Response to Question 4: ADS N12

The cell classification for ADS N12 BXS HDPE perforated, corrugated pipe provided does not meet all criteria of the Technical Specifications. Pelly should provide pipe manufacture information that shows a minimum compliance with all cell classification or an explanation from the pipe manufacture how a comparable test method shows compliance with the cell classifications.

Pelly should provide BGC specifications sheets showing that the perforations in the pipe meet the required standards referenced in the Technical Specifications.

Via an email sent by Dan Russel (Pelly) on June 21, 2018 Pelly has also asked for approval to remove wire ties from the ADS N12 installation. BGC recommends that the wire ties not be removed due to risk of pipe separation.

Pelly Construction Ltd.

Field Changes

- The backfill material above the HLF Embankment Underdrain header pipes has changed to Material 2 from Nuway. Pelly will construct in 30cm lifts and compacted by a CAT68B vibratory compactor. BGC has approved the backfill material, the size of the vibratory compactor, and the method of compaction.

Moisture will need to be added before placement to meet optimal moisture.

Information Request/Description of Issue:

1. Pelly is requesting from the EPCM, the approved plan for the artesian well drain system. The conceptual solution as understood by Pelly via email exchange with Clint and others in about June 22 was to order materials to satisfy two setups: 2 of HDPE 6" Y's connections, 2 of 24"HDPE:24"ADS_N12 butt fused adapters (vendor fabricated), 2 of 6" ADS end caps, and 72m of ADS N12 perforated pipe. These materials were procured on June 25th, awaiting delivery.
2. Pelly is requesting from the EPCM, the approved test fill plan (rock fill and structural fill) that outlines the material testing requirements and frequencies (ie. Tests per volume and/or lifts placed). This is needed by Pelly in its response to BGC RFI#8 in order to understand construction scheduling constraints associated with the embankment construction.

Information Request/Description of Issue:
Pelly is requesting details and requirements for the extension of the PLS header pipes from the PLS sump through the impoundment area. The header pipes will require to transition from horizontal to a 3:1 slope leaving the in heap sump as well as transition from the 24m spacing leaving the sump to the minimum 5m spacing through the impoundment. The rough liner shaping surface of the in heap area was supplied by JDS and creates significant grade changes between the top of the in heap sump and the 940 bench elevation.
Concerns:
-custom fittings required to match slope changes and allow for bending of PLS header pipes
-requirement for piping to lie directly on liner surface or allow for ODF material to be placed below the pipes
-corrugated collector piping will branch off of header pipes on transitioning slopes and angles

XD-06-02-Detail 47 and 49	

Information Request/Description of Issue:

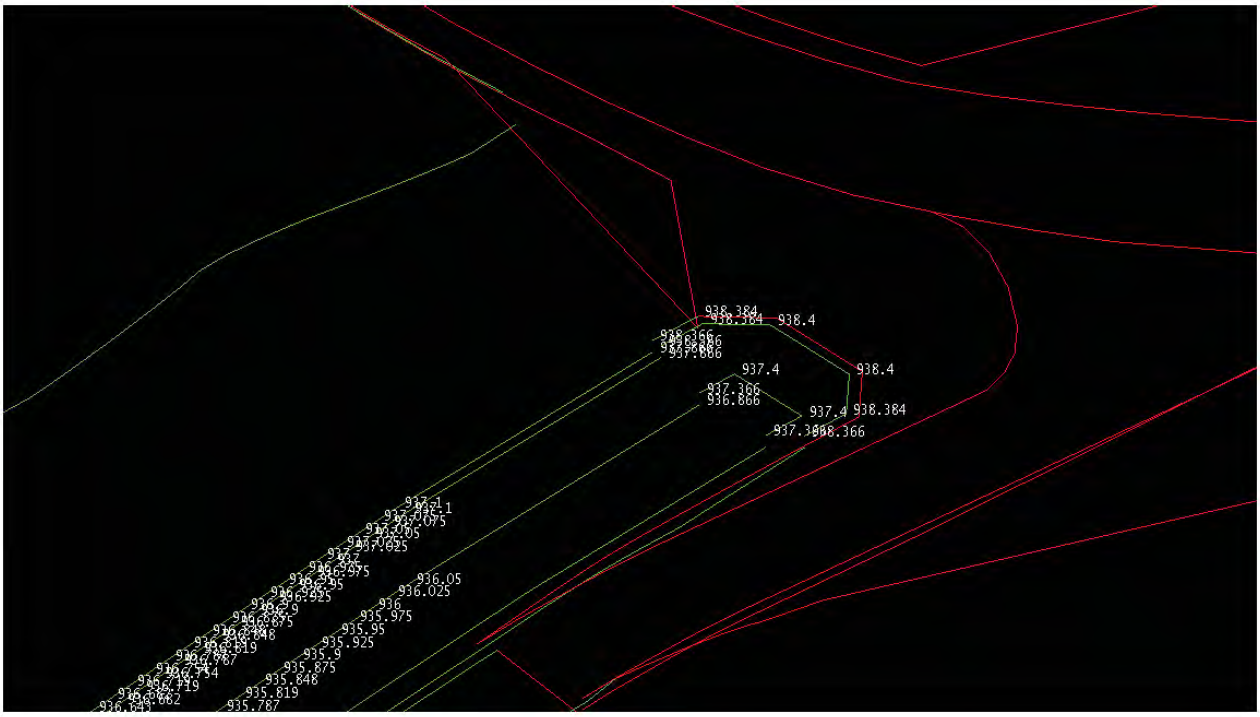
1) Regarding detail #47 (EGHLF-XD-06-02):
   -calls for 3m of 300mm SDR11 connected to 250mm Corrugated & Perforated PE N-12. I'd like to proceed as we did with the underdrain laterals with the ADS N-12 material fused onto the end of the HDPE pipe. This will require a slight change in the design whereby the upstream end of the 3m 12" HDPE pipe will have a 12"x10" HDPE reducer incorporated that is then fused with the ADS. Total assembly rated to 0 PSI due to the ADS end connection. For your reference I've attached the ADS-N12 manufacturer specifications.
2) Regarding detail #49 (EGHLF-XD-06-02):
   -Trying to understand the reasoning for this in the design?? Seems like a cumbersome requirement for installation, not to mention added cost.
   -for the double pipe section, are these required to be 1m minimum distance apart as noted in other detail?
   -assuming 1m clearance, I think a T connection with pair of 90's will be required versus a wye connection.
3) Use of sleepers. Constructability and fusing on top of liner, can we utilize sleepers (wood dunnage to prop pipe off of the liner) to provide clearance and for aligning pipe to perform fusing in place? Is this permissible, and what kind of precautions should we need in place to protect liner – I'm thinking in terms of point loading, ie. 16oz rub sheet on top of liner, overlain by plywood of sum area(?), overlain by dimensional blocking (8" sleeper) to support the pipe. If impractical to remove without risking damage to liner, can we leave these sleepers in place (permanently? -I anticipate this only for the 18" HDPE piping.

For (1) and (2), hoping to hear from you in next few hours so I can line up final ordering details and fabrication requirements by end of today.

Cost Impact:	
Schedule Impact:	

Requested by:

Shipeng Zheng		**Sept 21, 2018**
Name	Signature	Date



RESPONSE

☐ Approved ☐ Approved as noted ☐ Rejected as noted

Response: 1) the proposed pipe arrangement is acceptable. 2) detail #49 can be disregarded due to recent reduction in the design process flow rate. 3) BGC suggests the use of geosynthetics in place of wood, where possible. A geocomposite and geomembrane rub sheet combination should provide protection for the liner and could be left in place. Wood products shall not be left in place.

Re: BGC-RFI-015: Closure Sump Piping Design Clarification

BGC requests JDS provide acknowledgment of receipt of the following design clarification.

Figure 1 presents design Detail 37 from Drawing EGHLF-XD-05-05 for the closure sump piping plan. The 150mm solid PE closure drain pipes connecting the sump to the monitoring vault have been reduced from 3 pipes to 1 pipe due to the as-built pipe flow grade. The perforated pipework in the sump must be modified to accommodate a single outlet pipe. A configuration with elbows connectors and a single tee connector will be acceptable as shown on Figure 2.

Information Request/Description of Issue:

Pelly is requesting confirmation for the following:
1. 18" DR11 collection piping can be pulled over the HLF liner providing there is a rub sheet between the collection pipe and HLF liner.
2. The aforementioned rub sheet will consist of a 16oz non-woven geotextile over and under a layer of 2mm (80-mil) double-side textured LLDPE geomembrane.
3. There is no geomembrane on geomembrane contact permitted – meaning in the case where geomembrane rolls are wider than those of the geotextile, the geotextile will require multiple rolls in width (both over and under the geomembrane).
4. Rub sheets meeting these requirements will be permitted to be left in place.

Field Review Reports

BGC ENGINEERING INC.
AN APPLIED EARTH SCIENCES COMPANY

Project Name:	Eagle Gold Construction Support	**Project No.:**	0792021
Client:	Victoria Gold	**Date:**	April 26, 2018
Construction:	JDS Mining	**Inspection Number:**	FND09
BGC Personnel:	Tony Monasterio	**Approved:**	Y / N

Summary and Observations

Pelly area(s) approved by this document: Section 09, Survey drawing attached.
Approval/Rejection Observations and Recommendations:

- Areas was cleared in October 2017. However, BGC was demobilized before approval could be completed. BGC has inspected this area on April 26 and has approved it.
- Section 09 will require surface cleaning as ice removal activities in April 2018 has generated mud from pulverization of the upper portion (5 to 20 cm) of type 3 foundation. The area should be resurveyed once cleaning is complete and the final limits should be amended to this report, if needed.
- Section 09 has been excavated to the top of Type 3 bedrock or deeper, as required in the Technical Specifications.

Inspection Items

☐ Culverts/ trenches	☐ Foundation Treatment needed
☐ Clearing and grubbing complete	☐ Unusable material segregated
☐ Excavation beyond design limits	X Excavation to Type 3 bedrock
☐ Backfill compacted to spec	☐ Ruts backfilled and compacted
☐ Ice identified	☐ No geosynthetics stress points visible
☐ Ice extent delineated and removed (including method)	
☐	☐

Client:	Victoria Gold	**Date:**	May 2, 2018
Construction:	JDS Mining	**Inspection Number:**	FND10
BGC Personnel:	Roy Morlan	**Approved:**	Y / N

Summary and Observations

Pelly area(s) approved by this document: Section 10, Survey drawing attached.
Approval/Rejection Observations and Recommendations:

- Ground ice was encountered through most of the area. Foundation was over excavated in some areas between 30 to 50 cm as loose material at the surface was frozen to stronger material below and all material would be dislodged in one large frozen chunk. Type 3 foundation rock left had visible ice between joints in some sections. Ground temperature was measured between -1 C to 2C in Section 10.
- Frozen areas of type 3 will be inspected again after thaw to ensure that they did not lose strength. If frozen foundation has become loose after thaw it will have to be removed.
- As with all other approved sections, Section 10 will require minor cleaning of loose material and possibly benching/lift keying prior to construction.
- Section 10 has been excavated to the top of Type 3 bedrock or deeper, as required in the Technical Specifications.

Inspection Items

☐ Culverts/ trenches	☐ Foundation Treatment needed
☐ Clearing and grubbing complete	☐ Unusable material segregated
☐ Excavation beyond design limits	X Excavation to Type 3 bedrock

Section 14 Foundation Approval Limits

BGC ENGINEERING INC.
AN APPLIED EARTH SCIENCES COMPANY

Project Name:	Eagle Gold Construction Support	**Project No.:**	0792021
Client:	Victoria Gold	**Date:**	May 15, 2018
Construction:	JDS Mining	**Inspection Number:**	FND15
BGC Personnel:	Roy Morlan	**Approved:**	Y / N

Summary and Observations

Pelly area(s) approved by this document: Section 15, Survey drawing attached.
Approval/Rejection Observations and Recommendations:

- As with all other approved sections, Section 15 will require minor cleaning of loose material and possibly benching/lift keying prior to construction.
- Slopes built in colluvium to key in the embankment toe were wet and loose and, therefore, could not be approved. Further excavation likely would not have resulted in drier, denser material because of the amount of water reporting to this area. Once water has been controlled in this areas the slopes can be re-inspected and determination of foundation treatment can be evaluated.
- Section 15 has been excavated to the top of Type 3 bedrock or deeper, as required in the Technical Specifications.

Inspection Items

Summary and Observations

Pelly area(s) approved by this document: Section 10, Survey drawing attached.
Approval/Rejection Observations and Recommendations:

- Ground ice was encountered through most of the area. Foundation was over excavated in some areas between 30 to 50 cm as loose material at the surface was frozen to stronger material below and all material would be dislodged in one large frozen chunk. Type 3 foundation rock left had visible ice between joints in some sections. Ground temperature was measured between -1 C to 2C in Section 10.
- Frozen areas of type 3 will be inspected again after thaw to ensure that they did not lose strength. If frozen foundation has become loose after thaw it will have to be removed.
- As with all other approved sections, Section 10 will require minor cleaning of loose material and possibly benching/lift keying prior to construction.
- Section 10 has been excavated to the top of Type 3 bedrock or deeper, as required in the Technical Specifications.

Inspection Items

☐ Culverts/ trenches	☐ Foundation Treatment needed
☐ Clearing and grubbing complete	☐ Unusable material segregated
☐ Excavation beyond design limits	X Excavation to Type 3 bedrock
☐ Backfill compacted to spec	☐ Ruts backfilled and compacted
☐ Ice identified	☐ No geosynthetics stress points visible
☐ Ice extent delineated and removed (including method)	
☐	☐

PHOTOGRAPHS

Photo 1: Foundation excavation spoils.

Photo 2: Example of type 3 foundation with ice between the joints. In place strength will need to be re-evaluated after ice has thawed. Area may need additional cleaning of loose material after ice has thawed.

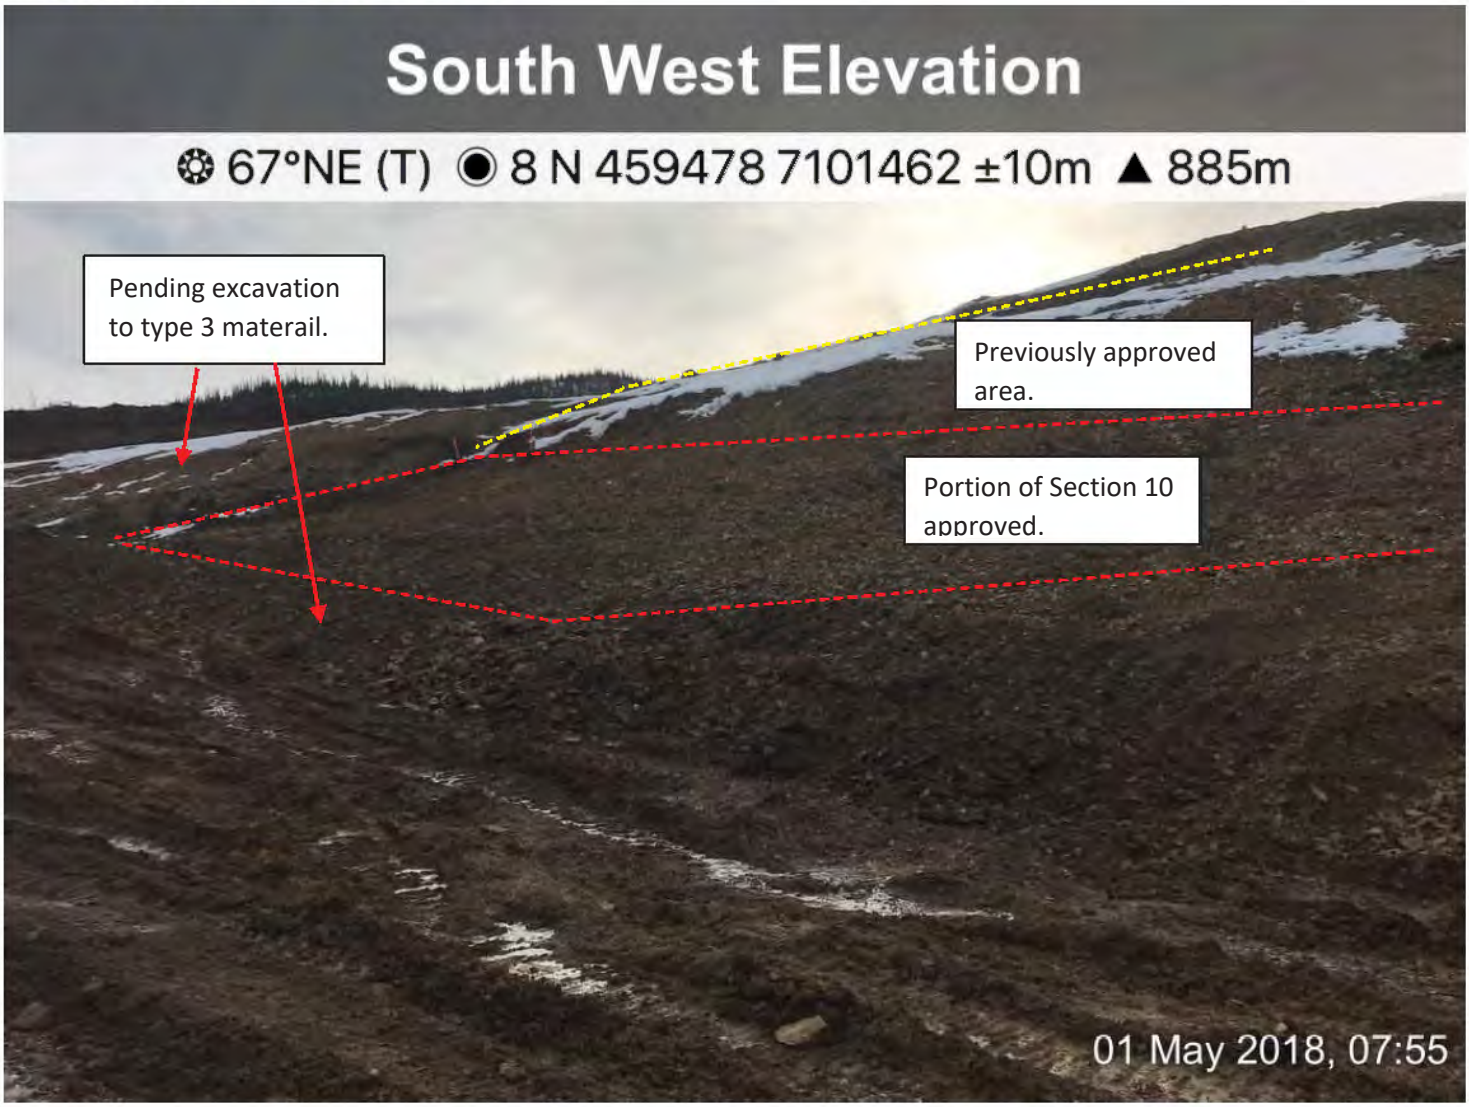

Photo 3: Portion of the area where type 3 foundation was approved in Section 10.

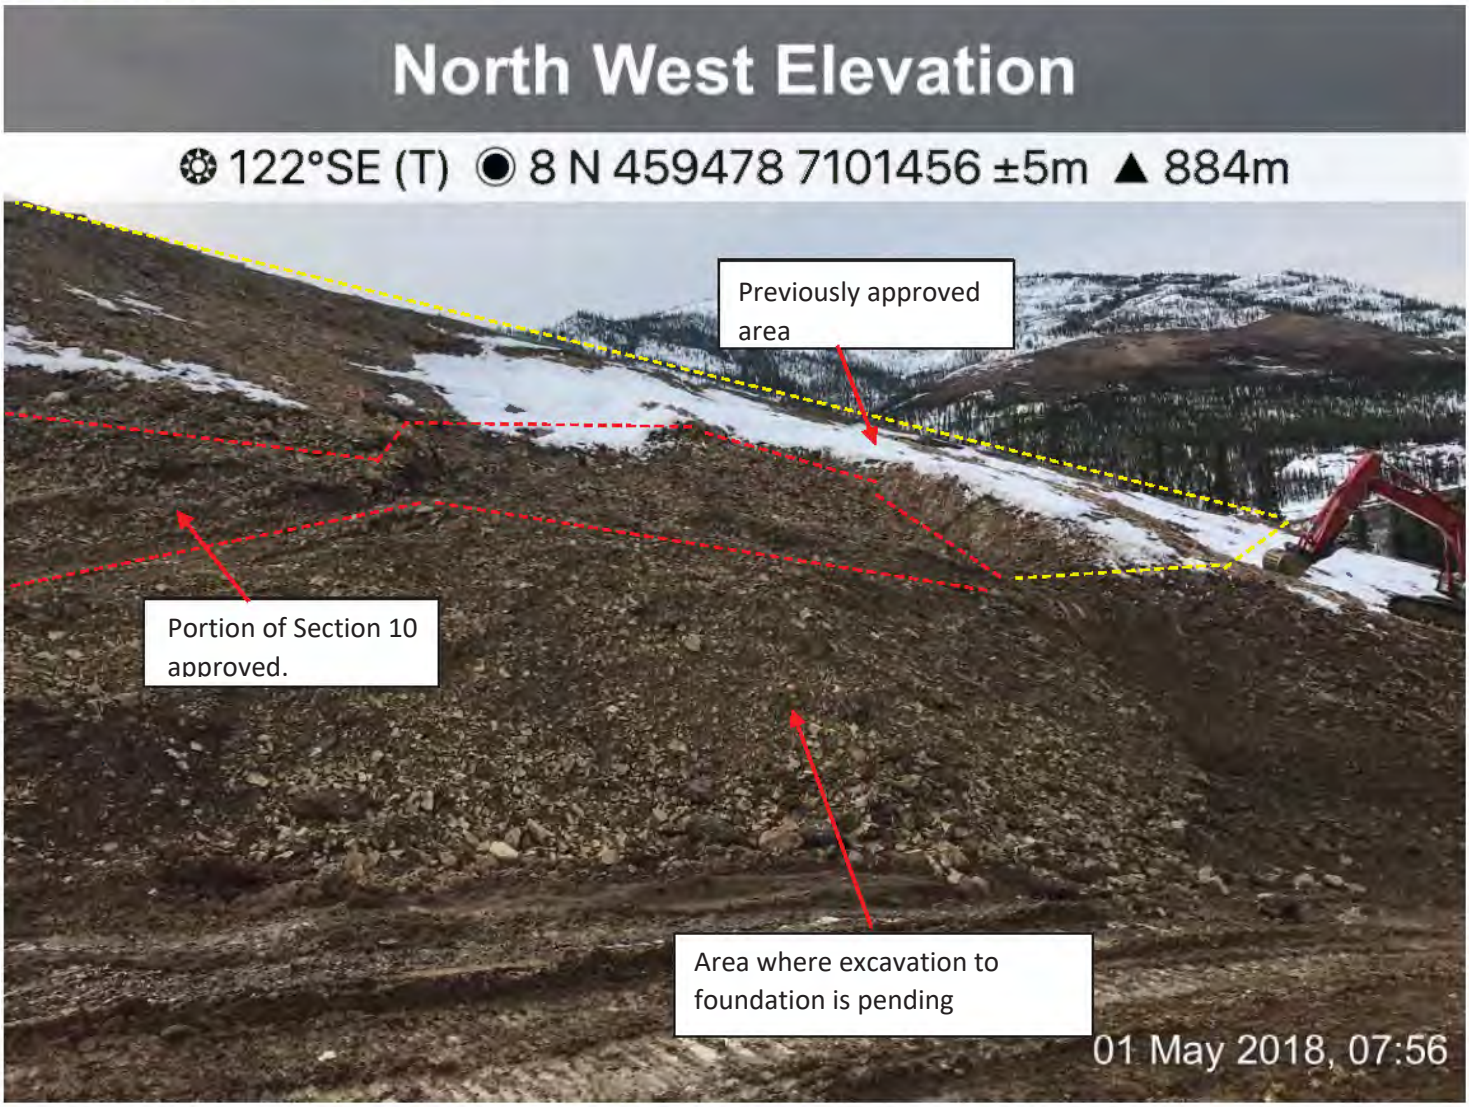

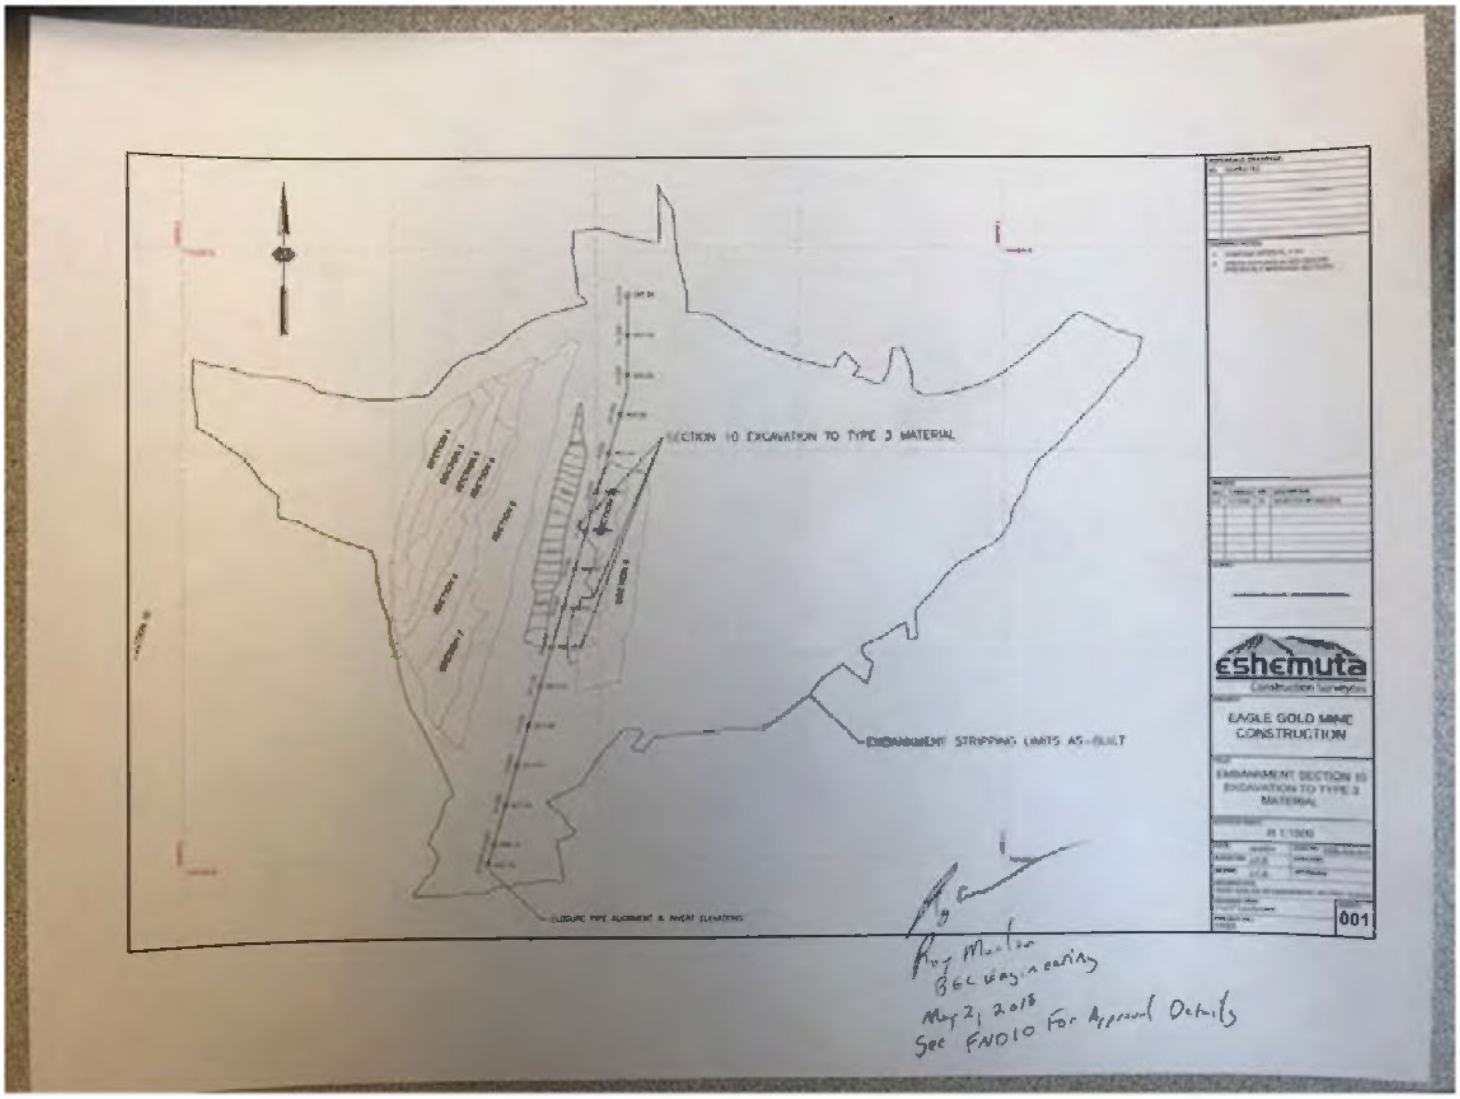

Photo 4: Remaining portion of Section 10 foundation approval.

Section 10 Foundation Approval Limits

Title: **INSPECTION AND TEST PLAN FOR HLF EMBANKMENT TOE REDESIGN**

Contractor: **PELLY CONSTRUCTION LTD**
Project: **EAGLE GOLD PROJECT**
Item: **9000.07**
CWP: **HLF Embankment Toe Redesign**
Revision: **0**

Contract No. **CC204**
ITP No. **0015**
Date: **02-Jun-18**

* Field approval. Final approval dependant on as-built. ERM & Roy Morlan
* Field approval pending as-builts for finger drains
* Final approval requiring survey thickness of Drain rock.
* @ STN 1+10, a 50cm x 50cm piece of geotextile was cut-out, it will be heat-tac @ a later stage per BGC request
* BGC approved the use of mini-Hoe CAT304 working on the 0.5m of material 2 above the closed off geotextile.

EXTRAS:

Lift 71 last one of "East" lifts - ties into old lift at this elevation

Lift 72 first "full" lift (continuing numbering system)

Lift 78 - Mostly completed by Night Shift, did not sign due to small area where haul truck broke down

Started 79 already

LIST ATTACHMENTS

Pelly Construction Ltd.

July 4, 2018

As of 13:00 on July 4, 2018, all the foundation areas up to Station 1+~~70~~ 45 (see drawing EMB-006-S14) has been conditionally approved by BGC.

Pelly can start the placement of the HLF Embankment Fill starting from the bottom at the toe and begin placing in lifts.

However, there are areas with loose rocks that will require a final clean up prior to the placement of the Embankment fill. A BGC representative must be present to approve the final clean up prior to the placement. Pelly will clean and load out all the loose rocks in the concern areas.

RE: Suitable Fill Materials for HLF Embankment Construction

The following items were a result of a collaborative in field meeting between BGC, Pelly, and JDS:

1. Type 3 bedrock material produced from the required excavation to re-expose type 3 bedrock can be blended into the rockfill (Type 7) lifts and be used as suitable material for embankment fill. PER DISCRETION OF ENGINEER, UNSUITABLE NOT CONSIDERED TYPE 3 BEDROCK WILL NEED REMOVAL.
2. All current stockpiles of material staged near the ADR pad (Pelly's stockpile management plan) including the remaining in-situ rock cut volume is approved to be used as rockfill (Type 7) and suitable material for embankment fill

AS APPROVED BY ENGINEER, AS MATERIALS MAY REQUIRE BLENDING, MIXING AND MOISTURE CONDITIONING.

Heap Leach Facility Embankment Construction:

Starting on nightshift on July 28, 2018, BGC has agreed to use the average elevation to determine the lift elevation. Previously, the lowest surveyed point would be used as the "actual elevation" but it was determined the select few outliers does not give a good representation of the overall data.

BGC Roy has agreed to monitor the first few lifts to determine if this is acceptable going forward.

Shipeng Zheng

Approved as a pilot test
Data will be reviewed over
First couple days to determine
if implemented permanently

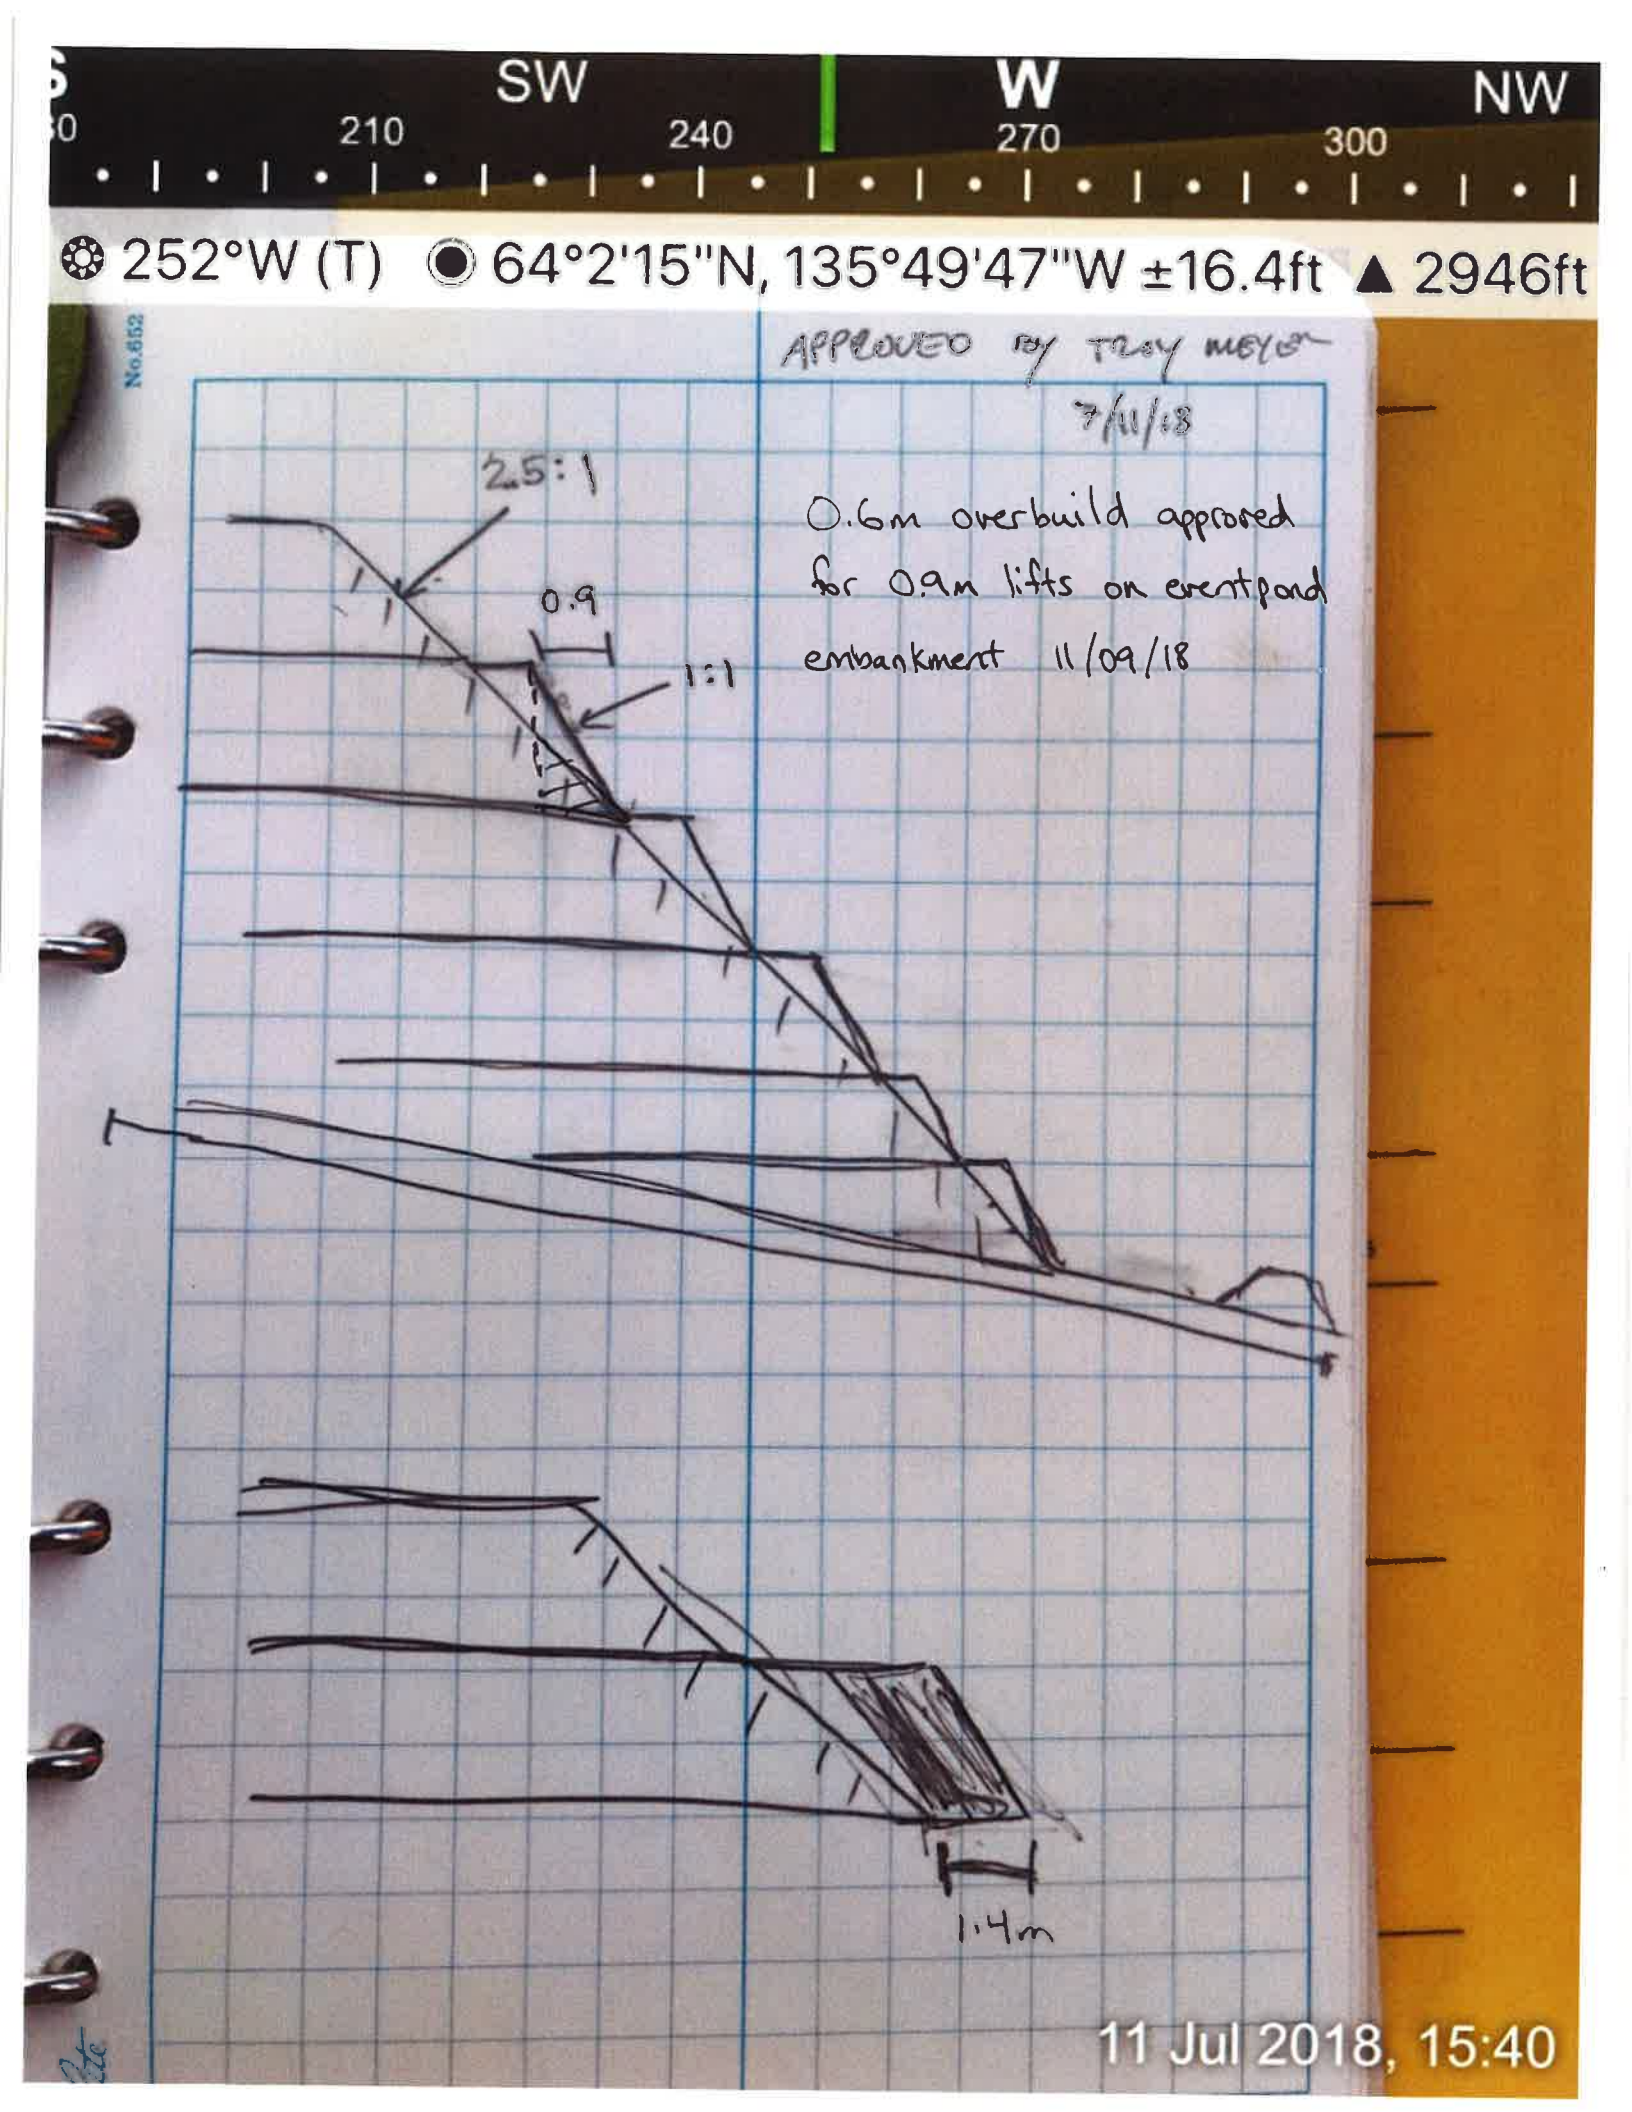
July 30, 2018

HLF Embankment Construction Grade Control

1. Surveyors will survey a few representative spots and the average elevation between the surveyed points will determine the base elevation

2. Pelly will target a placement of 0.40m for each lift

3. A laser level will be used to perform spot checks



4. The placed lift cannot be more than 0.10m above our target lift thickness

5. Any lift above our maximum allowable tolerance will have to be cut down

6. Surveyor to repeat Step 1

Pelly will continue to submit surveyed asbuilt to BGC for every 3rd compacted lift.

Re: Material 3 Test Fill 03

1.0 INTRODUCTION AND OBJECTIVE

On August 21, 2018 BGC developed and oversaw a test fill to evaluate the compaction of Material 3 – Structural Fill with loaded haul trucks.

2.0 TEST FILL CONSTRUCTION AND EXECUTION

BGC's representative, Troy Meyer, developed the test fills and was present during the execution. The test fill was constructed and surveyed by Pelly Construction. Material testing was performed by Tetra Tech. The following sections discuss the execution of the test fill.

2.1. Test Fill Materials and Borrow Description

The material used in the test fills was generated by Pelly as borrow from excavation of the ADR West stockpile. This material has been designated as Material 3 Structural Fill. Gradation, moisture, and proctor testing was performed by Tetra Tech. The results from this testing are included in ***Attachment 1***. The material generally consists of broken weak to moderately strong rock in a matrix of gravel and sand with few fines (***Photograph 1***).

Photograph 1: Photograph of loose material used in the test fill.

2.2. Test Fill Foundation

The HLF embankment fill placement areas was used as the test location (***Figure 1***). The test foundation was an approved compacted lift of structural fill (***Photograph 2***).

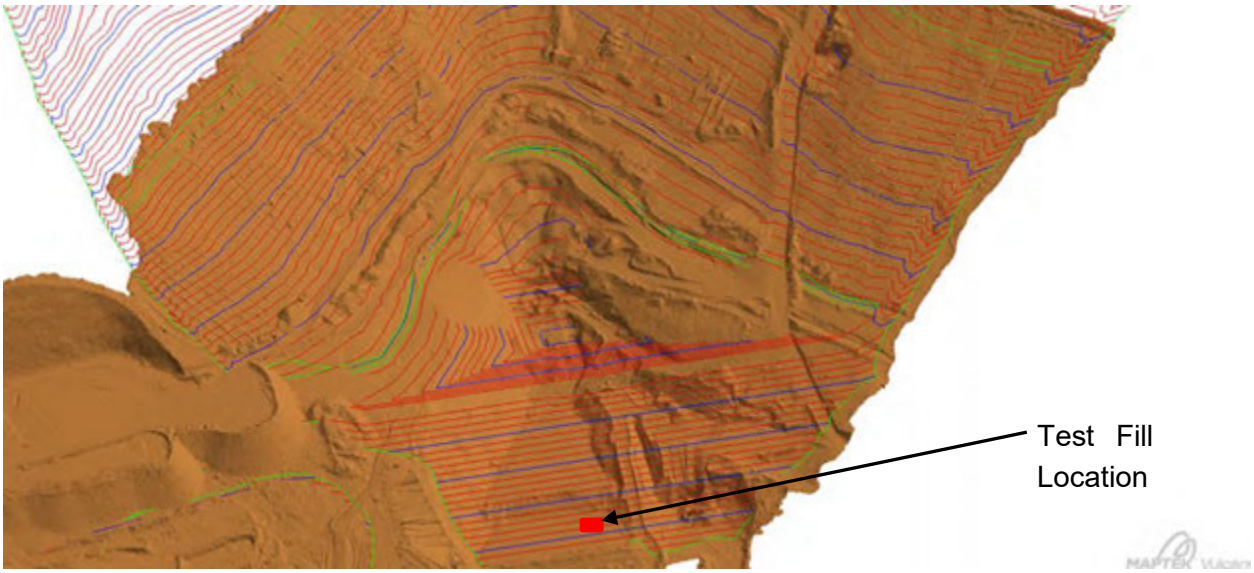

Figure 1: Test Fill Location

Photograph 2: Compaction of the test fill foundation.

2.3. Test Fill Lift Placement and Compaction

The test fill was constructed by dumping and pushing material with a D10 and D6 Dozer in a 0.5m loose lift. Lift thickness was measured by Pelly's surveyor using a mobile station. The test fill measured approximately 20m x 12m.

2.4. Moisture Conditioning

Moisture was added to the test fill material at the stockpile.

2.5. Test Fill Compaction and Settlement Measurements

To perform compaction tracking three steel plates were placed in a row down the center of the lift and used as a monitoring points (***Figure 2***). Initial survey of the settlement monitoring points was collected using a GPS surveying rod. Test fill surface was compacted with two cycles (1 forward pass and 1 reverse pass) of a loaded CAT 777 haul truck with an operating weigh of about 163,000 kg. After completion of one compaction pass, settlement was measured at the settlement points. This compaction/survey procedure was repeated for 2 full compaction cycles (4 passes). Specifications for the CAT 777 haul truck are included in ***Attachment 1***.

Photograph 3: Placement of material in test fill.

Photograph 4: Compaction of the test fill with loaded CAT 777.

Photograph 5: Survey of the settlement plates.

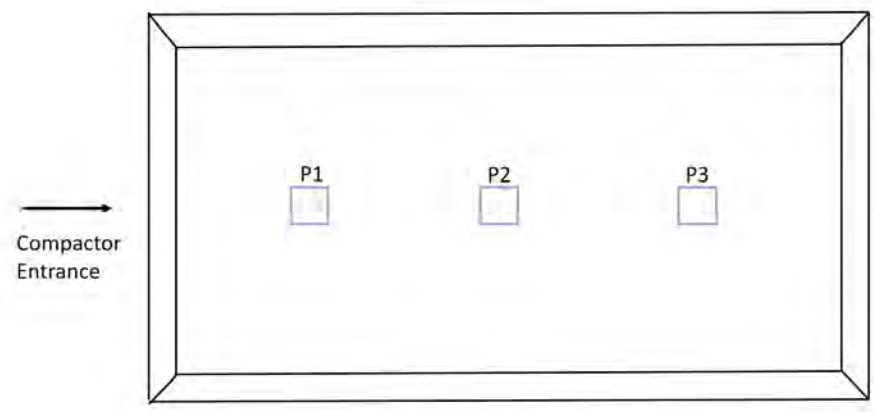

Figure 2: Approximation of test fill pad and survey points

Settlement data collected is included in ***Table 1***. A settlement graph is shown in ***Figure 3***.

	Pre-Compaction (m)	Pass 1 (m)	Pass 2 (m)	Pass 3 (m)	Pass 4 (m)
Survey Point 1 (P1)	898.404	898.366	898.371	898.36	898.404
Survey Point 2 (P2)	898.265	898.236	898.239	898.227	898.265
Survey Point 3 (P3)	898.326	898.287	898.297	898.287	898.326

Table 1: Survey elevation data collected during settlement tracking.

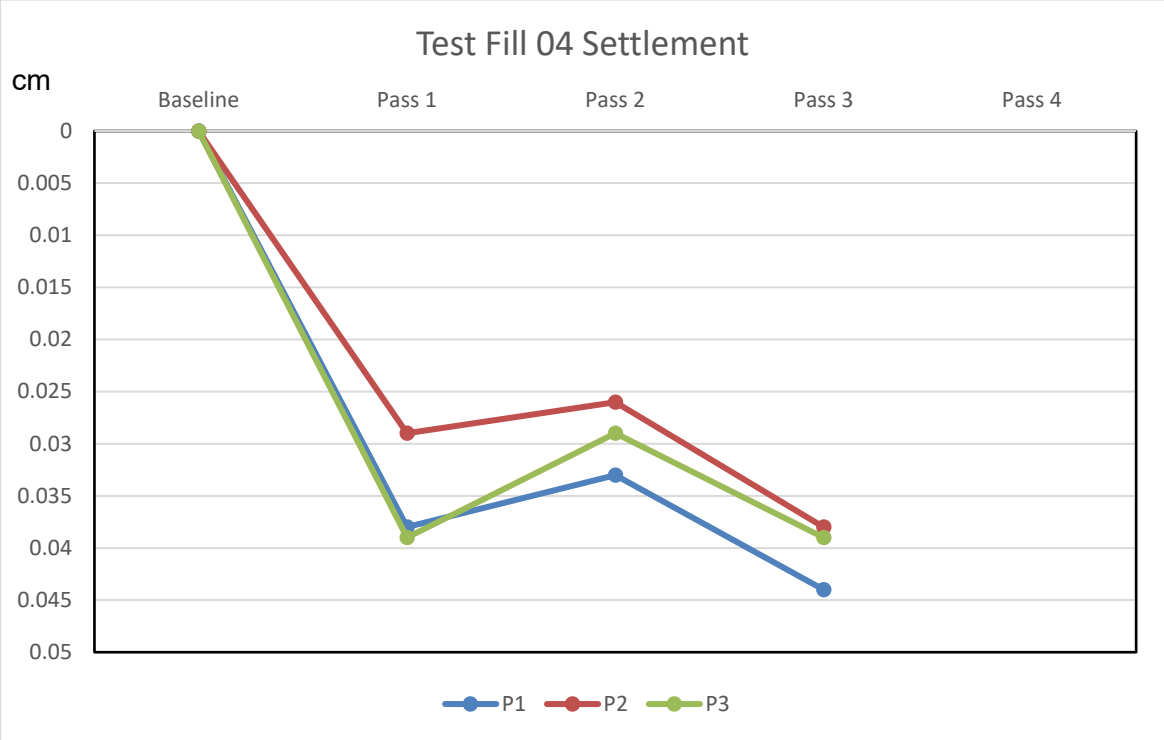

Figure 3: Test Fill 03 settlement recorded for each pass.

In-situ density and moisture testing was collected by Tetra Tech using a nuclear density gauge. Results were compared to the proctor for this material performed by Tetra Tech. The standard proctor performed on the material reported a maximum dry density (MDD) of 2,270 kg/m^3 at an optimum moisture of 6.7%. The test results indicated a dry density 2,208 kg/m^3 with a moisture content of 3.7%. The result is 97.3% of the MDD.

3.0 CONCLUSIONS

The results of the test fill indicate that Material 3 can achieve sufficient densities with a minimum of 1 pass of a minimum loaded CAT 777 haul truck and in lifts of up to 0.50m. These results were obtained with a moisture of 3.7%. Additional moisture conditioning of the material will aid compaction.

BGC recommends that the following criteria be used for placement and compaction of the Material 3 within the embankment:

- A maximum loose lift thickness of 0.50m should be used.
- Moisture content should be maintained between 3% and 6%.
- A minimum of 1 pass a loaded CAT 777 haul truck should be used. Unloaded haul trucks and smaller trucks will not provide the required compaction.

- If deflection of the compacted surface is observed with haul traffic, additional compaction will be required, either with loaded haul trucks or approved vibratory compactors.
- QC should be performed by tracking and reporting the above. In-situ QC testing using a nuclear density gauge should also be performed. Testing should report density and moisture. A minimum of 1 tests per compacted lift should be performed. The amount of tests can be reduced by the engineer after observing placement and compaction of the first several lifts and all criteria appear consistent. The average of the tests should determine to either pass or fail: 95% of 2,270 kg/m^3; moisture between 3% and 6%.

Attachment 1 – CAT 777 Specification Sheet.

ATTAHMENT 1

Engine

Engine Model	Cat® 3508B EUI	
Gross Power – SAE J1995	746 kW	1,000 hp
Net Power – SAE J1349	699 kW	938 hp
Net Power – Cat	699 kW	938 hp
Flywheel Power	699 kW	938 hp
Net Power – ISO 9249	699 kW	938 hp
Net Power – 80/1269/EEC	699 kW	938 hp
Peak Torque	4713 N·m	3,476 lb ft
Torque Rise	23%	
Bore	170 mm	6.7 in
Stroke	190 mm	7.5 in
Displacement	34.5 L	2,105 in^3

- Net power advertised is the power available at rated speed of 1750 rpm, measured at the flywheel when the engine is equipped with fan, air cleaner, muffler and alternator.
- Ratings based on standard air conditions of 25° C (77° F) and 99 kPa (29.32 Hg) dry barometer. Power based on fuel having API gravity of 35 at 16° C (60° F) and an LHV of 42 780 kJ/kg (18,390 BTU/lb) when engine used at 30° C (86° F).
- No engine derating required up to 2288 m (7,500 ft) altitude.
- Meets U.S. Environmental Protection Agency Tier 1 emissions standards.

Weights – Approximate

Target Gross Machine Operating Weight	163 360 kg	360,143 lb
Operating Weight – empty	64 670 kg	142,573 lb

Operating Specifications

Nominal Payload Capacity	90.4 tonnes	100 tons
Body Capacity – Struck	42.1 m^3	55.06 yd^3
Body Capacity – SAE 2:1	60.1 m^3	78.6 yd^3

- Refer to the Caterpillar 10/10/20 Payload Guidelines.

Transmission

Forward 1	10.5 km/h	6.5 mph
Forward 2	14.3 km/h	8.9 mph
Forward 3	19.3 km/h	12 mph
Forward 4	26 km/h	16.2 mph
Forward 5	34.9 km/h	21.9 mph
Forward 6	46.6 km/h	29.4 mph
Forward 7	60.4 km/h	39.9 mph
Reverse	11.9 km/h	7.4 mph

- Maximum travel speeds with standard 27.00-R49 tires.

Final Drives

Differential Ratio	2.74:1
Planetary Ratio	7.00:1
Total Reduction Ratio	19.16:1

- Planetary, full-floating.

Brakes

Brake Surface – Front	2787 cm^2	432 in^2
Brake Surface – Rear	102 116 cm^2	15,828 in^2

- Meets ISO 3450:1996 standards up to 163 293 kg (360,000 lb) gross operating weight.

Body Hoists

Pump Flow – High Idle	498 L/min	131.5 gal/min
Relief Valve Setting – Raise	18 962 kPa	2,750 psi
Relief Valve Setting – Lower	18 950 kPa	3,450 psi
Body Raise Time – High Idle	15 Seconds	
Body Lower Time – Float	13 Seconds	
Body Power Down – High Idle	13 Seconds	

Capacity – Dual Slope – 100% fill factor

Struck	42.1 m^3	55 yd^3
Heaped 2:1 (SAE)	60.1 m^3	78.6 yd^3

Weight Distributions – Approximate

Front Axle – Empty	47%
Front Axle – Loaded	33%
Rear Axle – Empty	53%
Rear Axle – Loaded	67%

Suspension

Effective Cylinder Stroke – Front	318 mm	12.5 in
Effective Cylinder Stroke – Rear	165 mm	6.5 in
Rear Axle Oscillation	5.4°	

Approximate Weights – Dual Slope

Empty vehicle	64 670 kg	142,573 lb
Chassis	46 600 kg	107,144 lb
Body	16 070 kg	35,428 lb

Service Refill Capacities

Fuel Tank	1137 L	300 gal
Cooling System	268 L	71 gal
Crankcase	91 L	24 gal
Differentials and Final Drives	306 L	81 gal
Steering Tank	40 L	11 gal
Torque Converter/Brake/ Hoist Hydraulic Tank	250 L	66 gal
Torque Converter/ Transmission Tank	95 L	25 gal

Tires

Standard Tire	27.00-R49 (E4) Tire

- Productive capabilities of the 777D truck are such that, under certain job conditions, TKPH (TMPH) capabilities of standard or optional tires could be exceeded and, therefore, limit production.
- Caterpillar recommends the customer evaluate all job conditions and consult the tire manufacturer for proper tire selection.

ROPS

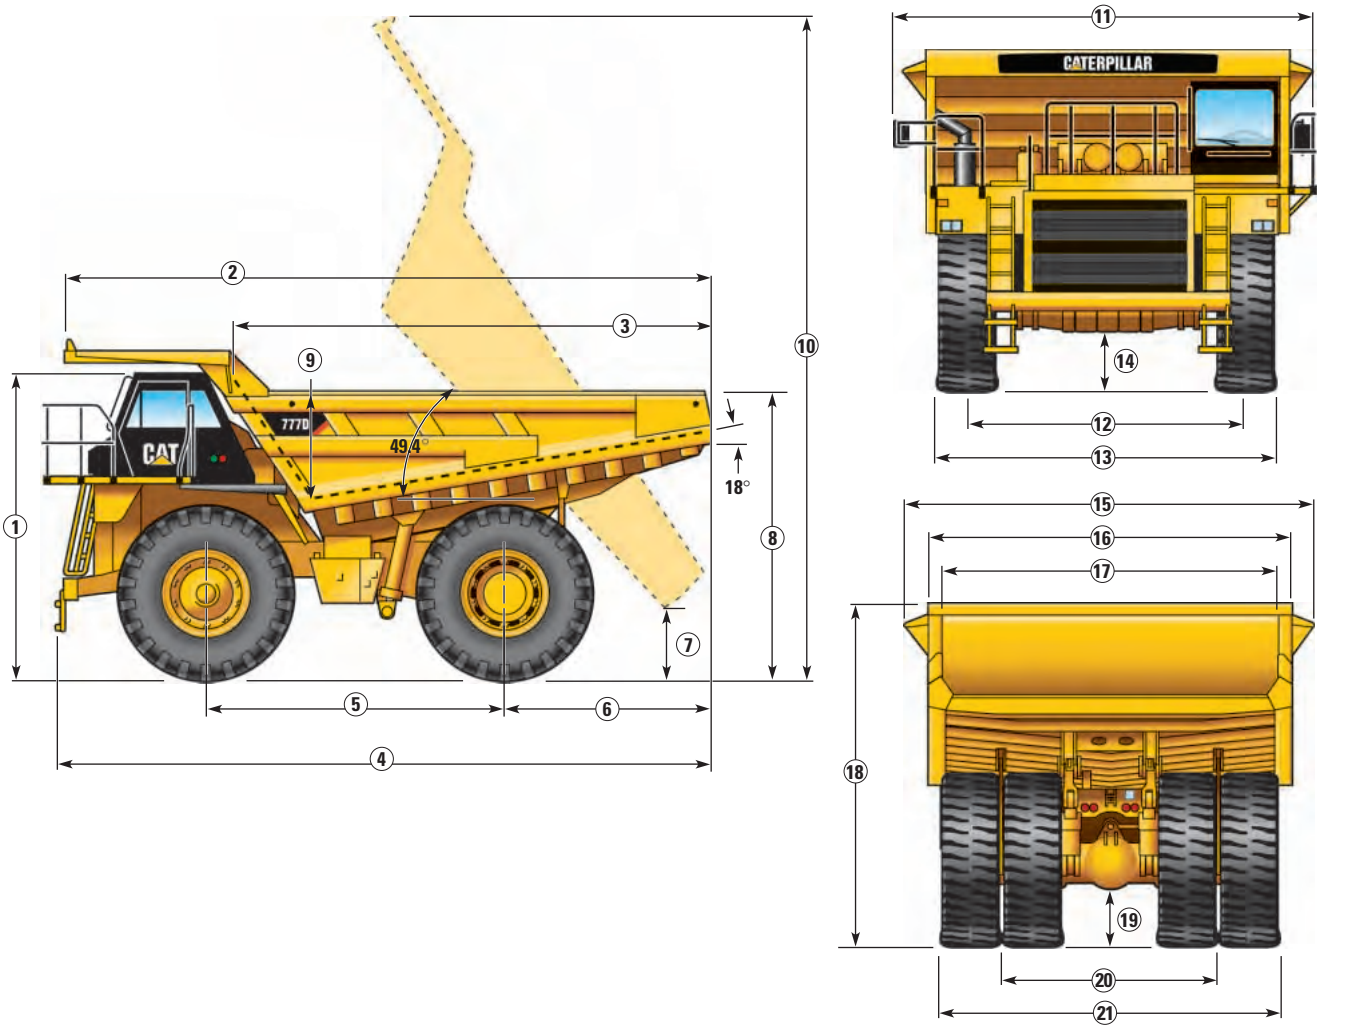
ROPS/FOPS Standards	SAE J1040 MAY94, ISO 3471:1997

- ROPS (Rollover Protective Structure) for cab offered by Caterpillar meets SAE J1040 MAY94 and ISO 3471:1997 Level II ROPS criteria.

Sound

Sound Standards	ANSI/SAE J1166 MAY90, SAE J88 JUN96

- The operator sound exposure Leq (equivalent sound pressure level) measured according to work cycle procedures specified in ANSI/SAE J1166 MAY90 is 78 dB(A) for cab offered by Caterpillar, when properly installed and maintained and tested with doors and windows closed.
- The exterior sound pressure level for the standard machine measured at a distance of 15 m (49 ft) according to the test procedures specified in SAE J88 JUN86, mid-gear moving operation is 90 dB(A).
- Hearing protection may be needed when operating with an open operator station and cab (when not properly maintained or doors/windows open) for extended periods or in a noisy environment.



Steering

Steering Standards	SAE J1511 OCT90, ISO 5010:1992 (E)

- Turning diameter on front wheel track with standard tires: 25.3 m (83 ft).
- Machine clearance turning circle: 28.4 m (93 ft 2 in).
- Steering angle, left or right: 30.5 degrees.
- Separate hydraulic system prevents cross contamination.

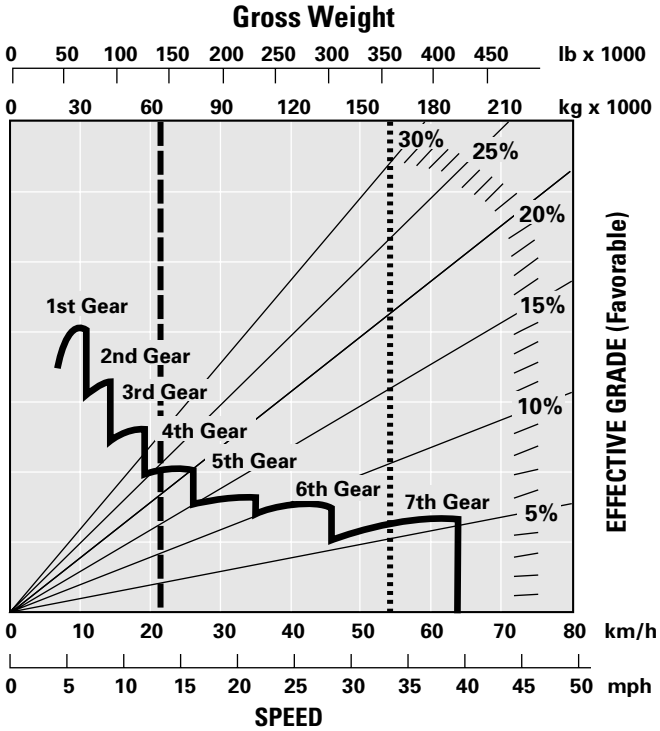
Dimensions

All dimensions are approximate. (Shown with dual slope body)

		Dual Slope	
1	Height to Top of ROPS – Full	4472 mm	14 ft 8 in
1	Height to Top of ROPS – Empty	4567 mm	15 ft
2	Overall Body Length	9525 mm	31 ft 3 in
3	Inside Body Length	7234 mm	23 ft 9 in
4	Overall Length	9780 mm	32 ft 1 in
5	Wheelbase	4570 mm	15 ft
6	Rear Axle to Tail	3020 mm	9 ft 11 in
7	Dump Clearance – Empty	1164 mm	3 ft 10 in
7	Dump Clearance – Loaded	1062 mm	3 ft 6 in
8	Loading Height – Empty	4380 mm	14 ft 4 in
9	Inside Body Depth – Max	1898 mm	6 ft 3 in
10	Overall Height – Body Raised	10 059 mm	33 ft

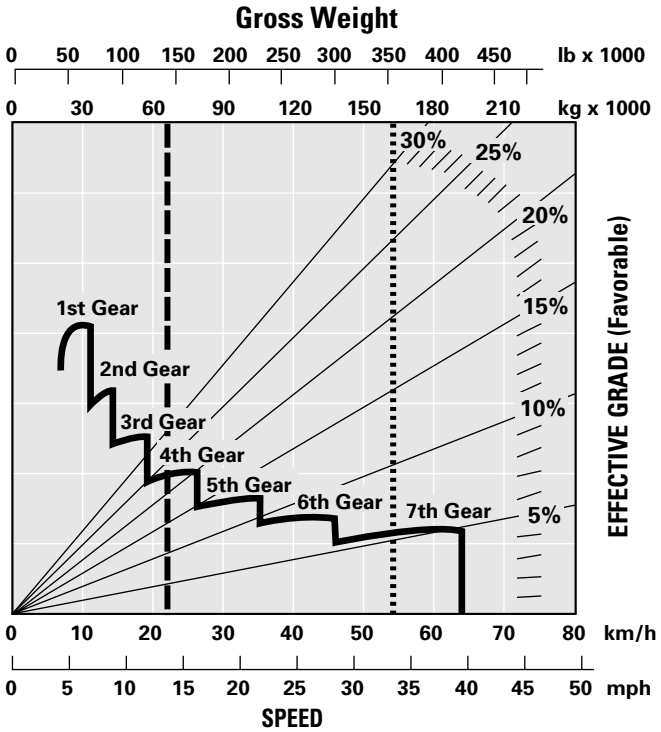
		Dual Slope	
11	Operating Width	6105 mm	20 ft
12	Centerline Front Tire Width	4173 mm	13 ft 8 in
13	Overall Front Tire Width	4961 mm	16 ft 3 in
14	Engine Guard Clearance – Empty	700 mm	2 ft 4 in
15	Overall Canopy Width	6048 mm	19 ft 10 in
16	Outside Body Width	5524 mm	18 ft 2 in
17	Inside Body Width	5200 mm	17 ft 1 in
18	Front Canopy Height – Empty	5147 mm	16 ft 10 in
18	Front Canopy Height – Loaded	5045 mm	16 ft 6 in
19	Rear Axle Clearance – Empty	750 mm	2 ft 6 in
20	Centerline Rear Dual Tire Width	3576 mm	11 ft 9 in
21	Overall Rear Dual Tire Width	5262 mm	17 ft 3 in

Gradeability/Speed/Rimpull

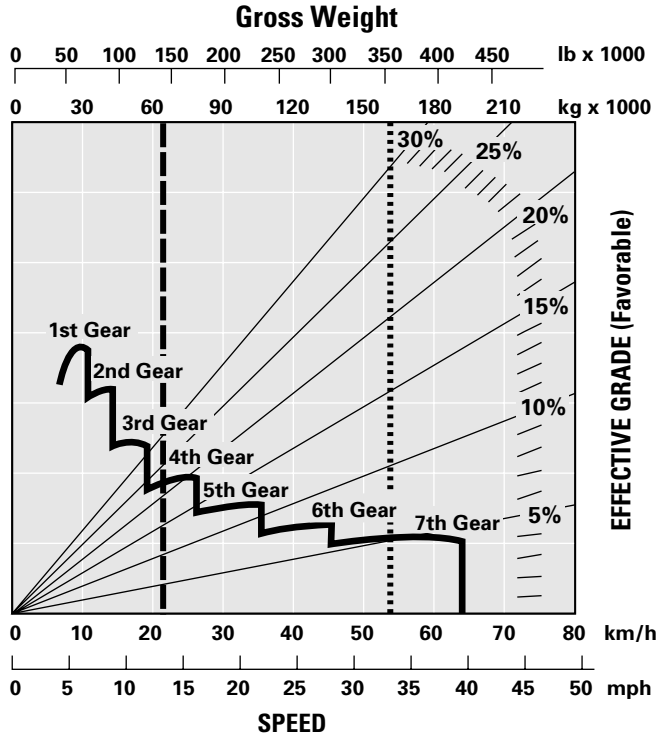


To determine gradeability performance: Read from gross weight down to the percent of total resistance. Total resistance equals actual percent grade plus 1% for each 10 kg/t (20 lb/ton) of rolling resistance. From this weight-resistance point, read horizontally to the curve with the highest obtainable gear, then down to maximum speed. Usable rimpull will depend upon traction available and weight on drive wheels.

Retarding Performance



Grade Distance — 450 m (1500 ft.)

