	553	0.20	111
Casino Creek Tributary 1 (below natural fish barrier) (TMF footprint)	149	0.0	0

Lower Britannia Creek Existing 'Roadway' Channel (reinstatement of historical channel for offsetting)	9,535	0.25	2,384
Lower Britannia Creek Existing 'Roadway' Channel Backwater Pool at Mouth (reinstatement of historical channel for offsetting)	1,728	1.0	1,728
Unnamed Tributary to Dip Creek (diversion around airstrip)	2,203	0.15	330
TOTAL	**62,735**		**19,169**

[a] *Based on analyses in Normandeau and PECG (2014); used in final habitat loss calculation (as shown below in* ***Table 3-8****)*

In order to estimate the anticipated *gain* in usable habitat associated with the reinstatement of the historical, meandering channel of lower Britannia Creek, in a manner that is consistent with the estimation of usable habitat loss along its existing lower channel, a 'reverse' HEP was completed. Fundamental to this approach is an understanding of the types, dimensions and distribution of different habitat units and substrates along the historical channel, but the current dry conditions necessitated modelling the flow parameters. Detailed topographic survey data collected along the channel using Trimble RTK GPS units established a digital elevation model of existing channel morphology. These data were analyzed in a River2D modelling program, assuming the same hydrology as in the adjacent existing channel, in order to generate a grid of two-dimensional flow parameters including depth and velocity vectors (magnitude and direction) (**Figure 3-2**). The resultant depth and velocity distribution provides an indication of the extent of different hydraulic habitats likely to be re-established once flow is diverted back into the historical channel.

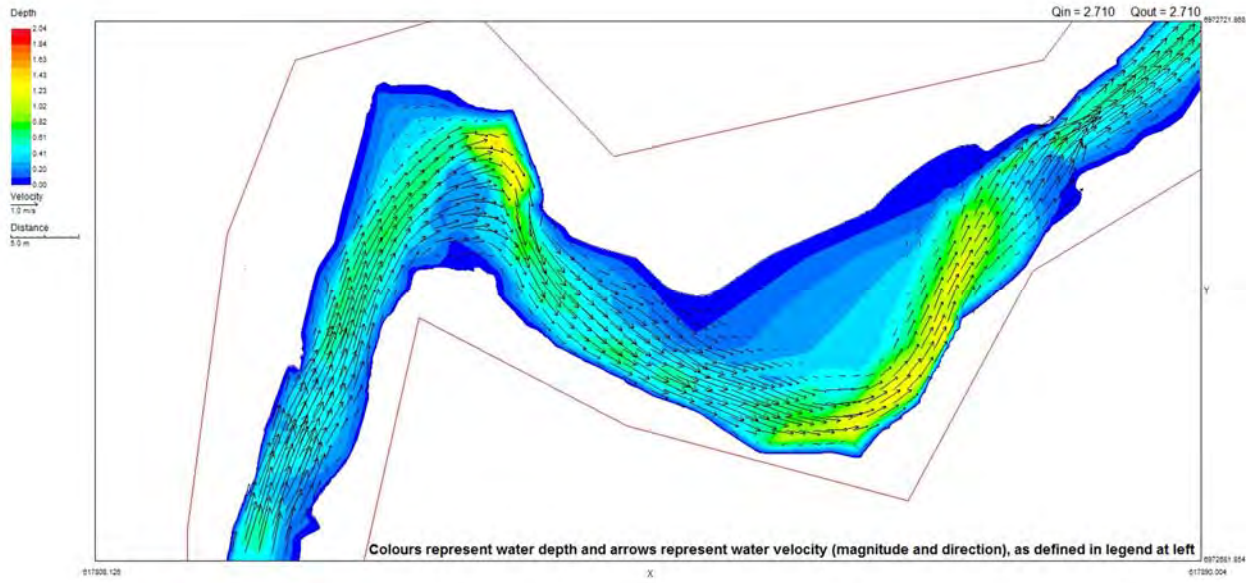

Figure 3-2. Typical River2D Modelling Results (2.71 m³/s) for Britannia Creek Historical Channel

Estimations of the length of each habitat unit were interpreted in ArcGIS based on River2D output rasters (grids) of depth and velocity, with reference to field photographs and notes, and consideration of typical flow dynamics through meanders. Habitat unit widths were determined by averaging multiple width measurements within each unit. Once completed, the habitat unit measurements were evaluated using the same HEP model used for other creeks in the Project area.

3.1.3 Riparian Habitat

Impacts to riparian habitat were calculated for the mine site area and along the access roads, wherever a project facility footprint or road crossing is predicted to result in a loss of riparian vegetation. Impacts were quantified by multiplying the length of stream alongside which the riparian habitat impacts are anticipated by one of three buffer widths, based on the suitability and sensitivity of fish habitat:

- 30 m riparian habitat buffer alongside stream sections that support Chinook salmon;
- 15 m riparian habitat buffer alongside stream sections that support fish other than Chinook salmon; and
- 5 m riparian habitat buffer alongside stream sections that do not support fish habitat, and within the upper Casino Creek watershed above the Reach 2/3 break where fish utilization is rare (i.e., Casino Creek Reach 3, lower Taylor Creek (downstream of a natural fish barrier) and the eastern Casino Creek Tributary 3 (**Figure 1-1**)).

Riparian habitat impacts may occur in association with corresponding in-stream habitat impacts, such as along upper Casino Creek within the TMF footprint, or they may occur independently, such as along watercourses proposed to be crossed by clear-span bridges along the access roads. Total riparian impacts were determined for both fish-bearing and non-fish bearing streams.

3.2 Habitat Impacts

Predicted impacts of the main Project components on in-stream and riparian habitat are summarized below in **Tables 3-8** and **3-9**, respectively, and described in Sections 3.2.1 to 3.2.6. The component-specific impacts are presented alphabetically for consistency with the detailed accounts of impacts provided in Section 10 of the Project Proposal.

3.2.1 Airstrip and Access Road

Construction of the airstrip and access road will require the clearing and grubbing of vegetation, the installation of culverts and bridges along the 14 km-long access road, and the construction of the airstrip and associated facilities. The 2000 m-long airstrip will be located in the Dip Creek valley approximately 12 km southwest of the mine site. A small, unnamed tributary crosses the proposed location of the airstrip. It is not feasible to convey streamflow from the watercourse beneath the airstrip through a culvert due to the risk of damage to the airstrip from irregular ground subsidence from thawing, ice-rich permafrost and from blockages by seasonal ice formation (AE, pers. comm., 2014). In order to safely convey streamflow around the airstrip and avoid the loss of upstream habitat, a naturalized diversion channel that accommodates fish passage is proposed to be constructed along an existing drainage path along the southern edge of the gentle alluvial fan on which the airstrip's southern portion is situated. This diversion will necessitate abandonment and loss of approximately 330 m^2 of usable in-stream habitat along the existing channel (based on a HEP), from its confluence at Dip Creek upstream to the proposed entrance to the diversion channel (**Table 3-8**). The proposed airstrip diversion channel will mimic existing channel morphology, minimize the risk of sedimentation to Dip Creek and provide connectivity to habitat upstream of the airstrip. Losses in riparian habitat (**Table 3-9**) will be offset by the proposed diversion channel's existing, mature riparian vegetation.

The airstrip access road will require the construction of six clear-span bridges over Dip Creek, Brynelson Creek and four unnamed fish-bearing creeks, and four major culverts along non-fish-bearing watercourses. As clear-span bridges will be installed on all fish-bearing creeks, only non-fish-bearing habitat will be lost along the access road due to culvert installations. In addition, riparian habitat loss and alteration will occur adjacent to both fish-bearing and non-fish-bearing crossings (**Table 3-9**).

3.2.2 Canadian Creek Diversion

The Canadian Creek diversion around the Open Pit is proposed for Year 10 of operations, when the Open Pit footprint intersects the creek. The upper section of Canadian Creek is non-fish bearing, with an identified high-gradient (>20%), cascade barrier located approximately 1.2 km downstream of the proposed diversion. Thus, there will be no fish-bearing habitat loss due to the diversion of Canadian Creek.

Table 3-8. Estimated In-stream Habitat Loss

Watercourse or Subwatershed (project impact in parentheses)	Impacted Stream Length (m)		Impacted Stream Area (m^2)		Impacted Modelled Area (m^2)	
	Fish-bearing	Non-fish-bearing	Fish-bearing	Non-fish-bearing	Fish-bearing	Non-fish-bearing
Total Habitat Loss within project footprint[a]						
Lower Britannia Creek (reinstatement of historical channel for offsetting)	1,405	0	11,263	0	4,112	n/a
Upper Canadian Creek (diversion into Open Pit)	0	3,483	0	17,415	n/a	n/a
Upper Casino Creek watershed above Reach 2/3 break (TMF footprint)[c]	7,217	4,509	19,375	7,572	8,900	n/a
Upper Casino Creek watershed below Reach 2/3 break (TMF footprint)[d]	12,832	0	25,384	0	5,827	n/a
95 watercourse crossings (Freegold Extension)	0	1,031	0	787	n/a	n/a
37 watercourse crossings (Freegold Upgrade)	0	30	6[f]	24	6[g]	n/a
Unnamed tributary of Dip Creek (diversion around Airstrip)	1,479	0	2,203	0	330	n/a
10 watercourse crossings (Airstrip Access Road)	0	91	0	54	n/a	n/a
Wetted Habitat Loss due to stream flow reductions[b]						
Lower Canadian Creek (downstream of open pit)	7,000	0	801	0	299	n/a
Lower Casino Creek (downstream of TMF)[e]	6,500	0	1,438	0	3,157	n/a
Dip Creek (downstream of TMF)	8,500	0	2,342	0	1,001	n/a
Total	**44,933**	**9,144**	**62,812**	**25,852**	**23,632***	**n/a**

[a] Areas experiencing "Total Habitat Loss" were obtained from a combination of field and 1:50,000 GIS base mapping measurements (Impacted Stream Area (m^2)), and from HEP analyses (Impacted Modelled Area (m^2)) (PECG and Normandeau, 2014), as summarized above in **Table 3-7**.

[b] Areas experiencing "Wetted Habitat Loss" were obtained from in-stream flow (PHABSIM) modelling results, where Impacted Stream Area (m^2) is the total change in rearing habitat as it represented the median loss of habitat for the entire ice-free season (May 15 – September 30); and Impacted Modelled Area (m^2) is based on the calculated change in usable Arctic grayling wetted habitat, where habitat loss was considered by project phase, with the maximum values by phase reported here (PECG and Normandeau, 2014).

[c] Includes Casino Creek Reach 3, Taylor Creek, Proctor Gulch and Tributary 3.

[d] Includes Casino Creek Reach 2, Meloy Creek, Tributary 1 and Tributary 2.

[e] Includes Casino Creek Reach 1 (i.e., downstream of Brynelson Creek).

[f] Habitat loss from the Nordenskiold River bridge pier.

[g] No modeled value available as there were no habitat limitation criteria identified.

* Denotes final *Fisheries Act* authorization value

Table 3-9. Estimated Riparian Habitat Loss

Watercourse or Subwatershed (Project Impact in parentheses)	Impacted Stream Length (m)		Impacted Riparian Area (m^2)		
	Fish-bearing	Non-fish-bearing	Fish-bearing	Non-fish-bearing	Total Area
Lower Britannia Creek (Reinstatement of Historical Channel for Offsetting)	1,405	0	46,495	0	46,495
Upper Canadian Creek (diversion into Open Pit)	0	3,483	0	34,830	34,830
Upper Casino Creek watershed (TMF footprint)	19,508	6,241	404,820	62,410	467,230
95 watercourse crossings (Freegold Extension)	728*	481	31,590	4,810	36,400
37 watercourse crossings (Freegold Upgrade)	286*	195	10,140	1,950	12,090
Unnamed tributary of Dip Creek (Diversion around Airstrip)	1,449	0	43,470	0	43,470
10 watercourse crossings (Airstrip Access Road)	73*	68	2,190	680	2,870
Total			**538,705**	**104,680**	**643,385**

Note: Riparian habitat setbacks were 30 m for Chinook salmon fish-bearing stream sections, 15 m for non-Chinook salmon fish-bearing streams, and 5 m for non-fish-bearing streams and the upper Casino Creek watershed where fish use is rare (i.e., upstream of the Reach 2/3 break). Asterisks (*) denote that only riparian habitat was impacted due to the installation of clear-span bridges on fish-bearing crossings.

During closure, the Canadian Creek diversion will be decommissioned, allowing headwaters to drain directly into the Open Pit. Non-fish-bearing in-stream and riparian habitat will be permanently lost within the footprint of the Open Pit and upstream to the creek headwaters (17,415 m^2 of in-stream habitat (**Table 3-8)** and 34,830 m^2 of riparian habitat (**Table 3-9**)).

The predicted change in usable fish habitat was assessed under closure conditions using a PHABSIM model (PECG and Normandeau, 2014). In lower Canadian Creek, usable habitat for Arctic grayling juvenile and fry rearing is predicted to increase under the new flow regime, while small decreases are predicted for adult rearing (59 m^2, or 0.6%) and spawning habitat (240 m^2, or 11.4%).

3.2.3 Fish Habitat Offsetting Construction

The reinstatement of the historical, meandering channel of lower Britannia Creek, an integral part of this FHOP, will result in habitat loss within the lowermost 1.4 km-long section of the existing, mostly straight channel of Britannia Creek (as described below in Section 5.1.1). A HEP analysis predicts a 4,112 m^2 loss of usable fish-bearing habitat in lower Britannia Creek (including assumed infilling and disconnection of the backwatered pool at its mouth) (**Table 3-8**). Losses in riparian habitat (**Table 3-9**) will be fully offset by reinstating the historical channel, which meanders through mature floodplain forest.

3.2.4 Freegold Road Extension

Construction of the Freegold Road extension will include 120 km of new road, including the installation of 39 culverts and 56 bridges at 95 stream crossings (**Figure 1-1**). This assessment assumes that clear-span bridges will be installed on all fish-bearing creeks, and therefore only non-fish-bearing aquatic habitat will be lost along the access road due to culvert installations (**Table 3-8**). In addition, riparian habitat loss and alteration will occur adjacent to both fish-bearing and non-fish-bearing crossings (**Table 3-9**).

3.2.5 Freegold Road Upgrade

The existing Freegold Road originates in Carmacks and extends approximately 85 km in a northwest direction towards the Casino mine site (**Figure 1-1**). The road crosses a total of 37 watercourses, 22 of which are fish-bearing. To accommodate Casino mine traffic, upgrades will include widening the road to two lanes with a design speed of 70 km/h; a 5 km by-pass around Carmacks; major new bridges over Nordenskiold River, Seymour Creek, Bow Creek and Crossing Creek; and nine short-span bridges to replace culverts requiring upgrading or relocation. All bridges will be single-lane, clear-span structures with the exception of the Nordenskiold River bridge, which will be two-span with a single pier located in the river.

This assessment assumes that clear-span bridges will be installed on all fish-bearing creeks, and therefore that only non-fish-bearing aquatic habitat will be lost along the access road due to culvert installations, with the sole exception of a 6 m^2 loss of in-stream habitat from the Nordenskiold River bridge pier (**Table 3-8**). Riparian habitat loss and alteration will occur adjacent to both fish-bearing and non-fish-bearing crossings (**Table 3-9**).

3.2.6 Tailings Management Facility

Construction of the TMF will cause direct habitat loss of the upper Casino Creek watershed, including main-stem Casino Creek from its headwaters to its confluence with Brynelson Creek, Proctor Gulch, Taylor Creek, Meloy Creek, and three unnamed tributaries that drain westward into Casino Creek (**Tables 3-8** and **3-9**). The majority of the upper watershed is considered fish-bearing with the exception of acidic Proctor Gulch; upper Taylor Creek, where a fish passage barrier is located approximately 275 m above its confluence with Casino Creek (1 m vertical drop within an 18% gradient segment); and upper Tributary 1, where permafrost-related slumping of the creek banks obstructs fish passage 179 m upstream of its confluence. While approximately 750 m of habitat will technically remain between the water management pond and the confluence of Casino and Brynelson Creeks (**Figure 1-1**), this section is included as lost habitat as the predicted flows are too low to support viable aquatic communities; this also allows for changes to the water management pond location and size, as required. A HEP analysis predicts a 14,727 m^2 loss of usable fish-bearing habitat in the upper watershed, which represents approximately 30% of the total habitat area (**Table 3-8**).

The reduction in stream flows in Casino Creek due to the construction of the TMF will alter downstream fish-bearing habitat. The reduction in flow will result in a net reduction of 1,438 m^2 (4.8%) of wetted area

in lower Casino Creek (**Table 3-8**). Farther downstream, Dip Creek will experience flow reductions from baseline values during the summer and winter months, resulting in predicted reductions in wetted area (3%), width (2%) and depth (3%) (as described in Section 10 of the Project Proposal). During the construction, operations and closure phases, in-stream flow modeling predicts an increase in usable habitat for all life stages of Arctic grayling in lower Casino Creek, with the exception of spawning habitat, which will be reduced by 3,157 m^2 (78.4%) (**Table 3-6**). PHABSIM models predict total adverse areal impacts of no more than 3% in Dip Creek due to reduced flows in Casino Creek (**Table 3-3**).

Following project closure, a spillway will periodically drain excess water from the reclaimed TMF to lower Casino Creek (**Figure 1-2**). Spillway discharge is predicted to produce modest increases in flow from baseline conditions in both lower Casino Creek and Dip Creek during the April-May period. During post-closure, the greatest habitat losses in lower Casino are predicted for adult rearing (1,083 m^2, or 7.2%) and juvenile rearing (1,038 m^2, or 7.6%), followed by fry rearing (360 m^2, or 11.8%) (**Table 3-6**).

In Dip Creek, small changes are predicted in Arctic grayling usable habitat during closure and post-closure (**Table 3-6**). During closure, adult and juvenile rearing usable habitat is predicted to increase relative to baseline conditions, whereas negligible decreases of 13 m^2 (0.3%) and 90 m^2 (1.1%) are predicted for fry rearing and spawning habitat, respectively. During post-closure, reductions in adult and juvenile rearing habitat are predicted to be 1,001 m^2 (2.7%) and 847 m^2 (2.6%), respectively, whereas minor increases are predicted for fry rearing and spawning.

3.3 Habitat Impacts Avoided or Mitigated by Project Re-Design

According to DFO's Hierarchy of Measures for Fisheries Protection (DFO, 2013a), proponents should initially place efforts on avoiding and mitigating potential serious harm to fish, prior to proposing offsetting measures for unavoidable residual effects. Thus, CMC has made several significant changes to the project design primarily to reduce or eliminate impacts to fish habitat that might otherwise have occurred. As suggested by DFO, these changes are briefly described below.

3.3.1 Bridges Instead of Culverts for Fish-Bearing Crossings

Large watercourses along the Freegold Road Upgrade, Freegold Road Extension and Airstrip Access Road, such as Hayes Creek, Big Creek and Dip Creek, have always been proposed to be crossed using clear-span bridges, both for technical reasons and to minimize impacts to aquatic habitat. This original plan has been carried through preliminary design, in association with this submission to YESAB.

Culverts (embedded or not) were originally proposed to convey all small watercourses beneath new or upgraded road crossings. During the late stages of preliminary design, however, CMC proposed to accommodate in its design and construction plan the crossing of all *fish-bearing* watercourses with short-span, precast concrete slab bridges ("short-span bridges"). AE (2013) cited several reasons for using short-span bridges instead of culverts, particularly in areas of permafrost, including "simple construction methods, faster construction schedule, robustness, and low maintenance requirements", in addition to a possible reduction in environmental impact. Non-fish bearing watercourses may still be crossed using conventional corrugated steel pipe culverts designed to convey water and bed material. The installation

of bridges or culverts at fish-bearing crossings will need to be confirmed during the detailed engineering phase of the Casino Project, as bridge installation is dependent on the appropriate geotechnical conditions at each crossing location.

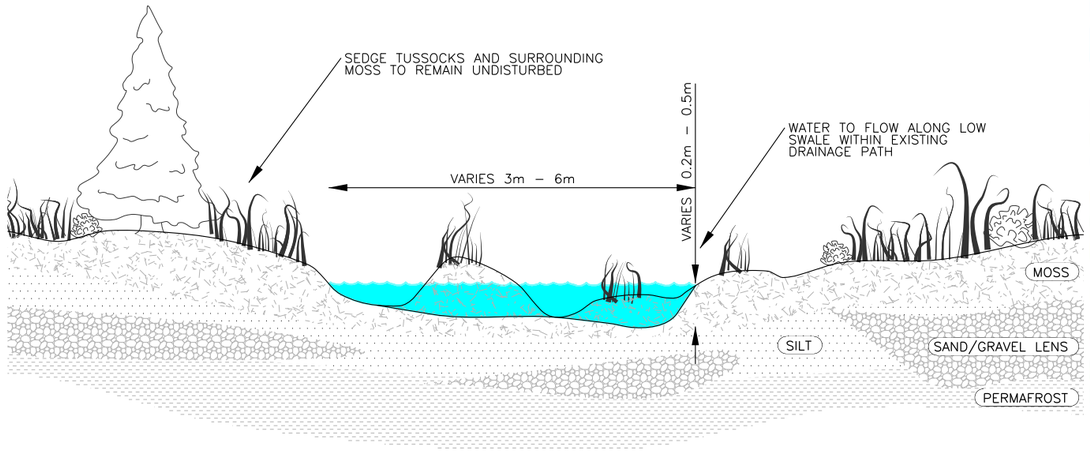
The crossing of fish-bearing watercourses with short-span bridges instead of new or replacement culverts along all access roads avoids impacts to approximately 7,300 m^2 of total in-stream fish habitat (length times width), which would otherwise have potentially required Authorization (and offsetting). Furthermore, the bridge crossings have been designed to minimize risk to in-stream habitat. All bridge abutments will be set back from the tops of banks, in order to avoid projections into the channel and changes in flow or habitat area. Stone will be placed on the bank beneath the bridge deck, flush with adjacent bank sections, to inhibit irregular and potentially severe erosion that might otherwise occur when riparian vegetation is lost due to year-round shading, especially in areas of permafrost. Impacts to riparian vegetation cannot reasonably be avoided, but the need for any riparian habitat offsetting will be minimized by bank stabilization and re-vegetation to mitigate local erosion and sedimentation.

3.3.2 TMF Spillway By-pass of Brynelson Creek

In association with project closure (Years 23 to 25, **Table 1-1**), an overflow spillway is proposed to be constructed to the north of the west embankment of the TMF (**Figure 1-2**). Its purpose is to facilitate control and discharge of excess water accumulation within the TMF and to provide safe passage of storm water volumes from the TMF (Knight Piésold, 2012b). This spillway, which has been situated to follow a natural draw on the north side of Brynelson Creek, was originally proposed to discharge to Brynelson Creek, just upstream of its crossing by the Airstrip Access Road. An integrated hydraulic, fluvial geomorphological and fish habitat assessment of the capacity of lower Brynelson Creek to convey the additional flow from the spillway was completed. The results indicated that both the hydraulic capacity and erosion threshold of Brynelson Creek would be exceeded, potentially resulting in adverse effects on local and downstream fish habitat. In light of these findings, CMC approved the realignment of the spillway such that it is now proposed to by-pass Brynelson Creek altogether (**Figure 1-2**). This spillway re-design avoids direct impacts to approximately 8,500 m^2 of total fish habitat (length times width) and considerable indirect impacts through increased sedimentation downstream in lower Casino Creek.

The period during which excess water will be drained from the TMF has also now been extended from just two months (April-May) to the full spring-summer period, in order to reduce the magnitude of flows and avoid potentially adverse effects on fish habitat in lower Casino Creek (Section 10 of Project Proposal).

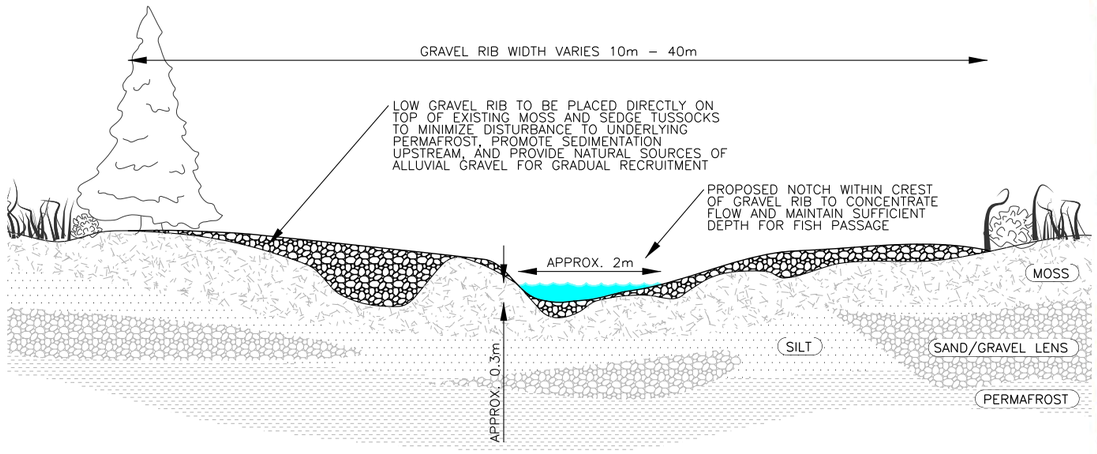
3.3.3 Naturalization of Airstrip Diversion Channel



The proposed airstrip for the Project requires considerable length on level ground, with good approaches in either direction. One of the few locations where these criteria are met is within the Dip Creek valley. The airstrip is proposed to extend onto a gentle alluvial fan across which a small, unnamed tributary of Dip Creek flows (**Figure 1-1**). In order to ensure stability and safety of the airstrip, the small tributary must be diverted around it, rather than being conveyed beneath it through a culvert. The tributary and local surface runoff were originally going to directed around the airstrip along a straight, gravel-filled

interceptor drain along the toe of a berm, built about 120 m upslope from the airstrip. This local filling of fish habitat and disconnection of the watercourse upstream of the airstrip would have resulted in a substantial amount of lost fish habitat.

In order to avoid as much as 9,000 m^2 in total lost fish habitat (length times width), CMC has changed its surface water diversion strategy to create a naturalized airstrip diversion channel to by-pass the airstrip and drain into an existing, natural drainage path (another distributary channel on the alluvial fan) (**Figure 3-3**). The diversion will begin at the apex of the gentle alluvial fan on which the southern portion of the airstrip is proposed, and will follow a natural drainage path along the southern edge of the fan downstream to its confluence with Dip Creek, the outlet of an oxbow lake. The diversion channel will be constructed with a form that mimics existing, natural channel morphology, minimizes disturbance to surface organics and underlying permafrost, and mitigates the risk of downstream sedimentation to Dip Creek. A pilot swale will be carefully formed to accommodate fish passage, and low gravel 'ribs' will be placed amongst the mosses and sedges to allow for future recruitment of alluvial gravels and to promote sedimentation against their upstream flanks. This decision to construct a naturalized diversion channel will reduce the amount of lost usable habitat to 330 m^2.



Surface runoff from the airstrip will flow overland through dense ground vegetation, where it will gradually infiltrate, thereby avoiding potential effects on in-stream water quality. Appropriate erosion and sediment control measures will be identified during detailed design and used during the construction of the diversion channel, consistent with procedures outlined below in Section 6.2, in order to protect the surrounding environment from off-site sedimentation.

4 Fish Habitat Offsetting Background

This section begins by outlining the objectives and rationale of the FHOP (Section 4.1), and then provides overviews and evaluations of each habitat offsetting candidate (Section 4.2). Full descriptions and preliminary design drawings of the offsetting opportunities considered for detailed design and ultimate implementation are provided in Section 5.

4.1 Objectives and Rationale

CMC has designed the Project to avoid serious harm to CRA fisheries, to the greatest extent possible, through project redesign, refinement and impact mitigation. Despite these efforts, some residual impacts (as described above in Section 3.2) are unavoidable and likely to require Authorization from DFO, pursuant to Section 35(2) of the *Fisheries Act*. Additionally, offsetting measures are necessary in order to counterbalance unavoidable serious harm to fish resulting from the Project with the goal of maintaining or improving the productivity of the CRA fishery, as outlined in DFO's *Fisheries Protection Policy Statement* (DFO, 2013b).

Three main categories of offsetting measures are described by DFO (2013a):

- Habitat restoration or enhancement;
- Habitat creation; and
- Chemical and biological manipulations (e.g., fish stocking, invasive species management).

In addition, the inclusion of complementary measures as a means for offsetting provides a new opportunity for proponents in cases where traditional offsetting measures are more difficult or less desirable to implement (DFO, 2013a). Complementary measures are described as "investments in data collection and scientific research related to maintaining or enhancing the productivity of commercial, recreational or Aboriginal fisheries", and are prescribed to make up to 10% of the total offsetting amount. DFO states that the use of complementary measures will be considered as an acceptable means of offsetting in areas where there are limited opportunities for habitat creation, restoration or enhancement, a demonstrated need for an increased understanding of fisheries productivity, and where program results would help facilitate the development and implementation of local fisheries management objectives. Further, any data collection and scientific research should take into account the DFO (2013a) guiding principles (presented below), and be undertaken in a transparent, and scientifically robust and timely manner by a qualified individual or organization approved by DFO.

The proponent's selection of offsetting measures should respect DFO's guiding principles, which are listed below and described further in the guidance document *Fisheries Productivity Investment Policy: A Proponent's Guide to Offsetting* (DFO, 2013a):

1. Offsetting measures must support fisheries management objectives or local restoration priorities.
2. Benefits from offsetting measures must balance project impacts.
3. Offsetting measures must provide additional benefits to the fishery.
4. Offsetting measures must generate self-sustaining benefits over the long term.

The following sections demonstrate how the offsetting opportunities proposed by CMC address each of these guiding principles, prior to describing each offsetting opportunity in detail (Sections 5.1 and 5.2).

4.1.1 Local and Regional Fisheries Objectives

Groups with a vested interest in the Project's local and regional fisheries resources include federal departments, provincial and territorial governments, First Nations, recreational fishing and angling groups, conservation organizations, and industry groups. Of particular importance to these partners and stakeholders is the Yukon River Chinook Salmon population, which has historically provided a significant ecological, cultural and economic contribution to Yukon communities and ecosystems, and has been plagued with drastic population declines in recent years (JTC, 2013). Given this context, the opportunity to focus habitat offsetting measures on creating, enhancing or investigating Chinook salmon fisheries and habitat is increasingly important, and is in accordance with local and regional fisheries objectives.

The following sub-sections outline the local and regional fisheries objectives in the project area by discussing regulatory and First Nations fisheries objectives, followed by the selection process for identifying Chinook salmon as the principal target species for offsetting.

Regulatory Context and Fisheries Management Objectives

Yukon freshwater fishery management is under the jurisdiction of the Fish and Wildlife branch of the Yukon Government. It has several principal objectives:

- To maintain and enhance the quality and integrity, including the biological diversity, of the aquatic environment for present and future generations;
- To ensure the sustainable use of fisheries resources through a balanced and integrated management of fish and their habitats;
- To manage resources in a manner that is collaborative and promotes environmental and socially responsible awareness, participation and stewardship; and
- To provide sustainable fish harvesting and viewing opportunities for social, cultural, recreational and, where appropriate, commercial purposes.

In addition, Status of Yukon Fisheries (Environment Yukon, 2010) outlined the need to focus on managing over-harvested species, such as potentially vulnerable populations of Arctic grayling, lake trout (*Salvelinus namaycush)*, northern pike (*Esox Lucius)* and burbot. Furthermore, recommendations were made to shift towards ecosystem or watershed-based management.

Anadromous fishes in the Yukon are managed and regulated by DFO. Additionally, the management of Yukon River salmon in the Yukon involves several coordinating and advisory agencies: the international Yukon River Panel, established under the USA/Canada Yukon River Salmon Agreement; and the Yukon Salmon Sub-Committee, established under the Yukon land claims' Umbrella Final Agreement. Both agencies provide recommendations to DFO regarding salmon harvest management, stock and habitat conservation, and the enhancement of renewable resource economies.

First Nations Fisheries Cultural Values

CMC has engaged the local First Nation communities with traditional territories encompassing the areas of predicted impacts early and regularly through the planning and development of the FHOP. The Project is of greatest interest to SFN, whose traditional territory encompasses the mine site area where greatest loss of fish habitat is anticipated. Negligible impacts to fish habitat are expected within the traditional territory of LSCFN, which encompasses the eastern end of the Freegold Road. The traditional territory of THFN overlaps a portion of the lower Britannia Creek watershed, where preferred offsetting measures are proposed (as described below in Section 5.1.1). CMC has hosted presentations and workshops within the communities and on-site to communicate the plans for the overall Project and its environmental supporting studies (Section 1.3). Specific input has been solicited from SFN on fish habitat offsetting objectives, strategies, sites and design priorities. Chinook salmon has consistently been identified as a highly valued species for all First Nations. SFN identified the lower reach of Britannia Creek as an area of cultural and ecological significance based mainly on traditional use and consideration of historical and potential Chinook spawning suitability. This reach was classified as an area of special consideration in the placer habitat suitability mapping process (**Figure 2-1**), with the most restrictive requirements and standards (Yukon Placer Secretariat, 2012).

Selection of Target Species

The high ecological, cultural and economic value of Chinook salmon in the Yukon makes it an ideal target species for habitat offsetting works. Although Chinook salmon do not reside in the primary impacted area of Casino Creek, they are found in nearby watercourses such as Dip Creek, lower Britannia Creek, in several major watercourses along the proposed Freegold Road, as well as in the adjacent Yukon River. Also, habitat offsetting that is designed to benefit Chinook salmon will also be advantageous to Arctic grayling and slimy sculpin, which are the dominant fish species residing in the proposed impacted area of the Project. Both Arctic grayling and slimy sculpin have habitat requirements in common with Chinook salmon, such as deep pools for juvenile rearing and overwintering.

4.1.2 Measuring Fisheries Impacts and Offsetting Outcomes

In accordance with the principles of the *Fisheries Act*, this FHOP aims to increase the productivity of fisheries by primarily focusing on improving Chinook salmon productivity, with additional benefits expected for other fish species such as Arctic grayling and slimy sculpin. A quantitative comparison of habitats at impact and offsetting sites is provided below in Section 5.4, following the descriptions of proposed in-stream and riparian habitat offsetting opportunities (Sections 5.1 to 5.3). To assess the relative contribution of impacts and offsetting measures to fisheries productivity, several factors were considered including the amount and type of habitat being lost or gained, distance between offsetting measures and the Project impacts, and the potential for risk of failure and time lags. Each of these factors is addressed below in relation to one of the principal opportunities for proposed habitat offsetting, reinstatement of the historical meandering channel of lower Britannia Creek (overviewed in Section 4.2.1 and detailed in Section 5.1.1):

1. *Variance in quality of habitat being replaced* – DFO recognizes two types of offsetting approaches: "in-kind" and "out-of-kind" offsetting (DFO, 2013a). While the first approach, "in-kind" offsetting, may provide the simpler route by replacing the same habitat type that was lost, there are several reasons why an "out-of-kind" approach may be the favourable choice. "Out-of-kind" approaches present the opportunity to offset common or poorer quality habitat types with habitat types that have been identified as limiting fisheries productivity. The *Fisheries Productivity Investment Policy: A Proponent's Guide to Offsetting* (DFO, 2013a) states the following:

   "The choice of appropriate offsetting measures will be guided by threats to fisheries productivity and fisheries management objectives. In some instances, the most desirable offsetting measures may be a replacement of the same type of habitat that is affected by the project. In other situations, better outcomes for fisheries may be achieved by undertaking offsetting in water bodies or for fish species other than those affected by the project."

   Accordingly, CMC proposes to offset impacts within the Casino Creek watershed off-site in the adjacent Britannia Creek watershed and elsewhere along major tributaries of the Yukon River. The proposed offsetting measures along lower Britannia Creek, a wider, higher-order reach in direct connection to the Yukon River, will benefit a much more diverse fish community, including Chinook salmon – a priority species for protection and restoration in Yukon. This restored channel will represent the highest suitability juvenile Chinook rearing habitat in the Project area, based on the placer stream classification (Yukon Placer Secretariat, 2012), and has some potential for Chinook salmon spawning. Pre-existing complex habitat features include sharp meanders; deep, asymmetric pools; undercut banks with overhanging trees; and diverse gravel bed material. The existing lower Britannia Creek channel follows a former road right-of-way (as explained in Section 5.1.1); its pattern is straight, its gradient is uniform and relatively steep, its flow is relatively fast over a uniform bed, and its bed is dominated by cobbles and boulders with little gravel.

   In comparison, Casino Creek and its tributaries are relatively isolated, occurring at high elevation far from the more productive reaches of Yukon River and its major tributaries. The impacted reaches also support only a few species (not Chinook salmon) or indirect, non-fish-bearing

habitat (tributaries), in part due to poor water quality, steep gradients, a lack of suitable substrate materials, and a lack of deep pools for rearing and overwintering (Section 2.3). Habitat offsetting along lower Britannia Creek, instead of within the Casino Creek watershed, is expected to yield far greater gains in fisheries productivity that will benefit more species and life history stages of these species. **Table 4-1** compares the types and supplies of different habitats at both the impact and offsetting sites, demonstrating that proposed offsetting habitats are generally less common and more productive than those at impact sites.

Table 4-1. Type and Supply of Habitat at Impact and Offsetting Sites

Habitat	Site	Type	Supply
IMPACTED	Lower Britannia Creek "Roadway" Channel (diversion of flow into historical channel)	Riffle-dominated, moderately steep, straight 4th-order channel (only 8% pools), with minimal functional large woody debris	N/A (Unnatural)
	Upper Casino Creek and its small tributaries (TMF footprint)	1st to 2nd order, straight to sinuous channels with cobble-boulder bed and riffle-dominated morphology; low seasonal usage based on high gradient, unsuitable substrates and lack of, and downstream distance to, overwintering habitats	Abundant in region
	Unnamed Tributary of Dip Creek (Airstrip)	1st order single- to multi-thread channel with irregular pool-riffle morphology	Abundant in watershed and region
	Lower Canadian Creek (flow reduction downstream of open pit)	3rd order meandering to braided channel (in areas of placer disturbance) with pool-riffle morphology	Abundant in region
	Lower Casino Creek (flow reduction downstream of TMF)	2nd order sinuous to meandering channel with gravel-cobble bed and pool-riffle morphology	Abundant in region
	Dip Creek (flow reduction downstream of TMF)	4th order tortuously meandering channel with gravel bed and pool-riffle morphology	Common in region
HABITAT OFFSETTING OPPORTUNITIES (Preferred and Contingency)	Reinstatement of Historical Lower Britannia Creek (Preferred)	Low-gradient, tortuously meandering, pool-riffle channel adjacent to Yukon River, with gravel-cobble substrate (30% pools) and abundant functional large woody debris	Limited in watershed and region
	Britannia Creek Ford Restoration (Preferred)	Riffles along 3rd to 4th order, irregularly meandering channel with gravel-cobble substrates	Common in watershed and region
	Diamain Lake Whitefish Fishery Creation (Preferred)	Large, fishless lake with large invertebrates	Common in watershed and region, except limited as mono-culture
	Dawson Dredge Pond Off-line Pool Habitat Creation (Preferred)	Interconnected seepage ponds within permafrost-free gravels (placer dredge piles) adjacent to major river	Limited in region
	Chinook Research Project (Preferred)	n/a	n/a
	Lower Britannia Creek Slope-toe Side Channel Extension and Enhancement (Contingency)	Off-line, groundwater-fed pools for rearing and overwintering	Limited in watershed
	Lower Britannia Creek Groundwater-fed Side Channel Extension and Enhancement (Contingency)	Off-line, groundwater-fed pools for rearing and overwintering	Limited in watershed
	Klondike River Side Channel Rearing Gallery at Germaine Creek (Contingency)	Off-line, groundwater-fed pools for rearing and overwintering	Limited in watershed
	Klondike River Side Channel Rearing Gallery at North Klondike River (Contingency)	Off-line, groundwater-fed pools for rearing and overwintering	Limited in watershed

2. *Geographical distance* – While the location of proposed impacts and offsetting are in adjacent watersheds, the distance via connected watercourses is substantial (commonly >200 km). Thus, it is not expected that realized productivity gains in lower Britannia Creek will resonate with populations in Casino or Dip Creeks where impacts will be concentrated. However, productivity gains are expected to be much greater by locating offsetting in Britannia Creek, for example, due to its proximity to the Yukon River (as discussed above). Thus, there is potential for a greater contribution to CRA fisheries.

3. *Risk of Failure* – This FHOP proposes more gains than losses and allows for the possibility that some habitat may not fully function as anticipated (**Table 4-2**). Focused monitoring and an allowance and expectation for adaptive management will ensure the long-term effectiveness of offsetting works. The proposed offsetting measures have been developed by a multi-disciplinary team with experience in fish habitat restoration and enhancement projects. All offsetting opportunities have been designed with consideration of local hydrology and hydraulics, geomorphology and fluvial processes, and ecological sensitivities and priorities. Therefore, the risk of failure is generally considered low. **Table 4-2** provides specific rationale for the interpreted risk of failure of each offsetting opportunity. For example, the reinstatement of the historical channel has a high certainty of success, given that it is relatively intact and was dynamically stable and provided high quality aquatic habitat for decades to centuries (based on analysis and extrapolation from historical aerial photographs), before the unnatural avulsion occurred along the historical access road right-of-way. Re-introduction of flow into the historical channel, once selectively 'cleaned' of woody obstructions, is expected to restore pre-existing, natural channel substrates and morphology, dynamic fluvial processes and complex micro-habitat features within a year or two of flow diversion. Riparian vegetation already consists of mature mixed forest of spruce and deciduous trees, which will immediately provide cover and important allocthonous inputs.

4. *Recognition of time lag* – DFO (2013a) specifies that "When a time delay is unavoidable, the offset must make up for fisheries productivity that has been lost because of the delay. For example, measures may include building more habitat than is lost so that once the habitat becomes functional it will produce enough fish to make up for the productivity lost during the time lag." Habitat offsetting works have been designed to minimize the time lag between implementation and full function. All habitat restoration, creation and enhancement measures will be completed at the start of construction of the Project, either before or in conjunction with the occurrence of authorized habitat loss (**Figure 4-1**). Habitat offsetting will greatly precede the minor impacts along lower Canadian Creek. **Table 4-2** anticipates the time lag associated with each habitat offsetting component. For example, the historical meandering channel already exists in mature form, from both a geomorphological and ecological perspective. Its reinstatement is proposed to occur before or in conjunction with the occurrence of the habitat loss in Casino Creek. Habitat is expected to be functional in less than two years, following the first post-reinstatement freshet.

Table 4-2. Risk of Failure and Time Lag for Habitat Offsetting

Habitat Offsetting Opportunity	Risk of Failure	Rationale	Lag Time	Rationale
Reinstatement of Historical Britannia Creek (Preferred)	Low	Channel dynamically stable for decades to centuries, with complex morphology and mature riparian vegetation	Short (<2 yr)	Complex in-stream and riparian habitat features already exist
Britannia Creek Ford Restoration (Preferred)	Low	Restoring natural (pre-existing) bank morphology and riparian vegetation	Short (<3 yrs)	Already surrounded by dense riparian vegetation and stable banks
Diamain Lake Whitefish Fishery Creation (Preferred)	Low - Moderate	Previous investigations documented large invertebrate populations (food source) and water quality consistent with whitefish habitat requirements	Moderate (<10 years)	Allowance for time before successful spawning and self-sustaining population growth
Dawson Dredge Pond Off-line Pool Habitat Creation (Preferred)	Low	Previous investigations already documented appropriate water quality and the presence of various species of fish, including Chinook salmon, in the dredge ponds to which a permanent connection is proposed to be established	Short (<3 yrs)	Fish already using some ponds, and riparian vegetation already colonizing shorelines
Chinook Research Project (Preferred)	Low	Clearly defined research objectives, methods and funding sources established by team experienced in research program development and implementation, with support from academic and other organizations	n/a	n/a
Lower Britannia Creek Slope-toe Side Channel Extension and Enhancement (Contingency)	Low	Spring-sourced side channel already exists, but with poor connection to main creek; proposed work will improve connection and expand habitat area around spring	Short (<3 yrs)	Rapid, natural stabilization following construction because only spring-fed (no erosion risk)
Lower Britannia Creek Groundwater-fed Side Channel Extension and Enhancement (Contingency)	Low	Spring-sourced side channel already exists, but with no surface connection to spring pond; proposed work will establish connection to spring pond and expand pool habitat upstream	Short (<3 yrs)	Rapid, natural stabilization following construction because only spring-fed (no erosion risk)
Klondike River Side Channel Rearing Gallery at Germaine Creek (Contingency)	Low	Spring-sourced side channel with documented use by juvenile Chinook salmon already exists; proposed work will expand and enhance opportunities for rearing and overwintering	Short (<3 yrs)	Rapid, natural stabilization following construction because only spring-fed (no erosion risk)
Klondike River Side Channel Rearing Gallery at North Klondike River (Contingency)	Low - Moderate	Groundwater-fed side channel already exists immediately upstream from proposed rearing gallery, demonstrating seepage flow through alluvial gravels, although connection to main river partially affected by meander dynamics	Short (<3 yrs)	Rapid, natural stabilization following construction because only spring-fed (no erosion risk)

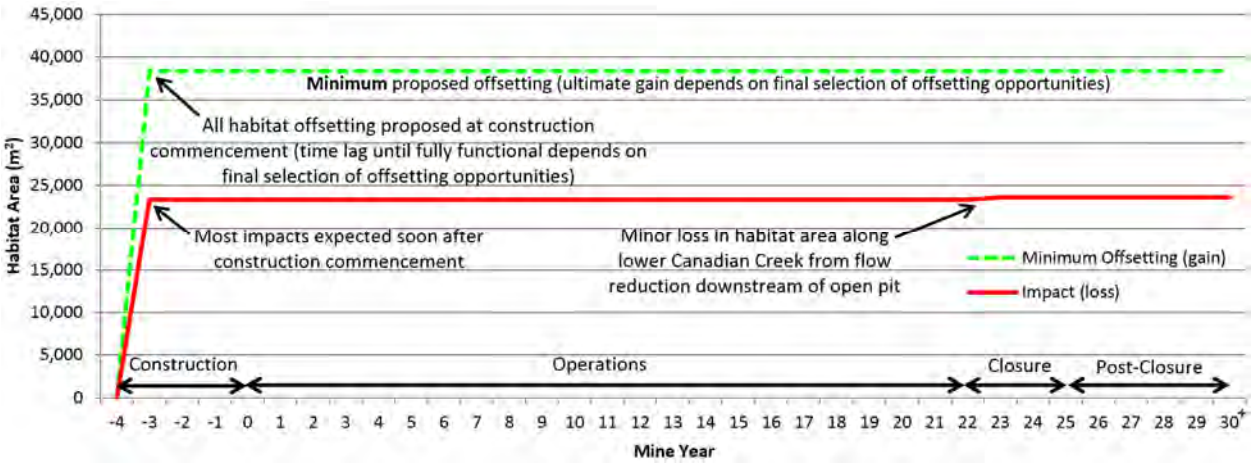

Figure 4-1. Schedule of Predicted Fish Habitat Impacts and Minimum Proposed Gains

4.1.3 Duration of Benefits

One of DFO's four key principles of offsetting is to "generate self-sustaining benefits over the long term" (DFO, 2013a). The intention is to encourage offsetting opportunities that are self-sustaining and do not require ongoing maintenance in order to maintain their effectiveness. All offsetting opportunities proposed in this FHOP meet this principle; each opportunity is designed to function within a setting of natural hydrologic, geomorphic and ecologic processes. Furthermore, all opportunities are designed to accommodate some degree of natural changes in the surrounding environment, over decades, without impacting their effectiveness. For example, the reinstatement of the historical channel of lower Britannia Creek allows for localized changes in channel dimensions and bank morphology, but minimizes the risk of avulsion back into the existing 'roadway' channel by incorporating a diversion berm and re-configured meander that will help guide flood flows along their original path.

4.2 Habitat Offsetting Candidates

Since the initiation of baseline aquatic studies for the Project in 2008, 22 fish habitat offsetting candidates have been identified through a comprehensive and systematic review of undisturbed and previously impacted aquatic ecosystems in the region encompassing the Project, giving priority to opportunities closest to the Project. Of the 22 candidates, 11 are within the relatively small watersheds directly affected by the Project (i.e., "on-site") (**Figure 4-2**), and 11 are elsewhere within the Yukon River watershed within the traditional territories of SFN, LSCFN and/or THFN (i.e., "off-site") (**Figure 4-3**). The naturalized airstrip diversion channel (described above in Section 3.3.3) is excluded from this summary because it is only a form of impact mitigation, not being considered as an element of habitat offsetting. The Chinook Research Project (described below in Section 5.1.5) is also excluded from this summary because it represents a complementary measure to habitat offsetting.

Off-site Fish Habitat Offsetting Candidates

CASINO PROJECT | **FIGURE 4-3** | FHOP REPORT | PN 10011

Each on-site (**Table 4-3**) and off-site (**Table 4-4**) habitat offsetting candidate was assessed relative to DFO's key factors for consideration in offset planning (as outlined above in Section 4.1), in consultation with DFO and other stakeholders during the planning stages of the FHOP. Approximate construction cost, in comparison to potential long-term benefits to productivity, was also considered. The screening process facilitated a consistent and transparent evaluation of each offsetting candidate, and provided a mechanism for assessing and comparing the potential of each option to address the various offsetting objectives. The selection of preferred and contingency options that have now been advanced to preliminary design, in support of the submission to YESAB, incorporates valuable input from First Nations and local communities, regulatory agencies and the multi-disciplinary project team.

Each of the 22 candidates considered for fish habitat offsetting is briefly described below, with reference to key screening criteria, as appropriate.

4.2.1 On-site Candidates

1. Lower Canadian Creek Placer Restoration

Placer mining has occurred intermittently along Canadian Creek since 1911 (MacDonald, 2012). Its long-lasting and locally significant impacts on aquatic habitat along several kilometres of lower Canadian Creek are primarily the result of haphazard channel realignment, dredging of the channel bed and floodplain, and widespread removal of riparian vegetation. The extent of impact to fish habitat along lower Canadian Creek is unlike any other within the Project area watersheds. Consideration was given to reconstructing natural channel morphology or at least re-vegetating riparian and floodplain vegetation, in order to help restore channel stability and reduce sediment loading along the creek (**Figure 4-2**). Such restoration would benefit Arctic grayling and may result in long-terms benefits in productivity, although it may have little effect on Chinook salmon farther downstream. A significant deterrent to further consideration of this offsetting candidate is the potential for future placer mining to disrupt or destroy any restoration works, given its dominant classification by the Yukon Placer Secretariat (2012) as "low suitability" habitat and a lack of adequate measures to ensure future protection; active placer mining licenses currently cover all of lower Canadian Creek.

2. Dip Creek Pond Connections

Numerous ponds exist within the Dip Creek valley, mainly in the form of oxbows and thermokarst (thaw) lakes (**Figure 4-2**). Consideration was given to establishing permanent connections between one or more of these ponds and Dip Creek or its tributaries, via constructed channels, to provide off-line pond rearing and/or overwintering habitat for fish species. Pond habitat would provide low-flow refuge areas outside Dip Creek itself, and would increase riparian habitat and feeding opportunities. The potential addition of overwintering habitat would be critical, as deep pools required for overwintering in the Casino Creek watershed are very limited. The primary obstacle to this option is the extent of ice-rich permafrost along the valley bottom. The establishment of permanent pond-creek connections would require costly, engineered structures and mobilization of heavy equipment to remote sites, with a high likelihood to fill in with flood sediment, become abandoned following channel migration, or collapse through permafrost degradation.

Table 4-3. Summary Evaluation of On-site Fish Habitat Offsetting Candidates

Screening Criteria	1. Lower Canadian Creek Placer Restoration	2. Dip Creek Pond Connections	3. Britannia Creek Ford Restoration	4. Lower Britannia Creek Rehabilitation	5. Lower Britannia Creek Groundwater Channel	6. Partial Flow Diversion into Historical Lower Britannia Creek	7. Reinstatement of Historical Lower Britannia Creek	8. Groundwater-Fed Pool near Britannia Creek Mouth	9. Artificial Lower Britannia Creek Chinook Spawning Channel	10. Lower Britannia Creek Slope-toe Side Channel Extension and Enhancement	11. Lower Britannia Creek Groundwater-fed Side Channel Extension and Enhancement
1 - Fisheries management objectives	Low-Moderate relevance - would likely increase local productivity of Arctic grayling populations, but may have little impact on Chinook salmon farther downstream	Moderate-High relevance – creation of rearing and potentially overwintering habitat for Arctic grayling, maybe also juvenile Chinook salmon	Moderate relevance - improvements to local and downstream habitat for Arctic grayling and likely juvenile Chinook salmon	Moderate-High relevance – may enhance existing Chinook rearing or overwintering habitat	High relevance – creation of Chinook salmon rearing and overwintering habitat	High relevance – creation of Chinook salmon rearing and overwintering habitat	High relevance – creation of Chinook salmon rearing and overwintering habitat	High relevance – creation of Chinook salmon rearing and overwintering habitat	High relevance – creation of Chinook salmon spawning habitat, in addition to rearing and overwintering benefits	Moderate relevance - improvements to local and downstream habitat for Arctic grayling and likely juvenile Chinook salmon	Moderate relevance - improvements to local and downstream habitat for Arctic grayling and likely juvenile Chinook salmon
2 - First Nations traditional uses and knowledge	Low (Chinook priority)	Moderate (difficult access)	Moderate	Moderate	Moderate-High	High	Very High	High	Very High	Moderate	Moderate
3 - Quantity of habitat at offsetting sites	25,000 m^2 potential offsetting area	1,000 - 17,000 m^2 potential offsetting area	0 m^2 potential offsetting area (riparian only)	10,000 m^2 potential offsetting area	12,000 m^2 potential offsetting area	16,000 m^2 potential offsetting area	14,871 m^2 potential offsetting area*	9,200 m^2 potential offsetting area	2,500 - 10,000 m^2 potential offsetting area	1,213 m^2 potential offsetting area*	1,831 m^2 potential offsetting area*
4 – Type and supply of habitat at offsetting sites	Re-instating moderate to good quality rearing habitat for Arctic grayling; limited in watershed and fairly common in region	Good quality rearing and possibly overwintering habitat for Arctic grayling; pond habitats are limited in watershed and region	Riffles along 3rd to 4th order streams; common in watershed and region	Good quality juvenile Chinook salmon rearing and possibly overwintering habitat; limited in watershed and region	High quality juvenile Chinook salmon rearing and overwintering habitat; very limited in watershed; limited in region	High quality juvenile Chinook salmon rearing and overwintering habitat; very limited in watershed; limited in region	High quality juvenile Chinook salmon rearing and overwintering habitat; very limited in watershed; limited in region	High quality juvenile Chinook salmon rearing and overwintering habitat; very limited in watershed; limited in region	Chinook salmon spawning habitat; very limited in watershed and region	Good quality rearing and possibly overwintering habitat for Arctic grayling and juvenile Chinook salmon; pool habitats are limited in watershed and region	Good quality rearing and possibly overwintering habitat for Arctic grayling and juvenile Chinook salmon; pool habitats are limited in watershed and region
5 – Approx. watercourse distance between offsetting sites and main impacts	310 km	7 km	300 km	300 km	300 km	300 km	300 km	300 km	300 km	300 km	300 km
6 - Risk of failure and time lag until offsetting habitats functional	Moderate risk of failure (potential for re-activation of placer mining, which could destroy restoration efforts), <5 yr time lag	High risk of failure (potential for ponds to become disconnected through lateral channel migration, degradation of ice-rich permafrost beneath connector, or sedimentation into connector), <1 yr time lag	Low risk of failure (potential for placer miners to re-activate road in future), <3 yr time lag	Moderate risk of failure (potential for long-term channel instability in response to constructed meander pattern and in-stream structures, in addition to existing sediment pulse), <5 yr time lag	High risk of failure (potential for groundwater to drop below bottom of excavations, or for flowing water to exacerbate permafrost degradation and collapse banks), <3 yr time lag	High risk of failure (potential for seasonal impediments to fish passage due to reduced depths from flow split, and maintenance to address localized sedimentation at channel divergence), <2 yr time lag	Low risk of failure (long-term stability anticipated, given historical function, although monitoring will determine need for any localized adjustments through adaptive management), <2 yr time lag	High risk of failure (groundwater levels may be too low to maintain surface connection, and juveniles may be at risk of predation from adults in adjacent Yukon River), <5 yr time lag	Moderate risk of failure (requirement for monitoring and periodic maintenance, in perpetuity, and potential for equipment failures during critical periods (e.g., winter)), <3 yr time lag	Low risk of failure (potential for side channel mouth to become disconnected to main creek), <3 yr time lag	Low risk of failure (potential for side channel pool habitats to accumulate fine sediment during major floods), <3 yr time lag

** Indicates estimated usable habitat based on 'reverse' HEP for target species*

3. Britannia Creek Ford Restoration (detailed below in Section 5.1.2)

The original placer mining access road along the Britannia Creek valley, which was established prior to the earliest available aerial photography in the area (1948), crosses Britannia Creek and lowermost Canadian Creek at several locations (**Figure 4-2**). At each of the fords, vehicle tracking has caused the banks to collapse, erode and retreat. Channels have become locally over-widened, promoting local sedimentation and further widening, in turn. Fine sediments continue to be eroded from the unvegetated banks during moderate to high flows and transported downstream. With relatively minimal effort, channel morphology at the now-abandoned fords can be restored, and riparian vegetation can be re-established. Although no areal gain in in-stream habitat is anticipated, the reductions to local and downstream sediment loading and corresponding extended downstream fish habitat benefits warrant such offsetting efforts.

4. Lower Britannia Creek Rehabilitation

The existing, mostly straight channel through which lower Britannia Creek flows follows a former road right-of-way (**Figure 4-2**). The roadway channel has responded to the unnaturally straight course and steep gradient, since the avulsion from its natural, meandering channel sometime in the 1970s, by altering its channel morphology. Long, cobble-substrate riffle and run sections dominate its straight length, with few deep pools for velocity refuge or cover. Undercut banks are limited in extent and size, given the relatively uniform flow pattern along the straight channel. Log jams derived from previously eroded mature trees continue to form and create sudden, sometimes dramatic changes in channel morphology and aquatic habitat. Consideration was given to rehabilitating habitat along this unnaturally straight section of lower Britannia Creek, by reconstructing meanders with variable channel dimensions and incorporating in-stream habitat features such as boulders and appropriately situated root wads. Channel naturalization, in this manner, has significant uncertainty and potential for failure. Additionally, the time frame before natural stability would be restored in a creek of this size may be considerable.

5. Lower Britannia Creek Groundwater Channel

Consideration was given to constructing a groundwater-fed channel east of the existing lower Britannia Creek channel, either within or alongside the historical channel of Britannia Creek (**Figure 4-2**). The channel would consist of a series of deep ponds, excavated below the groundwater table, connected by short segments of channel. It would drain into Yukon River and therefore provide rearing and/or overwintering habitat for Arctic grayling and Chinook salmon. However, an integrated field and desktop assessment of groundwater levels and gradients within the valley bottom determined that the groundwater table is as much as 4 m below the bed of the historical channel along some of its length. The depth and area of excavation required to maintain hydraulic connections between the ponds and channel segments would be impractical and result in a significant corridor of disturbance to mature floodplain habitat.

6. Partial Flow Diversion into Historical Lower Britannia Creek

For decades to centuries before its unnatural avulsion onto the former road right-of-way, lower Britannia Creek exhibited a tortuously meandering channel in its lower 2 km before entering Yukon River (**Figure 4-2**). This historical, meandering channel had much higher quality habitat than exists along the current

roadway channel followed by Britannia Creek. Consideration was given to diverting part (e.g., 50%) of the flow within existing Britannia Creek into its historical channel, following restoration of its overgrown channel, at the point of divergence between the two channels. The objective would be to maintain existing fish habitat along lower Britannia Creek, while at the same time restoring habitat along the historical, meandering channel. The primary obstacle to the success of this option, however, is the relatively low stream flows that occur in this semi-arid environment, particularly during the late summer to winter months. Halving the flow to each channel may result in net gains in wetted area, but the associated reductions in flow depth may reduce the usable habitat and prolong periods of flow discontinuity across riffles. A greater disparity in flow apportionment between the two channels (e.g., 80% and 20%) may be possible, but would still be inconsistent with the natural morphology and ecological function of this lower valley.

7. Reinstatement of Historical Lower Britannia Creek (detailed below in Section 5.1.1)

Full reinstatement of the historical, meandering channel of lower Britannia Creek would result in substantial, immediate improvements in the quality of lower creek habitat available to Chinook salmon, Arctic grayling and other species that currently use the existing lower reach and mouth of Britannia Creek (**Figure 4-2**). It is anticipated that this restoration would lead to measurable increases in productive capacity based on the creation of high suitability habitat that is naturally limited and in low abundance in the watershed. The historical channel provides flow and gravel substrate diversity through meanders, dense cover of overhanging vegetation and undercut banks, and micro-habitats on and around in-stream large woody debris and large cobbles. Its naturally deep pools would provide velocity refuge and improved potential for overwintering. The anticipated, long-term benefits to aquatic habitat associated with full reinstatement far outweigh temporary habitat displacement associated with the necessary abandonment of the existing roadway channel.

8. Groundwater-Fed Pool near Britannia Creek Mouth

One of the greatest limitations to the productive capacity of fish habitat within the watersheds encompassing the Project is the lack of deep pools that provide overwintering habitat. A field investigation along the lower Britannia Creek valley identified a zone of groundwater discharge near the mouth of the historical channel of lower Britannia Creek. The creation of a groundwater-fed, backwater pool alongside the main creek, near the confluence with Yukon River, would provide sufficiently deep water to inhibit pond freeze-up during the winter months and support overwintering of Chinook salmon and Arctic grayling (**Figure 4-2**). The incorporation of a 'leaky' bank at the upper end of the pool would enable throughflow for the purposes of maintaining appropriate water quality (e.g., dissolved oxygen concentrations) and periodically flushing fine sediments that accumulate in the channel connection with the main creek. However, field data collected during the 2013-2014 winter revealed that groundwater levels at the proposed pool site drop lower than anticipated, creating a stranding risk for any fish taking refuge in the pool. Furthermore, the FHOP Advisory Group cited opportunistic predation of juveniles by large fish within the adjacent Yukon River as part of the rationale for not pursuing this option further.

9. Artificial Chinook Spawning Channel alongside Lower Britannia Creek

Consideration was given to creating a Chinook spawning channel alongside lower Britannia Creek, either in the historical channel itself or in an excavated tributary (**Figure 4-2**), given First Nations interests and

historical information, and a low abundance of suitable spawning habitat. The critical issue is to establish a source of flow that would continue to flow year-round, including over the winter months when many tributaries to the Yukon River are frozen to their beds. Establishing a passive source of flowing water capable of maintaining an open channel is not feasible, given the absence of lakes in the watershed and the impracticality of intercepting enough groundwater flow upslope and delivering it to the spawning channel. Therefore, only one or multiple pumping wells that withdraw groundwater from the aquifer along Yukon River would represent a potential year-round source of water. The need for pumping to continue in perpetuity, the maintenance requirements, and the risk of equipment failure during critical winter periods precluded further consideration of this option.

10. Lower Britannia Creek Slope-toe Side Channel Extension and Enhancement (detailed below in Section 5.2.1)

As mentioned previously, a lack of deep pools limits the productive capacity of habitats along many watercourses in the Project area. Field reconnaissance along lower Britannia Creek, just upstream of the divergence between the existing and historical channel, identified a side channel that originates in a spring at the edge of a clearing at the toe of the steep, western valley side. The slope-toe channel is poorly connected to the main creek, due to an accumulation of woody debris and organic litter, and disturbance along its western bank has removed all riparian shrubs and trees. The extension of this spring-fed side channel into enlarged pool habitat up-valley from the spring, entirely within the existing areas of disturbance, would support additional rearing and overwintering habitat for species such as Arctic grayling and likely juvenile Chinook salmon (**Figure 4-2**).

11. Lower Britannia Creek Groundwater-fed Side Channel Extension and Enhancement (detailed below in Section 5.2.2)

The rarity of deep pools along the Britannia Creek valley can be addressed through opportunities to create or enhance off-line pool habitats. Field reconnaissance along lower Britannia Creek identified a side channel that originates in a spring at the toe of a terrace scarp that roughly parallels the main creek. About 20 m up-valley from this spring is what appears to be an overgrown placer test pit now filled with groundwater to a level approximately 0.5-1.0 m above the adjacent creek. The connection of this side channel to the existing pond (placer test pit) and then its extension into new pool habitat up-valley along the toe of the terrace scarp would support additional rearing and overwintering habitat for species such as Arctic grayling and possibly juvenile Chinook salmon (**Figure 4-2**).