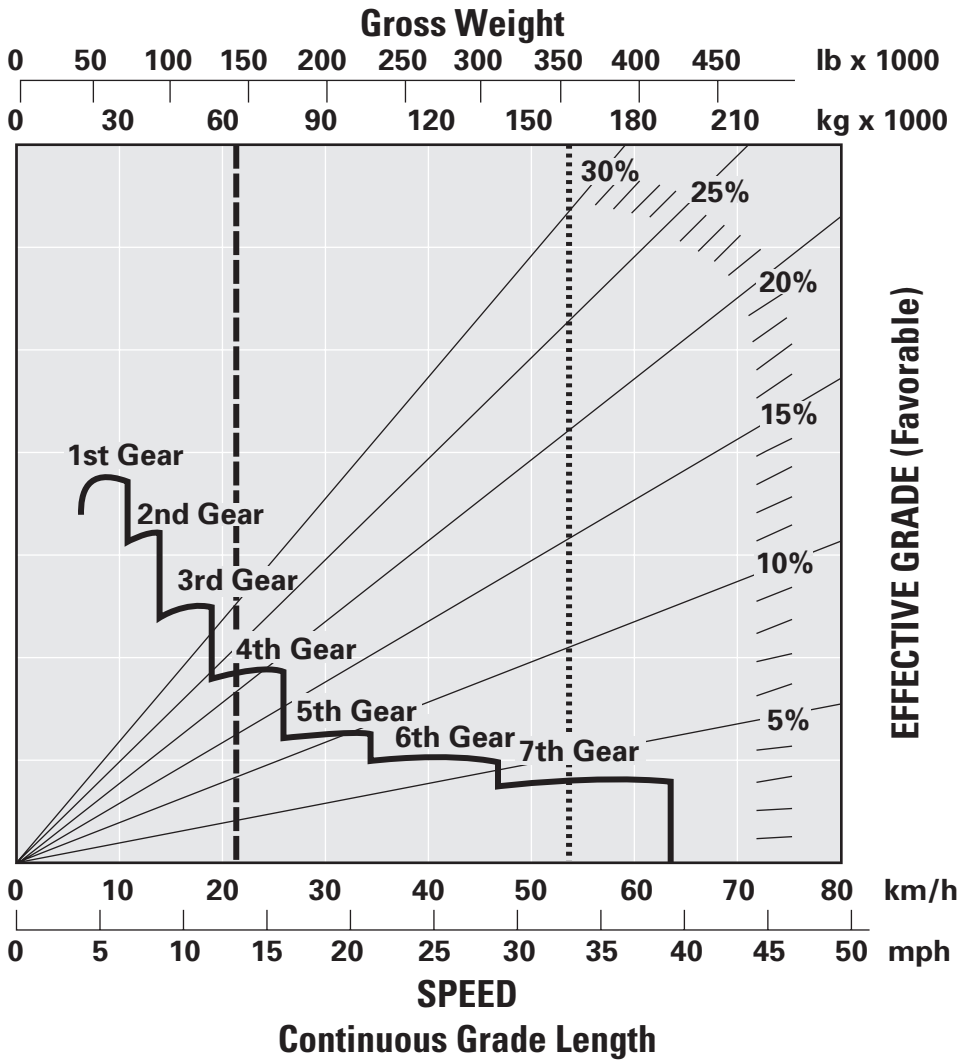


Grade Distance — 600 m (2000 ft.)

Retarding Performance

Grade Distance — 900 m (3000 ft.)

Grade Distance — 1500 m (5000 ft.)



Retarding Performance

To determine retarding performance: Add lengths of all downhill segments and, using this total, refer to proper retarding chart. Read from gross weight down to the percent effective grade. Effective grade equals actual % grade minus 1% for each 10 kg/t (20 lb/ton) of rolling resistance. From this weight-effective grade point, read horizontally to the curve with the highest obtainable gear, then down to maximum descent speed brakes can properly handle without exceeding cooling capacity. The following charts are based on these conditions: 32° C (90° F) ambient temperature, at sea level, with 27.00-R49 tires.

NOTE: Select the proper gear to maintain engine rpm at the highest possible level, without overspeeding the engine. If cooling oil overheats, reduce ground speed to allow transmission to shift to the next lower speed range.

Typical Field Empty Weight

Gross Machine Operating Weight 163 360 kg (360,143 lb)

Standard Equipment

Standard equipment may vary. Consult your Caterpillar dealer for details.

- Air Line Dryer
- Alternator (100-amp)

Date: Sept 11th, 2018

RE: HLF West Lateral Drain Within Impoundment

On September 4th, 2018 Pelly was informed by BGC Engineering that a lateral drain was not required below the 940 m elevation within the west HLF impoundment as there were no groundwater seeps identified during inspections. A finger drain was installed parallel to the underdrain system along the west face of the impoundment as a water mitigation measure for construction purposes.

RE: Suitable Fill Materials for HLF Embankment Construction

The following items were a result of a collaborative in field meeting between BGC, Pelly, and JDS:

1. Type 3 bedrock material produced from the required excavation to re-expose type 3 bedrock can be blended into the rockfill (Type 7) lifts and be used as suitable material for embankment fill

2. All current stockpiles of material staged near the ADR pad (Pelly's stockpile management plan) including the remaining in-situ rock cut volume is approved to be used as rockfill (Type 7) and suitable material for embankment fill

Dear Sir/Madam:

This is to certify that SKAPS GT112 (Layfield LP 12) is a high quality needle-punched nonwoven geotextile made of 100% polypropylene staple fibers, randomly networked to form a high strength dimensionally stable fabric. SKAPS GT112 (Layfield LP 12) resists ultraviolet deterioration, rotting, biological degradation. The fabric is inert to commonly encountered soil chemicals. Polypropylene is stable within a pH range of 2 to 13. SKAPS GT112 (Layfield LP 12) conforms to the property values listed below:

PROPERTY	TEST METHOD	UNITS	M.A.R.V. Minimum Average Roll Value
Grab Tensile	ASTM D 4632	lbs (kN)	300 (1.33)
Grab Elongation	ASTM D 4632	%	50
Trapezoidal Tear	ASTM D 4533	lbs (kN)	115 (0.51)
CBR Puncture	ASTM D 6241	lbs (kN)	850 (3.78)
Permittivity*	ASTM D 4491	sec^{-1}	1.00
Water Flow*	ASTM D 4491	$gpm/ft^2(l/min/m^2)$	75 (3056)
AOS*	ASTM D 4751	US Sieve (mm)	100 (0.15)
UV Resistance	ASTM D 4355	%/hrs	70/500

Notes:
* At the time of manufacturing. Handling may change these properties.

Lifetime of Exposed Wind Defender Ballast Netting

Introduction

Wind Defender is an engineered netting material that is used as a surface protection material and as a ballast over other geosynthetics including geomembranes and geotextiles. Figure 1 presents a photo of the material being discussed in this report. Since it is used in an exposed state, i.e., it is exposed to Sun, an important engineering concern is its lifetime. Wind Defender has been formulated specifically to perform satisfactorily for a long time. How long? is the question often asked by designers and regulators. The oldest use of the material is on projects that are about ten years old. The actual experience from these projects indicates that there is no noticeable degradation of the material during ten years of exposure. However, ten years is not close to the fifty years or more of lifetime expected of engineered materials.

The Geosynthetic Institute has recently published a methodology to determine the lifetime of exposed geosynthetics. This methodology involves the use of time-temperature superposition to calculate lifetime based on laboratory test data. The procedure involves three steps: i) laboratory exposure at three temperatures, ii) obtain lifetime at 20-degree Celsius by using Arrhenius modeling, i.e., extrapolate from higher laboratory temperature to a lower site temperature, and iii) account for the site specific UV exposure since much higher UV irradiance is used during the test. The reader may note the use of time-temperature superposition in Step (ii) which requires at least three different temperatures, and therefore, a considerable time and expense. Manufacturers typically rely on the GSI test data to answer questions about lifetime in a general manner.

To keep the test program within budget, only one temperature was used in this test program. Coupons of Wind Defender were exposed to UV light in a fluorescent ultraviolet device according to ASTM test method D7238. Test coupons were subjected to a 6-hour cycle that consisted of 5 hours of light at 50°C followed by 1 hours of condensation without light at 25°C. Therefore, the daily UV exposure is 20 hours with a ratio of 24 hours/20 hours = 1.2. This ratio is used later in the calculation to convert laboratory time to actual lifetime. The coupons were periodically retrieved and following three tests were performed: a) High Pressure OIT, b) tensile elongation and c) tensile strength. A separate report available from the manufacturer (Wind Defender, LLC) presents detailed results of the laboratory test program. The objective of this report is to analyze the data resulting from the test program, and to obtain a quantitative assessment of the lifetime.

Procedure and Test Data:

A 3 ft by roll width sample of Wind Defender engineered netting product was delivered to SAGEOS in Quebec, Canada. The laboratory tested the "AS-RECEIVED" material to determine the following baseline properties: i) Thickness, ii) Mass, iii) Tensile Strength, iv) Tensile Elongation and v) High Pressure OIT. Table 1 presents laboratory data on the virgin material. Coupons of the material were then cut and mounted within the UV Chamber. The exposed coupons were retrieved at 3-month interval over a time period of 15 months. Table 2 presents laboratory data on exposed coupons. The data presented in tables 1 and 2 was analyzed to obtain an estimate of lifetime of the material. Consistent with the GSI publications on this topic, half-life was used as the criteria for design life. The half-life of the material is defined here as the time required for the material to reach 50% of its strength and elongation at site-specific temperature and UV radiation.

Table 1 – "AS-RECEVED" and Exposed Properties of Wind Defender

Property	Test Method	Exposure Time (Months)				
		0	3	6	9	15
Mass per Unit Area ($oz./yd^2$)	ASTM D3776	6.5	-	-	-	-
Thickness (mils)	ASTM D5199	56.0	-	-	-	-
High Pressure OIT (min)	ASTM D5885	1549	936	809	475	487
Tensile Strength (lbs/2 inch)	ASTM D5035	157.2	163.1	146.5	146.3	137.5
Elongation at Max Force (%)	ASTM D5035	70.6	80.8	74.1	70.7	69.2

Analysis and Discussion:

Figure 2 presents the last three properties in Table 1 as percentage change with time. It may be noted that the HPOIT data shows a leveling off indicating no additional change with time. Tensile strength and elongation values reported in Figure 2 are replotted in figures 3 and 4 on a semi-logarithmic plot. These plots are of a similar nature as those utilized in the GSI reports as the basis of lifetime prediction for a number of different geosynthetics. These plots indicate that the target 50 percentage reduction (here half-life is used as the lifetime) in mechanical properties occurs at 55 years based on elongation and 50

years based on strength at a laboratory temperature of 50°C and the laboratory UV exposure. The next step is typically to extrapolate to 20°C and site-specific UV exposure.

In order to extrapolate from laboratory to field temperature, tests must be performed at three or more temperatures. Since only one temperature was evaluated, the time-temperature extrapolation is not feasible. Since temperature has a significant effect on rate of aging, life-time at 20 degrees is expected to be much higher than that at 50 degrees. The consideration of site-specific UV intensity is, however, possible and is illustrated for Phoenix, AZ. The UV-fluorescent weathering device has an irradiance of 42.42 W/m^2 between 250 and 400 nm wavelengths. UV radiation in Phoenix is 28 MJ/m^2-month. Lifetime predicted is 50 years at 50° C. Then (42.42/28)x50 = 75 years is the lifetime of Wind Defender in Phoenix at 50°C. However, the ratio between UV time in the lab and total time is 1.2 as calculated previously. Therefore, lifetime is 75x1.2 = 90 years at 50°C. The lifetime at ambient temperature of 20°C is expected to be much higher than the value calculated at 50°C.

Conclusion

The Wind Defender ballast and UV protection material was exposed to UV radiation according to ASTM test method D 7238. The material was subjected to UV at a temperature of 50°C to accelerate degradation. This information was then utilized to calculate lifetime at a conservative site-specific temperature of 50°C. The calculated lifetime was found to be 90 years if the material is installed in Phoenix, AZ. The actual lifetime at an ambient temperature of 20°C is expected to be more than 90 years.

WIND DEFENDER®

Product Data Sheet

WIND DEFENDER® HD

Special reinforced geotextile windscreen made of knitted, green, UV stabilized HDPE filament. Wind Defender® is deployed and tensioned over an installed geomembrane in order to achieve a stable and reliable ballast system. Wind Defender® can also standalone as a dust screen to prevent fugitive dust particles from leaving an area.

Typical Roll Dimensions	English	Metric
Roll Length	328 ft	100 m
Roll Width	20 ft	6 m
Roll Area	6,560 sf	609 m^2
Roll Weight	305 lbs	138 kg

Nominal product values are average values with an acceptable maximum variance of - 10%

KEY BENEFITS

- Aesthetically pleasing
- UV Stabilized
- Provides 60% UV block for underlying materials
- Installs quickly
- Available in large rolls
- Performs well under snow load
- Lasts 3 to 10 times longer than most traditional sandbag and rope anchoring systems
- Safer to install than making and deploying heavy sandbags

APPLICATIONS

- Landfill Covers
- Stockpile Covers
- Dust Screen
- Soil Cover

PRODUCT DATA SHEET

GSE BentoLiner NWL-60 Geosynthetic Clay Liner

GSE BentoLiner "NWL-60" is a heavily needlepunched reinforced composite geosynthetic clay liner (GCL) comprised of a uniform layer of granular sodium bentonite encapsulated between a nonwoven and a scrim-nonwoven geotextile for dimensional stability. The product is intended for steep slopes and high load applications where increased internal shear strength is required.

[*]

AT THE CORE:

This composite clay liner is intended for steep slopes and high load applications where increased internal shear strength is required.

Product Specifications

Tested Property	Test Method	Frequency	VALUE

TYPICAL ROLL DIMENSIONS			
Width x Length(7)	Typical	Every Roll	15.5 ft x 150 ft
Area per Roll	Typical	Every Roll	2,325 ft^2
Packaged Weight	Typical	Every Roll	2,600 lb

NOTES:

- (1)Minimum Average Roll Value.
- (2)At 0% moisture content.
- (3)Tested in machine direction.
- (4)Modified ASTM D 4632 to use a 4 in wide grip. The maximum peak of five specimens averaged in machine direction.
- (5)Deaired, deionized water @ 5 psi maximum effective confining stress and 2 psi head pressure.
- (6)Typical peak value for specimen hydrated for 24 hours and sheared under a 200 psf normal stress.
- (7)Roll widths and lengths have a tolerance of ±1%.

GSE is a leading manufacturer and marketer of geosynthetic lining products and services. We've built a reputation of reliability through our dedication to providing consistency of product, price and protection to our global customers.

Our commitment to innovation, our focus on quality and our industry expertise allow us the flexibility to collaborate with our clients to develop a custom, purpose-fit solution.

DRAINAGE PRODUCT DESCRIPTION SHEET

TRANSNET 220-2-8

Transnet 220-2-8 is a superior quality drainage media made by extruding two sets of HDPE strands together to form a diamond shaped net. The net is then heat laminated to an 8 ounce non-woven fabric. This three dimensional structure provides excellent planar liquid flow. The Transnet 220-2-8 conforms to the physical property values listed below:

NET PROPERTY	TEST METHOD	UNITS	MINIMUM AVERAGE ROLL VALUE
Thickness	ASTM D-5199	mm	5.0
Density of Polymer	ASTM D-1505	g/cm^2	0.94
Carbon Black	ASTM D-1603	%	2
Transmissivity (Geonet)	ASTM D-4716	m^2/s	1×10^{-3}*
Tensile Strength	ASTM D-5035	N/mm	7.9
Melt Flow Index	ASTM D-1238	g/10min	1(max)
Ply Adhesion	ASTM D-7005	g/cm	89

*Transmissivity measured using water at 20 Degrees C with a gradient of 0.1, between 2 steel plates, under a confining pressure of 480kPa after fifteen minutes. Values may vary based on dimension of the transmissivity specimen and specific laboratory.

STYLE GE-180

GE-180 is a superior quality, nonwoven geotextile produced by needlepunching together 100% polypropylene staple fibers in a random network to form a high strength dimensionally stable fabric. The polypropylene fibers are specially formulated to resist ultraviolet light deterioration, and are inert to commonly encountered soil chemicals. The fabric will not mildew, is non-biodegradable, and is resistant to damage from insects and rodents. Polypropylene is stable within a ph range of 2 to 13. GE180 conforms to the physical property values below:

FABRIC PROPERTY	TEST METHOD	UNITS	MINIMUM AVERAGE ROLL VALUE
Weight	ASTM D-5261	g/m^2	270
Grab Tensile	ASTM D-4632	N	975
Grab Elongation	ASTM D-4632	%	50
CBR Puncture	ASTM D-6241	N	2,557
Water Flow Rate	ATMD D-4491	$l/min/m^2$	3,865
Permittivity	ATMD D-4491	sec^{-1}	1.26
UV Resistance	ASTM D-4355	%	70@500hrs.

*At time of manufacturing. Handling may change these properties.

Tensile Strength	ASTM D-5035	N/mm	17.5
Melt Flow Index	ASTM D-1238	g/10min	1(max)
Ply Adhesion	ASTM D-7005	g/cm	89

*Transmissivity measured using water at 20 Degrees C with a gradient of 0.1, between 2 steel plates, under a confining pressure of 480kPa after fifteen minutes. Values may vary based on dimension of the transmissivity specimen and specific laboratory.

STYLE GE-180

GE-180 is a superior quality, nonwoven geotextile produced by needlepunching together 100% polypropylene staple fibers in a random network to form a high strength dimensionally stable fabric. The polypropylene fibers are specially formulated to resist ultraviolet light deterioration, and are inert to commonly encountered soil chemicals. The fabric will not mildew, is non-biodegradable, and is resistant to damage from insects and rodents. Polypropylene is stable within a ph range of 2 to 13. GE180 conforms to the physical property values below:

FABRIC PROPERTY	TEST METHOD	UNITS	MINIMUM AVERAGE ROLL VALUE
Weight	ASTM D-5261	g/m^2	270
Grab Tensile	ASTM D-4632	N	975
Grab Elongation	ASTM D-4632	%	50
CBR Puncture	ASTM D-6241	N	2,557
Water Flow Rate	ATMD D-4491	$l/min/m^2$	3,865
Permittivity	ATMD D-4491	sec^{-1}	1.26
UV Resistance	ASTM D-4355	%	70@500hrs.

*At time of manufacturing. Handling may change these properties.

Re: HDPE Pipe Leak Test

1.0 INTRODUCTION

The purpose of this memo is to provide a summary of the pipe testing observations made by BGC Engineering (BGC) during Pelly Constructions (Pelly) testing of the HDPE SDR 17 portion of the Closure Pipe to be used between stations 0+29.3 to 1+81.4. Pelly performed pressure testing on June 16th, 2018 between 11:30 HRS and 17:35 HRS based on ASTM F2164-13.

2.0 OBSERVATIONS AND RESULTS

Pelly provided a description of the test procedure and testing equipment components, which can be viewed in the attached memo from Pelly (Attachment 1).

BGC observed the HDPE pipe test throughout the time of testing. Pressure was checked by Pelly using a regulator attached to one end of the pipe. Photos were taken by BGC of each of the 9 butt-fused pipe joints at regular intervals in addition to the flange-pipe connections at the ends of the pipe (Attachment 2).

The test was started early in the morning following a night of light rain. The pipe at the start of the test was wet on the outside from the overnight rain. The pipe gradually dried during the test, assisting in potential leak detection. BGC observed that pressure within the pipe was stable through the duration of the test with fluctuations ranging between 0 and 5 psi. A summary of BGC's observations for each regular check interval can be viewed in the attachments (Attachment 3).

3.0 CONCLUSIONS

Pelly reported that the pipe passed the pressure test. BGC's observations confirm this. BGC's observations also confirm that Pelly followed the ASTM standard being used for the pipe test. Visual inspection of the pipe did not indicate the presence of air or water leaks. BGC attributed

the slight fluctuation in psi to compressor variation and regulator performance, not to a leak along butt-fused pipe joints.

4.0 CLOSURE

BGC Engineering Inc. (BGC) prepared this document for the account of JDS. The material in it reflects the judgment of BGC staff in light of the information available to BGC at the time of document preparation. Any use which a third party makes of this document or any reliance on decisions to be based on it is the responsibility of such third parties. BGC accepts no responsibility for damages, if any, suffered by any third party as a result of decisions made or actions based on this document.

As a mutual protection to our client, the public, and ourselves, all documents and drawings are submitted for the confidential information of our client for a specific project. Authorization for any use and/or publication of this document or any data, statements, conclusions or abstracts from or regarding our documents and drawings, through any form of print or electronic media, including without limitation, posting or reproduction of same on any website, is reserved pending BGC's written approval. If this document is issued in an electronic format, an original paper copy is on file at BGC and that copy is the primary reference with precedence over any electronic copy of the document, or any extracts from our documents published by others.

Yours sincerely,

BGC ENGINEERING INC.

Work Plan:	HLF Embankment Underdrain Pipe Leak Test	**Revision:**	0
Location:	HLF Embankment approx. 1.5km Dublin Road	**Date:**	2018-06-20

OBJECTIVE

The objective of this CWP is to outline the procedure and provide results of a leak test to be completed on the underdrain pipe(s) to be installed within the HLF Embankment in Response to BGC RFI-004.

SUMMARY

The scope of work includes:

1. Test pipe for leaks following guidelines outlined in ASTM F2164-13
2. Monitor and record test results
3. Approval of tested pipe

SAFETY

Potential Hazard	Precautions and Actions
Outlined in attached JHA	Job Hazard assessment completed for work to be done

SCOPE OF WORK

Description	
1. <u>Test pipe for leaks</u> **Test Pipe:** The test pipe will consist of approx. 150m length of HDPE SDR 17 pipe to be used as the closure pipe between station 0+29.3 (upstream vault contact) and 1+81.4 SDR 17 to SDR 11 connection as per drawing EGHLF-XD-03-05. • Pipe leak test will be completed guided by procedures and safety precautions included in ASTM F2164-13 (attached). Most recently fused pipe will be selected as a spot test to prove quality of welds and free of any leaks. In the event that the selected pipe fails the procedure, all pipes will then have to be tested as quality assurance. **Procedure:** • Flanges will be fused onto the selected pipe consisting of a cap and gasket to seal pressure at one end and introduce water and pressure into the other end. • The pipe will be placed into a confining ditch where all welds in question are visible. Pipe will be placed in a constant graded position to minimize undulations and air pockets. • The pipe will be filled with water to capacity. • Pneumatic pressure will be introduced into the pipe in stages of 20 – 30 psi up 100 psi agreed upon by BGC representative. Each stage must sustain constant pressure for 15 minutes while remaining free of any leaks. • The pipe will be required to sustain 100 psi of constant pressure and be

This international standard was developed in accordance with internationally recognized principles on standardization established in the Decision on Principles for the Development of International Standards, Guides and Recommendations issued by the World Trade Organization Technical Barriers to Trade (TBT) Committee.

Designation: F2164 – 13

Standard Practice for Field Leak Testing of Polyethylene (PE) and Crosslinked Polyethylene (PEX) Pressure Piping Systems Using Hydrostatic Pressure[1]

This standard is issued under the fixed designation F2164; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ε) indicates an editorial change since the last revision or reapproval.

1. Scope*

1.1 This practice provides information on apparatus, safety, pre-test preparation, and procedures for conducting field tests of polyethylene and crosslinked polyethylene pressure piping systems by filling with a liquid and applying pressure to determine if leaks exist in the system.

1.2 This practice does not address leak testing using a pressurized gas (pneumatic testing). For safety reasons, some manufacturers prohibit or restrict pneumatic pressure testing of their products. Failure during a pressure leak test can be explosive, violent, and dangerous, especially if a compressed gas is used. In a compressed gas test, both the pressure stress on the system and the energy used to compress the gas are released at a failure. Contact component manufacturers for information about testing with gas under pressure.

1.3 This practice does not apply to leak testing of non-pressure, gravity-flow, negative pressure (vacuum), or non-thermoplastic piping systems. For field-testing of plastic gravity flow sewer lines, see Test Method F1417.

1.4 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* Additional safety information is presented in Section 7 and throughout this standard.

3. Terminology

3.1 Abbreviations and terms are in accordance with Terminology D1600 and Terminology F412 unless otherwise indicated.

3.2 *Definitions of Terms Specific to This Standard:*

3.2.1 *authority having jurisdiction, n*—the organization, office, or individual responsible for "approving" equipment and installation, or a procedure.

3.2.1.1 *Discussion*—The term "authority having jurisdiction" is used in this practice in a broad manner since jurisdictions and "approval" agencies vary, as do their responsibilities. Where public safety is concerned, the "authority having jurisdiction" may be a federal, state, local, or other regional department or individual such as a Fire Chief, Fire Marshall, chief of a fire prevention bureau, labor department, building official, or others having statutory authority. For insurance purposes, an insurance inspection department, rating bureau, or other insurance company representative may be the "authority

[1] This practice is under the jurisdiction of ASTM Committee F17 on Plastic Piping Systems and is the direct responsibility of Subcommittee F17.40 on Test Methods.

Current edition approved April 1, 2013. Published April 2013. Originally approved in 2007. Last previous edition approved in 2010 as F2164–10$^{\varepsilon 1}$. DOI: 10.1520/F2164-13.

Jana Purmalis (BGC Engineering) pursuant to License Agreement. No further reproductions authorized.

having jurisdiction." In many circumstances, the property owner or his authorized engineer or agent assumes the role of the "authority having jurisdiction"; at government installations, the commanding officer or departmental official may be the "authority having jurisdiction."

3.2.2 *approved, vt*—acceptable to the authority having jurisdiction.

3.2.3 *pressure piping system, n*—a piping system where all components in the system are pressure rated and intended for conveying a fluid under continuous internal pressure. (See also Terminology F412, *pressure pipe* and *non-pressure pipe*.) To verify suitability for pressure service, consult the component manufacturer.

NOTE 1—PPI TR-4 provides information about stress ratings for some plastic materials and products.

3.2.4 *restraint, n*—temporary or permanent structural measures or devices which restrict, guide, prevent, or safely limit disjoining or movement of piping system components while the system is under pressure during testing or service conditions. Restraint may include backfill, anchors, thrust blocks, external clamps and tie rods (joint restraints), pipe guides, and so forth. Restraint means that if violent separation or failure occurs during the test, any movement of components or parts is sufficiently constrained such that damage or injury is prevented.

3.2.5 *system design pressure, n*—the limiting continuous internal pressure specified by the piping system designer. System design pressure may be less than the pressure ratings of components in the system. System design pressure may be limited by component pressure ratings, by code or application requirements, or by other restrictions.

3.2.6 *visible leakage, n*—the visible escape (drip, spray, stream, flow, and so forth.) of test liquid from the test section through components, joints, connections, appurtenances, and the like in the test section.

4. Summary of Practice

4.1 The section of the piping system to be tested is isolated from other parts of the system and restrained against movement to prevent catastrophic failure. Components that are not to be subjected to test pressure or could be damaged by test pressure are isolated or removed as necessary. Isolated components are vented to atmosphere. The test section is filled with the testing liquid, raised to the test pressure, and allowed to stabilize. The system is inspected or monitored for leakage, and then test pressure is relieved. If repairs or corrections are necessary, they are performed only when the test section is depressurized. If necessary, a retest is performed after a relaxation period. At the conclusion of an acceptable test, the test section may be placed in service. Purging and disposal of the test liquid from the test section may be necessary.

4.2 Acceptance is determined by the approval of the authority having jurisdiction.

4.3 The authority having jurisdiction may specify procedures or requirements for test liquid disposal or erosion control.

5. Significance and Use

5.1 If required by the authority having jurisdiction, hydrostatic pressure leak testing may be conducted to discover and correct leaks or faults in a newly constructed or modified polyethylene or crosslinked polyethylene pressure piping system before placing the system in service. Leakage or faults usually occur at connections, joints, and mechanical seals where sealing under pressure is required. (**Warning**—Safety is of paramount importance when conducting hydrostatic pressure leak tests because testing under pressure may cause sudden violent rupture or failure.)

5.2 This practice uses a pressurized liquid to test for leaks. It does not verify if a piping material or a piping system design is suitable for pressure service. The suitability of a piping system for pressure service and its pressure rating or operating pressure is determined solely by its design and its installed components.

5.3 Systems that are not suitable for pressure testing should not be pressure tested. Such systems may contain lower pressure rated or non-pressure rated components that cannot be isolated from test pressure, or temporary caps or closures may not be practical. In these systems, leak inspections should be conducted during and after installation. Inspections typically include visual examination of joint appearance, mechanical checks of bolt or joint tightness, and other relevant examinations. See also Test Method F1417.

5.4 *Leakage Allowance*—There is no leakage allowance for a section of heat-fusion joined polyethylene piping, because properly made heat fusion joints do not leak. See 7.6.1.

5.4.1 Other types of joints or connections in the system may have a leakage allowance. Contact the joint or connection manufacturer for information.

5.5 *Expansion Allowance*—When test pressure is applied, polyethylene or crosslinked polyethylene pipe will expand slightly due to elasticity and Poisson effects. To compensate for expansion, make-up water is added during the initial expansion phase. The amount of make-up water (expansion allowance) will vary because expansion is not linear. This procedure compensates for expansion with an initial expansion phase, followed by a test phase. In the test phase, expansion is suspended by slightly reducing test pressure. See 9.6.

5.6 *Poisson Effect*—When test pressure is applied to plastic piping systems that have fully restrained joints (joints such as heat fusion, electrofusion, bolted flanges, and so forth.), diametrical expansion of the pipe may reduce the overall length of the fully restrained section. Poisson-effect length reduction may affect or cause disjoining in other contiguous sections that have partially restrained or non-restrained joints, such as bell-and-spigot joints, when such joints are in-line with the test section. To prevent Poisson-effect disjoining, take measures such as the installation of external joint restraints (diametrical clamps and tie-rods) on in-line non-restrained joints, installing in-line thrust anchors at the ends of the fully restrained section, or isolating the fully restrained test section from piping with non-restrained or partially restrained joints.

NOTE 2—When a tensile stress is applied to a material, it will elongate

Copyright by ASTM Int'l (all rights reserved); Mon Jun 11 11:42:54 EDT 2018
Downloaded/printed by
Jana Purmalis (BGC Engineering) pursuant to License Agreement. No further reproductions authorized.

in the direction of the applied stress, and will decrease in dimension at right angles to the direction of the applied stress. The ratio of decrease to elongation is the Poisson ratio. Under test pressure, piping materials will expand slightly in diameter and contract in length slightly according to the Poisson ratio of the material.

6. Apparatus and Equipment for Hydrostatic Procedures

6.1 *General*—Components such as caps, valves, blind flanges, manual or automatic air release devices, vents, and other devices that are used to isolate the test section from other parts of the system, to purge air from the system, and to isolate components that are not to be subjected to test pressure are generally needed.

6.1.1 Test section isolation and closure components are to be rated for pressures equal to or greater than the test pressure applied to the test section.

6.1.2 Although section isolation and closure components may only be connected to the test section for the duration of the test, the joint between the test section and a closure or isolation component should be at least as strong as joints in the test section. Additional restraint may be required.

6.1.3 Air release devices should be located at all high points along the test section.

6.1.4 Excessively worn or deteriorated equipment is unsuitable and is not to be used.

6.2 *Test Liquid*—An adequate supply of a safe test liquid, such as water, is necessary. The test liquid should be of appropriate safety and quality so that the environment, system, test equipment, and disposal (if necessary) are not adversely affected.

6.2.1 Where an existing water supply is used to supply test water, protect the existing water supply from backflow contamination in accordance with local codes or as required by the authority having jurisdiction. Remove backflow protection and isolate the test section from the existing water supply before testing.

6.2.2 Excluding retesting (if necessary), the quantity of liquid needed to fill the internal volume of the pipe test section and accommodate test section expansion and possible leakage at non-fusion joints and seals is estimated using:

$$V_{gal} = 1.015 \times 0.04 \times (ID_{in.})^2 \times L_{ft} \quad (1)$$

$$V_{m^3} = 1.015 \times 0.785 \times 10^{-6} \times (ID_{mm})^2 \times L_m$$

where:

V_{gal} = pipe section volume, U.S. gal,
$ID_{in.}$ = pipe inside diameter, in.,
L_{ft} = test section length, ft,
V_{m^3} = pipe section volume, m^3,
ID_{mm} = pipe inside diameter, mm, and
L_m = test section length, m.

6.3 *Filling and Pressurizing Equipment*—Liquid filling and pressurizing equipment such as pumps, and pressure regulating devices will usually be necessary. Filling equipment should be capable of filling the test section in a reasonable time against any elevation head pressure that may be present. Pressurizing equipment should be able to maintain the necessary test pressure in the test section and provide sufficient quantities of make-up test liquid for the duration of the test. Pressure regulating equipment should be capable of maintaining test pressure for the duration of the test.

6.3.1 Filling equipment and pressurizing equipment do not need to be the same equipment.

6.4 *Pressure Monitoring*—Use at least one calibrated pressure gage or sensor accurate to within two percent (2 %) of full scale. It is preferred that the gage or sensor full scale value not be more than twice the test pressure, and that scale graduations be no greater than two percent (2 %) of the full scale value. Using a valved tee, a gage cock for bleeding, a pressure snubber, and a duplicate, back-up pressure gage are recommended. A continuous pressure-recording device may be required.

6.4.1 Locate the test pressure gage or sensor to monitor test pressure at the lowest point in the test section. Pressure may be monitored at other points in the test section as well.

NOTE 3—Test pressure is a combination of pump pressure and the height (head) of liquid in the pipeline. Therefore, test pressure is always monitored at the lowest elevation point in the section where pressure is highest. Test pressure will be lower at higher points in the section. If a minimum test pressure at higher elevations must also be met, select test sections so that the minimum test pressure is met at the higher elevation, but do not increase test pressure at the lowest point. Excessive test pressure can cause damage or pipeline failure.

6.5 Other equipment to connect the pump(s) to the test section and the test liquid supply, control the flow of test liquid, power the pump(s), connect the pressure gage(s) or sensor(s) to the test section, monitor pressure, and drain or purge the test liquid from the test section may also be necessary.

7. Specific Safety Precautions

7.1 This specific safety information is in addition to the safety information in other sections of this practice.

7.2 Always take precautions to eliminate hazards to persons near lines being tested. For the entire duration of the procedure, including filling, initial pressurization, time at test pressure, and depressurization, only persons conducting the test or inspecting the system being tested should be allowed near the section under test. These persons should be fully informed of the hazards of field pressure testing. All other persons should be kept a safe distance away.

7.3 The test section is to be supervised at all times during pressure testing.

7.4 Failure may result in sudden, violent, uncontrolled, and dangerous movement of system piping, or components, or parts of components.

7.5 *Restraint Against Movement*—Take measures to ensure that all parts of the section under test are restrained against movement if failure occurs. Such measures may include backfilling, anchoring, or other appropriate means.

7.5.1 *Partial Backfilling During Testing*—When underground connections, joints, and seals are to be exposed for observation during the test, use sufficient backfill material placed between the joints, and over the pipe to prevent movement, giving due consideration to restraining thrust forces. In particular, pipes connected to restrained joints that

Copyright by ASTM Int'l (all rights reserved); Mon Jun 11 11:42:54 EDT 2018
Downloaded/printed by
Jana Purmalis (BGC Engineering) pursuant to License Agreement. No further reproductions authorized.

derive their stability from the interaction of the pipe and soil are to be backfilled prior to testing.

7.6 Leakage usually occurs at a connection, joint, or seal in the system. Depending upon the type of connection, joint, or seal, leakage may be seepage, spray, or a stream of internal test liquid.

7.6.1 When properly made, heat fusion joints in polyethylene pipe are as strong as the pipe and do not leak. Leakage at a fusion joint indicates a faulty joint that may rupture completely at any time. If leakage is observed at a fusion joint, move away immediately, and depressurize the test section.

8. Pre-Test Preparation and Set-Up

8.1 *General:*

8.1.1 Before testing, heat fusion joints are to be completely cooled. Mechanical joints are to be completely assembled with all necessary seals and all fasteners installed and tightened.

8.1.2 Flushing, pigging, or other means of cleaning the system to remove dirt and debris that may damage valves, regulators, and so forth, may be required before testing.

8.1.3 Allow concrete supports and anchors in the test section to cure until they have developed sufficient strength to withstand test pressure thrust forces.

8.1.4 Restrain all parts of the test section against movement in the event of failure. Temporarily remove, restrain, or isolate expansion joints and expansion compensators before starting.

8.2 *Test Section*—Testing may be conducted on the entire system, or on sections of the system. Test section size is determined by the capacity of the filling and pressurizing equipment. It is necessary to fill, pressurize, and test the section within the allotted overall time for the test. Equipment that has inadequate capacity may not be able to complete the test within allowable testing time limits. If so, use higher capacity test equipment, or test a smaller (shorter) section of the system.

8.3 *Test Temperature*—Polyethylene and crosslinked polyethylene piping materials are typically pressure rated at 73°F (23°C). At higher temperatures, reduced pressure ratings and test pressures may be required. Contact pipe, fitting, or component manufacturers for assistance with elevated temperature pressure ratings.

8.4 *Maximum Test Pressure*—Maximum test pressure is designated by the authority having jurisdiction in accordance with 8.4.1 – 8.4.4.

8.4.1 The maximum test pressure for pressure-rated polyethylene or crosslinked polyethylene piping is not to exceed 1.5 × the system design pressure where lower pressure-rated components or devices are not present, or have been removed or isolated from the test section.

8.4.2 The maximum test pressure is not to exceed the pressure rating of the lowest pressure-rated component in the test section, where lower pressure-rated components or devices cannot be removed or isolated from the test section. Consult the component manufacturer for pressure ratings.

NOTE 4—Lower pressure-rated components or devices may include components or devices such as pipe or fittings made from other plastics or metals, or appurtenances such as valves, hydrants, regulators, pressure relief devices, or the like, or some types of mechanical connections such as lower pressure-rated compression couplings or flanges with lower pressure-rated back-up rings.

8.4.3 Do not use higher test pressure even though some components in the test section may have a higher pressure rating.

8.4.4 To determine the maximum test pressure at elevated temperature, apply an elevated temperature system design pressure reduction per 8.3.

8.5 *Test Duration*—Test duration is limited for safety reasons and to prevent damage to the system. Per 7.2 and 7.3, access to systems under test is controlled for the duration of the test.

8.5.1 When the maximum test pressure is between system design pressure and 1.5 × the system design pressure or at 1.5 × the system design pressure, total testing time including the time required to pressurize, stabilize, hold test pressure, and depressurize should not exceed 8 h.

8.5.1.1 If retesting is necessary, the test section should be depressurized for 8 h prior to retesting.

8.5.2 When the maximum test pressure is the system design pressure or less, the total test time including time required to pressurize, stabilize, hold test pressure, and depressurize should be limited to a practical time period. See 7.2 and 7.3. (A test time of about 72 h or less is suggested.)

8.5.3 Before pressure is applied, examine test equipment and all connections to and in the test section to ensure that all are in proper operating condition and tightly connected.

8.5.4 Before pressure is applied, isolated components or devices are to be vented to atmosphere.

8.5.5 Before pressure is applied, disconnect or isolate and vent all low pressure filling lines and other low pressure items.

9. Hydrostatic Test Procedure

9.1 Use appropriate apparatus per Section 6, and water or an appropriate test liquid per 6.2.

9.2 Observe all safety precautions and specific safety precautions per Section 7.

9.3 Prepare and set-up the test section for hydrostatic pressure leak testing per Section 8.

9.4 *Filling*—Fill the test section slowly. Purge all air. Take all appropriate precautions to ensure that no air is trapped in the test section. (**Warning**—Entrapped air can result in an explosive, violent, and dangerous catastrophic failure because both the pressure stress on piping and the energy used to compress the entrapped air are released.)

9.4.1 To allow air to escape from the test section, flow velocities during filling should not exceed the capacities of air release devices or other openings used to release entrapped air. To avoid or limit transient pressure surges, the filling flow velocity should not exceed the design velocity of the piping system.

9.5 *Temperature Equalization*—Allow the test section and the test liquid to equalize to a common temperature.

9.6 *Pressurizing—Initial Expansion Phase*—When the test section is completely filled and purged of air, gradually increase pressure in the test section to the required test pressure.

9.6.1 If the test pressure cannot be attained, or if it takes an unreasonably long time to reach test pressure, there may be faults such as excessive leakage, entrapped air, or open valving, or the pressurizing equipment may be inadequate for the size of the test section. If such faults exist, discontinue pressurizing, and correct them before continuing.

9.6.2 Add make-up water as necessary to maintain maximum test pressure for 4 h.

9.7 *Test Phase*—Reduce test pressure by 10 psi (69.0 kPa) and monitor pressure for 1 h. Do not increase pressure or add make-up water.

9.8 *Pass/Fail Criteria*—If no visual leakage is observed, and pressure during the test phase remains steady (within 5 % of the test phase pressure) for the 1 h test phase period, a passing test is indicated.

9.9 *Retesting*—If retesting is necessary, depressurize the test section per 9.10 and correct any faults or leaks in the test section. Do not attempt to correct faults or fix leaks while the test section is under pressure.

9.9.1 When maximum test pressure is between system design pressure and 1.5 × system design pressure or at 1.5 × the system design pressure, allow the test section to "relax" for at least 8 h before re-pressurizing. After the relaxation period, repeat the initial expansion and test phases per 9.6 and 9.7.

9.10 *Depressurization*—Depressurize the test section by reducing pressure or releasing test liquid at a controlled rate. Sudden depressurization can cause water hammer.

9.11 *After the Test*—Remove temporary closure and isolation devices from the test section. Depending upon the application, flushing, disinfecting, or draining may be necessary. Regulations and codes may restrict or require specific procedures for some post-test procedures such as test liquid draining and disposal.

10. Test Records

10.1 Information about the leak test may need to be recorded if required by the authority having jurisdiction. Documentation may include the following information:

10.1.1 The test liquid.

10.1.1.1 Backflow prevention devices, if used.

10.1.2 The weather conditions and ambient temperature at the site during the test.

10.1.3 The test pressure.

10.1.3.1 The type of test gages in the test section.

10.1.3.2 The placement of test gages in the test section, such as test gage location distances and elevations from the beginning of the section.

10.1.3.3 Test gage calibration records.

10.1.3.4 Test pressures recorded during the test.

10.1.3.5 Any adjustments made to test pressure for elevated temperature.

10.1.4 The test duration.

10.1.5 A description of the test section length, elevations, and site location.

10.1.6 A description of the test section components.

10.1.7 Description of any leaks or failures and the corrective actions taken.

10.1.8 The date and time of day of the test.

10.1.9 The identification of the party conducting the test.

11. Keywords

11.1 crosslinked polyethylene; field leak test; hydrostatic leak test; leak test; polyethylene pipe

SUMMARY OF CHANGES

Committee F17 has identified the location of selected changes to this standard since the last issue (F2164–10$^{\varepsilon 1}$) that may impact the use of this standard.

(1) Title was revised.
(2) 1.1 was revised.
(3) 5.1 was revised.
(4) 5.5 was revised.
(5) 8.3 was revised.
(6) 8.4.1 was revised.
(7) Section 11 was revised.

ASTM International takes no position respecting the validity of any patent rights asserted in connection with any item mentioned in this standard. Users of this standard are expressly advised that determination of the validity of any such patent rights, and the risk of infringement of such rights, are entirely their own responsibility.

This standard is subject to revision at any time by the responsible technical committee and must be reviewed every five years and if not revised, either reapproved or withdrawn. Your comments are invited either for revision of this standard or for additional standards and should be addressed to ASTM International Headquarters. Your comments will receive careful consideration at a meeting of the responsible technical committee, which you may attend. If you feel that your comments have not received a fair hearing you should make your views known to the ASTM Committee on Standards, at the address shown below.

Re: Material 7 Test Fill 01

1.0 INTRODUCTION AND OBJECTIVE

On June 30, 2018 BGC developed and oversaw a test fill to evaluate the engineering properties of Material 7 – Compacted Rockfill for use in the embankment construction. The rockfill was generated from the ADR excavation mostly from ripping and blasting bedrock.

2.0 TEST FILL CONSTRUCTION AND EXECUTION

The test fill was performed on June 30, 2018. BGC's representative, Roy Morlan, developed the test fill and was present during the test fills execution. Material 7 – Rockfill was placed in 0.9m loose lifts. The test fills were constructed and survey control was provided by Pelly Construction. Material sampling and testing was performed by Tetra Tech. Water replacement density testing was overseen by BGC. The following sections discuss the execution of the test fill.

2.1. Test Fill Materials and Borrow Description

The rockfill used in the test fill was generated by Pelly construction as borrow from excavation of the ADR plant foundation. Gradation testing was performed on the finer (3" minus) fraction of the material by Tetra Tech. Mid-fraction material (3" to 8") was estimated by Tetra Tech by scalping this material from the 3" sample. Larger fraction (>8") was visually estimated. Moisture content for the finer fraction of material was analyzed by Tetra Tech. The results from this testing are included in ***Attachment 1***. The material generally consists of a well graded gravel and sand matrix with approximately 30% rocks greater than 8" and a maximum size of 23". Moisture content of the fine fraction was reported as 3.2 %.

The rock used in the test fill was derived from a mostly quartzite source, which is the predominant rock type at this borrow. The quartzite material properties are mostly fine grained, orange brown, some banding present, slightly weathered (W2), strong to very strong (R4 to R5), and hard (H3).

Although not used in the test fill, zones of a weaker phyllitic rock (potentially phyllite or phyllonite) are also present within this borrow. This material is platy, very fine grained (aphantic), micaceous, has a significant amount of graphite, is gray, slightly weathered (W2), with rock quality ranging from (R1 to R3), and varies from soft (H6) to moderate hard (H4). The general recommended approach will involve mixing the stronger quartzite rock with the weaker phyllitic rock to produce an acceptable material for embankment fill. Additional test fills will be necessary to evaluate rock fill with significant portions of phyllitic rock. Alternatively, the weaker phyllitic material could be sorted and used as Material 3 fill.

2.2. Test Fill Foundation

An area on top of the ADR Material 3 Stockpile was used as the test location because it was close to the source material and relatively traffic free (***Figure 1***). The test location was hard, dry and previously compacted by heavy equipment traffic. However, the location was not flat so a leveling pad was constructed for the test fill. The leveling pad was constructed with Material 7 rockfill placed in an approximately 0.5m lift and compacted using a CAT CS68 B vibratory compactor and 4 passes. (***Photo 1***). The final foundation was flat, dry, and dense. No deflection from roller passes was noted in the foundation after compaction.

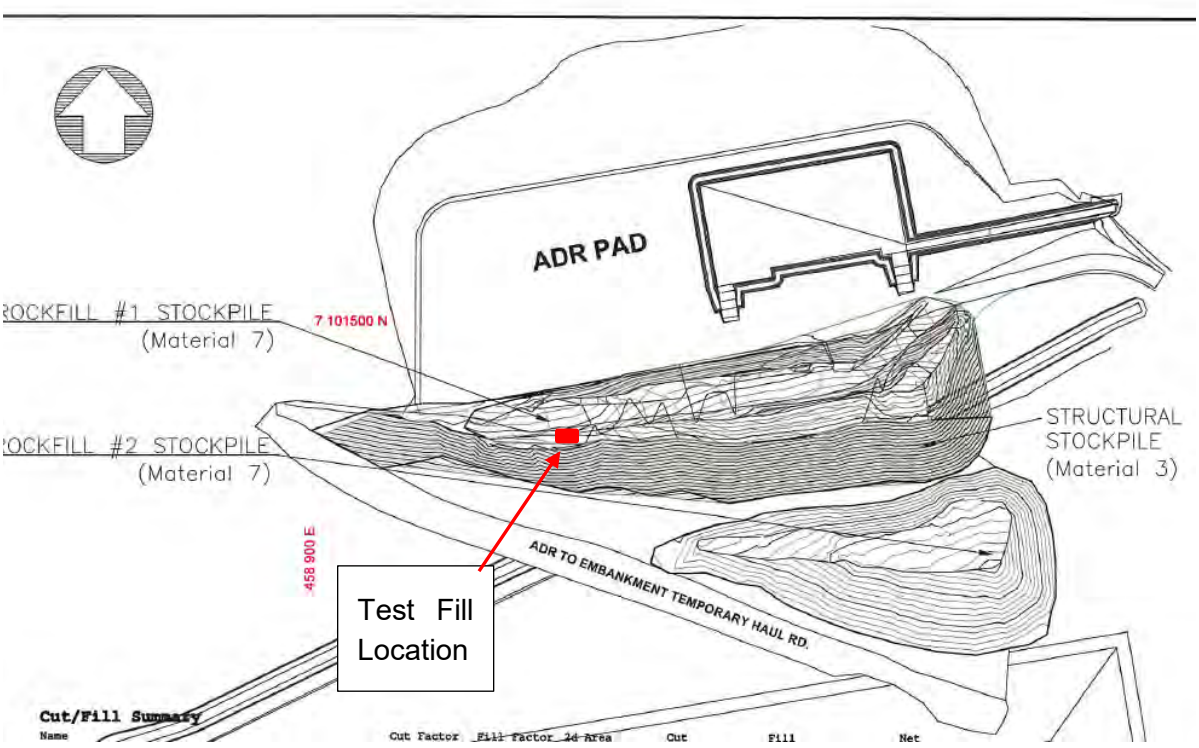

Figure 1: Test Fill Location

Photo 1: Construction of the test fill foundation leveling lift.

2.3. Test Fill Lift Placement

The test fill lift was placed by a Link Belt track mounted excavator directly from the stockpile. Material 7 – Test Fill 1 was placed in one 0.9 m loose lift. Lift thickness was measured by Pelly's surveyor using a mobile station. The test fill measured approximately 8m x 6m.

2.4. Moisture Conditioning

Moisture was not added to the material prior or during the test fill. However, moisture conditioning is generally encouraged during rock fill placement to facilitate compaction and will likely be necessary.

2.5. Compaction Testing and Settlement Surveying

To perform compaction tracking three steel plates were placed in a row down the center of the lift and used as a monitoring points (***Figure 2***). Initial survey of the settlement monitoring points was collected using a GPS surveying rod. The entire test fill surface was then compacted with one cycle (1 forward pass and 1 reverse pass) of a CAT CS68 B vibratory compactor with an effective

drum weight of 8,920 kg. After completion of one compaction cycle, settlement was measured at the settlement points. This compaction/survey procedure was repeated for 4 full compaction cycles.

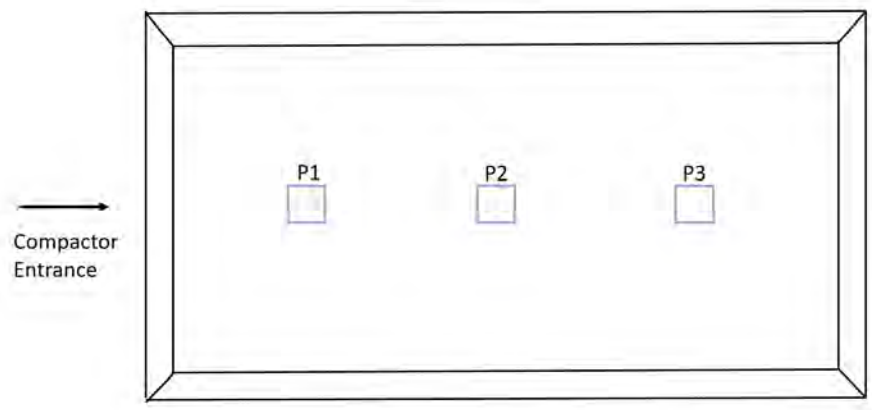

Figure 1**:** Approximation of test fill pad and survey points

Settlement data collected is included in ***Table 1***. A settlement graph is shown in ***Figure 3***.

	Pre-Compaction	Pass 1	Pass 2	Pass 3	Pass 4
Survey Point 1 (P1)	950.40 m	950.37 m	950.35 m	950.33 m	950.32 m
Survey Point 2 (P2)	950.55 m	950.46 m	950.46 m	950.43 m	950.43 m
Survey Point 3 (P3)	950.59 m	950.49 m	950.47 m	950.46 m	950.45 m

Table 1: Survey elevation data collected during settlement tracking.

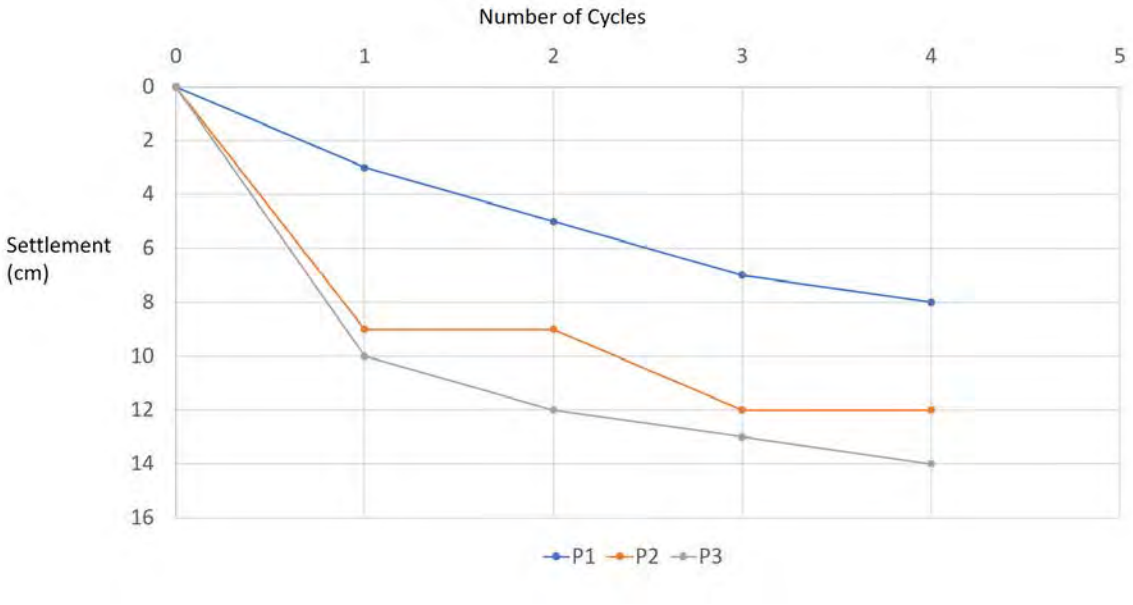

***Figure 3*:** Settlement recorded for each cycle.

2.6. In-situ Density and Moisture Testing

In-situ density and moisture collected by Tetra Tech

In-situ density and moisture testing was collected for reference by Tetra Tech using a nuclear density gauge. Results from nuclear density gauge testing on rockfill are known to be unreliable due to the presence of large, dense rocks and void spaces caused by displacement of rocks when hammering the steel rod. Therefore, these tests were performed for reference only. Water content was also analyzed by Tetra Tech in their field laboratory from a sample of the rockfill's finer material fraction (>3"). Density and moistures reported by Tetra Tech are included in ***Table 2***. Tetra Tech's data report for this testing is included in ***Attachment 1***.

	Dry Density (kg/m^3)	Moisture (%)
Nuclear Gage Test 1	2224	4.6
Nuclear Gage Test 2	2137	5.0
Standard Lab Testing	NA	3.2%

Table 2: Tetra Tech testing results

Water Replacement Test

A water replacement test was performed to determine the density of the compacted soil (***Photo 2 and 3***). A test pit was dug in the compacted lift. Material excavated from the pit was placed in three super sacks and weighed using Pelly's Terex Crane RT780 crane. The test pit was lined with 60 mil poly urethane liner and filled with water. The volume of water used was recorded and the density determined using the weight of the material excavated and the volume of the test pit.

The weight of the material was reported as 2,676 kg and volume of the test pit was determined to be 1.33 cubic meters. The density of the compacted rockfill was determined to be 2,012 kg/m^3 wet density and an estimated 1,965 kg/m^3 dry density assuming 70% rock smaller than 8".

Photo 2: Volume determination using water.

Photo 3: Super sacks with material excavated for the water replacement test.

2.7. Field Testing Observational

Little surface yield was observed in the lifts after the initial compaction pass. Excavations through the compacted material lifts revealed a well compacted, well graded matrix with little void space. Moisture within the lift was spread evenly. Rock was predominantly supported by the sandy gravel matrix. No material degradation or pulverization was observed. (***Photo 4***)

Photo 4: Compacted rockfill observed in the test fill trench cut.

3.0 CONCLUSIONS

The results of the test fill indicate that the rockfill produced from a mostly quartzite source at the ADR borrow can achieve sufficient compaction with a minimum of 4 cycles (1 forward and 1 reverse pass per cycle) of a minimum 9,000 kg compactor with vibration, and in lifts of up to 0.90m. These results were obtained with a stockpile moisture of 3.2% within the fill's fine fraction matrix.

BGC recommends that this criteria be used for placement and compaction of the rockfill within the embankment. If rock size and/or rock type, or general gradation varies significantly within this material an additional test fill will be required. If moisture content of the rockfill is below 3.2 % the Engineer may require additional moisture to be added before placement. Overly wet material may require the removal of moisture before placement. The Engineer will inspect the rockfill material during borrowing or placement to make these determinations.

As the rockfill generated from the ADR borrow area is variable due to the presence of weaker zones of phyllitic material, BGC recommends that the above criteria be used on rockfill produced from the zones of harder quartzite formations, which are more predominant at this borrow. Small zones of phyllitic material should be blended within the quartzite rockfill before use. Phyllitic material should not be allowed to be placed in a manner that would create lifts or zones within a lift composed of predominately weaker phyllitic material. Since these zones are more prone to material breakdown and develop a finer matrix they may be sorted and re-stockpiled for use as Material 3 – Structural Fill. A sperate test fill should be performed to determine if these phyllitic materials can be used as the predominant component of a Material 7 lift.

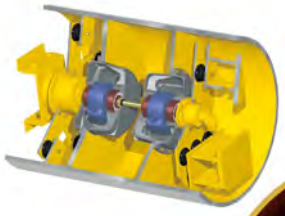
Smooth Drum
Vibratory Soil Compactors

Comfort to Operate with Confidence



- NEW • *Comfortable redesigned cab with best-in-class climate control, multi-position windows*
- NEW • *Control console and display are integrated with pivoting seat* (optional deluxe cloth seat available)*
- NEW • *Display provides instrumentation data and diagnostics at a glance**
- *Exceptional visibility to tires and drum edge*
- NEW – *Larger mirrors for enhanced rear visibility*
- NEW – *Narrower rear frame*
- NEW • *Optional light package upgrade provides four additional lights for excellent low light visibility*

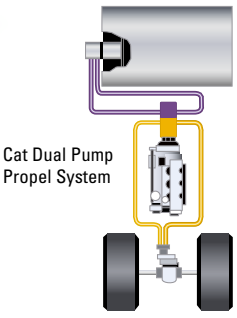
Do More

- NEW • *Exclusive Cat® dual pump propel system with electronic control† provides:*
  - *– Exceptional traction and gradeability*
  - *– Plenty of power for leveling blade*
- *Optional equipment:*
  - *– Leveling blade*
  - *– Oval pad or square pad shell kit*

Work Smarter with Optional Compaction Measurement Technology

- NEW • *Cat Compaction Control*
  - *– Factory installed, dealer supported; integrated with machine for better protection from theft, vandalism*
  - *– Two sensor options available:*
    - NEW *- Machine Drive Power (MDP): exclusive Cat technology, rolling resistance-based*
    - *- Compaction Meter Value (CMV), accelerometer-based*
  - *– Mapping/Positioning option*
    - *- SBAS GNSS; upgradeable to RTK*
    - *- Includes seperate display, GNSS antenna*

Cat® Pod-style Vibratory System



Cat Compaction Control with GNSS Mapping (SBAS)

Achieve Quality Compaction Faster

- *Enhanced compaction force*
- NEW – *More weight at the drum*
- NEW – *Best-in-class amplitude*
- NEW • *Enhanced propel system with electronic control for better performance†*
- NEW • *Standard technology automates functions that enable high quality and uniformity:*
  - *– Automatic Speed Control†*
  - *– Auto-vibe*

Best Value Available

- *Designed for easy maintenance, long service intervals*
- *High reliablity due to robust design*
- *Powerful and efficient engine*
  - *– Meets emissions standards where applicable*
  - NEW *– Reduces fuel burn when Eco-mode is used*
  - *– Self-monitors and alerts operator to abnormal engine performance*
- *Highest resale value in the industry*

Re: Material 3 Test Fill 01 and 02

1.0 INTRODUCTION AND OBJECTIVE

On July 27, 2018 BGC developed and oversaw two test fills to evaluate the engineering properties of Material 3 – Structural Fill for use in the embankment construction. The material was generated from the ADR excavation.

2.0 TEST FILL CONSTRUCTION AND EXECUTION

BGC's representative, Roy Morlan, developed the test fills and was present during the execution. Two tests were conducted using Material 3 – Structural Fill. The test fills were constructed and surveyed by Pelly Construction. Material sampling and testing was performed by Tetra Tech. The following sections discuss the execution of the test fill.

2.1. Test Fill Materials and Borrow Description

The material used in the test fills was generated by Pelly as borrow from excavation of the ADR plant foundation and the area labeled as ADR West. Gradation testing was performed on the finer (3" minus) fraction of the material by Tetra Tech. Mid-fraction material (3" to 8") was estimated by Tetra Tech by scalping this material from the 3" sample. Moisture content for the finer fraction of material was analyzed by Tetra Tech. The results from this testing are included in ***Attachment 1***. The material generally consists of a well graded gravel and sand matrix with approximately 15% rock between 3" and 8". Moisture content was measured at approximately 5%. (***Photograph 1***)

Photograph 1: Photograph of loose material used in both test fills.

The 3” to 8” rocks in the test fill material were mostly quartzite, which is the predominant rock type at this borrow. The quartzite material properties are mostly fine grained, orange brown, some banding present, slightly weathered (W2), strong to very strong (R4 to R5), and hard (H3). Rocks were resistant to scratching and broke after several blows with a hammer (***Photograph 2***).

Photograph 2: Example of material between 3” and 8”.

Phyllitic material is present in the Material 3 mixture. The phyllitic material content is approximately 20 to 30% and mostly present in particle sizes less than 0.5”. This material is platy, very fine grained (aphanitic), micaceous, has a significant amount of graphite, is gray, slightly weathered (W2), with rock quality ranging from (R1 to R3), and varies from soft (H6) to moderate hard (H4).

2.2. Test Fill Foundation

An area on top of the ADR Material 3 Stockpile was used as the test location because it was close to the source material and relatively traffic free (***Figure 1***). The test location was hard, dry and previously compacted by heavy equipment traffic. No deflection from roller passes was noted in the foundation.

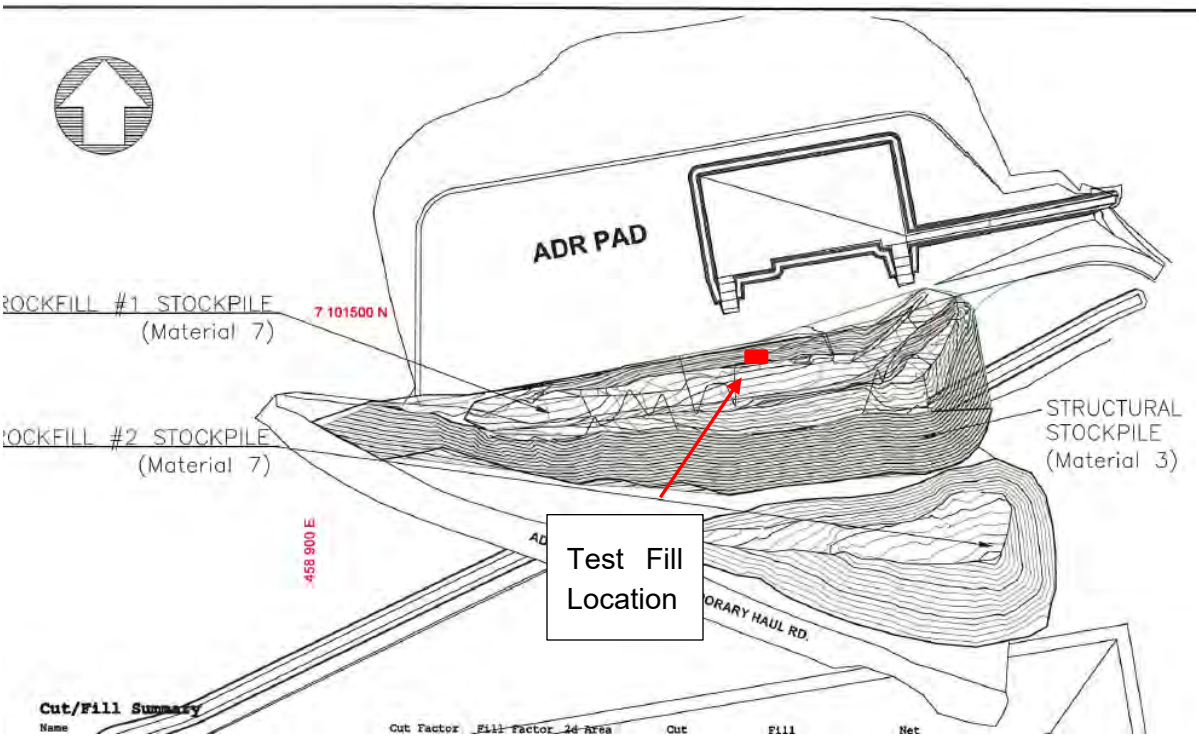

Figure 1: Test Fill Location

2.3. Test Fill Lift Placement and Compaction

Both test fills were constructed by pushing the material from the stockpile to the prepared foundation using a CAT D7 track mounted dozer. For Test Fill 01 material was placed in a 0.5m loose lifts. For Test Fill 02 material was placed in a 0.75 m loose lift. Lift thickness was measured by Pelly's surveyor using a mobile station. The test fill measured approximately 8m x 6m.

2.4. Moisture Conditioning

Moisture was not added to Test Fill 01 or Test Fill 02.

2.5. Test Fill 01 Compaction and Settlement Measurements

To perform compaction tracking three steel plates were placed in a row down the center of the lift and used as a monitoring points (***Figure 2***). Initial survey of the settlement monitoring points was collected using a GPS surveying rod. Test fill surfaces were compacted with one cycle (1 forward pass and 1 reverse pass) of a CAT CS78 B vibratory compactor with an effective drum weight of 13,440 kg. After completion of one compaction cycle, settlement was measured at the settlement points. This compaction/survey procedure was repeated for 3 full compaction cycles for Test Fill 01 and 4 full cycles for Test Fill 2. Specifications for the CAT CS78 B compactor are included in ***Attachment 1***.

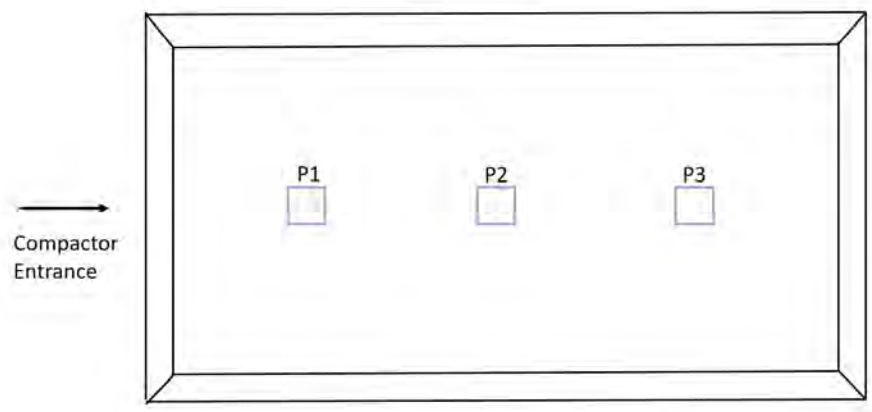

Figure 2**:** Approximation of test fill pad and survey points

Settlement data collected is included in ***Table 1***. Settlement graphs are shown in ***Figure 3 and 4***.

	Pre-Compaction (m)	Pass 1 (m)	Pass 2 (m)	Pass 3 (m)	Pass 4 (m)
Test Fill 01					
Survey Point 1 (P1)	948.80	948.79	948.76	948.75	NA
Survey Point 2 (P2)	948.80	948.79	948.75	948.74	NA

Table 1: Survey elevation data collected during settlement tracking.

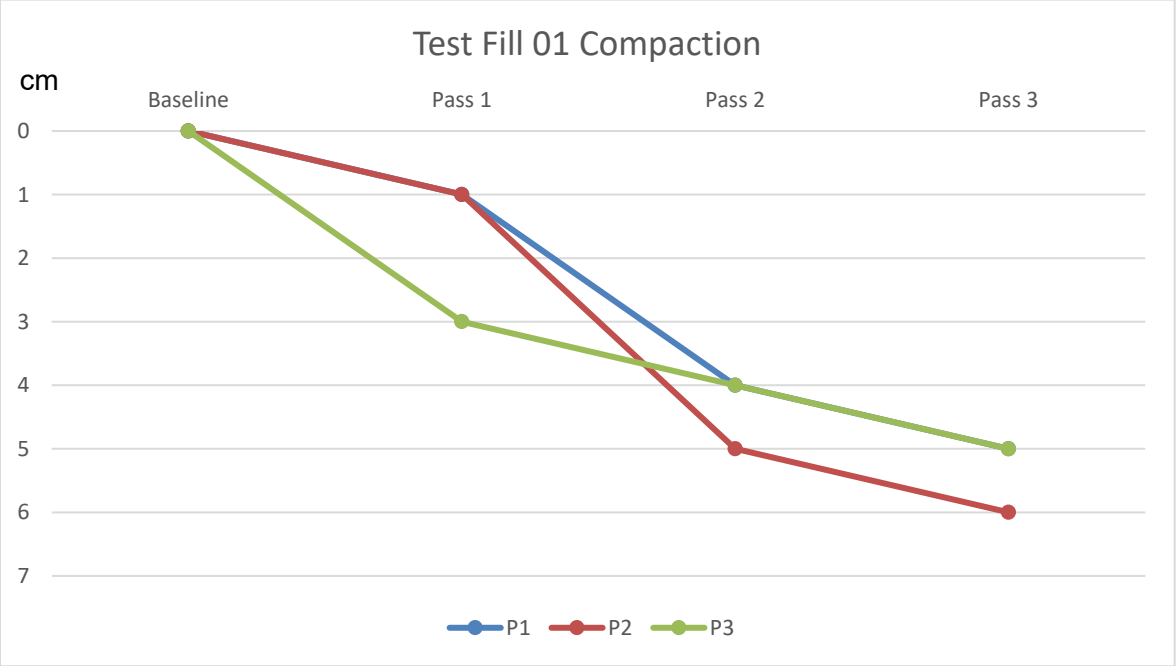

Figure 3: Test Fill 01 settlement recorded for each cycle.