4.2.2 Off-site Candidates

1. Big Creek Side Channel Enhancement

An existing side channel (meander scar) of Big Creek, which is flooded only during peak flow conditions, would be modified to allow year-round accessibility (**Figure 4-3**). The development of a permanent side channel would create good quality rearing habitat for both Arctic grayling and Chinook salmon. The off-channel position would facilitate a habitat with lower flows during peak flow events, as well as good protective cover and feeding opportunities for juvenile fish. In-stream habitat features such as boulders and cobble substrate could be added to enhance protective cover and the colonization of species on which fish feed (e.g., benthic invertebrates, periphyton). The key constraints to this option are the

potential for the main stem of Big Creek to re-occupy the side channel, given its lateral instability, and the relatively small area of habitat gained.

2. Mica Creek Side Channel Creation

SFN identified Mica Creek as a potential candidate for fish habitat offsetting in part due to its proximity to Pelly Crossing, where its mouth is located, and in part because it provides important rearing and spawning habitat for Chinook salmon and many other freshwater fish, including slimy sculpin, lake chub (*Couesius plumbeus*), longnose sucker (*Catostomus catostomus*), Arctic grayling and round whitefish (**Figure 4-3**). The watercourse meanders through a broad valley that is almost entirely undisturbed, with the exception of a road crossing near its mouth. Beaver activity has been identified as a recent obstacle to upstream fish migration in the lower reaches, hence the area's consideration for possible complementary research measures. Consideration was also given to creating off-line, groundwater-fed side channels to provide additional rearing and overwintering habitat for juvenile Chinook. This type of habitat is already present in reasonable abundance.

3. Needlerock Creek Side Channel Creation

Needlerock Creek enters the south side of the Pelly River a short distance upstream from Pelly Crossing (**Figure 4-3**). It exhibits a tortuous to irregular meander pattern within an undisturbed valley. A reconnaissance flight was conducted over the watershed with a representative from SFN to identify any opportunities for fish habitat offsetting. As for Mica Creek, consideration was given to creating off-line, groundwater-fed side channels to provide additional rearing and overwintering habitat for juvenile Chinook. However, this option was not pursued any further because of the pristine conditions and the existing presence of this type of habitat.

4. Diamain Lake Whitefish Fishery Creation (detailed below in Section 5.1.3)

Diamain Lake is a moderately large lake (approx. 20 km^2) located about 17 km straight northeast of the SFN community of Pelly Crossing, or about 25 km by highway (4 km), gravel road (18 km) and ATV trail (3 km) (**Figure 4-3**). It drains into the Pelly River via an outlet channel that drops steeply through a bedrock canyon. The lake is fishless, according to previous investigations, despite having acceptable water quality and invertebrates whose large size is attributed to a lack of predation (Archibald 1977; Lindsey et al, 1981). Consideration is being given to stocking the lake with whitefish, a culturally important species to SFN, to create a local fishery for the benefit of current and future generations of the local community. The whitefish (or other species selected by SFN) would be sourced from within the Pelly River watershed and supported by a hatchery operation in the initial phases of the stocking and monitoring program. Additional limnological and ecological studies would be completed to confirm the appropriate conditions for the proposed stocking program.

5. von Wilczek Creek Side Channel Creation

von Wilczek Creek is a small watercourse that originates in the hills south of Pelly Crossing and enters the east side of Yukon River just north of Minto (**Figure 4-3**). The watercourse loses much of its flow where it leaves its valley confinement and crosses a broad alluvial fan-terrace complex composed of sand and gravel. The lowermost 800 m of the creek support Juvenile Chinook salmon rearing, except during

periods of drought when water levels are too low. Consideration was given to creating constructing another distributary or parallel channel near the mouth of the creek, in order to provide additional habitat for juvenile Chinook salmon. However, mid to late summer water levels may be compromised by an additional, adjacent channel.

6. Tatchun Creek Stabilization and Enhancement

Tatchun Creek provides important Chinook salmon spawning and rearing habitat along the 7 km reach between Tatchun Lake and Yukon River (**Figure 4-3**). A number of natural and anthropogenic disturbances in recent decades appear to have contributed to a decline in the numbers of Chinook salmon that are returning to the reach to spawn. Logging in the mid-1900s was followed by the introduction of beavers, which have significantly altered the flow and sediment regime through the construction and subsequent breaching of their dams. Several large meanders are now undercutting the base of steep valley sides, causing shallow to deep-seated landslides that are delivering significant volumes of fine and coarse sediment into the creek. The high sediment supply has locally transformed the single-thread, meandering channel into a wandering to braided channel. Substantial efforts would be required to stabilize the valley bottom, and the potential benefits to Chinook salmon can only be speculated without prior research. In addition to considering opportunities to help promote self-stabilization, opportunities for research as a complementary measure for offsetting have also been identified.

7. Yukon River Slough Enhancement

Numerous 'blind' side channels without upstream surface connections, locally known as sloughs, occupy the downstream portions of large bars and islands within and alongside Yukon River between Carmacks and the Project area (e.g., **Figure 4-3**). These sloughs can provide high quality habitat to fish species seeking refuge from the higher velocity and higher turbidity water within the main Yukon River channel. Surface water seeps into the bar head, slowly filters through the alluvial sand and gravel, and then emerges as clear water within the open, downstream segment of an old side channel (i.e., hyporheic exchange). Chum salmon spawn near the mouths of these sloughs, and opportunistic usage by juvenile Chinook salmon is believed to occur (Al von Finster, pers. comm., 2014). Some of the sloughs remain open and mostly free of ice cover during winter, likely in areas where there is sufficient through-flow of relatively warm, shallow groundwater that ice is unable to form where it emerges. Consideration was given to excavating, extending and enhancing slough habitats, but concerns expressed by the FHOP Advisory Group included their stability within a dynamic river, their limited attractiveness to Chinook salmon (the principal target species for offsetting), and the challenges to authorization along the heritage river.

8. Klondike River Side Channel Restoration

One of the members of THFN identified a small side channel of the Klondike River in which he recalls observing large numbers of fish aggregating when he was younger. The side channel is located immediately southeast of the town centre of Dawson City, on the north floodplain of the Klondike River (**Figure 4-3**). Recent field reconnaissance revealed that the side channel has become perched above the normal water level of the adjacent river, such that it is entirely dry and drops approximately 0.5 m at its outlet onto a wide, gravel side-bar. A small pond at its head, presumably an overgrown placer test pit, is

the only permanent water in this portion of the floodplain. Past modifications to the bed of the river, immediately downstream near the former water intake, may explain some of the changes in river bed (and therefore water level) elevation relative to the floodplain (Al von Finster, pers. comm., 2014); localized down-cutting may now be occurring in the absence of gravel augmentation. Consideration was given to reconnecting the small pond to the river by deepening the infilled side channel, especially given the opportunities such efforts would provide for interpretive signage and education for youth in the local community. However, the maintenance that would likely be required to maintain a surface connection between the pond and the river discouraged further consideration of this offsetting option.

9. Dawson Dredge Pond Off-line Pool Habitat Creation (detailed below in Section 5.1.4)

Undeniably the most conspicuous 'landforms' within the lower Klondike River valley are the vast complexes of dredge piles and ponds left by placer mining that began intensifying locally in the 1960s (**Figure 4-3**). A unique characteristic of the dredge ponds is their remarkable depth (commonly >5 m) and their continuous, year-round through-flow of water that seeps into and out of the cobbley berms that separate them. Various fisheries scientists have recognized the opportunities the dredge ponds provide for off-line habitat creation and enhancement, especially for rearing and overwintering of juvenile Chinook salmon and other Klondike River species (e.g., slimy sculpin, round whitefish and Arctic grayling). EDI (2005) studied and reported on the potential for connecting and using some of the dredge ponds to offset predicted habitat impacts associated with the previously proposed replacement of the car ferry at Dawson with a bridge. Its sampling of fish and water quality within a number of the ponds confirmed fish presence, even in some isolated ponds, and demonstrated the capacity of the waterbodies to support rearing and likely overwintering habitat. Building on this previous ecological work, a network of interconnected ponds is proposed to increase opportunities for off-line rearing and overwintering of juvenile Chinook salmon, among other Klondike River species.

10. Klondike River Side Channel Rearing Gallery at Germaine Creek (detailed below in Section 5.2.3)

Germaine Creek enters a side channel on the south side of the Klondike River, where a pair of meanders was intentionally cut-off by earth-moving equipment in the 1970s, presumably to mitigate further erosion of the highway embankment (**Figure 4-3**). A small, spring-sourced channel meets Germaine Creek, where it drains from the culvert beneath the Klondike Highway. Annual visits and monitoring by Al von Finster since 2004 provide a basis for documenting successful use of this groundwater-fed channel by juvenile Chinook salmon for rearing and overwintering. Only once in ten years, when late fall and winter water level in the Klondike River was unusually low, did stranded fish within the groundwater-fed channel not survive the winter, likely as a result of river water levels being so low that much of the intercepted groundwater originated from the oxygen-poor, thawing permafrost to the south. A rearing gallery consisting of a trunk channel with several river-side branches is proposed to extend and deepen the pool habitat beyond the spring, thereby inducing greater interception of comparatively oxygen-rich, shallow groundwater flow from the Klondike River.

11. Klondike River Side Channel Rearing Gallery at North Klondike River (detailed below in Section 5.2.4)

Amid the general instability along the Klondike River, just upstream of its confluence with the North Klondike River, there is a mature white spruce forest growing on a stable, low terrace situated on the inside of a large meander (**Figure 4-3**). A groundwater-fed channel, maintained only by seepage intercepted through the alluvial gravels, flows around this low terrace to meet a continuously flowing side channel with upstream and downstream surface connections to the main Klondike River. A broad, V-shaped clearing within the terrace forest is a result of past gravel excavation, long ago abandoned and left to regenerate naturally. The existing area of disturbance within the relatively stable inner portion of the meander provides an opportunity to construct a gallery of interconnected, groundwater-fed pool habitats that would support both rearing and overwintering of local fish species, including juvenile Chinook salmon.

5 Description of Proposed Fish Habitat Offsetting

Eight of the 22 habitat offsetting candidates described above, plus a complementary contribution to Chinook salmon research, represent proposed offsetting opportunities for the Project (**Figure 5-1**). Four of the candidates plus the research project represent *preferred* opportunities, and four of the candidates represent *contingency* opportunities. CMC has identified preferred opportunities as those which are most feasible and best align with DFO's objectives for ensuring the sustainability and ongoing productivity of Canadian CRA fisheries. The contingency opportunities are also feasible, but only to be pursued if authorization for the preferred opportunities is not expected, as they offer more modest opportunities to increase the productivity of target species. CMC commits to restoring, creating or enhancing enough fish habitat to fully offset the predicted residual impacts from the Project (as quantified below in Section 5.4), but exactly which combination of habitat offsetting opportunities will be advanced to detailed design will be confirmed following additional consultation with First Nations and DFO.

Each of the preferred (Section 5.1) and contingency (Section 5.2) habitat offsetting opportunities is detailed below. Proposed offsetting for impacts to riparian habitat is described in Section 5.3. The overall habitat balance is outlined in Section 5.4.

5.1 Preferred Habitat Offsetting Opportunities

5.1.1 Reinstatement of Historical Lower Britannia Creek

Lower Britannia Creek is well suited for fish habitat offsetting given its historical disturbances related to placer mining, which has occurred intermittently in the area and has impacted Britannia Creek and its major tributary, Canadian Creek, since 1911 (MacDonald, 2012). Lower Britannia Creek's classification by the Yukon Placer Secretariat as "Areas of Special Consideration – Cultural" virtually precludes future placer mining activity (**Figure 2-1**). A narrow road, presumably providing access to upstream mineral prospects, is visible along the Britannia Creek valley in the earliest available aerial photography in the region (1948) (**Figure 5-2**). It forded Britannia Creek at several locations downstream of its confluence with Canadian Creek, before continuing up the Britannia Creek valley (**Figure 5-1**). Sometime between 1965 and 1988, based on available historical aerial photography, lower Britannia Creek abandoned its natural, meandering channel to follow the straight, road right-of-way, which offered little resistance and a direct, downhill path. Anecdotal accounts from a local trapper indicate the avulsion likely occurred in the early 1970s. After following the roadway for about 900 m, the streamflow diverged eastward and carved a sinuous path, forming a new mouth about 150 m west of the original mouth (**Figure 5-2**).

FHOP REPORT

PN 10011

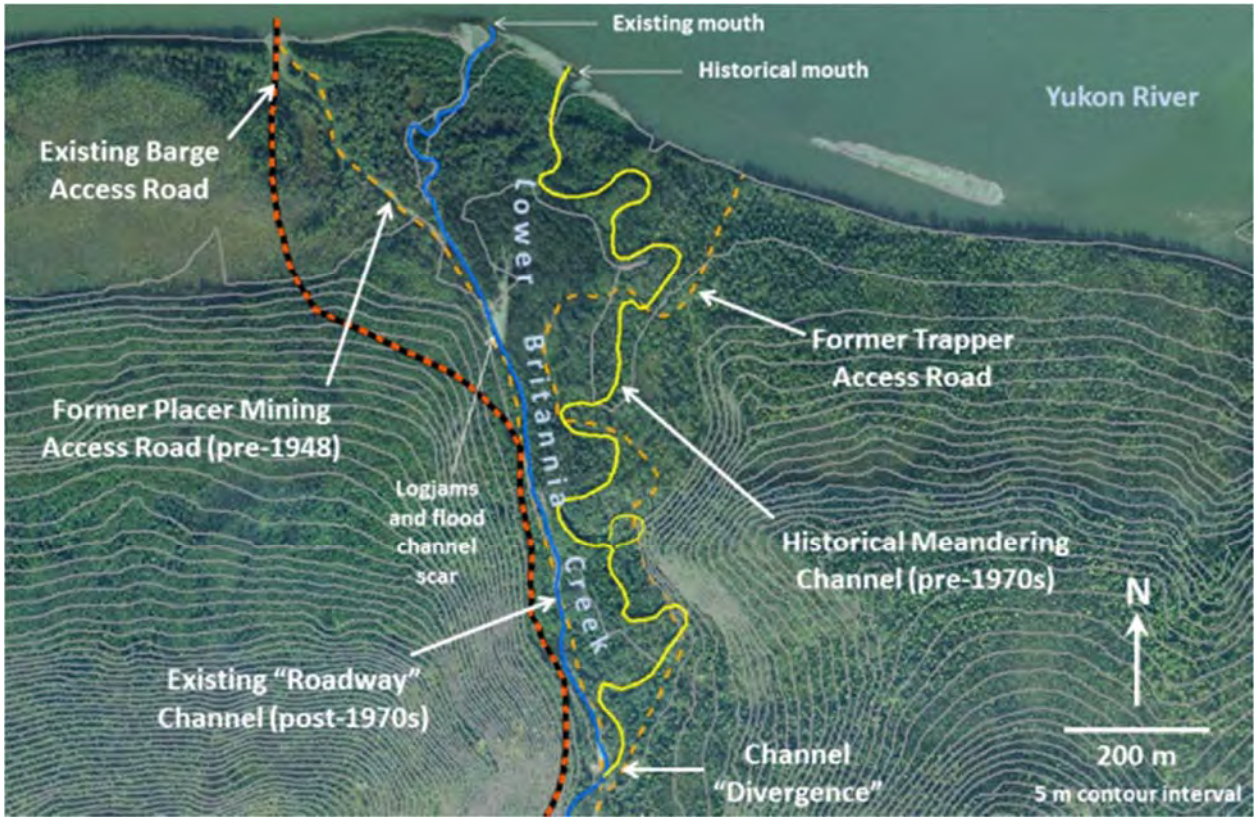

Figure 5-2. Existing and Historical Channels of Lower Britannia Creek

The unnatural avulsion of Britannia Creek onto the former road right-of-way resulted in a sudden and dramatic impact on fish habitat quality. Whereas the historical channel had a tortuous meander pattern, with deep, asymmetric pools along steep or undercut banks, the new roadway channel is mostly straight, shallow and comparatively steep with a large cobble bed and higher flow velocities (**Figure 5-3**). The historical channel, which was dynamically stable for decades to centuries, had regular sequences of riffles, runs and pools; the roadway channel is dominantly riffle-run habitat with few areas of refuge. The unstable roadway channel is expected to continue adjusting its pattern for decades, through irregular and locally severe bank erosion, until it re-adopts natural meander geometry. Logjams, major aggradation and a shallow, multi-thread channel near the divergence of the channel from the former road alignment are a testament to the continued instability of this roadway channel (**Figure 5-4**). Habitat offsetting is proposed along lower Britannia Creek to avoid this area of long-term instability and restore the lost, meandering habitat. Measures to address localized, upstream instabilities at abandoned fords are proposed as part of overall watershed restoration in Section 5.1.2.

Figure 5-3. Downstream View of 'Roadway' Channel of Lower Britannia Creek (Aug. 23, 2011)

Figure 5-4. Unstable, Debris-jammed 'Roadway' Channel of Lower Britannia Creek (Aug. 25, 2014)

At present, two distinct channels descend the gentle alluvial fan at the mouth of Britannia Creek: the mostly straight, roadway channel on the west side, which currently conveys all streamflow, and the dry, tortuously meandering historical channel on the east side (**Figure 5-2**). The reinstatement of the historical channel, which represents 14,870 m^2 of in-stream habitat[1] and 86,080 m^2 of riparian habitat, will be accomplished in two main steps: restoration of natural morphology free of obstructions, and re-introduction of flow (**Drawing 1, Appendix A**). Since its abandonment several decades ago, the historical channel has become locally overgrown with saplings and has accumulated woody debris and organic matter on its bed (**Figure 5-5**). This material, which otherwise would form major obstructions to flow, will be selectively removed through manual labour and/or the use of small equipment (e.g., Bobcat). Channel banks will be restored at four small fords, where a trapper access road crosses the (dry) historical channel (**Figure 5-2**). Once the natural morphology of the channel has been restored, entirely "in the dry", flow will be gradually re-introduced during a low to moderate flow, when water in Britannia Creek and the Yukon River is already naturally turbid (e.g., the waning stages of a freshet). This timing will minimize risk to downstream aquatic species and habitats. Further details, including the importance of conducting a fish salvage and release from the dewatered existing channel, are described below in Section 6.1.

Figure 5-5. Overgrown and Debris-littered Historical Channel of Lower Britannia Creek

[1] A 'reverse' HEP analysis of the historical channel of lower Britannia Creek, based on a two-dimensional hydraulic model combined with habitat indices for Arctic grayling (Hubert et al., 1985), determined that the total habitat area (length times width) is anticipated to be fully usable (HSI score of 1.0) (Section 3.1.2).

A permanent diversion berm is proposed at the divergence of the existing and historical channel in order to ensure in-stream and overbank flows are directed into the historical channel (**Drawing 2, Appendix A**). The most upstream meander of the historical channel will be realigned eastward in a way that approximately reflects its existing geometry, in order to avoid potential future avulsion back into the existing channel at the narrowing between the existing and historical channels. The cut-off meander will be abandoned to form a backwatered oxbow. The bed of the historical channel is elevated slightly (<0.5 m) relative to the bed of the existing channel, which has degraded (down-cut) slightly in response to the reduction in channel length and steepening of its gradient. Therefore, a riffle will form at the entrance to the historical channel, at the downstream end of a pool in the existing channel. A vegetated setback of at least 5 m is proposed for the berm from the channel bank, in order to provide a buffer for flood attenuation. Beyond the diversion berm, the existing channel will be abandoned and allowed to revegetate naturally with colonizing, pioneer species.

The restored historical channel will have the same gentle profile and localized, mid-reach steepening as it did prior to abandonment several decades ago (Profile, **Drawing 1, Appendix A**). The existing, natural cross-sectional shapes are distinct for pools and riffles, as would be expected. Pools typically exhibit strong asymmetry, which promotes scour and undercutting along the outer banks of meanders and deposition of gravel and fine sediments in point bars along the inside of the bends (Typical Pool Section, **Drawing 1, Appendix A**). Riffles tend to be shallower, slightly wider and composed of cobbles; they increase dissolved oxygen levels in water, provide critical habitats for benthic invertebrates, and form local sites of hydraulic grade control (Typical Riffle Section, **Drawing 1, Appendix A**). Runs exist as transitional features at the downstream ends of riffles and upstream limits of pools, typically located at inflection points between successive meanders.

5.1.2 Britannia Creek Ford Restoration

Historical access roads for placer mining forded lower Britannia Creek and lowermost Canadian Creek at six sites, in total (**Figure 5-1**[2]). Four of the fords cross lower Britannia Creek, one crosses Canadian Creek just upstream of its confluence with Britannia Creek, and one crosses Britannia Creek upstream of its confluence. All fords were formed historically at riffles (areas of natural widening and coarse bedload deposition), without regard for impacts to channel morphology and aquatic habitat, and are no longer required for access along the valley. The existing Barge Access Road is further elevated from the valley bottom, where no crossings of Britannia Creek are required, and has only one clear-span bridge over Canadian Creek and an adjacent side channel. The abandoned fords represent sites of localized instability and sources of fine sediment from road surface runoff.

CMC proposes to apply typical bank treatments to restore natural bank morphology and riparian vegetation at five of the six fords (Fords A to F, **Figure 5-1**), in order to reduce downstream sedimentation along the existing and historical channel (once flow is re-introduced) (**Drawing 4, Appendix A**). The sixth ford, located at the divergence of the existing and historical channels of lower Britannia Creek, will be addressed in association with the diversion berm construction (Section 5.1.1). Ford restoration is a measure without expected gains in in-stream habitat area (0 m^2), but it will restore 3,210 m^2 of riparian habitat and address a potential constraint on the success of the reinstatement of the historical

[2] Only the five fords where 'typical' bank and riparian restoration is proposed are explicitly identified.

meandering channel of lower Britannia Creek (Section 5.1.1). It also embodies the overall objective of restoring the channel and riparian vegetation along lower Britannia Creek. Ford restoration will be completed prior to re-introduction of flow into the historical channel.

Ford sites were originally selected for convenience at riffles, where the channel is naturally wide, flow depths are shallowest, the bed is flattest, and substrates are supportive to vehicle traffic. Therefore, the typical restoration plan in **Drawing 3** (**Appendix A**) reflects the restoration of bank morphology at a riffle. Small patches of fine sediment that have accumulated against the banks will be removed and used to re-build natural bank morphology. Brush layers will be constructed in both banks in order to slow channel-edge velocities and promote bank stability through deep rooting. Once the natural dimensions of the channel are restored to match upstream and downstream sections (as specified in the site-specific guidelines on **Drawing 3**, **Appendix A**), adjacent areas of floodplain will be replanted using live stakes of native willows and tree seedlings.

5.1.3 Diamain Lake Whitefish Fishery Creation

Diamain Lake is a 10 km-long, 2 km-wide, moderately deep (25 m maximum) oligotrophic lake located approximately 17 km northeast of the community of Pelly Crossing (**Drawing 4**, **Appendix A**). Historical limnological and fisheries surveys indicated that the lake was fishless despite having suitable conditions for supporting fish (Archibald, 1977; Lindsey et al., 1981). Fisheries sampling efforts consisted of bottom and surface overnight gillnet sets in 1970 and 1975, and seine net fishing in 1970 (Lindsey et al., 1981). Furthermore, the large plankton and invertebrates found in the lake suggested that fish predation was low or absent (Archibald, 1977). The lake drains via an unpassable, high-gradient outlet stream into the Pelly River, which drains west into the Yukon River (Lindsey et al., 1981).

Introducing fish to Diamain Lake provides an opportunity to create a high quality local fishery for SFN. Further, the newly modified *Fisheries Act* outlines the opportunity for biological manipulations, such as stocking, in order to offset serious harm to fish (DFO, 2013a). Diamain Lake is close to Pelly Crossing and can be accessed by an approximately 3 km long ATV trail on SFN land from a seasonal (gravel) road extending from the all-season (paved and maintained) Klondike Highway.

Whitefish are culturally important to the SFN, as traditional net fisheries existed on Tatlmain Lake, Towhata Lake and on Mica Creek near Pelly Crossing (Morrell, 1991; Pearse and Weinstein, 1998; Environment Yukon, 2010). While broad whitefish runs have declined in recent decades (Environment Yukon, 2010), lake whitefish are still commonly found in the Pelly River watershed (Selkirk Renewable Resources Council (SRRC), 2006). As there is an outlet stream that connects to the Pelly River, but prevents the upstream migration of fish, only native species will be released to the lake. Thus, whitefish from the Pelly River watershed or in nearby acceptable watersheds would be captured for facilitating a stocking program in conjunction with a local hatchery, such as the McIntyre Creek facility in Whitehorse. However, the choice of stocking species will ultimately be decided in consultation with SFN and DFO.

Prior to stocking, fisheries and limnological data will be collected in order to ensure that current lake conditions are still represented well by historical baseline studies. Specifically, field surveys will ensure fish absence using various fishing techniques over multiple days and seasons. They will also verify lake

conditions (e.g., water quality, primary productivity) are capable of supporting fish year-round. In addition, applications for the transfer or release of live fish will be submitted to YESAB and to DFO-Whitehorse/Yukon Government-Environment in accordance with Section 56 of the General Fishing Regulations[3]. Appropriate stocking methods (rate, timing, fish size) will be determined in consultation with regulatory agencies, and all released fish will adhere to the Fish Health Protection Regulations[4]. A monitoring program will be developed that will aim to evaluate the success of the introduction (fish abundance and health), and potential ecological effects on existing aquatic resources in the lake (e.g., plankton, benthos). It is anticipated that post-stocking monitoring will occur in cooperation with SFN to evaluate program success.

The determination of the anticipated gain in usable habitat in Diamain Lake, for the species of interest, requires more accurate limnological and physical habitat data than are currently available in existing publications (e.g., Archibald, 1977). If this Diamain Lake fishery opportunity is selected for advancement and ultimate implementation, bathymetric, water quality and ecological data will be collected to support its justification and the quantification of the expected gain in usable habitat.

5.1.4 Dawson Dredge Pond Off-line Pool Habitat Creation

The unusual dredge pile/pond morphology remaining following intensive placer mining operations along the lower Klondike River valley provides a unique opportunity to create important off-line rearing and overwintering habitat for a variety of fish species, including juvenile Chinook salmon, in an area that is otherwise of limited ecological value. The dredge piles are composed of rounded alluvial gravel and cobbles, generally in the form of long, sinuous berms with rippled crests (**Figure 5-6**). Many remain completely devoid of vegetation on their crests and flanks, despite decades of stability, due to their high permeability and lack of soil cover. The ponds amongst the dredge piles are relatively deep (commonly >5 m) and maintained at a level that is similar to, and primarily controlled by, the level in the adjacent Klondike River. A continuous, year-round through-flow of water seeps into and out of the cobbley berms, maintaining water quality capable of supporting fish habitat.

Figure 5-6. Dredge Pile/Pond Complex with Proposed Interconnected Pond Configuration

Approximately 7 km up-valley from the town centre of Dawson City, the Klondike River arcs northward around a vast complex of dredge piles and ponds (**Drawing 5**, **Appendix A**). This major bend in the river forms a drop in hydraulic head from the upstream to the downstream portions of the bend, which induces a down-valley seepage of water (hyporheic exchange) through the berms and ponds (dashed blue lines in **Drawing 5**, **Appendix A**). EDI (2005) first studied and reported on the potential for connecting and using dredge ponds in this area to offset predicted habitat impacts associated with the previously proposed bridge across Yukon River at Dawson City. It conducted fish sampling in October and December, 2005, using a combination of minnow traps (set for 24 hours) and short gill net sets (0.5 hours) for determining adult fish presence. Juvenile Chinook salmon and slimy sculpin were present within ponds with seasonal connections to the Klondike River, and a high density of juvenile Chinook salmon was documented in a pond with a permanent connection to the river – good evidence for the potential success of connecting other ponds to the Klondike. Even some ponds completely isolated from the river contained fish (i.e., slimy sculpin and juvenile burbot), reportedly from remnant populations that have survived since the original mining operations in the mid- to late-1900s enclosed the water body. No fish were captured in some of the smaller, isolated ponds. EDI (2005) notes that many of the ponds have significant fish habitat value, with the capacity to support overwintering beneath thick ice cover.

Subsequent field reconnaissance and research by PECG in association with the development of this FHOP has built on this initial work. Seepage flow was observed emerging from gravels at the water's edge of some ponds, colonizing riparian vegetation was observed to be providing cover and contributing woody debris and organic matter along pond shorelines. Beaver activity in the area has transient effects on water levels within the ponds, causing backwatering in some areas and driving faster berm through-

flow in areas of increased hydraulic head. The margins of the dredge pile/pond complex is gradually being eroded by floodwater and ice jams along the Klondike River, but at average rates of only a few centimetres per year (based on a comparison with historical aerial photography) (**Figure 5-7**).

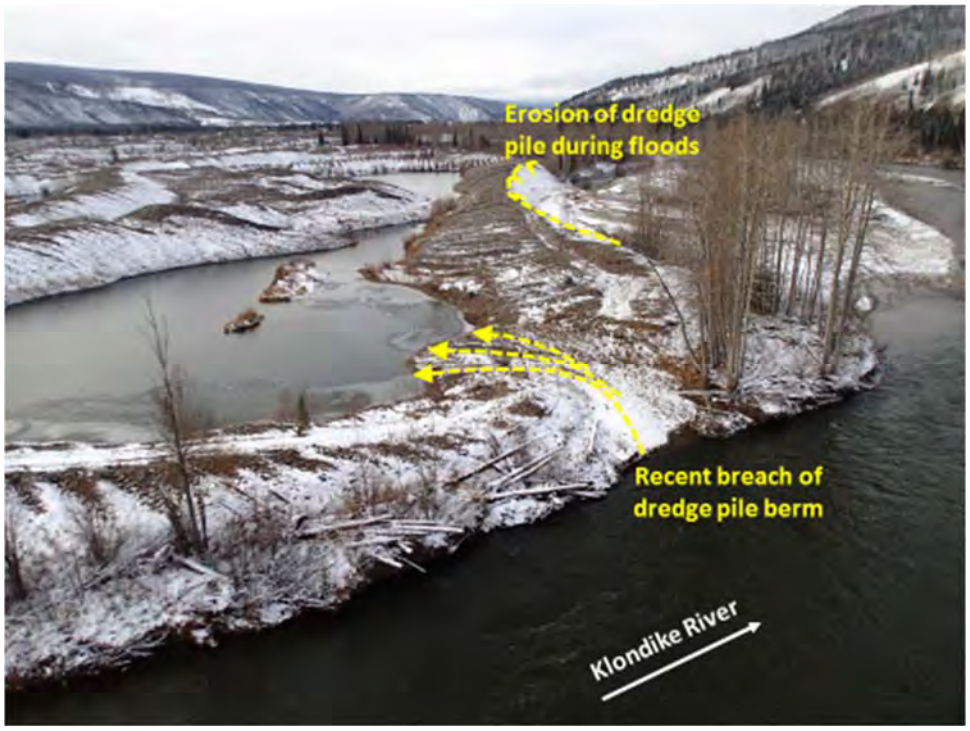

Figure 5-7. Localized Erosion along Edge of Dredge Pile/Pond Complex

A network of interconnected, off-line pool habitats is proposed to be created through the selective excavation of 'connector channels' through narrow dredge pile berms (**Drawing 5**, **Appendix A**). Four ponds that have no surface connection to one another or to the Klondike River are proposed to be connected, roughly in line with the natural pathway of seepage through the valley bottom dredge pile/pond complex. The four inter-pond excavations will form narrow connector channels at least 0.5 m below the low water level (to be determined by the collection of level logger data). The edges of the small channels will be benched and lined with locally sourced boulders in order to help maintain stability without planting riparian vegetation that attracts beaver activity. The narrow, channel-edge benches will accommodate minor raveling of the cut-slopes that is expected as a result of frost heave during natural freeze-thaw cycles. Material excavated from the berms will either be placed on nearby, unvegetated gentle ground, or will be incorporated strategically into shoreline habitat (e.g., beach-like shallows) to increase attractiveness for juvenile Chinook rearing. Typical riparian planting treatments (e.g., brush layers, rootwad/boulder complexes) will be implemented where shoreline gradients permit and with consideration for beaver activity. Regardless, there is likely to be an interest in monitoring and addressing beaver dams that may completely obstruct access between ponds.