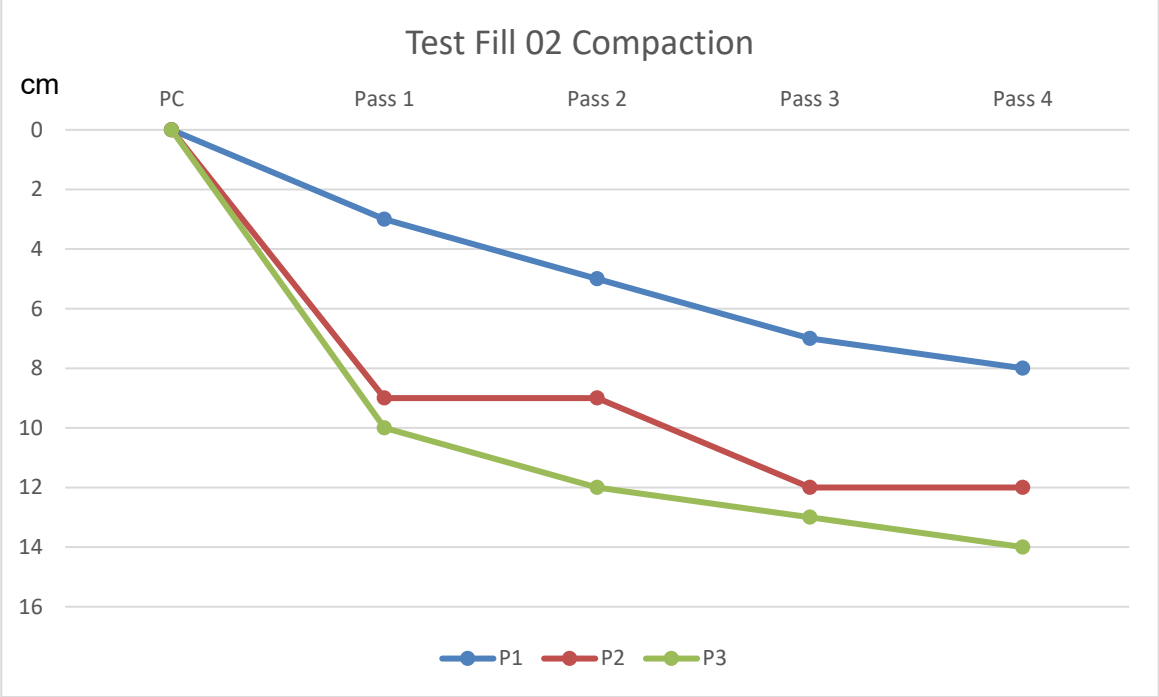

Figure 4: Test Fill 02 settlement recorded for each cycle.

2.5.1. In-situ Density and Moisture Testing

In-situ density and moisture testing was collected by Tetra Tech using a nuclear density gauge. Results were compared to the proctor for this material performed by Tetra Tech. The sample was scalped at material greater than 3". A rock correction was applied to the results by Tetra Tech. Optimum moisture was reported as 6.5% and density at this moisture was reported as 2,270 kg/m^3. Density and moistures reported by Tetra Tech are included in ***Table 2***. Tetra Tech's data report for this testing is included in ***Attachment 1***.

	Depth (cm)	Dry Density (kg/m^3)	Moisture (%)
Test Fill 01			
Test 1 (uncompacted)	30	2037	5.3
Test 2 (1 pass cycle)	30	2235	6.0
Test 3 (2 pass cycles)	30	2286	5.6
Test 4 (3 pass cycles)	30	2281	5.9
Test Fill 02			
Test 1 (uncompacted)	30	2,015	5.0
Test 2 (1 pass cycle)	30	2,160	5.4
Test 3 (2 pass cycles)	30	2,272	5.4
Test 4 (3 pass cycles)	30	2,271	5.2
Test 5 (4 pass cycles)	30	2,236	5.1
Test 6 (4 pass cycles)	70	1,812	5.3

Table 2: Tetra Tech nuclear density gauge testing results

2.5.2. Field Testing Observations

Some surface yield was observed in both test fills after the initial compaction pass. Excavations through each compacted test fill revealed a well compacted, well graded matrix with little void space. Moisture within the lift was spread evenly. Rock was predominantly supported by the sandy gravel matrix. No material degradation or pulverization was observed. A trench was photograph of Test Fill 01 is included as ***Photo 3***. A trench wall photograph of Test Fill 02 is included as ***Photo 4***.

Photo 3: Trench wall photograph from Test Fill 01.

Photo 04: Trench wall photograph from Test Fill 02.

3.0 CONCLUSIONS

The results of the test fills indicate that the Material 3 tested can achieve sufficient densities with a minimum of 2 passes of a minimum 13,000 kg compactor with vibration, and in lifts of up to 0.50m. These results were obtained with an average moisture of approximately 5.7%. Test Fill 02 did not achieve sufficient compaction below 0.5m even after 4 passes.

BGC recommends that the following criteria be used for placement and compaction of the Material 3 within the embankment:

- A maximum loose lift thickness of 0.45m should be used.
- Moisture content should be maintained between 5% and 7%. This will likely require moisture conditioning at the stockpile during loading for placement.
- Gradation of the material should not vary significantly from the material used in this test fill. If gradation varies significantly additional testing may be required.

- A minimum of two pass cycles (1 forward pass and 1 back pass per cycle) using a 13,000 kg vibrating compactor should be used. Use of lighter compactors should be approved by the Engineer and may require additional testing.
- Material should be sourced from a stockpile approved by the Engineer.
- QC should be performed by tracking and reporting the above. In-situ QC testing using a nuclear density gauge should also be performed. Testing should report density and moisture. A minimum of 6 tests per compacted lift should be performed. The amount of test can be reduced by the engineer after observing placement and compaction of the first several lifts and all criteria appear consistent. The average of the tests should determine to either pass or fail: 95% of 2,270 kg/m^3; moisture between 5% and 7%.

If general gradation or material composition (quartzite content) varies significantly within this material an additional test fill will be required. If moisture content of the rockfill is below 5 % the Engineer may reject the material until it is moisture conditioned. Overly wet samples may require the removal of moisture before placement. The Engineer will inspect the material during borrowing or placement and review QC reports to make these determinations.

BGC recommends that the above criteria be used on material produced from the zones of harder quartzite formations, which are more predominant at this borrow. Small zones of phyllitic material should be blended within the quartzite before use. Phyllitic rich material (25% to 100% phyllitic material) should be used on the upstream side of the lift. Phyllitic rich material should not constitute an entire lift or along the downstream face of the embankment.

Re: Material 7 Test Fill 02

1.0 INTRODUCTION AND OBJECTIVE

On November 5, 2018 BGC developed and oversaw a test fill to evaluate the engineering properties of Material 7 – Compacted Rockfill for use in the embankment construction. The rockfill was generated from the required excavation of the Event Pond and from blasted rock at the ADR West borrow.

2.0 TEST FILL CONSTRUCTION AND EXECUTION

The test fill was performed on November 5, 2018. BGC's representative, Troy Meyer developed the test fill and was present during the test fills execution. Material 7 – Rockfill was placed in a 0.9m loose lifts. The test fills were constructed and survey control was provided by Pelly Construction. Material sampling and testing was performed by Tetra Tech. Field density testing was overseen by BGC. The following sections discuss the execution of the test fill.

2.1. Test Fill Materials and Borrow Description

Two separate sources of rockfill were used in two separate test fills. The material referred to as "ADR Blast Rock" was generated by Pelly construction as borrow from blasting and excavation at the borrow located west of the ADR plant. he material referred to as "Event Pond Cut" was generated by Pelly construction from required excavations at the eastern end of the event pond.

The material generally consists of quartzite rock with low to moderate strength and a maximum size of 60 cm. The quartzite material properties are mostly fine grained, orange brown, some banding present, slightly weathered (W2), strong to very strong (R4 to R5), and hard (H3).

The ADR Blast Rock contains a higher percentage of large rock than the Event Pond Cut material, which is more well-graded with a gravel and sand matrix. Both materials classify as Material 7 – Rockfill having more than 30 percent particles larger than 19. Moisture content of the minus 6-inch fraction was reported as 3.2 % for ADR Blast Rock and 4.6 % for Event Pond Cut.

Although not used in the test fill, zones of a weaker phyllitic rock (potentially phyllite or phyllonite) are also present within each source area. This material is platy, very fine grained (aphantic), micaceous, has a significant amount of graphite, is gray, slightly weathered (W2), with rock quality ranging from (R1 to R3), and varies from soft (H6) to moderate hard (H4).

2.2. Test Fill Foundation

An area on top of the south Event Pond embankment crest was used as the test location. ***Figure 1*** shows the locations of the test pad and the borrow areas. The test location was frozen, hard and previously compacted by heavy equipment traffic. ***Photo 1*** shows initial placement of fill on the test pad.

Photograph 1: ADR Blast Rock Test fill construction.

Figure 1: Test Fill and Borrow Locations

Photograph 3: Event Pond Cut material as delivered.

2.3. Test Fill Lift Placement

The test fill lift was placed by dumping and spreading with a GPS enabled D6 dozer. Both test fills were placed in one 0.9 m loose lift. Lift thickness was controlled by the Dozer and spot checked by Pelly's surveyor using a mobile station. Each test fill measured approximately 8m x 10m.

2.4. Moisture Conditioning and Temperature

Moisture was not added to the material prior or during the test fill. The ambient air temperature was -19 deg C. The delivered material temperature was measured with a thermal gun:

- ADR Blast Rock +10 deg C
- Event Pond Cut +4 deg C

The temperature of both materials reduced to -5 to -10 deg C at the time of compaction.

2.5. Compaction Testing and Settlement Surveying

To perform compaction tracking three steel plates were placed in a row down the center of the lift and used as a monitoring points (***Figure 2***). Initial survey of the settlement monitoring points was collected using a GPS surveying rod. The entire test fill surface was then compacted with one cycle (1 forward pass and 1 reverse pass) of a CAT CS68 B vibratory compactor with an effective drum weight of 9,150 kg. After completion of one compaction cycle, settlement was measured at the settlement points. This compaction/survey procedure was repeated for 4 full compaction cycles.

A loaded CAT777 haul truck was also used for compaction on adjacent sections of the test pads. The truck was trafficked at a slow speed over the plates and settlement measure by survey after each single pass.

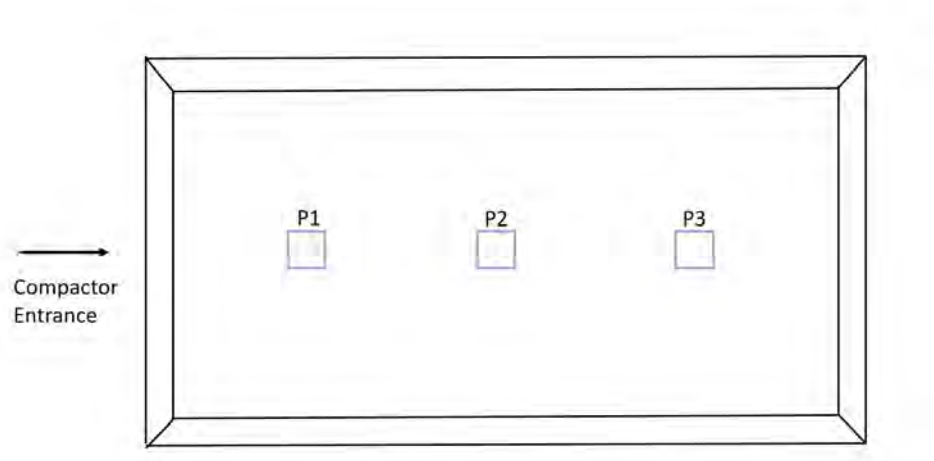

***Figure 2*:** Approximation of test fill pad and survey points

Settlement data collected is included in Table 1 through 4 and settlement graphs are shown as Figures 3 through 6.

Table 4: Survey Data for Event Pond Cut with Loaded Haul Truck.

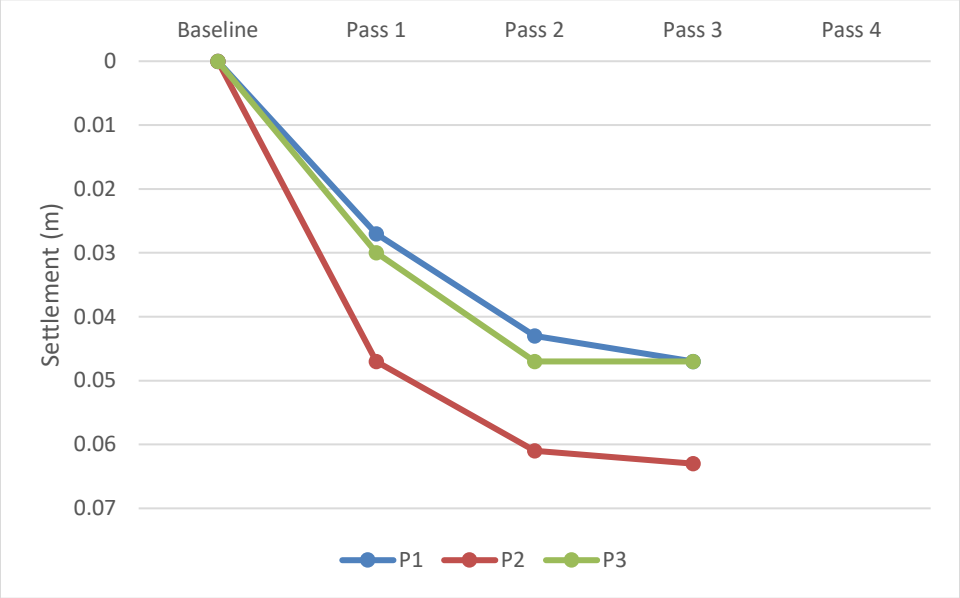

***Figure 6*:** Settlement for Event Pond Cut with Loaded Haul Truck.

2.6. In-situ Density and Moisture Testing

A volumetric test was performed to determine the density of the compacted soil (***Photo 4***). A test pit was dug in the compacted lift. Material excavated from the pit was placed in three super sacks and weighed using a digital scale suspended by a forklift. The test pit volume was determined from drone surveys by Underhill Surveyors.

Test Fill	Weight (kg)	Volume (m3)	Calculated Wet Density (kg/m3)	Estimated Moisture Content (%)	Calculated Dry Density (kg/m3)
ADR Blast Rock	2485	0.96	2588	3.2%	2508
Event Pond Cut	2766	1.1	2515	4.6%	2404

Table 5: Density data.

The dry density of the compacted rockfill was determined to be 2,508 kg/m^3 and 2,404 kg/m^3 for the ADR Blast Rock and Event Pond Cut material, respectively.

Photograph 5: Filling sacks for weighing.

3.0 CONCLUSIONS

The results of the test fill indicate that the rockfill produced from a mostly quartzite source at the ADR borrow and Event Pond cut can achieve sufficient densities with a minimum of 3 passes of a minimum 9,000 kg compactor with vibration, and in lifts of up to 0.90m. Alternatively, one pass with a loaded haul truck will provide adequate compaction. These results were obtained with a material moisture of under 6% within the fill's fine fraction matrix.

BGC recommends these criteria be used for placement and compaction of the rockfill within the Event Pond embankment. If rock size or general gradation varies significantly within this material an additional test fill will be required. If moisture content of the rockfill is above 6% the compaction may be inhibited by frost. Recommendations for placement of winter fills is provided in FM18-020 issued by BGC and dated October 27, 2018.

As the rockfill generated from both the ADR borrow area and Event Pond cut is variable due to the presence of weaker zones of phyllitic material, BGC recommends that the above criteria be used on rockfill produced from the zones of harder quartzite formations. Small zones of phyllitic material should be blended within the quartzite rockfill before use since these zones are more prone to material breakdown and frost. Phyllitic material should not be allowed to be placed in a manner that would create lifts or zones within a lift composed of predominately this material.

The Engineer will inspect the rockfill material during borrowing or placement to make these determinations. Quality control and assurance will be performed by BGC and Tetra Tech based on visual observations of material characteristics and proof rolling with loaded CAT777 trucks. Modifications to lift thickness may be recommended based on observations and additional field density tests may be required by the Engineer to verify compaction, as needed.

Cat®
CS68B

Smooth Drum
Vibratory Soil Compactor

Features:
The Cat® CS68B features a smooth drum and is ideally suited for granular soil applications:

- **Comfortable and ergonomic operator station** features pivoting seat with integrated multifunction LCD display and control console, outstanding visibility to the front and rear of machine, low sound levels and vibration for greater operator comfort and productivity.
- **World-class propel system** built around the exclusive Cat dual pump propel system, two pumps provide separate dedicated flow to drum drive motor and rear axle motor for exceptional gradeability and traction in forward and reverse. New electronic propel control enables more precise machine control.
- **Virtually maintenance free** due to maintenance-free hitch bearings and extended maintenance intervals for vibratory system and hydraulic system, providing more uptime and lower maintenance costs.
- **Enhanced compaction performance** due to more weight at the drum and greater amplitude. Automated propel and vibratory system functions make it easy to ensure consistent, high quality.
- **Optional Cat® Compaction Control** helps the operator determine when compaction has been completed to specification for greater productivity and uniform compaction quality.

Vibratory System Specifications

Frequency		
Standard	30.5 Hz	1830 vpm
During Eco-mode Operation	27.7 Hz	1664 vpm
Optional Variable Frequency	23.3-30.5 Hz	1400-1830 vpm
Nominal Amplitude @30.5 Hz (1830 vpm)		
High	2.1 mm	0.083 in
Low	0.98 mm	0.039 in
Centrifugal Force @ 30.5 Hz (1830 vpm)		
Maximum	301 kN	67,600 lb
Minimum	141 kN	31,670 lb
Static Linear Load		
w/ ROPS/FOPS Cab	42.9 kg/cm	240 lbs/in

Service Refill Capacities

Fuel Tank, total capacity	242 L	64 gal
Cooling System	27.8 L	7.3 gal
Engine Oil w/ Filter	11.6 L	3.1 gal
Eccentric Weight Housings	26 L	6.9 gal
Axle and Final Drives	18 L	4.8 gal
Hydraulic Tank (service refill)	50 L	13.2 gal

CS68B Vibratory Soil Compactor

Dimensions

1	Overall Length	6.05 m	19.8 ft
2	Overall Length w/ Optional Leveling Blade	6.55 m	21.5 ft
3	Overall Width	2.33 m	7.64 ft
4	Overall Width w/ Optional Leveling Blade	2.50 m	8.25 ft
5	Drum Width	2134 mm	84 in
6	Drum Shell Thickness	30 mm	1.18 in
7	Drum Diameter	1434 mm	56.5 in
8	Overall Height	3.11 m	10.2 ft
9	Wheelbase	2.9 m	9.5 ft
10	Ground Clearance	437 mm	17.2 in
11	Curb Clearance	489 mm	19.3 in
12	Optional Leveling Blade Height	688 mm	27.1 in
	Inside Turning Radius	3.68 m	12.07 ft
	Hitch Articulation Angle	34°	
	Hitch Oscillation Angle	15°	
	Optional Leveling Blade Height	688 mm	27.1 in

STANDARD EQUIPMENT *Varies by market- contact your Dealer for specifics.*

ELECTRICAL
- 24 volt Electrical System
- 100 ampere Alternator
- 750 Cold-cranking Amps Battery Capacity

OPERATOR ENVIRONMENT
- ROPS/FOPS Cab with Climate Control (Heat, Air Conditioning)
- Cloth Adjustable Pivoting Seat with Integrated Console and LCD Display, Seat Belt
- Multifunction LCD Display with gauges and/or audible warning alarm for: *Hydraulic oil temperature, Engine oil pressure, Engine coolant temperature, Alternator charge, Fuel level, Service hour meter, Engine RPM, Ground speed, Vibe frequency, Fuel rate, Air filter constriction, Engine load and Optional Cat Compaction Control*
- Adjustable Tilting Steering Column with Integrated Cup Holders
- 12-volt Power Outlet
- Floor Mat
- Interior Rear View Mirror
- Horn, Backup Alarm
- Radio-ready

POWER TRAIN
- Cat® C4.4 Diesel Engine
- Air Cleaner, Dual Element
- Three-speed Throttle Switch w/ Eco-mode, Automatic Speed Control
- Dual Propel Pumps; One for Drum Drive, One for Rear Axle
- Fuel Filter, Water Separator, Electronic Priming Pump, Water Indicator
- Tilting Radiator/Hydraulic Oil Cooler
- Dual Braking System
- Two-speed Hydrostatic Transmission

VIBRATORY SYSTEM
- Smooth Drum
- Dual Amplitude, Single Frequency
- Dual Pod-Style Eccentric Weight Housings
- Auto-vibe Function
- Front Adjustable Steel Scraper

OTHER
- Hydraulic Oil Level Sight Gauge
- Radiator Coolant Level Sight Gauge
- Cat® ToughGuard™ Hose
- S·O·S℠ Sampling Valves, Engine Oil and Hydraulic Oil

OPTIONAL EQUIPMENT
- Padfoot Shell Kit
- Leveling Blade
- Variable Vibration Frequency
- Beacon, Rotating
- Polyurethane Drum Scrapers
- Steel Rear-side Drum Scraper
- Bio-oil Factory Fill
- Sun Visor
- Deluxe High-back Air-ride Pivoting Seat
- Cat Compaction Control, Machine Drive Power or CMV
- SBAS GNSS Mapping for Cat Compaction Control (RTK available)
- Upgraded Halogen Light Package
- Cab Internal Rear View Mirrors
- Cab Internal Roll-down Sun Screen
- Product Link
- Additional Rear View Mirrors

Title: **FIELD CHECKLIST SUBSURFACE SIGN OFF**

Contractor: **PELLY CONSTRUCTION LTD**
Project: **EAGLE GOLD PROJECT**
Item: **4110.6.01**
Revised Item #: **Surface preparation**
Revision: **0**
Contract: **CC204**

Description: **Approval for Liner Surface Within In-Heap as per Activities and Criteria Outlined in ITP-010**

Details: **Stations Positioned East-West-Embankment Face From Top of 940 Bench Perpendicular to North Face of PLS Base. Stations are Positioned in 10m Increments in the Field. Stations to be Included in As-Built Drawings by Pelly.**

Machine Name	618 HF
Machine Model	618 HF
Piston Area	11.78 in²

Pipe Specifications

Pipe Material	PE4710
Pipe Size	6 " IPS
Wall Thickness	DR 17

Pressures

Drag Pressure	31 psi	
	Interfacial	Gauge
Bead Up	75 psi	80 psi
Heat Soak	0 psi	31 psi
Fuse/Cool	75 psi	80 psi

Fusion Specification

Fusion Type	Butt Fusion
Fusion Specification	ASTM F2620
Bead Time	0 seconds
Bead Size	3/16"
Heat/Soak Time	105 seconds
Fuse Time	257 seconds
Open/Close Time	10 seconds
Cool Time	0 seconds

	Minimum	Maximum
Bead Up	70 psi	89 psi
Heat Soak	0 psi	31 psi
Fuse	70 psi	89 psi
Cool	0 psi	0 psi

Machine Name	618 HF
Machine Model	618 HF
Piston Area	11.78 in²

Pipe Specifications

Pipe Material	PE4710
Pipe Size	6 " IPS
Wall Thickness	DR 17

Pressures

Drag Pressure	31 psi	
	Interfacial	Gauge
Bead Up	75 psi	80 psi
Heat Soak	0 psi	31 psi
Fuse/Cool	75 psi	80 psi

Fusion Specification

Fusion Type	Butt Fusion
Fusion Specification	ASTM F2620
Bead Time	0 seconds
Bead Size	3/16"
Heat/Soak Time	105 seconds
Fuse Time	257 seconds
Open/Close Time	10 seconds
Cool Time	0 seconds

	Minimum	Maximum
Bead Up	70 psi	89 psi
Heat Soak	0 psi	31 psi
Fuse	70 psi	89 psi
Cool	0 psi	0 psi

McElroy Joint Report

Reference Number 1041006

Job Details

Joint Number	61
Joint Time	2018-07-26 07:42:12 GMT
Job	1
Operator	jordan
Aborted Joint	No

Fusion Machine

Machine Name	618 HF
Machine Model	618 HF
Piston Area	11.78 in²

Pipe Specifications

Pipe Material	PE4710
Pipe Size	6 " IPS
Wall Thickness	DR 11

Pressures

Drag Pressure	32 psi	
	Interfacial	Gauge
Bead Up	75 psi	105 psi
Heat Soak	0 psi	32 psi
Fuse/Cool	75 psi	105 psi

Fusion Specification

Fusion Type	Butt Fusion
Fusion Specification	ASTM F2620
Bead Time	0 seconds
Bead Size	3/16"
Heat/Soak Time	162 seconds
Fuse Time	397 seconds
Open/Close Time	15 seconds
Cool Time	0 seconds

	Minimum	Maximum
Bead Up	90 psi	119 psi
Heat Soak	0 psi	32 psi
Fuse	90 psi	119 psi
Cool	0 psi	0 psi

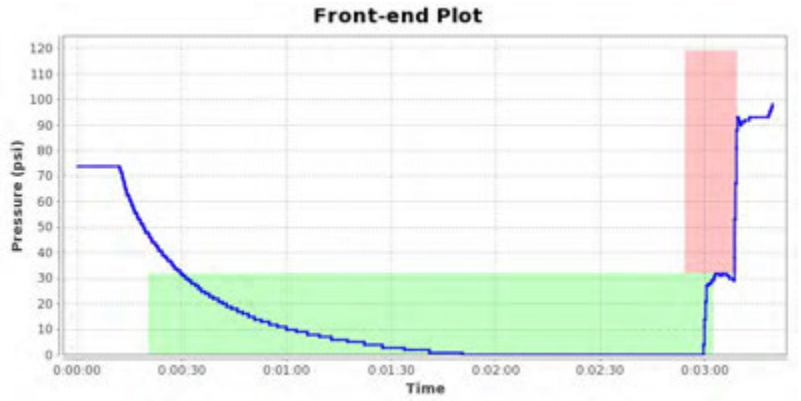
External Heater Temperatures

	Side A	Side B

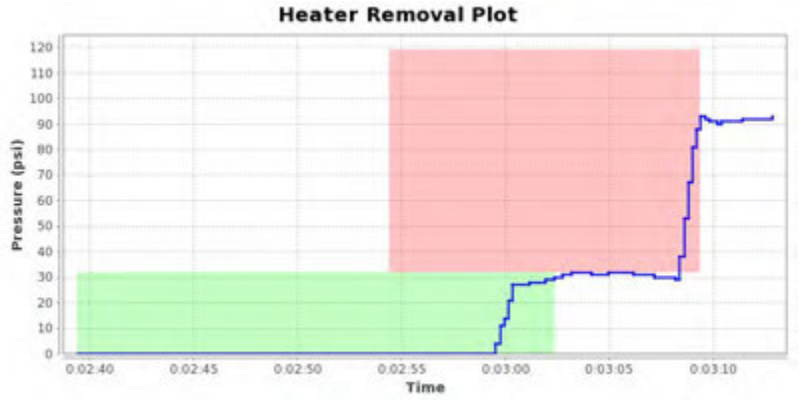
GPS Location

Date	Latitude	Longitude
2018-07-26 07:42:12.0	64°2'16.654800"N	135°49'45.282000"W

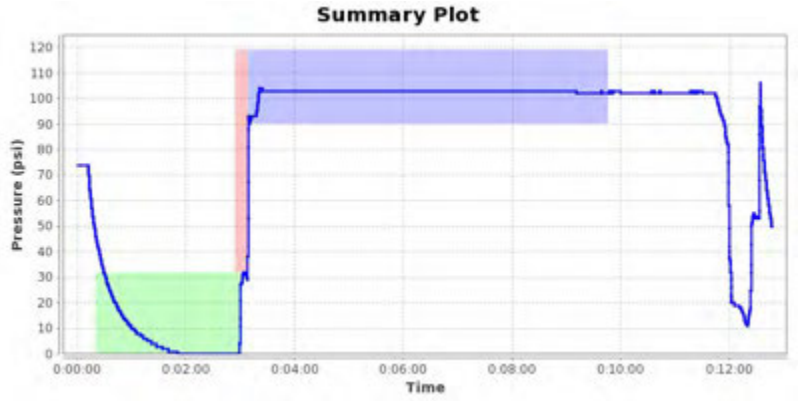
Logged Data Summary



Number of Data Points	520
Total Fusion Time	767 seconds
Maximum Recorded Pressure	106 psi



Device Information



DataLogger Serial Number	RH803Z0550
Sensor Serial Number	MDL6621
Calibration Date	2018-04-04
Firmware Version	v6.0
Software Version	1.08 (27)
Software Product Name	DataLogger 6

Data Source

Job	1
Operator	jordan
Aborted Joint	No

Fusion Machine

Machine Name	618 HF
Machine Model	618 HF
Piston Area	11.78 in²

Pipe Specifications

Pipe Material	PE4710
Pipe Size	6 " IPS
Wall Thickness	DR 11

Pressures

Drag Pressure	23 psi	
	Interfacial	Gauge
Bead Up	75 psi	96 psi
Heat Soak	0 psi	23 psi
Fuse/Cool	75 psi	96 psi

Fusion Specification

Fusion Type	Butt Fusion
Fusion Specification	ASTM F2620
Bead Time	0 seconds
Bead Size	3/16"
Heat/Soak Time	162 seconds
Fuse Time	397 seconds
Open/Close Time	15 seconds
Cool Time	0 seconds

	Minimum	Maximum
Bead Up	81 psi	110 psi
Heat Soak	0 psi	23 psi
Fuse	81 psi	110 psi
Cool	0 psi	0 psi

Joint Time	2018-08-04 11:52:31 GMT
Job	1
Operator	jordan
Aborted Joint	No

Fusion Machine

Machine Name	618 HF
Machine Model	618 HF
Piston Area	11.78 in²

Pipe Specifications

Pipe Material	PE4710
Pipe Size	6 " IPS
Wall Thickness	DR 11

Pressures

Drag Pressure	23 psi	
	Interfacial	Gauge
Bead Up	75 psi	96 psi
Heat Soak	0 psi	23 psi
Fuse/Cool	75 psi	96 psi

Fusion Specification

Fusion Type	Butt Fusion
Fusion Specification	ASTM F2620
Bead Time	0 seconds
Bead Size	3/16"
Heat/Soak Time	162 seconds
Fuse Time	397 seconds
Open/Close Time	15 seconds
Cool Time	0 seconds

	Minimum	Maximum
Bead Up	81 psi	110 psi
Heat Soak	0 psi	23 psi
Fuse	81 psi	110 psi
Cool	0 psi	0 psi

External Heater Temperatures

	Side A	Side B

GPS Location

McElroy Joint Report

Reference Number 1078027

Job Details

Joint Number	116
Joint Time	2018-08-11 10:29:10 GMT
Job	1
Operator	Rafel
Aborted Joint	No

Fusion Machine

Machine Name	618 HF
Machine Model	618 HF
Piston Area	11.78 in²

Pipe Specifications

Pipe Material	PE4710
Pipe Size	6 " IPS
Wall Thickness	DR 11

Pressures

Drag Pressure	57 psi	
	Interfacial	Gauge
Bead Up	75 psi	130 psi
Heat Soak	0 psi	57 psi
Fuse/Cool	75 psi	130 psi

Fusion Specification

Fusion Type	Butt Fusion
Fusion Specification	ASTM F2620
Bead Time	0 seconds
Bead Size	3/16"
Heat/Soak Time	162 seconds
Fuse Time	397 seconds
Open/Close Time	15 seconds
Cool Time	0 seconds

	Minimum	Maximum
Bead Up	115 psi	144 psi
Heat Soak	0 psi	57 psi
Fuse	115 psi	144 psi
Cool	0 psi	0 psi

External Heater Temperatures

	Side A	Side B

GPS Location

Joint Time	2018-08-21 07:40:34 GMT
Job	1
Operator	Rafel
Aborted Joint	No

Fusion Machine

Machine Name	618 HF
Machine Model	618 HF
Piston Area	11.78 in²

Pipe Specifications

Pipe Material	PE4710
Pipe Size	6 " IPS
Wall Thickness	DR 11

Pressures

Drag Pressure	46 psi	
	Interfacial	Gauge
Bead Up	75 psi	119 psi
Heat Soak	0 psi	46 psi
Fuse/Cool	75 psi	119 psi

Fusion Specification

Fusion Type	Butt Fusion
Fusion Specification	ASTM F2620
Bead Time	0 seconds
Bead Size	3/16"
Heat/Soak Time	162 seconds
Fuse Time	397 seconds
Open/Close Time	15 seconds
Cool Time	0 seconds

	Minimum	Maximum
Bead Up	104 psi	133 psi
Heat Soak	0 psi	46 psi
Fuse	104 psi	133 psi
Cool	0 psi	0 psi

External Heater Temperatures

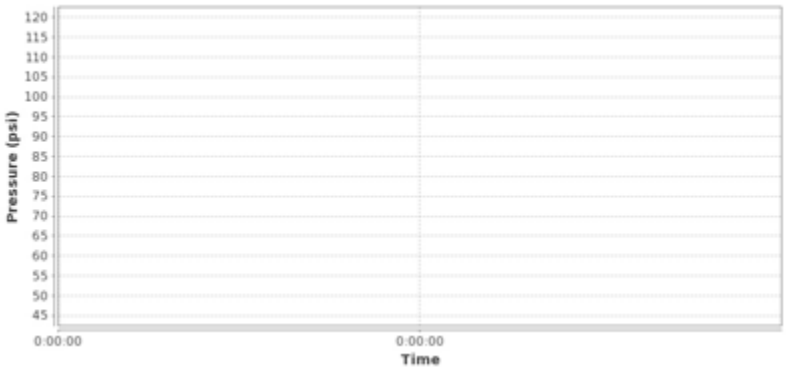
	Side A	Side B

GPS Location

Date	Latitude	Longitude
2018-08-21 07:40:34.0	64°2'19.640400"N	135°49'43.959000"W

Logged Data Summary

Number of Data Points	214
Total Fusion Time	260 seconds
Maximum Recorded Pressure	119 psi



Device Information

DataLogger Serial Number	RH803Z0550
Sensor Serial Number	MDL6621
Calibration Date	2018-04-04
Firmware Version	v6.0
Software Version	1.08 (27)

McElroy Joint Report

Reference Number 1164542

Job Details

Joint Number	157
Joint Time	2018-08-25 12:07:42 GMT
Job	1
Operator	Rafel
Aborted Joint	No

Fusion Machine

Machine Name	618 HF
Machine Model	618 HF
Piston Area	11.78 in²

Pipe Specifications

Pipe Material	PE4710
Pipe Size	6 " IPS
Wall Thickness	DR 11

Pressures

Drag Pressure	33 psi	
	Interfacial	Gauge
Bead Up	75 psi	106 psi
Heat Soak	0 psi	33 psi
Fuse/Cool	75 psi	106 psi

Fusion Specification

Fusion Type	Butt Fusion
Fusion Specification	ASTM F2620
Bead Time	0 seconds
Bead Size	3/16"
Heat/Soak Time	162 seconds
Fuse Time	397 seconds
Open/Close Time	15 seconds
Cool Time	0 seconds

	Minimum	Maximum
Bead Up	91 psi	120 psi
Heat Soak	0 psi	33 psi
Fuse	91 psi	120 psi
Cool	0 psi	0 psi

Reference Number 1164569

Job Details

Joint Number	184
Joint Time	2018-09-02 12:04:46 GMT
Job	1
Operator	Rafel
Aborted Joint	No

Fusion Machine

Machine Name	618 HF
Machine Model	618 HF
Piston Area	11.78 in²

Pipe Specifications

Pipe Material	PE4710
Pipe Size	6 " IPS
Wall Thickness	DR 11

Pressures

Drag Pressure	35 psi	
	Interfacial	Gauge
Bead Up	75 psi	108 psi
Heat Soak	0 psi	35 psi
Fuse/Cool	75 psi	108 psi

Fusion Specification

Fusion Type	Butt Fusion
Fusion Specification	ASTM F2620
Bead Time	0 seconds
Bead Size	3/16"
Heat/Soak Time	162 seconds
Fuse Time	397 seconds
Open/Close Time	15 seconds
Cool Time	0 seconds

	Minimum	Maximum
Bead Up	93 psi	122 psi
Heat Soak	0 psi	35 psi
Fuse	93 psi	122 psi
Cool	0 psi	0 psi

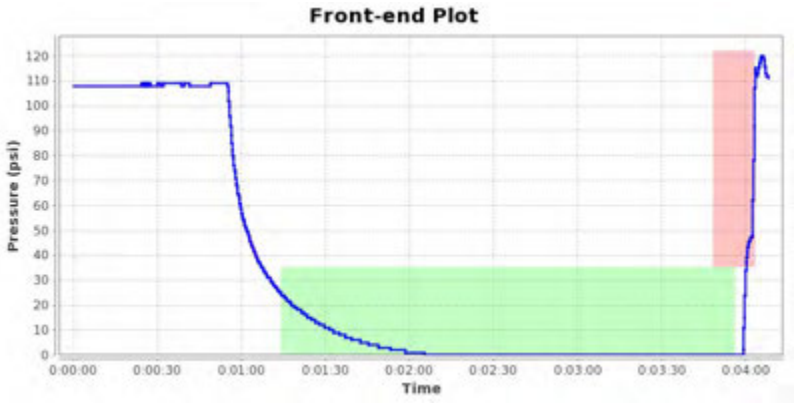
External Heater Temperatures

	Side A	Side B

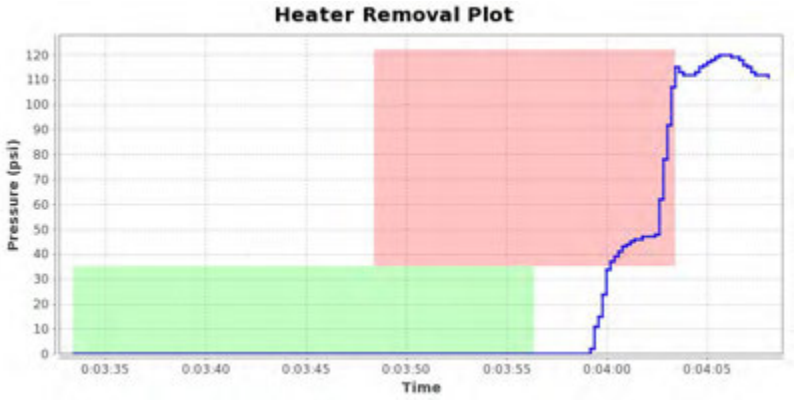
GPS Location

Date	Latitude	Longitude
2018-09-02 12:04:46.0	64°2'22.347600"N	135°49'43.312200"W

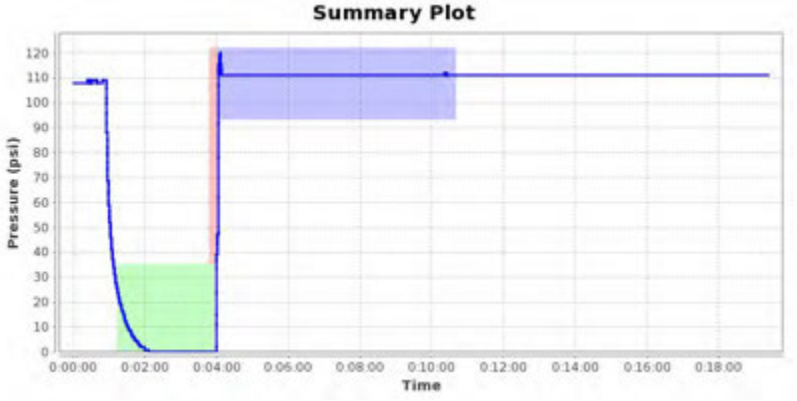
Logged Data Summary



Number of Data Points	272
Total Fusion Time	1162 seconds
Maximum Recorded Pressure	120 psi



Device Information



DataLogger Serial Number	RH803Z0550
Sensor Serial Number	MDL6621
Calibration Date	2018-04-04
Firmware Version	v6.0
Software Version	1.08 (27)
Software Product Name	DataLogger 6

1. Introduction

Victoria
GOLD CORP

1. Introduction

1.1 Scope of Report

This report presents a summary of all baseline streamflow data collected for the Eagle Gold Project (Project) since August 2007, including hydrometric information summarized in previous reports (Jacques Whitford 2008; Stantec 2010; Stantec 2011; Stantec 2012; Knight Piésold 2013, Lorax 2017 and Lorax 2018).

An overview of the streamflow monitoring program is provided in Section 2. Methods for the measurement of streamflow and stage (both spot and continuous) are presented in Section 3, along with the approach used to develop the rating curves for each station, the paired stage-discharge measurements and associated rating curve error. Stage record corrections (*e.g.*, due to station relocation, frost jacking of the staff gauge, channel aggradation, *etc*.) are also presented.

In Section 4, streamflow data is presented in the following formats:

- Monthly tables showing average, maximum and minimum 15-minute discharge values (m^3/s);
- Monthly tables showing average discharge (m^3/s), average unit yields ($L/s/km^2$) and total runoff (mm);
- Time-series plots of continous average daily discharge (m^3/s) and spot flow measurements (m^3/s), and;
- Time series plots of average daily unit yields ($L/s/km^2$), by year.

1.2 Previous Reports

The streamflow data collected at the Eagle Gold Project site from 2007 up to and including 2012, has been previously summarized in the following reports:

- *Dublin Gulch Project – Climate and Hydrology Environmental Baseline Report* (2008), prepared by Jacques Whitford AXYS (Burnaby, BC) for Strata Gold Corp. (Vancouver, BC).
- *Eagle Gold Project, Environmental Baseline Report: Hydrology* (2010), prepared by Stantec (Burnaby, BC) for Victoria Gold Corp., February 2010.
- *Eagle Gold Project, Environmental Data Summary Report: Hydrology 2011 Update* (2011), prepared by Stantec (Burnaby, BC) for Victoria Gold Corp., June 2011.

- *Eagle Gold Project, Surface Water Balance Model Report* (2011), prepared by Stantec (Burnaby, BC) for Victoria Gold Corp., June 2011.
- *Eagle Gold Project, Environmental Baseline Data Report: Hydrology 2011 Update* (2012), prepared by Stantec (Burnaby, BC) for Victoria Gold Corp., June 2012.
- *Victoria Gold Corp., Eagle Gold Project – Hydrology Baseline Data Summary. VA101-290/6-10,* prepared by Knight Piésold Ltd. (Vancouver, BC) for Victoria Gold Corp., August 2013.
- *Victoria Gold Corp., Eagle Gold Project – Hydrology Baseline Report* (2017), prepared by Lorax Environmental Ltd. (Vancouver, BC) for Victoria Gold Corp., March 2017.
- *Victoria Gold Corp. Eagle Gold Project – Hydrometeorology Report.* A413-3, prepared by Lorax Environmental Services Ltd. (Vancouver, BC) for Victoria Gold Corp., March 2017.
- *Victoria Gold Corp., Eagle Gold Project – Hydrology Baseline Report* (2018), prepared by Lorax Environmental Ltd. (Vancouver, BC) for Victoria Gold Corp., March 2018.

1.3 Project Area Characteristics

The majority of the Project site lies within the Dublin Gulch watershed, which is a second order tributary to the larger Haggart Creek watershed, which is a major tributary of the South McQuesten River. The South McQuesten River joins the Stewart River, which flows west to its eventual confluence with the Yukon River.

The hydrology of the region is characterized by a dominant snowmelt driven freshet signature, which typically occurs between early May and early June. The recession limb of the freshet tapers to a lower summer flow regime reflective of primarily groundwater, which is punctuated by periodic rainfall driven runoff events, typically one to four days in duration. Base flows are lowest in the winter and flow sub-ice; in the smaller creeks, groundwater is depleted and there is no flow under the ice.

In larger tributaries, groundwater discharge maintains limited amounts of streamflow below the ice throughout the winter (*i.e.*, November through end March). Aufeis (*i.e.*, groundwater that seeps and freezes onto- and adjacent to local watercourses) is present in several places throughout streams at the Project site, where sub-ice flow is not present. As with shelf ice in the streams, aufeis melts during the freshet, but may in some cases persist into the early summer.

Historical placer mining activities in the Project site streams have altered the natural channel conditions, and in some cases, have also altered the drainage areas of several sub-watersheds. More information is provided in Stantec (2012).

2. Streamflow Monitoring Program

Victoria GOLD CORP

2. Streamflow Monitoring Program

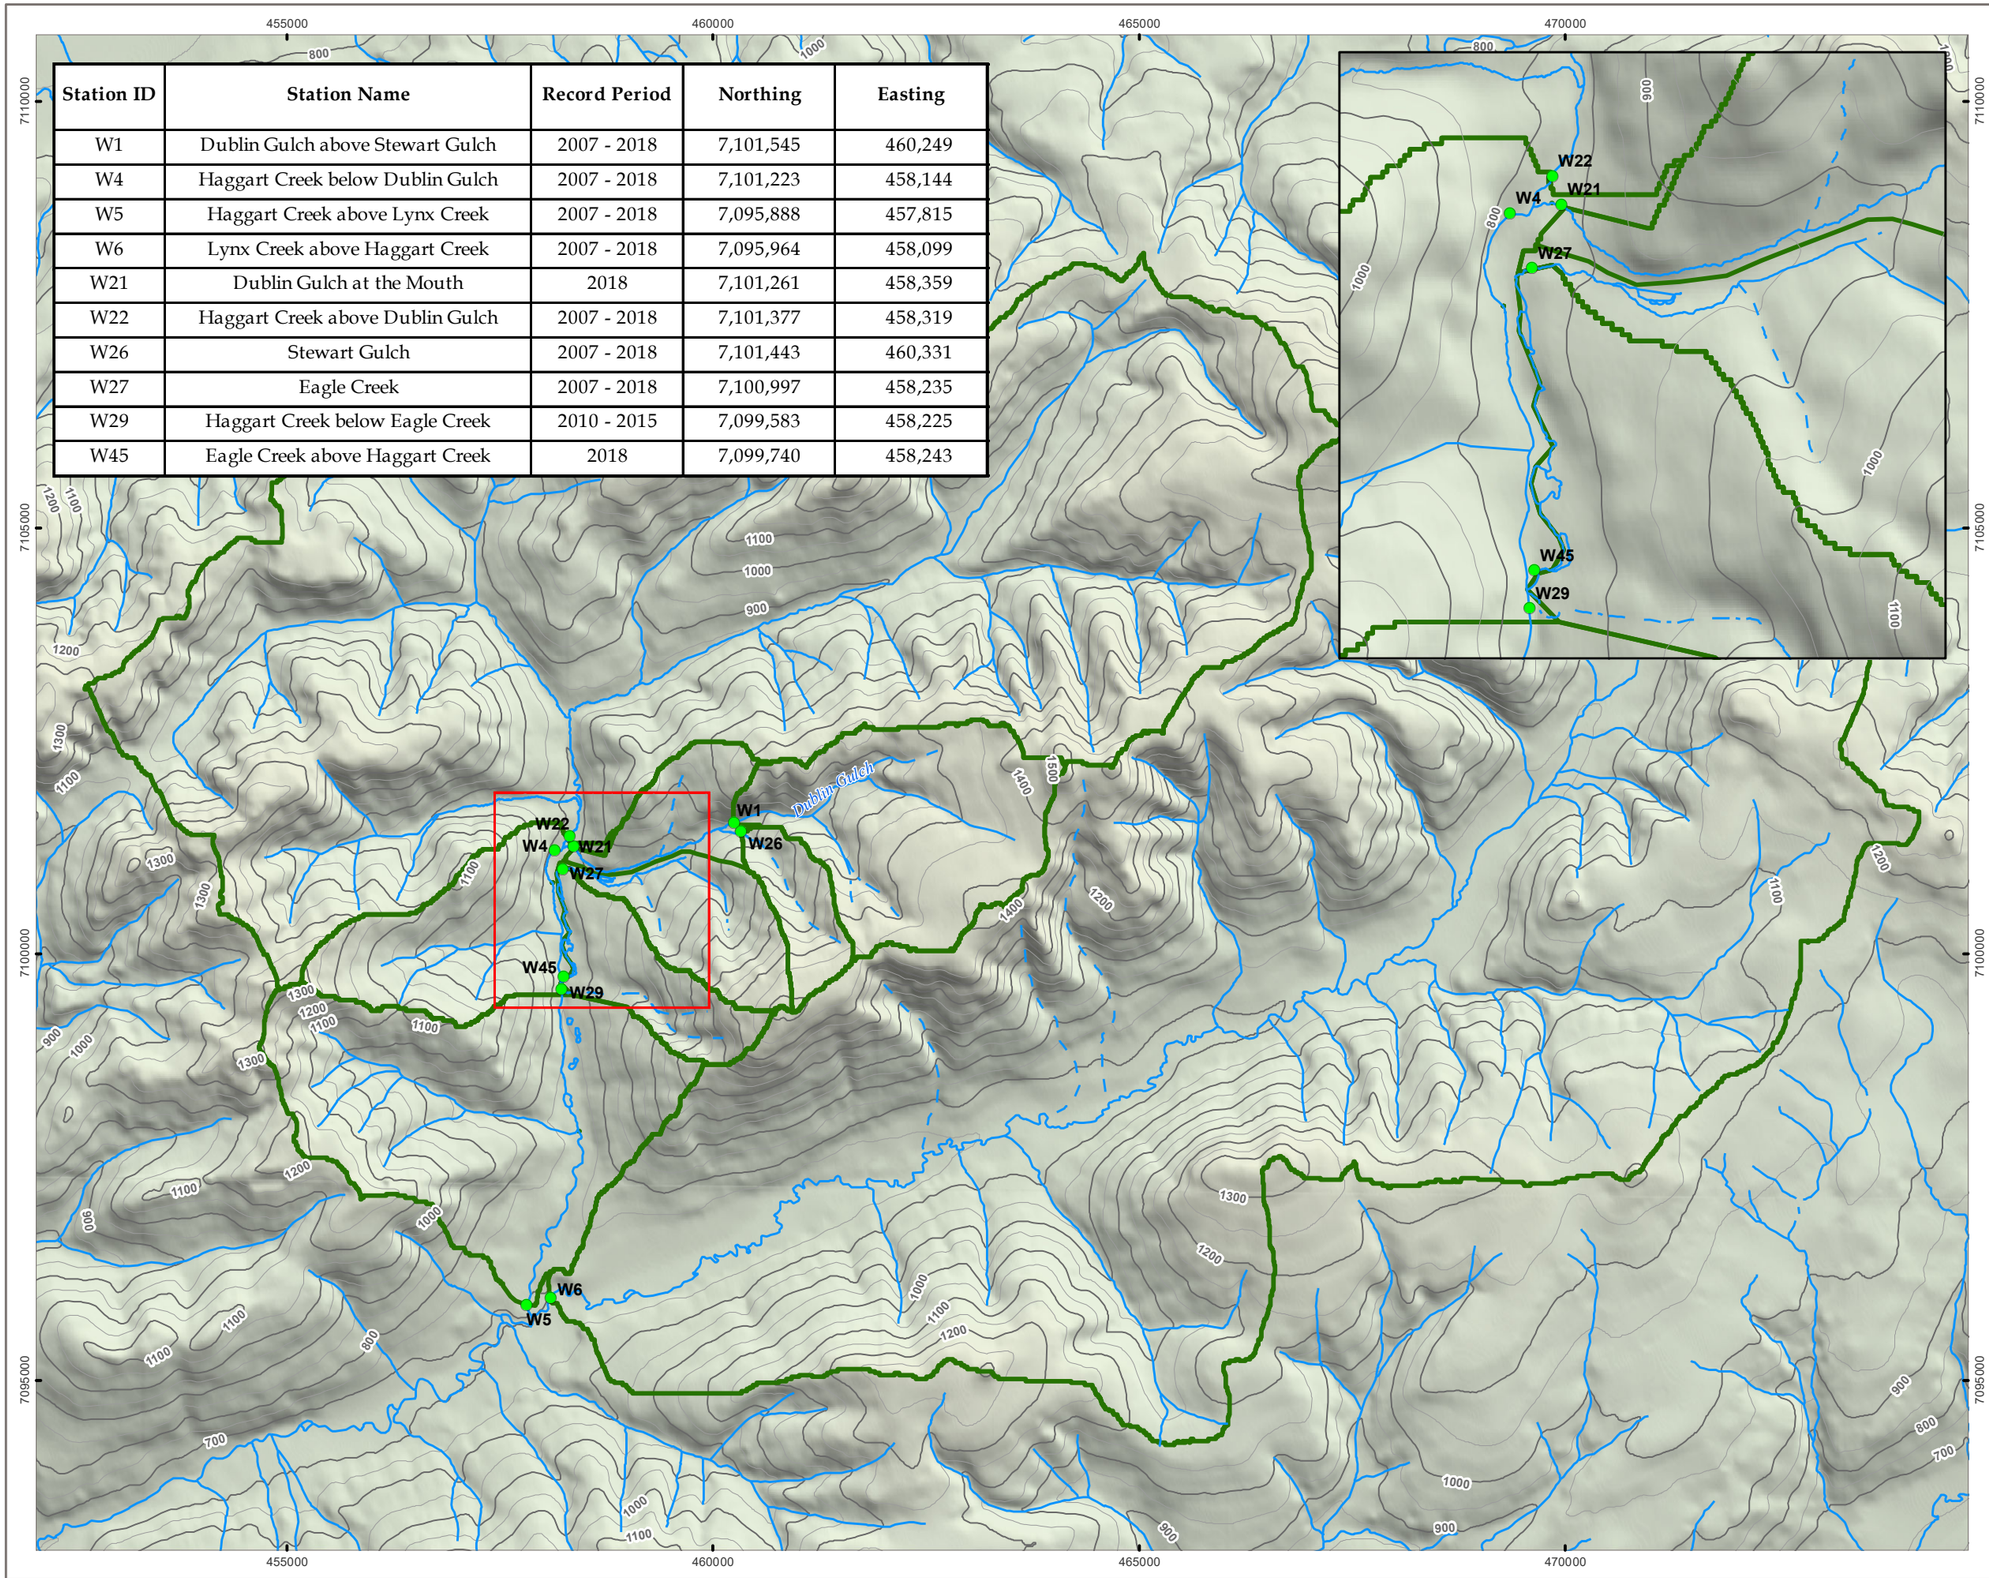
2.1 Data Sources

Data collection was originally undertaken by Hallam Knight Piésold (1993 to 1995), then a new program was initiated in 2007 by Jacques Whitford AXYS (now Stantec Consulting Ltd., or Stantec). Field support for this program has been provided by Laberge Environmental Services (Laberge), based out of Whitehorse since the inception of the program. All streamflow data collected at the Project site up to the end of 2017 has been previously summarized in the reports per Section 1.2.

Laberge continues to participate in the field program, conducting regular field visits with Victoria Gold staff in all seasons. Initial QA/QC of the streamflow data collected in 2018 and associated development and updates of rating curves were undertaken by Lorax Environmental. At the time report preparation, there are ten continuously recording hydrometric stations operating at the Project site. Of these, continuous data for nine stations are presented in this report. The tenth station, W45, has a water level record for 2018, but as it does not have a preliminary rating curve at this time, a continuous discharge record has not been developed.

2.2 Project Site Hydrometric Stations

The number of continuously recording hydrometric stations has varied over the period of record, but the eight of the nine stations presented in this report update have the most complete records (the ninth, W21, was installed in 2018). These stations and the associated metadata are presented in Table 2-1 and shown in Figure 2-1.



Additional manual streamflow measurements have been collected (often concurrently with water quality samples) at an additional 20 locations at the Project site. Previously collected continuous streamflow records for the Eagle Creek Pond (WECP), W13, W20 and W31 stations span shorter durations (1 to 3 years), and are presented in previous reports.

Table 2-1:
Eagle Gold Project hydrometric stations

Station ID	Station Name	Record Period	Northing	Easting	Drainage Area (km^2)	Median Basin Elevation (m)	Notes
W1	Dublin Gulch above Stewart Gulch	2007 – 2018	7,101,545	460,249	6.8	1,303	Continuous discharge time-series
W4	Haggart Creek below Dublin Gulch	2007 – 2018	7,101,223	458,144	76.9	1,125	Continuous discharge time-series
W5	Haggart Creek above Lynx Creek	2007 – 2018	7,095,888	457,815	97.5	1,091	Continuous discharge time-series
W6	Lynx Creek above Haggart Creek	2007 – 2018	7,095,964	458,099	100.9	1,049	Continuous discharge time-series
W21	Dublin Gulch near the Mouth	2018	7,101,261	458,359	10.1	1,216	Continuous discharge time-series
W22	Haggart Creek above Dublin Gulch	2007 – 2018	7,101,377	458,319	66.8	1,113	Continuous discharge time-series
W26	Stewart Gulch	2007 – 2018	7,101,443	460,331	1.3	1,183	Continuous discharge time-series, manual data only for 2007 - 2009, 2011.
W27	Eagle Creek near Camp	2007 – 2018	7,100,997	458,235	2.7	1,037	Continuous discharge time-series, manual data only for 2007
W29[2]	Haggart Creek below Eagle Creek	2010 - 2015	7,099,583	458,225	86.1	1,112	Manual measurements for 2010, continuous data thereafter
W45	Eagle Creek at mouth	2018	7,099,740	458,243	5.0	1,018	Continuous discharge time-series

Notes:
1. Source of UTM co-ordinates, drainage area and median basin elevation (Knight-Piésold, 2013).
2. No continuous water level data are available for this station for 2016-2018. See Section 2.2.3 for details.

Station ID	Station Name	Record Period	Northing	Easting
W1	Dublin Gulch above Stewart Gulch	2007 - 2018	7,101,545	460,249
W4	Haggart Creek below Dublin Gulch	2007 - 2018	7,101,223	458,144
W5	Haggart Creek above Lynx Creek	2007 - 2018	7,095,888	457,815
W6	Lynx Creek above Haggart Creek	2007 - 2018	7,095,964	458,099
W21	Dublin Gulch at the Mouth	2018	7,101,261	458,359

2.2.1 Hydrometric Station Summary

A brief summary of the hydrometric network history is provided below. Further details are available in the previous baseline reports listed in Section 1.2.

W1

- Installed in 2007 with a continuous water level recorder, staff guage, and stilling well and survey benchmarks
- Transducer malfunctions in 2013 and 2014 resulted in loss of data
- Bed can be unstable at high flows; channel condition reflects historical placer mining activity

W4

- Installed in 2007 with a continuous water level recorder, staff guage, and stilling well and survey benchmarks
- Datalogger failure resulted in no continuous water level data for 2016

W5

- Installed in 2007 with a continuous water level recorder, staff guage, and stilling well and survey benchmarks
- Staff gauge was knocked over in the 2013 freshet and repaired in July 2013

W6

- Installed in 2007 with a continuous water level recorder, staff guage, and stilling well and survey benchmarks
- A portion of the 2014 record is influenced by a beaver dam located downstream of the control section – influence is minimal and it was possible to correct for the artificially elevated stage.

W21

- A staff gauge, stilling well and water level logger were installed on June 13, 2018.
- Four paired staff gauge:discharge measurements are available for this site, therefore the rating curve and estimated discharges are considered preliminary.

W22

- Installed in 2007 with a continuous water level recorder, staff guage, and stilling well and survey benchmarks

- No data was available for 2011 due to a pressure transducer malfunction. The water level record estimated by Stantec was carried forward in this report.
- Staff gauge was knocked over in the 2013 freshet and repaired in July 2013

W26

- Manual measurements from 2007 to 2009, instrumented with a continuous water level recorder, staff guage, and stilling well and survey benchmarks in 2009.
- V-notch weir installed in 2009, and replaced with a Parshall flume in August 2011
- Technical issues with datalogger installation in 2011 resulted in loss of continous data – only manual measurements are available for this year.

W27

- Installed in 2007 with a continuous water level recorder, staff guage, and stilling well and survey benchmarks however data is not reported due to apparent sedimentation in the stilling well resulting in a continuously rising water level
- V-notch weir installed in 2009, and replaced with a Parshall flume in August 2011
- Malfunction of pressure transducer in August 2015 resulted in loss of data for remainder of this year

W29

- Manual measurements in 2010, instrumented with a continuous water level recorder, staff guage, and stilling well and survey benchmarks in 2011
- Station was destroyed in the 2013 freshet, and a replacement pressure transducer was deployed on an anchor in the streambed just upstream; water levels were surveyed at the old location and the temporary installation to determine the required offset. A new stilling well was installed in July 2015 at the original gauge location.
- Datalogger malfunctions and channel stability issues, including frost jacking of the stilling well resulted in the loss of continuous water level data for 2016 through 2018.

W45

- A staff gauge, stilling well and water level logger were installed on June 13, 2018
- Five paired staff gauge:discharge measurements are available for this site, therefore the rating curve and estimated discharges are considered preliminary.
- Culverts were installed near this station in 2018 shortly after installation, significantly altering the stage:discharge relationship. As a result, this station will

need to be relocated to a more stable location in 2019, and may require the installation of a flume.

The stations that were re-established in 2016 at Bawnboy Gulch upstream of Caskallen (W20) and Olive Gulch upstream of Dublin Gulch (W31) have water level records for 2016 and 2017, but these were not continued in 2018. Further, neither station has sufficient manual flow and stage measurements with which to develop rating curves, and thus continuous records of discharge for 2016 or 2017.

Spot manual measurements of flow were made once in 2017 and once in 2018 at W39 (Haggart Creek above South McQuesten River) and W49 (South McQuesten River below Haggart Creek). These measurements are not presented in this report but will be presented once the datasets are larger.

2.2.2 Manual Discharge Measurements

Over time, manual discharge measurements have been conducted using the following methods:

- Velocity area techniques using a current meter;
- Salt dilution;
- Calibrated V-notch weir;
- Calibrated Parshall flume;
- Bucket/Bag and stopwatch, and;
- Float-area method.

The majority of the manual discharge measurements were conducted using the velocity-area method, with approximately one quarter made using the salt dilution technique. Most winter measurements were made while ice encroached on the channel, and therefore salt dilution was the preferred method for winter flow measurements. Typically, one discharge measurement was made at each visit.

2.2.3 Stage Measurements and Corrections

All stations were instrumented with metric staff gauges, mounted to vertical angle iron in the stream channel, and regularly surveyed to nearby benchmarks. Continuously recording HOBO pressure transducers were installed in stilling wells and set to record water level every 15 minutes. These readings were corrected for fluctuations in barometric pressure in a post-processing step. During each site visit, the water level was noted on the staff gauge. These readings formed the basis for the continuous water level records, which were

adjusted to match the manual stage readings. Regular surveys were conducted to determine the staff gauge zero datum and water level, and these measurements were used to correct the station records for changes due to shifts in the channel bed (*i.e.*, aggradation or scour), frost-jacking or station relocation following a high-magnitude flood event.

At each station, an annual offset was developed to bring the staff gauge measurements into line with the reference datum from the 2012 benchmark surveys. W27 was the exception, as no survey information was available for 2012, so 2009 was used as the benchmark reference year for this station following Knight Piésold (2013). In this way, the reference datum at each station was kept consistent for the duration of the record period, regardless of station location or streambed conditions.

No notable issues were encountered with the stage records in 2018, with the exception of W29, where the datalogger failed. There are now three consecutive years with no continuous water level, as channel instability led to the rejection of the 2016 water level record, and in June 2017, the stilling well frost jacked completely out of the streambed. This station is located in a highly mobile channel that has not reached equilibrium yet, following historical placer mining disturbances, and is therefore challenging to gauge. This station will be re-installed in 2019.

3. Streamflow Record Development

Victoria
GOLD CORP

3. Streamflow Record Development

3.1 General Approach

To develop continuous time-series of discharge for the Project streams, spot measurements of stage and discharge are combined with continuous water level records collected by the pressure transducers. Mathematical relationships are derived to describe the relationship between water level and discharge, and then applied to the continuous water level records to estimate discharge. By convention, assembled stage and discharge relationships are commonly referred to as rating curves, where the relationship between stage and discharge are unique and specific to each monitoring station.

3.2 Rating Curve Development

Adjustments for stage (Section 2.2.3) were made prior to the assembly of rating curves. Winter spot flow measurements provided information on the magnitude of winter discharge, but due to ice effects and greater measurement uncertainty for both stage and discharge, these measurements were not employed in the rating curve development process.

Rating curves were developed using the standard rating equation, and the coefficient, offset and exponent were selected to conform to hydraulic theory (*e.g.*, Maidment, 1993) and the stream channel properties.

$$Q = C(h - a)^n$$

Where:

Q = discharge (m^3/s)

C = coefficient (function of channel geometry)

h = stage (m)

a = stage at point of zero flow, offset (m)

n = exponent (function of channel geometry)

The term C is usually 0.5 to 2.5 times the channel width at the control section, and n is often between 1.6 and 3 for moderate gradient streams. The BC RISC standards (RISC, 2009) state that ideally, a rating curve will be based on a minimum of 10 stage-discharge measurements. Given the long duration of monitoring activities at the Project site, all stations meet these guiding criteria, with the exception of W21 and W45. These stations were installed in 2018, and due to the limited record durations, the rating curves are based

on four and five paired measurements, respectively, and thus are considered preliminary. Survey benchmarks are installed at both stations, and future measurements of level and discharge will be used to refine the rating curves, at which point the preliminary discharge records computed for 2018 will be updated.

3.3 Rating Curve Error

The overall quality of the discharge record can be assessed by reviewing the average and standard errors calculated from the differences between the measured discharges, and those estimated from the rating equation. A positive rating curve error is defined where the discharge calculated from the rating curve overestimates the value when compared to the measured discharge, and vice-versa for a negative error.

A summary of the error metrics for all stations is presented in Table 3-1, with reporting for each station in Table 3-2 through Table 3-10. Table 3-1 also reports rating curve control percentages by monitoring station. These values indicate the percent of time that a continuously recorded observation (15-minute intervals) falls between the highest and lowest manually recorded measurements for each monitoring station. For example, at the W6 station, 96% of the 15-minute water level measurements are lower than the highest recorded manual stage measurement. Therefore, the measurements used in the rating curve development are able to represent 96% of the entire continuous water level record, and only 4% of the continuous discharge data derived from the rating curve are based on an extrapolation beyond the highest manually recorded stage-discharge measurement.

Additional manual measurements made at other stations throughout the duration of the streamflow monitoring program, for which rating curves and continuous discharge time-series have not been developed, are presented in Table 3-11 through Table 3-15.

Overall, the rating curves provide reasonable estimates of discharge across a wide range of flows at most of the Project stations. The rating curve errors presented in Table 3-1 indicate that the average errors are relatively low, ranging from -5% to 2%. The standard error, or the degree of variability about the average error values varies more between stations, from a high of 25% for station W1, to a low of 10% for stations W6 and W29. Note that as the W21 curve is currently comprised of only four paired stage:discharge measurements, this curve, and all data reported for W21 in 2018 are considered preliminary and subject to change.

Rating curves for the site hydrometric stations are presented in Figure 3-1 through Figure 3-7, covering the 2012 to 2017 period. For the 2017 update, the rating equations were compared to those previously developed for each station to ensure that the coefficients and exponents were consistent through time. After examining the 2018 data, no further

updates to the rating curves developed in 2017 were necessary, and the same curves were applied to the 2018 continuous water level data. Note that because stations W26 and W27 are instrumented with Parshall flumes, rating curves were not developed for these stations.

Table 3-1:
Rating curve error metric summary for Eagle Gold Project site hydrometric stations

Station	Measurements (n)	Average Error (%)	Standard Error (%)	Rating Curve Control
W1	36	-5%	25%	98%
W4	41	-1%	14%	98%
W5	35	2%	12%	97%
W6	31	-1%	10%	96%
W21	4	0%	7%	79%
W22	35	0%	16%	100%
W26	26	--	--	100%
W27	47	--	--	100%
W29	18	-2%	10%	95%
Average	34	-1%	14%	97%

Notes:
1. Stations W26 and W27 currently have Parshall flumes installed, and therefore rating curves have not been developed for these sites as part of this baseline streamflow update.

2018-12-18	Salt dilution	-	0.021	-	-	Stage affected by ice in channel
Average Error (%)					-5%	
Standard Error (%)					25%	

Notes:
1. Measurements highlighted in grey were conducted in ice-affected waters, and were not employed in rating curve development.
2. Stage measurements for the period 2007 to 2012 are as reported in Knight Piésold (2013). Stage measurements for the period 2013 to 2018 are the staff gauge readings relative to the staff gauge datum from 2012.

3.4 Winter Streamflow Interpolation

Due to extensive channel icing and complete freezing to the bed in some cases, reliable continuous water level data is not available for the winter season (mid-October to early May in most years). However, spot flow measurements collected during the winter water quality sampling trips are available for most years. Where these measurements span the majority of the winter season, streamflows were estimated by interpolating between the spot flow measurements. This was done by assuming that mid-winter melt or rain events do not occur at site, and that the streamflows are a result of recession from the open-water season discharge regime to a steady-state baseflow driven by the local groundwater system discharging to the stream channel. This recession curve is defined by the equation (Maidment, 1993):

$$Q_t = Q_0\, e^{-kt}$$

Where:

Q_t = discharge at time t (m^3/s)

Q_0 = initial discharge (both Q_t and Q_0 are measured within the same straight segment

k = decay rate (negative for declining flows)

t = number of days between spot measurements (interpolation period)

The decay rate k, was unique to each pair of subsequent discharge measurements, and was commonly in the range of -1×10^{-3} to -0.5×10^{-5}.

4.1 Streamflow Records – Discharge

The computed flow records for all site stations listed in Table 2-1 are presented as average daily discharge time-series and plotted with spot discharge measurements and interpolated baseflows in Figure 4-1 through Figure 4-9. The same flow records are also presented as unit yield plots, with each plot showing annual data for all stations on a single plot (refer to Figure 4-10 to Figure 4-21).

While discharge magnitude varies with watershed area (*i.e.*, larger basin areas result in higher discharge values), it is more often instructive to compare runoff and/or unit yields to remove the influence of watershed area. The variation in runoff and yields across the gauged basins at the Project site is relatively low, with unit yields averaging 14 ± 1.2 L/s/km^2 and an average runoff of 187 ± 33 mm for the open water season (Table 4-1).

W22 displays slightly lower average unit yields (12.8 L/s/km^2) than the other stations, and W27 and W29 yield slightly more water on average (15.0 and 15.4 L/s/km^2, respectively). There appears to be lower than average yields at W26, however, this result is biased lower by the absence of data for the month of May, which is typically the month with the highest proportion of annual runoff. W1 appears to experience the highest overall yields, and in particular, the highest magnitude freshet (in yield terms). Higher than average yields at this station are sustained throughout the seasonal falling limb from September through November.

Table 4-2 through Table 4-19 present the monthly summaries of streamflow as discharge, unit yields and runoff, by station. As noted in Section 2.2.3, reliable continuous water level data is not available for W29 for 2016 through 2018.

Table 4-1:
Summary of monthly average discharge, unit yield and runoff for Project site hydrometric stations.

1. Introduction

1.1 Project Description

The Eagle Gold Project (the Project) is owned by StrataGold Corporation, a wholly owned subsidiary of Victoria Gold Corp. (the "Company"). The Project is located in the Central Yukon Territory, approximately 350 km north of Whitehorse and approximately 45 km north of Mayo. Much of the mine site lies within the Dublin Gulch watershed, a tributary that reports to Haggart Creek, and which then flows to the South McQuesten River. Ultimately, the South McQuesten River joins the Stewart River, which flows west to its eventual confluence with the Yukon River.

A Type A Water Use License (QZ14-041) was issued for the Eagle Gold Project on December 3rd, 2015 to allow the construction, operation and closure of the open pit heap leach gold mine in central Yukon.

The Eagle Gold Mine water balance and water quality model (WBQM) has been updated to reflect the most recent baseline information, heap leach water balance modeling and updated geochemical source term modeling

1.2 Scope of Report

The Eagle Gold WBWQM is a GoldSim-based integrated water balance and quality model that was previously developed in two parts. The initial water balance model design was led by Knight-Piésold (KP) who used a runoff-based approach to determine natural and mine-impacted runoff from the catchments that comprise the Eagle mine site. Precipitation was back-calculated from runoff where a precipitation input was required. KP also integrated the Excel-based monthly heap leach facility (HLF) water balance model provided by the Mines Group. The water quality component was developed by Lorax Environmental Services Ltd. (Lorax) and integrated within the WBM to combine source concentrations of potential contaminants of concern with contact and non-contact flows to track contaminant loading throughout the mine site and into the receiving waters of Haggart Creek. The culmination of both these efforts was the 2014 water quality model used in support of StrataGold's Type A Water Use License Application submitted in August 2014 (Exhibit 1.11.1 on the Yukon Water Board Waterline website registry for StrataGold's Type A Water Use License).

Since submission of the 2014 WBWQM, the model has been updated in March 2018 and further revised in June 2018.

This report presents the most recent update of the Eagle Gold water balance model (WBM) and water quality model (WQM) that fully integrates the following:

- Description of the water management plan as described in: *Eagle Gold Project Construction and Operations Water Management Plan*. Version 2108-01. August 2018;
- Revisions to the heap leach facility water balance modeling as described in: *Weekly Water Balance Modeling for the Eagle Gold Mine Heap Leach Pad Facility*. Report prepared by The Mines Group, October 2018;
- Baseline climate and hydrology data collected since 2007 and inclusive of data collected in 2018;
- Updated baseline surface water quality monitoring data collected from 2007 to 2017 prior to initiation of construction in August 2017; and
- Geochemical source term data collected from active field bins of waste rock and leached ore materials, with consideration of data collected up through September 2018 ice-free season.

Following this introduction, Section 2 presents the updated input parameters and assumptions used to update the water balance and water quality models. Section 3 presents a summary of the water quality model results and Section 4 provides a summary of the results for water quantity.

2. Model Inputs and Assumptions

2.1 Water Balance Model Inputs and Assumptions

For the purposes of this 2019 update, the Goldsim model structure, parameterization and assumptions are largely unchanged from those presented in the previous water balance model report submitted in support of the WUL application (Knight Piésold, 2014) and the updates provided in 2018, with some exceptions, as described below. Section 2.1.1 discusses changes to the WBM based on hydrometeorological updates through 2017, while Section 2.1.1.1 uses 2018 data to help validate the WBM

2.1.1 Hydro-meteorological Updates

Following the issuance of WUL QZ14-041, the collection of baseline climate and streamflow data has continued at the Project site. This additional data has been incorporated into the site monitoring records, and the results are presented in the climate and hydrology baseline reports (Lorax 2019a and 2019b). These data were analyzed in conjunction with regional climate and streamflow records to estimate the necessary input parameters for use in the updated WBM. A summary of the updated values of interest is presented in Table 2.1-1, along with the previous estimates derived by Knight Piésold (2013). These estimates are considered representative of the reference elevation of 1,125 m asl, which is the mid-point of the catchment that drains to Haggart Creek below Dublin Gulch hydrometric station (W4; 76.9 km^2), and which contains the proposed Project footprint.

Overall, the incorporation of additional baseline climate data and updated synthetic precipitation and runoff estimates have resulted in non material changes to the Project site water balance. As in the previous WBM, annual runoff at the W4 hydrometric station is assumed to represent the effective precipitation at the Project site and forms the primary driver of the WBM. The changes from the initial estimates made by Knight Piesold in 2013 relevant to the WBM parameterization are consistent with Lorax (2018) and are as follows:

- Mean annual precipitation (MAP) at the 1,125 m elevation has decreased by 6%, from 500 mm to 472 mm;
- Mean annual runoff (MAR) for the W4 hydrometric station has increased by 7% from 230 mm to 247 mm;
- The annual orographic precipitation gradient has decreased from +10%/100 m for to +7%/100 m; and

- The monthly distribution of annual runoff used to distribute the MAR value for W4 has changed slightly, as outlined in Table 2.1-2.

Table 2.1-1:
Comparison of 2014 and updated 2017 runoff and precipitation estimates at the Eagle Gold Project site

Knight Piésold Hydrometeorology Report (2013)									
Parameter	**Camp (782 m)**			**1125 m**			**Potato Hills (1420 m)**		
	Annual	Oct-Apr (SWE)	May-Sept (Rain)	Annual	Oct-Apr (SWE)	May-Sept (Rain)	Annual	Oct-Apr (SWE)	May-Sept (Rain)
Potential Evapotranspiration (mm)	439	--	439	--	--		335	--	335
Mean Precipitation (mm)	357	205	152	500	310	190	652	432	220
Mean Annual Runoff (W4; mm)	--	--	--	230	--	--	--	--	--
Lorax Hydrometeorology Report (2017a)									
Potential Evapotranspiration (mm)	483	--	382	380	--	344	305	--	309
Mean Precipitation (mm)	375	160	214	472	227	245	581	306	275
Mean Annual Runoff (W4; mm)	--	--	--	247	--	--	--	--	--

Table 2.1-2:
Comparison of 2014 and updated 2017 monthly runoff distributions for the Eagle Gold Project site

Month	**2014 values**		**2017 values**	
	Distribution	**Precipitation (mm)**	**Distribution**	**Precipitation (mm)**
JAN	2%	3.6	3%	6.5
FEB	1%	2.8	2%	5.4
MAR	1%	3.0	2%	5.7
APR	2%	4.8	3%	8.4
MAY	30%	69.6	24%	60.5
JUN	21%	48.0	17%	41.1
JUL	12%	27.3	11%	28.4
AUG	10%	23.9	10%	23.9
SEP	10%	23.2	10%	24.2
OCT	6%	13.1	8%	20.7
NOV	3%	6.9	6%	14.0
DEC	2%	4.9	3%	8.2
Total		231		247

Overall, the changes listed above result in minor and immaterial alterations to the WBM inputs. Winter flows in the larger drainages tend to be higher than previous estimates, and freshet magnitudes are slightly lower.

Additional site monitoring confirms that winter flows within the smaller (and higher elevation) drainages at the Project site are lower relative to those measured at W4, and thus the multiplier of 0.1 for these drainages was carried forward in the WBM update.

The updated annual runoff volumes are higher overall in the larger basins, with the increases ranging from 2% to 10% above the values used in the 2014 WBM (Table 2.1-3). However, the slight increase in the updated winter flow estimates for the smaller basins that are modified by the winter low flow factor, in concert with the slight reductions in freshet volumes, has resulted in small decreases in annual runoff for the Stewart Gulch (W26) and the Eagle Pup drainages, on the order of -4% and -2%, respectively. Annual runoff for Suttles Gulch has increased slightly by 2%, and runoff from Platinum Gulch remains effectively unchanged.

Table 2.1-3:
Comparison of 2014 and 2017 updated monthly runoff distributions

Basin	Median Basin Elevation (m)	Area (km^2)	2014 Annual Runoff (mm)	2017 Annual Runoff (mm)	% change MAR from 2014 WBM
Upper Dublin Gulch (W1)	1303	6.8	274	279	2%
Stewart Gulch (W26)[1]	1183	1.3	219	212	-4%
Haggart Ck u/s Dublin Gulch (W22)	1113	66.8	228	245	7%
Haggart Ck d/s Dublin Gulch (W4)	1125	76.9	231	247	7%
Ann Gulch	1029	0.89	211	231	10%
Eagle Pup[1]	1116	8.88	206	202	-2%
Suttles Gulch[1]	994	0.22	183	186	2%
Platinum Gulch[1]	1070	0.77	197	196	0%
Haggart Ck (btwn W29 and W5)	1091	0.68	224	241	8%
Lynx Ck u/s Haggart Ck (W6)	1049	100.9	215	235	9%

Note:
[1]The runoff presented for these nodes was modified by the winter low flow factor of 0.1.

All other climatic and baseline streamflow inputs and assumptions remain unchanged from the previous WBM version.

2.1.2 Validation of Water Balance Model Hydrometric Inputs Using 2018 Data

Following the update of the baseline streamflow time-series to include data collected in 2018, a verification exercise was conducted to ensure that the water balance model inputs were still adequately representing site conditions. As outlined in Section 2.1.1, the model

inputs are scaled from the W4 synthetic monthly runoff series, with the winter runoff for the high-elevation sub-basins scaled further by a factor of 0.1 to account for the limited groundwater contributions to winter baseflows.

In most cases, the measured streamflow records cover the open water season from May to October, with May generally showing incomplete data due to extensive channel icing conditions. Therefore, depending on the availability of data for May at each station, it is expected that the measured runoff will be less than the model input. The winter flow data for November to April, where available, are based on monthly averages of manual measurements that are made concurrent with the water quality sampling trips.

Figures 2.1-1 to 2.1-6 present the results of the verification exercise and compare measured and model runoff from key locations within the Haggart Creek, Dublin Gulch and Lynx Creek catchments. Overall, the measured monthly runoff and model input match well, with the modelled runoff ranging from 3% less, to 2% more than the measured data on an annual basis, for those stations that have sufficient monitoring data for comparison. At the monthly scale, modeled June runoff is consistently higher than measured runoff for all nodes, while summer runoff is slightly underpredicted by the model, relative to the available measurements.

Given that the measured record spans from 8 to 12 years, and that many of the monthly averages calculated from this record are based on incomplete records, the long-term synthetic streamflow records upon which the water balance model is based are thought to best represent the long-term average runoff conditions at site. Accordingly, no changes to the runoff inputs to the water balance model are necessary at this time.

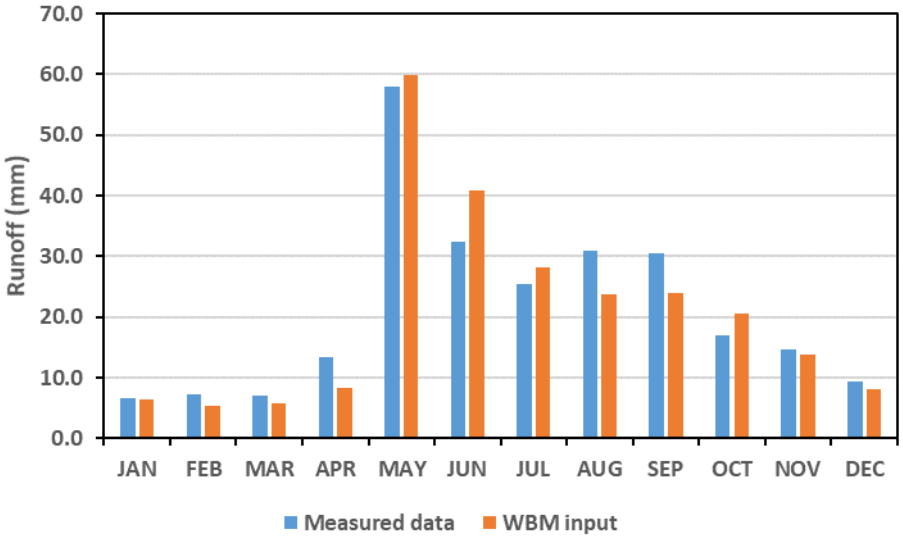

Figure 2.1-1: Measured and modeled runoff for the W22 station (Haggart Creek upstream of Dublin Gulch).

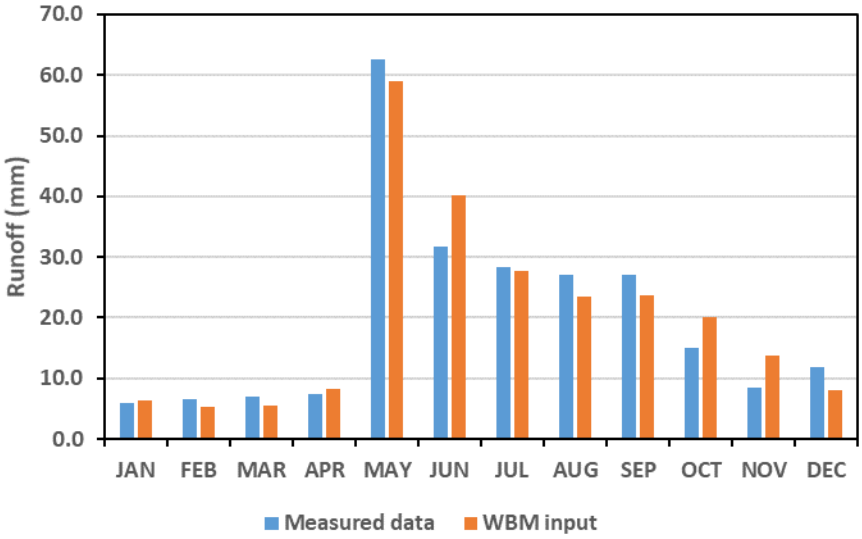

Figure 2.1-5: Measured and modeled runoff for the W5 station (Haggart Creek (immediately upstream of confluence with Lynx Creek).

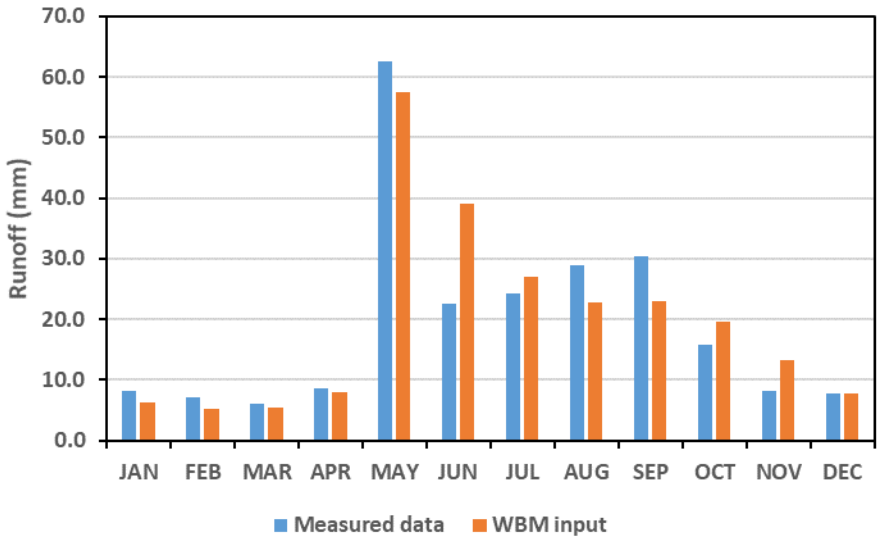

Figure 2.1-6: Measured and modeled runoff for the W6 station (Lynx Creek upstream of Haggart Creek).

2.1.3 Heap Leach Facility Water Balance Model Updates

The GoldSim HLF model required updates to accommodate the following changes described in: *Weekly Water Balance Modeling for the Eagle Gold Mine Heap Leach Pad Facility*. Report prepared by The Mines Group, October 2018:

1. Maximum In-Heap sump storage of 74,565 m^3 and maximum event pond storage of 299,851 m^3.
2. Pumped outflow from In-Heap sump storage of 8 L/s (max) to the MWTP beginning in May of mine year 5 and continuing until September of mine year 9.
3. The weekly HLF model includes pumped outflow from the Event Pond storage of 12.1 L/s (max) beginning in October of mine year 9; in practice, this superceded the existing pumping profile already adopted in the GoldSim model to handle required discharge from the Event Pond to the MWTP.

All other inputs, assumptions and parameterizations for the HLF WBM were carried forward from the 2018 update (Lorax 2018).

2.1.4 Mine Infrastructure

Since the 2014 WUL application was submitted, there have been some changes to the mine infrastructure layout, including reduction in size of the HLF, elimination of the Dublin Gulch Diversion Channel, realignment of the HLF embankment, minor changes to the progression of waste rock storage areas, slight alterations to the Lower Dublin South Pond (LDSP), and modifications to water management facilities including the addition of several

new contact water routing ditches. These updates were described in the 2018 WBMWQM update (Lorax 2018) and are outlined in detail again below for completeness. All other assumptions made in the 2014 water balance model were carried forward (e.g., camp potable water requirements, dust control water requirements).

2.1.4.1 Waste Rock Storage Area Progression and Assumptions

Waste rock storage facility placement phasing for Eagle Pup and Platinum Gulch are presented by year in Table 2.1-4.

Table 2.1-4:
Waste Rock Storage Areas Tonnages and Surface Area by Mine Year

Facility	Waste Type	Y-1	Y1	Y2	Y3	Y4	Y5	Y6	Y7	Y8	Y9
Eagle Pup WRSA	Mass incremental (t)	25,065	73,373	3,398,833	1,919,151	16,093,966	15,462,200	9,213,073	,535,787	7,668,221	10,344,666
	Mass cumulative (t)	25,065	198,438	3,597,271	5,516,421	21,610,387	37,072,587	46,285,660	53,821,447	61,489,668	71,834,334
	Area (ha)	2.0	5.2	16.2	31.4	55.1	61.2	74.1	75.5	77.1	81.8
Platinum Gulch WRSA	Mass incremental (t)	2,125,744	1,645,463	2,875,178	14,541,001						
	Mass cumulative (t)	2,125,744	3,771,207	6,646,385	21,187,386						
	Area (ha)	7.4	12.3	17.4	32.7						

The proportion of runoff versus infiltration for the WRSAs during operations was carried over from the 2014 WUL application model, with notable changes indicated below. This proportion is characterized as the percent of net precipitation minus AET losses:

- Operations (until closure covers are assumed to be effective):
    - WRSAs and HLF – 100% of net precipitation (e.g. total precipitation minus evaporation) assumed to infiltrate (consistent with the 2014 model).
- Closure (once closure covers are assumed to be effective):
    - WRSAs – 75% of net precipitation was targeted for infiltration to the WRSAs, with the remaining 25% modelled as surface runoff from the cover (consistent with the 2014 model).
        - Platinum Gulch WRSF – closure cover effective as of August in Year 5 (changed from June in Year 7);
        - Eagle Pup WRSA – closure cover effective as of June in Year 12 (consistent with the 2014 model), and;
        - HLF – partial reclamation (500,000 m^2) as of June in Year 12 (changed from 650,000 m^2 as of September in Year 13), and fully reclaimed (960,000 m^2) as of August in Year 21.

Water that infiltrates the WRSAs is assumed to have a 1-month lag time before that water reports to the collection pond (LDSP). This assumption reflects the influence of water retention within the pore spaces of the WRSA, and the slower release of water than would be seen in a natural catchment with thinner overburden cover.

2.1.4.2 Sediment Control Ponds

The LDSP serves as the primary contact water management pond for the Project throughout Operations, and all contact water from the Eagle Pup WRSA, 90-day ore stockpile, Open Pit and Platinum Gulch WRSA will be directed to this pond. The Platinum Gulch Pond will be constructed during the operations phase of the Project to serve as a trial passive treatment system (PTS). This PTS will continue in operation during the closure and post closure phases.

2.1.4.3 Contact Water Ditches

A detailed description of contact water ditches and design parameter are presented in StrataGold (2018), but the summary of ditch locations, and the specific water sources reporting to the contact water ditches is presented below.

Ditch A

Ditch A collects contact water from the Platinum Gulch WRSA, 90-day stockpile and open pit, as well as non-contact water from Platinum Gulch, and routes it northwards to the LDSP.

Ditch B/Eagle Creek

Ditch B/Eagle Creek collects contact water from the Eagle Pup WRSA, as well as non-contact water from the Eagle Pup and Suttles Gulch drainage. This ditch is aligned with the natural Eagle Creek drainage and flows west from the northern end of the Eagle Pup WRSA to the LDSP.

Ditch C

Ditch C routes the LDSP outflow westward to Haggart Creek where it discharges just downstream of the confluence of Dublin Gulch. At closure, the updated mine plan routes HLF draindown water to the MWTP and is then discharged directly to Ditch C. At post-closure, HLF seepage water is directed to a PTS, which discharges directly to Haggart Creek immediately upstream of the confluence with Dublin Gulch.

2.2 Water Quality Model Inputs and Assumptions

The Eagle Gold Project water quality model (WQM) is a mass-conserving mixing model that predicts water quality for 38 parameters at key monitoring and compliance points in the receiving waters affected by mine activity. The model was designed on the GoldSim® platform and utilizes a GoldSim® water balance model (WBM). Both the WBM and the WQM use a monthly time-step for 50 years, spanning operations, closure and several years into post-closure. Below is a brief description of water quality model inputs including seepage contact water source terms, Mine Water Treatment Plant (MWTP) and Passive Treatment Systems (PTS) effluent discharge requirements and background water quality for non-contact flows.

2.2.1 Seepage Contact Water – Geochemical Source Terms

The drainage chemistry from the various Eagle Gold mine facilities discussed herein is influenced by a variety of geochemical and physical aspects. Overarching controls that will govern the water quality associated with any facility that contains exposed waste rock and ore, include:

- Mineralogy and geochemistry of the exposed material;
- Grain size distribution;
- Water/rock ratio;

- Depositional environment (*e.g.*, saturated versus unsaturated conditions); and
- Temperature.

The rate at which minerals weather chemically in laboratory kinetic tests is typically observed to be many times faster than rates inferred from field observations of drainage from the toe of waste rock piles (Malmström, 2000). This discrepancy is in part due to the formation of distinct flow channels within the waste rock pile that results in the incomplete flushing of weathering products from the waste rock dump (Nichol et al., 2005).

The prediction of both the major and trace elemental geochemistry of waters in contact with the modelled facilities was conducted by upscaling of loading rates derived from kinetic tests (waste rock humidity cells). A flow chart of the work stages comprising this exercise is given in Figure 2.2-1. The following sections describe in detail the different modelling steps used in the generation of the predictive model.

2.2.1.1 Selection of Input Loading Rates

As a first step in the development of geochemical source terms, the appropriate input solution chemistry needed to be defined. Dissolved concentrations for all chemical species produced during recent and historical kinetic experiments were converted into geochemical loads (in $mg/kg_{rock}/wk$) by multiplying each species with the amount of leachate output volume (in L) and dividing this load by the mass of rock reacting with the leachate (standard humidity cell = 1 kg).

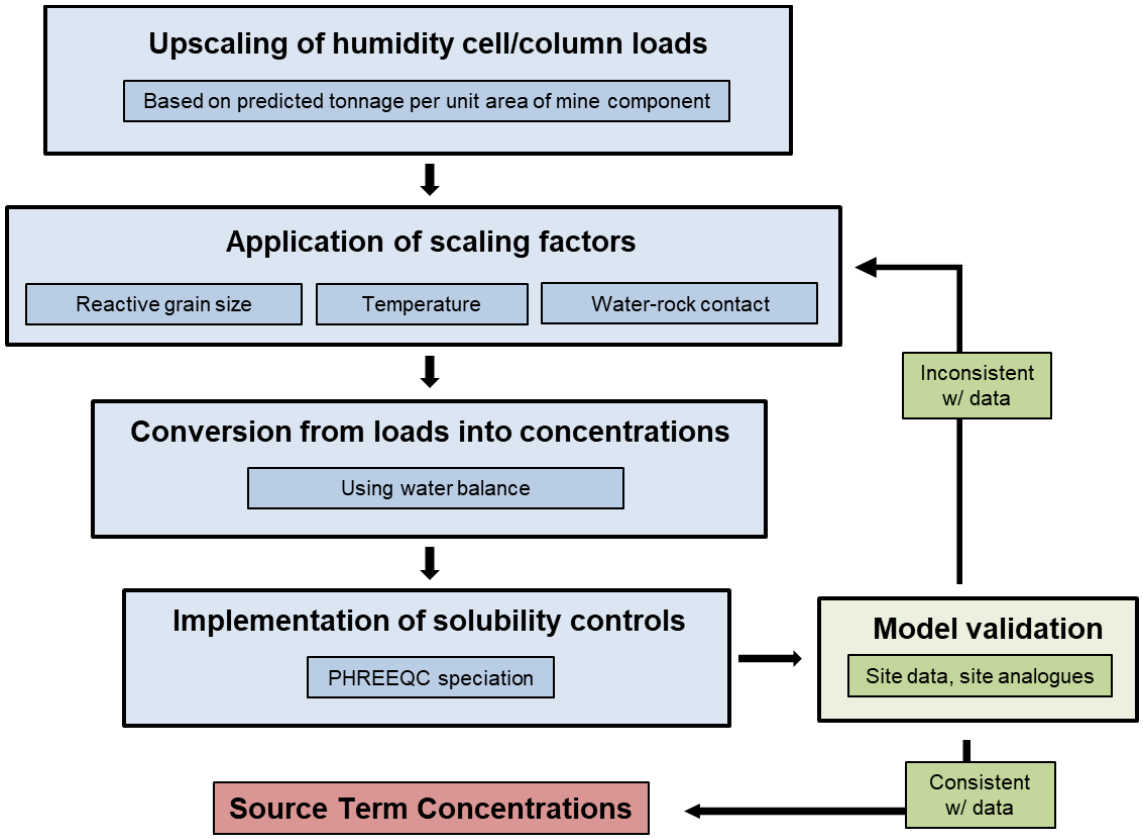

Figure 2.2-1: Work stages involved in the scaling of geochemical source terms

For WRSA and pit wall drainage chemistry predictions, Eagle Gold humidity cells were grouped to represent the various waste rock types expected to be exposed during mine development. Humidity cells used to produce the individual input solutions are listed in Table 2.2-1.

Two different scenarios are presented for the WRSA source terms; an operational and a post-closure scenario. More specifically, for the operational scenario, the 75th percentile of all available humidity cell leachates for a given species were used as the model input solution. In contrast, to model longer term ("stable") geochemical loading rates, the 75th percentile loading rates of the last three humidity cell cycles (weeks) with metal analysis were utilized to produce a solution input, assuming geochemical reaction rates reach a steady-steady state after soluble minerals have been flushed. Note that for the derivation of the model pH, the respective median value was used for operational and post-closure scenarios.

Drainage chemistry predictions for the 90-day ore stockpile are based on the 75th percentile of all leachates from two ore composite humidity cells (HC 7, 12; Table 2.2-1) to account for the relatively short duration of storage of material and expected initially high flushing

concentrations. Since changes in tonnage and water balance will repeat annually, one operational set of drainage quality predictions was found to be appropriate for this facility.

Table 2.2-1:
Summary of kinetic test cells used for the individual rock units modelled

Lithology/Material	Kinetic cell used
Oxidized Granodiorite (OGD)	DGK 3, HC 5, HC 10
Fresh Granodiorite (FGD)	DGK 2, HC 3, HC 9
Altered Granodiorite (AGD)	DGK 4, HC 4, HC 6, HC 11
Oxide Metasediment (OMS)	HC 8
Fresh Metasediment (FMS)	DGK 1, HC 1, HC 2, HC 8, HC 13
Overburden (OB)	HC 10
Stockpiled ore (SP)	HC 7, HC 12

Table 2.2-2 and Table 2.2-3 provide an overview of the input solution chemistries used for waste rock and ore-containing facilities, respectively. Note that these values are identical to from previous model iterations and a detailed list of all model inputs can be found in Lorax (2014). Refer to SRK (2014) for a detailed description of humidity cell sample selection rationale and solid phase characteristics.

2.2.1.2 Upscaling of Kinetic Test Loads

Once the input solution chemistry was defined, the geochemical loads were upscaled to match the tonnage of the mine component in question. Up-to-date estimates of mine tonnage stored in WRSA, ore stockpile and HLF were provided by StrataGold and are based on optimizations made to the Project in 2017 and 2018. The waste production schedule and pit wall exposures used for this assessment are given in Table 2.2-4. Note that a detailed discussion of site analogues used for the calibration and comparison of scaling factors was provided in Lorax (2014).

The 90-day ore stockpile will vary in tonnage seasonally between zero to ~2.8 Mt. More specifically, it will be constructed every year between January and March (maximum tonnage) at which point the ore is removed and transported to the HLF until all material is consumed by December of the following year.

While the rock mass of the described mine components can be easily translated from the waste and ore production schedule, the derivation of reactive rock mass within the exposed pit walls is less straightforward. The final pit walls are expected to be fractured as a result of blasting operations. Fracturing of the pit walls exposes a greater proportion of the wall rock to weathering and hence wall rock drainage will have the geochemical signature of the respective rock type. In this assessment, it was assumed that controlled blasting would be used at the limits of the proposed open pit mine. However, controlled blasting of rock does not completely eliminate fracture of underlying rock but results in a blast-damaged transition zone extending into the pit walls. This blast-damaged transition zone comprises a blast-fractured zone and a blast-influenced zone that would be subject to oxidative weathering. The penetration depth of the blast-damaged zones into the wall rock is dependent on a variety of parameters. Hustrulid (1999) estimated ranges of 0.85 to 1.05 m and 2.65 to 3.15 m for the blast-fractured and the blast-influenced zones, respectively. These estimates are based on controlled blasting and an intermediate rock strength. For the Eagle Gold pit walls, penetration depths of 0.9 and 2.9 m were chosen for the blast-fractured and the blast-influenced zones, respectively. Using a bulk density of 2.5 t/m^3 along with the annual surface areas broken out into waste rock type, these thicknesses were subsequently used to calculate a rock mass that will come in contact with infiltrating waters and produce a geochemical load.

Alkalinity is generally limited by the solubility of carbonate phases and is closely related to pH. Upscaling alkalinity in the same manner as dissolved metals would lead to unrealistically high values affecting the PHREEQC input file and cause extensive carbonate precipitation which would, in turn, alter the output pH inordinately. In that context, field barrels represent a useful analogue (see Section 2.2.1.7) with an acid-base balance and climatic conditions similar to those expected in the Eagle Gold mine components. Therefore, constant typical values seen in field barrel leachates were used for the predictive model (100 mg $CaCO_3$/L for WRSA, and ore stockpile; 60 mg $CaCO_3$/L for pit walls; between 100 and 200 kg $CaCO_3$/L for different HLF scenarios).

2.2.1.3 Adjustment of Upscaled Loads

Owing to several lab-to-field comparison studies it has been recognized that drainage chemistry predictions based on direct mass upscaling often strongly overestimate the quantities of dissolved solids that are in fact leached from the mine rock (Malmström et al., 2000; Sapsford *et al*., 2009; Plante *et al.,* 2014; Kirchner & Mattson, 2015). This is

likely due to a variety of differences between lab and field conditions such as climate, water/rock ratios, hydrogeological pathways, grain size distribution and secondary mineral controls all of which would reduce geochemical loads in the field. As a result, it is the industry standard to implement scaling factors when upscaling humidity cell leachate results to account for these discrepancies. The following describes the scaling factors applied in the Eagle Gold source term model along with their rationale as it relates to the difference in field conditions. Refer to Kempton (2012) for a review of the various scaling factors commonly considered for geochemical source term predictions.

Temperature

The Eagle Gold project is located in the Yukon with average monthly temperatures ranging from approximately -21 to 10.5˚C for January and July, respectively. Kinetic experiments used for the source term model were conducted at SGS laboratories at a temperature of 22˚C and it is well known that the rate of many geochemical reactions leading to the release of acidity and dissolved metals is highly temperature-dependent. For Eagle Gold ore and waste rock, the oxidation of pyrite can be considered the driving force in terms of contaminant leaching for most parameters of concern. This reaction has been extensively studied and its rate has been determined over a range of temperatures that can be expressed in terms of an Arrhenius correlation. The Arrhenius relationship describing pyrite oxidation rate as a function of temperature is given by:

$$Temperature\ adjustment\ [\%] = e^{[E_a * (T_x - T_y)/(R * T_x * T_y)]}$$

With E_a = activation energy;

R = universal gas constant;

T_x = temperature of interest; and

T_y = experimental temperature.

The activation energy determines the slope of this function and, therefore, the temperature-dependence of the oxidation reaction. For the purposes of this model, an E_a of 30 kJ/mol was chosen to be consistent with the range of values reported in the literature (e.g., Lowson, 1982; Nicholson *et al.*, 1988; and, Kamei and Ohmoto, 1999).

The bulk portion of waste and ore piles will not adopt ambient air temperatures with a much smaller amplitude in temperature variation to be expected throughout the year. To account for this thermal inertia, monthly temperatures were adjusted for these mine components to produce a smoother temperature distribution curve while still maintaining average annual temperatures and an average temperature scaling factor of approximately 28% (range from 24-34% depending upon month; Table 2.2-5). For the pit walls, the temperature distribution was only smoothed slightly, yielding a wider range in scaling factors (16-41%) while showing a similar average scaling factor throughout the year.

Table 2.2-5:
Summary of Temperature Correction Factors Applied to Scaling

Month	Pit walls	Stockpiles*
Jan	16%	24%
Feb	17%	24%
Mar	19%	25%
Apr	28%	29%
May	33%	31%
Jun	39%	33%
Jul	41%	34%
Aug	37%	33%
Sep	33%	31%
Oct	24%	28%
Nov	21%	26%
Dec	16%	24%
Average	27%	28%

*Stockpiles include WRSA, HLF, and the 90-day ore stockpile

Grain Size Distribution

Before representative material is placed into laboratory kinetic test cells, rock samples are crushed to a nominal grain size of <1/4" to allow for better comparability of reaction rates between different cells containing different geological material. The smaller the grain size, the higher the amount of surface area that is exposed to weathering. Therefore, reaction rates are generally elevated in the fine fraction of a rock sample. Studies investigating the effect of grain size distribution on drainage chemistry in mine environments found that likely >80% of the geochemical loads are leached from the <25 mm fraction (Strömberg and Banwart, 1999; Stockwell *et al*., 2006). Highly dependent on the rock type and blasting method, it was estimated that this fraction represents between 10 and 40% by mass of a typical waste dump with the majority of studied waste dumps falling into the lower end of this range. Wickland and Wilson (2004) measured the particle size distribution of a waste rock dump and material less than 6 mm accounted for approximately 15% of the total dump mass. For the lack of detailed work regarding the grain size distribution at Eagle Gold WRSA and the pit wall blast-fractured zone, a reasonably conservative scaling factor of 30% was implemented to account for the mass of relatively unreactive rock fractions. A grain size scaling factor of 15% was assigned to the less damaged pit wall blast-influenced zone.

For optimized gold recovery, ore grade material will go through one crushing cycle before being stored in the 90-day ore stockpile and additional two crushing cycles before being stacked on the heap leach pads. The final crushed ore product will have a target grain size of 80% <6.4 mm, roughly equivalent to particle size distribution used in kinetic testing. The primary crusher setting is designed to produce a particle size of 150 mm or less in the

temporary ore stockpile, which falls between the expected grain sizes of waste rock and the final ore product, so a grain size correction factor of 50% was implemented.

Contact Water

Humidity cell experiments are conducted using water/rock ratios that allow for the flushing of all rock material placed into the cells. Various studies suggest that only a portion of the rock mass contained in a waste dump is contacted by infiltrating water. In one study, for example, a small-scale waste rock dump was disassembled one year after its construction and the distribution of moisture contents within the dump indicated that the development of preferential flow paths is an important process (Marcoline *et al.,* 2006). Under low-flow conditions, water is retained in and will travel along the fine fractions within the waste dumps, whereas heavy rainfalls may flush relatively higher proportions of the coarser grain sizes (Andrina, 2009). It has also been suggested that, in months of higher rain intensity, a larger overall portion of the dump is contacted as more pathways are being activated. In accordance with this concept, a contact water scaling factor was applied that was dependent on the infiltration volume in each month. Furthermore, as the WRSA becomes larger with time during operations, it was assumed that the percentage of contact water decreases with increasing dump size over time as larger areas become isolated from infiltration as a result of the increasing volume-to-area ratio. An overview of the maximum assumed contact water factor for the two WRSA is provided in Table 2.2-6.

Table 2.2-6:
Maximum contact water scaling factors implemented over time for the WRSA prediction model

	Eagle Pup	Platinum Gulch
Year 1*	80%	45%
Year 2*	60%	35%
Year 3*	50%	30%
Year 4	25%	10%
Year 5	20%	10%
Year 6	15%	-
Year 7	10%	-
Year 8	7.5%	-
Year 9	6%	-
Year 10	5%	-
PC	5%	-

*concentrations were set to initial field barrel concentrations if found to be higher than the modeled concentrations

A similar approach was taken for the 90-day ore stockpile where seasonal changes in water balance and material tonnage were considered as best as possible leading to a contact water factor of 0.1 or 10% throughout the year. Note that the maximum contact water factor was held constant for pit walls over time with 90% and 60% assumed to come in contact with the blast-fractured and blast-influenced zones in the highest infiltration month, respectively.

WRSA will be covered with soil as part of the closure process to reduce infiltration into these mine facilities. A reduction of infiltration will simultaneously reduce the geochemical loads being released from the waste rock and ore. Cover performance studies relating infiltration to geochemistry have shown, however, that the reduction in infiltration is not equivalent to the reduction of geochemical loads with the latter generally being attenuated to a lesser degree (Marcoline, 2008). Consequently, while the water infiltration reduction in response to soil cover placement is typically >50%, a geochemical loading reduction of only 25% (i.e., cover correction factor = 0.75) was conservatively assumed.

Stored Loads

Pyrite oxidation occurs at relatively low moisture contents (down to <1%) and may therefore even proceed in the unfrozen portions of the waste dump and pit walls that are not regularly flushed. Conceptually, in months with relatively low infiltration rates, a portion of hydrogeological pathways are not actively rinsed, however the moisture content in these months is still sufficient to promote sulphide weathering. Geochemical loads produced during these months are then temporarily stored and subsequently released when these pathways become activated again (*e.g.*, during heavy rainfall events in May). This mechanism has been observed in various mine settings where increased concentrations correlated with heavy rainfalls, especially after extended dry periods (Kempton and Atkins, 2000). This seasonal variation of the load distribution was accounted for by tracking the amount of loads being produced in lower-infiltration months followed by subsequent release of a small portion (2%) of these stored loads in April and May.

2.2.1.4 Mineral Solubility Control

Water/rock ratios in humidity cell testing are high enough to prevent supersaturation of most species such that secondary mineral precipitation in the test cells is unlikely to occur to a high degree. Upscaling of geochemical loads as described above is generally carried out with no consideration given to mineral phases that may limit the dissolved concentrations of insoluble elements such as Fe, Al, and Ba (at circum-neutral pH). In order to avoid the calculation of unrealistically high concentrations of species that are known to form secondary phases in mine drainage, PHREEQC - a thermodynamic mineral solubility model (Minteq v.4) - was employed on the upscaled concentrations to account for mineral

solubility controls (Parkhurst and Appelo, 1999). Minerals commonly seen in mine drainage and allowed to precipitate from the predicted drainage solutions are listed in Table 2.2-7. Phases that were in fact identified to be supersaturated in at least one output solution draining from the individual mine components are indicated by a check mark. Unmarked phases merely served as a theoretical concentration cap.

Adsorption is known to be an important (and for some species dominant) mechanism in reducing dissolved concentrations in mine drainage (Cheng et al., 2009). PHREEQC has the capability of modelling adsorption attenuation onto surfaces of hydrous ferric oxides (HFO) such as ferrihydrite. Commonly, the effect of adsorption is most prominent in acidic Fe-rich seepage that becomes neutralized downstream and precipitates significant amounts of these HFO. For Eagle Gold drainage, high Fe-concentrations are not expected, and while ferrihydrite was found to be supersaturated in most of the modelled solutions, it should be noted that a thermodynamic database may overestimate the amount of HFO precipitating in the field, therefore overestimating potential adsorption impacts. To maintain conservatism with respect to the dissolved parameters of concern, and to not overcomplicate the prediction model, adsorption modelling was omitted in this approach. This is further justified by the fact that the drainage prediction model was calibrated using site analogue data and bulk scaling factors that already account for adsorption, as "real" drainage data is used as a reference point (Lorax, 2014).

Table 2.2-7:
Mineral phase allowed to precipitate in the Eagle Gold speciation model

Mineral	Ideal Formula	Eagle Pup	Platinum Gulch	Pit walls	90-day SP	Heap Leach

Smithsonite	$ZnCO_3$					

2.2.1.5 Nitrogen Source Term Derivation

Nitrogen based blasting reagents have been identified by Pommen (1983) as a source of nitrogen compounds from surface mining operations. The nitrogen compounds ammonia (NH_3) and nitrate (NO_3) are constituents of the explosives, while nitrite (NO_2) is typically

an intermediate oxidation product of ammonia. The release of nitrogen compounds from blasting reagents can occur within the pit during mining operations and from residual reagents stored within blasted rock. The release of nitrogen from explosives loaded in boreholes and from explosive residue on blasted rock surfaces occurs by dissolution of nitrogen compounds into water and subsequent aqueous transport to the downstream receiving environment.

A detailed discussion of the Eagle Gold nitrogen-specific source term assumptions and results was presented in Lorax (2014). For this iteration, no changes to this approach were made and the model output remains the same; the reader is referred to Lorax (2014) for an overview of these results.

2.2.1.6 Field Kinetic Experiments

Larger mass, field-based experiments are advantageous because, compared to humidity cell testing, they more suitably resemble the actual conditions present within WRSA and pit walls including site-specific climate, scale, grain-size, and water-rock ratios. A total of eight field barrels (FB) containing ~225 kg of representative waste rock lithologies were constructed by StrataGold in 2012. Specifically, the barrels were composed of:

- FB 1: Oxide metasediment
- FB 2: Fresh metasediment
- FB 3: Oxide/fresh metasediment
- FB 4: Oxide granodiorite
- FB 5: Fresh granodiorite
- FB 6: Altered granodiorite
- FB 7: Oxide/fresh granodiorite
- FB 8: Overburden (mixed oxide metaseds and oxide granodiorite)

To date, 21 leachate sampling events have occurred over a time span of six years and analyzed for physical and geochemical parameters. This section serves as an overview of the field bin (FB) data, including incorporation of the most recent 2018 results, relevant to the geochemical source term predictions for the updated model. Details with regards to the construction and sampling protocol for the FB are discussed in detail in SRK (2014). Figure 2.2-2 to Figure 2.2-5 illustrate the temporal leaching behaviour observed from 2012 to September 2018 of some species of interest for the various waste types relative to geochemical source term predictions.

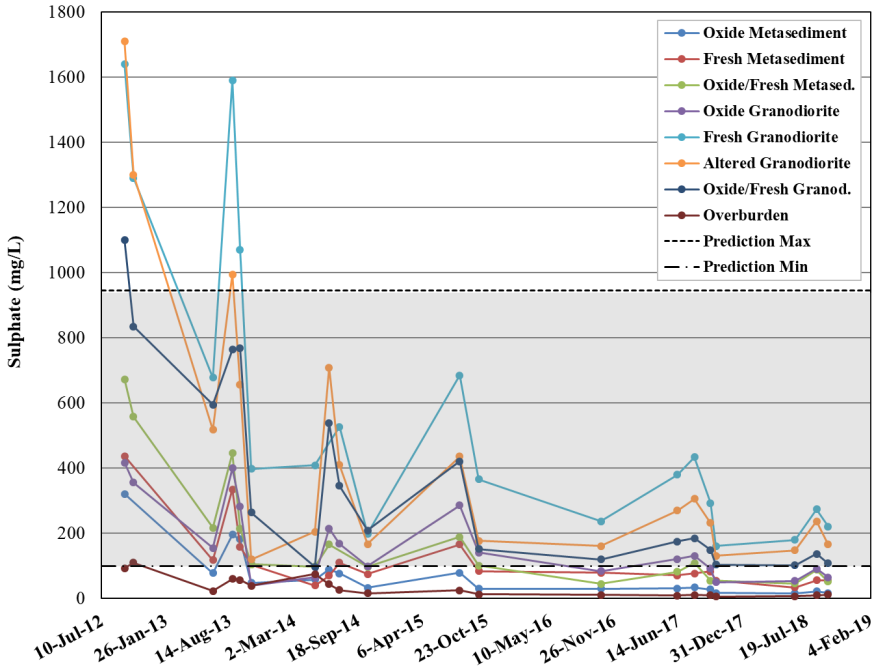

Figure 2.2-2 Sulphate concentrations over time in leachates from Eagle Gold field barrels. The range of predicted concentrations for the Eagle Pup and Platinum Gulch WRSF is shaded

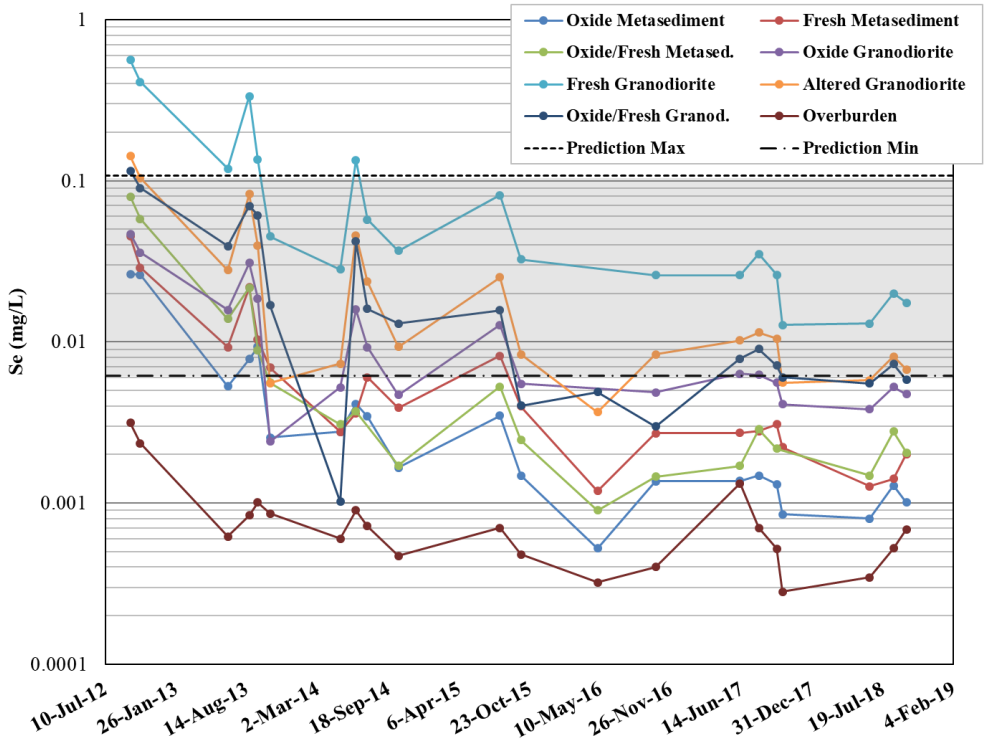

Figure 2.2-3 Selenium concentrations over time in leachates from Eagle Gold field barrels. The range of predicted concentrations for the Eagle Pup and Platinum Gulch WRSF is shaded

With pH remaining relatively stable between 7.5 and 8.5 (not shown), dissolved sulphate and Se concentrations display a generally decreasing trend over time with occasional spikes in concentration likely being caused by rain fall events (Figure 2.2-2 and Figure 2.2-3). The initially relatively high concentrations are inferred to be a result of stored loads that may (at least in part) have accumulated in the waste rock pores during storage of drill core.

Conversely, the As and Sb concentrations remain relatively constant over the 5-year period (Figures 2.2-4 and 2.2-5). The single exception to these trends is the increase in As concentration observed in the Oxide Granodiorite field barrel. For As, a marked increase to a value of approximately 3.0 mg/L in the most recent sampling cycle was observed in the oxide granodiorite sample (Figure 2.2-4); this has the highest solid-phase As content (1065 ppm) and is well above the respective 90th percentile value (607 ppm) of the static test database for Eagle Gold waste rock. In other words, less than 10% of oxide granodiorite rock is expected to have an As content as high as that measured in the field barrel sample.

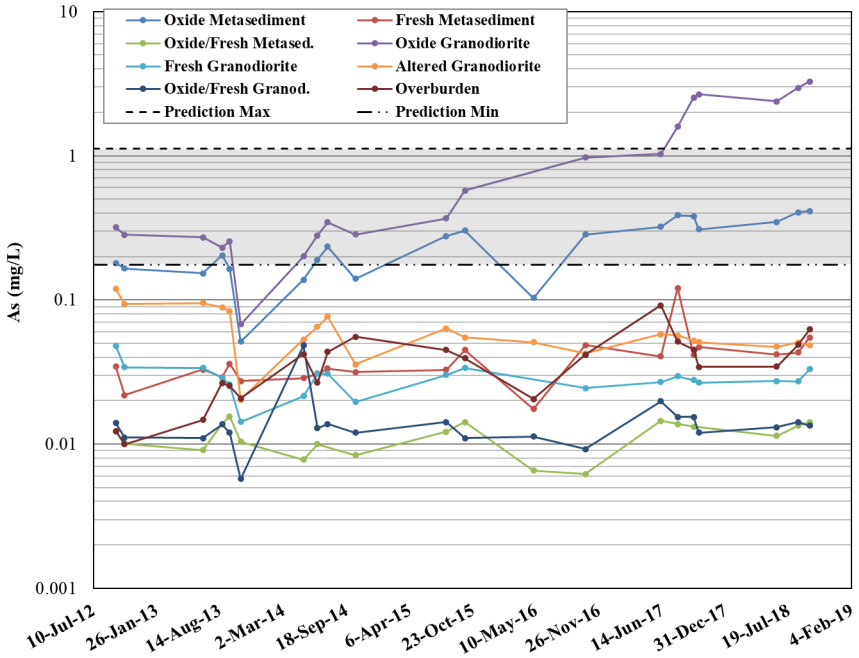

Figure 2.2-4 Arsenic concentrations over time in leachates from Eagle Gold field barrels. The range of predicted concentrations for the Eagle Pup and Platinum Gulch WRSF is shaded

However, there does not seem to be a correlation of maximum dissolved As concentrations, in field barrel leachates, which are remarkably constant over the six years, and the solid-phase As content for the remaining tested materials. Variability in concentration that is consistent across field barrel leachates (e.g., drop in As concentration in October 2013) is most likely due to response to precipitation infiltration, where increased or decreased

flushing rates directly affect the leachate concentrations. The more systematic increase in arsenic seen in the oxide granodiorite barrel over the last 3 to 4 years may be explained by either the accumulation and flushing of stored loads or saturation within the field bins due to blockage resulting in reductive dissolution of arsenic.

As mine wastes oxidize in stockpiles, material surfaces may only be irregularly flushed and contribute to seepage geochemical loadings from low water/rock ratios and the development of preferential flow paths. Nevertheless, the moisture content within a waste rock storage facility may still be sufficiently high to promote sulphide oxidation in portions of the pile that are not continuously rinsed. This leads to the local accumulation of stored loads in temporarily immobile pore waters or in the form of secondary mineral phases. During episodes of higher water/rock ratios (e.g. snowmelt, rainfall/storm events) a larger amount of flow paths may become activated, thereby releasing a portion of the stored loads (Kempton and Atkins, 2000) which may result in higher seepage concentrations. However, this effect commonly encompasses various species and is temporary in nature. While the seasonal variability in As concentration across the different field barrels may be attributed to this mechanism, it is unlikely that the more systematic As increase seen in the oxide granodiorite barrel is caused by stored loads rinsing. This process is represented in the source term model leading to seasonal fluctuations in As release rates (Lorax, 2014).

The observation that the highest As concentrations are leaching from the two field barrels made up entirely of oxide materials (5-10 times higher than the other six barrels), although FB1 (oxide metasediment) has relatively low S content, suggests that these materials contain As-bearing phases that are relatively mobile. By definition, oxide materials are made up of rocks that have been naturally weathered via oxidation processes. While this does not mean that these rock types are benign after blasting and exposure to the atmosphere, the reaction and metal leaching rates under oxidizing conditions are commonly lower than those observed in sulphide bearing un-oxidized mine waste. Conversely, one scenario under which oxide waste rock is expected to be more reactive is when stored in a sub- or anoxic environment (e.g., under a water cover). Secondary phases (e.g. hydrous ferric oxides and/or Mn oxides) that formed during the weathering process may then become unstable and remobilized as a result of reductive dissolution. Similarly, metals and or metalloids that are sorbed or were coprecipitated with the oxides are also prone to redissolution. Oxide waste rock from the Eagle Gold deposit is known to contain scorodite, a secondary Fe-As mineral which under neutral and reducing conditions dissolves incongruently, with As being preferentially released into solution as the mineral starts to break down (Bluteau and Demopoulos, 2007). If the field barrels have become blocked with fines or were constructed in a way that does not allow adequate drainage, a saturated layer may develop in the barrel over time promoting suboxic conditions. This saturated layer is likely to become thicker with time, mobilizing more and more As.

Malfunctioning field experiments are not uncommon and given the observed relative As trends along with the mineralogical make-up of the oxide rock, reductive dissolution processes are considered the most likely cause for the observed increasing As concentrations in FB1 and FB4. Investigations in the summer of 2019 are planned to evaluate whether the field barrel data is biased.

Sb concentrations are typically around 0.4 mg/L in leachate from FB6 (altered granodiorite barrel), which has the highest Sb content at 37 ppm suggesting that the solid-phase composition has a direct effect on leaching behaviour in these materials. Except for FB4 and FB6, all the barrels have Sb concentrations in leachate below 0.05 mg/L (Figure 2.2-5).

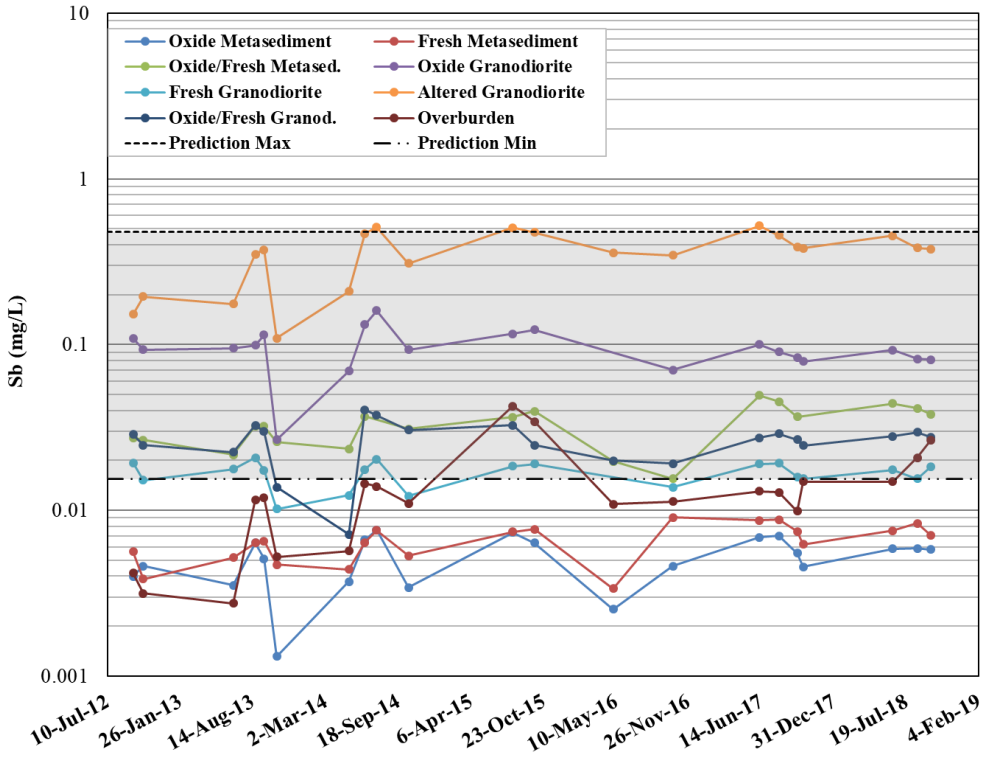

Figure 2.2-5 Antimony concentrations over time in leachates from Eagle Gold field barrels. The range of predicted concentrations for the Eagle Pup and Platinum Gulch WRSF is shaded

Interestingly, there is no one lithology that consistently releases the highest loads for all metalloids. Of note is that the Se trend mimics that of sulphate suggesting that these two species are mineralogically associated. The relationship between these species was used to derive Se concentrations from predicted sulphate values in the source term model.

2.2.1.7 Results

One of the most important model results is that drainage from all facilities is expected to show a circum-neutral pH around 8 for all mine phases or, in other words, no acid rock drainage is expected at the Eagle Gold mine.

Analysis of the WRSA model output data lead to the finding that seepage concentrations were unrealistically low for some species in the first three years of operations using the adjusted humidity cell scale-up alone. Based on professional judgement, low values (*e.g.* sulphate) were set to a "first flush" value taken from field barrel leachates. This value was derived by calculating the median concentration observed over the first year of field barrel testing and accounts for the release of geochemical loads from freshly blasted materials.

Another adaption made to the upscaled loads is the derivation of selenium concentrations. Kinetic test data suggest that Se is strongly correlated with dissolved sulphate and is interpreted to be mineralogically associated with sulphur in both sulphate and sulphide minerals. For predictions made based on humidity cell upscaling, Se concentrations were modeled as a function of the sulphate concentration using Se/SO_4 ratios observed in the individual field barrels and proportioned according to rock type.

Figure 2.2-6 to Figure 2.2-9 show time-series plots of predicted source term concentrations for the main parameters of potential concern. The relatively large range in the values within a scenario and mine component presented can be explained by the consideration of temperature effects as well as stored loads release (in response to water balance) leading to a pronounced seasonal variability in geochemical loading. Where the predicted concentrations were adjusted to field barrel results, no seasonal variability may be observed (*e.g.*, for SO_4 in the ore stockpile predictions).

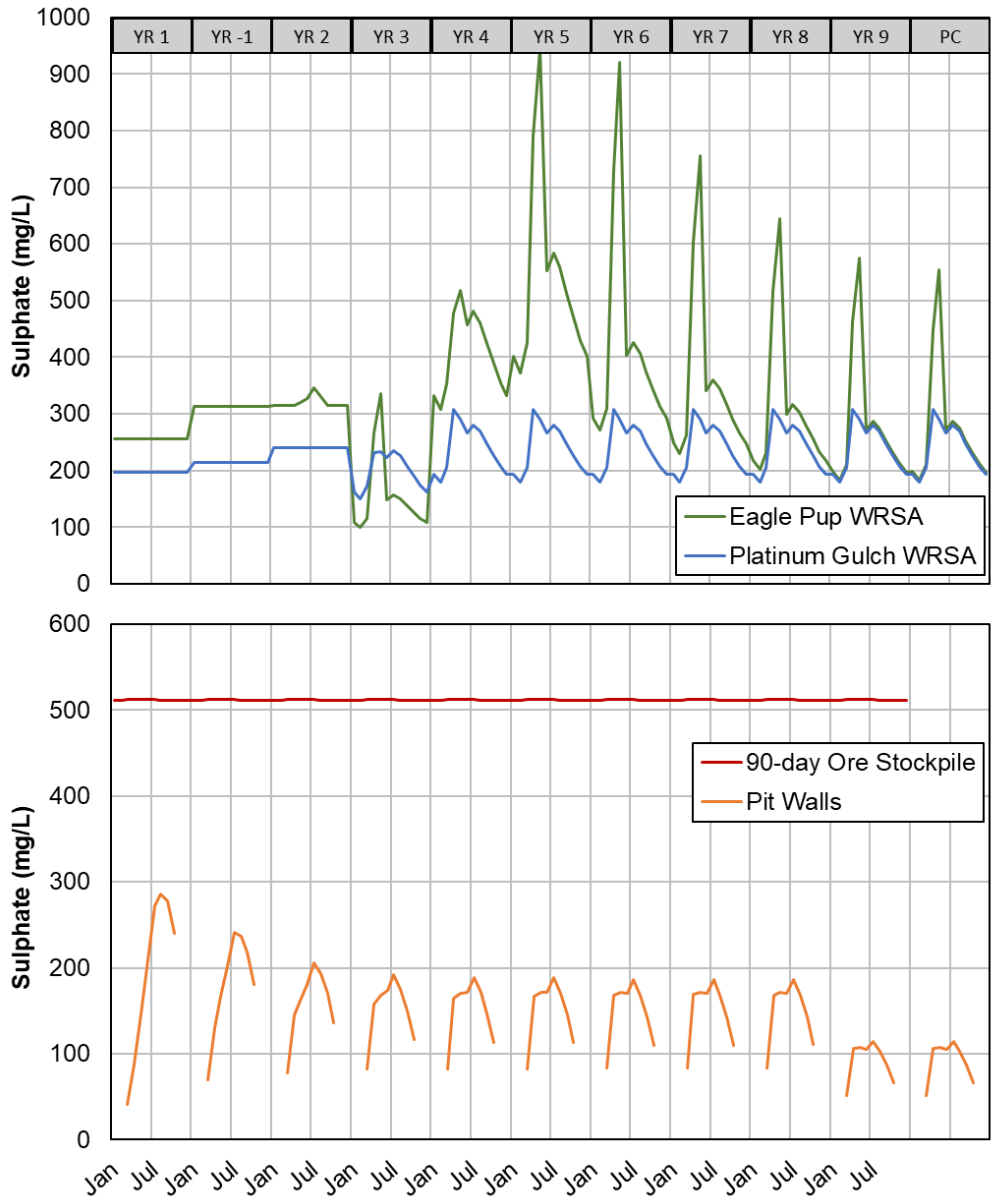

Figure 2.2-6 Predicted sulphate concentrations for the modelled Eagle Gold mine facilities (PC = Post-closure).

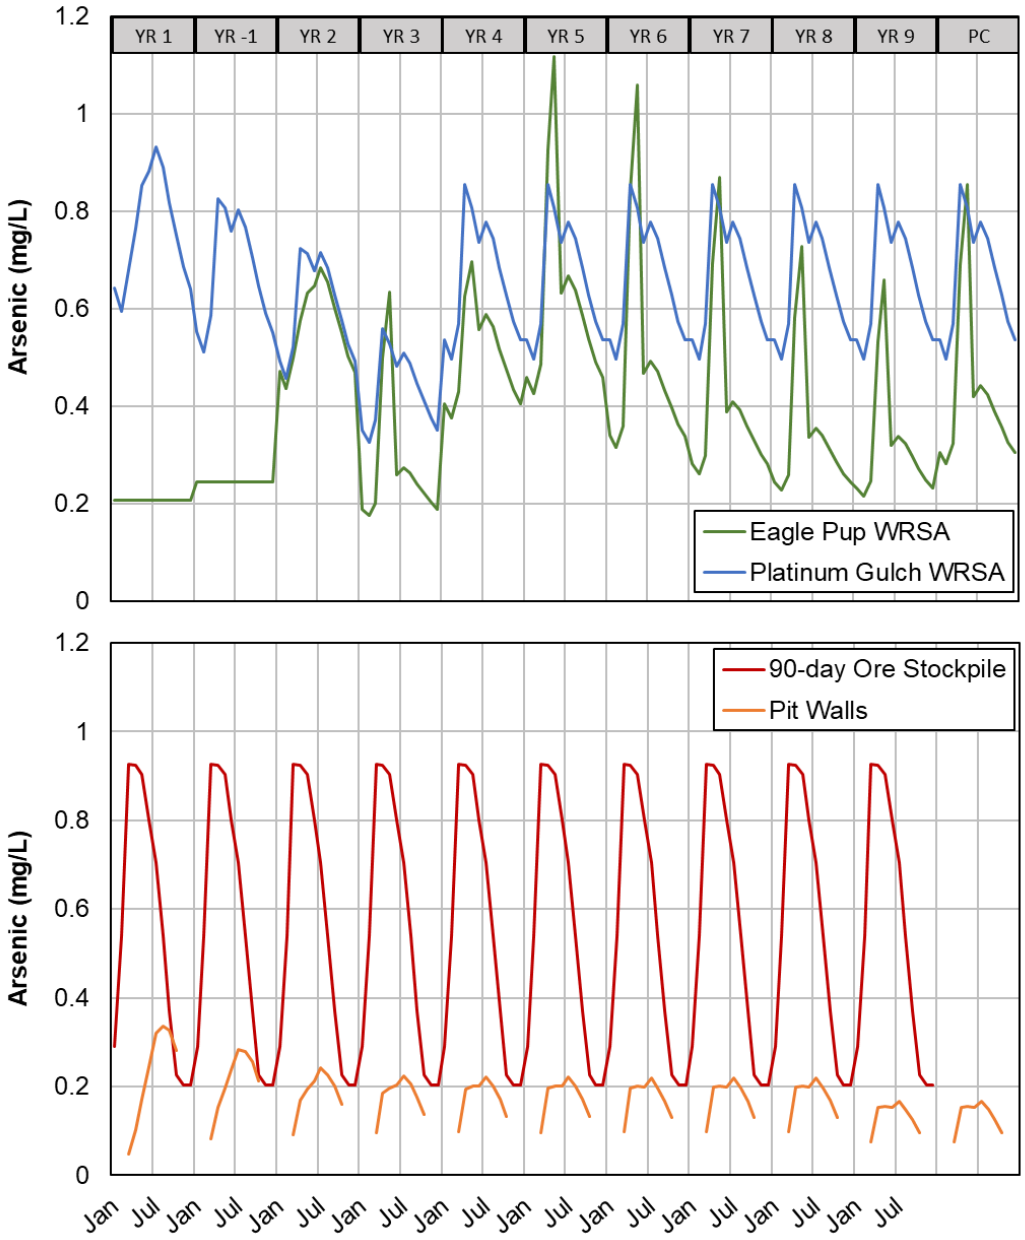

Figure 2.2-7: Predicted arsenic concentrations for the modelled Eagle Gold mine facilities (PC = Post-closure).

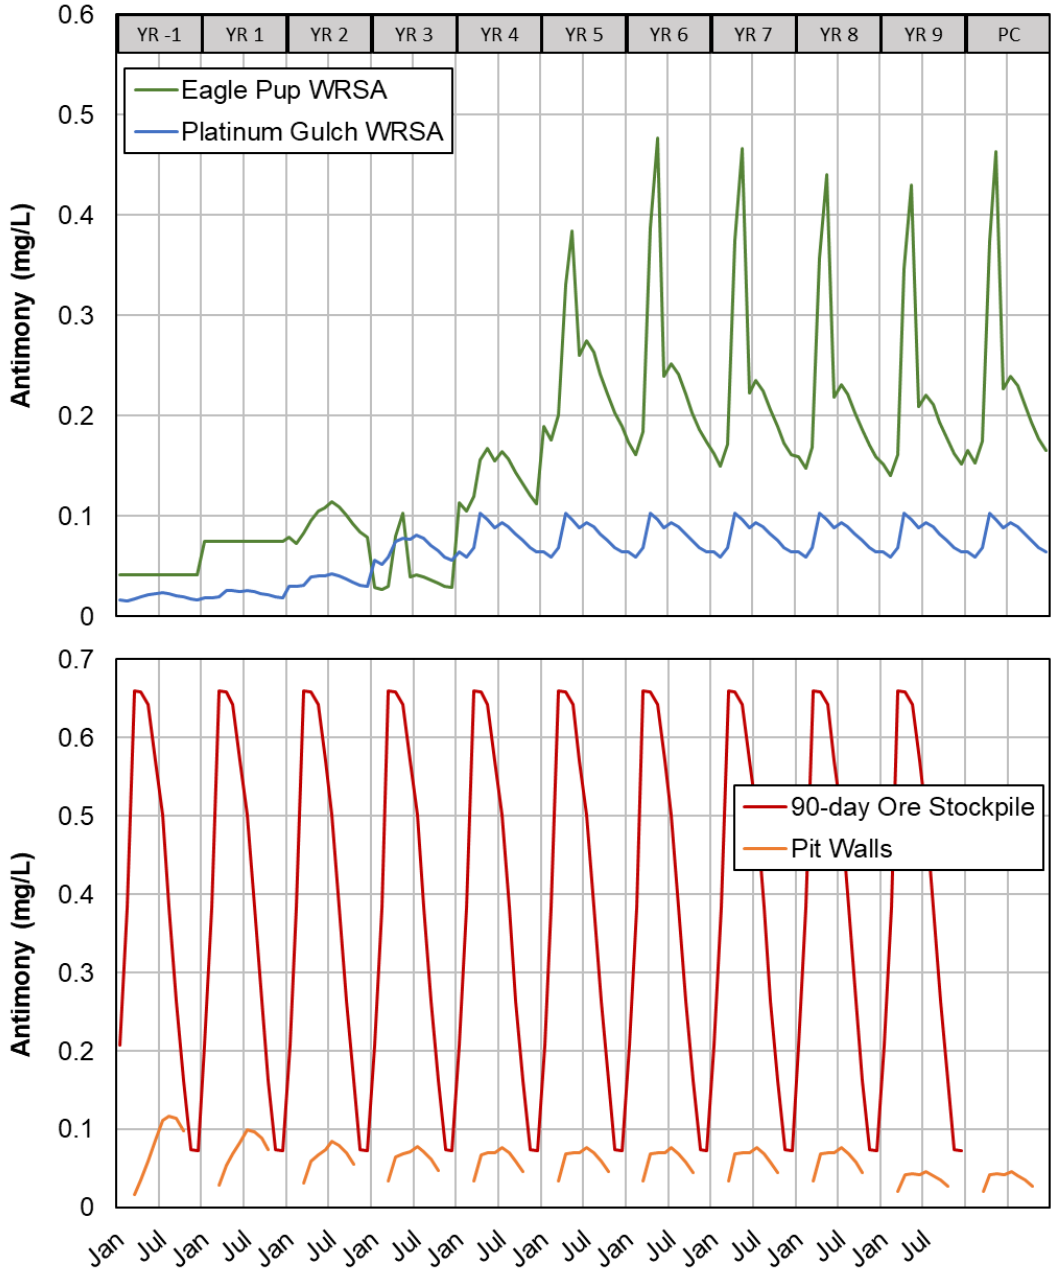

Figure 2.2-8 Predicted antimony concentrations for the modelled Eagle Gold mine facilities (PC = Post-closure).