The quantification of usable habitat expected to be gained through the creation of off-line pool habitats requires consideration of the habitat preferences of juvenile Chinook salmon, which is the main target species for habitat offsetting efforts in the Klondike River valley. Juvenile Chinook salmon have been documented to prefer water with depths of up to about 1 m for rearing (Martin et al., 2013), so only areas within the ponds with depths of 1 m or less were considered to represent a gain in usable habitat. Subaqueous shoreline slopes of approximately 2H:1V were observed in the field, so the area of a 2 m-wide buffer along the shorelines of each of the four ponds was measured as an indicator of existing high quality juvenile Chinook rearing habitat potential. Of the 43,790 m^2 of total pool area provided by the four newly connected dredge ponds, approximately 6,230 m^2 is currently less than or equal to 1 m in depth. In order to optimize more of the habitat for juvenile Chinook, gravels and cobbles excavated while creating the connector channels will be carefully placed in select areas of the ponds to provide additional shallow (<1 m) areas for rearing, bringing the total usable habitat to 9,120 m^2. Notwithstanding this, a principal objective of this offsetting opportunity is to increase access to reliable overwintering habitat, so deep (>1 m) areas of the ponds must be maintained. Follow-up field investigations and data analysis are anticipated to include bathymetric surveys, water quality monitoring and additional fish sampling (targeting both juvenile and adult fish species), as a basis for developing a more refined habitat suitability model for juvenile Chinook salmon rearing and overwintering in off-line pools in Yukon.

The entire area within which works are proposed in association with this habitat offsetting opportunity has been withdrawn from areas eligible for placer mining (Placer Mining Act) and bedrock mining (Quartz Mining Act), in accordance with Order in Council 2001/81 (Yukon Government, 2003). The land is in the traditional territory of THFN and is managed by the City of Dawson, which has considered different uses of this land. Two of the main considerations are to protect the land from development, establishing it as park land to preserve the heritage value of the unique landscape, or to expand new residential development into the area. Neither option precludes the development of the off-line pool habitat described above; in fact, such minor modifications may actually enhance the value of either park land or residential development.

5.1.5 Research Contribution: Chinook Salmon Stock of Origin in Natal and Non-natal Streams

Rationale

As described in Section 4.1, complementary measures are a new component of *Fisheries Act* policy, allowing proponents to undertake a more flexible approach for offsetting impacts (DFO, 2013a). The geographical location and limited ecological understanding of aquatic systems in northern environments make the Project an ideal candidate for pursuing alternate offsetting measures such as scientific research initiatives that will ultimately benefit local fisheries.

The Project is located in a relatively remote and pristine area of west-central Yukon with limited nearby opportunities for creating, restoring or enhancing habitat. While there are nearby abandoned sites that have been previously affected by industry (e.g., placer mining), these sites are often located in small and/or high elevation headwater valleys with minimal potential for increasing local fisheries productivity.

Further, locations with existing placer claims are at risk of future disturbances, precluding any potential long-term gains in fisheries productivity.

It has been well established that there is a growing and significant need to identify and understand the driving factors responsible for the drastic population decline of the Yukon River Chinook salmon population (Arctic-Yukon-Kuskokwim Sustainable Salmon Initiative Chinook Salmon Expert Panel (AYK), 2013). Due to their long-distance migrations, Yukon River Chinook salmon face a myriad of potential impacts over a wide geographical area, including habitat loss and alterations, climate change, overfishing, disease, reductions in productivity, changes in water chemistry and quality, and barriers to migration (AYK, 2013). Accordingly, understanding the stressors faced by Yukon River Chinook is an important ongoing focus of fisheries managers, First Nations, recreational fishing groups, and conservation organizations in the territory. Further, several collaborative working groups and expert panels have been founded with the specific purpose of facilitating research and management efforts for Yukon River Chinook salmon (e.g., Arctic-Yukon-Kuskokwim Sustainable Salmon Initiative, Yukon River Joint Technical Committee, Yukon Salmon Sub-Committee).

Given the demonstrated need for research, and the lack of potential opportunities for more traditional offsetting measures nearby, CMC proposes to allocate the maximum allowable proportion of the overall offsetting amount to research efforts (10%, the equivalent of 3,840 m^2 of habitat offsets), recognizing that the Project offers a unique case where a greater contribution to regional fisheries productivity may be made through research initiatives, rather than through localized habitat creation or modification initiatives. Exactly what funding commitment is required on CMC's part to facilitate the research program will be outlined in the final offsetting plan, in association with detailed design, based on the average cost per square metre estimated for the construction of the other project-specific habitat offsets. Research programs will be designed and conducted in consultation with DFO and First Nations, with the potential to consult with other partners (e.g., Yukon River Panel, Yukon Salmon Sub-Committee, Yukon College) in order to ensure that collective fisheries objectives are deeply rooted in study objectives. It is envisaged that local engagement is critical to this research, not only in the objectives of the study, but also in the collection and dissemination of data to provide learning opportunities and capacity building with local communities. Previous and ongoing consultations with several stakeholder groups, First Nations and fisheries experts in the region have led to the identification of one leading research proposal, which is described in the following sub-sections.

Background Information

Chinook salmon have a complex life cycle, similar to other anadromous salmonids, and stressors at certain life cycle stages may significantly affect recruitment back into the population. One of the potential bottlenecks to production for Yukon River Chinook salmon is the availability of suitable overwintering habitat. Juveniles need to not only survive the winter, but also to grow and attain the necessary size and fitness to be able to successfully migrate to the marine environment the following year. For a sustainable population, it is critical that sufficient numbers of healthy juveniles undergo this transformation and withstand additional stressors encountered in the marine environment so that they can return to freshwater as spawning adults.

For effective fisheries management and identification of local conservation priorities, it is important to understand the use of natal (stream of birth) and non-natal (non-spawning streams) creeks by juvenile salmon. Stock of origin genetic assessments for juvenile Chinook salmon can provide an understanding of juvenile migrations within a watershed, as well as the potential contribution of key physical and environmental factors influencing juvenile overwintering habitat. A study by the Alaska Sustainable Salmon Fund found that juvenile abundance (2003-2007) was significantly related to adult abundance for Canadian-origin Yukon River Chinook salmon (Murphy et al., 2014). This exemplifies the importance of the contribution of early freshwater life-history stages to the survival and production of Canadian-origin Chinook salmon.

There are a growing number of studies focused on using genetics to distinguish Chinook salmon populations in the Yukon River drainage (e.g., Bradford et al., 2009; Daum and Flannery, 2011; Beacham and Candy, 2012; Taylor, 2013). These studies help to address critical data gaps regarding the variation in population abundances, run timing and population composition (age, sex, length) that may differ among salmon stocks. An accurate understanding of stock characteristics underpins fisheries management and is the basis for setting fishery harvesting quotas that do not negatively affect the overall productivity of the fish stock.

Chinook salmon of Pelly River origin have been identified by SFN as a highly valued fishery. While genetic baselines have been identified for at least six of the 24 known sub-populations within the Pelly watershed (Beacham and Candy, 2012), there remains considerable opportunity to contribute to this growing database and support fisheries management within the area. Furthermore, no juvenile Chinook genetic studies have been conducted to date to determine the stock composition in any of the numerous natal or non-natal streams supporting juvenile overwintering activities in the Pelly River watershed.

Studies developed in the Pelly River watershed will be used in other areas of interest such as Tatchun Creek (**Figure 4-3**). Tatchun Creek is within the traditional territory of LSCFN, is easily accessible by road, and supports Chinook spawning and juvenile rearing activities.

Objectives and Hypotheses

The objectives of the study will be (1) to determine the genetic stock identification (GSI) of juvenile Chinook salmon within the lower Pelly River watershed and Tatchun Creek, (2) to investigate and compare the habitat and environmental qualities in natal and non-natal streams, and (3) to determine if habitat and environmental qualities are related to juvenile Chinook salmon habitat productivity. Both of the identified study areas support the rearing and overwintering of juvenile Chinook salmon that have originated from the same streams (natal origin) or have potentially left natal streams for non-natal streams downstream (Al von Finster, pers. comm., 2014). Factors influencing the selection of juvenile Chinook salmon habitat for rearing and overwintering will be investigated, such as migration distance and orientation, the presence of fish passage barriers, individual fish fitness (e.g., size), habitat quality and quantity, and environmental variability among streams and years. It is predicted that (1) watercourses in the lower Pelly watershed and Tatchun Creek will comprise mixed stocks from upstream spawning streams, (2) that juvenile Chinook salmon dispersal will be non-random and that juveniles will favour accessible streams with suitable overwintering conditions, and (3) that juveniles selecting higher quality overwintering habitats will demonstrate higher growth rates and freshwater survival.

This study will also investigate the feasibility of sampling the GSI and fitness of outmigrating salmon to the marine environment from these systems. The relationship to escapement for the identified stocks will be explored depending on the availability of long-term data sets for the area, and will provide some understanding of the influence of overwintering on population productivity.

General Methods

Target sampling areas will be identified in Tatchun Creek and in the Pelly River watershed for conducting fisheries studies. Live or recently deceased Chinook salmon adults will be captured in their natal spawning streams in the Pelly River watershed and sampled as described in the Yukon/Transboundary DNA Sampling Protocols (MacDonald, 2011). Juvenile Chinook salmon will be captured using baited minnow traps following the Yukon River Panel Protocol (Taylor, 2011), non-lethally sampled for DNA work, and then released (e.g., Taylor, 2013). All tissue samples will be preserved in 100% ethanol and sent to an analytic laboratory for genetic testing. Juvenile abundance will be measured relative to minnow trapping effort, and individual length and weight measurements will be collected for growth analyses. A minimum of two juvenile Chinook sampling periods per year will be completed, once in the spring to determine overwintering survival, and once at the end of the summer to determine young-of-the-year growth.

Fish habitat and environmental data (e.g., groundwater, ice conditions, food availability, distance to natal stream, stream temperature, flow) will be collected from selected juvenile Chinook sampling sites and analyzed relative to population densities, growth, survival and stock composition. Akaike's Information Criteria (i.e., a measure of the relative quality of a statistical model for a given set of data) may be applied to models of environmental factors to determine the influencing factors on juvenile overwintering habitat. Where possible, juvenile data will be related to knowledge of stock escapement quality using genetic linkages. There is currently a fish enumeration facility on one Pelly River population, Blind Creek, and more cost-effective aerial spawning surveys may be conducted on other major spawning areas in the watershed.

Community Participation

The lower Pelly River watershed is in the traditional territory of SFN. The community of Pelly Crossing is located adjacent to Mica Creek, which is the most downstream Chinook salmon spawning stream in the watershed. The community will continue to be engaged during the development and implementation of the research program to ensure that the program aligns with local fisheries objectives and cultural values. Opportunities for community participation in the investigation include the employment of community members in fisheries sampling activities, fish habitat assessments, environmental data collection, and trail development. Risk-averse sampling methods, such as use of baited minnow traps rather than electrofishing, will be used to facilitate the involvement of community members. In addition, demonstration projects such as juvenile Chinook capture and fin clipping may be showcased for students to gain insight into aquatic ecosystems and research methods. Program updates and study findings will be shared within the community via reports, presentations and workshops. Traditional knowledge is anticipated to play an important role in advancing specific hypotheses under this over-arching research theme.

Other Partnerships

CMC will engage other potential partners such as DFO, Genome BC, Yukon River Panel, Yukon Salmon Sub-Committee, Yukon College, or university researchers, and state and federal US agencies in order to broaden and strengthen the research program and its potential applications. Partners may provide additional value to the research program by providing "in-kind" support, such as personnel, equipment, training opportunities, producing technical reports or scientific publications, or presenting work at meetings or conferences. The Yukon River Panel provides annual funding for Yukon River restoration and enhancement projects, which have in the past included several baseline genetics studies (e.g., Beacham and Candy, 2012). DFO will be engaged to provide guidance on prioritizing additional genetic baseline collection data. Previous consultation has been conducted with the research organization Genome BC, which has expressed an interest in supporting projects that will use genomics to better understand the health of Chinook salmon, their interactions with their environment, and potential stressors that may impact Chinook salmon productivity.

PECG, on behalf of CMC, has discussed research opportunities with Dr. Scott Hinch (University of British Columbia), who is interesting in investigating the links between various stressors that may be operating in either the freshwater or marine environment (for example, dams and barriers to migration or by-catch from recreational or commercial fishing) and delayed effects. Dr. Hinch's group and collaborators have shown that delayed effects can result in impacts to the population, and that stressors from catch-and-release fishing, for example, may ultimately effect the fitness and fecundity of adults, and therefore ultimately recruitment back into the population. Even though the effects on the population may be most obvious in the freshwater (for example, spawning and egg survival), factors that are operating in the marine environment may be ultimately controlling these processes. There exist opportunities to conduct similar research studies on Yukon River Chinook salmon, depending on interest and availability of research funds under this offsetting fund.

Study Applications

The proposed study will considerably strengthen the genetic baseline of Pelly River Chinook salmon and support data already collected by DFO and others to inform fisheries management decisions. The results will provide a greater understanding of the relative contributions of populations within the watershed to the overall Pelly River stock, and subsequently identify the most important areas for supporting spawning, rearing and overwintering activities. Identification of important habitats is useful for watershed management, as the information can be used to determine specific habitats that may require protection, or candidate sites for future enhancement or restoration efforts. In addition, knowledge of the genetic origin of juveniles may provide insight into the physical and environmental variables driving productivity in the Pelly River watershed

Evidence for climate change effects on aquatic species is becoming increasingly prevalent, and effects are predicted to be greater at higher latitudes. Thus, a better understanding of how environmental variables (e.g., stream temperature, flow) affect juvenile Chinook productivity is essential for the future protection and management of northern stocks. In this study, environmental data collected in conjunction with fisheries sampling will investigate if differences in temperature or flow among streams or years relate to differences in productivity. Information about how environmental variability affects Chinook salmon

productivity may ultimately be applied to stock assessment models under varying future climate scenarios.

5.2 Contingency Habitat Offsetting Opportunities

5.2.1 Lower Britannia Creek Slope-toe Side Channel Extension and Enhancement

Candidates sites for restoring, creating or enhancing aquatic habitats were sought along lower Britannia Creek, downstream of its confluence with Canadian Creek. Priority was given to sites close to Yukon River, where potential gains in productivity are greatest, and to disturbed sites where additions to existing fish habitat could be made with minimal disturbance or risk to the natural environment. A small, but worthwhile opportunity to increase off-line rearing and overwintering habitat for Arctic grayling and potentially juvenile Chinook salmon was identified just 500 m upstream from the proposed diversion of Britannia Creek back into its historical meandering channel (Section 5.1.1). A small, spring-sourced side channel originating in a clearing on the west side of the existing Barge Access Road conveys water through a small (0.2 m-diameter), perched steel pipe culvert beneath the road, parallels the road with limited riparian vegetation, and then flows through mature floodplain vegetation to Britannia Creek (**Drawing 6**, **Appendix A**). Accumulated woody debris and organic matter at the confluence inhibits fish passage except during high flows.

Offsetting measures proposed along this side channel include establishing a permanent connection with Britannia Creek, through the removal of the woody obstruction; restoring a riparian buffer between the road and the channel edge; replacing the small, perched culvert beneath the road with a larger culvert that accommodates natural bed material; and extending the side channel into enlarged pool habitat up-valley from the spring, entirely within the existing area of disturbance (**Drawing 6**, **Appendix A**). Total usable habitat for Arctic grayling, which currently dominate this reach of Britannia Creek, will be approximately 1,210 m^2 (based on the assumption that the entire pool habitat will be usable by Arctic grayling). The pool habitat will be excavated below the groundwater table in order to intercept seepage flow within the valley bottom alluvium and support overwintering of local fish species, including juvenile Chinook salmon, which will have improved access to this site following reinstatement of the historical channel. Large woody debris and boulder structures will diversify pool-edge habitat and provide important cover features.

5.2.2 Lower Britannia Creek Groundwater-fed Side Channel Extension and Enhancement

Another 500 m farther upstream from the slope-toe side channel described above (Section 5.2.1), or approximately 1,000 m upstream from the diversion into the historical channel, is a second side channel well suited to extension and enhancement. The channel originates in a spring about 20 m downstream from what appears to be an overgrown placer test pit filled with groundwater. The channel follows the base of a terrace scarp that roughly parallels the meander of the main creek. At the time of survey in August 2014, about 10 L/s of water was flowing through this channel, which exhibits relatively deep pools (>0.5 m) and good cover beneath fallen trees.

The side channel is proposed to be extended to establish a surface connection with the existing pond and then further extended into pool habitat excavated along the toe of the continuation of the aforementioned terrace scarp (**Drawing 7**, **Appendix A**). The excavation of the pool below the groundwater table at the base of the terrace scarp will intercept groundwater within the alluvial terrace and will induce seepage from the main creek through the alluvial gravels comprising the valley bottom. Approximately 1,830 m^2 of new habitat usable by Arctic grayling and juvenile Chinook salmon for rearing and overwintering will be created (based on the assumption that the entire pool habitat will be usable by Arctic grayling). Trees felled within the footprint of excavation will be incorporated into the design of the pool shoreline as cover habitat in the form of boulder-buttressed rootwads. The existing forest canopy will contribute allocthonous inputs and further shelter the pool.

5.2.3 Klondike River Side Channel Rearing Gallery at Germaine Creek

A small, groundwater-fed channel flows along a flood-scoured meander scar alongside Klondike River, at the confluence with Germaine Creek, approximately 27 km up-valley from the town centre of Dawson. Water flowing through the side channel is sourced from a spring at its head, which intercepts shallow groundwater seeping through alluvial gravels alongside the Klondike River; from thawing permafrost underlying low terraces to the south; and from groundwater that discharges to surface at the base of the gentle alluvial fan of Germaine Creek. Annual monitoring of the uppermost portion of this groundwater-fed channel has revealed its use by numerous juvenile Chinook salmon seeking off-line rearing and overwintering habitat (Al von Finster, pers. comm., 2014). Only once in ten years did fish stranded in the spring-fed pool over the winter not survive, likely due to the unusually low water level in the Klondike River allowing a greater contribution of seepage inflow to originate in the relatively oxygen-poor, thawing permafrost to the south.

In order to improve and increase the availability of off-line rearing and overwintering habitat, a ‘gallery’ of pool habitat consisting of a trunk channel with several sub-perpendicular branch channels is proposed to be excavated up-valley and riverward of the existing spring (**Drawing 8**, **Appendix A**). The pools would be benched along their edges in order to maximize opportunities for juvenile Chinook rearing in shallow (<1 m depth) water. Deeper (~1.5 m) areas will be maintained along their centrelines to intercept groundwater originating in the alluvial gravels alongside the Klondike River, even during low water periods, and to support overwintering beneath ice cover. Trees felled within the footprint of the gallery will be incorporated into the pool-edge habitats as cover features, secured with locally sourced boulders. In total, the pool gallery will introduce approximately 4,000 m^2 of off-channel habitat, of which about 2,680 m^2 is anticipated to be preferred by juvenile Chinook salmon (<1 m), the target species for local offsetting initiatives.

5.2.4 Klondike River Side Channel Rearing Gallery at North Klondike River

An area of stable alluvial terrace exists along the inside of a large meander of the Klondike River, immediately upstream of its confluence with the North Klondike River. A side channel, active even during low flows in the main river (~200 L/s estimated), arcs around the low terrace and flows into a backwatered pool within a recently formed oxbow alongside the main river. A small groundwater-fed channel (~20 L/s estimated), which intercepts seepage within alluvial gravels, joins the surface channel near the edge of

the terrace. An overgrown, shallow borrow pit with direct highway access is the only disturbance in an otherwise mature white spruce and cottonwood forest growing on the terrace.

A 'gallery' of interconnected pool habitats is proposed to be excavated entirely within the existing area of disturbance (i.e., abandoned borrow pit) and the relative protection of the terrace (**Drawing 9**, **Appendix A**). Its purpose is to increase the availability of off-line rearing and overwintering habitat for juvenile Chinook salmon, as well as other Klondike River species. The grid-like pattern of the gallery, although unnatural in form, is designed to maximize edge habitat, where small fish can find shelter beneath overhanging vegetation and constructed rootwad features. It also maximizes the channel-like habitat area within the broad, V-shaped area of disturbance. The pools will be overdeepened along their centrelines in order to support overwintering and increase the interception of groundwater flowing between the upstream and downstream arms of the large meander. Along the edges, however, pool bottoms will be benched such that at least two-thirds of the pool area is less than 1 m in depth – the habitat preferences for juvenile Chinook salmon rearing. In total, the interconnected pools will create 7,200 m^2 of new pool habitat, of which 4,820 m^2 will be ideally suited to juvenile Chinook salmon rearing (<1 m).

5.3 Riparian Habitat Offsetting

Riparian vegetation, and the habitat it supports, helps maintain the productivity of adjacent and downstream fish habitat. Riparian habitat provides shading for cover, moderates fluctuations in water temperature, contributes allocthonous inputs, stabilizes banks and helps maintain overall channel morphology. Riparian habitat also has indirect value to fish habitat productivity by protecting water quality, temperature and stream hydrology, although these indirect values are more important in highly disturbed watersheds. In recognition of these important ecological functions, riparian habitat restoration, creation or enhancement is integrated into all proposed in-stream habitat offsetting opportunities.

Table 5-1 summarizes the gains in riparian habitat that can be achieved through the implementation of the proposed in-stream habitat offsetting opportunities outlined in Sections 5.1 and 5.2. A 30 m buffer of riparian habitat is assumed to be gained in association with in-stream habitat offsetting anticipated to support juvenile Chinook salmon use within a buffer of trees and dense shrubs. Narrower buffers of riparian habitat (i.e., 15 m or 5 m) are assumed to be created in association with other offsetting opportunities, as noted below in **Table 5-1**.

Table 5-1. Summary of Riparian Habitat Offsetting Opportunities

Opportunity	Riparian Habitat Area (m^2)	Description
Reinstatement of Lower Britannia Creek (Preferred)	86,080	Existing mature forest adjacent to historical channel, with localized placement of large woody debris structures along the banks (assumes 30 m buffer)
Britannia Creek Ford Restoration (Preferred)	3,210	Replanted riparian vegetation with live willow stakes and brush layers, and native tree seedlings (assumes 30 m buffer)
Diamain Lake Whitefish Fishery Creation (Preferred)	393,460	Existing mature forest along undisturbed lake shoreline (assumes 15 m buffer)
Dawson Dredge Pond Off-line Pool Habitat Creation (Preferred)	16,000	Mixture of existing shrubs and trees that have colonized the pond shorelines, and installed live willow stakes and brush layers, with some areas of large woody debris structures (assumes 5 m buffer, given local initiative to maintain form of landscape)
Lower Britannia Creek Slope-toe Side Channel Extension and Enhancement (Contingency)	9,600	Mixture of existing mature forest (edges of disturbance area) and planted native shrubs (within disturbance area), with large woody debris structures around perimeter of pool (assumes 30 m buffer)
Lower Britannia Creek Groundwater-fed Side Channel Extension and Enhancement (Contingency)	10,510	Existing mature forest and replanted shoreline embankments, with large woody debris structures, around perimeter of pool (assumes 30 m buffer)
Klondike River Side Channel Rearing Gallery at Germaine Creek (Contingency)	22,500	Existing mature forest and replanted shoreline embankments, with large woody debris structures, around perimeter of pool (assumes 30 m buffer)
Klondike River Side Channel Rearing Gallery at North Klondike River (Contingency)	18,900	Mixture of existing mature forest and naturally regenerating shrubs (to be supplemented with shoreline plantings), with large woody debris structures around perimeter of pool (assumes 30 m buffer)
Naturalized Airstrip Diversion Channel (Mitigation Only)	30,950	Existing mature forest and wetland vegetation encompassing area of proposed naturalized channel diversion (assumes 15 m buffer)
Total Opportunity:	**591,210**	**Final gain-to-loss ratio for riparian habitat along fish-bearing watercourses depends on final selection of offsetting opportunities**

Table 5-1 identifies opportunities for riparian habitat offsetting that, in combination, can fully offset the lost riparian habitat (assuming a gain-to-loss ratio of >1:1). The final amount of riparian habitat offsetting will depend on exactly which of the preferred and/or contingency opportunities are selected for detailed design and ultimate implementation. Combinations of riparian habitat offsetting measures that exclude the Diamain Lake opportunity cannot offset the impacts solely in association with the in-stream habitat offsetting opportunities outlined in Sections 5.1 and 5.2 for two main reasons. First, some impacts to riparian habitat are anticipated to occur without impact to adjacent in-stream fish habitat. For example, the abutments and approaches to clear-span bridges at new watercourse crossings along the access roads will impact riparian habitat but not in-stream habitat. Few to no opportunities for on-site or nearby offsetting exist in the undisturbed (natural) watersheds, although these crossing areas will have fully stabilized and re-vegetated banks to ensure that water quality degradation from erosion and surface runoff does not occur. Second, the creation of pool habitats, such as in the case of the Dawson dredge ponds opportunity (Section 5.1.4), does not provide the same opportunity for riparian habitat creation as would the buffer of a linear watercourse. The re-vegetation of the shoreline and incorporation of large woody debris structures will fully buffer the pool and provide the maximum benefit of riparian habitat to in-water habitat.

In the determination of requirements for riparian habitat offsetting, consideration must also be given to the suitability and sensitivity of fish habitat supported by adjacent riparian habitat. The majority of impacts to riparian habitat are expected to occur within the upper Casino Creek watershed, alongside non-fish-bearing watercourses or reaches of creek rarely frequented by fish. The contribution of the riparian habitat in the upper Casino Creek watershed to adjacent and downstream fish habitat productivity would be relatively low, given that the overall level of disturbance in the watershed is very low to negligible. Along the high-elevation reaches, riparian trees and shrubs are low, sparse or absent, and terrestrial insects are less abundant; the potential for allocthonous inputs is low. In comparison, the contributions of riparian habitat to fish habitat productivity are anticipated to be much higher in association with the proposed offsetting along lower Britannia Creek, among other higher-order watercourses where offsetting opportunities have been proposed. Within the low-elevation Britannia Creek reach, deciduous and coniferous trees are tall, forming a high, dense canopy that overhangs the historical channel, and terrestrial insects are more abundant.

In association with the placer restoration offsetting candidate along lower Canadian Creek (**Table 4-3**, Section 4.2.1), consideration was given to widespread restoration of riparian vegetation. Restoration and enhancement of riparian habitat alongside the 4 km-long reach of lower Canadian Creek most severely impacted by placer mining could yield gains of more than 100,000 m^2. Such efforts would also help mitigate the continued downstream migration of the sediment pulse in the unnaturally braided reach. However, the aforementioned risk of disturbance or destruction of the riparian zone in association with future placer mining activity justifies not considering this opportunity further at this time.

If necessary, impacts to riparian habitat beyond what can be offset in association with the ultimate implementation of the in-stream habitat offsetting opportunities can be considered through other opportunities identified in consultation with First Nations and DFO, or can be offset equivalently as part of the complementary research measures aimed at benefiting Chinook (Section 5.1.5).

5.4 Habitat Balance

A habitat balance has been prepared to summarize the predicted impacts to fish habitat from the Project and the potential gains from proposed fish habitat offsetting opportunities. **Table 5-2** provides a summary of the habitat balance between impacted in-stream fish habitat and proposed restoration, creation and enhancements of in-stream habitat. The total area of in-stream habitat impact, based on modeled losses of habitat area (where available, Section 3.2), is 23,632 m^2. The total area represented by preferred and contingency in-stream habitat offsetting opportunities is 38,370 m^2, excluding the currently undetermined, yet significant gain made possible by the Diamain Lake opportunity. These totals include an equivalent 10% of offsetting through a proposed research contribution aimed at benefiting knowledge of Chinook salmon populations in Yukon. The ultimate habitat offsetting ratio (gains:losses) will be determined based on the final selection of preferred and/or contingency opportunities that are advanced to detailed design and ultimately implemented. This selection will be made in consultation with First Nations, DFO and other stakeholders.

Regardless of which offsetting opportunities are advanced, CMC commits to offsetting in-stream habitat impacts with a 2:1 ratio for all impact sites with the exception of the uppermost Casino Creek watershed (above a transient fish barrier), where its markedly low baseline fisheries value justifies offsets with a 1:1 ratio for several reasons. Habitat in the upper Casino Creek watershed predominantly provides indirect, non-fish-bearing habitat, which was conservatively included in the habitat budget due to challenges associated with proving definitive fish absence in stream headwaters. Further, in areas where fish have been caught, they have generally been in low densities of exclusively adult or sub-adult Arctic grayling that have migrated upstream for temporary summer feeding activities. Summer feeding habitat for these older age-classes of Arctic grayling is common both locally and regionally, and the contribution of Casino Creek to the overall Arctic grayling production in this watershed (Casino/Dip Creek) is likely low. Fish use in Reach 3 of Casino Creek was only documented in one of four years of sampling, and fish were caught within the most downstream section of Reach 3 where habitat quality is relatively higher, and accessibility is greater for upstream migrating fish. No overwintering habitat has been observed in upper Casino Creek, and the potential for Arctic grayling spawning was similarly absent. In terms of fish food communities, sites in upper Casino Creek exhibited the lowest benthic invertebrate densities, richness, diversities, and EPT abundances within the project area, likely due to low water temperatures, high velocities and turbidity, low habitat complexity, and acid rock drainage present in the upper watershed.

Considering the new *Fisheries Act* is re-focused on improving fisheries productivity, rather than fish habitat, it is proposed that providing a 2:1 offsetting ratio for the majority of the Project impact sites, and a 1:1 ratio for uppermost Casino Creek watershed, appropriately counterbalances serious harm to fish in the Project study area. Even without inclusion of the preferred Diamain Lake opportunity (Section 5.1.3) in the preliminary habitat balance, sufficient opportunities exist to offset Project impacts (**Table 5-2**). In addition to proposing greater gains than losses in the quantity of habitat, this FHOP proposes to offset impacts to relatively low quality, low productivity habitat (e.g., upper Casino Creek) by restoring, creating or enhancing relatively high quality, high productivity habitat (e.g., lower Britannia Creek).

Table 5-2. Habitat Balance Summary

In-stream Habitat Impacts (losses)	**Usable Area (m^2)[a]**
Lower Britannia Creek "Roadway" Channel (diversion into historical channel)	4,112
Upper Casino Creek Watershed above Reach 2/3 Break (TMF footprint)	8,900[b]
Upper Casino Creek Watershed below Reach 2/3 Break (TMF footprint or influence)	5,827
Unnamed Tributary of Dip Creek (diversion around airstrip)	330
Lower Canadian Creek (flow reduction downstream of open pit)	299
Lower Casino Creek (flow reduction downstream of TMF)	3,157
Dip Creek (flow reduction downstream of TMF)	1,001
Nordenskiold River bridge (in-stream pier footprint)	6
Total Impact:	**23,632**
In-stream Habitat Offsetting Opportunities (gains)	**Usable Area (m^2)**
Reinstatement of Lower Britannia Creek (Preferred)	14,870
Britannia Creek Ford Restoration (Preferred)	0 (riparian)
Diamain Lake Whitefish Fishery Creation (Preferred)	TBD[c]
Dawson Dredge Pond Off-line Pool Habitat Creation (Preferred)	9,120
Research Contribution: Chinook Salmon Stock of Origin in Natal and Non-natal Streams	3,840[d]
Lower Britannia Creek Slope-toe Side Channel Extension and Enhancement (Contingency)	1,210
Lower Britannia Creek Groundwater-fed Side Channel Extension and Enhancement (Contingency)	1,830
Klondike River Side Channel Rearing Gallery at Germaine Creek (Contingency)	2,680
Klondike River Side Channel Rearing Gallery at North Klondike River (Contingency)	4,820
Total Offset Opportunity (excluding undetermined gain from Diamain Lake opportunity):	**38,370**

[a] *Footnotes below **Table 3-8** specify method by which each impact area was determined*
[b] *Only in-stream habitat impact proposed to be offset with a 1:1 offsetting ratio; all other impacts to be offset with a 2:1 ratio*
[c] *To be determined, if opportunity advanced, following collection of bathymetric, water quality and ecological data*
[d] *Complementary measure, equivalent to 10% of habitat offsets*

An area-for-area accounting of riparian habitat losses and gains is not necessarily appropriate, given that all in-stream habitat offsetting will incorporate riparian buffers to ensure full productivity. Based on such an area-by-area accounting, however, ample opportunities for creating or restoring riparian habitat are available to offset Project impacts to riparian vegetation in association with the preferred and contingency in-stream habitat offsetting opportunities (**Table 5-2**). Any remaining deficit in riparian habitat offsetting could be resolved if necessary through riparian plantings and habitat enhancement alongside impacted watercourses utilized by Chinook salmon, or through complementary research efforts.

6 Implementation Strategy

6.1 Timeline and Construction Phasing

The timing of proposed habitat offsetting relative to predicted impacts is an important consideration, given its determination of the potential for a temporal loss of productive capacity within the affected watersheds. As shown in **Figure 4-1**, offsetting measures are proposed to be implemented before or in conjunction with habitat impacts. The intention is to provide the greatest opportunity possible for offsetting measures to become fully functional, providing the designed benefits to aquatic ecosystems, prior to project impacts. All offsetting works will be completed at the commencement of project construction. All impacts will occur during the construction phase of the Project, except for the minor impacts to lower Canadian Creek, which are not anticipated to occur until project closure (Years 23-25) when flows from upper Canadian Creek are allowed to drain into the open pit.