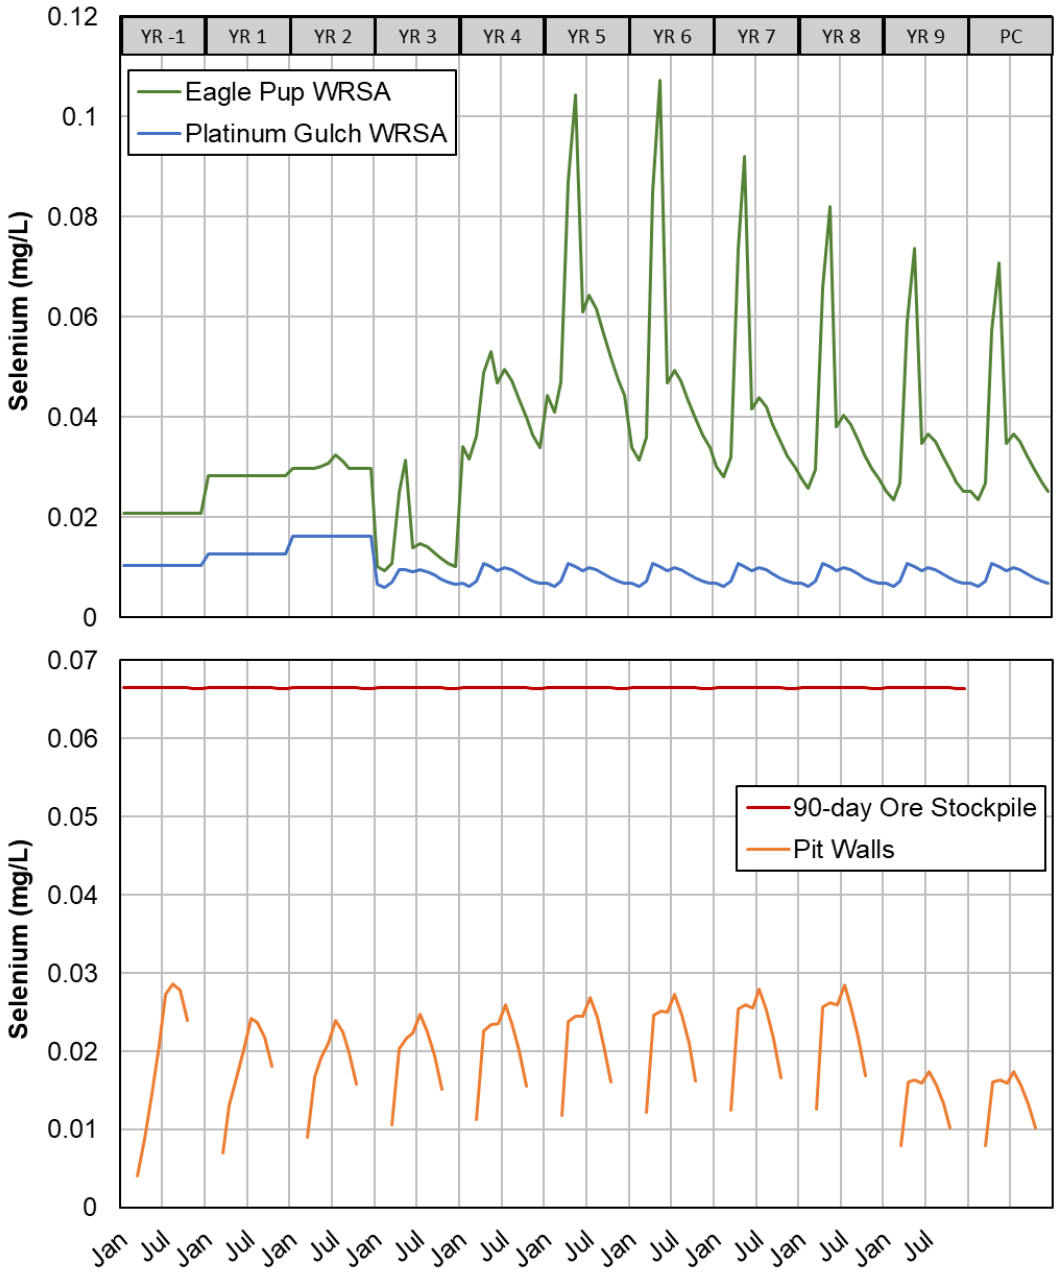

Figure 2.2-9 Predicted selenium concentrations for the modelled Eagle Gold mine facilities (PC = Post-closure).

For the 2018 WBWQM update, geochemical source term predictions were updated for four Eagle Gold mine components, namely the Eagle Pup and Platinum Gulch Waste Rock Storage Areas (WRSA), Pit Walls, and the 90-day Ore Stockpile. The Heap Leach Facility (HLF) was not re-modelled in the 2018 source term update as drainage from the HLF following the end of heap leaching is expected to be in geochemical equilibrium and therefore relatively insensitive to minor changes in the facility tonnage. As such, HLF

geochemical source term results presented in Lorax (2014) are still considered valid and have been carried forward in the current water quality model update.

The geochemistry data of field barrel leachates collected through September 2018 were reviewed by Lorax and the potential effect of the expanded database on the source term model was assessed. It was found that, since the last model update in the summer of 2018, the concentrations of major parameters of concern (As, Sb, Se, SO_4) remain relatively steady in leachates from the various field barrels and generally fall in the range of the source term predictions One exception to these trends is the increase of As concentration observed in 2017 and 2018 in the Oxide Granodiorite field barrel. It should be noted that this material's solid phase As content (1065 ppm) is well above the respective 90th percentile value (607 ppm) of the static test database for Eagle Gold waste rock. In other words, less than 10% of oxide granodiorite rock is expected to have an As content as high as that measured in the field barrel sample. It is also important to keep in mind that the field barrel leachates are generally only used for semi-quantitative model validation purposes. Overall, the upscaling exercise to derive source term predictions relied primarily on humidity cell testing which is considered the industry standard. Since the field barrels are operated in a less controlled environment than the humidity cells, the geochemical trends observed should be regarded with a larger degree of scrutiny.

In light of the observations from field kinetic testing and the assumption that inputs from the 2018 source term model update remain valid, no changes were made to the 2019 model. Predicted source terms concentrations are provided in Appendix A for all facilities that were considered in the 2018 source term model update and are reproduced herein.

2.2.2 MWTP and PTS Effluent Quality Standards

Effluent quality standards were set during the Water Use License process for the MWTP during operations and PTS for the closure phase (Table 2.2-8). The effluent quality standards for each component are utilized in the model representing treatment flows and chemistry.

During the Water Use License application process, it was agreed upon by all parties that the Project would be required to go through additional evaluation to support establishment of final effluent quality standards for the closure phase. As a conservative approach to closure and post closure water quality modeling, it has been assumed that the higher discharge criteria initially proposed by StrataGold would represent the effluent quality discharge. It is understood that continued modeling and eventual field trials of passive treatment systems for the Project will be undertaken by StrataGold to support the planned final reclamation and assessment and permitting for the closure plan of the Project.

Table 2.2-8:
MWTP and PTS Effluent Water Quality Used in Model

Parameter	*Effluent Quality Standards (mg/L)*

Zn	0.23

2.2.3 Background Water Quality Inputs

Background flows and water quality from runoff (e.g. non-contact water) and background receiving environment water chemistry were fully characterized and included in the model. Baseline water quality data collected from project area streams from 2007 and including data collected in 2016 to August 2017, prior to construction, were incorporated into the water quality baseline dataset.

2.2.4 Modeling Approach

Flows from background sources and mine facilities were taken directly from the WBM, with the exception of the seepage from the waste rock facilities. As with the 2014 water quality model submitted as part of the Water Use License application (14WQM), infiltration through the waste rock is provided to the WQM; the model then uses a function that attenuates the flow within the waste rock pile in a manner consistent with observed waste rock seepage hydrographs from other sites.

Water quality parameters tracked by the model are listed in Table 2.2-11. Each parameter is treated as a conservative tracer which is mixed at model nodes (confluences) by the following equation:

$$C_r = \frac{\sum_i Q_i C_i}{\sum_i Q_i}$$

where C_r is the resultant concentration, $Q_i$are the source flows into the mixing point and $C_i$are the concentrations associated with the source flows. The only exceptions to this flow-weighted instantaneous mixing scheme are for the Lower Dublin South Pond (LDSP) and for the open pit lake which are represented by constituent transport flow cells in GoldSim. The water quality for each of these two facilities is handled slightly differently during operations and draindown/closure:

1. During operations, the LDSP and the open pit (drained via sump from a small holding pond) are treated as flow-through reservoirs; their respective outflow chemistries are the same as those of their respective flow-weighted source flows.
2. During post-operations (draindown, closure) the LDSP and open pit lake accumulate and release contaminant load relatively slowly, and their water qualities are determined by the finite volume flow cell concentration (not the input concentration as before).

Table 2.2-9:
Eagle Gold Project Water Quality Model Parameters

Parameter	Cont'd	Cont'd
NH_4	Al	Mn
Cl	Sb	Hg
F	As	Mo
NO_3	Ba	Ni
NO_2	B	K
N	Cd	Se
P	Ca	Si
SO_4	Cr	Ag
WADCN	Co	Na
	Cu	Tl
	Fe	U
	Pb	V
	Mg	Zn

This difference in methodology has a very small impact in the particular case of the LDSP and helps reduce artificial spikes in concentration during operations which can occur through the rapid filling/draining activities of the pond dring operations.

As previously indicated, the WQM simulates 50 years of mine life, beginning in operation and ending several years into post-closure. The model time step is monthly, and the three principal mine periods for reporting are:

1. Operations (Corresponds to mine–years 1 to 12) with LDSP treated in the MWTP; in Phase 5 the heap is rinsed during cyanide destruction;
2. Early Closure (Corresponds to mine–years 13 to 20): LDSP is decommissioned and the heap drain-down is controlled with the MTWP operating to treat heap seepage. Eagle Pup WRSA and Platinum Gulch WRSA seepage waters are passively treated before discharge to receiving waters;
3. Late Closure (Years 20+): Waste rock, pit overflow contact water and heap seepages are passively treated before discharge to receiving waters.

Source terms were developed for the median and 75th percentile case. To remain conservative, the discussion is based on the results of the 75th percentile source terms coupled with the median WBM flow scenario.

Water quality from mine discharge during operations is driven by the contact water reporting to the Lower Dublin South Pond. Contact water from the Eagle Pup and Platinum Gulch WRSAs, the temporary ore stockpile, and the sump water from the open pit all report to the LDSP at some point during operations. Excess water from the LDSP is treated through the MWTP to meet the effluent quality standards in Table 2.2-8 and discharged to Haggart Creek upstream of W4. Figure 2.2-10 and Figure 2.2-11 are schematic illustrations of the water balance and water quality model for mine year 2 and 9, respectively.

Beginning in year 12, both the Eagle Pup and Platinum Gulch waste rock seeps are treated by the LDSP passive treatment system to meet the discharge criteria in Table 2.2-9. It is conservatively assumed that the Platinum Gulch Pond PTS (established in approximately year 4) does not result in any alteration to the effluent quality from the open pit and Platinum Gulch waste rock seep that reports to the LDSP PTS. During this time period (Phase 6), HLF drain-down water reports to the MWTP and is treated to meet discharge criteria as indicated in Table 2.2-8. Figure 2.2-12 illustrates the water balance conditions for mine year 15.

The late closure period begins with the decommissioning of the MWTP and the full application of passive treatment for all contact mine waters including pit overflow waters (year 20+). At this time, the HLF has little excess water to drain, and post-closure monthly

discharge is driven largely by infiltration. After year 20, the HLF seep is treated solely through a PTS to values indicated in Table 2.2-10 (Figure 2.2-13).

The WQM provides monthly predictions of water quality at key locations in Haggart Creek, namely:

- W4 in Haggart Creek just downstream of the chief compliance point (i.e., MWTP discharge);
- W29 in Haggart Creek downstream of all project influences; and
- W23 in Haggart Creek, immediately downstream of the confluence with Lynx Creek.

3. Water Quality Predictions

The results of the 19WQM (WBMWQM v3.4) update are presented in this section. Results are presented in downstream order for the three Haggart Creek receiving environment stations (W4), (W29) and (W23), for the main parameters of interest, namely As and Se. Time-series of all predicted parameters are provided in Appendix B of this report and all raw output data is provided in Appendix C (electronically).

3.1 Station W4 – Haggart Creek

Station W4 in Haggart Creek is located just downstream of the chief compliance location for the Eagle Gold project (i.e., discharge via Ditch C from the MWTP and/or the LDSP). Water quality objectives for W4 were developed during the licensing process (Table 3.1-1) and were based on the effluent quality standards specified in QZ14-041.

Table 3.1-1:
Water Quality Objectives for Haggart Creek at W4

	U	0.015
	Zn	0.038

All values as mg/L

Figure 3.1-1 summarizes the updated 2019 water quality model predictions for As at W4 in Haggart Creek. The updated model predicts peak As concentrations at W4 of approximately 0.0085 mg/L that occur in the higher flow periods of May during late operations. During HLF draindown (Yr 13 to Yr 22), As concentrations range from approximately 0.007 to 0.008 during the higher flow months of May to July with corresponding As values during the winter low flow months of approximately 0.0065 mg/L during this same period.

Post closure As concentrations (Yr 23 onwards) are predicted to be on the order of 0.0067 mg/L with winter low flow peak concentrations of approximately 0.004 mg/L (Figure 3.1-1).

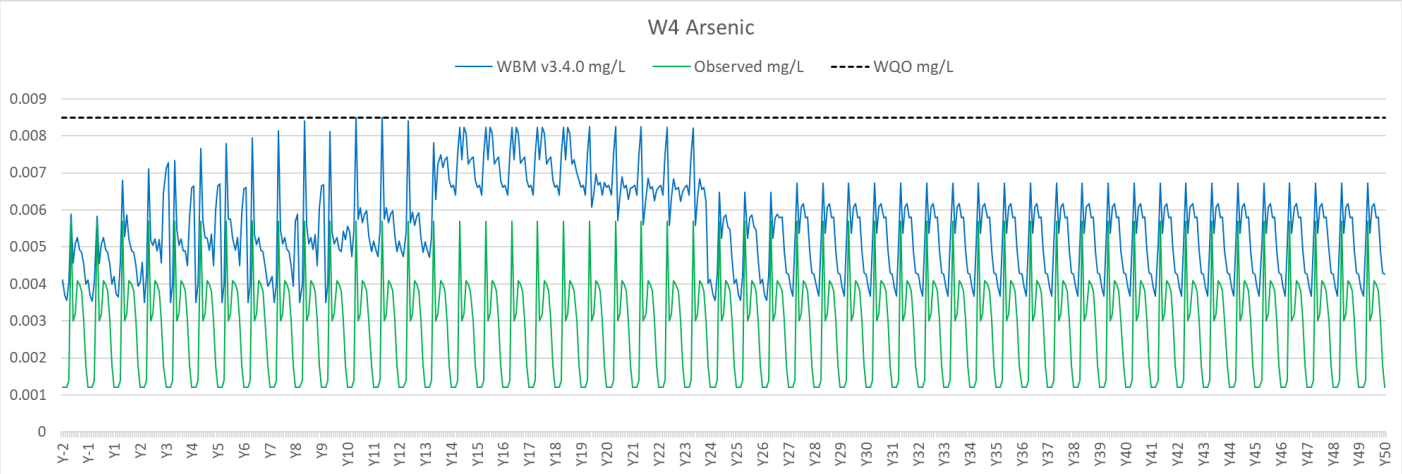

Figure 3.1-1: Predictions for Total As at W4 in Haggart Creek for 19WQM (WBMWQM v3.4). Baseline mean monthly concentration denoted by blue line; Water Quality Objective denoted by dashed line.

Similar results are observed for Se at W4 in Haggart Creek (Figure 3.1-2). The primary source of Se is associated with the HLF. Updated predictions indicate that Se concentrations are highest during the HLF draindown period and peak concentrations are predicted to be roughly 0.0019 mg/L. However, throughout the remainder of the life of mine, Se concentrations are predicted to be well below water quality objectives at W4. During post-closure, peak Se concentrations are predicted to be only approximately 0.0007 mg/L.

Table 3.1-2 summarizes the maximum 19WQM predicted concentrations for all parameters at W4 in Haggart Creek. As illustrated, all parameters are predicted to be below their respective water quality objective. 19WQM output for all parameters for station W4 can be found in Appendix B and Appendix C.

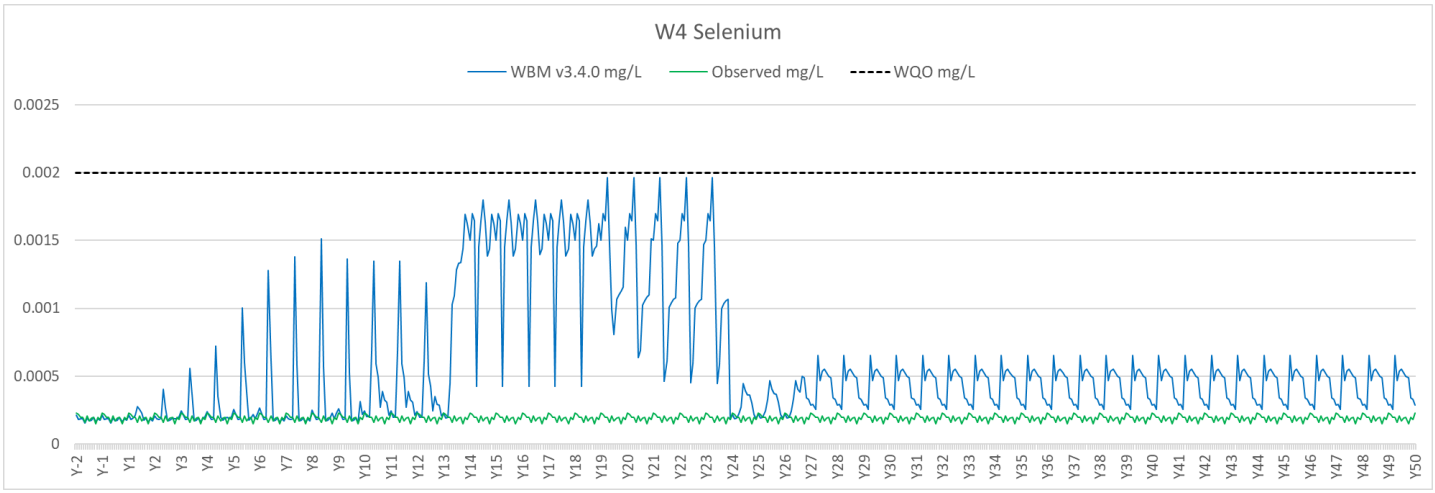

Figure 3.1-2: Predictions for Total Se at W4 in Haggart Creek for 19WQM (WBMWQM v3.4). Baseline mean monthly concentration denoted by blue line; Water Quality Objective denoted by dashed line.

Table 3.1-2:
Maximum 19WQM Predicted Concentrations Compared to Water Quality Objectives at W4 for Haggart Creek

All values as mg/L

3.2 Station W29 – Haggart Creek

19WQM output is graphically presented in Figure 3.2-1 for As at station W29 in Haggart Creek. Peak As concentrations at W29 are predicted to be slightly lower as compared to station W4 during the operation and draindown period (e.g. Yr 1 to Yr 22) and well below the water quality objective. Peak As concentrations for this period are approximately 0.0077 mg/L and occur during the higher flow month of May. During post closure, additional As loadings occur to Haggart Creek upstream of W29 from Platinum Gulch PTS, which treats water from waste rock seepage and pit overflow water. These additional As loadings increase concentrations at W29 to values of approximately 0.0074 mg/L as compared to W4 of approximately 0.0067 mg/L (Compare Figure 3.2-1 and Figure 3.1-1).

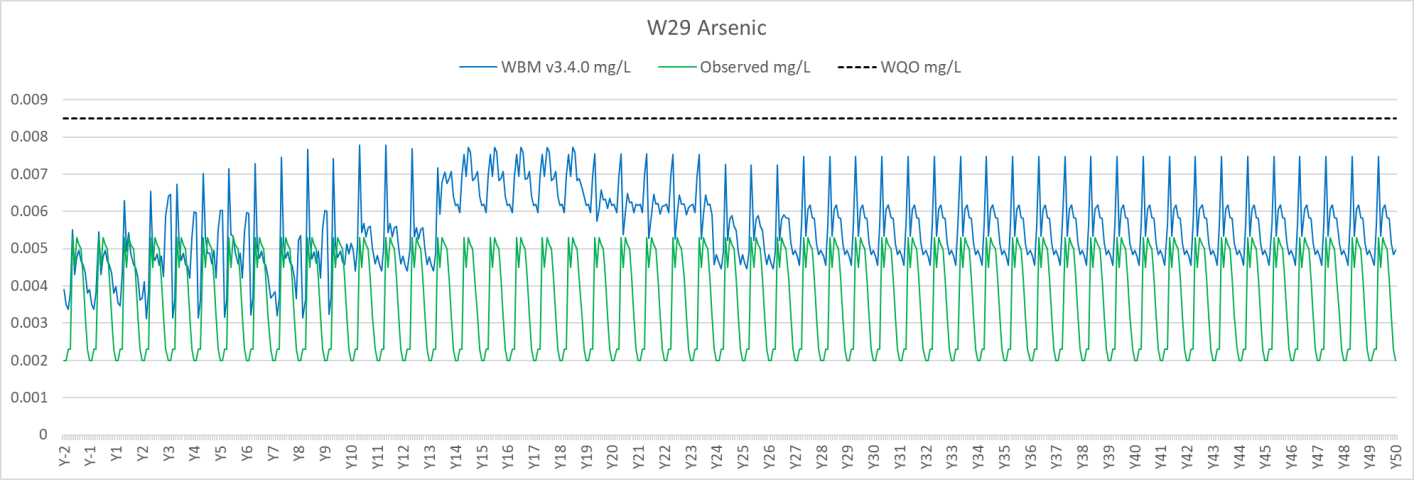

Figure 3.2-1: Predictions for Total As at W29 in Haggart Creek for 19WQM (WBMWQM v3.4). Baseline mean monthly concentration denoted by blue line; Water Quality Objective denoted by dashed line.

Similar to arsenic, the predicted peak Se concentrations at W29 are slightly higher than predicted concentrations at station W4 in Haggart Creek. The primary reason for this is additional loadings from the Platinum Gulch PTS.

Full excel output data for all parameters modeled at station W29 is presented in Appendix C.

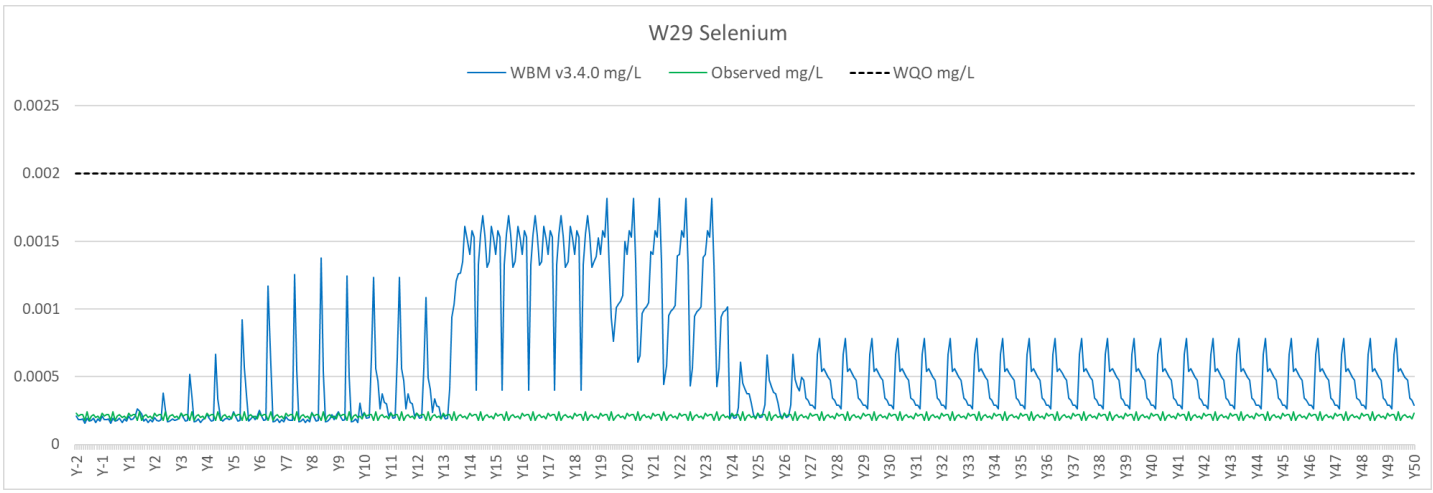

Figure 3.2-2: Predictions for Total Se at W29 in Haggart Creek for 19WQM (WBMWQM v3.4). Baseline mean monthly concentration denoted by blue line; Water Quality Objective denoted by dashed line.

3.3 Station W23 – Far-Field Haggart Creek

19WQM predictions for total As at W23 in Haggart Creek are graphically presented in Figure 3.3-1. Unlike stations more proximal to the Eagle Mine in Haggart Creek (e.g. W4 and W29), predicted peak As concentrations at W23 are less variable throughout the life of mine period. For example, peak As concentrations during the operations, draindown and closure are approximately 0.0072 mg/L. The less variable As concentrations at W23 are a result of the natural background As loadings from Lynx Creek that enter Haggart Creek immediately upstream of W23. Predicted concentrations of As at W23 throughout the mine life are all well below the water quality objective.

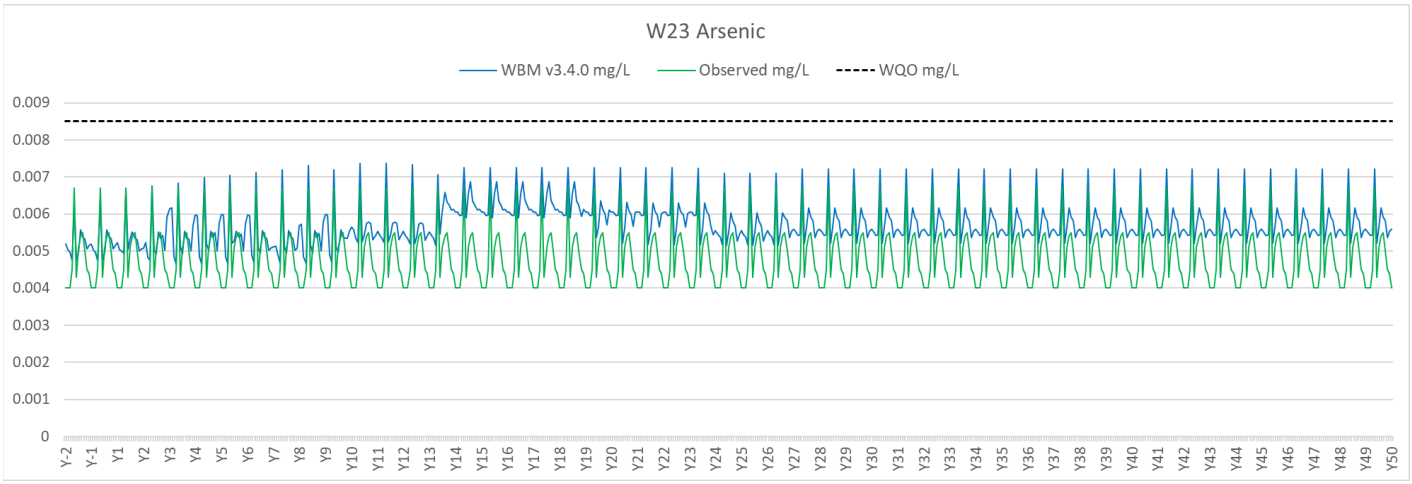

Figure 3.3-1: Predictions for Total As at W23 in Haggart Creek for 19WQM (WBMWQM v3.4). Baseline mean monthly concentration denoted by blue line.

Water quality predictions for total Se at W23 are presented in Figure 3.3-2. Maximum predicted total Se concentrations in 18WQM are slightly above 0.001 mg/L and occur during the HLF draindown. Post closure total Se concentration predictions are between 0.005 mg/L and 0.0006 mg/L (Appendix B). All predicted concentrations are well below the water quality objective for Se of 0.002 mg/L

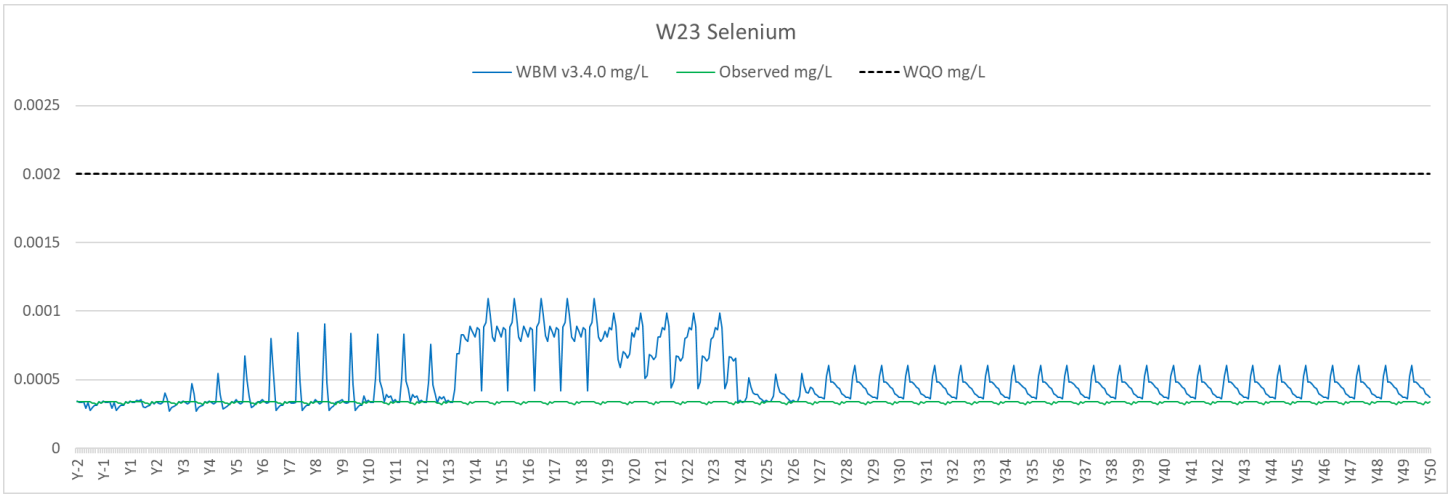

Figure 3.3-2: Predictions for Total Se at W23 in Haggart Creek for 19WQM (WBMWQM v3.4). Baseline mean monthly concentration denoted by blue line; Water Quality Objective denoted by dashed line.

4. Water Quantity Predictions

4.1 Predicted Streamflow Changes

The results of the 19WBM are presented in this section. There have been no substantive changes from the 2014 WBM outputs as a result of the changes in the mine plan since 2014. The predicted changes to the baseline streamflow regime as a result of mine development and operation are presented for the average monthly discharge for four distinct years of the mine life – representative of key changes to the management of site water. These correspond to the WBM/WQM schematics presented in Figure 2.2-10 through Figure 2.2-13.

- Modeled Year 2002 = Year 2 (between Phase 1 and 2 of the HLF)
- Modeled Year 2010 = Year 10 (first year of rinse/gold recovery)
- Modeled Year 2013 = Year 13 (first year of HLF draindown)
- Modeled Year 2023 = Year 23 (end of active closure)

The average monthly baseline and mine affected streamflows are presented for two key receiving environment nodes W4 (Haggart Creek downstream of Dublin Gulch) and W29 (Haggart Creek downstream of Platinum Gulch) in tabular (Table 4.1-1) and figure formats (Figure 4.1-1 through Figure 4.1-8).

Table 4.1-1:
Predicted percent change in receiver stream flows for key years in the Project life, for the W4 and W29 nodes.

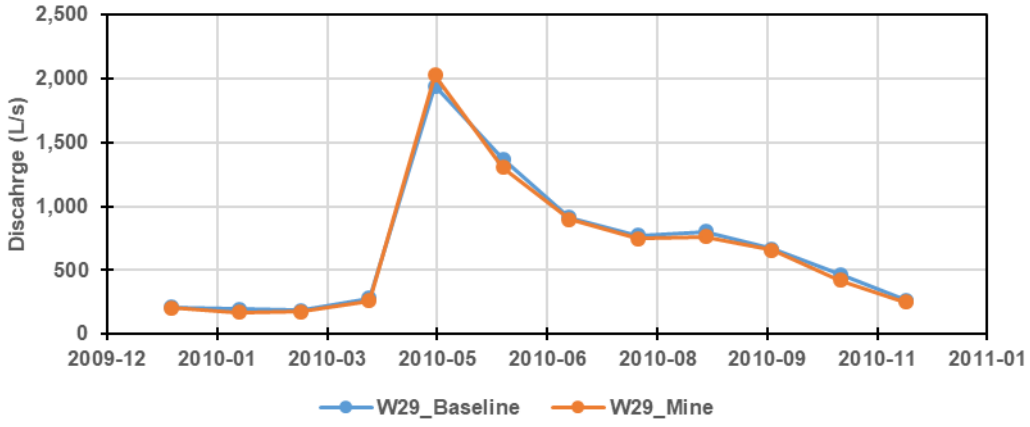

Figure 4.1-6: Average monthly and predicted mine affected streamflows for the W29 node (Year 10; 19WQM).

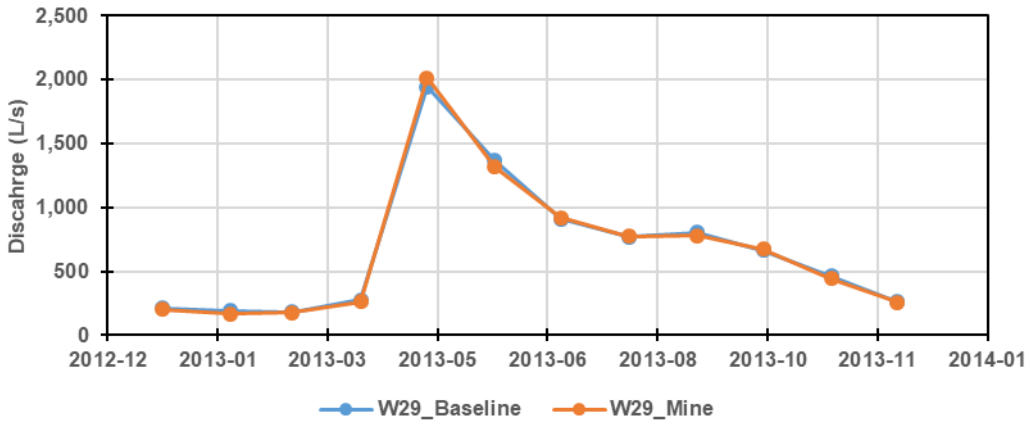

Figure 4.1-7: Average monthly and predicted mine affected streamflows for the W29 node (Year 13; 19WQM).

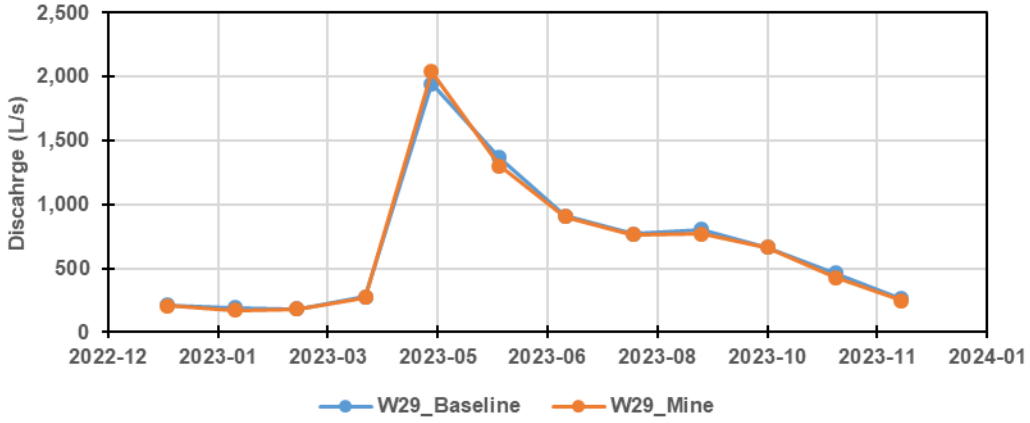

Figure 4.1-8: Average monthly and predicted mine affected streamflows for the W29 node (Year 23; 19WQM).

Maximum expected decreases in the baseline streamflow volumes occur in February (-5% to -13%), and the minimum predicted changes occur in June (-5% to 2%; Table 4.1-1). On average, the average open water season (May-September) flow changes are predicted to be negligible, varying from 2% to 5% at W4 for Operations (Year 13). On an average annual basis, flows in Haggart Creek at W4 are predicted to change from baseline by 0% to 2%, and by -2% to 0% at W29. Note that due to the low flows experienced in Haggart Creek during the winter and shoulder seasons (October to April), small changes in predicted flows due to mine operations result in larger relative predicted changes to the baseline streamflow regime. This is also the period for which continuous flow data are not available due to extensive channel icing, and thus characterization of the baseline flow regime is based largely on infrequent spot flow measurements. For these reasons, relatively less weight is placed on the predicted changes to the winter streamflow regime in Haggart Creek.

5. Closure

We trust that this report meets your expectations. Please contact the undersigned with any questions or comments.

Sincerely,

LORAX ENVIRONMENTAL SERVICES LTD.

all concentrations in mg/L

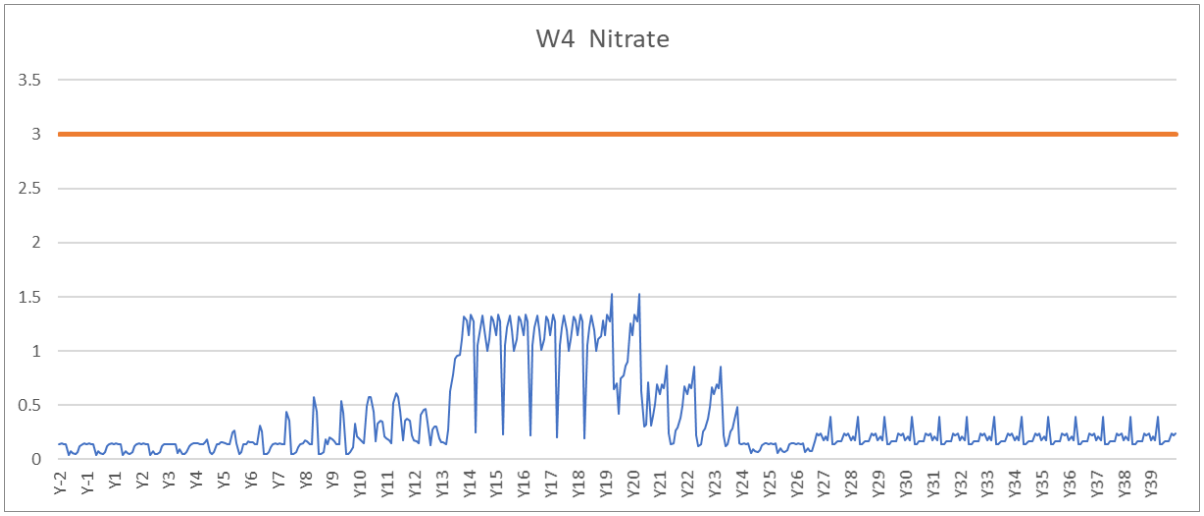
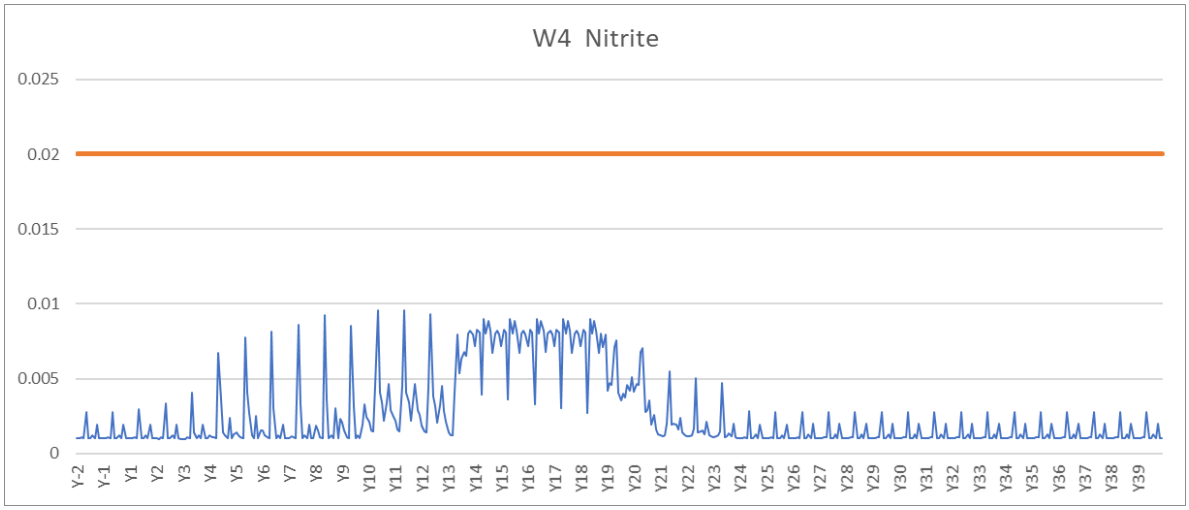
Appendix B: Water Quality Model Plots for all Parameters

B.1. Haggart Creek below Dublin Gulch (W4) – Water Quality Predictions

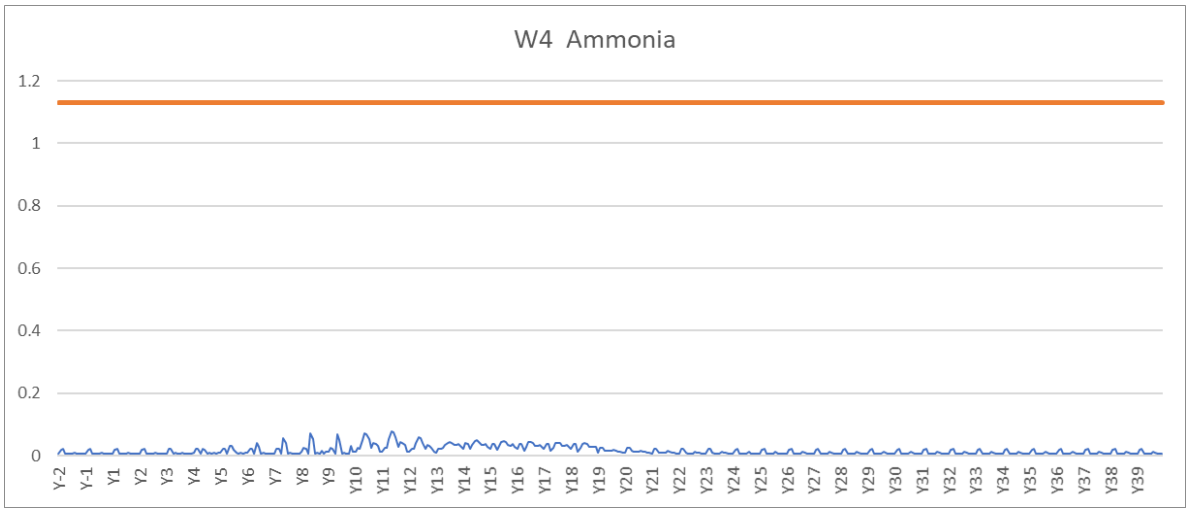


B.2. Haggart Creek below Eagle Creek (W29) – Water Quality Predictions

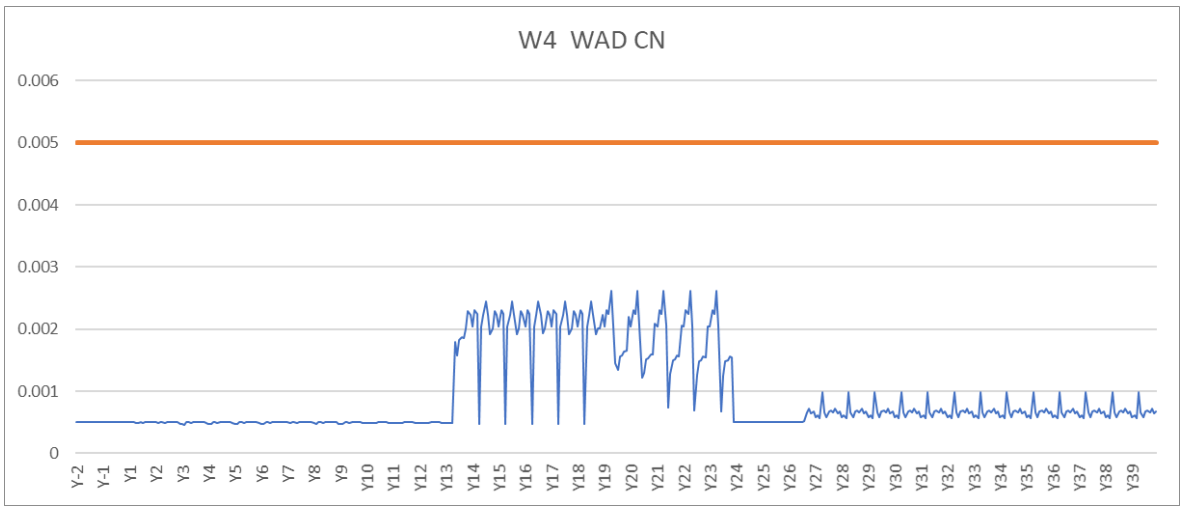
B.3. Haggart Creek below Lynx Creek (W23) – Water Quality Predictions



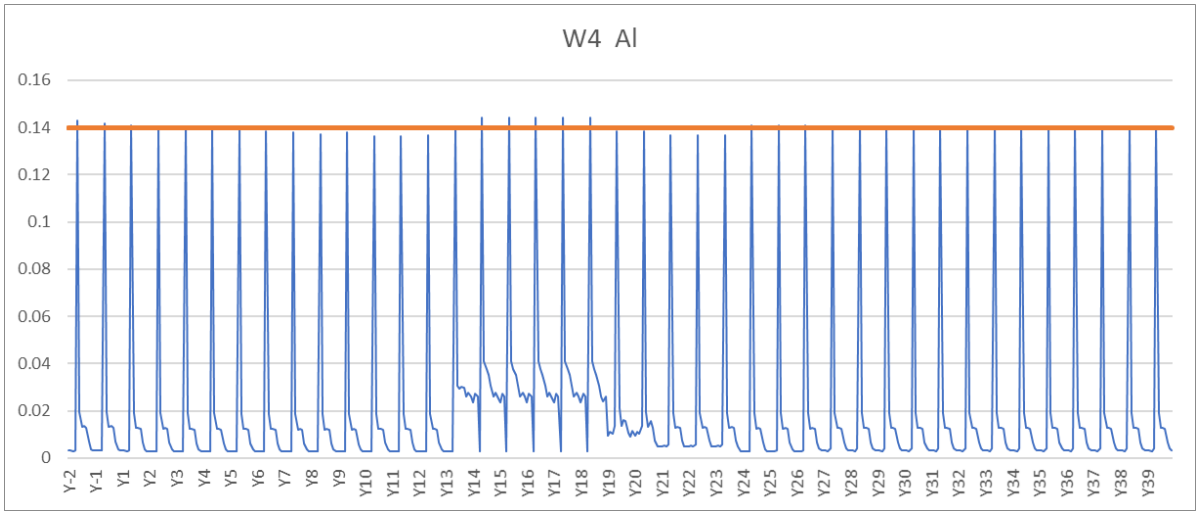
B.1. Haggart Creek below Dublin Gulch (W4) – Water Quality Predictions



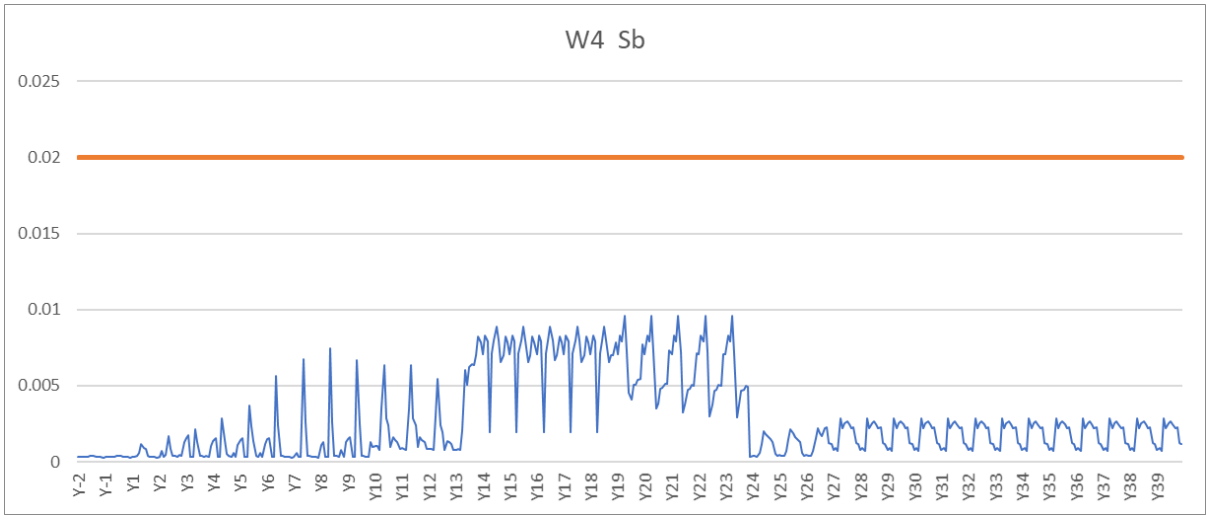
B.1-1: Time series of predicted sulphate concentrations (mg/L) for W4. Water Quality Objective is shown by red line.



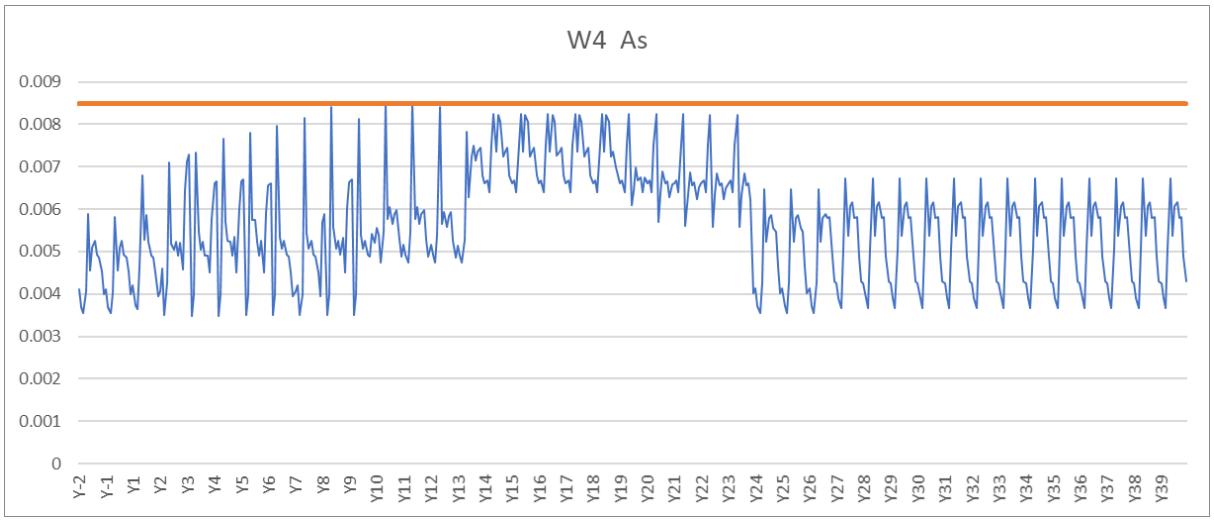
B.1-2: Time series of predicted nitrate concentrations (mg/L) for W4. Water Quality Objective is shown by red line.



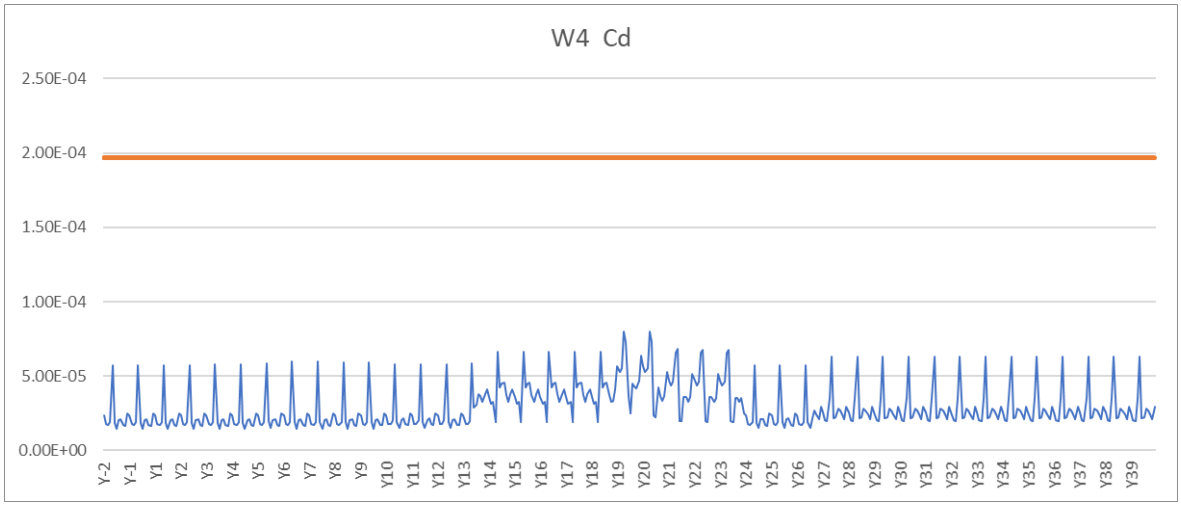
B.1-3: Time series of predicted nitrite concentrations (mg/L) for W4. Water Quality Objective is shown by red line.



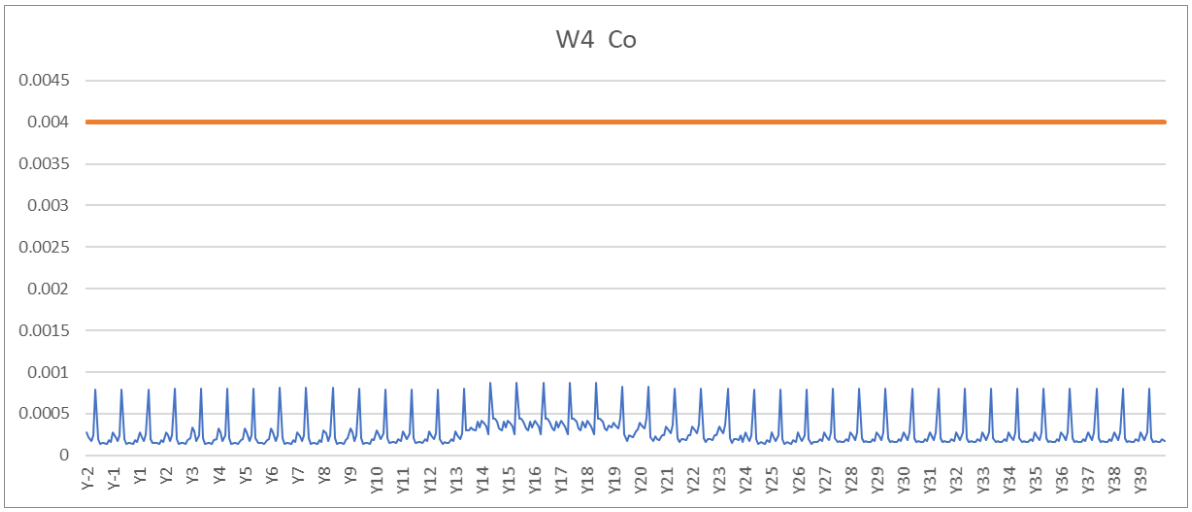
B.1-4: Time series of predicted ammonia concentrations (mg/L) for W4. Water Quality Objective is shown by red line.



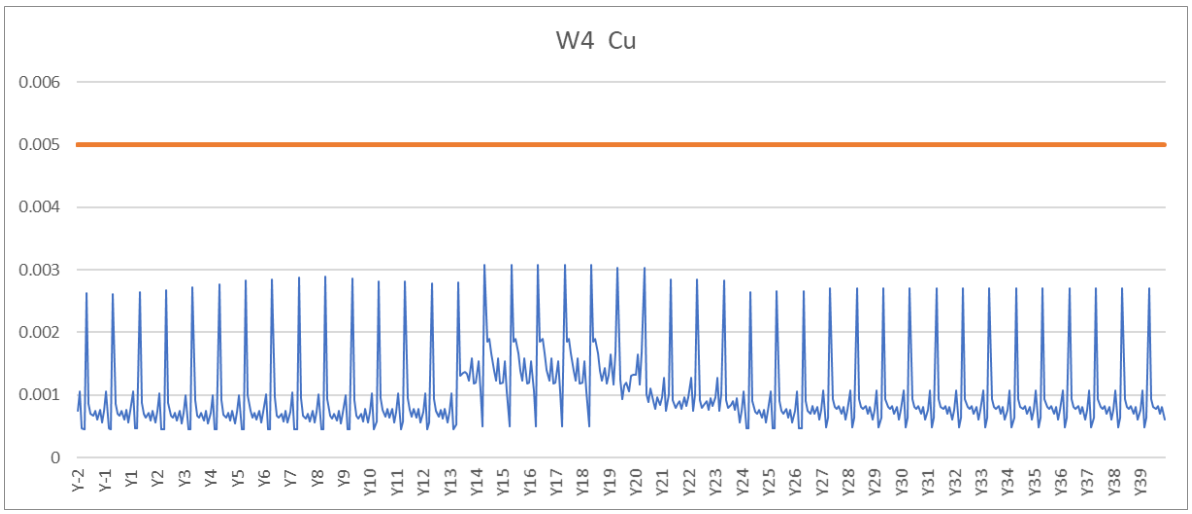
B.1-5: Time series of predicted WAD-CN concentrations (mg/L) for W4. Water Quality Objective is shown by red line.



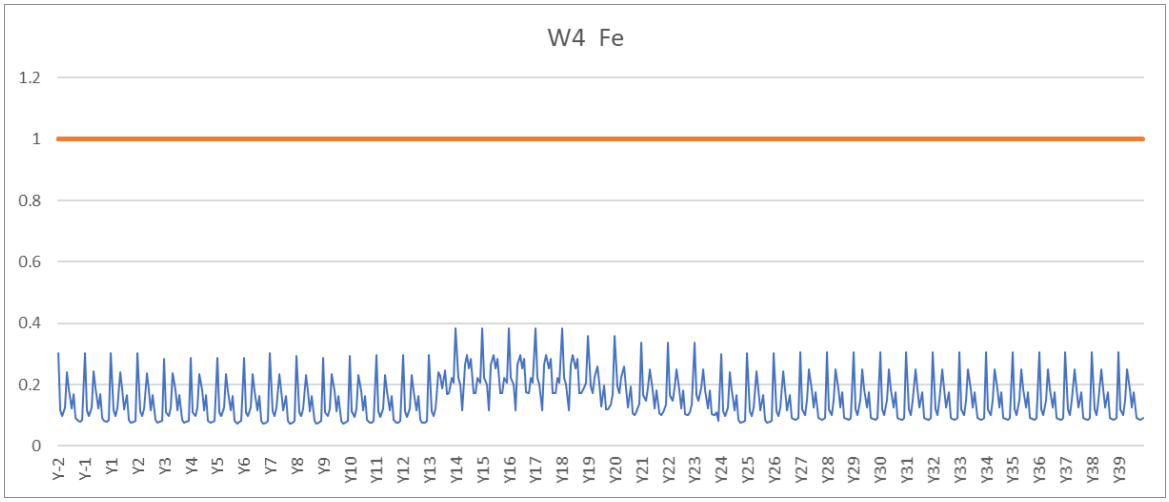
B.1-6: Time series of predicted aluminum concentrations (mg/L) for W4. Water Quality Objective is shown by red line.



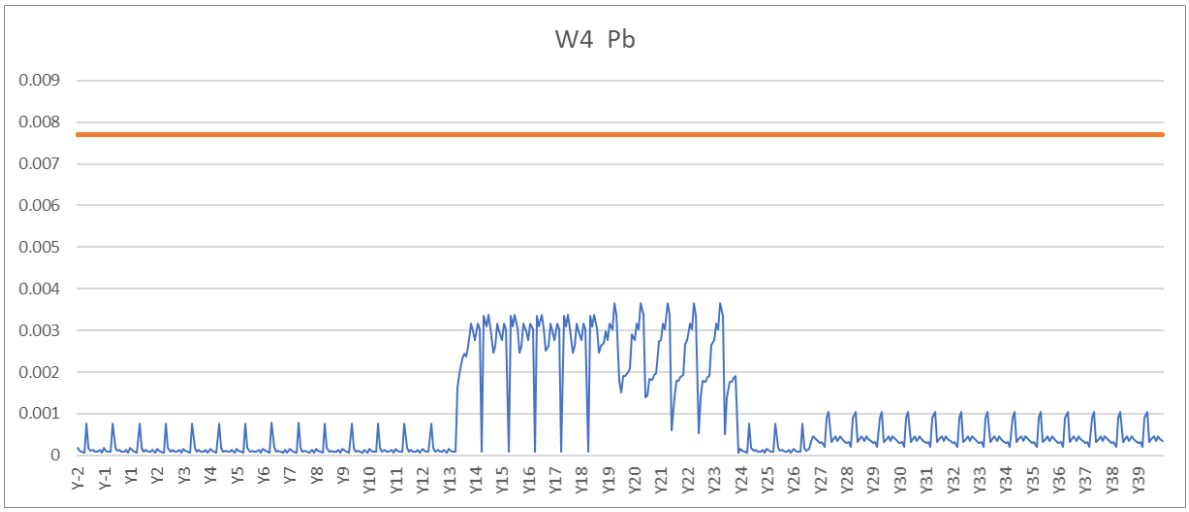
B.1-7: Time series of predicted antimony concentrations (mg/L) for W4. Water Quality Objective is shown by red line.



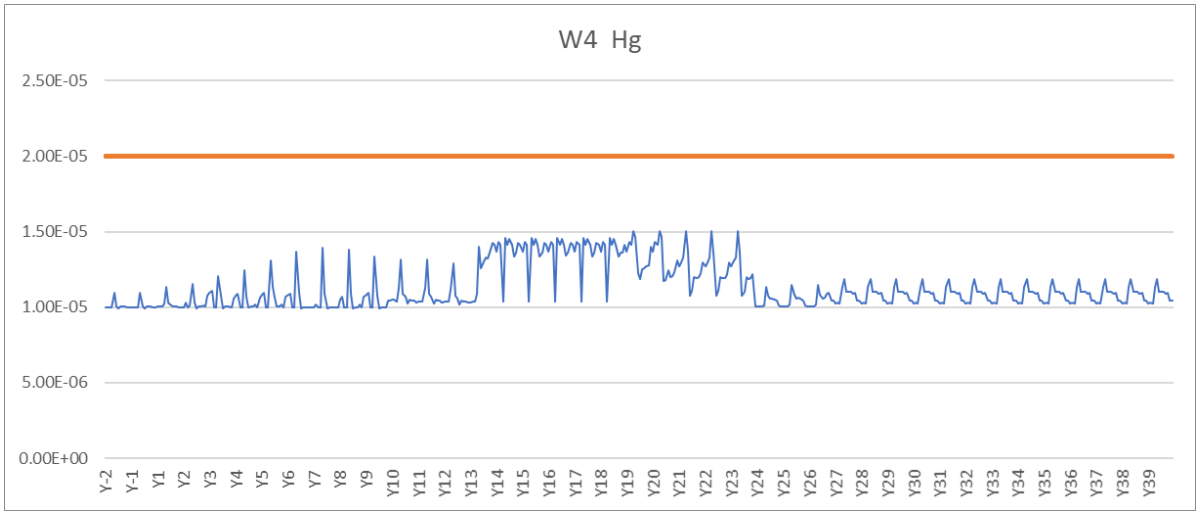
B.1-8: Time series of predicted arsenic concentrations (mg/L) for W4. Water Quality Objective is shown by red line.



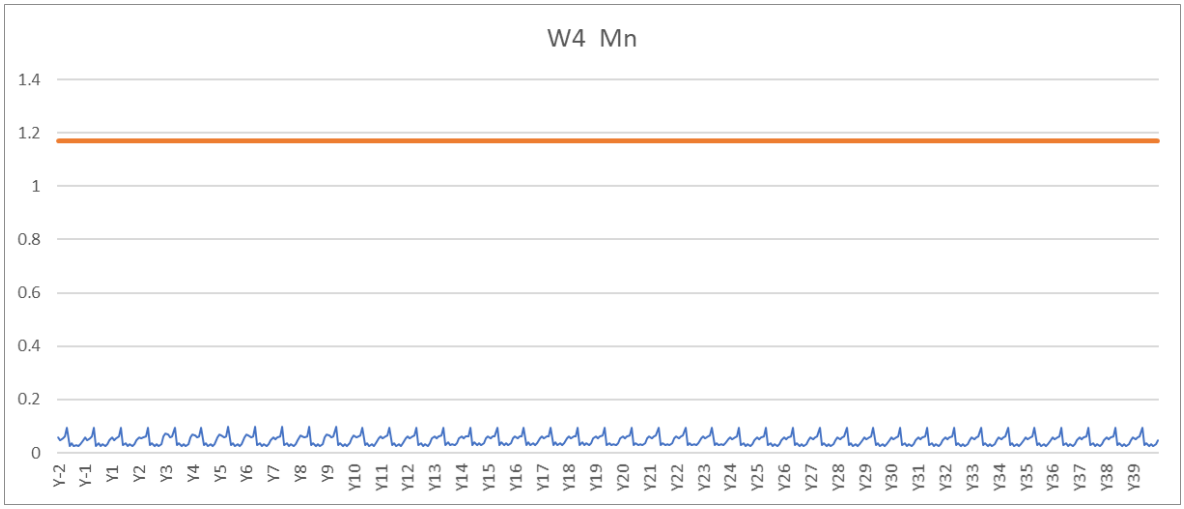
B.1-9: Time series of predicted cadmium concentrations (mg/L) for W4. Water Quality Objective is shown by red line.



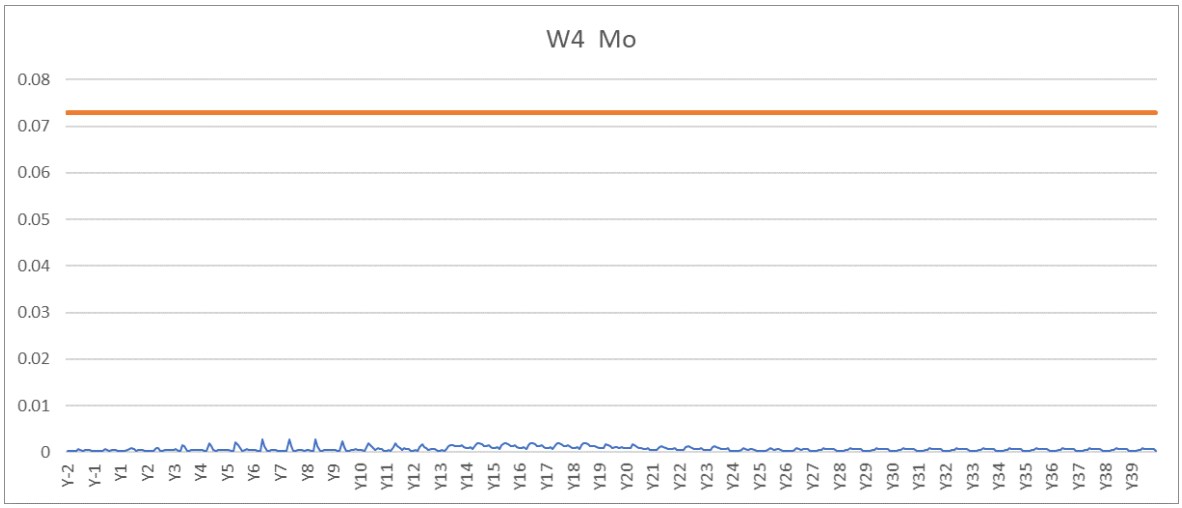
B.1-10: Time series of predicted cobalt concentrations (mg/L) for W4. Water Quality Objective is shown by red line.



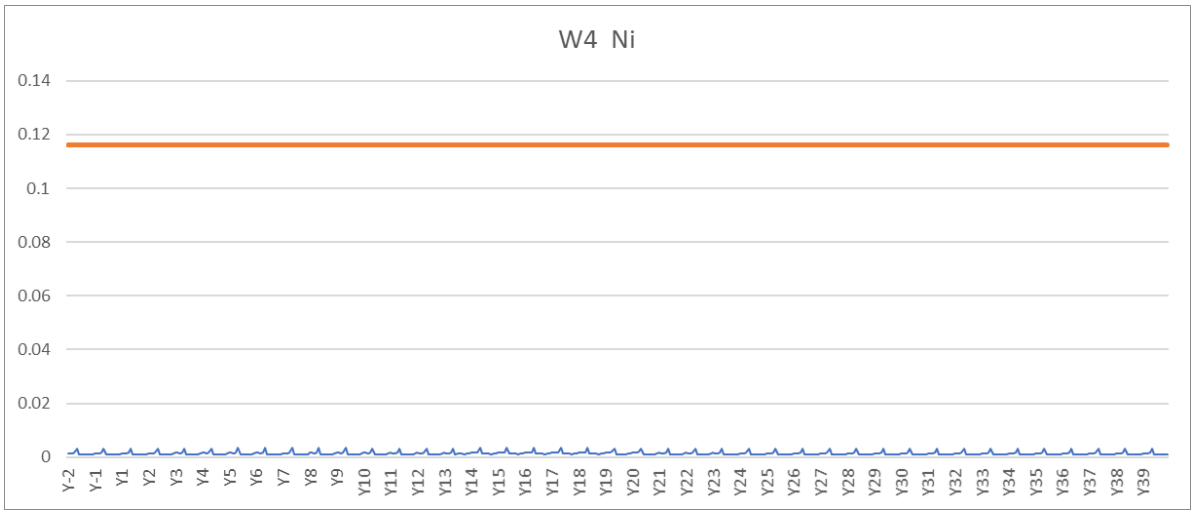
B.1-11: Time series of predicted copper concentrations (mg/L) for W4. Water Quality Objective is shown by red line.



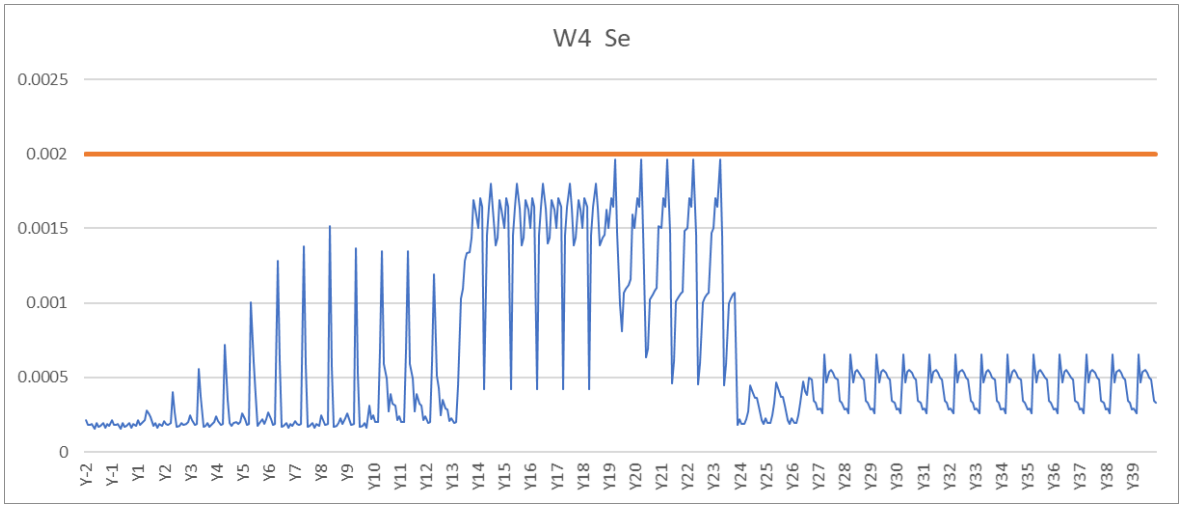
B.1-12: Time series of predicted iron concentrations (mg/L) for W4. Water Quality Objective is shown by red line.



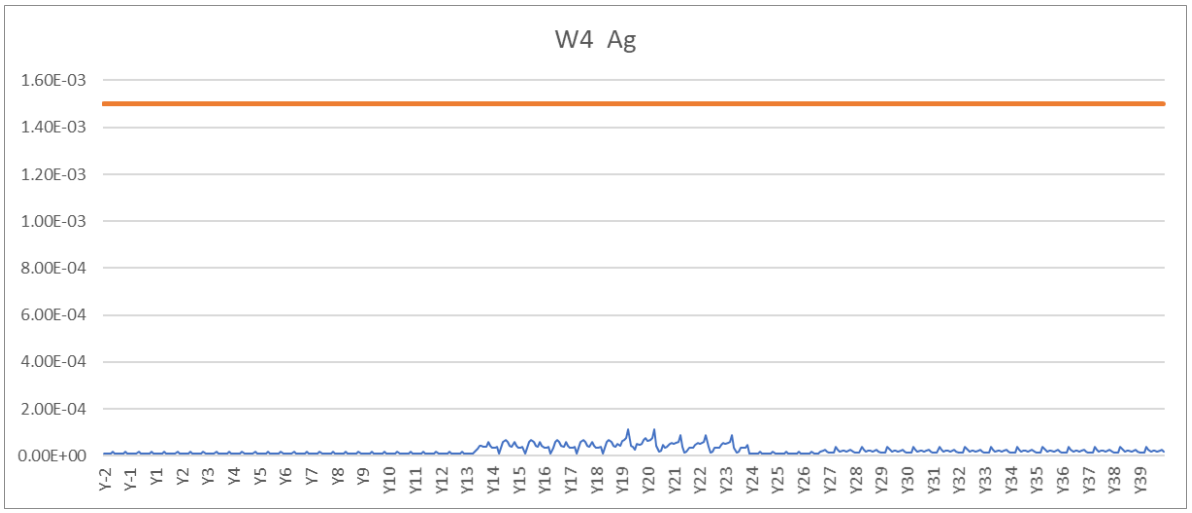
B.1-13: Time series of predicted lead concentrations (mg/L) for W4. Water Quality Objective is shown by red line.



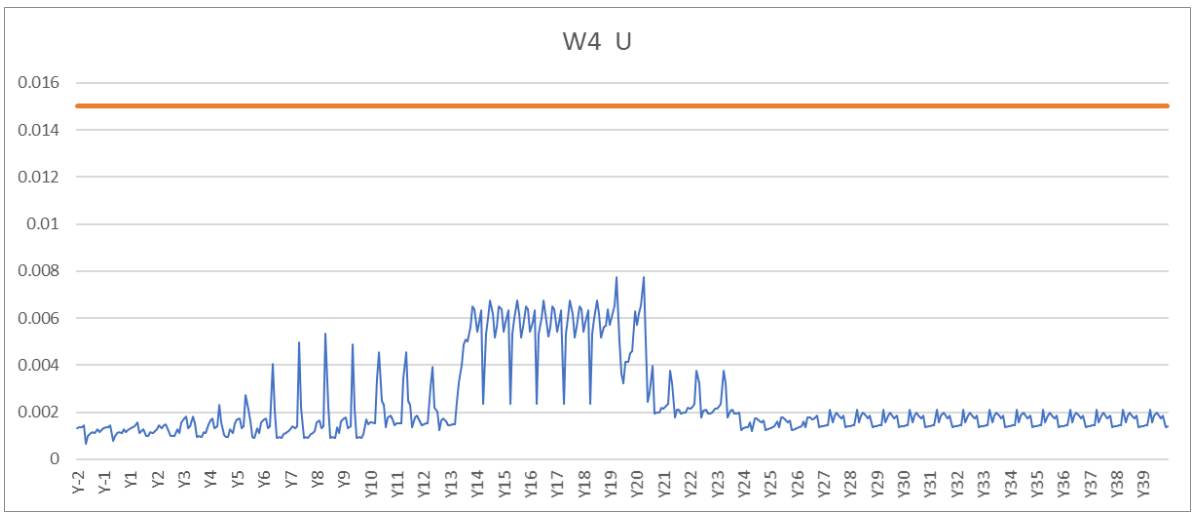
B.1-14: Time series of predicted mercury concentrations (mg/L) for W4. Water Quality Objective is shown by red line.



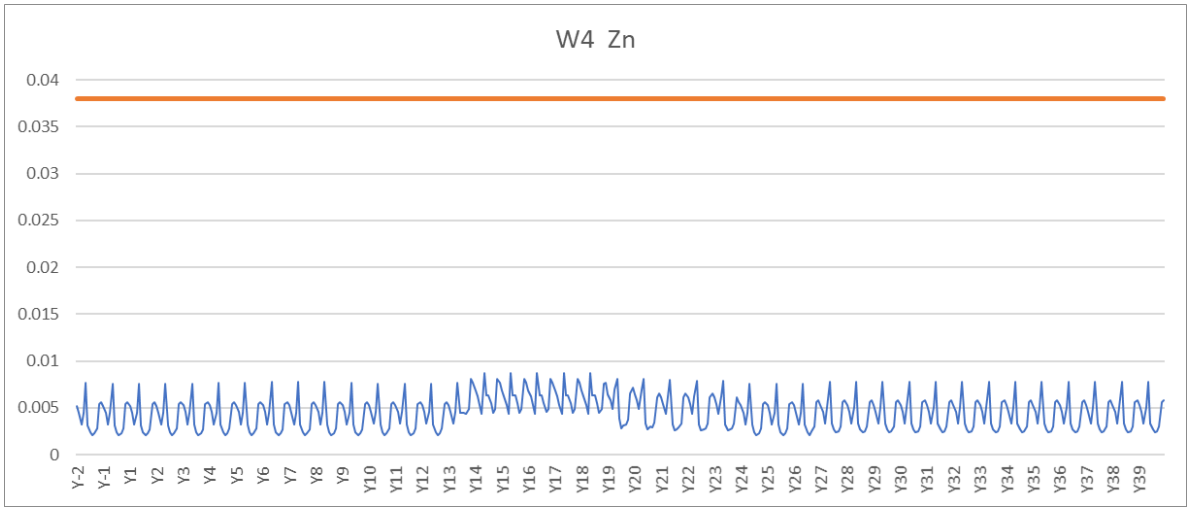
B.1-15: Time series of predicted manganese concentrations (mg/L) for W4. Water Quality Objective is shown by red line.



B.1-16: Time series of predicted molybdenum concentrations (mg/L) for W4. Water Quality Objective is shown by red line.

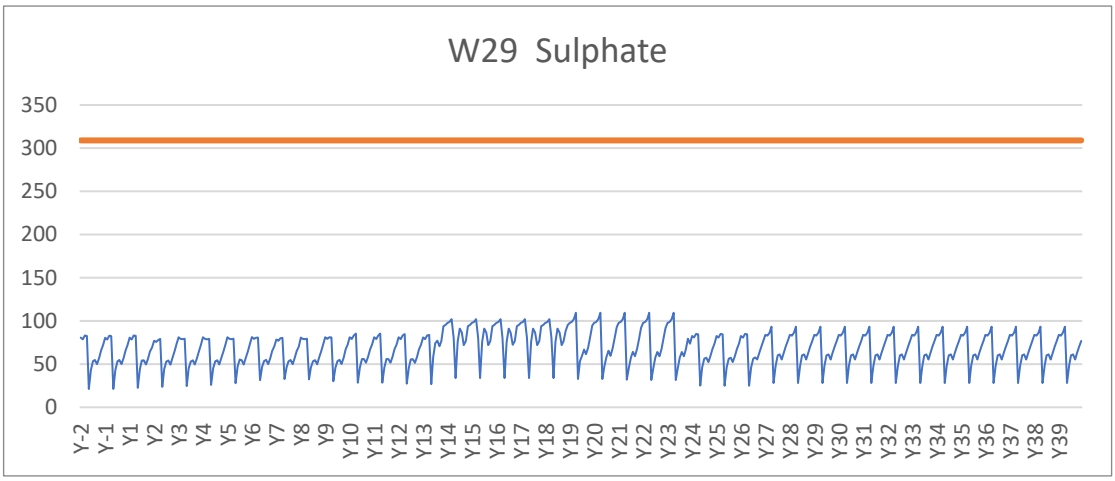


B.1-17: Time series of predicted nickel concentrations (mg/L) for W4. Water Quality Objective is shown by red line.

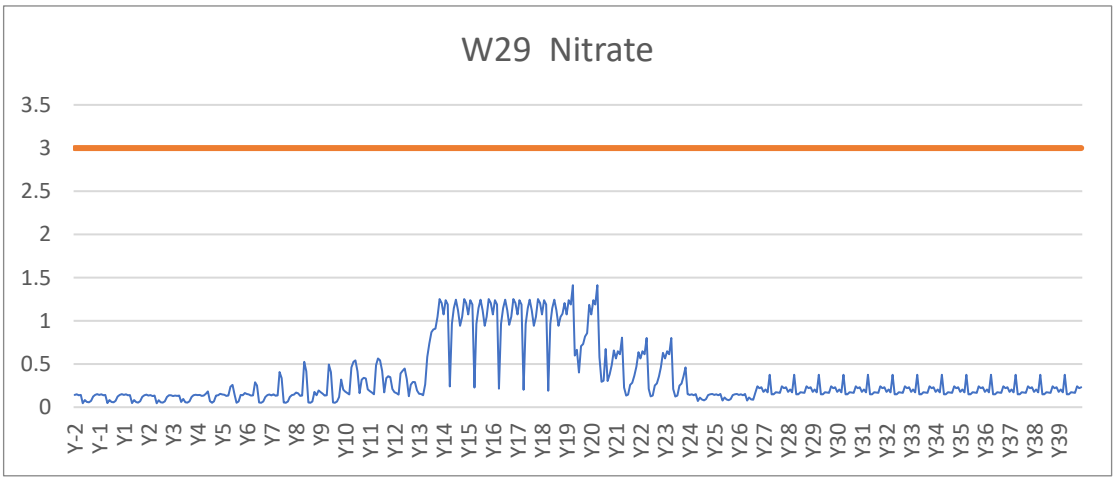


B.1-18: Time series of predicted selenium concentrations (mg/L) for W4. Water Quality Objective is shown by red line.

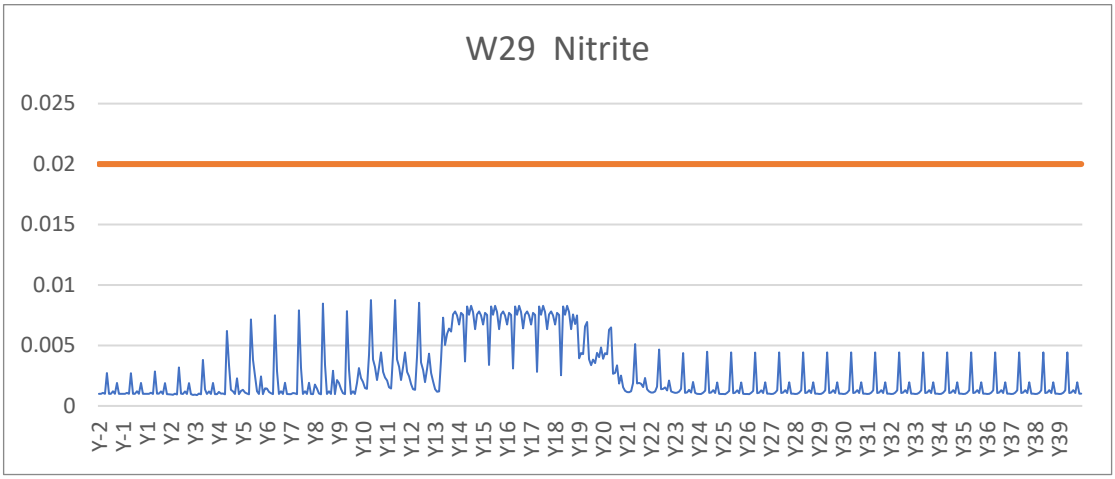
B.1-19: Time series of predicted silver concentrations (mg/L) for W4. Water Quality Objective is shown by red line.



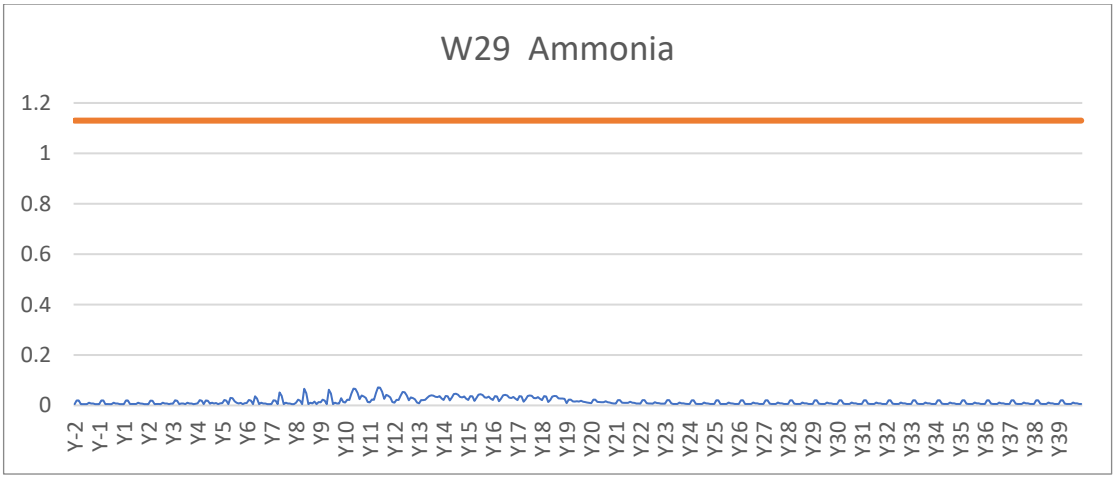
B.1-20: Time series of predicted uranium concentrations (mg/L) for W4. Water Quality Objective is shown by red line.



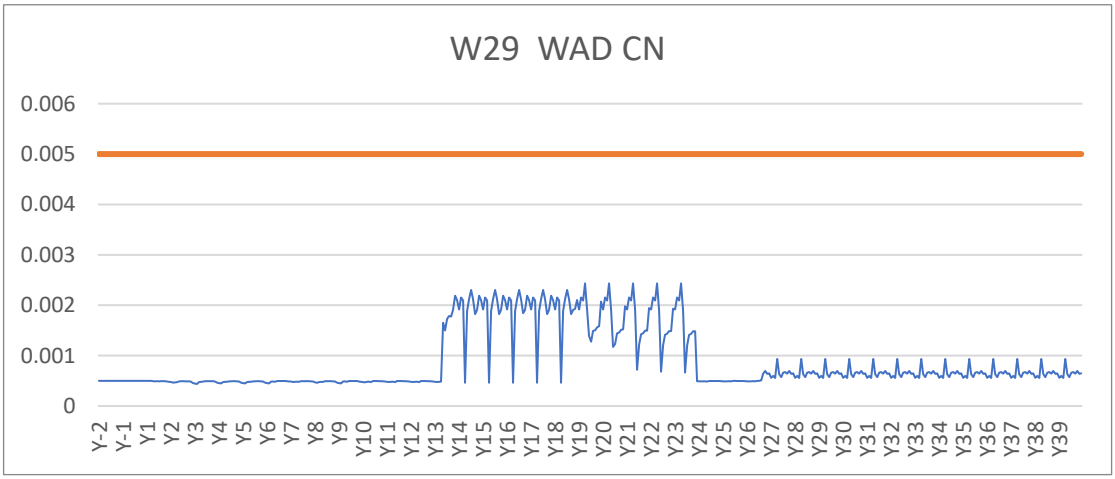
B.1-21: Time series of predicted zinc concentrations (mg/L) for W4. Water Quality Objective is shown by red line.



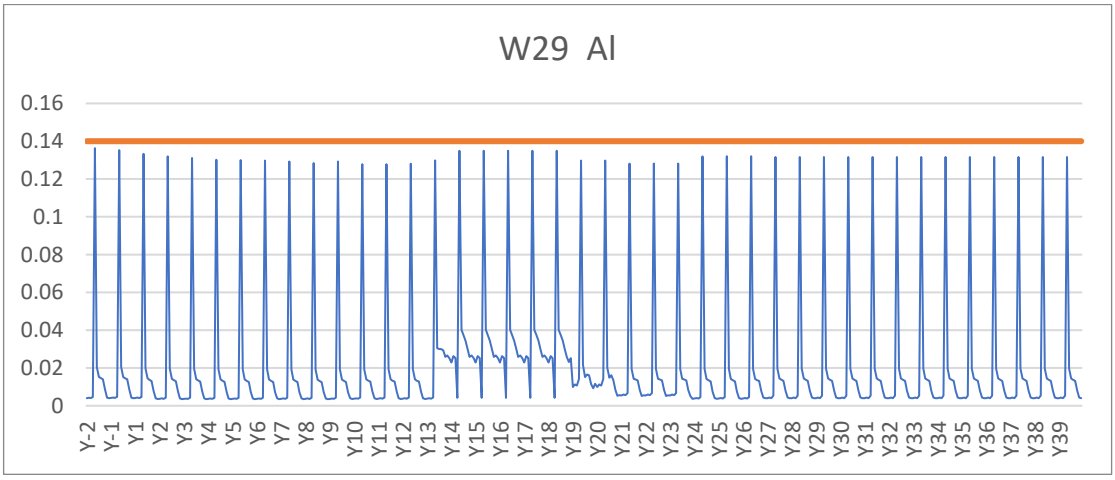
B.2. Haggart Creek below Eagle Creek (W29) – Water Quality Predictions



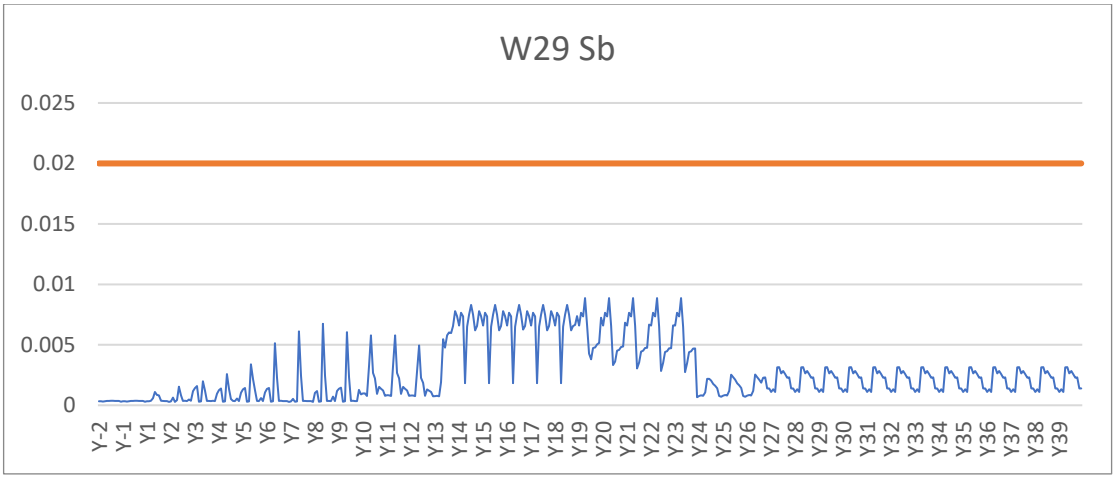
B.2-1: Time series of predicted sulphate concentrations (mg/L) for W29. Water Quality Objective is shown by red line.



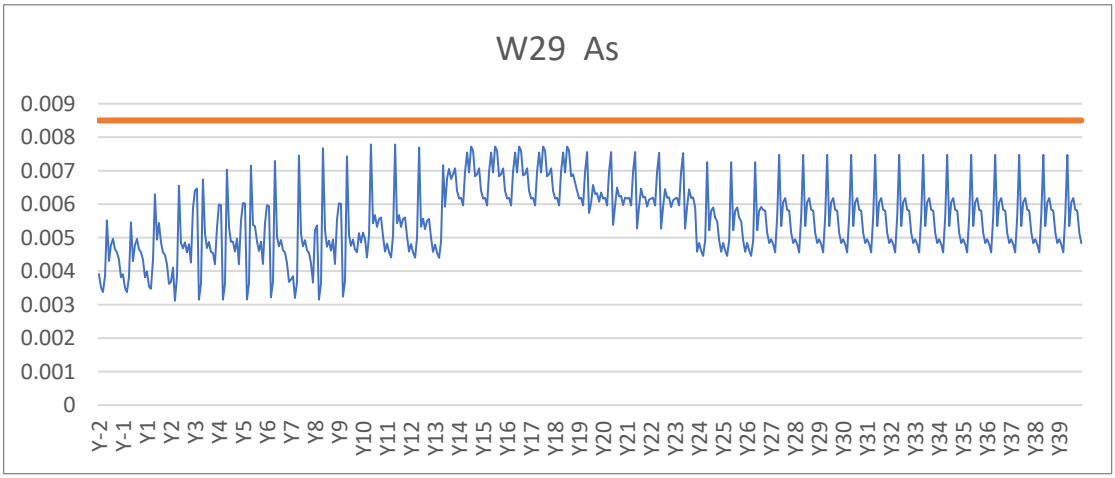
B.2-2: Time series of predicted nitrate concentrations (mg/L) for W29. Water Quality Objective is shown by red line.



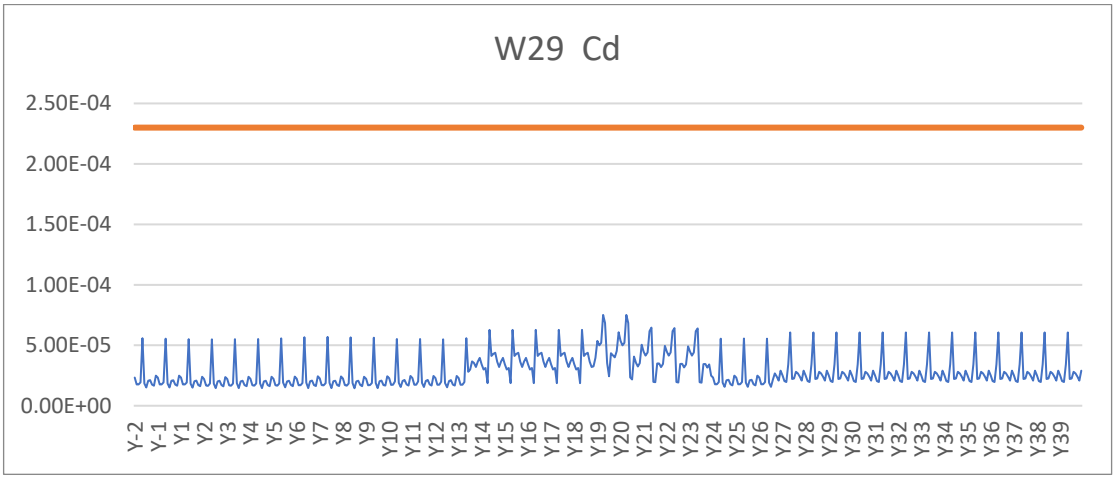
B.2-3: Time series of predicted nitrite concentrations (mg/L) for W29. Water Quality Objective is shown by red line.



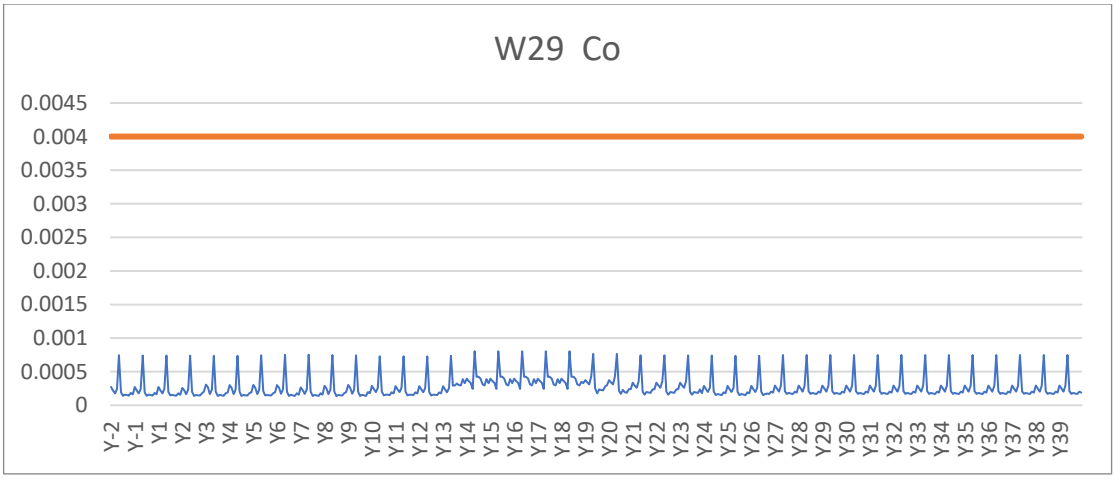
B.2-4: Time series of predicted ammonia concentrations (mg/L) for W29. Water Quality Objective is shown by red line.



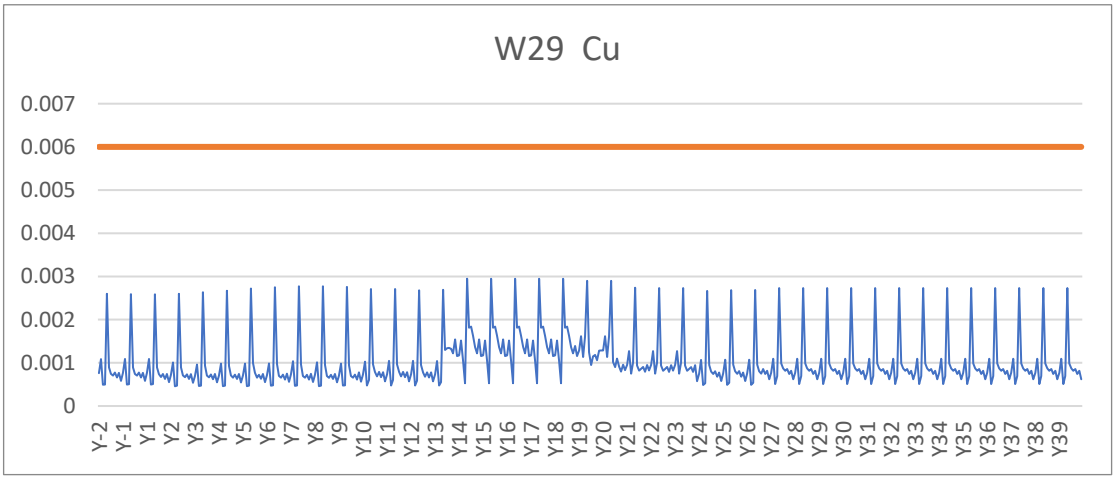
B.2-5: Time series of predicted WAD-CN concentrations (mg/L) for W29. Water Quality Objective is shown by red line.



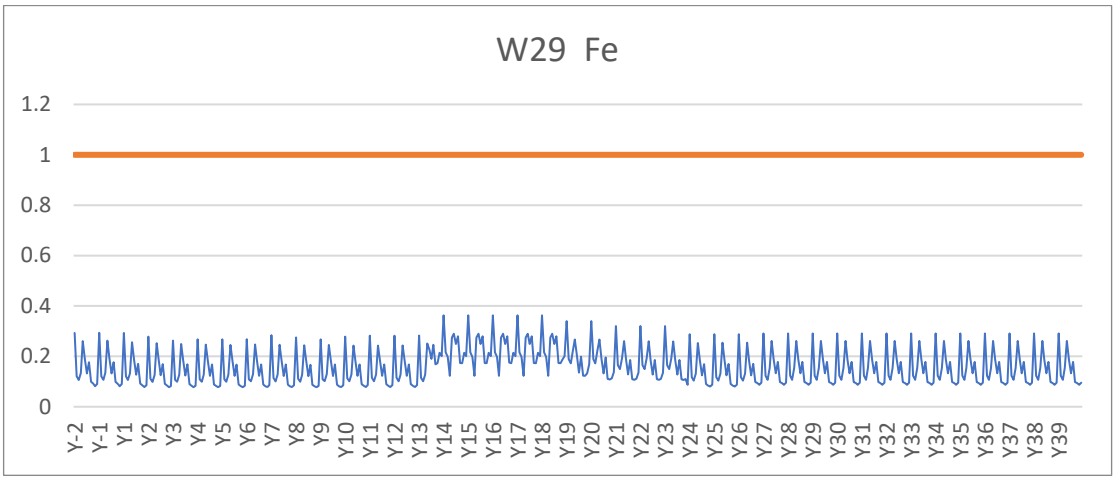
B.2-6: Time series of predicted aluminum concentrations (mg/L) for W29. Water Quality Objective is shown by red line.



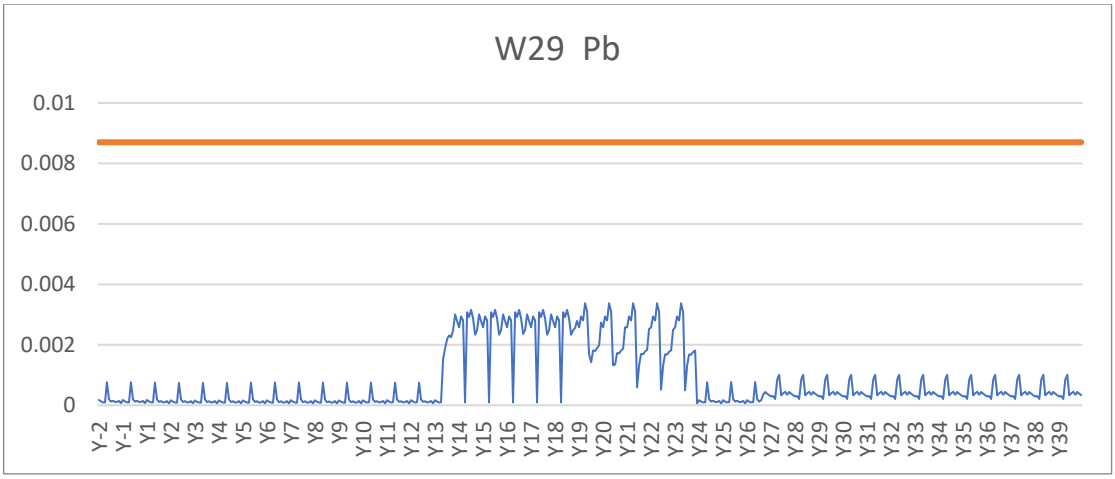
B.2-7: Time series of predicted antimony concentrations (mg/L) for W29. Water Quality Objective is shown by red line.



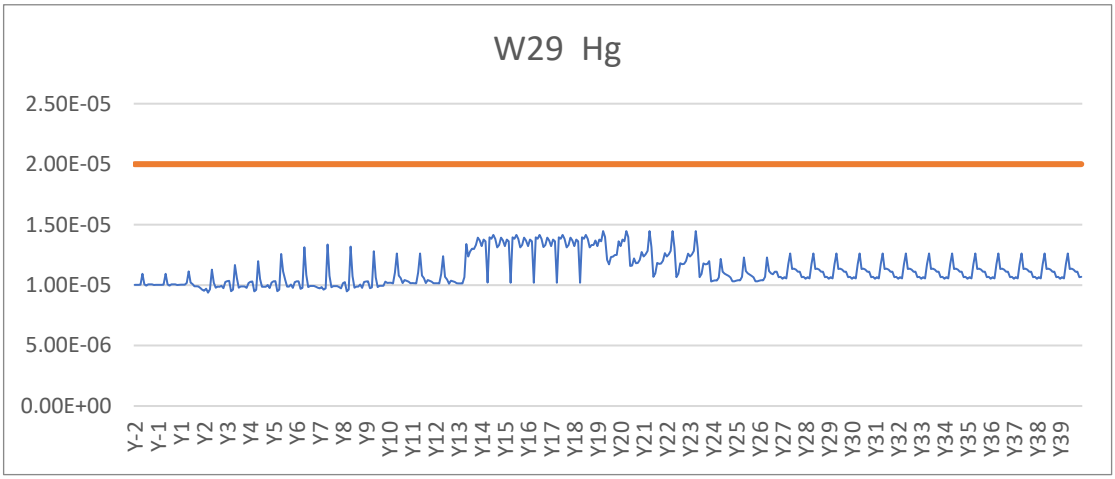
B.2-8: Time series of predicted arsenic concentrations (mg/L) for W29. Water Quality Objective is shown by red line.



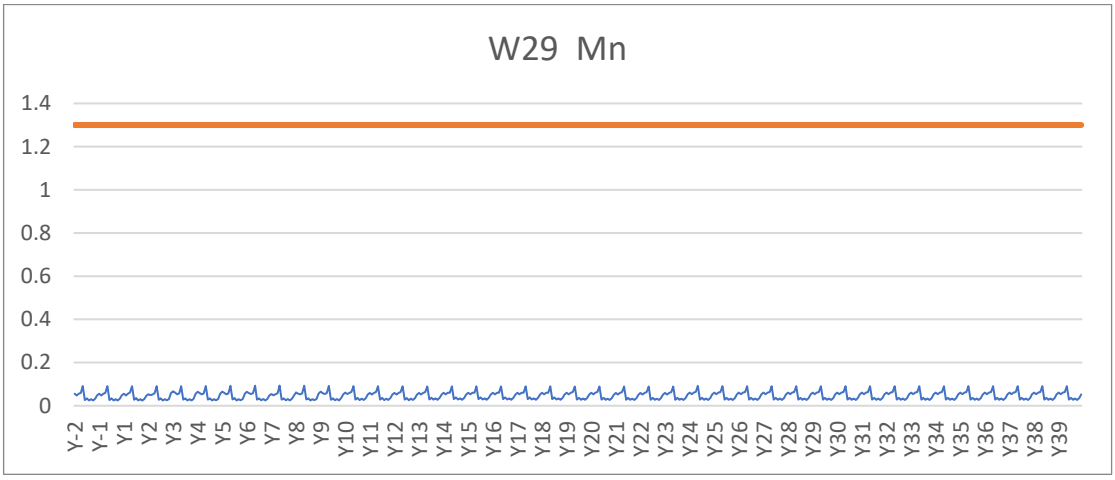
B.2-9: Time series of predicted cadmium concentrations (mg/L) for W29. Water Quality Objective is shown by red line.



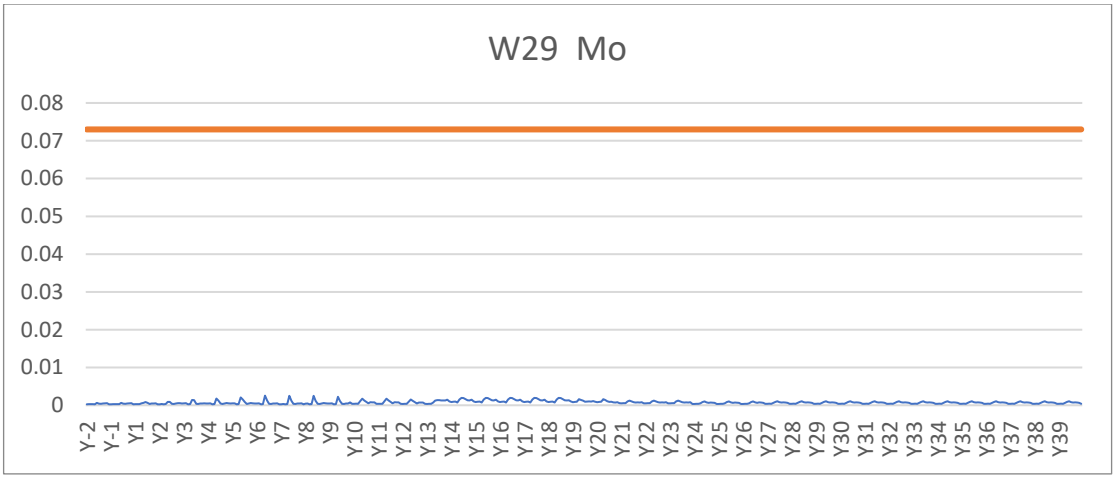
B.2-10: **Time series of predicted cobalt concentrations (mg/L) for W29. Water Quality Objective is shown by red line.**



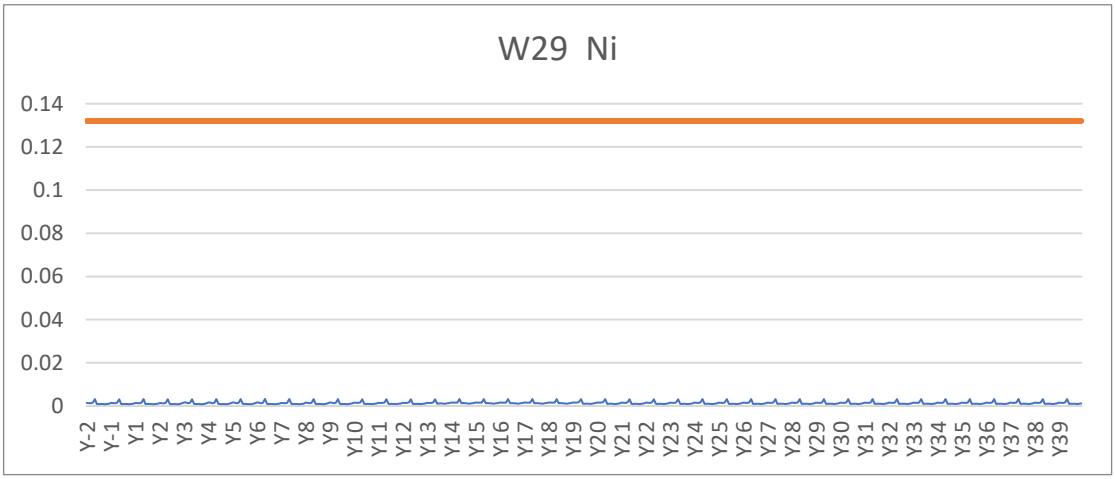
B.2-11: **Time series of predicted copper concentrations (mg/L) for W29. Water Quality Objective is shown by red line.**



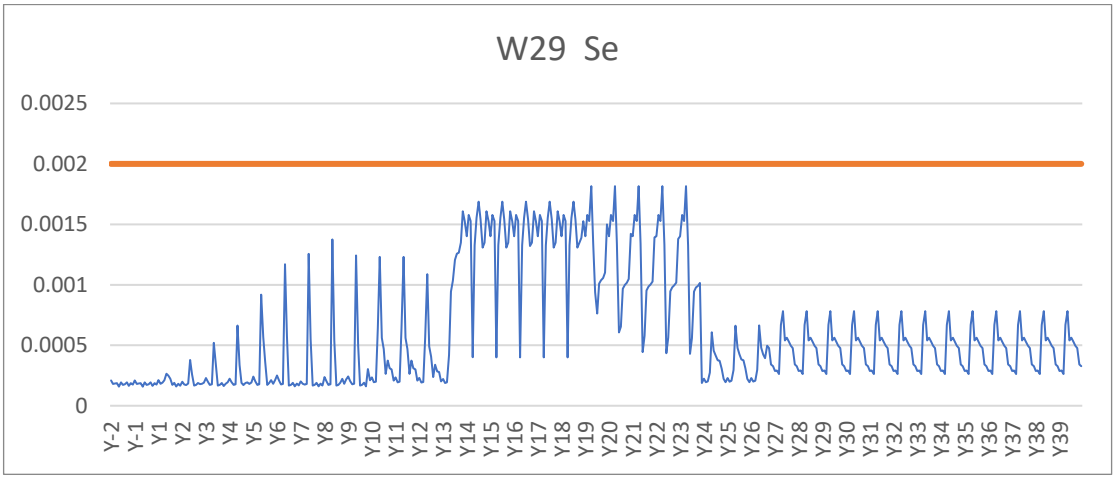
B.2-12: **Time series of predicted iron concentrations (mg/L) for W29. Water Quality Objective is shown by red line.**



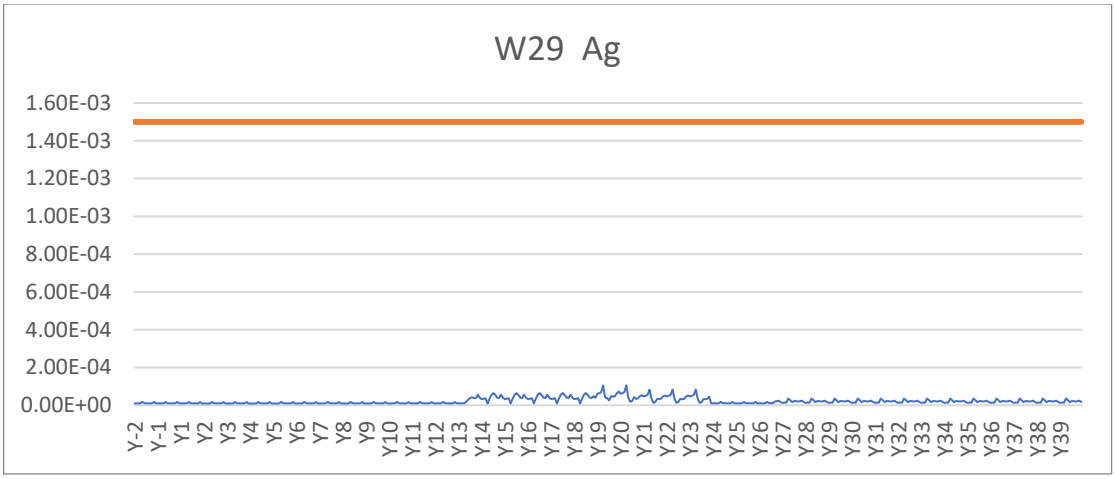
B.2-13: Time series of predicted lead concentrations (mg/L) for W29. Water Quality Objective is shown by red line.



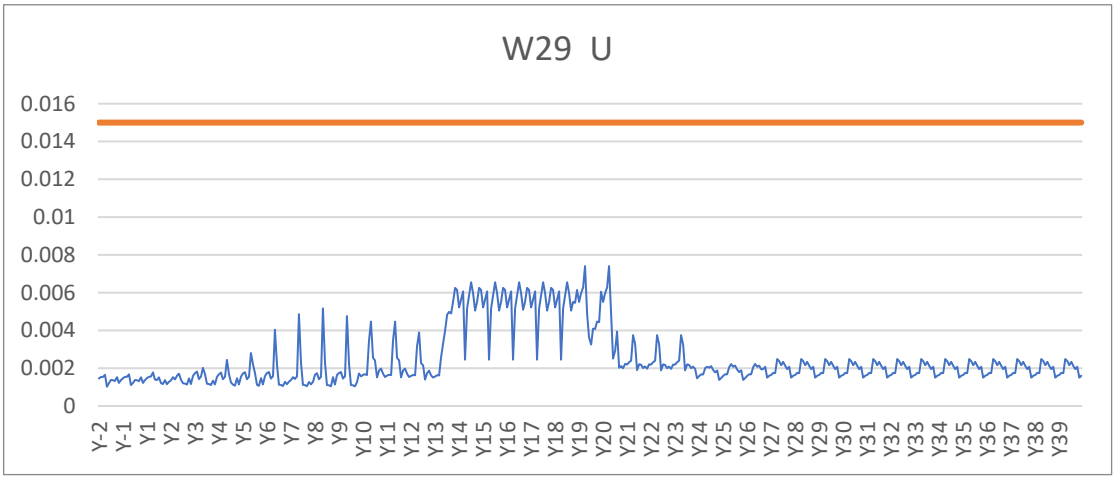
B.2-14: Time series of predicted mercury concentrations (mg/L) for W29. Water Quality Objective is shown by red line.



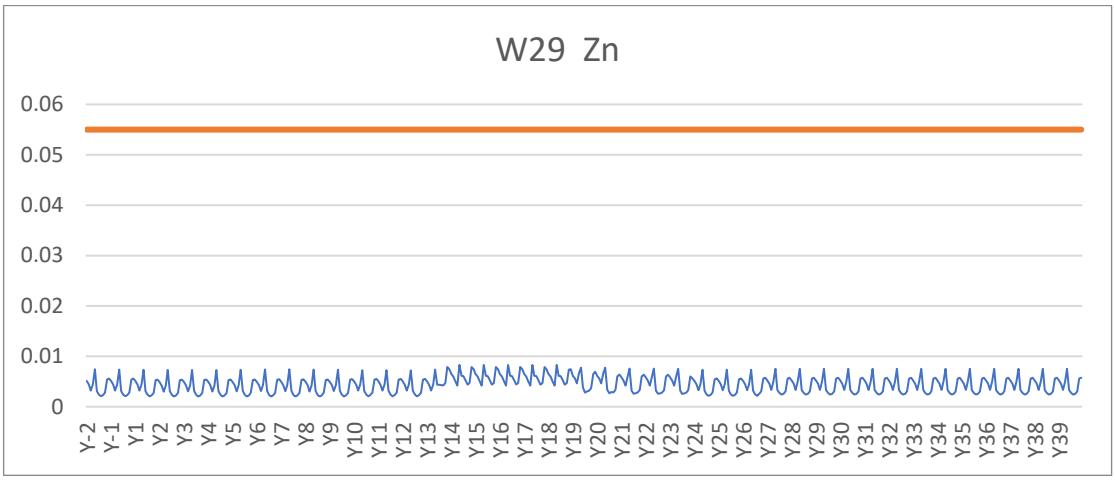
B.2-15: Time series of predicted manganese concentrations (mg/L) for W29. Water Quality Objective is shown by red line.



B.2-16: Time series of predicted molybdenum concentrations (mg/L) for W29. Water Quality Objective is shown by red line.

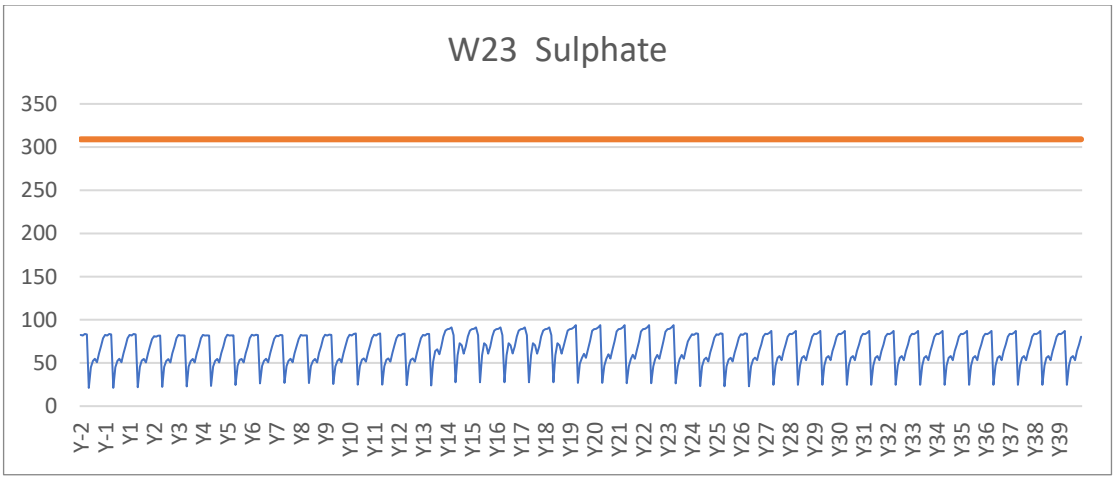


B.2-17: Time series of predicted nickel concentrations (mg/L) for W29. Water Quality Objective is shown by red line.

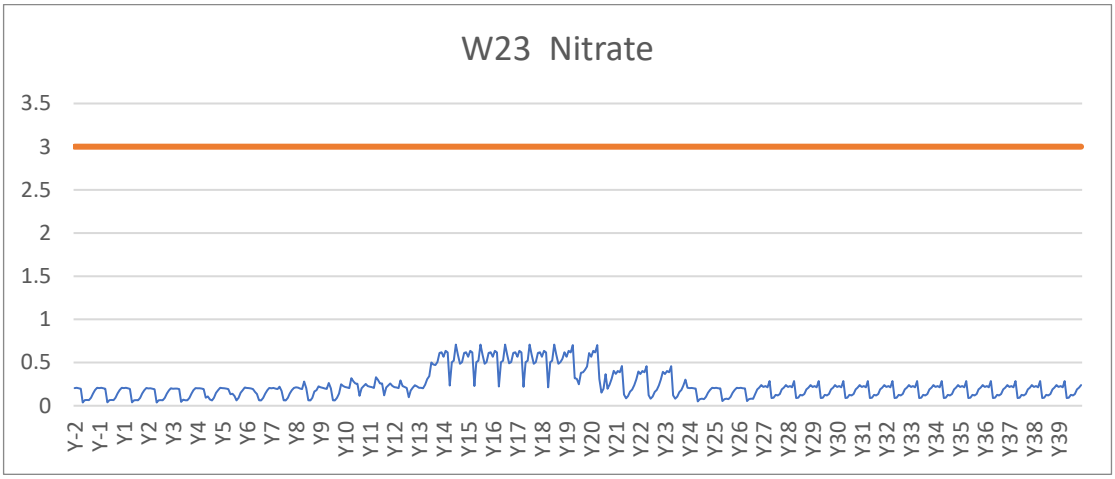


B.2-18: Time series of predicted selenium concentrations (mg/L) for W29. Water Quality Objective is shown by red line.

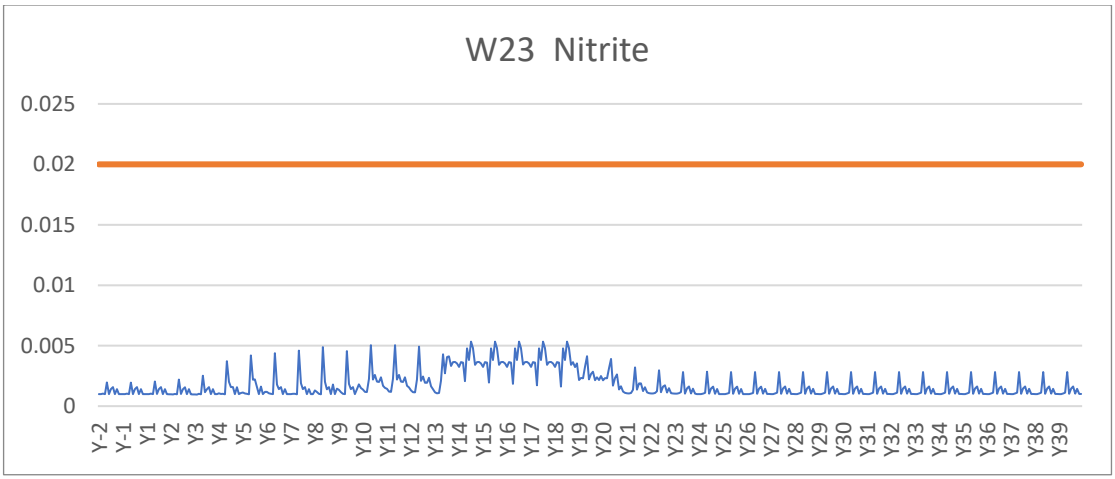
B.2-19: **Time series of predicted silver concentrations (mg/L) for W29. Water Quality Objective is shown by red line.**



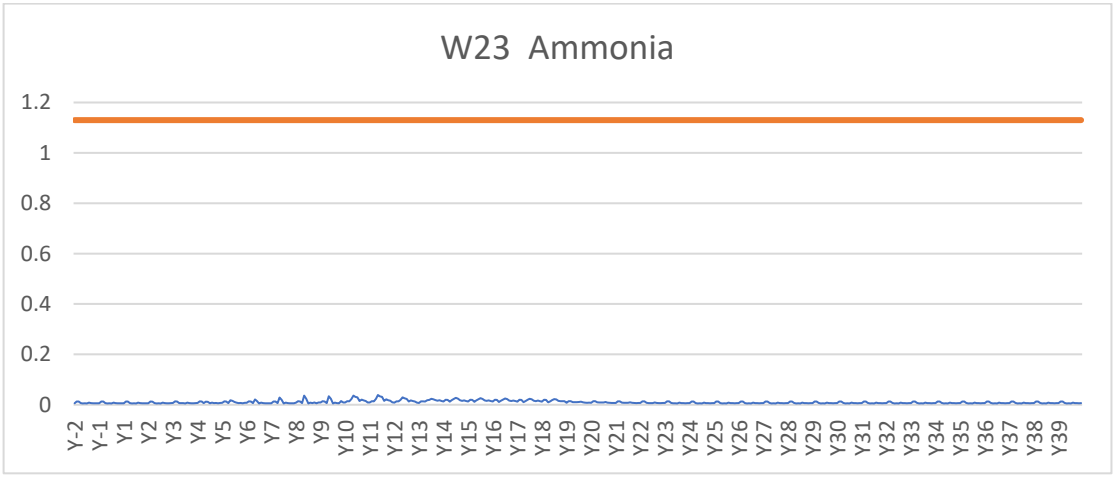
B.2-20: **Time series of predicted uranium concentrations (mg/L) for W29. Water Quality Objective is shown by red line.**



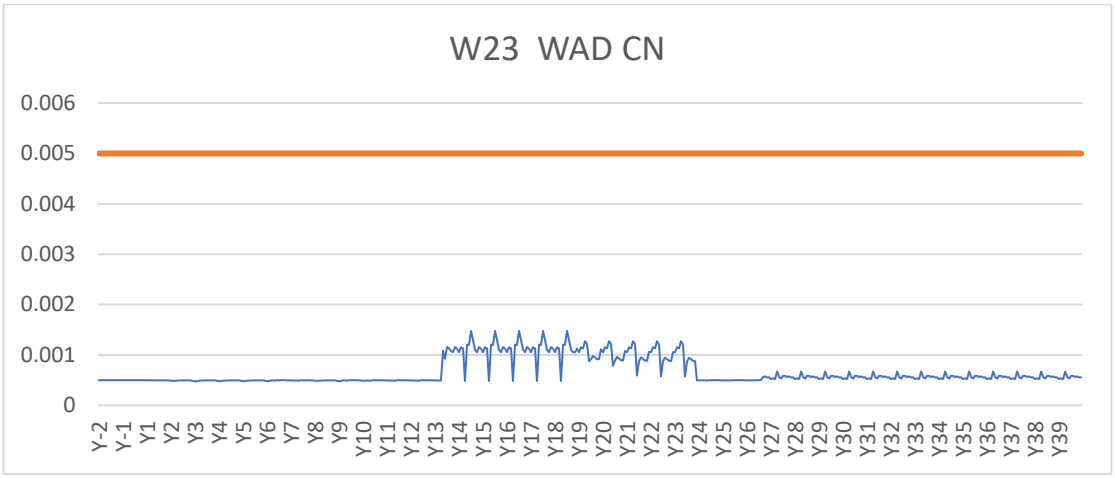
B.2-21: **Time series of predicted zinc concentrations (mg/L) for W29. Water Quality Objective is shown by red line.**



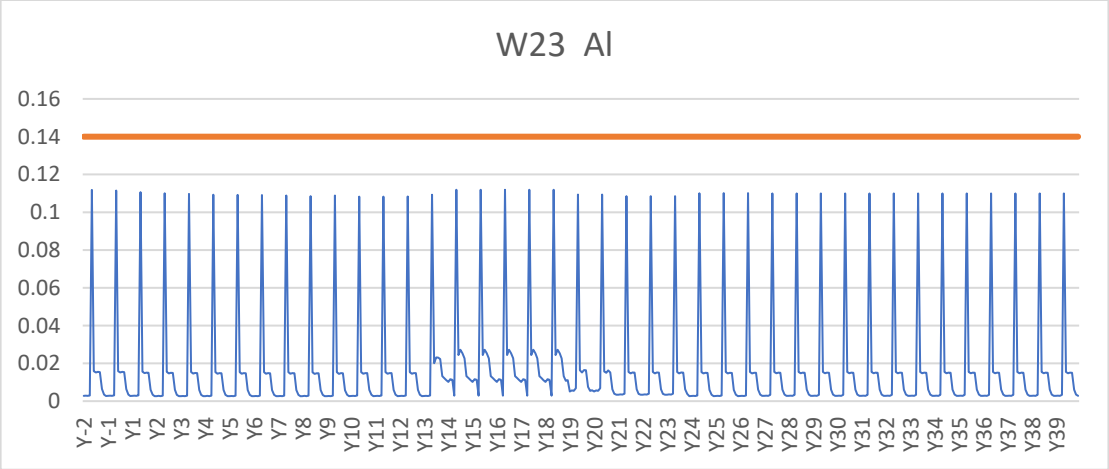
B.3. Haggart Creek below Lynx Creek (W23) – Water Quality Predictions



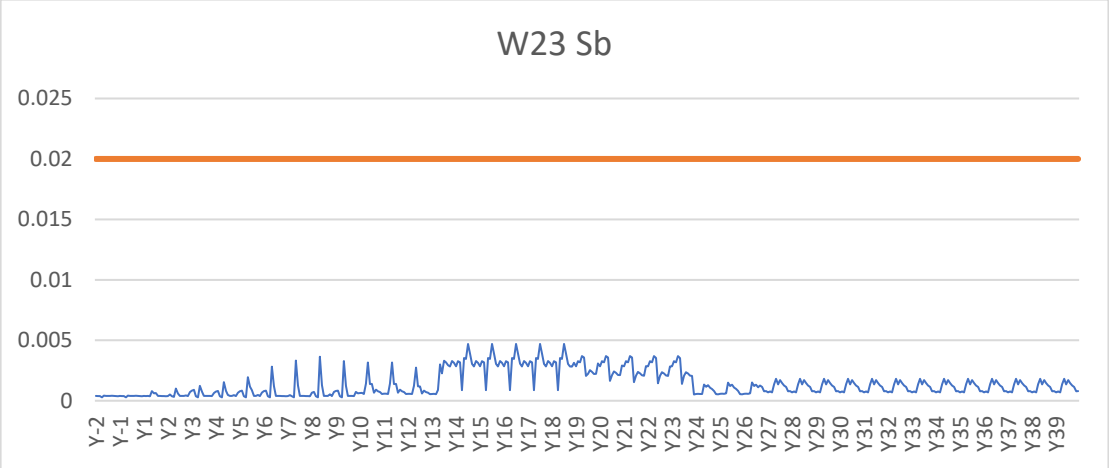
B.3-1: Time series of predicted sulphate concentrations (mg/L) for W23. Water Quality Objective is shown by red line.



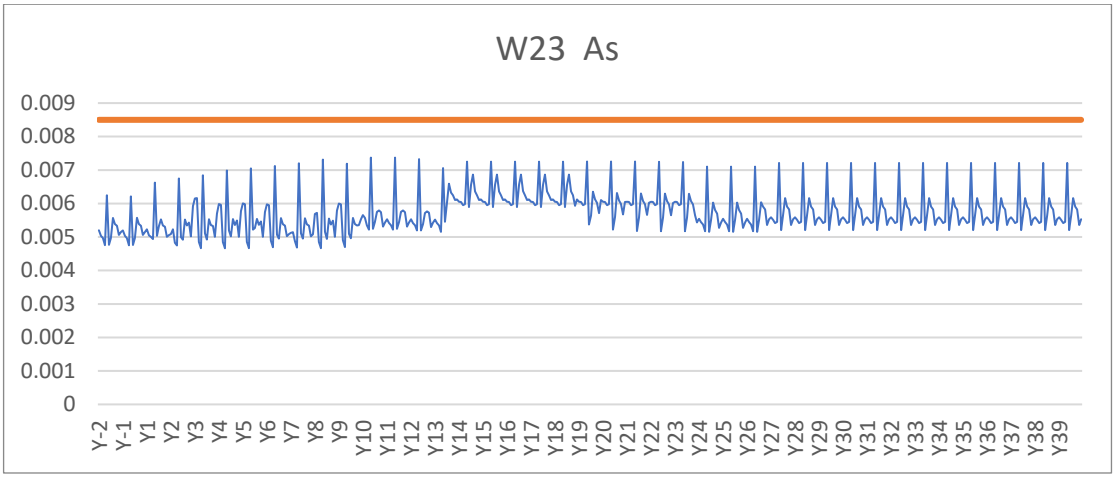
B.3-2: Time series of predicted nitrate concentrations (mg/L) for W23. Water Quality Objective is shown by red line.



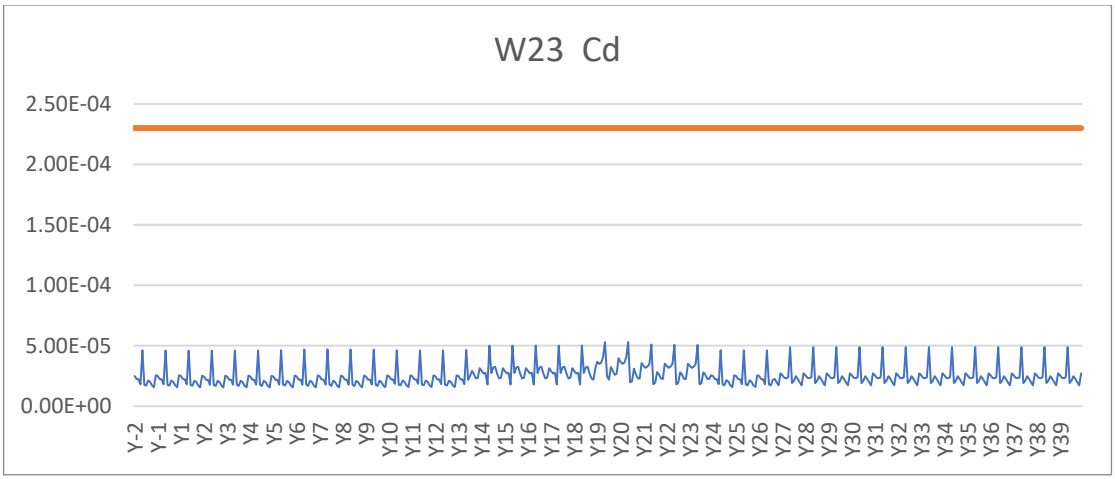
B.3-3: Time series of predicted nitrite concentrations (mg/L) for W23. Water Quality Objective is shown by red line.



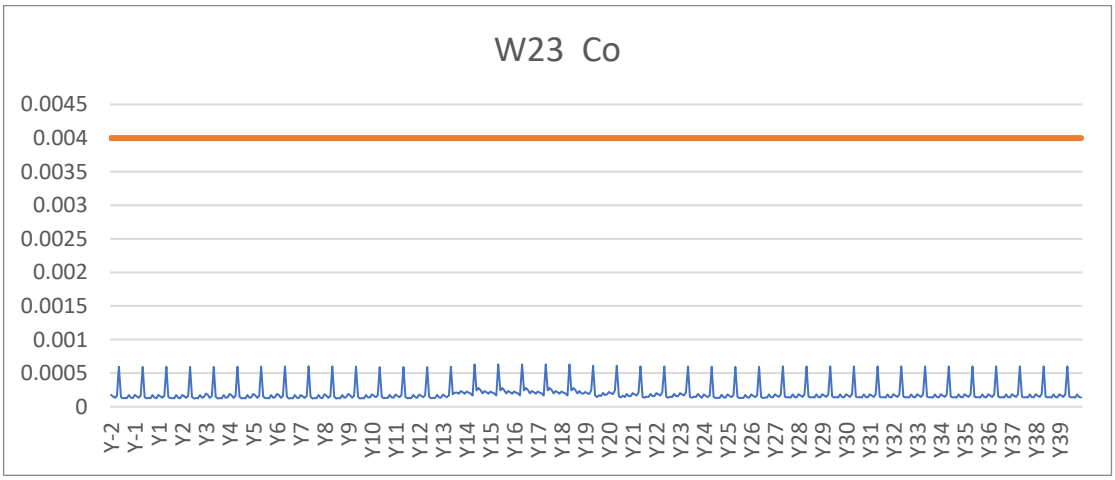
B.3-4: Time series of predicted ammonia concentrations (mg/L) for W23. Water Quality Objective is shown by red line.



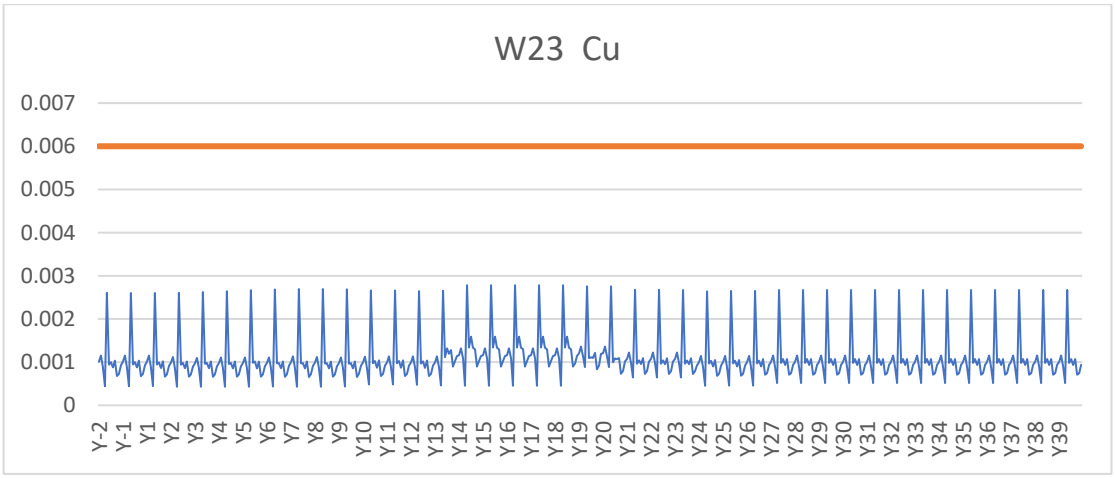
B.3-5: Time series of predicted WAD-CN concentrations (mg/L) for W23. Water Quality Objective is shown by red line.