Another important consideration in offsetting planning is the phasing, or sequencing, of construction of the offsetting measures. The proposed habitat restoration and enhancement measures will be completed in accordance with the applicable "reduced risk timing window" for in-water work, as established by DFO. This will minimize risk to Chinook salmon, Arctic grayling and other local fish species during activities within the channel and adjacent riparian zones. All channel works will be completed "in the dry", either by conducting work along sections of channel that are dry or completely frozen (preferred) or by isolating the work area from flowing water. The channel restoration and enhancement works will be completed as efficiently as possible, thereby minimizing the period during which a portion of habitat is isolated from the adjacent channel.

An overview of the proposed construction of each of the preferred and contingency offsetting opportunities is provided below in order to demonstrate to DFO the feasibility of protecting fish and fish habitat during implementation of offsetting works:

1. **Reinstatement of Historical Lower Britannia Creek** – The restoration of the historical channel is proposed to be completed through the following steps:

    i. Isolate historical (dry) channel by blocking upstream and then downstream ends with coffer dams.

    ii. Conduct a fish salvage, if necessary, from any remnant pools especially at the lower end of the channel near the Yukon River. After recording the fish species, release them into the Yukon River.

    iii. Selectively remove woody debris that does not have an important, well-established ecological role (including any existing logjams), in order to minimize channel obstructions during reintroduction of flow, or incorporate and anchor it for increased cover and rearing pool habitats.

    iv. Remove the downstream and then upstream coffer dams within the historical channel.

v. During a low to moderate flow when turbidity is still naturally high (e.g., tail-end of a freshet), divert a small portion of the flow (e.g., 10-20%) from the existing Britannia Creek 'roadway' channel into the historical channel, by temporarily placing appropriately sized rip-rap on the existing channel bed to form a riffle immediately downstream of the slightly raised entrance to the historical channel. Allow the back-water formed upstream of the artificial riffle in the existing channel to spill into the historical channel. Station field crews alongside the historical channel to monitor the reintroduction of flow and identify any areas where in-stream work is required once flows have subsided.

vi. Incrementally and gradually (over a period of a few days during which flows remain low to moderate) raise the height of the riffle with additional rip-rap, each time diverting a greater portion of flow into the historical channel. Continue raising the riffle until all of the flow (100%) has been diverted into the historical channel.

vii. Install a coffer dam immediately downstream of the artificial riffle, in order to inhibit throughflow and allow the roadway channel to passively dewater to its mouth.

viii. Conduct a fish salvage from remnant pools, walking downstream along the entire length of the straight reach to the Yukon River. After recording the fish species, release in Britannia Creek upstream of the flow diversion (or into Yukon River, whichever is closer).

ix. Construct a permanent flow diversion earth berm, armoured on its upstream face and ends with rip-rap, set back at least 5 m from the coffer dam.

x. Install a coffer dam along the upstream edge of the artificial riffle.

xi. Remove the coffer dam from the downstream side of the artificial riffle, then re-distribute the rip-rap forming the riffle along the toe of the diversion berm, and fill the former channel to its tie-in with the surrounding floodplain and bank of the reinstated historical channel.

xii. Remove the coffer dam that was built along the upstream edge of the riffle.

2. **Britannia Creek Ford Restoration** – Restoration of the fords will completed at or prior to project construction commencement, in order to stabilize and restore the banks to reduce downstream sedimentation. Coffer dams will be placed in the channel to isolate one half of the channel at a time, while allowing flow to continue in the other half. Any fish that become stranded in the isolated work area will be captured, identified and released upstream by a qualified fisheries technician with a collection license. Patches of channel-edge sand and gravel washed from the road surface will be used in the reconstruction of the channel banks. Once bank restoration on one side is complete, work will be completed on the other side of the channel in the same manner, with the same precautions for the protection of local and downstream habitat.

3. **Diamain Lake Whitefish Fishery Creation** – Minimal to no ground disturbance is required in the implementation of the proposed stocking program. However, any vehicles or equipment that must be stored along the existing access trail near the lakeshore will be set back at least 30 m within an area isolated by appropriate erosion and sediment control measures (e.g., silt fence, impermeable pad).

4. **Dawson Dredge Pond Off-line Pool Habitat Creation** – The extension of any access routes along the crests of the dredge pile berms will be completed only where necessary, following isolation of the road alignment with appropriate erosion and sediment control measures (e.g., silt fence). Only localized excavations through select dredge piles are required in order to connect adjacent ponds with a small stone-lined channel. At these locations, coffer dams or a silt curtain would be temporarily installed at the shoreline in order to isolate the excavation area and inhibit sedimentation in the adjacent lakes. All excavated gravel and cobbles will be incorporated into shoreline benches temporarily isolated by coffer dams (as described above in Section 5.1.4), placed with gentle slopes on level ground well away (>30 m) from any waterbodies, or trucked off-site. Only once the connector channels have been properly formed will the isolation barriers be removed and disposed of at an approved location off-site. Any materials or equipment stored on-site will be isolated from the surrounding environment with appropriate erosion and sediment controls.

5. **Lower Britannia Creek Slope-toe Side Channel Extension and Enhancement** – Most of the area within which offsetting works are proposed is already disturbed. Regardless, the area proposed for pool excavation will first be isolated within appropriate erosion and sediment control measures (e.g., silt fence) to minimize the potential for sediment to be washed into the existing side channel. A small coffer dam will be temporarily installed at the upstream end of the side channel to prevent sediments from continuing downstream during connection to the expanded pool habitat. The replacement of the small culvert beneath the existing gravel road will be completed within an isolated work area when the channel is dry (e.g., winter), removing the need for a flume or dam-and-pump by-pass.

6. **Lower Britannia Creek Groundwater-fed Side Channel Extension and Enhancement** – A narrow, temporary road will be required to provide site access for construction equipment. Both sides of the corridor will first be enclosed within appropriate erosion and sediment control measures (e.g., silt fence). Disturbance to vegetation and ground cover will be minimized through the use of small equipment, a carefully planned access route and matting (if necessary). The area encompassing the proposed channel extension and pool excavation will be isolated from the surrounding environment using erosion and sediment control measures (e.g., silt fence), in order to minimize the risk of sedimentation to the existing side channel or adjacent Britannia Creek. A small coffer dam will be temporarily installed at the upstream end of the side channel to prevent sediments from continuing downstream during connection to the existing pond. The access route will be fully restored following completion of the offsetting works.

7. **Klondike River Side Channel Rearing Gallery at Germaine Creek** – Good access to the area adjacent to the proposed rearing gallery already exists in the form of a 4x4 trail on the west side and a gentle gravel road on the east side. A bailey bridge may be used, if necessary, to cross the small, groundwater-fed channel. The area encompassing the proposed pool excavations will be isolated from the surrounding environment using appropriate erosion and sediment control measures (e.g., silt fence). Excavated material will be stockpiled within the isolated work area and placed on high ground well away (>30 m) from any waterbodies or trucked to an authorized location off-site. A small coffer dam will be temporarily installed at the upstream end of the groundwater-fed channel to prevent sediments from continuing downstream during connection to

the expanded pool habitat upstream. All work will be completed during a period of normal (low) water levels in the Klondike River, to minimize any access challenges during flood conditions.

8. **Klondike River Side Channel Rearing Gallery at North Klondike River** – Access to the area within which all work is proposed is excellent: a gravel road descends gently to the edge of the abandoned borrow pit. The area encompassing the proposed interconnected pool excavations will be isolated from the surrounding environment using appropriate erosion and sediment control measures (e.g., silt fence). Excavated material will be stockpiled within the isolated work area and placed on high ground well away (>30 m) from any waterbodies or trucked to an authorized location off-site. To facilitate the final connection to the active side channel, a small coffer dam will be temporarily installed at the edge of the side channel. Once the connection has been excavated, the coffer dam will be removed and disposed of at an appropriate location off-site. All work will be completed during a period of normal (low) water levels in the Klondike River, to minimize any access challenges during flood conditions.

6.2 Erosion and Sediment Control

An erosion and sediment control (ESC) plan will be developed as part of an overall environmental management plan, prior to initiation of habitat offsetting activities as a basis for protecting aquatic and riparian ecosystems during construction of habitat restoration, creation and enhancement measures. The plan will focus on controlling surface run-off and minimizing the extent and duration of exposed soils, in order to inhibit erosion and sedimentation along any watercourses. The plan will reflect best management practices as outlined in *Best Management Practices for Works Affecting Water in Yukon* (Environment Yukon, 2011) to fulfill Section 36(3) of the *Fisheries Act* and Section 9(1) of the *Yukon Waters Act*, which prohibit the deposit of any waste (i.e., any substance that is detrimental to people, animals, fish or plants), including sediment, into any water body. In addition to detailing all physical ESC measures, the plan will specify the necessary frequency of inspection, relative to key construction activities, weather conditions and site-specific environmental conditions. Inspection should be completed regularly during the construction process to ensure that ESC measures are functioning as intended and to provide for the timely cleaning, repair and ultimate removal of ESC measures (as further described below in Section 6.3).

The appropriate combination and distribution of ESC measures will be finalized during detailed design and specified on the ESC plan. All measures will be in place and operational prior to construction commencement. Key details of the plan may include, but not be limited to, the following:

- Strategies for preventing off-site water from entering the work area, and for managing on-site water;
- Erosion control strategies, including techniques, materials and installation methods;
- Sediment control strategies, including techniques, materials and installation methods;
- Delineation of areas of greatest ecological risk;
- Site restoration and re-vegetation prescriptions;

- Locations for storing and refueling all equipment (>30 m from any water feature);
- Contingency plans for unforeseen high flow events; and
- Monitoring program details.

6.3 Monitoring, Adaptive Management and Contingency Planning

In accordance with DFO's (2013b) guidelines, two main types of monitoring will be conducted to ensure the success of this FHOP: *construction monitoring* and *effectiveness monitoring*. Adaptive management is the process of promptly responding to and alleviating any identified deficiencies or failures in offsetting works, based on the results of monitoring.

The purpose of *construction monitoring*, as alluded above in Section 6.2, is to minimize risks to fish and fish habitat during implementation of the offsetting works. An environmental monitoring technician will be on-site throughout the period of in-water work to document compliance with all environmental protection measures and inspect and report on all ESC measures. It is recommended that field inspections be conducted periodically before and during construction to document and photograph site conditions associated with offsetting works. The field inspections should be conducted at least once prior to construction and weekly during the construction period. Photographs should be collected from the same vantage point and with the same field of view to allow for time series comparison. A qualified professional with experience in the supervision of channel restoration projects (e.g., fluvial geomorphologist, habitat restoration specialist) will visit the site at critical times during construction to ensure all elements of offsetting works are completed according to design specifications, and to assist with field-fit modifications, where required.

Key elements of construction to supervise include, but are not limited to, the following:

- Implementation of functional erosion and sediment control measures, including flow by-pass measures;
- Removal of existing vegetation within, and protection of vegetation in close proximity to, the works area and access route;
- Establishment of key profile (elevation) points and channel dimensions;
- Installation of habitat cover features (e.g., root wads, boulders, brush layers, live stakes); and
- Construction of transitions to the upstream and downstream tie-in points.

The purpose of *effectiveness monitoring* is to ensure that offsetting measures are functioning as designed, providing an opportunity for adaptive management where necessary, and achieving fisheries productivity goals over the long-term. Detailed site-specific monitoring plans will be created in consultation with DFO to determine the key indicators for monitoring and the criteria for evaluating 'ecological functionality'. An adaptive management approach will be adopted in order to periodically identify the need for any further mitigation or offsetting measures. The monitoring program will be designed to include various metrics for assessing fisheries productivity and habitat structural integrity and quality. For example, monitoring may include measurements of channel morphology and fish habitat

features, monitoring of water quality, sampling of fish communities, and riparian vegetation assessments. Maintenance may include selective irrigation, removal of invasive species, documentation and replacement of unsuccessful plantings, stabilization of erosion sites, and mitigation of animal intrusion or damage. To evaluate the overall changes in fisheries productivity, multi-year baseline fish and aquatic resources data in the proposed impacted areas (e.g., Casino Creek) may be compared to fisheries data collected in offsetting areas (e.g., Pearson et al., 2005). A general overview of the proposed post-construction monitoring plan is provided below:

Immediate Post-Construction

- Detailed as-built surveys and drawings should be completed immediately following construction by the contractor and habitat design consultant in order to assess the functionality and structural integrity of habitat relative to construction design specifications. In the reinstated historical lower Britannia Creek, multiple seasonal habitat assessments will be carried out, including immediately after freshet.
- Fish and aquatic resources summer sampling will be conducted in offsetting and reference sites to determine the state of key biological indicators as identified in a forthcoming site-specific detailed monitoring plan. Examples of biological indicators may include fish community composition, fish abundance and distribution, life history use, fish condition, and characterization of the lower food web (e.g., periphyton and benthic invertebrates).

Follow-up Monitoring

- Summer assessments of fish and fish habitat will continue with similar methods as before;
- Data collected will be compared to baseline and immediate post-construction data to ensure that offsetting goals are being met; and
- At this point, the need for any further mitigation or offsetting will be identified and implemented. Opportunities to rehabilitate offsetting sites, if needed, will be considered before considering new offsetting options.

The monitoring program will be concluded when habitat offsetting sites have reached the defined criteria for determining success, and thus when the goal of counterbalancing serious harm to fish has been achieved.

A specific trigger-response action plan will be established during detailed design in order to standardize how and when follow-up to particular identified conditions should be completed. This will allow remedial or adaptive measures to be taken at an appropriately early time. Contingency offsetting opportunities (Section 5.2) remain available for implementation should elements of the preferred offsetting opportunities function less effectively than intended.

6.4 Cost Estimate

A cost estimate will be provided in association with detailed design and the ultimate request for authorization of the proposed offsetting works, following additional consultation with First Nations, DFO and other stakeholders, at which time the exact combination of preferred and/or contingency offsetting opportunities will have been finalized. This approach is consistent with feedback recently received from DFO, indicating that its verification of the feasibility of the opportunities outlined above (Section 5) should precede consideration of opportunity-specific costs. As mentioned above in Section 5.1.5, the amount of funding CMC will make available to the complementary research opportunity (should it be selected for advancement) will be based on the product of the 10% equivalent of habitat offsets (in this case 3,840 m^2) and the average cost per square metre to construct the final section of offsetting opportunities.

6.5 Uncertainties and Next Steps

The success of habitat restoration and enhancement projects depends, in part, on the identification of uncertainties and strategies for their management. Key uncertainties and their management are outlined below:

- **Uncertainty in the final selection of offsetting opportunities** – A commitment to offsetting unavoidable, residual impacts of the Project has been made, but the exact combination of preferred and/or contingency offsetting opportunities is proposed to be finalized in consultation with First Nations, DFO and other stakeholders. This FHOP has demonstrated that ample, worthwhile and feasible opportunities to offset impacts exist. The intention is to ensure that the final selection of offsetting opportunities accounts for a variety of perspectives and local community objectives.
- **Uncertainty in the feasibility of offsetting opportunities** – The preliminary designs included in this FHOP have been prepared by multi-disciplinary teams, leveraging past experience on other similar habitat offsetting projects. During detailed design, more comprehensive, site-specific topographic and geomorphic information will be collected to support the development of construction drawings and specifications. An investigation into land access, rights and ownership encompassing the proposed offsetting sites has not revealed any significant obstacles to implementation.
- **Uncertainty in the quantity and quality of proposed offsetting habitats relative to impacted habitats** – This FHOP proposes net gains in habitat, with an offsetting ratio of 2:1 for most in-stream habitat impacts, in order to allow for the possibility that certain elements of the offsetting may not fully function as intended. In addition, proposed offsetting habitats have higher ecological value than impacted habitats, given an emphasis on addressing known limitations to the productive capacity of local habitats.
- **Uncertainty in the timeframe over which the benefits of offsetting will be realized** – Many of the offsetting habitats proposed in this project will take advantage of existing, mature riparian vegetation, thereby minimizing the period before which habitat is fully functional. Also, offsetting work will be completed before or in conjunction with occurrence of the impacts.

Hydrological, geomorphological and biological data have been collected over a period of several years to support the preparation of this FHOP. The level of detail provided is commensurate with that required by DFO and other review organizations to confirm the feasibility and appropriateness of the habitat offsetting opportunities outlined above. Additional information is still required to support detailed design and permitting in association with the FHOP.

Dear Ms. Mioska,

Re: Casino Project – Fish Habitat Evaluation: Dip Creek and Casino Creek Instream Flow and HEP Study

Palmer Environmental Consulting Group Inc. and Normandeau Associates are pleased to submit this final report describing the results of our fish habitat evaluation study using Physical Habitat Simulation Modeling (PHABSIM) and Habitat Evaluation Procedure (HEP) methods to understand and quantify the loss or change in aquatic habitat as a result of the Casino Project.

If there are any questions or comments on this report, please contact Rick Palmer at (604) 629-9075.

Thank you for the opportunity to work on this project.

Yours truly,

Palmer Environmental Consulting Group Inc.

Executive Summary

The Casino Project is a proposed porphyry copper-gold-molybdenum mine located in west-central Yukon, approximately 300 km northwest of the territorial capital of Whitehorse. Tailings generated from the mine, as well as process water, treated sewage effluent, leachate from the waste rock dumps and surface runoff from the mine site will be directed to a Tailings Impoundment Area (TIA) located north of a proposed tailings dam in the headwaters of Casino Creek.

The proposed Casino Mine TIA will create a physical loss of fish habitat in the upper portion of Casino Creek and will alter habitat downstream of the TIA, within lower Casino Creek and Dip Creek, due to reduced flow. This report presents the results of a Fish Habitat Evaluation Study conducted to evaluate and to quantify, the amount of aquatic habitat that will be lost or altered as a result of the proposed project. The study area consists of Casino Creek from the confluence of Dip Creek upstream to the upper extent of the proposed TIA, and Dip Creek, below the confluence of Casino Creek, downstream for a distance of 1.5 km, as well as Meloy and Taylor Creek. Lost habitat was also quantified in the Lower Britannia Creek as a result of a proposed stream diversion under the Fish Offsetting Plan, and in Canadian Creek, due to the diversion of upper Canadian Creek in to the open pit. As Arctic grayling compose the majority of the species composition within the Casino Creek/Dip Creek watershed, it was chosen as the target species for this study.

Two types of impacts on Arctic grayling habitat associated with the proposed Casino Project were evaluated as part of the Fish Habitat Evaluation Study:

- The physical loss of all aquatic habitat in upper Casino Creek due to the TIA; and
- The change in aquatic habitat area in Lower Casino Creek and Dip Creek due to a reduction of flow out of the TIA.

The first type of aquatic habitat impact, loss of all aquatic physical habitat, was assessed with a quantitative Habitat Evaluation Procedure (HEP) method, which gives a quality rating, based on biological parameters, to the total surface area of lost habitat. The second type of aquatic habitat impact, flow reduction, due to the TIA or partial diversion of a creek, was assessed using a Physical Habitat Simulation Model (PHABSIM) method that provides an index to habitat that varies with discharge. The net change in the PHABSIM habitat index under varied pre-project and modeled post-project flow regimes provides a relative quantitative measure that can be used to develop prospective compensation approaches.

The PHABSIM analysis showed that the reduction in flow in Casino Creek during construction and operation phases of the project results in a median increase in habitat for adult and juvenile grayling of between 16% and 22% for lower Casino Creek, and 10% to 15% for middle Casino Creek. This outcome is due to the tendency for these life stages to prefer lower velocities, and that at lower flows there is an increase in available low velocity refuge areas. Changes in habitat during the closure and post-closure phases are generally less than 10% based on the median habitat values.

Grayling fry habitat duration curves in both lower and middle Casino Creek exhibit similar results to adult and juvenile with increased habitat under project conditions. The median habitat values increase in the range of 95% for lower Casino Creek and around 125% for middle Casino Creek during construction and operation phases. Changes in habitat during the closure and post-closure phase are generally less than 7% to 15% based on the median habitat values.

Spawning is the only life stage which shows a decrease in habitat due to flow reduction during the projects construction and operation phases. The median habitat value percent change shows a decrease in lower Casino Creek (-72%) and middle Casino Creek (-83%) for the construction and operation phases of the project. This is an end result of lower availability of higher velocities generally used by grayling during spawning, the opposite condition of what is preferred during other life stages. Changes in habitat during the closure and post-closure phases are between 6% and 9% based on the median habitat values.

Habitat for adult and juvenile grayling in Dip Creek show a slight increase during construction and operation phases of the project. Fry and spawning life stages show virtually no difference in habitat during all project phases. The percentage change at the median habitat index value is between 7 and 8 per cent for juveniles and adults and a decrease of 2 to 3 per cent for fry and spawning life stages during construction and operation phases of the project. Habitat index values for closure phases differ little from baseline.

The Habitat Evaluation Procedure analysis was used to estimate the changes in habitat for Arctic grayling in Upper Casino Creek. The estimate of net habitat loss was based on the assumption that rearing habitat would limit fish population. The result is a net reduction of usable habitat of 2,451 m^2 in Reach 2a (the section of stream between Brynelson Creek and the proposed TIA), and 2,433 m^2 in Reach 2b (between the TIA and the identified barrier to fish migration). A loss of potentially usable habitat of 5,715m^2 is anticipated from the upper reaches of Casino Creek, upstream of a seasonal fish barrier. This is a conservative estimate as it is unlikely that this area provides year-round or critical habitat for Arctic grayling. The TIA will also impact upon the lower reaches of Meloy Creek, although this creek was found not to provide useable habitat for Arctic grayling,

The Habitat Evaluation Procedure analysis was used to evaluate the changes in habitat for both juvenile Chinook salmon and Arctic grayling in Lower Britannia Creek. There will be some loss of habitat if offsetting plans proceed in this area. The historic channel would be reinstated and the flow from the existing channel would be diverted. The estimate of the net loss in habitat in this reach was based on the most limiting factor, the percent pool habitat. The final net habitat loss was calculated as 2,384m^2, which would be offset by proposed restoration works in this area.

There was no detectable change in habitat for grayling adult and juvenile life stages under all project phases in Canadian Creek. A small increase in habitat for fry and a slight decrease in spawning habitat would occur during project closure phases. This equates to an increase in fry habitat by 28% and a decrease in spawning habitat of 11%.

1 BACKGROUND

The Casino Project (the "Project") is a proposed porphyry copper-gold-molybdenum mine located in west-central Yukon, approximately 300 km northwest of the territorial capital of Whitehorse (**Figure 1**). In August 2008, a pre-feasibility study of the Project was completed by M3 Engineering (2008), which described a conventional truck-shovel, open pit mine. Tailings generated from the mine, as well as process water, treated sewage effluent, leachate from the waste rock dumps and surface runoff from the mine site would be directed to a Tailings Impoundment Area (TIA) located north of a proposed tailings dam in the headwaters of Casino Creek.

The proposed Casino Mine TIA will create a physical loss of fish habitat in the upper portion of Casino Creek and will alter habitat downstream of the TIA, within lower Casino Creek and Dip Creek, due to reduced flow. This report presents the results of a Fish Habitat Evaluation Study conducted to evaluate and to quantify, the amount of aquatic habitat that will be lost or altered as a result of the proposed project.

All habitat evaluations outlined in this report were conducted during 2011 to 2013 and based on the known mine footprint and potential impacts identified at this time. Additional habitat evaluations and field assessments were conducted in summer 2014, as additional potential impacts to fish habitat were identified. This work conducted in 2014 consisted of habitat mapping in three small tributaries to Casino Creek, and a tributary of Dip Creek, which has been identified as crossing the proposed airstrip in the Dip Creek valley. The results from these evaluations were included in the Fish Habitat Offsetting Plan (PECG, 2014) but detailed HEP and calculations and approach will be outlined in an addendum to this report in 2015.

1.1 Project Overview and Study Area

The study area consists of all water bodies within the project footprint or where impacts are predicted from a reduction in flow to downstream reaches, or from proposed offsetting fish habitat plans (**Figure 1**). The following habitats were evaluated as part of the Fish Habitat Evaluation Study:

- The physical loss of all aquatic habitat in upper Casino Creek due to the Tailings Impoundment Area (TIA);
- The change in aquatic habitat area in lower Casino Creek and Dip Creek (downstream for a distance of 1.5km) due to a reduction of flow out of the TIA;
- Meloy Creek – to quantify the amount of fish habitat lost as a result of the proposed TIA;
- Canadian Creek – the uppermost reach around the revised open pit area;
- Lower Britannia Creek – to quantify the amount of fish habitat lost as a result of diverting stream from the existing channel[1] back into a historical channel as part of the Fish Habitat Offsetting Plan (FHOP).

[1] At present, the existing lower reach of Britannia Creek artificially follows a former road alignment, and therefore, this reach has poor habitat quality relative to the historical channel. It is estimated that the channel "jumped" from its original path in the early 1970's and it is proposed as part of the FHCP to restore lower Britannia Creek to its original or historical channel.

The first type of aquatic habitat impact, loss of all aquatic habitat, was assessed with a quantitative Habitat Evaluation Procedure (HEP) method, which gives a quality rating, based on biological parameters, to the average surface area of the lost habitat. Potential compensation for loss of upper Casino Creek can be calculated and compared on an equivalent basis to candidate offsetting sites, such as stream segments above modified barriers or constructed spawning/rearing channels.

The second type of aquatic habitat impact, flow reduction below the TIA and diversion around the open pit area, was assessed using a Physical Habitat Simulation Model (PHABSIM) method that provides an index to habitat that varies with discharge. The PHABSIM is a suite of hydraulic and habitat models developed as part of the Instream Flow Incremental Methodology (IFIM) approach for evaluating flow alteration on aquatic habitat. The index is the sum of habitat suitability at each point multiplied by the area it represents. The index can be thought of as usable area. The net change in the PHABSIM habitat index under varied pre-project and probable post-project flow regimes provides a relative quantitative measure that can be used to develop prospective compensation approaches.

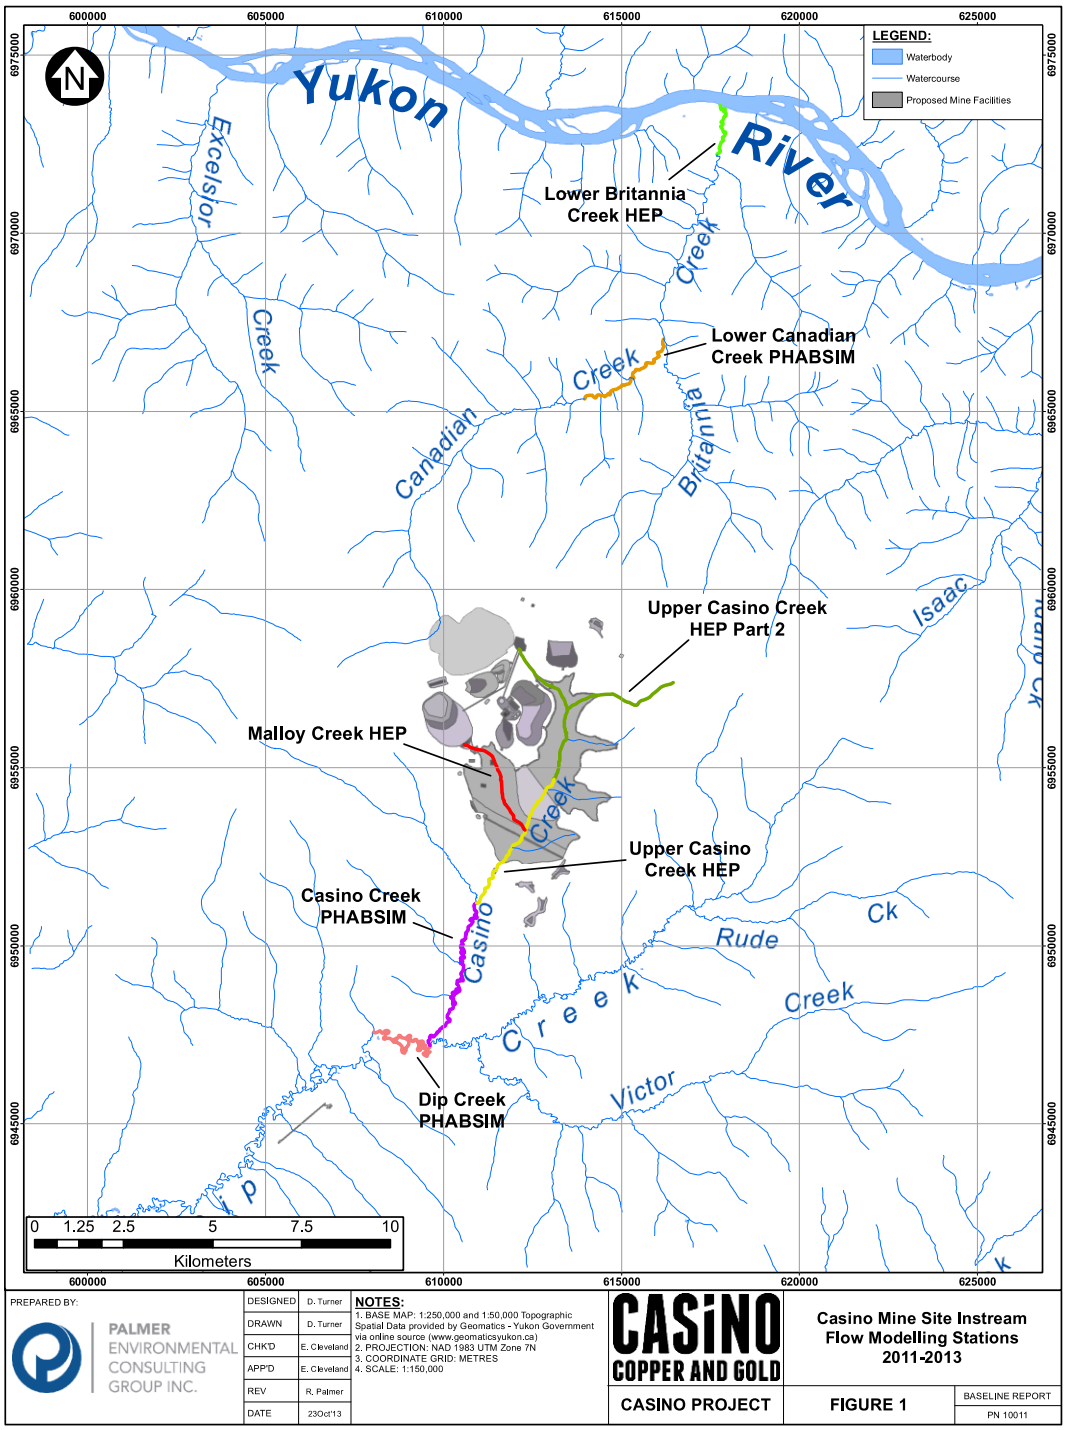

Figure 1. Locations of Fish Habitat and Instream Flow Evaluations.

Both HEP (USFWS 1980) and PHABSIM (Bovee 1982; Bovee et al. 1998) have been used recently for similar mining projects in Canada within accepted environmental assessment proceedings (e.g., Mount Milligan, Doris North, Kemess). These methods have also been applied extensively in many areas of the world since being developed in the late 1970s and have a proven track record for project evaluation and determination of impacts and acceptable compensation for fish habitat.

A summary of each study area reach and the specific method used to evaluate the aquatic habitat and function is provided below:

- Reach 1. Lower Casino Creek from the Dip Creek Confluence to Brynelson Creek was evaluated using PHABSIM.

- Reach 2. Upper Casino Creek was evaluated using HEP.
    - 2a - Casino Creek from Brynelson Creek upstream to the proposed TIA dam (an area that would be dewatered)
    - 2b - from the proposed TIA dam to an identified potential fish barrier (within the footprint of the TIA)

- Reach 3. Casino Creek from the fish barrier to the upper extent of the TIA (non-fish bearing) was evaluated using HEP. This also included the lower reach of Taylor Creek, a tributary of Casino Creek, up until a barrier to fish passage 400m upstream of the confluence with Casino Creek.

- Reach 4. Dip Creek, downstream of the confluence of Casino Creek was evaluated using PHABSIM.

- Meloy Creek. HEP was used to evaluate the lower 400m from the connection to Casino Creek, as the proposed TIA will overlay this section.

- Lower Britannia Creek, HEP was used to evaluate habitat from the Yukon River to approximately 1km upstream, where the habitat may be lost due to construction of fish offsetting plans.

Prior to initiating field investigations, the study team met with stakeholders to discuss study scope, design elements, and overall decision-making for the study. This is type of engagement is commonly instituted under the framework of the IFIM and PHABSIM as one of the first steps. As such, a study plan was developed and provided to participants outlining the proposed study design in June 2011 prior to the beginning of field data collection.