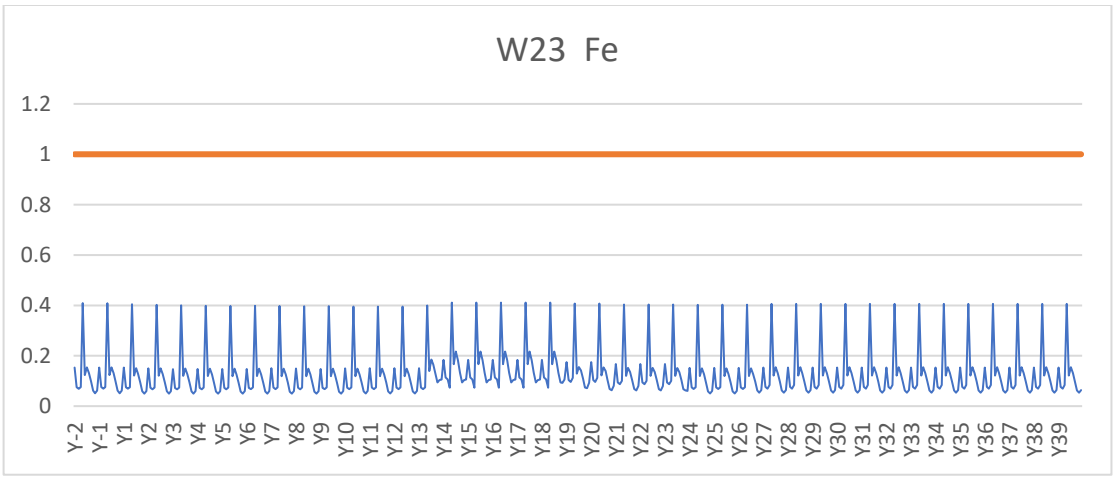
B.3-6: **Time series of predicted aluminum concentrations (mg/L) for W23. Water Quality Objective is shown by red line.**



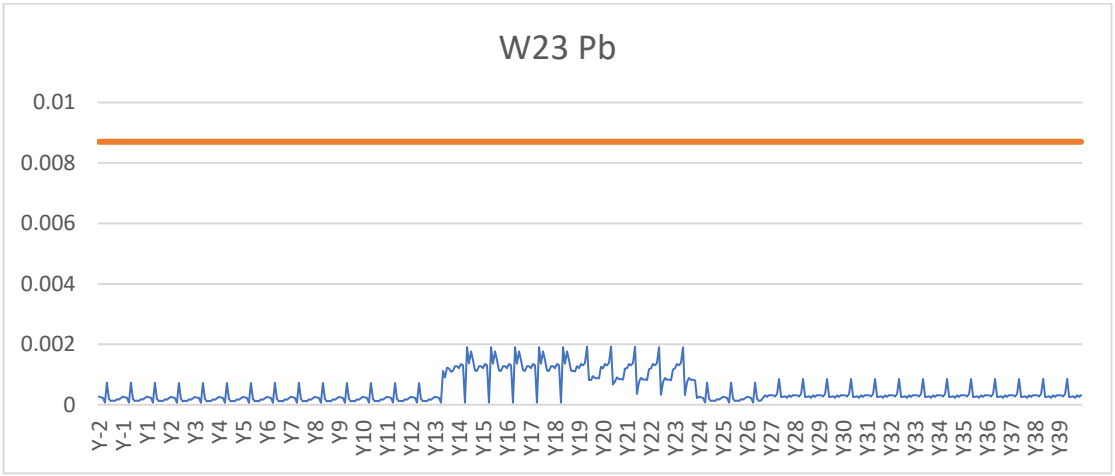
B.3-7: **Time series of predicted antimony concentrations (mg/L) for W23. Water Quality Objective is shown by red line.**



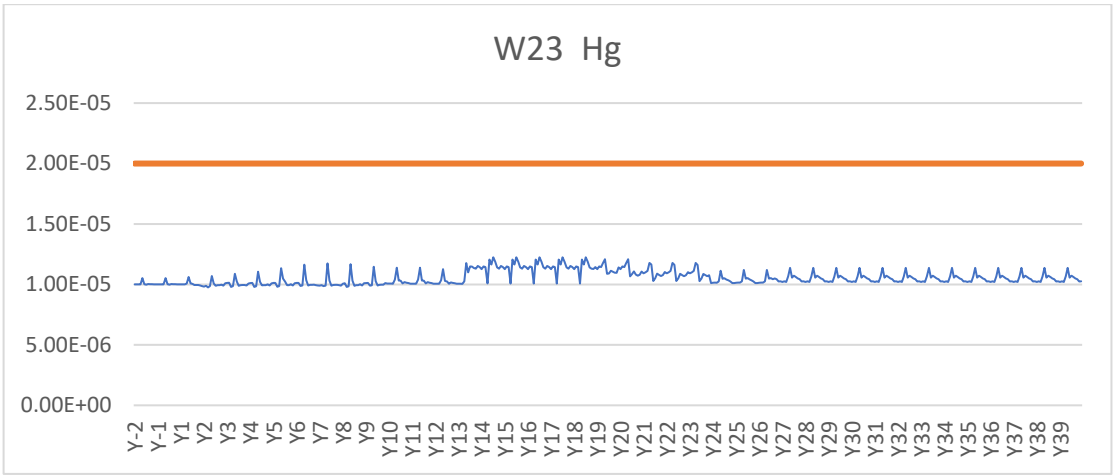
B.3-8: **Time series of predicted arsenic concentrations (mg/L) for W23. Water Quality Objective is shown by red line.**



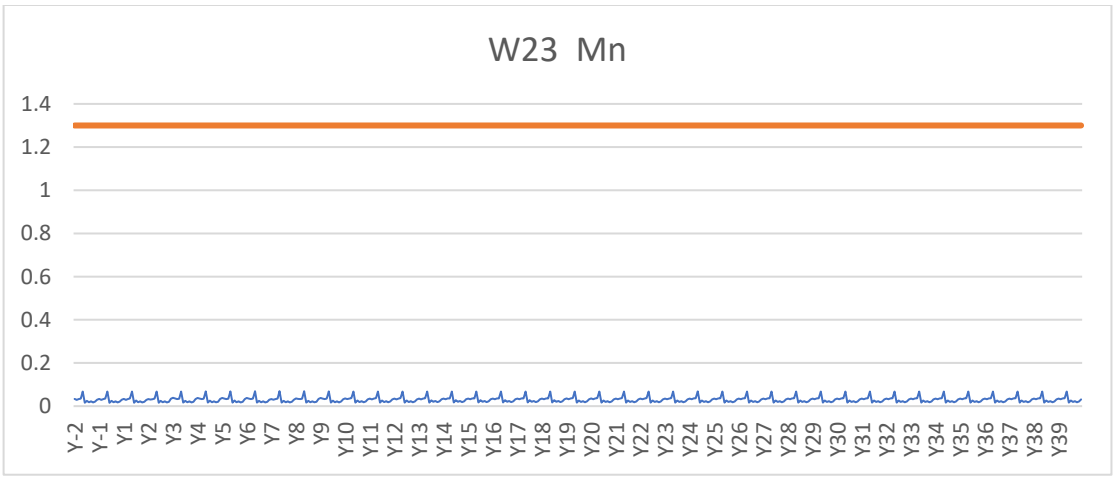
B.3-9: **Time series of predicted cadmium concentrations (mg/L) for W23. Water Quality Objective is shown by red line.**



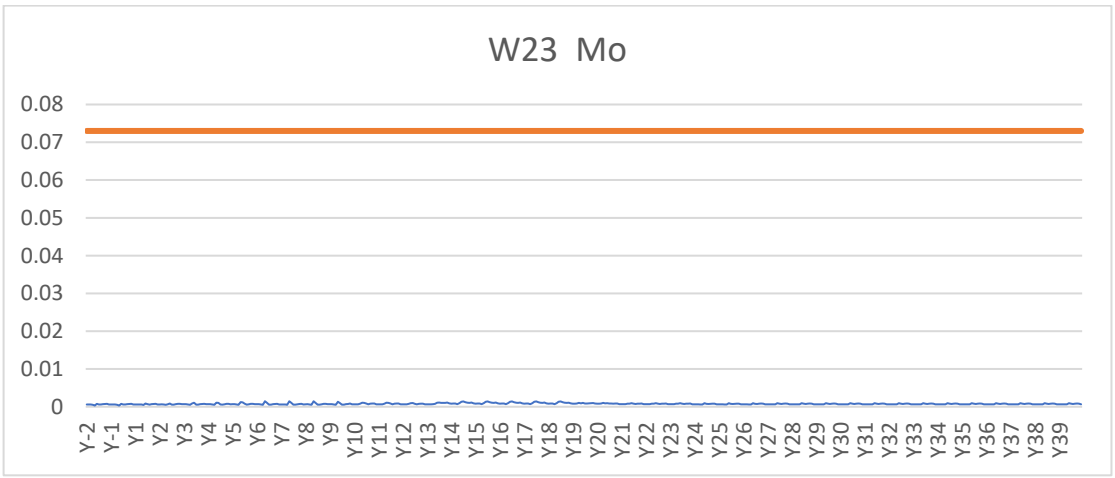
B.3-10: **Time series of predicted cobalt concentrations (mg/L) for W23. Water Quality Objective is shown by red line.**



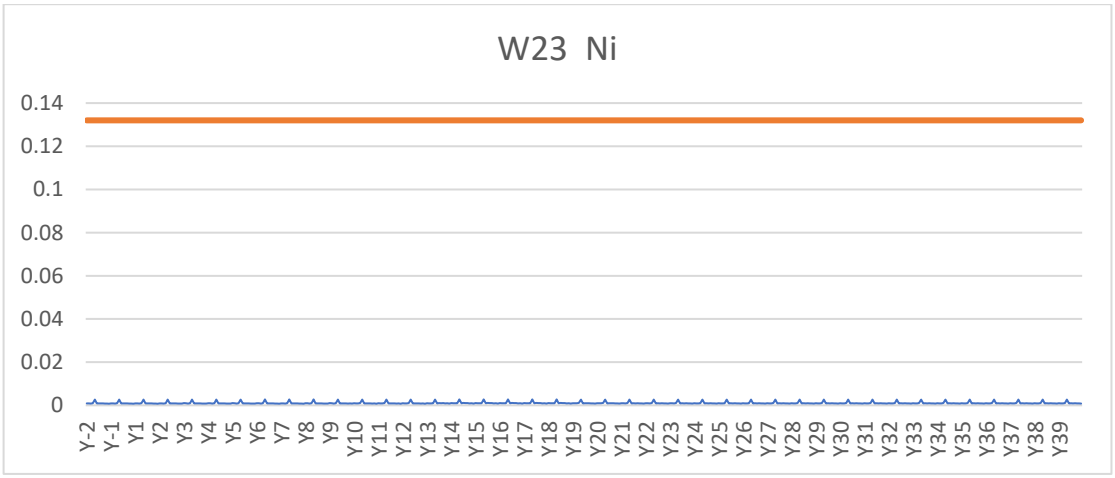
B.3-11: **Time series of predicted copper concentrations (mg/L) for W23. Water Quality Objective is shown by red line.**



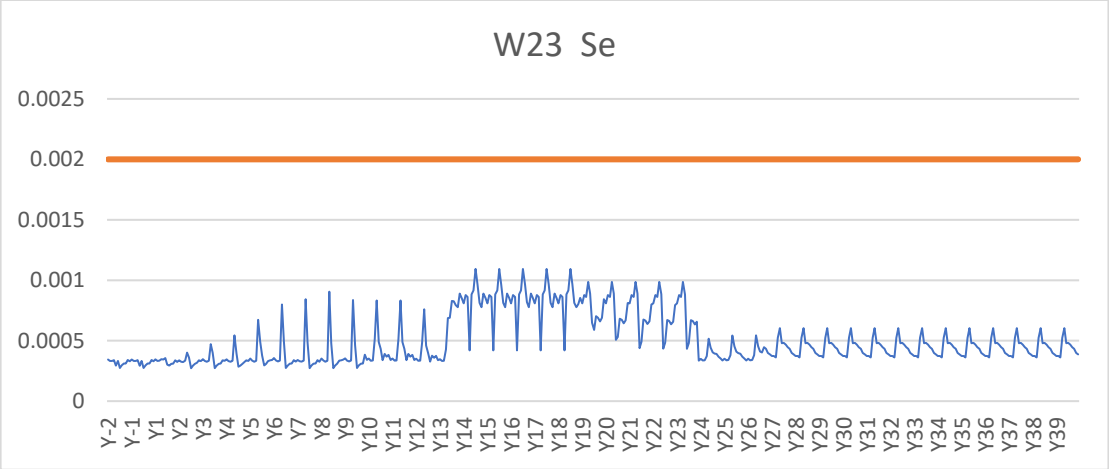
B.3-12: Time series of predicted iron concentrations (mg/L) for W23. Water Quality Objective is shown by red line.



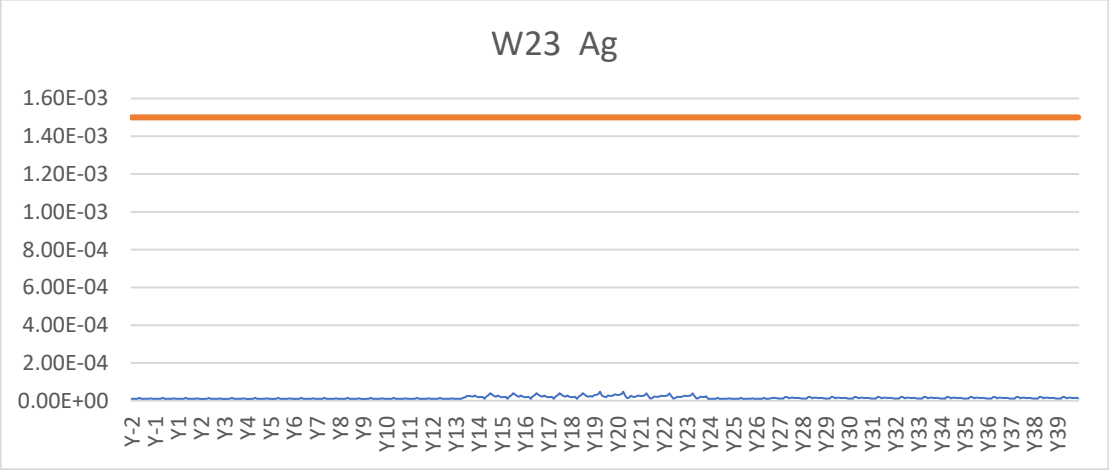
B.3-13: Time series of predicted lead concentrations (mg/L) for W23. Water Quality Objective is shown by red line.



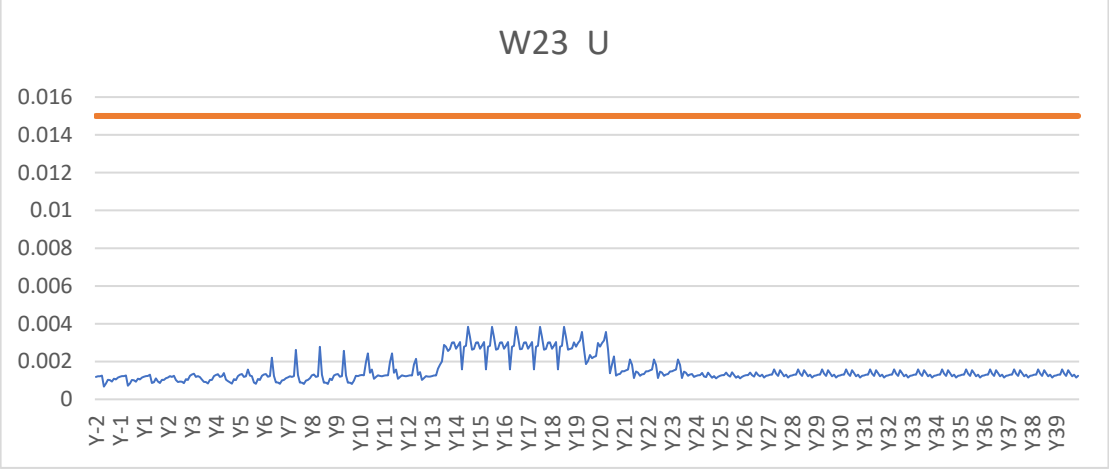
B.3-14: Time series of predicted mercury concentrations (mg/L) for W23. Water Quality Objective is shown by red line.



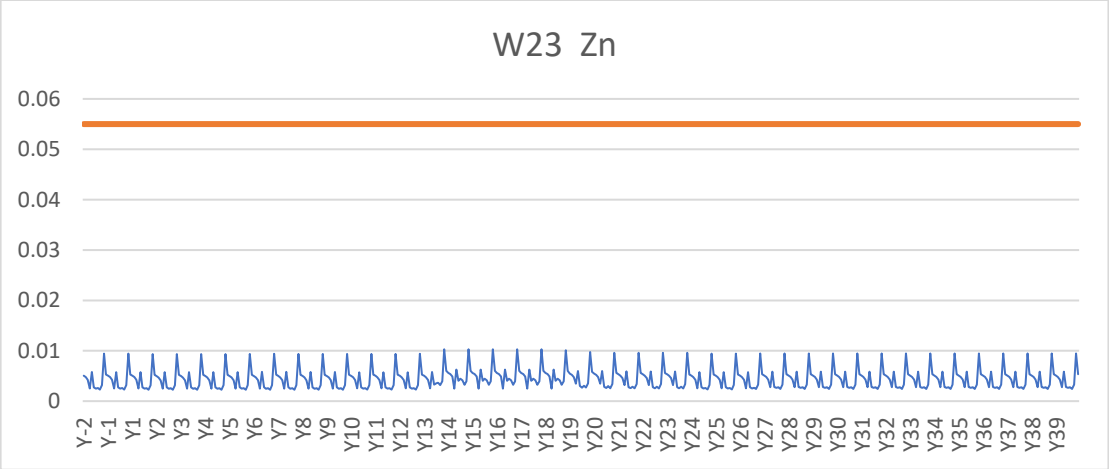
B.3-15: Time series of predicted manganese concentrations (mg/L) for W23. Water Quality Objective is shown by red line.



B.3-16: Time series of predicted molybdenum concentrations (mg/L) for W23. Water Quality Objective is shown by red line.



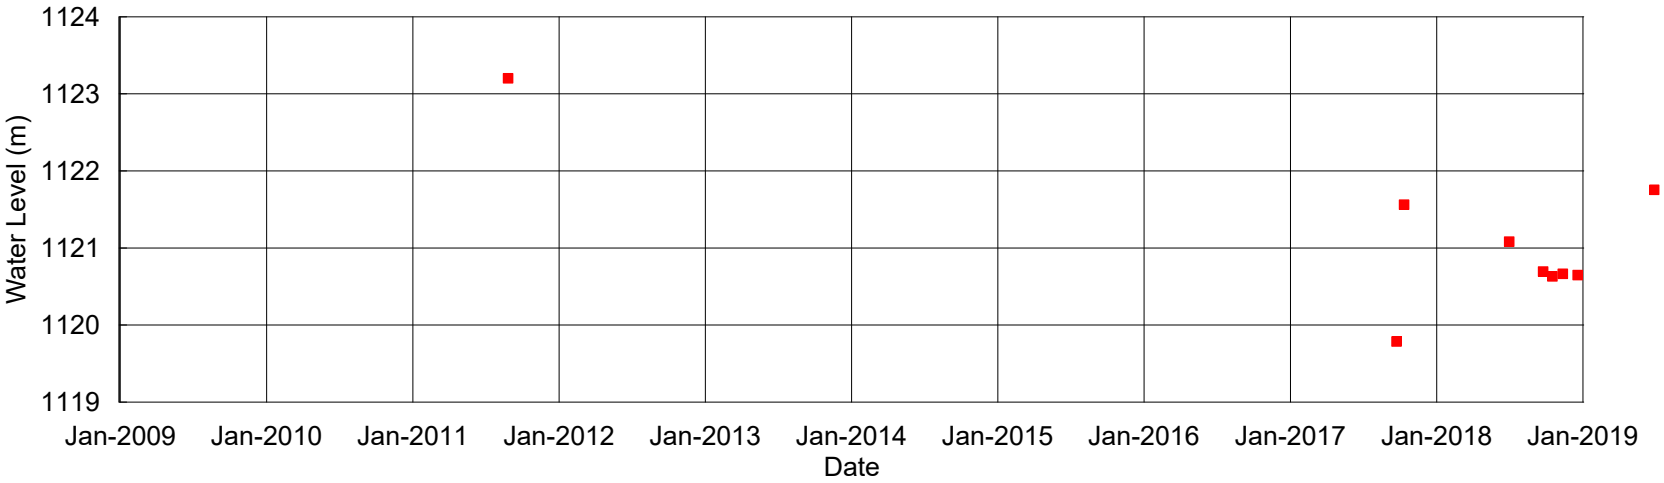
B.3-17: Time series of predicted nickel concentrations (mg/L) for W23. Water Quality Objective is shown by red line.



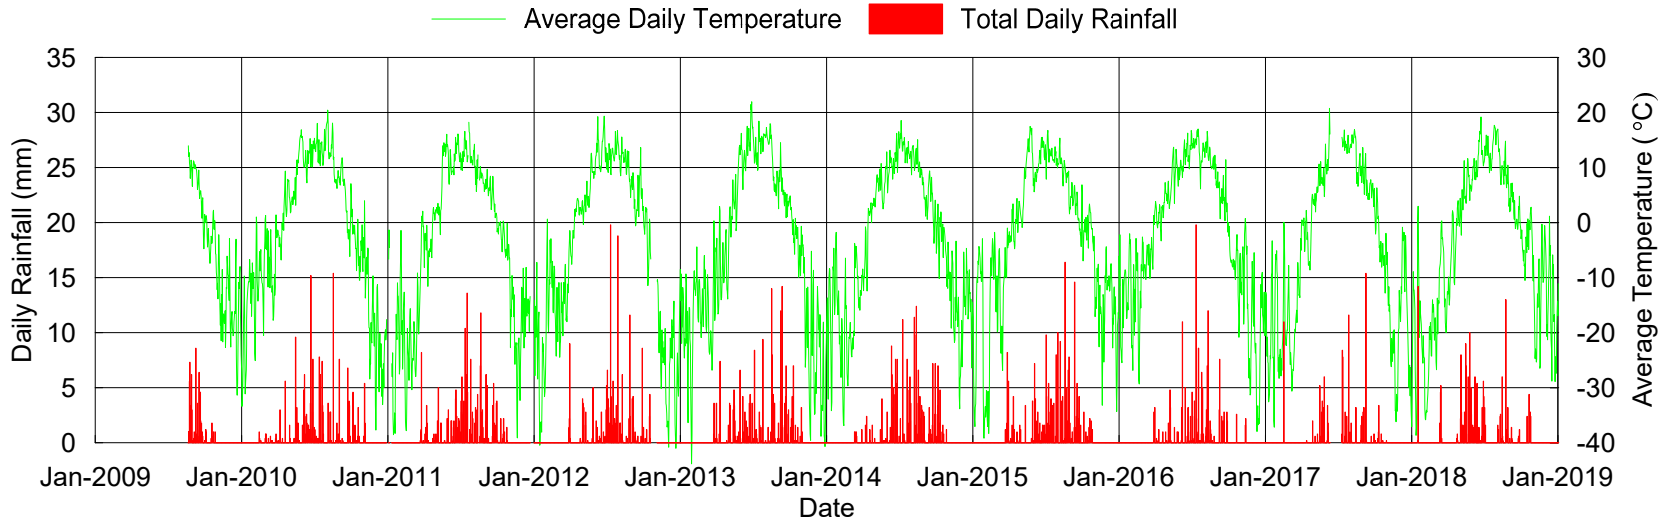
B.3-18: Time series of predicted selenium concentrations (mg/L) for W23. Water Quality Objective is shown by red line.

B.3-19: Time series of predicted silver concentrations (mg/L) for W23. Water Quality Objective is shown by red line.

B.3-20: Time series of predicted uranium concentrations (mg/L) for W23. Water Quality Objective is shown by red line.



B.3-21: Time series of predicted zinc concentrations (mg/L) for W23. Water Quality Objective is shown by red line.



Appendix C: Water Quality Model Output for all Parameters

APPENDIX H

2018 Update on Geochemical Source Terms

TECHNICAL MEMORANDUM

To:	**Stephen Wilbur, Victoria Gold Corp.**	**Date: February 26, 2018**
From:	**Timo Kirchner & David Flather**	**Project #: A445-1**
Subject:	**Eagle Gold Mine – 2018 Update on Geochemical Source Terms**	

For the application of the Eagle Gold Water Use Licence (WUL QZ14-041), Victoria Gold Corporation (VIT) retained Lorax Environmental Services Ltd. (Lorax) to provide geochemical source term predictions for the waste rock storage facilities as well as the heap leach pad to be used for the site-wide water quality model. The source term model produced by Lorax was primarily based on laboratory- and field-kinetic testwork conducted on samples representing waste rock and ore.

As a condition of the WUL, VIT is required to prepare an updated water quality model that is reflective of changes climate, hydrology and water quality data collected since the submission of the WUL application. For the current update, the geochemistry of field bin leachates collected through 2017 was compiled and reviewed by Lorax and the potential effect of the additional data on the source term model was assessed. It was found that the major parameters of concern (SO_4, As, Sb, Se) show generally steady (As, Sb) or decreasing trends in concentrations leached from the field barrels. One exception is the Oxide Granodiorite field barrel which produces leachates that steadily increase in As concentration up to a value of 2.67 mg/L (Figure 1) in the most recent sample collected (October 2017). It should be noted, however, that this material's solid phase As content (1065 ppm) is well above the respective 90th percentile value (607 ppm) of the static test database for Eagle Gold waste rock. In other words, less than 10% of oxide granodiorite rock is expected to have an As content as high as that within the field barrel sample. Furthermore, this lithology is expected to comprise only around 16% of the total waste produced.

Overall it can be said that the most recent source term model output is still valid and does not currently require updating for the following reasons:

- The field bin leachate data were only directly used in the source term model to calculate a "first flush" value representing the effect of flushing easily soluble species. The values used for this approach have not changed since the last model iteration;
- Overall, the trends observed in field bin leachates over time were used qualitatively for model validation purposes. While variable, these trends have not changed sufficiently to warrant a re-mdoelling of the Eagle Gold waste rock facilities as a whole.

This document has been prepared by Lorax Environmental Services Ltd. ("Lorax") for the benefit of the client named in this document. No person other than the named client may use or rely upon this document or any of its contents, and Lorax has no liability, obligation or responsibility to any person other than the named client. In addition, Lorax has no liability, obligation or responsibility for any changes to this document or any of its contents made by any person other than Lorax or its authorized personnel.
Any reader or user of this document or any part of it hereby indemnifies Lorax and its directors, officers, employees, representatives and agents from and against, and releases Lorax and its directors, officers, employees, representatives and agents from, any and all liabilities, obligations, claims, proceedings and costs arising out of or relating to the use of or reliance upon this document or any of its contents by any person other than the named client or any changes to this document or any of its contents made by any person other than Lorax or its authorized personnel.

Should changes to the mine plan be made or new data become available, the source term model will be re-evaluated at that time.

1.0 INTRODUCTION

Various monitoring projects are to be undertaken at the Eagle Gold Project during all phases of the site; construction, operation and closure as outlined in the updated Environmental Monitoring, Surveillance and Adaptive Management Plan (EMSAMP) version 2018-01 (StrataGold Corporation, 2018). The site is currently in the second year of construction and the first annual late summer stream sediment monitoring program was conducted in September 2017. This report presents the findings of the 2018 survey.

The purpose of the study is to continue to obtain data on the stream sediment quality of the watercourses in the study area to evaluate changes related to all phases of the Project. Previous sampling, prior to the implementation of the EMSAMP, has been conducted throughout the project area from 1976 to 2010 on the various watersheds. Relevant past data has been examined and is presented with the current study where appropriate.

2.0 METHODS

Triplicate stream sediment samples were collected from nine sites representing four drainage basins. Each sample was a composite of five or more individual sites within the sampled area. Depositional sites were targeted to obtain fine-grained sediment. Samples were collected with a steel trowel, well mixed and placed into acid washed glass jars. All samples were kept cool until delivered to the ALS laboratory in Whitehorse, Yukon.

These samples were collected from four drainage areas within the Victoria Gold footprint and the sites are detailed below in Table 1 and illustrated on Figure 1.

TABLE 1 LOCATION OF SAMPLE SITES

Drainage	Site	Date Sampled	Site Description	Coordinates	
				Northing	Easting
Haggart Creek	W22	9/9/2018	Haggart Creek upstream Dublin Gulch	7101377	458319
	W4	9/9/2018	Haggart Creek downstream Dublin Gulch	7101223	458144
	W29	9/9/2018	Haggart Creek downstream Eagle Creek	7099583	458225
	W5	9/10/2018	Haggart Creek upstream Lynx Creek	7095887	457815
	W23	9/8/2018	Haggart Creek downstream Lynx Creek	7095682	457790
Dublin Gulch	W1	9/9/2018	Dublin Gulch upstream Stewart Gulch	7101545	460249
	W26	9/9/2018	Stewart Gulch upstream Dublin Gulch	7101443	460331
Eagle Cr	W27	9/9/2018	Eagle Creek near Camp Climate Station	7100997	458235
Lynx Cr	W6	9/10/2018	Lynx Creek upstream Haggart Creek	7095964	458099

At the laboratory, all samples were sieved and the portion passing 63 microns was analyzed for metals using inductively coupled plasma mass spectrophotometry (ICP-MS) or optical emission spectrophotometry (ICP-OES) as appropriate. Mercury was analyzed by cold vapour atomic fluorescence spectrophotometry (CVAFS).

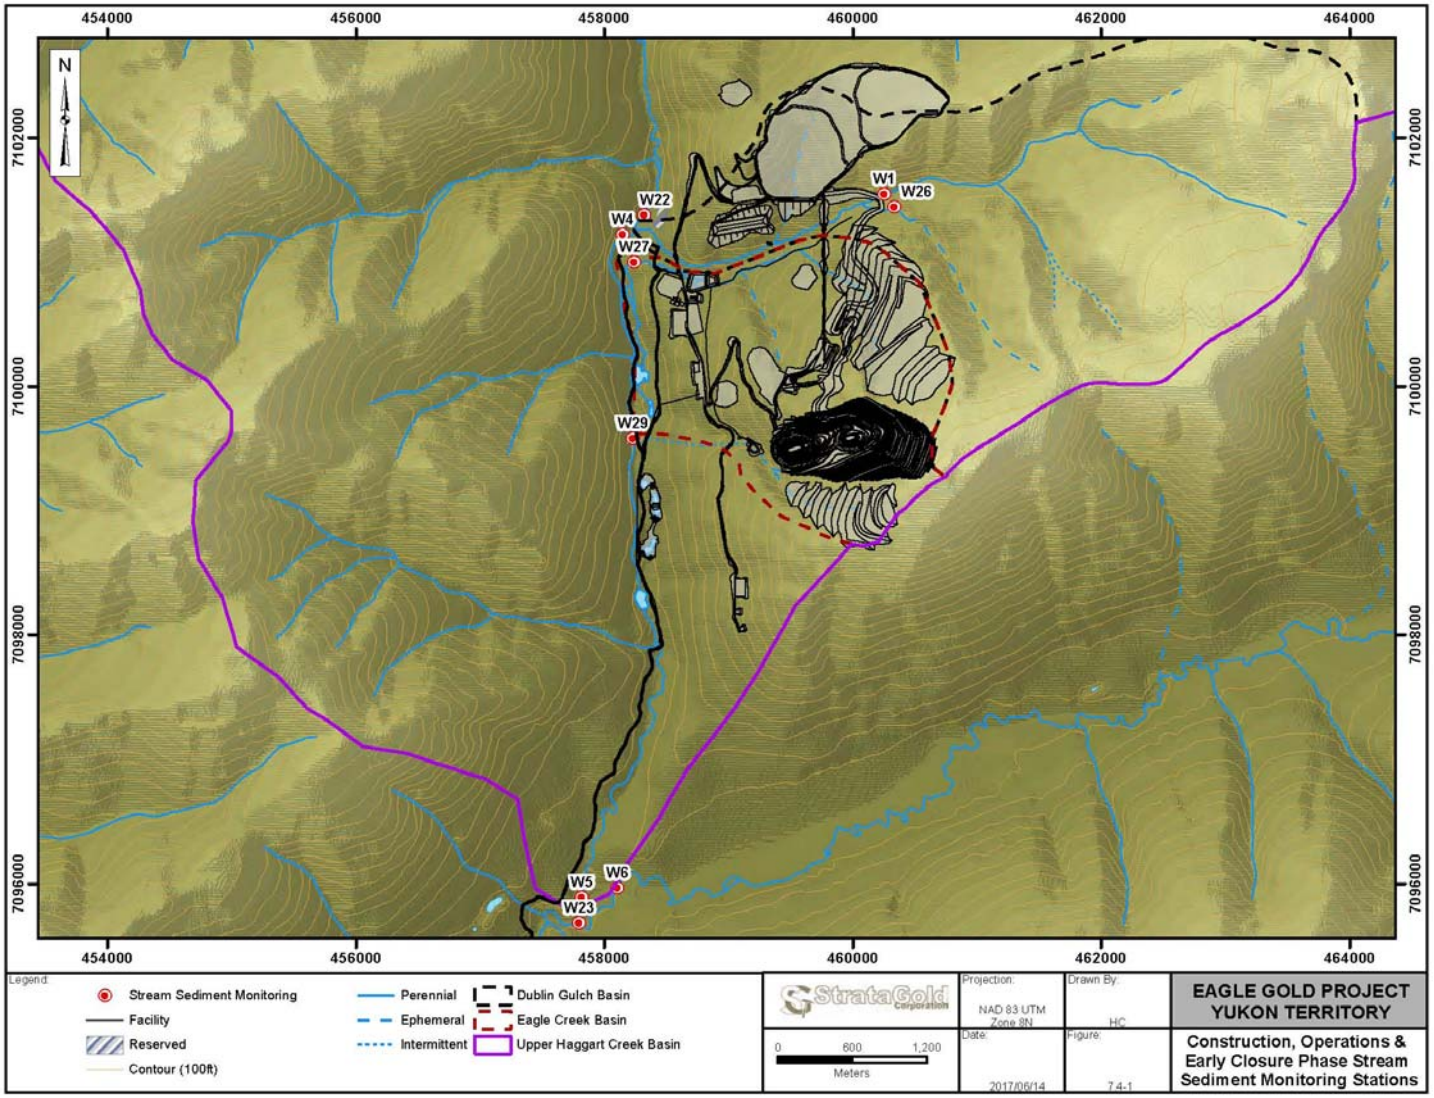

Figure 1 Locations of Stream Sediment Sample Sites During Construction Phase

As a measure of quality assurance/quality control (QA/QC) one duplicate set of sediment samples was collected. Strict sampling protocols were adhered to throughout the field study; sampling equipment was cleaned between samples and sites, disposable gloves were worn per sample and samples were kept cool until relinquished at the laboratory. The lab also performed their own QA/QC by analyzing spiked samples with known concentrations of various parameters.

Upon receipt of the data various metrics were performed. To characterize the stream sediment conditions at each site the triplicates were averaged. Standard deviation was performed to determine the spread of the values. As each of the triplicate samples was collected at different depositional areas within each site, the coefficient variation was calculated (standard deviation divided by mean multiplied by 100) to assess heterogeneity of the stream environment.

3.0 RESULTS AND DISCUSSION

3.1 2018 Data

Samples were analyzed for soil pH and a suite of 32 metals. The analytical report is presented in Appendix A. The triplicate samples at each site were averaged and these data were used for the tables and discussions. The sites have been arranged per watershed from upstream to downstream in the tables and graphs for ease of interpretation.

The streams throughout the study area are near neutral to slightly alkaline ranging from a pH of 7.34 at W1, Dublin Gulch to 8.17 at W27, Eagle Creek (Table 2).

Of the 32 metals analyzed, boron was not detected in any of the samples. The averages of selected metals are also presented in Table 2. These elements were chosen for closer examination as they can potentially be toxic to aquatic systems, some may be present in the mineral deposit and several have environmental guidelines for the protection of freshwater aquatic life. Since there are no Canadian Environmental Quality Guidelines established for nickel, selenium and silver, the British Columbia Working Sediment Quality Guidelines (BCWSG) were used. Concentrations that exceeded the Interim Sediment Quality Guidelines (ISQG) are displayed in bold and gray highlighted. The ISQG guideline represents where adverse biological effects may only rarely occur. Concentrations that exceeded the Probable Effects Level (PEL) are displayed in bold and highlighted in orange, and indicate a 50% incidence of creating adverse biological effects.

Several guidelines were exceeded for the protection of freshwater aquatic life. The PEL for arsenic, 17 mg/kg, was significantly exceeded at all of the sites ranging from 79.5 mg/kg at W6, Lynx Creek to 383.0 mg/kg at W1, Dublin Gulch.

The concentration of nickel exceeded the BCWSG low level effect guideline (16 mg/kg) in the stream sediments at all of the sites and ranged from 25.0 mg/kg at W29 to 53.2 at W22.

The ISQG was exceeded for cadmium at W6 and W22, both of which are background sites. The ISQG was exceeded for chromium at W26, for copper and lead at W27, and for zinc at W22. Guidelines were met in the study area for mercury, selenium and silver.

TABLE 2 SUMMARY OF MEAN STREAM SEDIMENT CONCENTRATIONS, SEPTEMBER 2018

Drainage	Haggart Creek					Dublin Gulch		Eagle Cr	Lynx Cr	CEQG Guidelines	
Site	**W22**	**W4**	**W29**	**W5**	**W23**	**W1**	**W26**	**W27**	**W6**	**ISQG**	**PEL**
pH	7.75	7.51	7.49	7.98	7.74	7.34	7.77	8.17	7.44	na	na

* BCWSG na = not applicable

In attempts to determine the reliability of the current data set and the heterogeneity of each site, standard deviation (SD) and coefficient variation (CV) were calculated on the means of the triplicates. The target for CV is no more than 20% when replicate samples collected at the same time and location are all at least five times the detection limit. These results are tabulated in Table A-1 in Appendix A.

The CV was less than 20% at W4, W5 and W29, indicating homogeneous substrates at these sites. Other sites had one to four parameters exceeding 20%, except for W26, Stewart Gulch where 13 parameters had CVs greater than 20%. The composition of the stream sediments at Stewart Gulch had much greater heterogeneity throughout the sampled reach.

The parameters where CV was 20% or less for all sites were pH, aluminum, barium, beryllium, calcium, lithium, magnesium, phosphorus, selenium, strontium, thallium, tin, titanium, uranium vanadium and zinc.

As a measure of quality control and quality assurance, a set of duplicate stream sediment samples was collected from W22. The relative percent difference (RFP) for all parameters in each sample was calculated to determine the representativeness of sample collection and thus the validity of the data (Table A-2, Appendix A). Different sources have determined an acceptable range of RFP of 20% in aqueous media and up to 50% in sediment. A conservative value of 20% RFP was used for this study. Based on this, the representativeness of arsenic, silver and titanium in W22-A, sodium in W22B, and sodium and titanium in W22C, may be questionable. However, the vast majority of RFP for the remaining parameters and samples

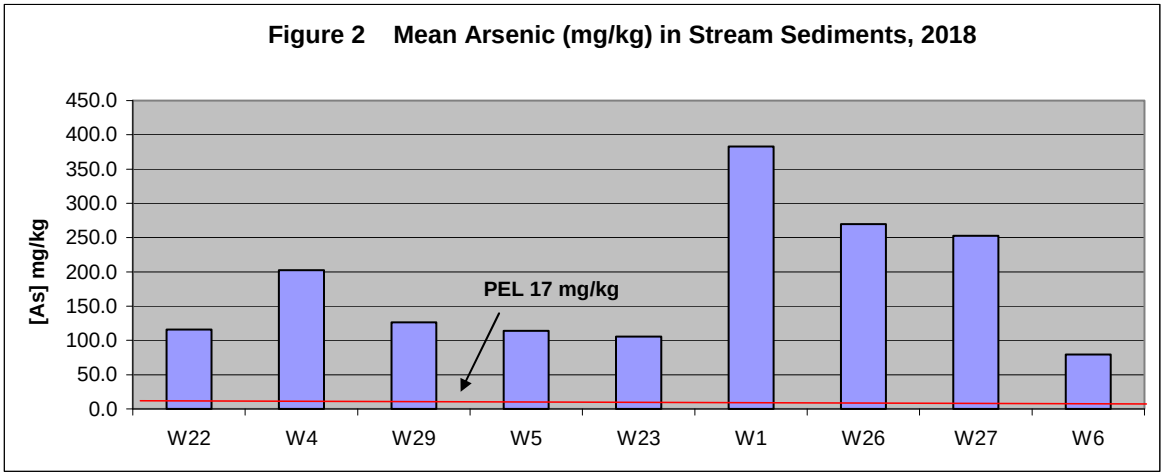
were well below 20% and would indicate that the sediment samples are representative of the locations sampled and that data integrity is intact.

Arsenic is prevalent in the stream sediments throughout the study area and as previously mentioned the PEL was exceeded at all sites. Arsenic is typically associated with the mineralogy of gold. The high concentrations documented at W1, Dublin Gulch upstream of Project activities, indicate that this stream drains a mineralized area. The standard deviation showed a small spread of values and the CV was only 7.0% (Table A-1, Appendix A) confirming that the arsenic concentrations at W1 are representative of the site.

Nickel also was widespread throughout the study area and concentrations in the stream sediments exceeded the ISQG at all sites.

These two elements have been graphed below in Figures 2 and 3. Concentrations of arsenic fluctuate throughout the study area whereas nickel concentrations are relatively similar.

Figure 2 Mean Arsenic (mg/kg) in Stream Sediments, 2018



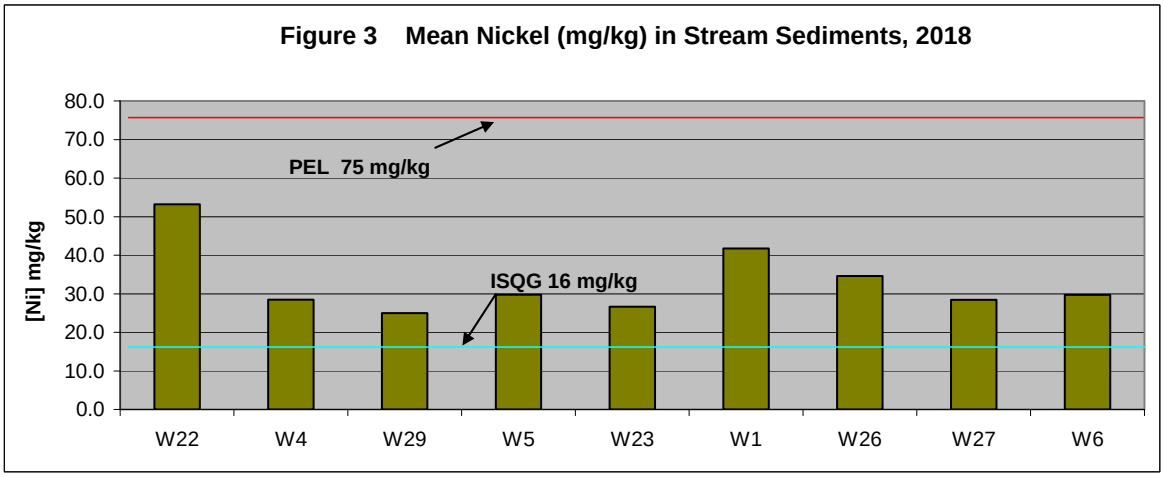


Figure 3 Mean Nickel (mg/kg) in Stream Sediments, 2018

3.2 Previous Data

Stream sediment samples have been collected in the general Project area in 1976, 1977, 1993, 1995, 2007, 2009 and 2010 (Stantec, 2011) and in 2017 (Laberge, 2017). The number of sites sampled, and the number of replicates collected varied in a given year. Data was examined from these surveys where the analysis was completed on the portion of the sediment that was less than 63 microns and for sites that were sampled in 2018. The mean concentrations for arsenic and nickel over time have been tabulated (Table 3) and graphically represented in Figures 4 and 5 with the 2018 data.

High levels of arsenic were reported at all sites and on all occasions, exceeding the PEL. Concentrations tended to fluctuate year to year at the sites.

Concentrations of nickel exceeded the ISQG throughout the study area and study period with the exception in 2007 at Stewart Gulch (W26), and 2009 at Dublin Gulch (W1).

There were periodic exceedances of guidelines of other metals. This data has not been presented here but is available in a report prepared by Stantec (2011).

TABLE 3 MEAN CONCENTRATIONS OF ARSENIC AND NICKEL IN STREAM SEDIMENTS, 1995 - 2018

Drainage	Site	ARSENIC (mg/kg)						NICKEL (mg/kg)

Not detected in any samples

NOTE: Se and Sn had CVs greater than 20% however, the concentrations reported were not greater than five times the method detection limit.

Values whre the CV is greater than 20% are highlighted in red and with dark red text.

Reference Information

QC Samples with Qualifiers & Comments:

QC Type Description	Parameter	Qualifier	Applies to Sample Number(s)
Duplicate	Titanium (Ti)	DUP-H	L2162014-20, -21, -22, -23, -24

Qualifiers for Individual Parameters Listed:

Qualifier	Description
DUP-H	Duplicate results outside ALS DQO, due to sample heterogeneity.
PSAL	Limited sample was available for PSA (100g minimum is standard). Measurement Uncertainty for PSA results may be higher than usual.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
C-TIC-PCT-SK	Soil	Total Inorganic Carbon in Soil	CSSS (2008) P216-217

A known quantity of acetic acid is consumed by reaction with carbonates in the soil. The pH of the resulting solution is measured and compared against a standard curve relating pH to weight of carbonate.

C-TOC-CALC-SK	Soil	Total Organic Carbon Calculation	CSSS (2008) 21.2

Total Organic Carbon (TOC) is calculated by the difference between total carbon (TC) and total inorganic carbon. (TIC)

C-TOT-LECO-SK	Soil	Total Carbon by combustion method	CSSS (2008) 21.2

The sample is ignited in a combustion analyzer where carbon in the reduced CO2 gas is determined using a thermal conductivity detector.

HG-63UM-CVAF-VA	Soil	Hg in Soil by CVAAS	EPA 200.2/245.7

This analysis is carried out using procedures from CSR Analytical Method: "Strong Acid Leachable Metals (SALM) in Soil", BC Ministry of Environment, 26 June 2009, and procedures adapted from EPA Method 200.2. The sample is manually homogenized, dried at 60 degrees Celsius, sieved through a 63 um (230 mesh) sieve, and a representative subsample of the dry material is weighed. The sample is then digested at 95 degrees Celsius for 2 hours by block digester using concentrated nitric and hydrochloric acids. Instrumental analysis is by atomic absorption spectrophotometry (EPA Method 245.7).

Method Limitation: This method is not a total digestion technique. It is a very strong acid digestion that is intended to dissolve those metals that may be environmentally available. By design, elements bound in silicate structures are not normally dissolved by this procedure as they are not usually mobile in the environment.

Deviation from Reference Method: This procedure deviates from the BC CSR SALM method, which specifies sieving to 2 mm (10 mesh).

IC-CACO3-CALC-SK	Soil	Inorganic Carbon as CaCO3 Equivalent	Calculation
MET-63UM-CCMS-VA	Soil	Metals in Soil by CRC ICPMS (63um)	EPA 200.2/6020A

Soil/sediment is dried, disaggregated, and sieved (2 mm). Strong Acid Leachable Metals in the <2mm fraction are solubilized by heated digestion with nitric and hydrochloric acids. Instrumental analysis is by Collision / Reaction Cell ICPMS.

Limitations: This method is intended to liberate environmentally available metals. Silicate minerals are not solubilized. Some metals may be only partially recovered (matrix dependent), including Al, Ba, Be, Cr, S, Sr, Ti, Tl, V, W, and Zr. Elemental Sulfur may be poorly recovered by this method. Volatile forms of sulfur (e.g. sulfide, H2S) may be excluded if lost during sampling, storage, or digestion.

PH-1:2-VA	Soil	pH in Soil (1:2 Soil:Water Extraction)	BC WLAP METHOD: PH, ELECTROMETRIC, SOIL

This analysis is carried out in accordance with procedures described in the pH, Electrometric in Soil and Sediment method - Section B Physical/Inorganic and Misc. Constituents, BC Environmental Laboratory Manual 2007. The procedure involves mixing the dried (at <60°C) and sieved (No. 10 / 2mm) sample with deionized/distilled water at a 1:2 ratio of sediment to water. The pH of the solution is then measured using a standard pH probe.

PSA-1-SK	Soil	Particle Size Analysis:Mini-Pipet Method	SSIR-51 Method 3.2.1

Dry, < 2 mm soil is treated with sodium hexametaphosphate to ensure complete dispersion of primary soil particles. The homogenized suspension is allowed to settle in accordance with Stoke's Law so that only clay particles remain in suspension.To determine the clay fraction, an aliquot of the clay suspension is removed, then dried and weighed. The sand fraction is determined by wet sieving the remaining suspension, then drying and weighing the sand retained on the sieve. The silt fraction is determined by calculation where % Silt = 100 - (%Sand+%Clay)

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
SK	ALS ENVIRONMENTAL - SASKATOON, SASKATCHEWAN, CANADA
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

1 of 2 2 of 2

Reference Information

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.
mg/kg - milligrams per kilogram based on dry weight of sample.
mg/kg wwt - milligrams per kilogram based on wet weight of sample.
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.
mg/L - milligrams per litre.
< - Less than.
D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

EXECUTIVE SUMMARY

The 2018 annual benthic invertebrate monitoring program represents the second survey completed during the construction phase of the Eagle Gold Project. Nine sites were investigated within four drainages. The 2018 data indicates healthy robust benthos communities at all sites with good representation of pollution sensitive species.

Water quality and stream sediment programs were also undertaken during the benthic invertebrate assessment to support characterization of the existing habitat conditions. Victoria Gold (VG) staff conduct monthly water quality sampling throughout the Project area, including the nine sites of the benthic invertebrate monitoring program. Sampling was coordinated to occur simultaneously with VG staff while the Laberge Environmental Services staff were on site to complete the benthic and stream sediment programs.

As with all previous studies since before construction, arsenic concentrations were high in the water column and in the stream sediments at all monitoring sites and except for one site (W22) exceeded the recommended federal guidelines for the protection of aquatic life for both media types. The two major uptake vectors of contaminants are through the ingestion of metal enriched sediments or suspended particles and/or uptake from solution. Although concentrations of arsenic were high, it is likely that it is not in a bioavailable form. The presence of pollution-sensitive insects, as reflected in the high numbers of Ephemeroptera, Plecoptera and Trichoptera (EPT) at all of the sites, support this conclusion.

1.0 INTRODUCTION

Various monitoring tasks are to be undertaken at the Eagle Gold Project during all phases of the site, including construction, operation and closure as outlined in the Environmental Monitoring, Surveillance and Adaptive Management Plan (EMSAMP) version 2018-01 (StrataGold Corporation, 2018). The construction phase began in August 2017 and the first annual benthic invertebrate monitoring program was conducted in September 2017. The current benthic survey was conducted September 19th to 22nd, 2018.

Monthly water quality samples are collected under the EMSAMP, with nine of these locations coinciding with the benthic invertebrate sites. Victoria Gold (VG) environmental staff collected water quality from these nine sites during the benthic invertebrate survey to characterize the existing aquatic conditions.

The surveys included four drainage areas within the Eagle Gold footprint and the sites are detailed below in Table 1 and illustrated on Figure 1.

TABLE 1 LOCATION OF SAMPLE SITES

Drainage	Site	Date Sampled	Site Description	Coordinates	
				Northing	Easting
Haggart Creek	W22	9/9/2018	Haggart Creek upstream Dublin Gulch	7101377	458319

2.0 METHODS

2.1 Water Quality

Water quality samples were collected by VG staff at each benthic invertebrate site in a fast-flowing section of the stream, prior to any other sampling activity. In-situ water quality measurements were obtained using a YSI multi-probe.

Samples were collected in bottles supplied by Analytical Laboratory Services (ALS) from their Whitehorse, Yukon depot. At each site, samples were collected in a 500 mL plastic bottle for general physical parameters. Samples to be analyzed for anions and nutrients were collected in 120 mL plastic bottles. Samples to be analyzed for metals were collected in 60 mL plastic bottles and preserved with nitric acid (HNO_3). Total cyanide samples were collected in pre-charged (NaOH) 60 mL brown plastic bottles. Samples to be analyzed for dissolved organic carbon and total organic carbon were collected in 120 mL amber glass bottles and preserved with sulfuric acid.

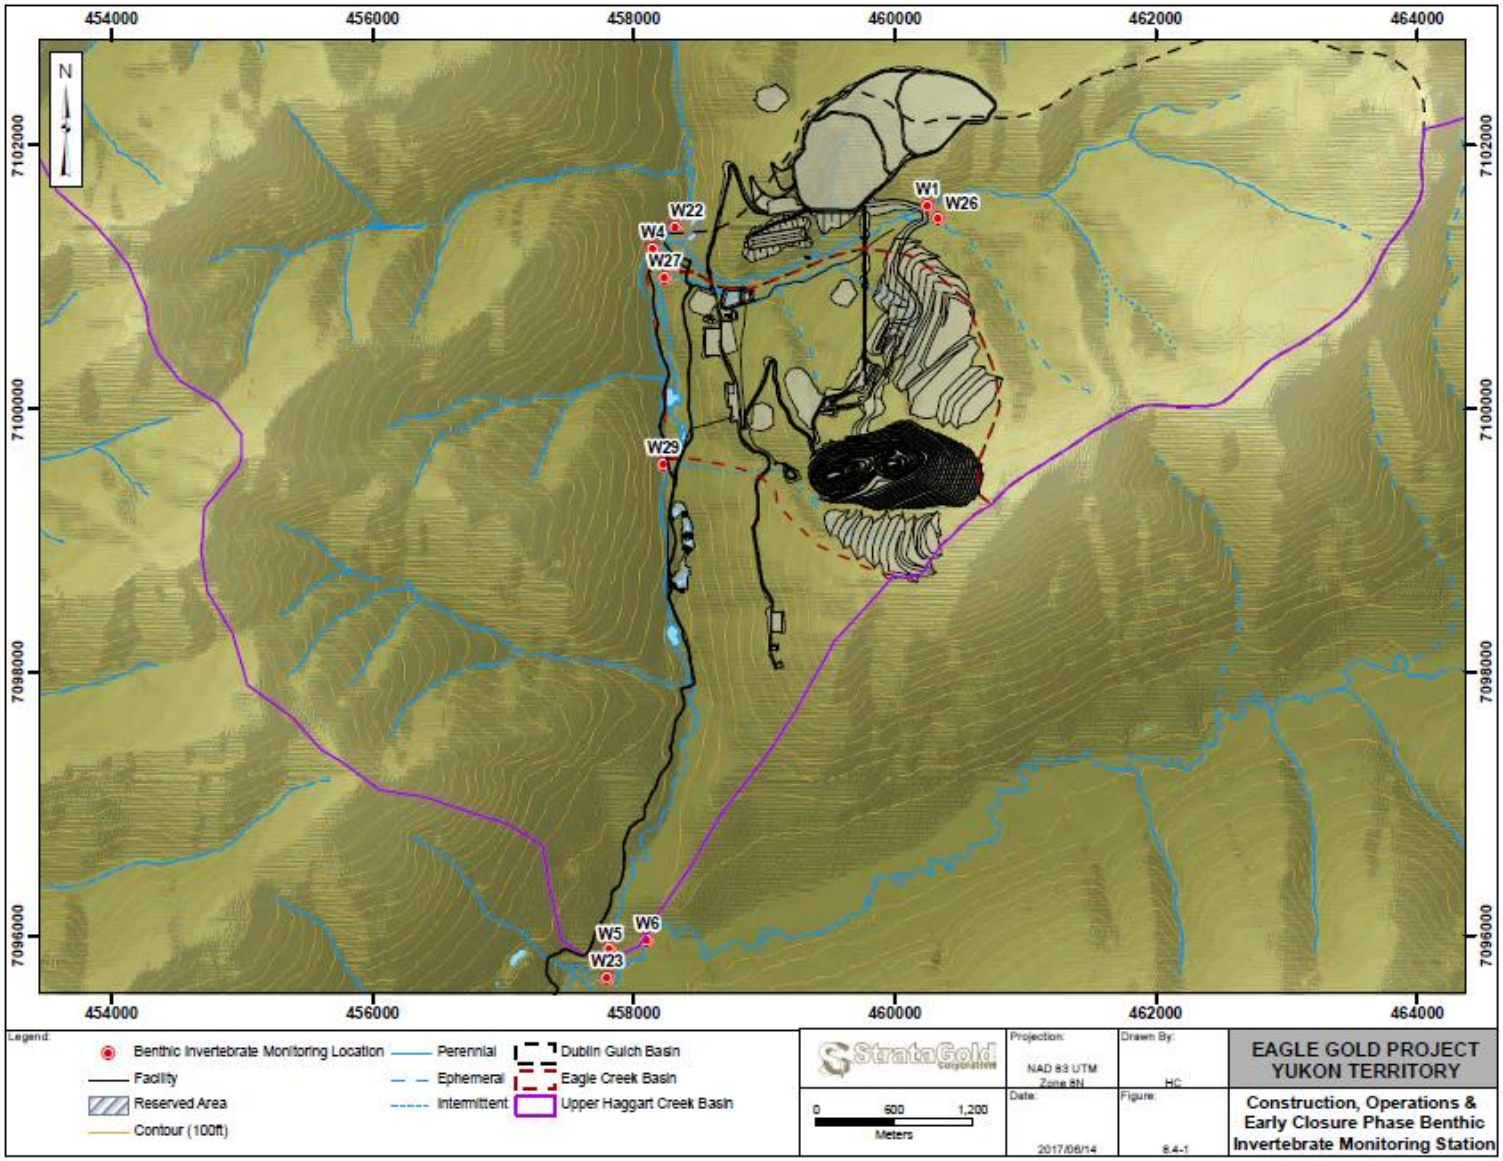

Figure 1 Locations of Benthic Invertebrate Sampling Sites for the Construction Phase

The dissolved metals, dissolved mercury and dissolved organic carbon samples were filtered in the field using disposable sterile syringes and in-line filters (filter pore size 0.45 microns) prior to preservation.

The methods used by ALS are based on the B.C. Ministry of Environment & Climate Change Strategy (BC-MOE) and American Public Health Association (APHA) standard methods and are included in the analytical reports in Appendix A.

2.2 Benthic Invertebrates

Triplicate samples were collected from the nine sites using a Surber sampler (area = 0.0920m^2) with a mesh size of 300 microns. The sampler was positioned securely at a random location on the stream bottom, parallel to the water flow. The bed material within the frame was cleaned and washed by hand with the fast-flowing current carrying the disturbed bottom fauna and detritus into the collection bag. The remaining sediment was stirred to a 10 cm depth to dislodge invertebrates. The level of effort for each sample and at each site was comparable. Riffle areas were targeted at each site as this habitat supports the greatest density and diversity of invertebrates (Epele et al, 2012). The triplicate samples were collected approximately 5m to 15m apart, as the site-specific geomorphology allowed, starting downstream and moving upstream to minimize substrate disruption and avoid potential contamination.

The captured invertebrates and detritus were transferred from the collection bags to one litre nalgene bottles and preserved with 10% buffered formalin. Samples were shipped by ground transport to an entomologist for sorting, identification and enumeration.

Analysis of the benthic invertebrate samples was conducted by Cordillera Consulting in Summerland, BC. Once the samples were received at the laboratory they were assigned a Cordillera Consulting code (CC#) and entered into a database. Samples were sorted and evaluated for total numbers. If the numbers were estimated to be greater than 600 the sample was subsampled to achieve a minimum number of 300 organisms. Organisms were identified to genus or species level for all insects and if possible to that level for non-insect specimens. For full details on the methodology used, Cordillera Consulting's method and QC report is provided in Appendix B.

2.2.1 Quality Assurance / Quality Control (QA/QC)

Quality assurance and quality control (QA/QC) procedures for the field component consisted of; ensuring all personnel were adequately trained, sampling methods per site and between sites were consistent, samples were correctly collected, labeled and preserved, equipment was properly maintained, detailed field notes were kept, chain-of-custody forms were used, and safe shipping and storage methods were followed.

As a measure of QA/QC for the laboratory component, refer to Cordillera Consulting's report in Appendix B.

2.2.2 Data Analysis

The data was subjected to several metrics and indices to describe the benthic populations. Abundance was determined by summing all of the individuals present in the sample. As the area of substrate sampled was known, the abundance per site was calculated as density (organisms/m^3) to allow comparisons with previous surveys.

Taxonomic richness is a simple measure of diversity where each type of invertebrate is counted per site. Diversity can be further refined using many different indices and the Simpson's Index of Diversity was performed on this dataset using the equation:

$$D = 1 - \frac{\sum n(n-1)}{N(N-1)}$$

Where n = number of individuals of each species and N = total number of individuals of all species.

The Simpson's Diversity Index takes into account the number of species present, as well as the relative abundance of each species, and was chosen to allow comparisons to previous surveys.

Biotic indices are often used to ascertain the general water quality at a particular site. The Hilsenhoff Biotic Index (HBI) is based on a formula using pre-assigned pollution tolerance scores for families. The following equation was used where n equals the number of individuals in taxa i, a is the preassigned pollution tolerance value assigned to taxa i, and N is the total number of individuals in the sample.

$$HBI = \frac{\sum n_i \times a_i}{N}$$

3.0 RESULTS

All data in the tables and figures have been grouped into drainages and arranged from upstream sites to downstream sites per drainage.

3.1 Water Quality

In-situ data were collected at each site and are presented with the benthic field conditions presented in Table B-1 in Appendix B. Water temperatures were generally cool and reflected late summer/early autumn conditions, ranging from 0.2°C to 6.3°C.

All sites were near neutral to slightly alkaline with pH ranging from 6.10 at W27 to 8.50 at W29. Conductivity is generally a measurement of the dissolved ions present and ranged from 103 µS/cm at W1 to 411 µS/cm at W27.

Water quality samples were also collected from the benthic invertebrate sites as a component of the regular monthly monitoring program. The water quality data for the benthic sites has been tabulated in Table A-1 in Appendix A.

With the exception of W29, the water was clear throughout the study area during the time of sampling. The total suspended solids (TSS) concentration at W29 on the date the benthic samples were collected (September 9th, 2018) was 176 mg/L. The water cleared up the following day when samples were again collected, with a TSS concentration of <3.0 mg/L (see Photos #5 and 6, Appendix C). Both sets of data for W29 are presented in Table A-1.

Except for arsenic, metal concentrations were generally low throughout the study area. The CCME guideline for arsenic for the protection of freshwater aquatic life was exceeded at all of the sites in the both the total and dissolved metals samples, except at the upstream site W22. Arsenic concentrations ranged from 0.00073 mg/L at W22 where it met the guideline, to 0.317mg/L at W29 on September 9th. On September 10th the concentration at W29 was 0.00758 mg/L, and still

exceeded the guideline. Cadmium, chromium, copper and iron total concentrations at W29 also exceeded the guideline on September 9th due to the high sediment load. These parameters met the applicable guidelines in the dissolved sample.

3.2 Benthic Invertebrates

Five phyla were found in the study area: Arthropoda, Mollusca, Annelida, Nematoda, and Platyhelminthes (Appendix B). Of these, taxonomists do not consider Nematoda and Platyhelminthes to be benthic organisms. However, the presence of these groups has been noted where encountered in each sample. The numbers for these taxa reported in Appendix B reflect presence, not total numbers of individuals in the sample.

Of the organisms that were enumerated, a total of 9,741 invertebrates, representing 124 different taxonomic groups were identified throughout the study area. The following sections pertain to these taxa.

3.2.1 Abundance and Taxonomic Richness

The total number of organisms for the triplicates from each site was summed to give a total abundance value for that site. Densities were calculated based on the total area sampled per site. Community size varied throughout the study area with densities ranging from 1,206 individuals/m^2 at W4, Haggart Creek downstream of Dublin Gulch, to 8,715 individuals/m^2 at W6, Lynx Creek (Table 2).

Diversity was determined for each site by enumerating all the taxonomic groups identified from species to phylum. For biomonitoring purposes, total taxa richness is the index of choice (Reice and Wohlenberg, 1993). All communities were diverse, ranging from 38 different taxonomic groups at W26, Stewart Gulch, to 65 different taxonomic groups at W23, Haggart Creek downstream of Lynx Creek. The Simpson's Index of Diversity was determined for each sample (Appendix B) and the average per site is presented below in Table 3. This index takes into account the number of species present as well as the relative abundance of each species, and ranges from 0 to 1, with numbers approaching 1 representing greater diversity. This method showed that all communities were very diverse and ranged from 0.86 at W26, Stewart Gulch, to 0.94 at W4, Haggart Creek downstream of Dublin Gulch.

TABLE 2 GENERAL STATISTICS ON THE BENTHIC COMMUNITIES, 2018

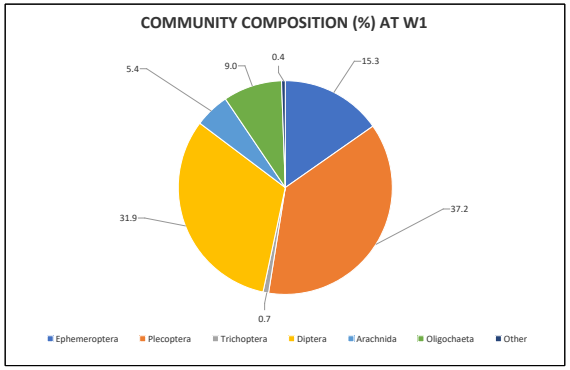
Drainage	Site	Abundance (organisms /site)	Density (organisms/m^3)	Taxonomic Richness/site	Simpson's Index of Diversity/site
Haggart Creek	W22	731	2,623	60	0.93
	W4	336	1,206	50	0.94
	W29	933	3,348	55	0.91
	W5	519	1,862	57	0.91
	W23	1039	3,728	65	0.91
Dublin Gulch	W1	849	3,046	43	0.87
	W26	2196	7,879	38	0.86
Eagle Creek	W27	709	2,544	43	0.87
Lynx Creek	W6	2429	8,715	52	0.88

4.2.2 Distribution

The composition of the benthos communities was calculated as a percentage of the major taxonomic groups present, with pie charts generated for each site (Figure 2). The grouping "Other" consists of invertebrates from Coleoptera, Hemiptera, Lepidoptera, Thysanoptera, Crustacea, Malacostraca, Maxillipoda, Copepoda, Gastropoda and Collembola.

The Insect orders Ephemoptera (mayflies), Plecoptera (stoneflies) and Diptera (true flies) formed the bulk of each community. Significant numbers of Oligochaeta (aquatic earthworms) were also present at W29 where it was the dominant group forming 33.5% of the community. Oligochaeta was common at W1 and represented 15.4% of the population. The majority of Oligochaeta belonged to the Family Lumbriculidae. The lumbriculids are commonly found in freshwater environments but prefer habitats of the quiet reaches of flowing water that have silt, mud and roots in the littoral zone (Pickavance, 1971).

A significant portion of the community at W27, Eagle Creek, was comprised of Collembola (springtails) within the category "Other". Springtails formed 24.5% of the population but was either absent or present in very low numbers at the other sites. They are semiaquatic rather than aquatic organisms and the high catch here is considered atypical as they are very rare in lotic environments (Christiansen, 2009).



Many aquatic insects require good water quality to thrive. Larvae of mayflies (Ephemeroptera), stoneflies (Plecoptera) and caddisflies (Trichoptera) require clear, clean, well oxygenated water and have very low tolerance to pollution (Rosenberg and Resh, 1993). Analyzing the combined EPT (Ephemeroptera, Plecoptera, Trichoptera) at a site, gives an indication of the overall health of the stream (Hauer and Lamberti, 2006, Resh and Jackson, 1993, DFO-Streamkeepers). Table 3 summarizes the number of EPT found per site, the proportion of EPT in the benthic invertebrate community and the number of EPT taxa (richness) in each community.

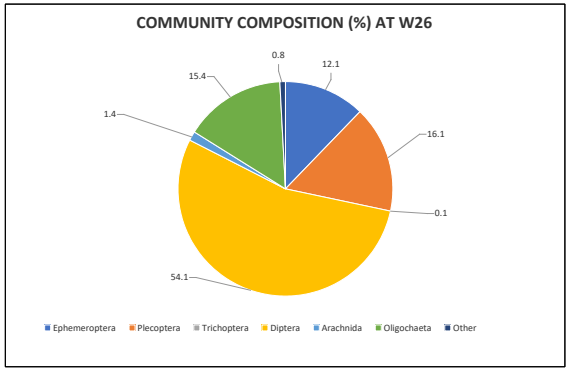


TABLE 3 EPT ABUNDANCE, PROPORTION & RICHNESS, 2018

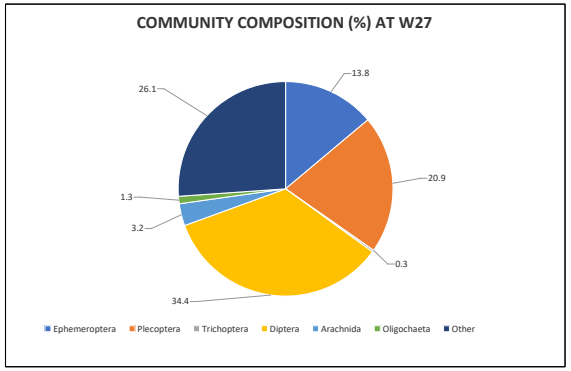
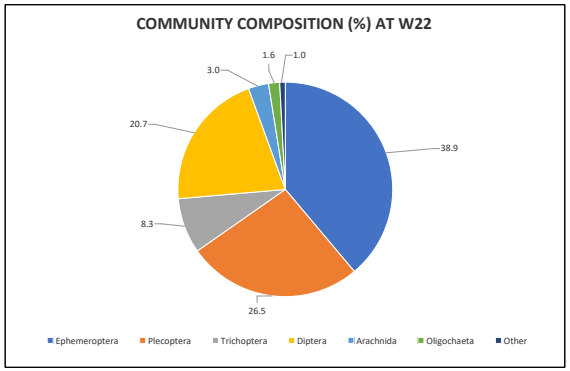


Drainage	Site #	Site Description	EPT Abundance	EPT %	EPT Richness
Haggart Creek	W22	Upstream Dublin Gulch	539	73.7	27
	W4	Downstream Dublin Gulch	216	64.3	23
	W29	Downstream Eagle Creek	433	46.4	26
	W5	Upstream Lynx Creek	344	66.3	26
	W23	Downstream Lynx Creek	645	62.1	28
Dublin Gulch	W1	Upstream Stewart Gulch	452	53.2	20
	W26	Stewart Gulch	623	28.4	16
Eagle Creek	W27	Eagle Creek	248	35.0	11
Lynx Creek	W6	Upstream Haggart Creek	1954	80.4	23



Overall, all communities in the study area had good representation of pollution sensitive invertebrates. The highest abundance of EPT occurred at W6, Lynx Creek, with 1954 individuals present. The highest proportion of EPT was also documented at W6, forming 80.4% of the community. The community at W23 had the greatest EPT richness with 28 different taxa identified. The population at W4, had the lowest abundance, W26 had the lowest richness and W27 had the lowest proportion of EPT.

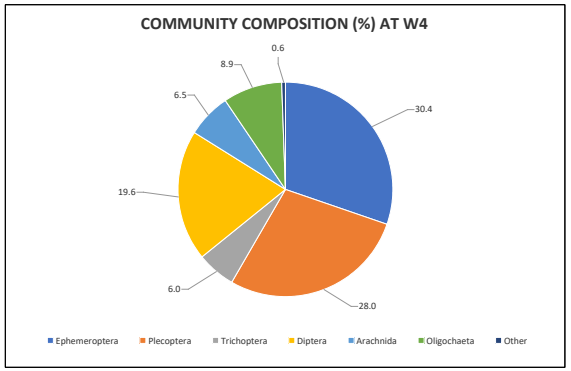


FIGURE 2 THE COMPOSITION OF THE BENTHIC INVERTEBRATE COMMUNITIES, EAGLE GOLD PROJECT 2018

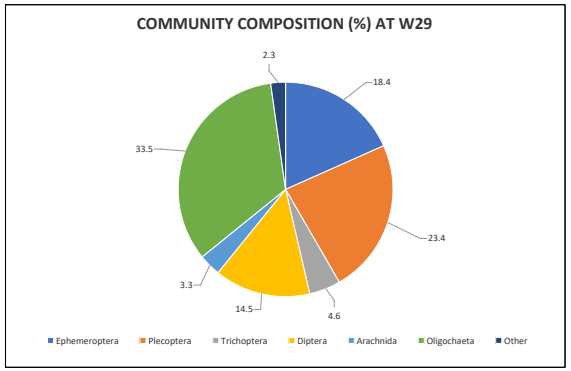

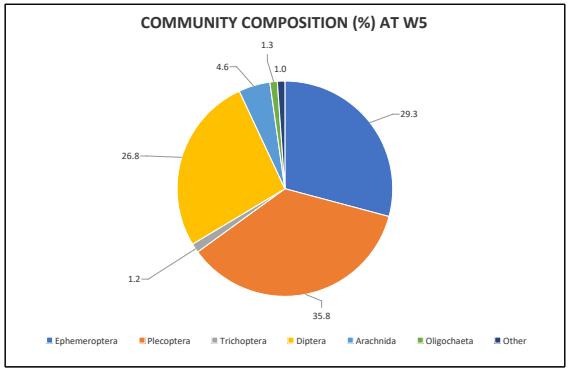

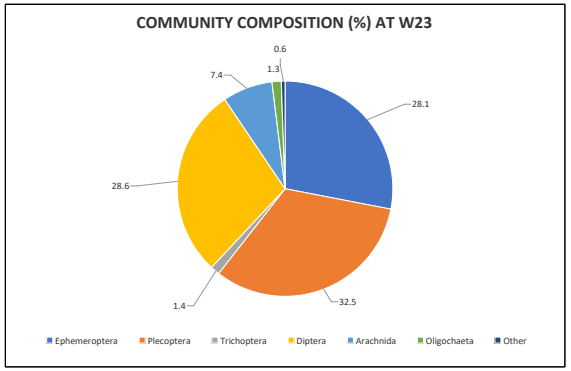

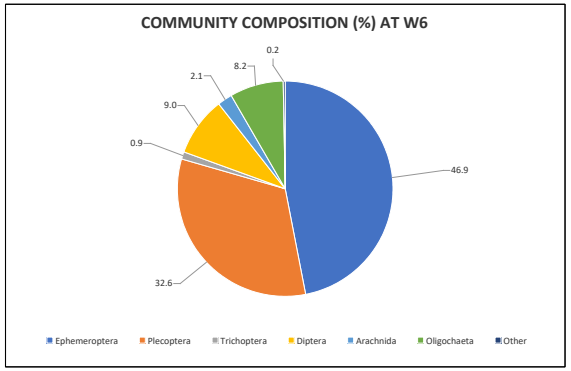

The Pacific Stream Keepers Federation has indicated that streams with an EPT richness greater than 8 are of good quality (DFO). Based on this water quality assessment protocol, all sites in the Eagle Gold Project study area are of good quality.