1.2 Existing Aquatic Ecosystem

Historical studies on the aquatic ecosystem of the Project property were conducted between 1993 and 1995 by Hallam Knight Piésold (1997). Recent studies of the aquatic ecosystem were initiated by AECOM in 2008 (AECOM 2009), and were continued by Palmer Environmental Consulting Group (PECG) from 2009 to 2012 (PECG 2011a; PECG 2011b; PECG 2012; PECG 2013).

Over the course of these investigations, detailed background data was collected on: water quality, sediment quality, periphyton, benthic invertebrates, fish species, fish habitat, and flow regime. It was

shown that the fish community in Casino Creek is dominated by two fish species, Arctic grayling (*Thymallus arcticus*) and Slimy sculpin (*Cottus cognatus*), with limited occurrences of burbot (*Lota lota*). As Arctic grayling compose the majority of the species composition within the Casino Creek/Dip Creek watershed, it was chosen as the target species for this study. This species was also used for habitat suitability indices for the Lower Britannia Creek as it shares habitat preferences with juvenile Chinook salmon, which also inhabits this section of the watershed.

2 STUDY OBJECTIVES

The fish communities and ecological characteristics of the watercourses outlined in this report have been determined, and are outlined in previous reports as outlined in section 1.2. The objective of this Fish Habitat Evaluation Study was to focus on available fish habitat for the existing fish community. As the fish community is limited in this area (a function of the northern environment, and the generally low productivity in these systems), one species was chosen as the focus of this assessment. The Arctic grayling is the dominant species in all watercourses outlined in this report, and provides a representation of habitat suitability for additional species, in particular, Chinook salmon.

The study objectives were to first establish baseline fish habitat conditions in Casino Creek, Dip Creek (downstream of the confluence with Casino Creek), Meloy Creek, Canadian Creek and Lower Britannia Creek,. This baseline aquatic habitat was then characterized as a function of flow. Project impacts to these watercourses are anticipated through a reduction or permanent loss, of flow. This objective was completed through a detailed fish habitat characterization and instream flow assessment study. Second, the results of the habitat characterization and instream flow study were evaluated using PHABSIM (for Reaches 1 and 4) and HEP analysis (for Reaches 2a, 2b, and 3, Meloy Creek, Lower Britannia Creek) to understand and quantify the loss or change in aquatic habitat as a result of the Project.

Specific study objectives include:

- Calculate the habitat versus flow relationship using PHABSIM for life stages of Arctic grayling in lower and upper Casino Creek and Dip Creek;
- Use the relationship between habitat and flow along with hydrological records to develop estimates of net habitat change (loss or gain) based on reduced streamflow from the upper Casino Creek watershed;
- Establish baseline habitat conditions for Arctic grayling in upper Casino Creek using a HEP analysis. Use the results along with known fish distribution and relative abundance estimates to quantify habitat loss in the proposed TIA; and
- Quantify the area (in m^2) of habitat lost or gained for each life stage of Arctic grayling to be compared on an equivalent basis to candidate compensation sites as potential compensation for loss of upper Casino Creek from the TIA, and from Lower Britannia Creek from a proposed offsetting option.

3 METHODS

3.1 PHABSIM Study

The Physical Habitat Simulation Modeling (PHABSIM) program been a standard approach to instream flow analysis since 1980 and allows comparison of changes in aquatic habitat with changes in flow (Bovee et al. 1998). The two primary products are the computation of a habitat index versus flow relationship for key aquatic species, and the development of a habitat time series to evaluate effects of current or proposed flow regimes.

Specific elements and steps of a PHABSIM study that will each be discussed in this section include:

- Habitat Mapping;
- Study Site and Transect Selection;
- Hydraulic Data Collection;
- Hydraulic Modeling;
- Identify Key Aquatic Species and Life Stages;
- Select Habitat Suitability Criteria;
- Habitat Modeling; and
- Time Series Analysis.

3.1.1 Habitat Mapping

A PHABSIM study begins with a representative sample of hydraulic and physical habitat conditions within the study area. The samples are obtained by establishing cross-sectional transects over a range of habitat types to produce 1-dimensional (1-D) models. The sample can be obtained in a variety of ways, including selecting:

- Representative Reaches – a short section of river is assumed to represent other unsampled portions; or

- Individual Mesohabitats – individual stream habitat features (e.g. pools, runs, and riffles) are selected within the study reach and sampled in proportion to their frequency by stream length to represent other unsampled portions.

Whichever method is chosen to select samples for modeling hydraulics and habitat, it is important to have an overall picture of habitat type distribution within the study reach. A habitat typing approach, termed habitat mapping, that was originally described by Morhardt et al. (1983) and summarized by Bovee et al. (1998), was chosen for this study. Habitat mapping not only assists in selecting study sites, but also with weighting and proportioning resulting habitat indexes from various study sites or reaches.

Habitat mapping consists of a ground level or aerial survey to identify and delineate major habitat types within the stream reach under study (Table 1). As part of the habitat mapping protocol, additional types or sub-types can be added according to the best judgment of the field personnel.

Table 1. Aquatic Habitat Types for Casino Creek Habitat Evaluation.

Habitat Type	Description
Pool	• Low velocity flow • Generally deep across the channel or scoured along one bank • Often contain eddy's along one or both banks • Retains standing water as discharge approaches zero
Glide	• Shallow, uniform channel with smooth or laminar flow • Normally little or no exposed substrate • Typically do not have defined thalweg • May also occur in tailouts of pools or interspersed with runs
Run	• Generally deep, higher velocity flow • Can contain intermittent exposed boulders, bedrock or coarse substrate • Well-defined thalweg, often along a single bank
Low Gradient Riffle	• Shallow and turbulent white-water flow, exposed substrate at low flows • Usually composed of gravel/cobble substrate • Lacks any definitive thalweg • Generally act as controls for lower gradient habitat types
High Gradient Riffle	• Fast, high gradient (usually greater than 4%) habitat type • Substrate generally cobble or boulder dominated • May have interspersed steps and small pools at low flow
Cascade	• Steep, high gradient habitat type • May have interspersed pools at low flow
Other	• Includes any uncommon habitat type (e.g., falls, bedrock chutes)

Habitat unit boundaries were delineated using a hand-held GPS unit with an accuracy of less than 3 meters (m) horizontal on average. This level of precision is considered adequate for defining habitat unit lengths and locations. In instances of islands or split channels, the primary channel was mapped and a cursory examination was performed on the secondary channel to determine habitat correspondence between the two channels. The survey crew also noted major stream features such as high flow channels, split channels, backwaters and woody debris accumulations.

3.1.2 Study Site and Transect Selection

Establishment of study sites and transects can be based on an array of techniques, from professional judgment to random selection, and often depends on the extent and quality of stream habitat data available. Because the entire study reach on lower Casino Creek could be mapped, a stratified random selection approach was chosen which incorporates the least-available habitat type (Payne 1992). This approach minimizes any selection bias, results in transect clusters thereby limiting travel time and cost, and assures representative transects in proportion to habitat availability.

The process involves the following:

- Only reasonably accessible areas within the project study area or study reach are designated for potential selection;

- Within the study area or reach, the habitat type with the lowest percentage abundance from habitat mapping is used a basis for random selection. Generally only habitats which represent greater than 5% of the total are used unless lower percentage habitats are deemed important;

- All least-available habitat units within the selected reach or sub-section are sequentially numbered and, depending on the number of units, three to five units are randomly selected;

- Using the first randomly selected unit, a cursory examination of habitat mapping data is conducted to determine habitat distribution and representation near the selected unit. If the availability of some habitat types is deemed too limited, the second randomly selected unit is used and so forth; and

- Depending on the anticipated number of study sites and/or number of transects per study site, the process is continued until an agreed upon sample is obtained.

Essentially, habitat units are being selected not transects. Actual transect placement is accomplished using professional judgment as to the location within the unit that best represents the overall habitat. The total number of transects required to adequately represent a stream reach is between 15 and 20, which precludes overrepresentation of any single transect or habitat type. In addition, at least two transects are used to represent the lowest percent habitat type to allow for variability.

3.1.3 Hydraulic Data Collection

Field data collection and data recording generally followed the guidelines established by the USGS and in the instream flow field techniques manuals (Trihey and Wegner 1981; Milhous et al. 1984; Bovee 1997). Data collection at each transect consists of water surface elevation (WSE), cross-section profile elevation (calculated from survey data or water depths), velocity measurements and stream discharge. Depth and velocity are measured at points (stations on a tape) across each transect at a minimum of one flow. The number of points established (referred to as cells in the PHABSIM model) depends on the width and complexity of a given transect.

3.1.3.1 Quality Control

Standard quality assurance/quality control (QA/QC) measures were followed during field data collection for the instream flow study. The following procedures and protocols were used:

- Staff gauges were established and monitored throughout the study at each selected site. Significant changes in gauge readings were recorded;

- An independent benchmark was established for each transect or set of transects. The benchmark was a spike placed at an immovable tree, boulder, or other naturally occurring object that would not be subject to tampering, vandalism, or movement. Pins marking the right and left

banks consisted of rebar or spikes, depending on bank topography and substrate composition. Allowable error tolerances on level loops or elevation measurements from separate field visits were set at 0.006 m. This tolerance is applicable to pin and benchmark measurements except where extenuating circumstances explain discrepancies such as elevation measurements made through foliage, leaning leveling rod or loose pins. All elevation surveying was made with an auto-level and telescoping fiberglass leveling rod;

- WSEs were measured on both banks of each transect. On more complex transects with stepped WSEs, additional measurements were taken across a given transect;

- For velocity measurements, an electromagnetic Marsh-McBirney Flow-mate Model 2000 flow meter was used. The flow meter was continually monitored during the daily course of data collection to ensure it was functioning properly; and

- Photographs were taken of all transects at all calibration flows. An attempt was made to shoot each photograph from the same location, though this was not always possible. The photographic record provides a valuable resource of streamflow conditions, water surface levels, and channel configurations.

3.1.3.2 Velocity Measurements

An electromagnetic Marsh-McBirney Flow-mate Model 2000 flow meter, attached to a top-set rod was used for all stream velocity measurements. Mean column velocity was determined by a single measurement at six-tenths of the water depth in depths less than 0.7 meters, and the mean of two-tenths and eight-tenths measurements for greater depths. In instances where the vertical velocity distribution was judged to be variable due to upstream obstructions, two-tenths and eight-tenths measurements were made regardless of depth. The number of points (stations on tape or cells) to sample was determined by transect width and proximity of high velocity areas. An attempt was made to establish a minimum of 20 points and allocate no more than 5-10% of the total flow passing through one cell.

Under PHABSIM, one set of velocities per transect measured at the highest calibration flow is the recommended method. However, if conditions are unsafe or collecting velocities at the highest flow level is not feasible, data is generally collected at the next highest calibration flow. By default, depth measurements are obtained at the same time as velocity.

3.1.3.3 Stage-Discharge Measurements

Discharge and WSE's are used to develop hydraulic rating curves for each transect. WSE is collected at each transect during each field data collection effort. At the highest flow level, or velocity acquisition flow, discharge is computed for each transect. If streamflow conditions are steady (i.e. no changes in WSE are noted through the course of data collection) the average of all transect discharges can be used to compute the best overall discharge. Under varying streamflow and fluctuating WSE conditions, the best discharge may be different for individual transects or groups of transects. Subsequent measurements at lower flow levels consist of a single discharge for each group of transects. Generally three sets of stage-discharge measurements are collected for each transect at different flow levels. However, under

unregulated flow situations coupled with the remote location of Casino and Dip Creek, the number and range of measurements was restricted by timing and access by field crews.

3.1.4 Hydraulic Modeling

PHABSIM was originally developed and maintained by the United States Fish and Wildlife Service Instream Flow Group (now USGS, Aquatic Systems and Technology Application Group, Fort Collins Science Center, Colorado). PHABSIM calculates a habitat index (referred to as Weighted Usable Area or WUA) based in part on simulation of river depths and velocities from 1-D hydraulic models that represent the river by cross-sections. For this study, the hydraulic and habitat index simulations were derived from the computer program RHABSIM (Riverine Habitat Simulation). RHABSIM is software developed by Thomas R. Payne & Associates (TRPA) that implements the equivalent algorithms of PHABSIM. RHABSIM is an enhancement of many of the original PHABSIM model's component programs and includes expanded input, output, graphic, error-checking, calibration, and interpretation capabilities.

Data collected in the field is entered into a spreadsheet module (FIELDAT) in RHABSIM for each individual transect. After error checking, each transect is brought into a hydraulic simulation module (HYDSIM), which includes several hydraulic modeling options. Hydraulic model calibration involves generating stage-discharge relationships, which are used to predict depth, and examining velocity calculations and distributions at the measured flows and over a range of simulated flows. Simulated velocities can be calculated by regression, by interpolation, or extrapolation based on measured velocities at multiple flows or by calculating velocity using Manning's equation and the velocity measured at a single flow.

3.1.4.1 Stage-Discharge Calibration

Stage-discharge relationships, or rating curves, for most 1-D transects are developed from measured discharge and WSE using either an empirical log/log formula or a channel conveyance method (MANSQ). Under these methods, each transect is treated independently. The log/log method generally needs three sets of stage-discharge measurements and an estimate of stage-at-zero-flow (SZF) for each transect. SZF is the point at which water no longer flows and is the lowest bed elevation of a transect or in the case of a pool the lowest bed elevation (control point) downstream. The quality of the rating curves is evaluated by examination of mean error and slope output from the model. Mean errors of less than 10% is considered acceptable and less than 5% is very good. In general the slope within groups of transects should be similar.

MANSQ only requires a single stage-discharge pair and utilizes Manning's equation and channel shape to determine a rating curve; however, it is generally validated by additional field stage-discharge measurements to determine how Manning's n changes with flow. This modeling method involves an iterative process where a beta coefficient is adjusted until a satisfactory result is obtained. In situations where irregular channel features occur on a cross section, for instance bars or terraces, MANSQ is often better at predicting higher stages than log/log. MANSQ is most often used on riffle or run transects and is generally not considered as effective in establishing a rating curves for transects that have backwater effects from downstream controls, such as pools. It can also be useful as a test and verification of log/log relationships.

Overall the degree of accuracy of rating curves for a group of transects is based on comparable logarithmic line slopes and intercepts, and similar changes in stage elevation between both measured and simulated flows. Water depths are calculated from transect rating curves that give the rise or fall in water surface.

3.1.4.2 Velocity Calibration

The single set of velocities measured at each transect was used to predict individual cell velocities over the range of flows to be modeled. Referred to as the 1-flow method, simulated velocities are based on measured data and a relationship between a fixed hydraulic roughness coefficient (Manning's n) and depth. In some cases, roughness is modified for individual cells if substantial velocity errors are noted at higher or lower simulation flows. Velocity adjustment factors (VAFs) are calculated by the hydraulic model for each simulated flow to account for increase or decrease in water levels and total discharge for each transect relative to the calibration flow. VAFs are examined to detect any significant deviations and determine if velocity distribution remains consistent with changes in stage and total discharge. VAFs also change because the point values of Manning's n change as the flow changes. VAFs in the range of 0.8 to 1.2 at the velocity acquisition flow (calibration flow) are considered acceptable.

3.1.4.3 Target Flows

Target flows are usually set based on the range of flows of interest, range of exceedance levels or project potential. Ideally, controlled flow release from a containment structure is best for acquiring target flows and stable flows. In instances where flow control is nonexistent, obtaining target flows is based on a combination of hydrological record and closely monitoring current flows and weather. For this study, an examination of limited hydrological records was used to establish a field schedule that would potentially allow for a range of flows to be measured. Because flows of interest were at the lower end of the hydrograph, measurements of very high flows were not necessary.

3.1.5 Target Aquatic Species and Life Stages

Fish species collected in the Casino Creek watershed during aquatic baseline surveys in 2009 consisted of Arctic grayling, slimy sculpin and a single burbot (PECG 2011). Arctic grayling and slimy sculpin are also both present in lower Canadian Creek. In addition to these species, round whitefish (*Prosopium cylindraceum*) and Chinook salmon juveniles (*Oncorhynchus tsawytscha*) are known to occur, or have been historically present, in Dip Creek. There are no known suitability criteria for slimy sculpin and this species was not evaluated for this study. As Arctic grayling compose the majority of the species composition within the Casino Creek/Dip Creek watershed, it was chosen as the target species for the study.

3.1.6 Habitat Suitability Criteria

The PHABSIM habitat index is computed by combining the hydraulic model with habitat suitability criteria (HSC). The most commonly used source for Arctic grayling riverine populations is Hubert et al. (1985). HSC for grayling includes depth, velocity for all life stages, substrate (fry and spawning only) and temperature (all life stages). Temperature was not incorporated into the PHABSIM model for this study

based on the assumption it is not a limiting factor during summer flows. Criteria from Hubert et al. (1985) have been used as a basis for habitat compensation planning as recently as 2006 on the Ruby Creek Project near Atlin B.C. (Adanac Moly Corporation, Ruby Creek Molybdenum Project EAC Application, Appendix 11 – Fish Habitat Compensation Plan, July 2006).

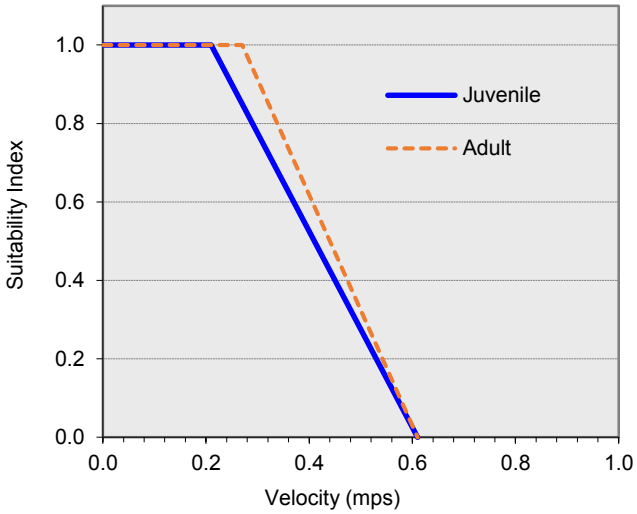
Based on suitability criteria categories, substrate was visually assessed and categorized into the following classes:

- Organics/Silt/Mud;
- Fines (<0.2 cm);
- Gravel (0.2 – 6.4 cm);
- Rubble (6.4 – 17.0 cm);
- Cobble (17.0 – 25.6 cm);
- Boulders (>25.6 cm); and
- Bedrock.

Rubble (basically small cobbles) was added as a substrate category based an examination of Arctic grayling life history and habitat use studies in the Northwest Territories (Stewart et al. 2007). They found some investigations that identified this size class as being important to spawning and adults.

There are no known Arctic grayling suitability criteria for cover. However, cover information was collected in the event of additional aquatic species analyses or new information. Cover was visually assessed using the following types:

- Large woody debris (LWD);
- Boulder;
- Bank overhang or ledge;
- Instream vegetation; and
- Overhanging vegetation.



Velocity HSC for adult and juvenile Arctic grayling reported by Hubert et al. (1985) show a maximum suitability up to 0.25 m/s before declining to not suitable above 0.6 m/s (**Figure 2**). This is lower than that reported by Stewart et al. (2007) where typical mean velocity ranged from 0.5 to 1.1 m/s. However, another study reported adult grayling preferred water velocities between 0.2 and 0.45 m/s (Vehanen et al. 2003), similar to values used for this study. Adult and juvenile depths are broken into summer and winter (**Figure 2**). Winter depth suitability is zero below 1.2 m, a function of winter survival in pools that freeze over.

Grayling fry depth and velocity HSC are indicative of most young-of-year salmonids species with highest suitability for low velocities and shallow depths (**Figure 3**). Fry criteria also include a substrate component related to cover elements, with highest suitability for cobble and boulder (**Figure 3**).

Spawning suitability is 0.5 at a velocity of 0.4 m/s and 1.0 between velocities of 0.6 and 0.9 m/s (**Figure 4**). This matches well with an average range of 0.3 – 0.8 m/s reported by Stewart et al. (2007). Depth suitability for spawning is not limited except below 0.3 m (**Figure 4**).

Temperature criteria for spawning are shown for reference purposes on **Figure 5**. The relatively broad range, particularly for incubation, indicates that only under extreme conditions would this variable enter into a flow related habitat estimate.

3.1.7 Habitat Modeling

The PHABSIM habitat index combines the hydraulic model attributes with HSC curves (**Figures 2** through **5**). Each cell in the calibrated hydraulic model has a predicted depth and water velocity associated with a type of substrate or cover for a particular flow. A fish habitat index is computed for each cell by multiplying the suitability of each variable from the HSC (velocity, depth, substrate, and/or cover) to produce a composite factor. The cell suitability composite index value was computed based on a multiplicative procedure:

$$Ci = Vi * Di * Si$$

Where:

Ci = Cell suitability composite index value
Vi = Velocity suitability value associated with cell
Di = Depth suitability value associated with cell
Si = Substrate or other channel suitability value associated with cell

The cell suitability composite index value is then multiplied by the number of square meters of area in that cell. For each transect, all the cells' areas are summed to produce a total number of square meters of usable habitat available at a specified flow. This result is then multiplied by the percentage (weight) the individual transect represents as a proportion of all transects being modeled (formula below). The final result is the Habitat Index value that represents the sum of all transects given in units of square meters of habitat per 1,000 m of stream length corresponding to each simulated flow.

$$Habitat\ Index\ (WUA) = \sum_{i=1}^{n} Ai * Ci$$

Where:

Ci = Cell suitability index value
Ai = Cell area weighted by transect representation based on 1,000 m stream length

3.1.8 Habitat Time Series Analysis

The amount of habitat available at any given time of year is a function of hydrology, incorporating a time-series analysis provides a more practical view of available habitat. Such an analysis is important when determining effects of different flow regimes that may result from project operations. Times series involves matching the habitat index for a given species or life stage to flow, as illustrated in **Figure 6**. Habitat duration indicates the amount of time habitat remains at certain levels over the range of flows to be evaluated, generally natural flow versus project related flow.

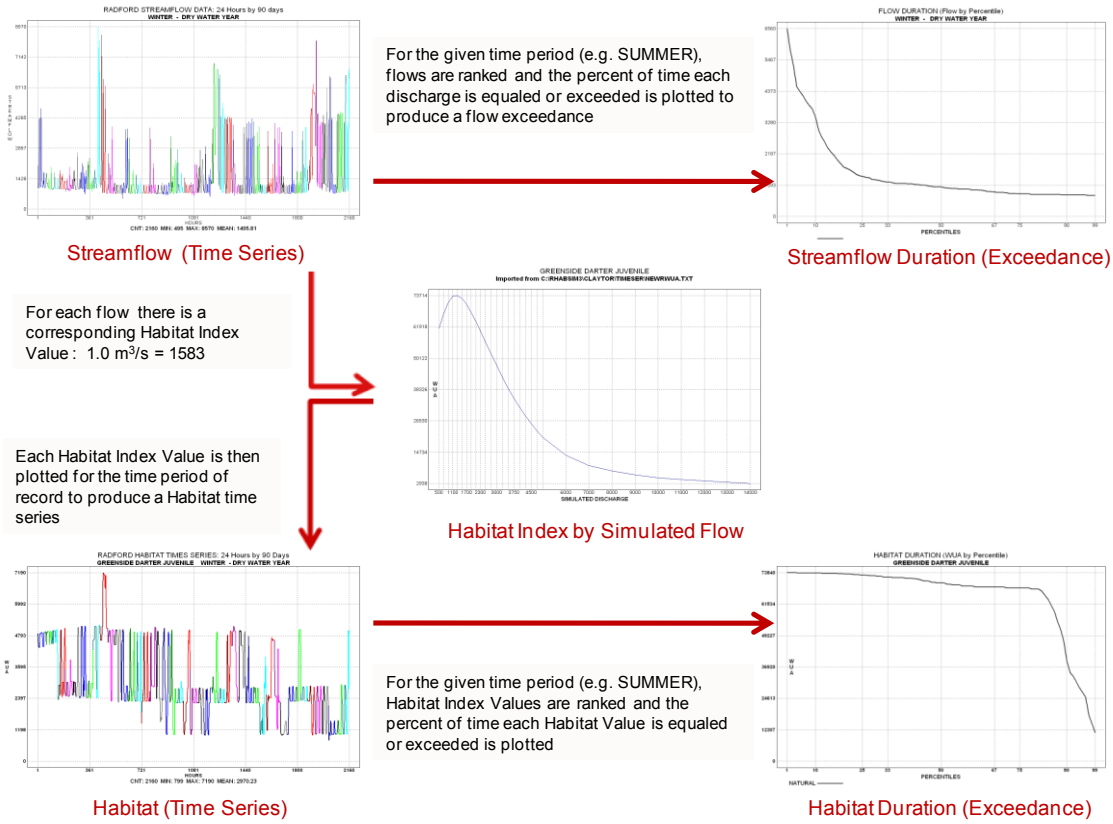

Figure 6. Habitat Time Series Evaluation Flow Chart.

Arctic grayling life stage periodicity, as it applies to the time series analysis, is presented in **Table 2**. The spawning period was limited to the end of June. Juvenile and adult life stages are assumed to occur throughout the ice-free period. Fry are generally considered age 0 until the end of their first year.

Table 2. Arctic grayling Life Stage Periodicity.

Life Stage	May	June	July	Aug	Sept	Oct.
Adult	X	X	X	X	X	X
Juvenile	X	X	X	X	X	X

3.2 HEP Study

A Habitat Evaluation Study (HEP) was conducted in Casino Creek upstream of Brynelson Creek in Dip Creek, Meloy Creek and Lower Britannia Creek, to quantify the habitat value of these reaches (**Figure 1**). Measurements were taken along the entire length of each reach and habitat type was recorded, along with the length of each section, average depth, average width, dominant and sub-dominant substrate, cover (type and percent), and maximum pool depth, if any. Additionally, if the habitat unit appeared to be suitable for Arctic grayling spawning, additional information including percent gravel and rubble, percent fines, area of suitable habitat, and estimated velocity were also taken. Similarly to the PHABSIM assessment, Arctic grayling were chosen as the target species for the HEP study.

The value of fish habitat for a HEP Study is evaluated using species specific Habitat Suitability Index (HSI) models. Hubert et al. (1985) provides a detailed description of the HSI model:

> "The HSI model consists of two components: (1) spawning and embryo development; and (2) migratory and wintering habitat for juvenile and adult life stages.
>
> The spawning, embryo and fry development component includes six habitat variables that are believed to govern spawning success and embryo survival of Arctic grayling. Variables V1 and V2 describe water temperature and dissolved oxygen concentrations required, while variables V3 and V4 describe substrate requirements. Variable V5 assesses current velocity and V6 assesses pool availability.
>
> The migratory and winter component uses four habitat variables that probably influence the quality of juvenile and adult habitat. Variables V7 and V8 describe water temperature and dissolved oxygen concentrations needed by these life stages. Variable V9 describes the need for migratory routes between wintering areas and spawning streams, while V10 assesses overwinter habitat quality."

To develop the HSI model, data for each of the variables are derived either from field data or regional information, and the resulting index is multiplied by the water surface area of the affected habitat. Some variables may not be employed depending on their availability or perceived importance to the stream under study. For example, water temperature may not be an issue at any time of the year and therefore would not be applied to the model.

Field survey data were compiled and totaled to provide an un-adjusted estimate of habitat within the potentially affected area. HSI curves were then applied to the data in order to quantify the suitability of the habitat to the target species (i.e., Artic grayling). The total amount of habitat was then recalculated, subtracting areas that the HSI calculations indicated were of no or low value.

The HEP method for Arctic grayling comes with the qualifier that "The model includes physical habitat variables believed important in maintaining viable populations of Arctic grayling. If the model is correctly structured, a high HSI for a habitat would indicate near optimal physical conditions for Arctic grayling and a low HSI would indicate poor habitat conditions. An HSI of zero does not necessarily mean that the species is not present; it does however indicate that the habitat is very poor and the species is likely to be scarce or absent (Hubert et al. 1985). The same qualification can be applied to WUA calculated using

PHABSIM. It is also worth noting that the habitat and population densities in these watersheds are generally low, and a further reduction in poor quality habitat is unlikely to have any effect on the species at the population level.

4 RESULTS

The results of the Fish Habitat Evaluation are presented based on the method used for evaluating the potential loss or change in fish habitat as a result of the Casino Project. Reaches 1 and 4 were evaluated using PHABSIM, and Reaches 2a, 2b and 3 were evaluated using HEP analysis (**Figure 1**). The results of each methodology are discussed separately.

4.1 PHABSIM Study

4.1.1 Habitat Mapping

4.1.1.1 Casino Creek – Reach 1

Habitat mapping of lower Casino Creek (Reach 1), located between Brynelson Creek and Dip Creek (**Figure 1**), was performed on June 8 and 9, 2011 under varying streamflow conditions estimated to range between 0.5 and 1.0 m^3/s. Habitat mapping field data were entered into a spreadsheet to compute habitat unit lengths from GPS coordinates and to summarize the data (**Appendix A**). Run habitat accounted for 36% of habitat mapped, and was the predominate type (**Table 3**); followed by pool (27.5%), low gradient riffle (23.4%), glide (12.4%) and high gradient riffle (0.8%). The total stream length mapped was about 6.5 km.

Table 3. Habitat Type Composition and Percent by Length on Lower Casino Creek (Reach 1).

Habitat Type	Number of Units	Habitat Length (m)	Average Habitat Length (m)	Percent by Length (%)
Pool	112	1783	16	27.5

Low Gradient Riffle	82	1514	18	23.4
High Gradient Riffle	4	49	12	0.8
Other	0	0	0	0.0

4.1.1.2 Dip Creek – Reach 4

Habitat mapping on Dip Creek, downstream of Casino Creek (Reach 4), was conducted on September 13 and 14, 2011. Mapping and transect selection was conducted by helicopter, in order to obtain general estimates of habitat percentages in the area. Habitat estimates can be found in **Table 4**, below. Once the helicopter survey was completed, specific study sites and transects were established at accessible locations near identified limited habitat units.

Table 4. Habitat Type Composition and Estimated Percent by Length on Dip Creek (Reach 4).

Habitat Type	Estimated Percent by Length (%)
Pool	30
Glide	50
Run	10
Low Gradient Riffle	10

4.1.1.3 Canadian Creek

Habitat mapping on lower Canadian Creek was conducted on May 25, 2013. Mapping and transect selection was conducted by helicopter, in order to obtain general estimates of habitat percentages in the area. Habitat estimates can be found in **Table 5**, below. Once the helicopter survey was completed, transects were established at accessible locations near identified limited habitat units.

Table 5. Habitat Type Composition and Estimated Percent by Length on Canadian Creek.

Habitat Type	Estimated Percent by Length (%)
Low Gradient Riffle	30
Run	30
Pool	20
Glide	20

4.1.2 Study Sites and Transects

4.1.2.1 Casino Creek – Reach 1

Habitat mapping of lower Casino Creek (Reach 1) identified no major differentiation in channel configuration or substrate composition along the mapped length. As a result, the reach was considered uniform and it was therefore, not necessary to segment it into sub-sections. Still, for the purposes of

further, detailed analysis, it was decided to split the mapped 6.5 km reach equally into 3.25 km upper and lower sections.

Using glide habitat as the least available habitat type, one glide unit each in the lower and upper portion of the reach was randomly selected. After a cursory examination of mapping data to ascertain availability of all habitat types near the selected unit, field crews visited the potential sites. Upon confirmation that the selected glide habitat unit was suitable for the PHABSIM model, a transect was established that best represented the habitat type. The crew then continued establishing transects upstream and downstream within the vicinity of the selected habitat unit with the goal to place 10 transects per study site in proportion to predetermined reach representation from habitat mapping results.

Two study sites were established: CAS 1 – in the upper portion of the study reach, 1.5 km downstream of Brynelson Creek, and CAS 2 – in the lower portion of the study reach, 1.9 km upstream of Dip Creek. A total of 20 transects were established, with 10 transects in the upper reach (CAS 1) and 10 transects in the lower reach (CAS 2) (**Table 6**).

LGR – Low Gradient Riffle

4.1.2.2 Dip Creek – Reach 4

Similarly to lower Casino Creek, Dip Creek (Reach 4) was also observed to be generally uniform along its length. Based on habitat composition estimates, Low Gradient Riffles (LGR) were determined to be the limiting habitat type. Two suitable transects within LGR Habitat were established, followed by 10 upstream and downstream transects from the selector.

The two study sites in Dip Creek are: Dip 1 – located approximately 1km downstream of the confluence with Casino Creek, and Dip 2 – located a further 1 km downstream. A total of 20 transects were established, with 10 transects in the upper reach (Dip 1) and 10 transects in the lower reach (Dip 2).

The results of the habitat mapping for both Dip 1 and Dip 2 are presented in **Table 7**.

4.1.2.3 Canadian Creek

Twenty (20) transects were selected on Canadian Creek based on proportions of habitat type determined by an aerial flyover. Transects were selected beginning at the existing bridge over Canadian Creek, and

proceeded upstream (**Figure 1**). Transects were all within the lower reach of Canadian Creek, as this is the only section of stream identified as fish bearing (PECG, 2013c). Transect numbers were established in the following proportions based on habitat type (low gradient riffle, 6; run, 6; pool, 4; glide, 4). Each transect was established according to PHABSIM methodology with pins driven into each bank above the high water line to ensure consistent cross section measurements, and to provide secondary benchmarks. Each cross section was visited at three times during the course of the season in order to capture high flow, mid flow and low flow conditions.

The results of transect selection for Canadian Creek are presented in **Table 8**.

4.1.3 Field Data Collection

4.1.3.1 Casino Creek – Reach 1

Field measurements took place in 2011 on June 10-12, September 13 and October 5 at both study sites on Casino Creek (CAS1 and CAS2). During the initial data collection rebar pins were positioned on both banks of each transect. Benchmarks consisting of nails or spikes were driven into stumps or conifers to

serve as fixed reference points for surveying groups of transects during subsequent site visits. A measuring tape attached to the rebar working pins was used to establish stations (points) across each transect for stream channel measurements. Due to unusually high precipitation during the June10-12, 2011 time period, it was anticipated this survey would constitute the highest of the three planned data collection efforts. Therefore, velocities and depths along with WSE and streambed elevation profiles were measured at each transect at this time. Data collection requirements for subsequent site visits on September 13 and October 5, 2011 consisted of WSE at each transect and a single discharge for each group of transects.

On June 10, 2011, at the CAS 1 study site total discharge increased from 0.64 m^3/s to 0.93 m^3/s during measurements of the 6 transects sampled that day (**Table 9**). On June 11, 2011, flow remained steady for the 4 remaining transects at this site, although measured flows were substantially higher than were recorded on the previous day. Overall, during the June high flow sampling event at CAS 1, the measured stream discharge ranged between 0.64-1.18 m^3/s (**Table 9**). During follow up visits to CAS 1 in September and October, 2011, measured discharges were 0.84 m^3/s and 0.44 m^3/s, respectively (**Table 10**).

At the CAS 2 study site, field measurements began on June 11, 2011. During the stream flow measurement at transect 10, a heavy rain caused a rise in stage and increased stream discharge from 1.64 m^3/s (transect 10) to 2.23 m^3/s (transect 7) (**Table 9**). As a result additional data collection was suspended until June 12. Starting the following day at transect 6, a slow decline in discharge was noted during stream discharge measurements that ranged from 1.90-2.14 m^3/s. Overall, during the June high flow sampling event at CAS 2, the measured stream discharge ranged between 1.64-2.23 m^3/s (**Table 9**). During the follow up visits made to CAS 2 in September and October, 2011, measured discharges were 0.91 m^3/s and 0.65 m^3/s, respectively (**Table 10)**.

4.1.3.2 Dip Creek – Reach 4

The first of three stage-discharge data sets were collected from Dip Creek on September 13 and 14, 2011, at sites DIP 1 and DIP 2 (**Table 11**). During this visit, transects were established with rebar at 20 locations, and benchmarks were created for each transect or group of transects. One discharge

measurement was taken for each group of transects, and water surface elevations were taken at each transect. Water levels were low and no recent precipitation had occurred in the area. Discharges of 2.58 m^3/s and 2.35 m^3/s were recorded at the DIP 1 and DIP 2 sites, respectively.

Additional data were collected on May 25, 2012, and September 5 and 6, 2012 (**Table 12**). The May site visit consisted of WSE at all transects, in addition to two discharge measurements (7.35 m^3/s and 7.09 m^3/s at DIP 1 and DIP 2). The May site visit was timed as closely as possible with the estimated timing of the spring freshet in the area, in order to collect maximum high flow measurements at all sites.

The third site visit occurred during September, 2012. This visit included velocity/depth measurements at each transect as well as measurements of WSE. Recorded discharges were 2.39 m^3/s and 2.40 m^3/s at DIP 1 and DIP 2, respectively. Despite low flows in Dip Creek, pool depth continued to provide a challenge to accurate data collection. An inflatable float tube was used to assist in obtaining measurements in the deeper pools.

4.1.3.3 Canadian Creek

High flow sampling occurred between May 25 and 27, 2013, after the cross sections were first established. During this event, water elevations were surveyed using a level and stadia rod and elevations were tied to a nearby established benchmark. Discharge measurements were taken at each of the 20 cross sections (**Table 13**).

Table 14. Lower Canadian Creek Discharge Measurements (Low and Mid Flow Conditions)

Study Site	Transect #	Habitat Type Waypoint #	Measured Discharge (m3/s)	Date (2013)
Canadian Creek	7	CC Glide 7	0.38	June 18 (Low Flow)
	7	CC Glide 7	0.66	July 4 (Mid Flow)

During each of the remaining two visits, conducted on June 18 and July 4, 2013 to capture mid and low flow conditions, a single discharge measurement was taken at a representative cross section, (**Table 14**) and water surface elevations were taken at each transect . Discharge measurements are taken at all locations during setup of the study, in order to obtain calibration data, and multiple point velocities at each cross section. During subsequent visits, it is only necessary to take one representative flow at the best cross section, in order to determine discharge for the study site.

Following sampling, velocities and habitat data was entered into the RHABSIM (Riverine Habitat Simulation) model for analysis. Time series analysis was conducted using the SEFA (System for Environmental Flow Analysis) model as it allowed for more efficient processing of the time series data.

4.1.4 Hydraulic Modeling

Hydraulic modeling for PHABSIM analysis involves constructing stage-discharge rating curves and calibration of velocity distributions for each transect. This is done in the HYDSIM component of RHABSIM. The measured stage-discharge pairs are referred to as calibration flows. For each simulated flow. WSE is calculated from the stage-discharge rating curve and water depths are calculated from the WSE and bed elevation. Velocities are simulated and an associated roughness coefficient (Manning's n) generated by the hydraulic model. Hydraulic model calibration details may be found in Appendix C.

4.1.4.1 Stage-Discharge

Developing stage-discharge rating curves is based on the assumption that no change in bottom profile occurs between calibration flow measurements. Casino Creek experienced several precipitation events during the summer of 2011, some of which produced bank full and over-the-bank flows. One effect of these high flows was bedload movement and consequently bottom profile changes on a number of transects. Bottom profile alteration can alter WSE controls (e.g. by scouring at pool tails, sediment deposition in riffles), and this can result in poor cross section rating curves, and consequently poor predictions of depth and velocity.

Water levels dropped as expected between the high and middle measured calibration flows for most transects at all three study sites (**Tables 15 to 19)**. Exceptions are found in the CAS 1 study site for transects 6-8, where high and middle measured calibration flows were virtually identical, but stages were not (**Table 15**). Of the 10 transects in the CAS 1 study site, 8 had higher stages at the lowest flow versus the middle flow. This indicates substantial bed aggradation occurred between site visits, raising the stream bed and as a result the water surface. Changes in stage were much more consistent at the CAS 2 study site with the exception of transects 8-10 (**Table 16**).

Dip Creek low and middle flow discharge and water surface levels were nearly identical at both study sites (**Tables 17** and **18**). Unlike Casino Creek there were no significant bed profile changes between site visits.

Stage dropped as expected between high, middle and low calibration flows at Canadian Creek. No issues with bedload movement were experienced (**Table 19**).

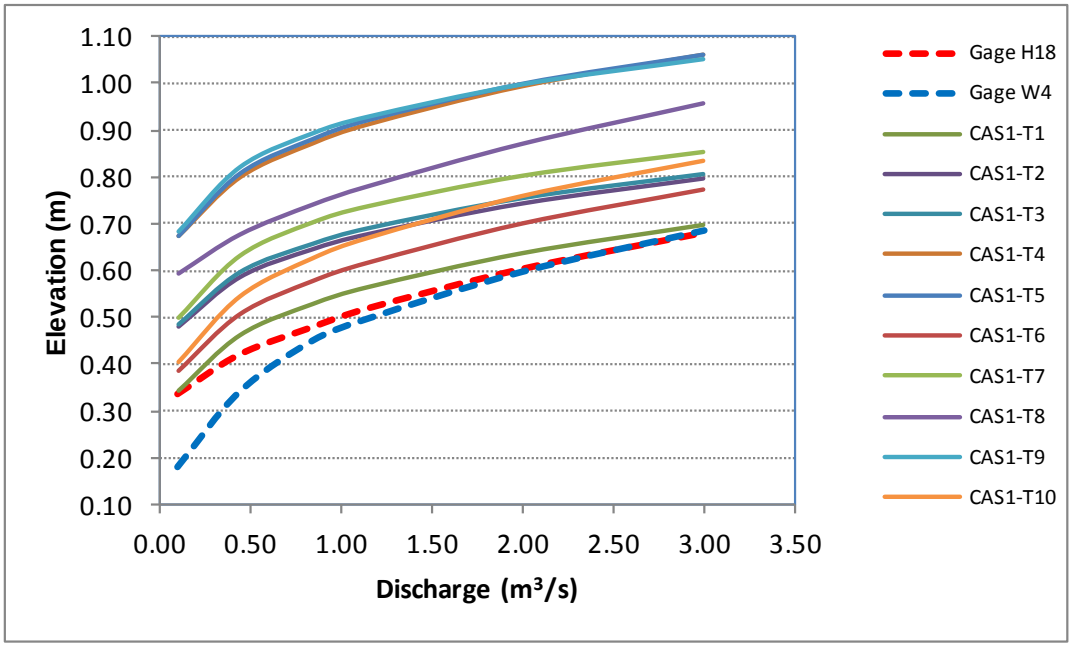
Each study site was examined and calibrated separately to establish individual transect stage-discharge relationships. Working with specific sites permitted examination of relationships between transects tied to common benchmark elevations, allowing general modeling errors to be detected. Grouped transects also assist in determination of SZF, by comparing thalweg elevations and plotting stages between transects.

Log/log rating curves could not be established for any transects in the CAS 1 study site and for only a few of transects in the CAS 2 study site. Except for transect #7 (LGR 343) in the CAS 1 study site, all stage-discharge rating curves were established using the MANSQ channel conveyance method.

MANSQ, rating curves were calculated based on the measured calibration and velocity acquisition flow, generally the highest flow for each transect, as a beginning point. Because only one stage-discharge pair was used in the model calibration, beta coefficients that show how Manning's n changes with flow are required. For the CAS 2 study site, log/log relationships for two transects, Glide 344 and LGR 343, were used initially. Because there were no transects in the CAS 1 study site that could be used for validation or comparison, an alternative was to evaluate rating curves using established stream gauge rating curves. As documented in "Western Copper Corporation Casino Copper-Gold Project. 2010 Hydrometric Data Collection Summary Report" (Knight Piesold 2011) site W4 in lower Casino Creek and site H18 in middle Casino Creek had established stage-discharge curves suitable for validation of MANSQ results. By plotting changes in stage versus calibration flows for the gauges and transects it was confirmed that the final rating curves for CAS 1 and CAS 2 were appropriate (**Figure 7**). Differences in slope of the curves is mostly attributed to channel width of individual transects. For example, the channel is narrower



at the W4 gauge versus the H18 gauge, which results in a steeper rating curve for the W4 gauge due to water level increasing more rapidly in a narrow channel compared to a wide channel.

An additional validation check was to examine longitudinal WSE profile plots to detect obvious issues with simulated WSEs between groups of transects, such as water flow uphill and degree of separation between simulated flows.

For transects in Dip Creek (DIP 1 and DIP 2), log/log rating curves were used for all stage-discharge relationships (**Figure 8**). Since these ratings were based on essentially two data points, low/middle and high, it was important to verify the curves were accurate. This was accomplished by comparing each transects rating curve to those produced by the MANSQ channel conveyance method, and examining longitudinal simulated WSE plots. Resulting rating curve comparisons, which also includes the gage in Upper Casino Creek (W9), showed little difference and longitudinal WSE plots revealed a consistent variation between transects, indicating adequate hydraulic ratings.

4.1.4.2 Velocity Calibration

Velocity simulation was evaluated based on examination of (VAF's) and reasonableness of individual cell velocities over the range of flows being simulated. Point Manning n adjustments to individual cells were kept to a minimum and when applied were made primarily to edge cells. VAFs are considered excellent if they are near 1.0, and good if they fall between 0.8 and 1.2 at the velocity calibration flow. The range of VAF's is a function of the degree in which velocities are adjusted by the model so that the calculated discharge matches each simulation flow. VAFS also adjust for changes in manning n. As Manning n changes more in runs and riffles than in pools. Fast water transects such as riffles and runs generally require more velocity adjustment than deep slow transects such as pools. Final VAF's were within acceptable ranges and are presented for Casino Creek and Dip Creek on **Figures 9 and 10.**

4.1.5 Habitat Modeling Results

Usable fish habitat is calculated by combining predicted depths and velocities from the hydraulic model with suitability criteria for individual fish species and life stages using the HABSIM module of RHABSIM. To produce a composite habitat index (presented as square meters of habitat per 1,000 m of stream), results from individual transects are combined based on amount of stream each transect represents. For this study transects were "weighted" based on the proportion of the corresponding habitat type within the study reach (refer to **Tables 3 to 5**).

Habitat index results for all life stages of Arctic grayling reflect characteristics of the HSC, particularly velocity. Lower velocities have the highest suitability for all life stages but spawning. The shape of the curves is a response to overall lower velocities at low flows. As flow increases, velocities in the middle of the channel become unsuitable and the amount of usable area is reduced to the margins, as long as depth is sufficient.

Within Casino Creek, adult and juvenile Arctic grayling show the most amount of habitat at flows below 1.0 m^3/s, and this is because of preference for low velocities that occur at low flows (**Figure 11** and **Table 20**). Adult and juvenile rearing curves climb slightly with increased discharge, before falling as flows continue to increase, due to increasing channel velocities. In addition, **Figure 11** shows that Arctic grayling spawning habitat has a large range of highly suitable flows between 0.6 and 2.0 m^3/s. Arctic grayling fry habitat index curve falls abruptly as flows increase before flattening out. The flat portion of the curve indicates the amount of habitat stays constant, mainly along the banks, with increased flow.

The habitat index was also simulated for winter flow values for adult and juvenile Arctic grayling (results shown in **Table 20** and not graphed). The results indicate there is very little winter habitat available in Casino Creek for adult and juvenile Arctic grayling due to lack of adequate pool depth.

Within Dip Creek, adult and juvenile Arctic grayling show the most amount of habitat at flows below 4.0 m^3/s (**Figure 12** and **Table 21**). Spawning habitat for Arctic grayling is primarily found at flows between 1.5 and 5.0 m^3/s. Fry habitat stays relatively constant over the range of flows and increases slightly under higher flow conditions due to increased available habitat.

Similarly to Casino Creek, the habitat index in Dip Creek was also simulated based on winter depths for adult and juvenile Arctic grayling. **Table 21** provides a summary of winter habitat index values for Arctic grayling in Dip Creek and shows that little winter habitat available in Dip Creek.

4.1.6 Habitat Time Series

Long-term synthetic daily stream flow series hydrology for Casino Creek, Dip Creek and Lower Canadian Creek were developed by Knight Piesold (Knight Piesold, 2013). Estimated mean monthly percent flow change for each project phase were calculated (**Table 22**). Flow change percent values are averages for each project phase, and therefore do not represent the maximum change in each phase. The closure values are for the period after the Tailings Management Facility (TMF) begins to spill. The current assumption is that the TMF will be pumped back to the Open Pit and will not spill for the first 10 years of closure in order to establish a clean pond. The post-closure values are for the period after the Open Pit begins to spill.

Table 22. Mean monthly percent change in flow by station and project phase.

Project Phase	Station[1]	May	June	July	Aug.	Sep.
Construction	Casino Cr Middle- H18	-48%	-68%	-61%	-61%	-62%
	Casino Creek Lower - W4	-41%	-60%	-55%	-53%	-54%

	Canadian Creek – W3	-17%	-21%	-18%	-15%	-14%

[1] Dip Creek station W9 is upstream of Casino Creek and not affected by the project. Adjusted flows for Casino Creek were added to flows from Upper Dip Creek to calculate flows for Lower Dip Creek.

Mean monthly percent flow change estimates were applied to the baseline daily flow data for the period 1990 to 2013 to construct flow time series hydrology by station and project phase. Graphic presentation of flow time series hydrology is based on average daily flow over the entire period. Streamflow duration (exceedance) is based on all daily flows over the entire period. Note that for Arctic Grayling spawning evaluation only those flows from May 15 to June 30 were used.

As would be expected, lower and middle Casino Creek have similar hydrology and flow duration for all project phases (**Figures 13 and 14**). In general flows are uniformly lower during construction and operation phases and similar to baseline for closure phases. Dip Creek shows little difference between all project phases (**Figure 15**). This is primarily attributed to the fact that flows from upper Dip Creek account for two to three times the flow in Casino Creek. Only the upper portion of Canadian Creek would be affected by the project. The result is little difference in flow for all project phases would be detected at the gage station (W3), located near the mouth of Canadian Creek (**Figure 16**). However, flows would be slightly lower after closure phases of the project.

4.1.7 Potential Change in Habitat – Casino Creek

The Habitat Index Duration from the time series analysis presented above demonstrates how the amount of fish habitat will vary with flow in different years (**Figures 17 to 20**). In this way, the results of the PHABSIM instream flow modeling are not static and will vary from year to year based on flow conditions and Arctic grayling life stage. Ideally, an average daily flow based on an extended gauge record for average, wet and dry years should be applied to this analysis

In order to assess change in amount of usable habitat based on flow we can examine habitat that occurs at various exceedance intervals. Using the 50% habitat exceedance, the median amount of habitat that occurs over the time period examined, should provide the best estimate of habitat gains or losses due to a change in stream flow.

Duration curves are similar for adult and juvenile grayling based on flows in lower (W4) and middle (H18) Casino Creek (**Figures 17 and 19**). The reduction in flow in Casino Creek during construction and operation phases of the project results in a median increase in habitat for adult and juvenile grayling of between 16% and 22% for lower Casino Creek, and 10% to 15% for middle Casino Creek (**Tables 23 and 24**). This outcome is due to the tendency for these life stages to prefer lower velocities, as indicated by the Habitat Suitability Curves (HSC) (Hubert et al., 1985), and that at lower flows there is an increase in available low velocity refuge areas. Changes in habitat during the closure and post-closure phases are generally less than 10% based on the median habitat values (**Tables 23 and 24**).

Grayling fry habitat duration curves in both lower and middle Casino Creek exhibit similar results to adult and juvenile with increased habitat under project conditions (**Figures 18 and 20**). The median habitat values increase in the range of 95% for lower Casino Creek and around 125% for middle Casino Creek during construction and operation phases (**Tables 23 and 24**). Again these results are a product of preference for low velocities by this life stage. Changes in habitat during the closure and post-closure phase are generally less than 7% to 15% based on the median habitat values (**Tables 23 and 24**).

Spawning is the only life stage which shows a decrease in habitat due to flow reduction during the projects construction and operation phases (**Figures 18 and 20**). The median habitat value percent change shows a decrease in lower Casino Creek (-72%) and middle Casino Creek (-83%) for the construction and operation phases of the project (**Tables 23 and 24**). This is an end result of lower availability of higher velocities generally used by grayling during spawning, the opposite condition of what is preferred during other life stages. Changes in habitat during the closure and post-closure phases are between 6% and 9% based on the median habitat values (**Tables 23 and 24**).

Table 23. Habitat Index values (m²/1000 meters) for Arctic grayling life stages at selected habitat duration percentages under baseline and project phases for lower Casino Creek.

4.1.8 Potential Change in Habitat – Dip Creek

Similarly to Casino Creek, in order to assess change in amount of usable habitat based on flow we can examine habitat that occurs at various exceedance intervals within Dip Creek (**Figures 21 to 22**). Using the 50% habitat exceedance, the median amount of habitat that occurs over the time period examined, should provide the best estimate of habitat gains or losses due to a change in streamflow.

For Dip Creek habitat for adult and juvenile grayling shows a slight increase during construction and operation phases of the project (**Figure 21**). Fry and spawning life stages show virtually no difference in habitat during all project phases (**Figure 22**). The percentage change at the median habitat index value is between 7% and 8% for juveniles and adults and a decrease of 2% to 3% for fry and spawning life stages during construction and operation phases of the project (**Table 26**). Habitat index values for closure phases differ little from baseline.

Table 26. Habitat Index values (m^2/1000 meters) for Arctic grayling life stages at selected habitat duration percentages under baseline and project phases for Dip Creek.

4.1.9 Canadian Creek

No detectable change in habitat occurs for grayling adult and juvenile life stages under all project phases in Canadian Creek (**Figure 23**). A small increase in habitat for fry and a slight decrease in spawning habitat would occur during project closure phases (**Figure 24**). This equates to an increase in fry habitat by 28% and a decrease in spawning habitat of 11% (**Table 27**).

Habitat index values presented in **Tables 23 to 27** are expressed in m^2/1,000 meters of stream length. To determine the overall change in habitat in lower Casino Creek these values were converted to m^2 based on the total stream length affected, which is 6,500 m for Casino Creek, 8,500 meters for Dip Creek and 7,000 meters for Canadian Creek. **Table 28** presents the result of these calculations to show the overall change in habitat for the 50% habitat exceedance for each stream and project phase in addition to total available habitat.

Table 28. Usable habitat (m^2), total available habitat (m^2) and net change from baseline for Arctic grayling life stages for Casino Creek, Dip Creek and Canadian Creek under all project phases.

4.2 HEP Study

A Habitat Evaluation Procedure (HEP) study was carried out on the fish-bearing reaches of Upper Casino Creek, where the proposed TIA will completely remove available habitat in the creek. This includes reaches 2a and 2b, as well as Reach 3 and Meloy Creek, and Lower Britannia Creek (**Figure 1**).

Surveys in upper Casino Creek examined variables which may affect habitat quality and can be applied using HSI curves to determine net loss (**Appendix B**). All habitats were first surveyed, and each habitat feature was identified and measured. Measured habitat components were then tabulated, and usable habitat was calculated using HSI curves available for Arctic grayling. Major habitat features from the field surveys are shown in **Table 29**.

Table 29. Major Habitat Features in Upper Casino Creek

Habitat Feature	Total (%)	Reach 2a Brynelson to TIA (%)	Reach 2b TIA to Fish Barrier (%)
Pool [1]	7.9	12.0	6.1
Glide	6.6	5.9	6.9
Run	30.9	41.7	26.2
Low Gradient Riffle	28.2	34.0	25.6
High Gradient Riffle	26.4	6.4	35.2
Fines (Total Area)	4.0	5.5	3.4
Fines in Spawning Gravels	26.4	25.2	27.8

[1] *Includes Backwater (BW) Areas*

Total length and area for the three stream reaches examined in upper Casino Creek are given in **Table 30**, below. Estimates between Brynelson Creek and the identified seasonal barrier to fish migration are based on field measurements. Information between the identified seasonal barrier and the upper extent of the TIA is an estimate taken from a composite of mapping data in order to estimate total creek length affected, and an estimate of widths along this section of creek.

Table 30. Habitat Unit Areas for Upper Casino Creek

Stream Reach	Length (m)	Unadjusted Area (m^2)
Reach 2a - Brynelson Creek to TIA	1,601	5,979
Reach 2b - TIA to Fish Migration Seasonal Barrier	3,641	13,520
Reach 3 – Seasonal Barrier to Upper Extent of TIA	4,779	19,707
Meloy Creek	5,229	4,222
Total	**8,842**	**25,619**

After reviewing habitat data collected during the course of this study, as well as examining water quality data (maximum observed temperature and dissolved oxygen) collected during past sampling, it was determined that five variables would be used from the HSI model (**Table 31**). Scores based on suitability of measured values were calculated for each variable to determine habitat quality. The lowest score is applied to further calculations based on the assumption that the most limiting factor will have the most effect on fish habitat. Though overwinter habitat had the lowest score, a zero, applying this would result in no net habitat loss. This of course would not be appropriate because of known fish usage in summer in these reaches. The next lowest score in each reach was percentage of pools and backwaters, 12% in the reach between Brynelson Creek and the lower extent of the TIA, and 6% in the area from the TIA dam to the observed seasonal barrier to fish passage, and 8% in the area above the seasonal barrier.

Table 31. Summary of HSI variables for Upper Casino Creek

HSI Variable	Reach 2a - Brynelson to TIA		Reach 2b - TIA to Seasonal Fish Barrier		Reach 3 – Seasonal Barrier to Top of Watershed	
	Value %	Score	Value %	Score	Value %	Score
% Spawning Substrate	70	1.0	58	1.0	0	0
% Fines Spawning Areas	25	0.6	27	0.56	0	0
% Fines Total Area	5.5	1.0	3.4	1.0	7.7	1.0
% Pools and Backwaters	12	0.41	6	0.18	8	0.29
Overwinter Habitat[1]	0	0	0	0	0	0

[1] *Pools greater than 1.2 m in depth*

The HSI scores of 0.41, 0.18, and 0.29 were then applied to the unadjusted total area of each reach to determine net habitat loss (**Table 32**). The result is a net reduction of usable habitat of 2,451 m^2 in Reach 2a (the section of stream between Brynelson Creek and the proposed TIA), and 2,433 m^2 in Reach 2b

(between the TIA and the identified barrier to fish migration). Although a seasonal fish barrier was identified on Upper Casino Creek, a habitat evaluation was completed and net habitat loss calculated, based on percent pool rearing habitat as the limiting factor, based on the time of year that grayling can access this reach (summer and high flows).

A HEP study was conducted on Meloy Creek, a tributary of Casino Creek, as the proposed TIA will include the lower section of Meloy Creek. As the Meloy Creek valley consists of dense willow shrubs up to 2.5m in height, a sub-sampling technique was used to measure habitat for the HEP study. The lower 400m of the creek was measured, as this is the area most likely to be utilized by fish due to its proximity with Casino Creek. All habitats which could be accessed were measured for the HEP, with areas which were inaccessible due to dense vegetation inferred between measured sections of creek. During analysis, measured habitat was multiplied over the remaining length of creek which was not accessed during the time of the survey.

The bed of Meloy Creek consisted almost entirely of sand (*i.e*., fines) along its length (95.6% of total length) and contains almost no pool habitat. Therefore, a HSI score for adult Arctic grayling of 0.0 is appropriate for this creek. This HSI score was applied to the total area of Meloy Creek (calculated to be 4,222 m^2) to arrive at a calculated net habitat loss of 0 m (Table 32).

The Britannia Creek HEP study involved walking the reach of Britannia Creek from the Yukon River, to a location approximately 1 km upstream, where historic road activity had allowed the stream to “jump” from its historic channel and establish a new channel down the roadway. The habitat in this stretch is proposed to be lost as part of the construction of fish habitat compensation works at the mine site. Although some of the area within this reach (approximately 300 m length near the confluence with the Yukon River) is known to support juvenile Chinook salmon, the similarity in habitat usage between juvenile Chinook salmon and Arctic grayling allow the application of the HSI curves for Arctic grayling to be used in the HEP analysis.

The estimate of the net loss in habitat in this reach was based on the most limiting factor, in this case percent pool habitat. Using this limited habitat type, a HSI score of 0.25 was applied to the total area contained in the study reach (calculated to be 9535 m^2), in order to determine a final calculated net habitat loss of 2384 m^2.

Table 32. Net Habitat Loss in Upper Casino Creek Post-Project

Stream Reach	Unadjusted Area (m^2)	HSI Score Applied	Net Habitat Loss (m^2)
Reach 2a - Brynelson Creek to TIA	5,979	0.41	2,451
Reach 2b - TIA to Seasonal Fish Migration Barrier	13,520	0.18	2,433
Reach 3 - Seasonal Barrier to Upper Extent of TIA (Non-Fish Bearing)(incld Taylor Creek)	19,707	0.29	5715
Meloy Creek	4,222	0	0
Lower Britannia Creek	9,535	0.25	2384
Total	**48,741**	-	**12,983**

The estimate of net habitat loss was based on what was perceived as the most limiting factor, percent pool habitat for rearing, though other factors should also be considered. For example spawning habitat was found to be limited, though there is no evidence spawning takes place in these reaches. Additionally, had over-winter habitat (pools greater than 1.5 m in depth) been applied to this analysis the resulting habitat loss would have been zero. But it is unlikely that Arctic grayling use these stream reaches for over-wintering and basing the analysis on summer habitat is considered appropriate given our understanding of existing conditions and Arctic grayling life cycle.

5 DISCUSSION

The process of determining mitigation measures involves taking into account numerous factors. Instream flow studies using PHABSIM and HEP analysis are only one piece of the process and need to be discussed in the context of the long-range water and fishery management objectives desired by local regulatory agencies including Fisheries and Oceans Canada, Government of Yukon, the Yukon River panel and affected First Nations as well as fish habitat experts.

The study results must be put in context with other variables that may affect fish use and distribution such as water quality, temperature, and additional limiting factors that may be present. Initial results indicate that reduction in flows in Casino Creek downstream of the proposed project may have a minimal effect on Arctic grayling habitat.

Unlike the Habitat Evaluation Procedure (HEP) analysis which allows specific quantification of habitat loss due to the proposed project, the instream flow study conducted using PHABSIM modeling does not

provide a specific set of values based on habitat because it recognizes that flow related fish habitat requirements is not static. The time series analysis demonstrates how the amount of fish habitat will vary with flow under different flow scenarios and different life stages. Because the gain or loss of habitat varies by year and flow, there is no absolute estimate of net habitat change. In order to assess change in amount of habitat based on flow we can examine habitat that occurs at various exceedance intervals. The 50% habitat exceedance value (i.e., the median amount of habitat that occurs over the time period examined) was used to estimate habitat gains or losses due to changes in stream flow under the various phases of the project. Since lower and middle Casino Creek display virtually identical results, only those for lower Casino Creek are presented here.

Results from the instream flow studies using PHABSIM analysis indicate that there will be a small net gain in habitat for Arctic grayling adult and juvenile in lower Casino Creek downstream of the proposed project TIA, as well as in Dip Creek downstream of Casino Creek. However, the amount of spawning habitat in Casino Creek would be reduced. Whether this reduction in spawning habitat would have a significant effect on production is questionable given the low level of utilization and naturally low productivity of the existing habitat. At the same time, juvenile (fry) habitat would almost double in Casino Creek under predicted project flows, though again, if little spawning occurs in the reach this may not result in a significant increase in fisheries productivity. The net change in Arctic grayling habitat is based on a conservative estimate. Results based on alternate flows indicate an even greater increase in adult and juvenile habitat could take place, but with little difference in fry or spawning habitat. To determine the overall change in habitat in lower Casino Creek, values were converted to m^2 based on the total stream length affected, which is, 6,500 m for Casino Creek, 8,500 meters for Dip Creek and 7,000 meters for Canadian Creek.

The net change in habitat from the HEP analysis is based on the percent of pool and backwater habitat in the upper portions of Casino Creek. Pools and backwaters are considered critical to early life stages of Arctic grayling (and Chinook salmon in this area). Though other factors may be considered, it is assumed that the most limiting factor will control fish production and abundance. It should also be noted that spawning habitat is rare in the upper Casino Creek watershed and fish surveys have found no indication that spawning occurs there. The results presented here for habitat loss are therefore conservative, and habitat loss in these areas are unlikely to have significant impacts on the productivity of Arctic grayling, or the existing fish community as a whole.

6 CONCLUSIONS

Between June 2010 and July of 2013, in-stream flow studies using PHABSIM and HEP modeling analysis were conducted in order to examine potential impacts of the proposed Casino copper-gold project on fish habitat in Casino and Dip Creeks. These studies included: PHABSIM studies and modeling on lower Casino Creek and Dip Creek downstream of the confluence with Casino Creek in order to determine the impact of reduced flows due to the creation of a tailings management facility on Casino Creek, and a HEP study on upper Casino Creek in order to determine the loss of usable fish habitat due to the construction of the tailings management facility. Results of these studies were:

6.1 Lower Casino Creek

The reduction in flow in Casino Creek during construction and operation phases of the project results in a median increase in habitat for adult and juvenile grayling of between 16% and 22% for lower Casino Creek, and 10% to 15% for middle Casino Creek. This outcome is due to the tendency for these life stages to prefer lower velocities, as indicated by the Habitat Suitability Curves (HSC) (Hubert et al., 1985), and that at lower flows there is an increase in available low velocity refuge areas. Changes in habitat during the closure and post-closure phases are generally less than 10% based on the median habitat values.

Grayling fry habitat duration curves in both lower and middle Casino Creek exhibit similar results to adult and juvenile with increased habitat under project conditions. The median habitat values increase in the range of 95% for lower Casino Creek and around 125% for middle Casino Creek during construction and operation phases. Changes in habitat during the closure and post-closure phase are generally less than 7% to 15% based on the median habitat values.

Spawning is the only life stage which shows a decrease in habitat due to flow reduction during the projects construction and operation phases. The median habitat value percent change shows a decrease in lower Casino Creek (-72%) and middle Casino Creek (-83%) for the construction and operation phases of the project. This is an end result of lower availability of higher velocities generally used by grayling during spawning, the opposite condition of what is preferred during other life stages. Changes in habitat during the closure and post-closure phases are between 6% and 9% based on the median habitat values.

6.2 Dip Creek

Habitat for adult and juvenile grayling show a slight increase during construction and operation phases of the project. Fry and spawning life stages show virtually no difference in habitat during all project phases. The percentage change at the median habitat index value is between 7 and 8 per cent for juveniles and adults and a decrease of 2 to 3 per cent for fry and spawning life stages during construction and operation phases of the project. Habitat index values for closure phases differ little from baseline.

6.3 Upper Casino Creek

HEP analysis was used to estimate the changes in habitat for Arctic grayling in Upper Casino Creek. The estimate of net habitat loss was based the most limiting habitat factor of pool habitat for rearing. The result is a net reduction of usable habitat of 2,451 m^2 in Reach 2a (the section of stream between Brynelson Creek and the proposed TIA), and 2,433 m^2 in Reach 2b (between the TIA and the identified barrier to fish migration) (**Table 32**). A loss of potentially usable habitat of 5,715m^2 is anticipated from the upper reaches of Casino Creek, upstream of a seasonal fish barrier. This is a conservative estimate as it is unlikely that this area provides year-round or critical habitat for Arctic grayling. The TIA will also impact upon the lower reaches of Meloy Creek, although this creek was found not to provide useable habitat for Arctic grayling,

6.4 Lower Britannia Creek

HEP was used to evaluate the changes in habitat for both juvenile Chinook salmon and Arctic grayling. There will be some loss of habitat if offsetting plans proceed in this area. The historic channel would be reinstated and the flow from the existing channel would be diverted. The estimate of the net loss in habitat in this reach was based on the most limiting factor, the percent pool habitat. The final net habitat loss was calculated as 2,384m^2, which would be offset by proposed restoration works in this area.

6.5 Canadian Creek

There was no detectable change in habitat occurs for grayling adult and juvenile life stages under all project phases in Canadian Creek. A small increase in habitat for fry and a slight decrease in spawning habitat would occur during project closure phases. This equates to an increase in fry habitat by 28% and a decrease in spawning habitat of 11%.

Lower Casino Creek and Dip Creek PHABSIM Calibration Data

Casino Creek - Final Calibration Summary
CAS2 and CAS1 Study Sites Combined

CROSS-SECTION # 1 CAS2 RUN119
Points = 27
Slope = .0025
SZF = 98.2

Cross-section represents 6.050% of Total Reach.

>>> WSL Calibrations <<<
WSL Calculation Method: Channel Conveyance
Channel Conveyance Equation: Manning N
Use Weighted Area Hydraulic Radius: Yes
Reduce Hydraulic Radius to HR at S.Z.F.: Yes
BETA = .3692
>>> Velocity Calibrations <<<
Vel Calculation Method: 1-vel calibration
Vel Algorithm: Manning's N
Use Given N's: Yes
Vels calibrated to VelSet: 1

CROSS-SECTION # 2 CAS2 RUN121
Points = 26
Slope = .0025
SZF = 98.4

Cross-section represents 6.050% of Total Reach.

>>> WSL Calibrations <<<
WSL Calculation Method: Channel Conveyance
Channel Conveyance Equation: Manning N
Use Weighted Area Hydraulic Radius: Yes
Reduce Hydraulic Radius to HR at S.Z.F.: Yes
BETA = .415
>>> Velocity Calibrations <<<
Vel Calculation Method: 1-vel calibration
Vel Algorithm: Manning's N
Use Given N's: Yes
Vels calibrated to VelSet: 1

CROSS-SECTION # 3 CAS2 LGR347
Points = 34
Slope = .0025
SZF = 98.43

Cross-section represents 4.710% of Total Reach.

>>> WSL Calibrations <<<
WSL Calculation Method: Channel Conveyance
Channel Conveyance Equation: Manning N
Use Weighted Area Hydraulic Radius: Yes
Reduce Hydraulic Radius to HR at S.Z.F.: Yes
BETA = .09
>>> Velocity Calibrations <<<
Vel Calculation Method: 1-vel calibration
Vel Algorithm: Manning's N
Use Given N's: Yes
Vels calibrated to VelSet: 1

CROSS-SECTION # 4 CAS2 POOL346
Points = 26
Slope = .0025
SZF = 98.6

Cross-section represents 5.540% of Total Reach.

>>> WSL Calibrations <<<
WSL Calculation Method: Channel Conveyance
Channel Conveyance Equation: Manning N
Use Weighted Area Hydraulic Radius: Yes
Reduce Hydraulic Radius to HR at S.Z.F.: Yes
BETA = .34
>>> Velocity Calibrations <<<
Vel Calculation Method: 1-vel calibration
Vel Algorithm: Manning's N
Use Given N's: Yes
Vels calibrated to VelSet: 1

CROSS-SECTION # 5 CAS2 LGR345
Points = 29
Slope = .0025
SZF = 98.06

Cross-section represents 4.710% of Total Reach.

>>> WSL Calibrations <<<
WSL Calculation Method: Channel Conveyance
Channel Conveyance Equation: Manning N
Use Weighted Area Hydraulic Radius: Yes
Reduce Hydraulic Radius to HR at S.Z.F.: Yes
BETA = .4717668
>>> Velocity Calibrations <<<
Vel Calculation Method: 1-vel calibration
Vel Algorithm: Manning's N
Use Given N's: Yes
Vels calibrated to VelSet: 1

CROSS-SECTION # 6 CAS2 GLD344
Points = 30
Slope = .0025
SZF = 98.15

Cross-section represents 3.120% of Total Reach.

>>> WSL Calibrations <<<
WSL Calculation Method: Channel Conveyance
Channel Conveyance Equation: Manning N
Use Weighted Area Hydraulic Radius: Yes
Reduce Hydraulic Radius to HR at S.Z.F.: Yes
BETA = .4844
>>> Velocity Calibrations <<<
Vel Calculation Method: 1-vel calibration
Vel Algorithm: Manning's N
Use Given N's: Yes
Vels calibrated to VelSet: 1

CROSS-SECTION # 7 CAS2 LGR343
Points = 37
Slope = .0025
SZF = 98.68

Cross-section represents 4.710% of Total Reach.

>>> WSL Calibrations <<<
WSL Calculation Method: Log/Log Regression
Log/Log Regression A = .4623462
Log/Log Regression B = .192027
WSL = 0.4623 * Flow ^ 0.1920 + 98.68

1.2	January 2015	Incorporated reviewer input from the YESAB adequacy review of the Project Proposal.	EDI: M.Setterington

1 - INTRODUCTION

Casino Mining Corporation (CMC) is proposing to develop the Casino Project (the Project), a copper-molybdenum-gold mine at their Casino Mine property located at latitude 62°44' N and longitude 138°50' W, approximately 300 km northwest of Whitehorse, Yukon. The proposed Project will have a mine life of 34 years comprised of four phases: construction (4 years), operation (22 years), closure and decommissioning (3 years), and post closure (5 years). The Project includes the following primary components:

- Mine site — including open pit; stockpiles for low grade ore, gold ore, topsoil and overburden; a plant site; heap leach facility;
- Tailings management facility;
- Extension and upgrade of the Freegold Road (previously referred to as the Casino Trail). The Freegold Road will be upgraded and extended to connect the Casino mine site to Carmacks, Yukon area. The existing 70 km of the Freegold Road will require upgrading and route adjustments to meet design standards. The final road will be approximately 200 km long and maintained as an all-season gravel road suitable for ore and fuel transport;
- Construction and operation of a new airstrip; and
- Access road and water pipeline to the Yukon River.

Project components and activities will interact with and potentially affect wildlife by:

- Removing available habitat by land clearing and reducing adjacent habitat effectiveness because of sensory disturbances;
- Creating filters (semi-permeable barrier) or barriers to wildlife movement because of sensory disturbance or physical barriers created by mine infrastructure;
- Increasing mortality risk due to vehicle collisions, or increased harvest, or death as a result of defence of life or property; and
- Reducing quality of health of individual animals that may be attracted to the tailings management facility during operations or at closure.

The purpose of the Wildlife Mitigation and Monitoring Plan (WMMP) is to minimize effects to wildlife and wildlife habitat, monitor the results of mitigation to ensure effectiveness, and adaptively manage for any unanticipated effects given the final Project footprint and description as provided to the Yukon Environmental and Socio-economic Assessment Board (YESAB). The plan is intended to ensure that wildlife continue to use habitat in areas adjacent to the Project footprint and within the broader area, as well as reduce potential Project-related injury or mortality, while accounting for operational requirements and human health and safety requirements. The WMMP provides guidance to protect and limit disturbances to wildlife and wildlife habitat from Project activities.

Mitigation of Project effects on wildlife and avoidance of key habitat features were considered in the Project design and in preparation of the Project description and effects assessment. Wildlife management, monitoring, and/or protection plans from similar mining projects in the Yukon (e.g. Eagle Gold Project, Wolverine Mine, Minto Mine, Bellekeno Mine) were reviewed to provide details on mitigations and monitoring that has been implemented in the Yukon and to determine the effectiveness of those actions. This document does not provide detailed methods (i.e., study designs), cost estimates, or schedules. It is anticipated that further details will be developed in continued discussion with the management agencies, Renewable Resource Councils (RRCs), working groups established to monitor Project effects, and other interested parties.

1.1 REGULATORY AND MANAGEMENT CONTEXT

The following legislation and regulations may be relevant to the management and conservation of wildlife in the Project area, and in some circumstances may supersede the commitments made in this plan.

1.1.1 Federal Government

Yukon Act (2002)

The Yukon Act (2003) gives authority to the Yukon Legislature to make laws in relation to the conservation of wildlife and its habitat within Yukon Territory, other than in a federal conservation area. This Act prohibits the Yukon government from making laws that limit subsistence hunting by aboriginal people on lands where Final Agreements are not in effect. Where Final Agreements are in effect, such as the Project area, the Yukon government has the legislative authority to regulate all hunting, and must conform to the provisions of First Nation Final Agreements when addressing subsistence harvesting.

Yukon Environment and Socio-economic Assessment Act (YESAA)

YESAA gives authority and rules to the Yukon Environment and Socio-economic Assessment Board to administer the assessment process that applies to all lands within Yukon. It was called for in Chapter 12 of the Yukon First Nations Final Agreements and came into effect in 2003.

Migratory Birds Convention Act (1994) (MBCA)

MBCA and its regulations provide protection for migratory birds, their eggs, their nests, and their habitats, and regulate the hunting of migratory game birds. The MBCA and its regulations prohibit the incidental take of migratory birds, their eggs, or active nests. Hunting regulations can be updated annually. Proposed regulatory amendments in the Yukon are publicly reviewed by the Yukon Fish and Wildlife Management Board and recommended to the federal Minister of Environment.

Species at Risk Act (SARA)

SARA implements in part Canada's obligations under the United Nations *Convention of Biological Diversity*. It provides for the legal protection of wildlife species and the conservation of their biological diversity. The Act prevents wildlife species in Canada from disappearing, provides for the recovery of wildlife species that are extirpated (no longer exist in the wild in Canada), endangered or threatened as a result of human activity, and manages species of special concern to prevent them from becoming endangered or threatened. Within the Act, the Committee on the Status of Endangered Wildlife in Canada (COSEWIC), an independent body of experts, is responsible for identifying and assessing wildlife species considered at risk, which may then qualify for legal protection and recovery under SARA. Once listed under SARA, species plans are legal requirements to secure the necessary actions for species recovery and management. The only species at risk in the Project area with an existing management plan is the Northern Mountain Population of caribou (which includes the Klaza caribou herd).

Canadian Wildlife Act

The Canadian Wildlife Act allows for the creation, management and protection of wildlife areas to preserve habitats, and to permit wildlife research and interpretive activities. There are no such protected areas in the LSCFN and SFN traditional territories.

Convention on Wetlands (Ramsar, Iran, 1971)

RAMSAR commits the federal government to maintain the ecological character of wetlands of international significance and to plan for the sustainable use of all wetlands. The Federal Wetlands Policy was established in 1991 in response to RAMSAR. The policy provides goals, guiding principles and strategies for conserving wetlands on federal lands and those significant to Canadians. There are no wetlands of interest in the LSCFN and SFN traditional territories.

1.1.2 Yukon Government

Environment Act

The Yukon's Environment Act and regulations provide for the protection of land, water, and air. It applies on lands throughout the Yukon, including private property, Crown lands, lands within municipal boundaries, and First Nation settlement lands where the First Nation has not developed equivalent laws. This Act is primarily used for regulations related to air quality, waste, recycling, spills and contaminated sites, and not wildlife. However, the act provides for natural resource planning and management, including wildlife, and conservation easements for conserving and enhancing wildlife habitats. There are currently no regulations for the protection of wildlife and habitats under this act.

Yukon Wildlife Act (2002)

The Wildlife Act (2002) defines "wildlife" as any vertebrate animal of any species or type that is wild by nature, and includes wildlife in captivity, but does not include fish. This Act provides rules for hunting and trapping, outfitting and guiding, licensing, enforcement, and habitat protection. It also gives authority to make various regulations. Regulations include prescribing specially protected wildlife and measures to protect, prescribing areas to be wildlife sanctuaries and measures for management, methods of hunting and trapping wildlife, licensing and permitting conditions, zoning the Yukon to administer the Act, and the submission of harvest information. The Act is typically emended every 10–20 years while regulations can to updated annually. The four Habitat Protection Areas in the LSCFN and SFN traditional territories are administered under this Act.

1.1.3 Little Salmon/Carmacks First Nation (LSCFN) and Selkirk First Nation (SFN) Governments

LSCFN and SFN were established in 1997 through Settlement Legislation in Canada and the Yukon that gives effect to their final agreements. LSCFN and SFN are responsible for their settlement lands and resource management on these lands. Under their Self-Government Agreements, LSCFN and SFN have the legislative powers to manage, administer and control the rights or benefits of persons enrolled under their final agreements. SFN has established a Constitution for the purpose of protection of its settlement lands and resources, and governing the rights of its citizens on these lands. LSCFN has not established legislation for the management and administration of settlement lands and wildlife.

1.1.4 Carmacks (CRRC) and Selkirk (SRRC) Renewable Resources Councils

The Councils were established in 1997 pursuant to Section 16.6.0 of Little Salmon/Carmacks and Selkirk First Nations Final Agreements as instruments of public government for local renewable resource management in their respective traditional territories. The Councils can make recommendations to the affected Minister, the affected First Nation, the Yukon Fish and Wildlife Management Board, and the Salmon Sub-Committee on any matters related to the conservation of fish and wildlife, and on forest resource management on settlement and non-settlement lands. Governments (Yukon and First Nations) are required to make available to the Councils

information in their possession reasonably required by the Councils to carry out their functions. The Councils may establish bylaws under the Wildlife Act (2002) for the management of furbearers, although they have not yet done so. The Councils do not have powers in areas where traditional territories overlap until such time as the resolution of overlapping claims is resolved according to Schedule B of Chapter 2 of First Nation Final Agreements.

1.1.5 Management Plans

Community-Based Fish and Wildlife Work Plan for the Little Salmon/Carmacks First Nation Traditional Territory 2012–2017 (Little Salmon/Carmacks Fish and Wildlife Planning Team 2011)

This work plan addresses issues related to fish and wildlife populations, habitat, harvest and information gaps in the Little Salmon/Carmacks Traditional Territory. LSCFN, CRRC and the Yukon government developed this plan. Its purpose is to coordinate the efforts of the parties to address local concerns about fish and wildlife in the LSCFN traditional territory for the period 2012–2017. This plan provides management actions for a number of wildlife populations, including the Klaza caribou herd. Access and enforcement themes are integrated through each section of the plan.

Selkirk First Nation May Gatherings

Each year in May, the SFN and Yukon government meet to review their cooperative management actions for fish and wildlife, discuss new and pressing issues, and update their management actions for the coming year. This activity serves the purpose of a fish and wildlife work plan with annual updates.

Management Plan for the Northern Mountain Population of Woodland Caribou (Rangifer tarandus caribou) in Canada (Environment Canada 2012)

The Northern Mountain population (NMP) of woodland caribou was assessed by COSEWIC in 2002 and listed under SARA as a species of “special concern” in 2005. The purpose of this plan is to summarize the threats facing Northern Mountain caribou, set out management goals and objectives, and recommend a series of recovery measures for consideration by the responsible authorities for the management of the population’s 36 herds. The goal of the plan is to prevent the NMP from becoming threatened or endangered by engaging responsible agencies to carefully manage the NMP and their habitat. The plan is focused on achieving the following goals that are re-evaluated on a 5-year basis:

- NMP herds are maintained or recovered, and populations operate within the natural range of variability;
- The ecological integrity of key habitats and ecosystems required by the NMP are maintained; and
- First Nations, local communities, government agencies and other interested parties are meaningfully involved in the stewardship of the NMP and its habitats.

The objectives and recommended recovery measures are based on a set of principles developed by the Northern Mountain Caribou Steering Committee and Technical Working Group. Recommended management objectives for the NMP are:

- Objective 1: Determine herd status and trends over time.
- Objective 2: Manage harvest for sustainable use.
- Objective 5: Identify and assess the quality, quantity and distribution of important habitats for the population.
- Objective 6: Manage and conserve important habitats to support caribou herds.

Of particular relevance to the Casino Project’s effects assessment is management objective 7:

- Objective 7: Promote conservation of the NMP through environmental and cumulative effects assessments.

Yukon Fish and Wildlife Woodland Caribou Management Decision Guidelines (July 1996)

These interim guidelines (no update or final guidelines are known to exist) were developed by a caribou management team from the Yukon government. The guidelines were intended to provide a framework for consistent departmental input and responses to management plans and programs. Among many guidelines related to harvest, of particular relevance to the Casino Project is guideline no. 16 (habitat), stating:

- *Management experience in North America has shown that virtually any type of development activity that increases access for hunters results in a herd decline. Hunter access must be very carefully controlled, particularly where roads bisect caribou winter range*.

The WMMP should also be considered in association with the following Project-specific environmental management plans:

- **Road Use Plan** — includes details about road management, access controls, monitoring of use.
- **Waste and Hazardous Materials Management Plan** — may include details on handling kitchen waste that, if mishandled, could attract problem wildlife to the site.
- **Spill Contingency Management Plan** — provides background planning and operational procedures for spills response to minimize exposure of wildlife to deleterious substances.
- **Sediment and Erosion Control Management Plan** — provide details on what types of erosion and sedimentation control measures will be used and where and when they will be applied.
- **Invasive Species Management Plan** — summarizes the management and monitoring proposed to prevent the introduction and propagation of invasive plant species.
- **Air Quality Management Plan** — may include guidelines related to reducing noise, dust, and emission levels that would ultimately reduce the Project's zone of influence (ZOI) on adjacent habitat use by wildlife.
- **Air Quality and Fugitive Dust Deposition Monitoring Program** in the Environmental Monitoring, Surveillance and Reporting Plan provides a link to fugitive dust and potential effects on wildlife forage.
- **Progressive Reclamation Effectiveness Monitoring Program** in the Environmental Monitoring, Surveillance and Reporting Plan provides a link to Project footprint and wildlife habitat reclamation.
- **Water Quality Monitoring** in the Environmental Monitoring, Surveillance and Reporting Plan, summarizing water quality monitoring of potential contact waters for waterfowl.

2 - WMMP REPORTING

Once the Casino Project is permitted and all necessary licences are acquired, CMC will report annually on Project mitigation and monitoring activities, which will generally include the following key pieces of information:

- A summary of Project activities;
- Description of updates to relevant wildlife and bird baseline information — either collected by CMC or other inventories/research known to CMC;
- A review of annual monitoring results relative to levels of natural variability in the region (as described in the baseline report and new knowledge gained through successive annual reporting);
- A presentation of the analyses of wildlife distribution and abundance in relation to Project facilities;
- A description of stakeholder involvement (e.g., Governments, RRCs);
- Summary of key monitoring initiatives, as deemed necessary; and
- A discussion of proposed changes to mitigation and monitoring plans as necessary.

CMC will review the results of annual monitoring every three to five years and include in a detailed report the following information:

- An examination of trends in variability of wildlife distribution and abundance relative to natural trends;
- An analysis of measured wildlife responses to Project-related disturbances, including habitat use and measures of barriers/filters to wildlife movement;
- A description of how Project effects monitoring contributes to cumulative effects monitoring in the region;
- Detailed analyses of other variables as identified in individual monitoring programs as the Project evolves; and
- Description of changes to monitoring programs, statistical procedures, and proposed changes to mitigation activities to adaptively manage for unforeseen effects.

2.1 ADAPTIVE MANAGEMENT AND PLAN UPDATES

The WMMP will be updated periodically to include management reviews, incident investigations, regulatory changes, or other Project-related changes. The WMMP will also be updated as new methods or technologies become available. Mitigation and monitoring strategies for Species at Risk will be updated to maintain consistency with status reports, recovery strategies, action plans, or management plans that may become available during the life of the Project. The wildlife mitigation and monitoring measures will likely evolve during the life of the Project as a result of new resource discoveries, a better understanding of local wildlife behaviours, improved scientific techniques, stakeholder values, and to adapt to natural variability in wildlife distribution and abundance.

To address environmental and Project changes through time, an adaptive management approach is adopted for this mitigation and monitoring plan. It is anticipated that the plan will evolve and be adjusted to incorporate practical and workable solutions to minimize Project effects on wildlife and support regional wildlife research and management initiatives. The changes may be a result of inadequacies in the sampling methods or from increased awareness of environmental personnel, regulators, First Nations, or other public concerns. An adaptive approach means that increasing monitoring or changes to the monitoring program can occur if unanticipated adverse effects are detected, to further understand effects, or to change mitigation practices. Concomitantly, if no effects are detected over a reasonable time period, some mitigation and monitoring tasks may be removed from the program so that the resources may be applied elsewhere. To facilitate adaptive management and react to changing environmental and Project conditions, a process needs to be established to ensure regular review of the WMMP that includes regular and transparent reporting (Figure 2.1-1).

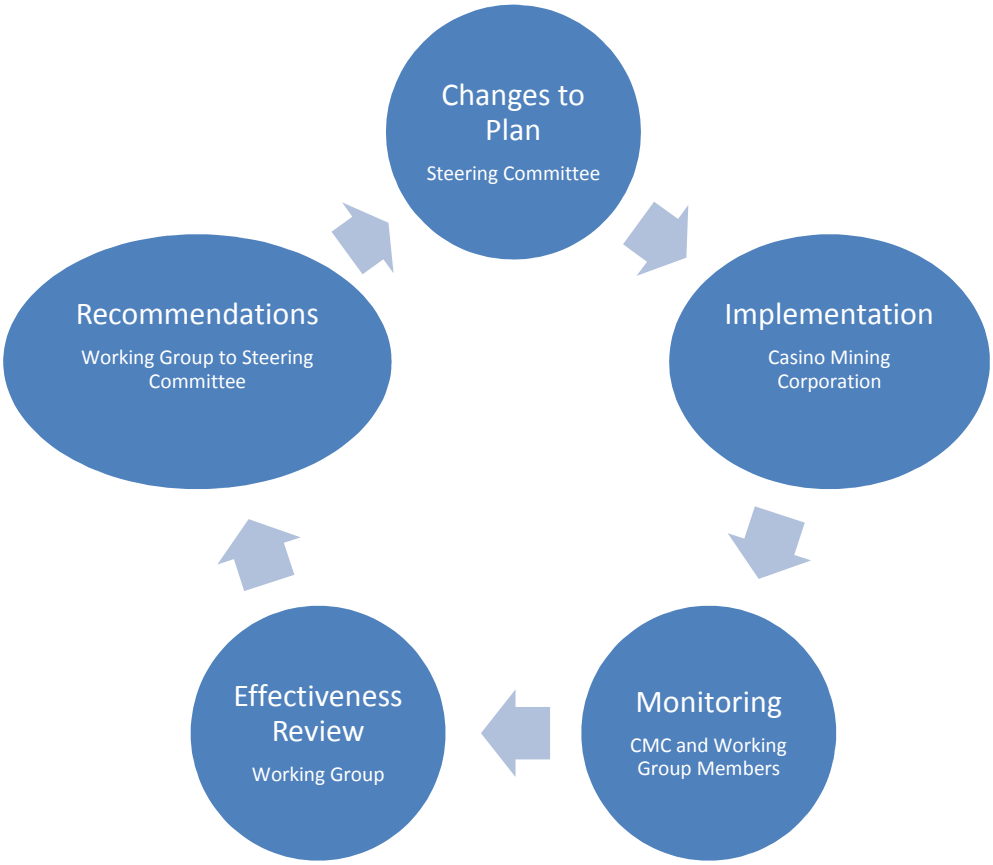

Figure 2.1-1 Schematic of the Adaptive Wildlife Mitigation and Monitoring Process

3 - CASINO MINING CORPORATION'S COMMITMENTS

CMC is committed to working with governments and stakeholders to ensure that wildlife populations remain healthy and can successfully coexist with the Project through construction, operation and closure phases of the mine. The WMMP is the primary management tool to achieve this. CMC will provide the necessary human, material, and financial resources to implement and maintain the WMMP. CMC has the capacity and authority to implement mitigation and monitoring actions and plans; however, CMC will not make decisions regarding wildlife management (e.g. harvest levels). Nonetheless, CMC is committed to actively supporting regional wildlife management initiatives.

3.1 WILDLIFE WORKING GROUP

CMC will establish a Wildlife Working Group (the working group) — the role of which is to act as an advisory body to support ongoing cooperation and communication, as well as to review and provide advice on all aspects of the WMMP, including:

- Develop and finalize the WMMP Program;
- Implement the WMMP Program;
- Monitor reports and results;
- Assess Project effects and effects predictions for wildlife;
- Assess effectiveness of mitigation measures; and
- Develop action plans for implementation of appropriate mitigation measures.

The working group may make recommendations to CMC and government agencies with wildlife management responsibilities on any aspects of the WMMP program or for the adoption of mitigation measures which are technically and economically feasible. It is expected that the working group would consist of a number of members including members from affected First Nations (particularly Selkirk First Nation and Little Salmon/Carmacks First Nation), CMC, Yukon Government, and Environment Canada. Other members can be considered as appropriate or necessary. The role of the working group is not intended to either duplicate or affect the regulating authorities or stakeholder responsibilities for wildlife management of participating members.

To keep the working group on task and focused on their roles and responsibilities, a draft Terms of Reference (TOR) can be developed that could address the following points:

- Purpose, objectives and duties
    - Partially identified in this WMMP
- Establishment
    - Working group time frame and meeting frequency
    - Working group membership and reporting structure
        - Assuming the key parties such as the LSCFN, SFN and Yukon governments, CRRC, SRRC, and possibly the federal government.
    - Working group chair and chair duties
- Communications, proceedings and recommendations
    - Identify obligations of the parties to provide information to the working group

- External communications protocol
- Working group recommendations — what is done with them (CMC will be obligated to respond to recommendations related directly to possible mine effects)

- Decision-making process
- Funding and expenses

3.2 WILDLIFE SPECIALISTS

The monitoring program established by CMC requires the input of specialists to carry out many of the wildlife surveys and studies required to monitor Project effects. Throughout the life of the Project, CMC will endeavor to hire qualified personnel to conduct these studies. As much as possible, CMC will insist on inclusion/participation of local experts/individuals in the execution of these surveys and studies.

3.3 INCORPORATION OF TRADITIONAL KNOWLEDGE

The monitoring program established by CMC requires the input and knowledge of First Nation hunters, trappers, and land users to design, conduct and review results of some of the surveys and studies required for monitoring. Throughout the life of the Project, CMC will endeavor to consult with knowledgeable individuals to conduct these studies. As much as possible, CMC will include participation of local experts/individuals in the conduct of the surveys and studies.

4 - MITIGATION FRAMEWORK

CMC recognizes that there will be disturbances and effects on wildlife and wildlife habitat as a result of the construction, operation, and closure of the Project. To reduce or eliminate potential Project effects on wildlife and wildlife habitat, CMC commits to a number of mitigation actions, some of which are general and apply to all Project phases, some that are specific to Project phases, some that are temporal and apply only at certain times of year or in certain years when wildlife are present, and some that are specific to identified sensitive habitat features. Sensitive habitat features are mineral licks, active den sites, wetlands, bat roosts, and re-used nest sites (e.g., cliff nests, stick nests or swallow colonies). CMC expects that some of the mitigation actions will be modified through the life of the Project as more information becomes available about the effectiveness of the mitigation and wildlife and habitat/vegetation response to Project-related disturbances. To inform CMC, Project regulators, and stakeholders about mitigation effectiveness and Project effects, the mitigation framework is supported by a Project effects monitoring framework described in Section 5.

Mitigation actions that are more general in nature and are applicable to the Project design phase or during all Project phases, throughout the year, are described in Section 4.1 (Project Design and General Mitigation). Mitigation actions that are most relevant to reducing the effects of construction activities (Section 4.2), operations (Section 4.3), and closure and post-closure (Section 4.4) are described in the appropriate sections. Species-specific mitigation is mentioned separately where warranted.

4.1 PROJECT DESIGN AND GENERAL MITIGATION

The construction footprint of the Project will have residual effects on wildlife and wildlife habitat because there will be long-term habitat removal, and sensory stimuli during the construction, operation, and closure and decommissioning phases will disturb wildlife. There are several elements that were considered in the Project design that will help to mitigate some of those effects, which are described below.

4.1.1 Minimize Project Footprint and Sensory Disturbance

To minimize loss of habitat, the Project footprint (~23.5 km²) is designed to be as small as possible. Examples of considerations made to minimize the Project footprint are further described in the Project description (YESAB Project Proposal, Section 4).

- To minimize disturbance to wildlife and wildlife habitat where Project design allows, Project infrastructure will be constructed outside of identified sensitive habitat features, and areas with sensitive habitat or vegetation (e.g., rare plant locations).
    - The number of gravel pits/borrow pits in Klaza caribou winter habitat will be minimized to the extent possible.
    - Visual and auditory construction disturbances near animals will be minimized to the extent possible.
    - Mineral licks will be avoided (two mineral licks were identified during baseline studies that are outside of the PDA).
    - Disturbance near active or re-used den sites will be minimized to the extent possible during the denning period (October to May).

- CMC recognizes that a section of the Freegold Road extension will be in late-winter habitat for the Klaza Caribou Herd. Further species-specific mitigation measures will be incorporated to accommodate the potential disturbances associated with the road footprint and sensory disturbances.

4.1.2 Minimize Barriers and/or Filters to Wildlife Movement

CMC will commit to the following measures to minimize barriers and/or filters to wildlife movement:

- Design and build roads with a low profile embankment that will reduce the potential for the road to filter, or act as a barrier, to wildlife movement.
- Construct the water pipeline so that it does not impede wildlife movement.
    - Design considerations for the pipeline could include the following components:
        - Raised sections of the pipeline will allow for wildlife movement under the pipeline. Using moose as a precedent, pipeline clearance (i.e., distance from ground to bottom of pipeline will be a minimum of 180 cm every 400 to 700 m (depending on terrain; Dunne and Quinn 2009) for minimum section lengths of 10 m (i.e., 10 m long section of the pipeline will be raised).
        - Pipeline crossing structures (made of vegetated fill or soil) may be constructed in high density crossing/movement areas or areas where the pipeline cannot be raised or buried completely.
    - Further baseline studies to determine high probability wildlife crossing areas (e.g., trail surveys, snow track surveys, camera surveys) along the proposed pipeline route prior to construction.
- Equipment laydown will not be placed in an area of known wildlife movement or areas of wildlife concentration (e.g., mineral licks).
    - No-clearing buffer zones will be established around riparian areas to minimize disturbance to movement corridors (see Sediment and Erosion Control Management Plan).
- Access roads will be designed to avoid blind spots and reduce potential for wildlife collisions.
    - Speed limits will be posted and enforced on all facility roads and on the CMC managed portion of the Freegold Road.
    - Signage will be posted in high collision risk areas (e.g., blind or obstructed turns or hills, water crossings).