Another method to determine the health of a stream is to calculate the Hilsenholf Biotic Index (HBI) (Hauer and Lamberti, 2006). Due to differences in their tolerance to pollution, the presence or absence of certain invertebrate families can provide valuable information on stream water quality. The HBI ranges from 0 to 10, where lower numbers indicate the presence of pollution sensitive organisms and the higher numbers represent a greater presence of pollution tolerant families. Therefore, sites with excellent water quality would contain benthic communities with a high number of pollution sensitive families. This index was calculated for each sample (Appendix B) and averaged for each site. Table 4 gives the listing of the categories for the condition of the water and Table 5 summarizes the mean data for the study area.

With the exception of W26, Stewart Gulch, which rated fair, all other sites were of good to excellent quality.

TABLE 4 WATER QUALITY CATEGORIES BASED ON HBI

Hilsenhoff Biotic Index	Water Quality Category
0.00 - 3.75	Excellent
3.76 - 4.25	Very Good
4.26 - 5.00	Good
5.01 - 5.75	Fair
5.76 - 6.50	Fairly Poor
6.51 - 7.25	Poor
7.26 - 10.00	Very Poor

TABLE 5 WATER QUALITY BASED ON HBI FOR THE EAGLE GOLD PROJECT

Drainage	Site	Hilsenhoff Biotic Index	Water Quality Category
Haggart Creek	W22	2.74	Excellent
	W4	2.91	Excellent
	W29	4.28	Good
	W5	3.03	Excellent
	W23	3.96	Very good
Dublin Gulch	W1	3.33	Excellent
	W26	4.78	Good
Eagle Creek	W27	5.52	Fair
Lynx Creek	W6	2.57	Excellent

4.3.3 Comparisons with Past Data

Benthic invertebrate monitoring was conducted in the Eagle Gold Project area in 1995, 2007, 2009 and 2010. These studies have been summarized in a report prepared by Stantec (2011). The first year of the EMSAMP program was undertaken in 2017 (Laberge, 2018a). Data from all of these surveys have been compared to the data collected in 2018 for the sites that overlap. Note that W1 and W5 are the only sites where benthic invertebrates have been collected during each period.

Two parameters were chosen to detect any changes or trends over time; abundance as density, and diversity using the Simpson's Index (Table 6).

The highest densities were documented in the Dublin Gulch watershed in 1995 and have not been duplicated since. There has been some fluctuation in numbers at some of the sites between years. Many variables come into play regarding population numbers including climate (flooding, drought, rainfall events, unusually high or low temperatures), time of year sampled, sampling methods, wildfires in the area or upstream, disturbance to riparian zones, etc.

Generally, it appears that all sites have been diverse over time. The highest diversities generally occurred in 2018.

Although not the same number of sites nor the same frequency of sampling is available per

drainage, averages have been performed to give an overall idea of possible differences between watersheds. These indicate that although Haggart Creek had the lowest densities the communities were the most diverse. The benthic communities in Dublin Gulch had the greatest populations but were not as diverse. Eagle Creek had similar diversity as Dublin Gulch and a slightly higher density than Haggart Creek. High densities were also documented in Lynx Creek with diverse communities. Overall, the limited data suggests stable benthic communities at the sites sampled.

When comparing the site upstream of the project, W22, with the site downstream of the project, W23, the densities and diversities are very similar, suggesting that there is little, if any, impact to Haggart Creek from construction activities at the Eagle Gold project site.

TABLE 6 DENSITY AND DIVERSITY IN STREAMS OVER THE STUDY PERIOD

Drainage		Haggart Creek					Dublin Gulch		Eagle Creek	Lynx Creek
Site		W22	W4	W29	W5	W23	W1	W26	W27	W6
Site Description		Upstream Dublin Gulch	Downstream Dublin Gulch	Downstream Eagle Creek	Upstream Lynx Creek	Downstream Lynx Creek	Upstream Stewart Gulch	Stewart Gulch	Eagle Creek	Upstream Haggart Creek
Density (organisms/m^3)	1995		2,700		2,200		20,000	19,000		9,100

Average/Drainage		0.84					0.75		0.75	0.80

4.0 DISCUSSION

The 2018 benthic invertebrate data indicates healthy robust populations at each of the sites sampled, with good representation of EPT throughout. When examined against previous surveys (Stantec, 2011 and Laberge, 2018a) the 2018 habitat conditions have not changed significantly and appear to support healthy benthic populations at all sites.

In contrast to the benthic invertebrate data, water quality and sediment data (specifically arsenic) collected since 1995 are reflective of a less healthy aquatic environment. Stream sediment samples were collected during the benthic survey and the findings have been submitted under separate cover (Laberge, 2018b). The high concentrations of arsenic found in the water column and in the stream sediments were well above the guidelines for the protection of freshwater aquatic life. The CCME guideline of 0.005 mg/L for arsenic in water was exceeded at all of the sites with the exception of W22. The concentrations of arsenic in the stream sediments exceeded the Probable Effects Level (PEL) of 17 mg/kg at all sites, and at some locations significantly. The arsenic levels have been tabulated and depicted graphically below (Table 7 and Figures 3 and 4). The sites have been arranged in the table and on the X-axes of the graphs to depict site locations from upstream to downstream throughout the study area.

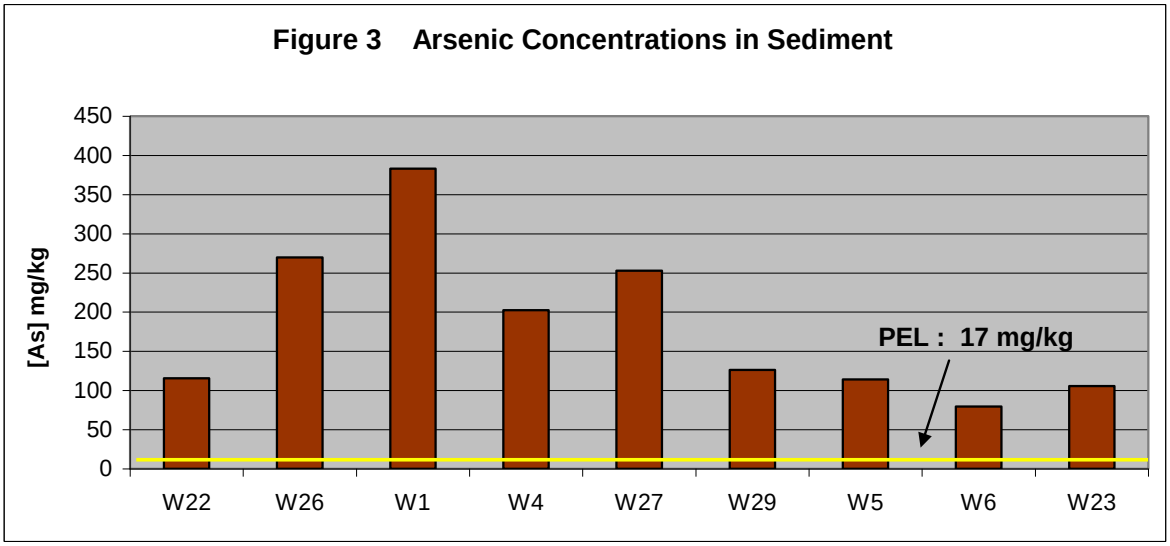
The highest concentrations of arsenic in the stream sediments were reported at W1, Dublin Gulch upstream of all Project activities. Levels were generally lower throughout the Haggart watershed, but likely are influenced by Dublin Gulch. Concentrations in the water and stream sediments were quite high in Stewart Gulch (W26) (also upstream of Project activities) and Eagle Creek (W27). Lynx Creek (W6) unaffected by Project activities, had similar concentrations to W5 and W23.

The highest concentration of arsenic in the water occurred at W29 when TSS was also high. Dublin Gulch, W1, had the next highest concentration.

TABLE 7 ARSENIC CONCENTRATIONS IN DIFFERENT MEDIA, 2018

Site #	Arsenic in Sediment (mg/kg)	Arsenic in Water (ml/L)
W22	115.6	0.00073
W26	269.7	0.0234
W1	383.0	0.0408
W4	202.3	0.00929
W27	252.7	0.0184
W29	126.3	0.31700
W5	114.0	0.00898
W6	79.5	0.00616
W23	105.6	0.00706

Figure 3 Arsenic Concentrations in Sediment



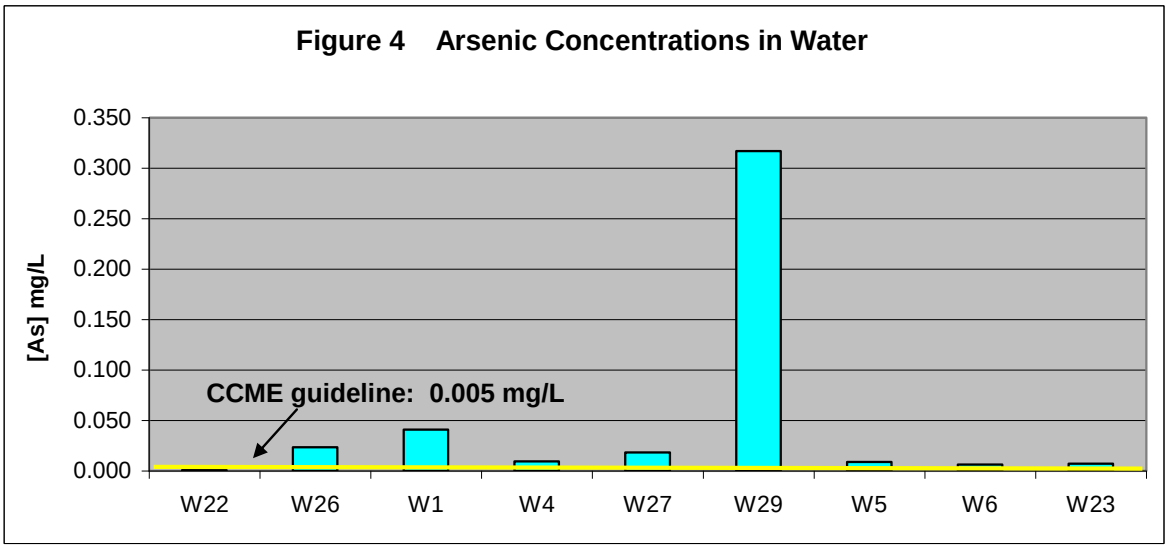


Figure 4 Arsenic Concentrations in Water

The metalloid arsenic is ubiquitous in the aquatic environment as a result of natural processes (mineral rock weathering, volcanic emissions and biological activities) (Irving et al, 2007). It undergoes multiple electron transfer reactions and forms a variety of inorganic and organic compounds of different toxicity to aquatic organisms (Moore and Ramamoorthy, 1984). The toxicity of arsenic is dependent on speciation. Arsenite (AsO_3^{-3}) forms are much more toxic to biological species. Metallo-organic forms of arsenic also may be much more bioavailable than inorganic forms; however, organic-bound arsenic is excreted by most species and does not appear to be highly toxic (Luoma, 1983). The two major uptake vectors are through the ingestion of metal enriched sediments or suspended particles, and/or uptake from solution.

The abundant presence of pollution sensitive organisms at each of the sites suggests that the arsenic concentrations found in the water column and in the stream sediments are not in a bioavailable form.

It is concluded that the benthos populations documented in 2018 are healthy, stable and had good representation of the major groups of organisms that are typically present in lotic waters.

QC Samples with Qualifiers & Comments:

QC Type Description	Parameter	Qualifier	Applies to Sample Number(s)
Matrix Spike	Arsenic (As)-Dissolved	MS-B	L2163219-1, -10, -11, -2, -3, -4, -5, -7, -8, -9
Matrix Spike	Barium (Ba)-Dissolved	MS-B	L2163219-1, -10, -11, -2, -3, -4, -5, -7, -8, -9
Matrix Spike	Calcium (Ca)-Dissolved	MS-B	L2163219-1, -10, -11, -2, -3, -4, -5, -7, -8, -9
Matrix Spike	Magnesium (Mg)-Dissolved	MS-B	L2163219-1, -10, -11, -2, -3, -4, -5, -7, -8, -9
Matrix Spike	Strontium (Sr)-Dissolved	MS-B	L2163219-1, -10, -11, -2, -3, -4, -5, -7, -8, -9
Matrix Spike	Uranium (U)-Dissolved	MS-B	L2163219-1, -10, -11, -2, -3, -4, -5, -7, -8, -9
Matrix Spike	Arsenic (As)-Total	MS-B	L2163219-1, -10, -11, -2, -3, -4, -5, -6, -7, -8, -9
Matrix Spike	Barium (Ba)-Total	MS-B	L2163219-1, -10, -11, -2, -3, -4, -5, -6, -7, -8, -9
Matrix Spike	Calcium (Ca)-Total	MS-B	L2163219-1, -10, -11, -2, -3, -4, -5, -6, -7, -8, -9
Matrix Spike	Magnesium (Mg)-Total	MS-B	L2163219-1, -10, -11, -2, -3, -4, -5, -6, -7, -8, -9
Matrix Spike	Strontium (Sr)-Total	MS-B	L2163219-1, -10, -11, -2, -3, -4, -5, -6, -7, -8, -9
Matrix Spike	Uranium (U)-Total	MS-B	L2163219-1, -10, -11, -2, -3, -4, -5, -6, -7, -8, -9

Qualifiers for Individual Parameters Listed:

Qualifier	Description
DLM	Detection Limit Adjusted due to sample matrix effects (e.g. chemical interference, colour, turbidity).
MS-B	Matrix Spike recovery could not be accurately calculated due to high analyte background in sample.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
ALK-TITR-VA	Water	Alkalinity Species by Titration	APHA 2320 Alkalinity

This analysis is carried out using procedures adapted from APHA Method 2320 "Alkalinity". Total alkalinity is determined by potentiometric titration to a pH 4.5 endpoint. Bicarbonate, carbonate and hydroxide alkalinity are calculated from phenolphthalein alkalinity and total alkalinity values.

BE-D-L-CCMS-VA	Water	Diss. Be (low) in Water by CRC ICPMS	APHA 3030B/6020A (mod)

Water samples are filtered (0.45 um), preserved with nitric acid, and analyzed by CRC ICPMS.

BE-T-L-CCMS-VA	Water	Total Be (Low) in Water by CRC ICPMS	EPA 200.2/6020A (mod)

Water samples are digested with nitric and hydrochloric acids, and analyzed by CRC ICPMS.

BR-L-IC-N-WR	Water	Bromide in Water by IC (Low Level)	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

CARBONS-DOC-VA	Water	Dissolved organic carbon by combustion	APHA 5310B

This analysis is carried out using procedures adapted from APHA Method 5310 "Total Organic Carbon (TOC)". Dissolved carbon (DOC) fractions are determined by filtering the sample through a 0.45 micron membrane filter prior to analysis.

CARBONS-TOC-VA	Water	Total organic carbon by combustion	APHA 5310B TOTAL ORGANIC CARBON (TOC)

This analysis is carried out using procedures adapted from APHA Method 5310 "Total Organic Carbon (TOC)".

CL-IC-N-WR	Water	Chloride in Water by IC	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

CN-T-CFA-VA	Water	Total Cyanide in water by CFA	ISO 14403:2002

This analysis is carried out using procedures adapted from ISO Method 14403:2002 "Determination of Total Cyanide using Flow Analysis (FIA and CFA)". Total or strong acid dissociable (SAD) cyanide is determined by in-line UV digestion along with sample distillation and final determination by colourimetric analysis. Method Limitation: This method is susceptible to interference from thiocyanate (SCN). If SCN is present in the sample, there could be a positive interference with this method, but it would be less than 1% and could be as low as zero.

CN-WAD-CFA-VA	Water	Weak Acid Diss. Cyanide in water by CFA	APHA 4500-CN CYANIDE

This analysis is carried out using procedures adapted from APHA Method 4500-CN I. "Weak Acid Dissociable Cyanide". Weak Acid Dissociable (WAD) cyanide is determined by in-line sample distillation with final determination by colourimetric analysis.

EC-PCT-VA	Water	Conductivity (Automated)	APHA 2510 Auto. Conduc.

This analysis is carried out using procedures adapted from APHA Method 2510 "Conductivity". Conductivity is determined using a conductivity electrode.

EC-SCREEN-VA	Water	Conductivity Screen (Internal Use Only)	APHA 2510

Qualitative analysis of conductivity where required during preparation of other tests - e.g. TDS, metals, etc.

Reference Information

F-IC-N-WR	Water	Fluoride in Water by IC	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

HARDNESS-CALC-VA	Water	Hardness	APHA 2340B

Hardness (also known as Total Hardness) is calculated from the sum of Calcium and Magnesium concentrations, expressed in CaCO3 equivalents. Dissolved Calcium and Magnesium concentrations are preferentially used for the hardness calculation.

HG-D-CVAA-VA	Water	Diss. Mercury in Water by CVAAS or CVAFS	APHA 3030B/EPA 1631E (mod)

Water samples are filtered (0.45 um), preserved with hydrochloric acid, then undergo a cold-oxidation using bromine monochloride prior to reduction with stannous chloride, and analyzed by CVAAS or CVAFS.

HG-T-CVAA-VA	Water	Total Mercury in Water by CVAAS or CVAFS	EPA 1631E (mod)

Water samples undergo a cold-oxidation using bromine monochloride prior to reduction with stannous chloride, and analyzed by CVAAS or CVAFS.

IONBALANCE-VA	Water	Ion Balance Calculation	APHA 1030E

Cation Sum, Anion Sum, and Ion Balance (as % difference) are calculated based on guidance from APHA Standard Methods (1030E Checking Correctness of Analysis). Because all aqueous solutions are electrically neutral, the calculated ion balance (% difference of cations minus anions) should be near-zero.

Cation and Anion Sums are the total meq/L concentration of major cations and anions. Dissolved species are used where available. Minor ions are included where data is present. Ion Balance is calculated as:

Ion Balance (%) = [Cation Sum-Anion Sum] / [Cation Sum+Anion Sum]

MET-D-CCMS-VA	Water	Dissolved Metals in Water by CRC ICPMS	APHA 3030B/6020A (mod)

Water samples are filtered (0.45 um), preserved with nitric acid, and analyzed by CRC ICPMS.

Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.

MET-T-CCMS-VA	Water	Total Metals in Water by CRC ICPMS	EPA 200.2/6020A (mod)

Water samples are digested with nitric and hydrochloric acids, and analyzed by CRC ICPMS.

Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.

NH3-F-VA	Water	Ammonia in Water by Fluorescence	J. ENVIRON. MONIT., 2005, 7, 37-42, RSC

This analysis is carried out, on sulfuric acid preserved samples, using procedures modified from J. Environ. Monit., 2005, 7, 37 - 42, The Royal Society of Chemistry, "Flow-injection analysis with fluorescence detection for the determination of trace levels of ammonium in seawater", Roslyn J. Waston et al.

NO2-L-IC-N-WR	Water	Nitrite in Water by IC (Low Level)	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

NO3-L-IC-N-WR	Water	Nitrate in Water by IC (Low Level)	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

P-T-PRES-COL-VA	Water	Total P in Water by Colour	APHA 4500-P Phosphorus

This analysis is carried out using procedures adapted from APHA Method 4500-P "Phosphorus". Total Phosphorus is determined colourimetrically after persulphate digestion of the sample.
Samples with very high dissolved solids (i.e. seawaters, brackish waters) may produce a negative bias by this method. Alternate methods are available for these types of samples.

Arsenic (5+), at elevated levels, is a positive interference on colourimetric phosphate analysis.

P-TD-PRES-COL-VA	Water	Total Dissolved P in Water by Colour	APHA 4500-P Phosphorous

This analysis is carried out using procedures adapted from APHA Method 4500-P "Phosphorus". Total Dissolved Phosphorus is determined colourimetrically after persulphate digestion of a sample that has been lab or field filtered through a 0.45 micron membrane filter.
Samples with very high dissolved solids (i.e. seawaters, brackish waters) may produce a negative bias by this method. Alternate methods are available for these types of samples.

Arsenic (5+), at elevated levels, is a positive interference on colourimetric phosphate analysis.

PH-PCT-VA	Water	pH by Meter (Automated)	APHA 4500-H pH Value

This analysis is carried out using procedures adapted from APHA Method 4500-H "pH Value". The pH is determined in the laboratory using a pH electrode

It is recommended that this analysis be conducted in the field.

PO4-DO-COL-VA	Water	Diss. Orthophosphate in Water by Colour	APHA 4500-P Phosphorus

Reference Information

This analysis is carried out using procedures adapted from APHA Method 4500-P "Phosphorus". Dissolved Orthophosphate is determined colourimetrically on a sample that has been lab or field filtered through a 0.45 micron membrane filter.
Samples with very high dissolved solids (i.e. seawaters, brackish waters) may produce a negative bias by this method. Alternate methods are available for these types of samples.

Arsenic (5+), at elevated levels, is a positive interference on colourimetric phosphate analysis.

SO4-IC-WR	Water	Sulfate in Water by IC	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

TDS-CALC-VA	Water	TDS (Calculated)	APHA 1030E (20TH EDITION)

This analysis is carried out using procedures adapted from APHA 1030E "Checking Correctness of Analyses".
The Total Dissolved Solids result is calculated from measured concentrations of anions and cations in the sample.

TKN-F-VA	Water	TKN in Water by Fluorescence	APHA 4500-NORG D.

This analysis is carried out using procedures adapted from APHA Method 4500-Norg D. "Block Digestion and Flow Injection Analysis". Total Kjeldahl Nitrogen is determined using block digestion followed by Flow-injection analysis with fluorescence detection.

TN-CALC-VA	Water	Total Nitrogen (Calculation)	BC MOE LABORATORY MANUAL (2005)

Total Nitrogen is a calculated parameter. Total Nitrogen = Total Kjeldahl Nitrogen + [Nitrate and Nitrite (as N)]

TSS-VA	Water	Total Suspended Solids by Gravimetric	APHA 2540 D - GRAVIMETRIC

This analysis is carried out using procedures adapted from APHA Method 2540 "Solids". Solids are determined gravimetrically. Total Suspended Solids (TSS) are determined by filtering a sample through a glass fibre filter, TSS is determined by drying the filter at 104 degrees celsius.
Samples containing very high dissolved solid content (i.e. seawaters, brackish waters) may produce a positive bias by this method. Alternate analysis methods are available for these types of samples.

TURBIDITY-VA	Water	Turbidity by Meter	APHA 2130 Turbidity

This analysis is carried out using procedures adapted from APHA Method 2130 "Turbidity". Turbidity is determined by the nephelometric method.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
WR	ALS ENVIRONMENTAL - WHITEHORSE, YUKON, CANADA
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

1 of 1

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.
mg/kg - milligrams per kilogram based on dry weight of sample.
mg/kg wwt - milligrams per kilogram based on wet weight of sample.
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.
mg/L - milligrams per litre.
< - Less than.
D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

Reference Information

QC Samples with Qualifiers & Comments:

QC Type Description	Parameter	Qualifier	Applies to Sample Number(s)
Method Blank	Dissolved Organic Carbon	B	L2170240-1, -2, -3, -4, -5
Method Blank	Molybdenum (Mo)-Total	B	L2170240-1
Method Blank	Silver (Ag)-Total	B	L2170240-1
Matrix Spike	Arsenic (As)-Total	MS-B	L2170240-1, -2, -3, -4, -5
Matrix Spike	Barium (Ba)-Total	MS-B	L2170240-1, -2, -3, -4, -5
Matrix Spike	Calcium (Ca)-Total	MS-B	L2170240-1, -2, -3, -4, -5
Matrix Spike	Magnesium (Mg)-Total	MS-B	L2170240-1, -2, -3, -4, -5
Matrix Spike	Sodium (Na)-Total	MS-B	L2170240-1, -2, -3, -4, -5
Matrix Spike	Strontium (Sr)-Total	MS-B	L2170240-1, -2, -3, -4, -5
Duplicate	Total Kjeldahl Nitrogen	TKND	L2170240-1, -2, -3, -4, -5

Qualifiers for Individual Parameters Listed:

Qualifier	Description
B	Method Blank exceeds ALS DQO. Associated sample results which are < Limit of Reporting or > 5 times blank level are considered reliable.
DLM	Detection Limit Adjusted due to sample matrix effects (e.g. chemical interference, colour, turbidity).
MS-B	Matrix Spike recovery could not be accurately calculated due to high analyte background in sample.
RRV	Reported Result Verified By Repeat Analysis
TKND	TKN duplication was poor due to interference from high nitrate, which causes negative bias on TKN.

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
ALK-TITR-VA	Water	Alkalinity Species by Titration	APHA 2320 Alkalinity

This analysis is carried out using procedures adapted from APHA Method 2320 "Alkalinity". Total alkalinity is determined by potentiometric titration to a pH 4.5 endpoint. Bicarbonate, carbonate and hydroxide alkalinity are calculated from phenolphthalein alkalinity and total alkalinity values.

BE-D-L-CCMS-VA	Water	Diss. Be (low) in Water by CRC ICPMS	APHA 3030B/6020A (mod)

Water samples are filtered (0.45 um), preserved with nitric acid, and analyzed by CRC ICPMS.

BE-T-L-CCMS-VA	Water	Total Be (Low) in Water by CRC ICPMS	EPA 200.2/6020A (mod)

Water samples are digested with nitric and hydrochloric acids, and analyzed by CRC ICPMS.

BR-L-IC-N-WR	Water	Bromide in Water by IC (Low Level)	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

CARBONS-DOC-VA	Water	Dissolved organic carbon by combustion	APHA 5310B

This analysis is carried out using procedures adapted from APHA Method 5310 "Total Organic Carbon (TOC)". Dissolved carbon (DOC) fractions are determined by filtering the sample through a 0.45 micron membrane filter prior to analysis.

CARBONS-TOC-VA	Water	Total organic carbon by combustion	APHA 5310B TOTAL ORGANIC CARBON (TOC)

This analysis is carried out using procedures adapted from APHA Method 5310 "Total Organic Carbon (TOC)".

CL-IC-N-WR	Water	Chloride in Water by IC	EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

CN-T-CFA-VA	Water	Total Cyanide in water by CFA	ISO 14403:2002

This analysis is carried out using procedures adapted from ISO Method 14403:2002 "Determination of Total Cyanide using Flow Analysis (FIA and CFA)". Total or strong acid dissociable (SAD) cyanide is determined by in-line UV digestion along with sample distillation and final determination by colourimetric analysis. Method Limitation: This method is susceptible to interference from thiocyanate (SCN). If SCN is present in the sample, there could be a positive interference with this method, but it would be less than 1% and could be as low as zero.

CN-WAD-CFA-VA	Water	Weak Acid Diss. Cyanide in water by CFA	APHA 4500-CN CYANIDE

This analysis is carried out using procedures adapted from APHA Method 4500-CN I. "Weak Acid Dissociable Cyanide". Weak Acid Dissociable (WAD) cyanide is determined by in-line sample distillation with final determination by colourimetric analysis.

EC-PCT-VA	Water	Conductivity (Automated)	APHA 2510 Auto. Conduc.

This analysis is carried out using procedures adapted from APHA Method 2510 "Conductivity". Conductivity is determined using a conductivity electrode.

EC-SCREEN-VA	Water	Conductivity Screen (Internal Use Only)	APHA 2510

Reference Information

Qualitative analysis of conductivity where required during preparation of other tests - e.g. TDS, metals, etc.

F-IC-N-WR Water Fluoride in Water by IC EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

HARDNESS-CALC-VA Water Hardness APHA 2340B

Hardness (also known as Total Hardness) is calculated from the sum of Calcium and Magnesium concentrations, expressed in CaCO3 equivalents. Dissolved Calcium and Magnesium concentrations are preferentially used for the hardness calculation.

HG-D-CVAA-VA Water Diss. Mercury in Water by CVAAS or CVAFS APHA 3030B/EPA 1631E (mod)

Water samples are filtered (0.45 um), preserved with hydrochloric acid, then undergo a cold-oxidation using bromine monochloride prior to reduction with stannous chloride, and analyzed by CVAAS or CVAFS.

HG-T-CVAA-VA Water Total Mercury in Water by CVAAS or CVAFS EPA 1631E (mod)

Water samples undergo a cold-oxidation using bromine monochloride prior to reduction with stannous chloride, and analyzed by CVAAS or CVAFS.

IONBALANCE-VA Water Ion Balance Calculation APHA 1030E

Cation Sum, Anion Sum, and Ion Balance (as % difference) are calculated based on guidance from APHA Standard Methods (1030E Checking Correctness of Analysis). Because all aqueous solutions are electrically neutral, the calculated ion balance (% difference of cations minus anions) should be near-zero.

Cation and Anion Sums are the total meq/L concentration of major cations and anions. Dissolved species are used where available. Minor ions are included where data is present. Ion Balance is calculated as:

Ion Balance (%) = [Cation Sum-Anion Sum] / [Cation Sum+Anion Sum]

MET-D-CCMS-VA Water Dissolved Metals in Water by CRC ICPMS APHA 3030B/6020A (mod)

Water samples are filtered (0.45 um), preserved with nitric acid, and analyzed by CRC ICPMS.

Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.

MET-T-CCMS-VA Water Total Metals in Water by CRC ICPMS EPA 200.2/6020A (mod)

Water samples are digested with nitric and hydrochloric acids, and analyzed by CRC ICPMS.

Method Limitation (re: Sulfur): Sulfide and volatile sulfur species may not be recovered by this method.

NH3-F-VA Water Ammonia in Water by Fluorescence J. ENVIRON. MONIT., 2005, 7, 37-42, RSC

This analysis is carried out, on sulfuric acid preserved samples, using procedures modified from J. Environ. Monit., 2005, 7, 37 - 42, The Royal Society of Chemistry, "Flow-injection analysis with fluorescence detection for the determination of trace levels of ammonium in seawater", Roslyn J. Waston et al.

NO2-L-IC-N-WR Water Nitrite in Water by IC (Low Level) EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

NO3-L-IC-N-WR Water Nitrate in Water by IC (Low Level) EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

P-T-PRES-COL-VA Water Total P in Water by Colour APHA 4500-P Phosphorus

This analysis is carried out using procedures adapted from APHA Method 4500-P "Phosphorus". Total Phosphorus is determined colourimetrically after persulphate digestion of the sample.
Samples with very high dissolved solids (i.e. seawaters, brackish waters) may produce a negative bias by this method. Alternate methods are available for these types of samples.

Arsenic (5+), at elevated levels, is a positive interference on colourimetric phosphate analysis.

P-TD-PRES-COL-VA Water Total Dissolved P in Water by Colour APHA 4500-P Phosphorous

This analysis is carried out using procedures adapted from APHA Method 4500-P "Phosphorus". Total Dissolved Phosphorus is determined colourimetrically after persulphate digestion of a sample that has been lab or field filtered through a 0.45 micron membrane filter.
Samples with very high dissolved solids (i.e. seawaters, brackish waters) may produce a negative bias by this method. Alternate methods are available for these types of samples.

Arsenic (5+), at elevated levels, is a positive interference on colourimetric phosphate analysis.

PH-PCT-VA Water pH by Meter (Automated) APHA 4500-H pH Value

This analysis is carried out using procedures adapted from APHA Method 4500-H "pH Value". The pH is determined in the laboratory using a pH electrode

Reference Information

It is recommended that this analysis be conducted in the field.

PO4-DO-COL-VA Water Diss. Orthophosphate in Water by Colour APHA 4500-P Phosphorus

This analysis is carried out using procedures adapted from APHA Method 4500-P "Phosphorus". Dissolved Orthophosphate is determined colourimetrically on a sample that has been lab or field filtered through a 0.45 micron membrane filter.
Samples with very high dissolved solids (i.e. seawaters, brackish waters) may produce a negative bias by this method. Alternate methods are available for these types of samples.

Arsenic (5+), at elevated levels, is a positive interference on colourimetric phosphate analysis.

SO4-IC-WR Water Sulfate in Water by IC EPA 300.1 (mod)

Inorganic anions are analyzed by Ion Chromatography with conductivity and/or UV detection.

TDS-CALC-VA Water TDS (Calculated) APHA 1030E (20TH EDITION)

This analysis is carried out using procedures adapted from APHA 1030E "Checking Correctness of Analyses".
The Total Dissolved Solids result is calculated from measured concentrations of anions and cations in the sample.

TKN-F-VA Water TKN in Water by Fluorescence APHA 4500-NORG D.

This analysis is carried out using procedures adapted from APHA Method 4500-Norg D. "Block Digestion and Flow Injection Analysis". Total Kjeldahl Nitrogen is determined using block digestion followed by Flow-injection analysis with fluorescence detection.

TN-CALC-VA Water Total Nitrogen (Calculation) BC MOE LABORATORY MANUAL (2005)

Total Nitrogen is a calculated parameter. Total Nitrogen = Total Kjeldahl Nitrogen + [Nitrate and Nitrite (as N)]

TSS-VA Water Total Suspended Solids by Gravimetric APHA 2540 D - GRAVIMETRIC

This analysis is carried out using procedures adapted from APHA Method 2540 "Solids". Solids are determined gravimetrically. Total Suspended Solids (TSS) are determined by filtering a sample through a glass fibre filter, TSS is determined by drying the filter at 104 degrees celsius.
Samples containing very high dissolved solid content (i.e. seawaters, brackish waters) may produce a positive bias by this method. Alternate analysis methods are available for these types of samples.

TURBIDITY-VA Water Turbidity by Meter APHA 2130 Turbidity

This analysis is carried out using procedures adapted from APHA Method 2130 "Turbidity". Turbidity is determined by the nephelometric method.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
WR	ALS ENVIRONMENTAL - WHITEHORSE, YUKON, CANADA
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.
mg/kg - milligrams per kilogram based on dry weight of sample.
mg/kg wwt - milligrams per kilogram based on wet weight of sample.
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.
mg/L - milligrams per litre.
< - Less than.
D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

1.0 INTRODUCTION

The Eagle Gold Project currently under development by StrataGold Corporation, a subsidiary of Victoria Gold Corporation, is located in Dublin Gulch in the upper reaches of Haggart Creek in north-central Yukon near the town of Mayo, about 400 km north of Whitehorse. The project as proposed is comprised of an open pit mine and associated mine features, improvements to the Haggart Creek Road, and a 44 kilometer, 69 kV transmission line. It is within the Mayo Mining District where placer mining activities on Haggart Creek have occurred intermittently since 1895 (Tempelman-Kluit 1964).

Various monitoring projects have been prepared to oversee all phases of development at the Eagle Gold Project and are outlined in the Environmental Monitoring, Surveillance and Adaptive Management Plan (EMSAMP) version 2017-01 (StrataGold 2017). The purpose of this study is to report on fish and fish habitat monitoring sites related to the construction phase of the Project. Relevant past data (de Graff 2017; Stantec 2010) has been examined and is presented where appropriate. This study represents the second annual late summer fish monitoring program and was completed in mid-September 2018.

2.0 STUDY AREA

The Eagle Gold Project is accessible via the Silver Trail and the South McQuesten and Haggart Creek Roads. The Project is situated within the traditional territory of the First Nation of the Na-Cho Nyäk Dun. The watersheds in the study area originate in the low lying mountains between the East and South McQuesten drainage basins of the Stewart Plateau in the north-central Yukon.

The principle drainage is Haggart Creek of which Dublin Gulch, Eagle, Ironrust and Lynx creeks are tributaries. Haggart Creek flows southwest and eventually discharges into the South McQuesten River. The South McQuesten River is a tributary of the Stewart River, a large tributary of the Yukon River drainage basin.

The study area is located in the Boreal Cordillera ecozone that is characterized by mountain ranges that contain numerous high peaks and extensive plateaus, and are separated by wide valleys and lowlands. Landscape features of the region are primarily the result of past glacial activity, erosion and widespread deposits however the majority of the study area remained un-glaciated during the last glacial period (Bostock 1965). Much of the Project area displays physiographic characteristics of the unglaciated areas of the region, with narrow, deep valleys that extend to the head of streams, where they rise steeply and end abruptly (StrataGold 2015).

Black spruce, trembling aspen, balsam poplar, and white birch are the most common forest types. At higher elevations, scrub birch and willow occur in subalpine sections with extensive landscapes of rolling alpine tundra characterized by sedge-

dominated meadows, and lichen-colonized rock fields. The climate in this region is an interior subalpine type with long cold winters and summers that are brief and cool.

3.0 METHODS

A total of 5 monitoring sites (HC1, HC2, HC3, IR2, and L1) were assessed in Haggart, Ironrust and Lynx creeks during this study. Figure 1 depicts the locations of each monitoring site. All monitoring sites are consistent with locations that were previously identified and assessed in past baseline studies (de Graff 2017; Stantec 2015) and are referred to in the Environmental Monitoring, Surveillance and Adaptive Management Plan (StrataGold 2017). Descriptions of the drainages included in this project are presented in Table 1.

3.1 Aquatic Habitat Surveying

A section of the stream containing representative mesohabitat type (riffle, rapid, run, glide, pool or backwater) was surveyed at each monitoring site (HC1 225 meters, HC2 175 meters, HC3 160 meters, IR2 100 meters and L1 100 meters). CABIN (2018) field assessment sheets and British Columbia Fish and Fish Habitat Inventory (BCMSRM 2001) field protocols were used to record biophysical data. This included the geo-referencing of each monitoring site with a hand-held Garmin GPS (datum WGS 87). Determined attributes from field measurements included those related to site (date, elevation and UTM coordinates), channel characteristics (channel and wetted widths, gradient, stage, fish cover, residual pool depth, crown closure and riparian vegetation) and substrate data (Wolman pebble count, embeddedness, interstitial material and periphyton coverage). Digital photographs included upstream and downstream perspectives of each sampled site. Basic water quality parameters were additionally recorded (clarity, conductivity, pH and temperature).

3.2 Fish Sampling

Fish sampling was conducted under a permit (XR 282 2018) obtained from Fisheries and Oceans Canada (Appendix III). At each monitoring site backpack electrofishing (Smith-Root model LR-24) and minnow trapping were the primary techniques used to establish fish presence. For electrofishing, the conductivity of the water was first noted to assist in the initial setup. Captured fish were placed in a water filled bucket. Any fish that were observed or "flipped" and avoided capture with the dipnet were also noted. Voltage was adjusted to enable fish in the bucket to recover within 5 to 20 seconds. A standard waveform of between 180 to 285 volts, a frequency of 60 Hz. and a duty cycle ranging from 14 to 18 percent was effectively used throughout the project. A single-pass methodology with a minimum of 500 seconds of active fishing time was completed at each monitoring site.

Galvanized ¼ inch "Gee" type minnow traps, which were baited with suspended sacs of Yukon River salmon roe, were also utilized at each monitoring site using methods described by the Yukon River Panel (2007). Minnow traps were set in various habitat types such as scour pools, side-channels, undercut banks or in woody debris that provided cover for fish. A total of five minnow traps were set for an overnight period at each monitoring site. Soak times were recorded for each trap. Angling employed the use of small spinners. The time spent angling was used as an index of sampling effort.

All captured fish were measured for either a fork or total length (± 1 mm) and weight (± 0.1 gm). Weight was determined using a digital scale by first blotting excess water from the fish and then placing each fish into a container on the scale. Total length was recorded for slimy sculpin and burbot while fork lengths were noted for Arctic grayling. All captured fish were given time to recover in a water filled bucket before being live-released in a slack water area near the capture site.

4.0 RESULTS AND DISCUSSION

4.1 Aquatic Habitat

A comparative summary of aquatic habitat characteristics determined for the five monitoring sites is presented in Table 2. Individual site summary tables are presented in Appendix I. While all sites share a similar riffle-pool-run morphology, specific habitat characteristics varied and were dependent on the gradient of the site that link hydrological processes to substrate materials and channel form.

Site HC1, situated on the mainstem of Haggart Creek upstream of the confluence with Lynx Creek, had the greatest average channel width of 11.8 meters. Deep pool and undercut bank microhabitats were the dominant fish cover types with total cover estimated to be about 15 percent of the available aquatic habitat at this location. Residual pool depth (0.5 m) was similar to the other two sites on Haggart Creek however the pools were generally larger and more frequent at this location. Based on the pebble counts, small cobble dominated the substrates and the embeddedness of individual rocks averaged 45 percent (Table 2). Gravel (0.2-1.6 cm) was the predominant type of interstitial material. Periphyton coverage was moderate with rocks having a noticeable slippery feel, with patches of thicker green to brown algae. The irregular wandering channel contained some disturbance indicators in the form of elevated bars, eroding banks, abandoned and multiple channels that appear to reflect past upstream activities related to historic mining.

Monitoring site HC2 is situated between sites HC1 and HC3 at the Dublin Gulch confluence, the principle drainage associated with the Eagle Gold Project. The landscape at this location has been previously disturbed from historic placer mining. Access roads and construction activities associated with the current mine development are in close proximity to this site. The mean channel width at this location was only marginally narrower and of slightly higher gradient than HC1.

Total fish cover was low and estimated to be only 5 percent of the available aquatic habitat available. Fish cover was mainly in the form of boulders however other cover types when present included undercut banks, overhanging vegetation and the occasional deep scour pool with residual depths of about 0.4 meters. Course gravels dominated the substrate and the embeddedness of individual rocks averaged 53 percent. The interstitial material was largely composed of fine sands (<0.2 cm) and gravel (0.2 to 1.6 cm). Periphyton coverage was noticeable with rocks having a definite slippery feel with a yellow brown to light green coloration on the surface. The channel pattern was sinuous with several disturbance indicators including elevated bars, eroding banks, multiple and abandoned channels, and areas of extensive bed scour.

Monitoring site HC3 is situated less than a kilometer upstream of site HC2 and upstream of all project influence. Higher stream velocities associated with the more confined channel (6.1 meters) resulted in the predominance of riffles, rapids and straight runs at this site. Boulders and undercut banks were the dominant forms of fish cover. The only other cover type present was overhanging vegetation along the channel margins. Total cover was estimated to be only 10 percent of the available habitat in the channel. Course gravel dominated the substrate. The embeddedness of individual rocks averaged 53 percent and the interstitial material was predominantly course gravel (1.6 to 3.2 cm). Similar to site HC1 further downstream, periphyton coverage was again noticeable with rocks having a definite slippery feel with a yellow brown to light green coloration on the surface. The channel was sinuous in pattern and occasionally confined by the valley wall. No disturbance indicators were observed in the channel.

The stream morphology at monitoring site IR2 in Ironrust Creek, a water course unaffected by the project, was dominated by riffles and rapids. The channel width of approximately 4.3 meters was the smallest of the surveyed sites. Fish cover was low and represented only 5 percent of the aquatic habitat that was present. Boulders and overhanging vegetation were the primary fish cover types. Scour pools, when present, had very low residual depths (<0.2 meters). While small cobbles dominated the substrate, there were good quantities of course gravel throughout the channel. The site gradient was estimated to be 2.9 percent and was reflected by the substantial cobble armoring that characterized the stream bed. The embeddedness of individual rocks averaged 48 percent and the interstitial material was composed of coarse gravel (1.6 to 3.2 cm). Periphyton thickness was thin with only a slightly slippery feel to the rocks. The sinuous channel was frequently confined in the valley and no disturbance indicators were observed.

The stream channel of Lynx Creek (a water course unaffected by the project) at site L1 was a classic riffle-pool-glide sequence. Total fish cover was estimated to be 20 percent of the aquatic habitat present. Deep pools and undercut banks were the dominant fish cover types but small woody debris and overhanging vegetation also contributed when present. The estimated residual pool depth of 0.8 meters was the deepest in comparison to the other sites providing excellent habitat for fish. The low

channel gradient at this site (0.1 percent) is likely a result of a backwater effect of the large alluvial fan that forms the confluence of Lynx Creek with Haggart Creek. Substrates were composed of varying size classes of gravels making for some of the best substrates for fish in the project area. The interstitial material was mostly composed of fines (<0.1 cm) and the embeddedness of the rocks was 6 percent, the lowest of all the sites studied. Periphyton on the rock surfaces was thin with only a slightly slippery feel apparent. The channel pattern was characterized with irregular meanders, well-defined streambanks and unconfined by the valley walls. The channel at this site is situated near the center of the Lynx Creek valley and no disturbance indicators were observed.

A comparison between 2017 and 2018 substrate size classes as determined by pebble counts are presented in Figure 2. With the exception of some of the class proportions, mainly between coarse gravel and small cobble, little change is apparent between years. The slight differences at each of the sites are thought to be mainly due to the natural variability of the substrate. In particular, high flows at some stations in 2017 (i.e. site IR2) prevented the sampling of substrates across the main channel.

4.2 Fish Distribution

The composition of the catch in 2018 was represented by three fish species that included in decreasing frequency of capture: slimy sculpin (21) Arctic grayling (11) and burbot (1). A summary of sampling effort and catch at each of the five monitoring sites is presented in Table 3. A comparison of annual fish catches in 2017 and 2018 is presented in Table 4.

The three fish species captured in 2018 have been previously documented to inhabit Haggart Creek (Hallam Knight Piésold 1995, 1996; Madrone 2006; Stantec 2010, de Graff 2017). Other fish species that have been reported to occur in the drainage, primarily in the lower reaches of Haggart Creek, include Chinook salmon, round whitefish, northern pike and Arctic lamprey. Several Chinook salmon fry (age 1^{+}) were captured at sites HC1 and HC3 in 2017 however during this study none were captured at any of the sites in 2018. In the baseline assessment by Stantec (2010) only slimy sculpin and Arctic grayling were reported in the catch after study of 10 watercourses representing 38 sampling sites associated with the local study area.

Slimy sculpin dominated the overall catch in 2018 and were found at all five monitoring sites. Site L1 in Lynx Creek had the greatest catch with many others being readily observed along the stream bottom while working at the site. Sculpin captures were few at sites HC3 and IR2 with only a single fish represented in the catch at both sites. Sculpin total lengths ranged from 45 to 120 mm indicating the presence of both juvenile and adult life history stages. This size range was similar to those reported by Stantec (2010) in their baseline study. A length frequency histogram of captured sculpin from both the 2017 and 2018 monitoring programs is presented in Figure 4. Overall captures of sculpin at all of the sites were generally

lower in 2018 compared to 2017 (Table 4). It is believed that the cold-water temperatures during the study (-1.0 to 1.0 ° C) combined with the abundance of frazil ice during the survey likely resulted in fewer captures. This was especially evident with the minnow traps becoming engulfed in frazil ice at some of the monitoring sites (Figure 3). Future monitoring projects should consider an earlier sampling window to avoid these affects.

Arctic grayling were represented in the catch in low numbers at each of the monitoring sites with the exception of sites HC3 and IR2. A single Arctic grayling was observed but not captured at IR2 during the survey. Grayling sampled during this project were thought to be exclusively young-of-the-year and ranged in fork lengths from 67 to 94 mm. Older age classes and larger grayling were noticeably absent in the catch. This artifact may have been a function of seasonal movements initiated by cooler stream temperatures and ice conditions associated with the mid-September sampling window.

Previous studies reported the presence of Chinook salmon in the lower reaches of Haggart Creek (Madrone 1996; Hallam Knight Piésold 1995, 1996). In the baseline study by Stantec (2010) juvenile Chinook salmon were not captured at any of the Haggart Creek monitoring sites, nevertheless, two were captured at HC1 and five at HC3 in 2017 (de Graff 2017). Presence at these locations represents their furthest upstream occurrence in the Haggart Creek watershed. Chinook salmon juveniles (age 0^+) were not captured during 2018 and may be the result of lower densities in the drainage from a weaker brood year.

5.0 CONCLUSION

The results from the current monitoring program was similar to the 2017 program and past baseline studies based on the measured biophysical characteristics and fish species found at each of the five monitoring sites. Notable during this project was the capture of burbot at the Lynx Creek site. While the absolute number of fish captures varied, the species composition continues to be consistent and indicative of a stable fish community. The absence of Chinook salmon juveniles (age 0^+) in the mainstem of Haggart Creek is consistent with previous surveys. Chinook salmon juveniles have only been sporadically documented in the upper reaches of Haggart Creek (i.e. upstream of the Lynx Creek confluence).

APPENDIX III
Fisheries and Oceans Canada
Collection Permit

Fisheries and Oceans Canada | Pêches et Océans Canada

Licence Number: XR 282 2018
Valid From: 01-Sep-2018
Expiry Date: 31-Oct-2018

This licence and/or permit is issued under the authority of SECTION 52 OF THE FISHERY (GENERAL) REGULATIONS.

This licence and/or permit authorizes the person(s) listed below, subject to the following terms and conditions, to collect the species and quantity of fish identified below for: Scientific purposes. Non-compliance with any condition of this licence and/or permit may result in the cancellation of this licence and/or permit.

Licence/Permit Activity Description:
To sample fish within various tributaries associated with Haggart Creek to monitor fish presence/absence/utilization and population density.

Licence Holder:
FIN: 125575

CAN-NIC-A-NICK
ENVIRONMENTAL SERVICES

BOX 10106, 138 ARCTIC DRIVE
WHITEHORSE YT Y1A 7A1

Contact Number: 867-668-4682

Contact Party:
FIN: 125576 DE GRAFF, NICHOLAS Contact Number: 867-335-4099

Individuals or groups assisting with the authorized activity:

Any additional assistants not listed below, must be named as part of the notification prior to sampling. Detailed information requirements is found under conditions of this licence.

FIN: 125576	NICHOLAS DE GRAFF	Contact Number: 867-335-4099
FIN: 129960	JOE DE GRAFF	Contact Number: 867-668-4682
FIN: 142042	CRYSTAL DAWN	Contact Number: 867-335-4099
FIN: 129730	BONNIE BURNS	Contact Number: 867-335-4099

Species, Quantity of Fish, Area(s) and Gear:

Species:	CHINOOK SALMON (Oncorhynchus tshawytscha); NORTHERN PIKE (Esox lucius); SLIMY SCULPIN (Cottus cognatus); ARCTIC GRAYLING (Thymallus arcticus); ARCTIC LAMPREY (Lampetra camtschatica);
Gear:	Seine Net, Beach Rod & Reel (unspecified) Electroshocker (Maximum Second per Site: 600 Seconds) Trap, Gee/Minnow (Set Duration Max: 24 Hours)
Licence Area:	Yukon/Transboundary: Haggart Creek - inc tributaries of (Watershed code: 83199973027969)
To be Retained:	0
Additional Descriptions:	Note: as per conditions of this licence electrofishing is not permited in the vicinity of spawning fish or their redds. Electrofishing activities will cease if spawning-condition fish are encountered.

Reporting Requirements:

XR 282 2018 Summary Data Report **Due Date** 31-Oct-18
See "Terms and Conditions" of this licence for detailed reqirements.

Terms and Conditions:

This licence authorizes collections to be made by the licensee and employees, volunteers and students of the licensee provided that all persons, other than minors who are engaged in activities under the authority of this licence, are carrying suitable photo identification to be produced upon request of a Fishery Officer or Guardian.

This license is subject to immediate termination upon written or verbal notice from a representative of the Yukon Government- Department of Environment, or of Fisheries and Oceans Canada.

Samplers: It is the responsibility if the license holder to ensure that samplers are experienced and competent in the fish collection methods authorized in this license.

Need to carry and produce permit: A copy of this license must be in the immediate possession of the samplers during sampling, and must be produced upon the request of any representative designated as a Fishery Officer or Fishery Guardian pursuant to the Fisheries Act (Canada).

Notice: Prior to commencing sampling, notice is to be given to:

• Fisheries and Oceans Canada, Yukon/Transboundary Rivers Area - Tel: (867) 393-6722 Fax (867) 393-6738 or Email: YTLicence@dfo-mpo.gc.ca

• Oliver Barker, YG Fisheries - Email: fisheries@gov.yk.ca

• Appropriate First Nation Government in whose Traditional Territory the activity is taking place.

The notice is to include following information:
i. The Collection License number,
ii. The watercourse or water body on which, and the location where the sampling is to take place,
iii. The dates on which sampling will occur
iv. The names of all assistants which will be engaged in the sampling.

• Note: Notice is also to be given to the Government of Yukon Conservation Officer responsible for any area where sampling is to take place at least 24 hours prior to the start of sampling.

Release of fish: All live fish must be released unharmed into the water body or course from which they originated and as near as possible to the location from which they were captured. Exception to this is where fish are retained for identification or forensic purposes.

Electrofishing: Is not permitted in the vicinity of spawning fish or their redds. A trained and certified electrofisher operator must be a part of the electrofishing crew.

Gear: All gear left unattended must be clearly labelled with the Licence Number and must not interfere with the public right of navigation.

Aquatic Invasive Species To prevent the introduction of aquatic invasive species there are a few simple things that

can be considered: a) Before leaving an area: Drain water from boat, trailer and gear, remove all plant parts and mud and b) Before entering another water body: Wash all your gear including waders with soapy water. For Further Information:
http://www.dfo-mpo.gc.ca/species-especes/index-eng.htm,
http://www.dfo-mpo.gc.ca/science/environmental-environnement/ais-eae/publications/plan/page01-eng.html

Disposition of fish: Any fish captured and retained under the authority of this license are not to enter any commercial markets or establishments. Any fish collected and retained, or incidental mortalities associated with non-lethal sampling, are not to be utilized for human consumption or personal use purposes unless authorized by Fisheries & Oceans Canada.

Species at Risk: Section 32 (1) of the federal Species at Risk Act prohibits killing, harming, harassing, capturing or taking an individual of a wildlife species which is listed on Schedule 1 as an extirpated species, an endangered species or a threatened species. Refer to the SARA Public Registry at http://www.sararegistry.gc.ca to determine if species at risk may be in your research area and to apply for a permit if required.

Transport or transplant of live fish and/or eggs/milt: Live fish and/or eggs (spawn) cannot be transported without prior written approval of the transplant committee or transplanted without a licence granted pursuant to Section 56 of the Fishery (General) Regulations.

Report: A report must be submitted after completion of sampling, in electronic spreadsheet form as provided by email with permit. The report must be in the form of the spreadsheet provided but is not limited to and may also include photocopied data sheets or field notes, or the final report for the project, and must include the following:

a. The Collection License number
b. The location(s) of the sampling with GPS coordinates (lat & long decimal degrees), where GPS coordinates were not possible a map or detailed described may be submitted;
c. Names of all individuals engaged in sampling;
d. The dates on which the sampling occurred;
e. The number of fish sampled, by species;
f. Any mortalities

If no sampling takes place a "nil report" is required in the form of a letter or identified in the mandatory spreadsheet provided.
A summary report is to be submitted by December 31, 2018 to:

Area Licensing Manager
Fisheries and Oceans Canada
100-419 Range Rd

1. Introduction

Victoria
GOLD CORP

1 Introduction

1.1 Scope of Report

This report presents a summary of all climate data collected for the Eagle Gold Project (Project) since August 2007[1]. Monitoring data from two Project climate stations and three local snow courses are presented to characterize local conditions for the following variables:

- Air temperature;
- Rainfall;
- Snow depth and snow water equivalent (SWE);
- Barometric pressure;
- Relative humidity;
- Wind speed and direction, and;
- Solar radiation.

Measured data are also used to estimate potential evaporation for the Project site.

1.2 Previous Reports

The climate data collected at the Eagle Gold Project site from 2007, up to and including December 2017, have been previously summarized in the following reports:

- *Dublin Gulch Project - Climate and Hydrology Environmental Baseline Report* (2008), prepared by Jacques Whitford AXYS (Burnaby, BC) for StrataGold Corp. (Vancouver, BC), December 2008.
- *Snow Survey Environmental Baseline Report* (2009), prepared by Jacques Whitford Stantec AXYS (Burnaby, BC) for StrataGold Corp. (Vancouver, BC).
- *Eagle Gold Project, Environmental Baseline Report: Climate* (2010), prepared by Stantec (Burnaby, BC) for Victoria Gold Corp., February 2010.
- *Eagle Gold Project, Surface Water Balance Model Report* (2011), prepared by Stantec (Burnaby, BC) for Victoria Gold Corp., June 2011.

[1] Historic climate data collected during 1993 to 1996 for the Project area is summarized in *Eagle Gold Project, Environmental Baseline Report: Climate*, prepared by Stantec (Burnaby, BC) for Victoria Gold Corp., March 2012

- *Eagle Gold Project, Environmental Data Summary Report: Climate 2011 Update* (2011), prepared by Stantec (Burnaby, BC) for Victoria Gold Corp., June 2011.
- *Eagle Gold Project, Environmental Baseline Report: Climate* , prepared by Stantec (Burnaby, BC) for Victoria Gold Corp., March 2012.
- *Victoria Gold Corp., Eagle Gold Project – Climate Baseline Data Summary. VA101-290/6-9*, prepared by Knight Piesold Ltd. (Vancouver, BC) for Victoria Gold Corp., August 2013.
- *Victoria Gold Corp., Eagle Gold – Climate Baseline Report.* Prepared by Lorax Environmental Services Ltd., October 2016. 34 pp.
- *Victoria Gold Corp. Eagle Gold Project – Hydrometeorology Report.* A413-3, prepared by Lorax Environmental Services Ltd. (Vancouver, BC) for Victoria Gold Corp., March 2017.
- *Victoria Gold Corp., Eagle Gold – Climate Baseline Report.* Prepared by Lorax Environmental Services Ltd., March 2018. 35 pp.

2. Climate Monitoring Locations

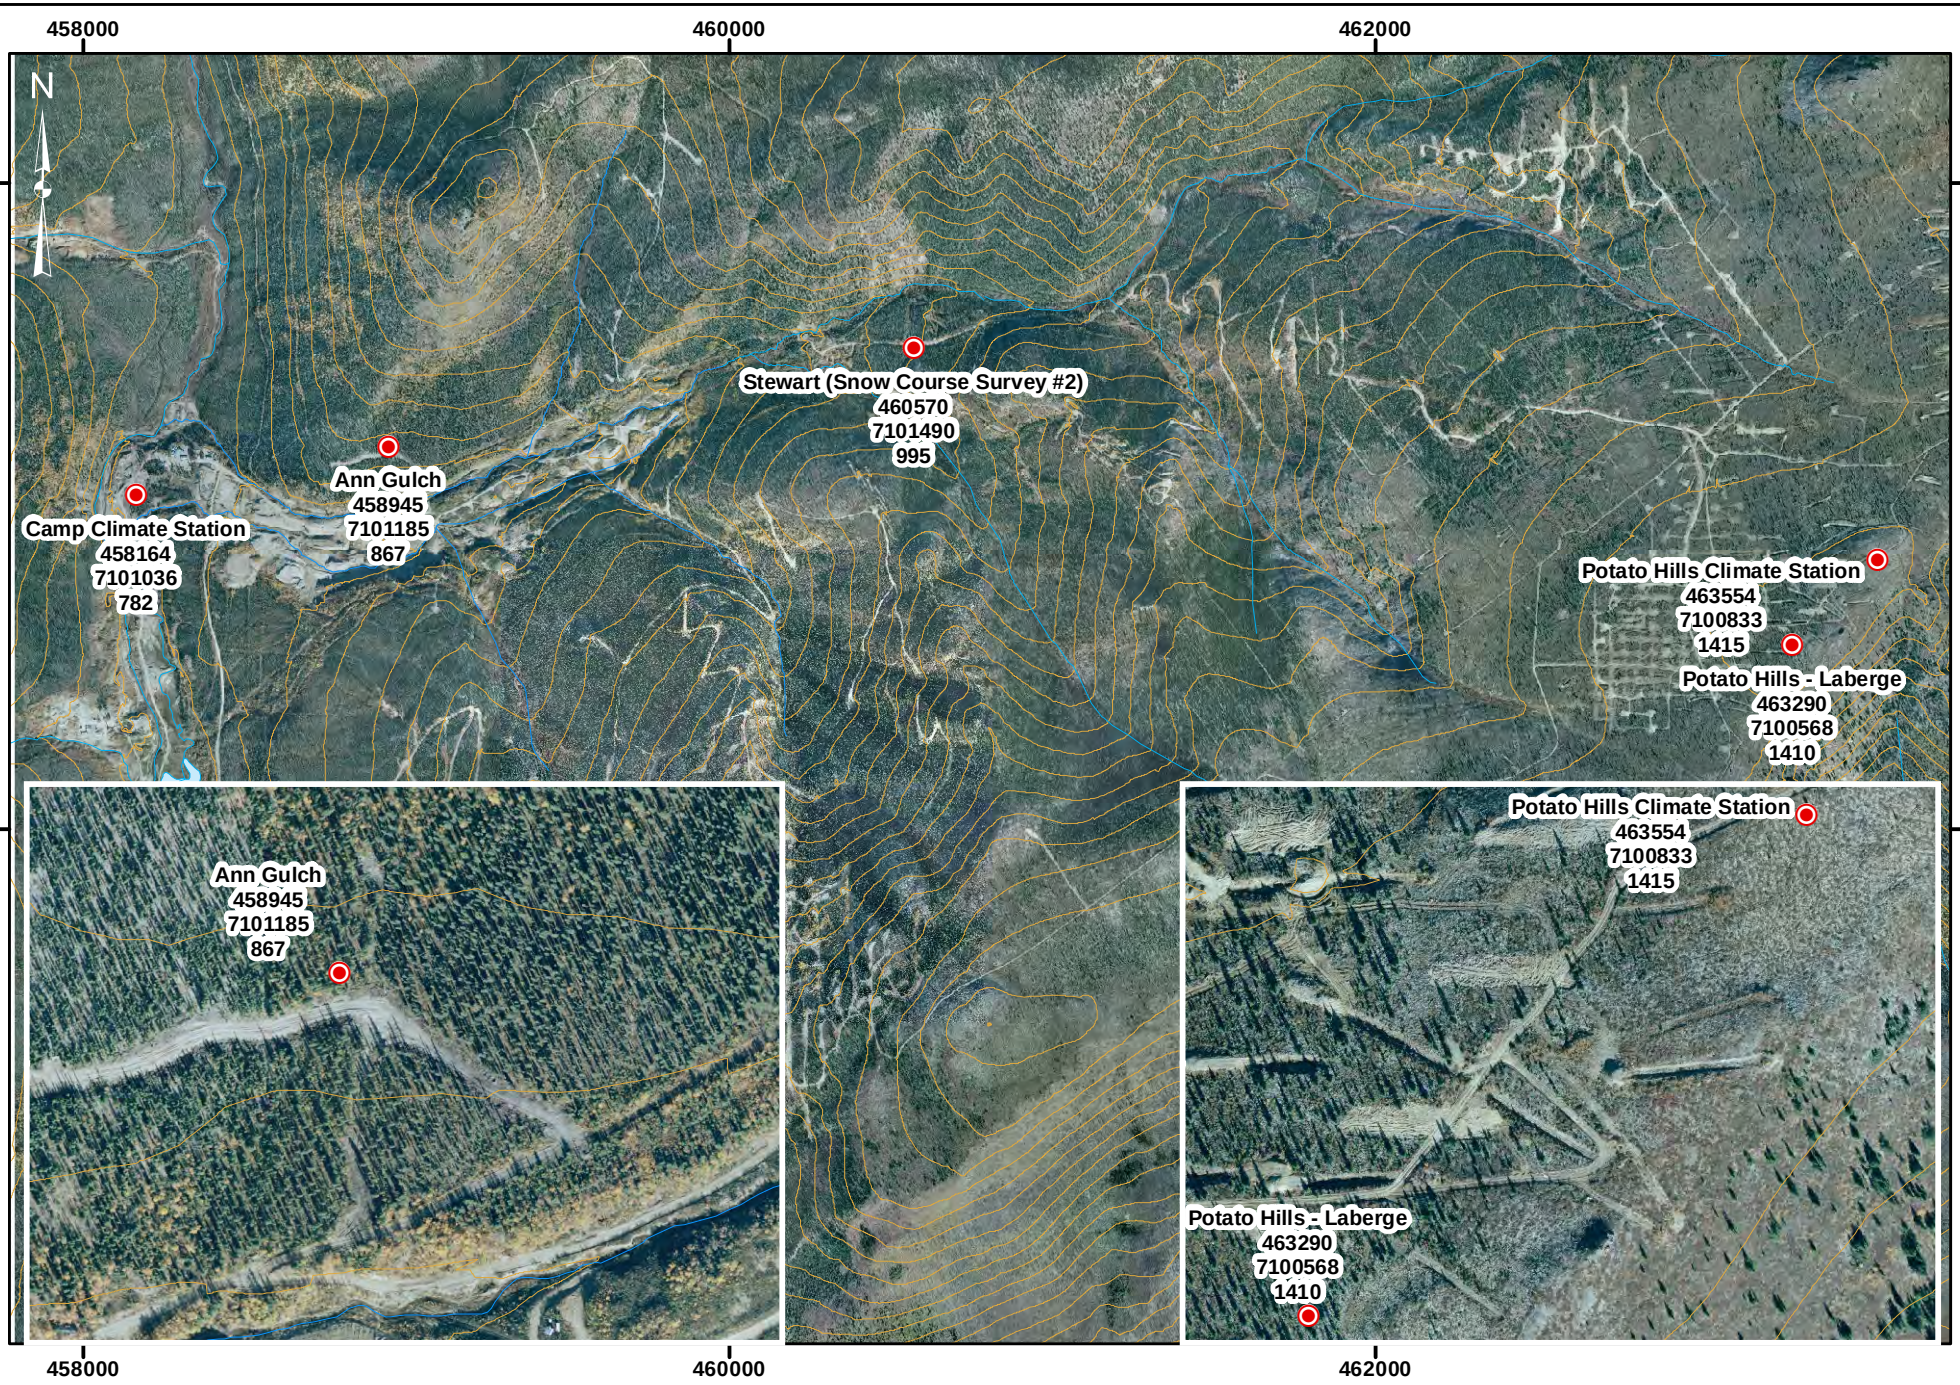
Victoria
GOLD CORP

2 Climate Monitoring Locations

2.1 Meteorological Stations

Climatic parameters are measured at the Project site by two weather stations that were originally installed by Stantec (formerly Jacques Whitford AXYS). The Potato Hills station is situated near the eastern basin divide (1420 m) and was installed in August 2007. The second station was originally installed near the camp at 823 m in August 2009, and subsequently was moved to its current location in September 2010 (782 m) following construction of new camp facilities.

The Potato Hills station uses an ONSET Hobo datalogger to measure air temperature, rainfall, wind speed and direction, barometric pressure, relative humidity, snow depth and solar radiation at 15-minute intervals. The recording interval was initially set to record at 60-minute intervals from August 14, 2007 to August 13, 2008 and then was switched to 15-minute intervals as of August 13, 2008. A snow sensor was added to the station in April 2011.



The Camp station includes a Campbell Scientific CR800 datalogger measuring air temperature, rainfall, wind speed and direction, barometric pressure, snow depth, solar radiation and relative humidity. All data are recorded at a 15-minute interval at this location. The snow sensor and pyranometer (measuring solar radiation) were added on April and October 2011, respectively.

Since snow sensor installation, the continuous snow depth data for the Potato Hills station have not been reliable and therefore these data are not presented in this report. Continuous snow depth data are provided herein for the Camp station, as are records of snow survey measurements for actively measured stations through spring 2018.

The Project climate stations and snow survey locations are presented in Table 2-1 and Figure 2-1.

Table 2-1:
Climate station and snow survey locations.

Station	Elevation (m asl)	UTM E	UTM N	Record Period
Climate Stations				
Camp Station	782	458,164	7,101,036	2009-present
Potato Hills Station	1420	463,544	7,100,833	2007-present

PROJECT SITE CLIMATE STATION AND SNOW SURVEY LOCATIONS

2.1.1 Data Gaps for 2018

This section of the report summarizes data gaps in the climate record for the Potato Hills and Camp climate stations during the period January 2018 to December 2018. Data gaps prior to January 2018 are discussed in previous reports.

Potato Hills Station – Between January 2018 and December 2018, a number of data gaps exist in the Potato Hills climate station record.

- Air temperature, wind speed, relative humidity and atmospheric pressure data were not recorded to the central datalogger at Potato Hills for the following time periods in 2018: April 28 to May 16; June 7 to June 29; July 3 to July 13; August 5 to September 22; and December 2 to December 16.
- Data gaps with respect to wind direction data are essentially the same as for other sensors. Since field staff attributed power outages at the central datalogger to battery drain from the wind direction sensor, the sensor was disconnected during the October site visit.
- The snow depth sensor installed at the Potato Hills climate station did not return usable data for the period January 2017 to December 2018.
- A separate Onset event logger is used to record rainfall accumlation at the Potato Hills climate station. The event logger was deployed on May 16 and collected rainfall data without gap until October 16.

Camp Station – There are no data gaps for the Camp climate station in 2018.

2.2 Snow Surveys

Snow surveys were completed in 2018 at the Camp (Lower) snow course and Potato Hills (Upper) snow course. The Ann Gulch station was no longer available due to construction activities in the area. A new location will be established in Ann Gulch upgradient from construction activities for the 2019 snow survey season. All snow surveys were generally conducted at, or near to the date that Water Resources Branch of Environment Yukon conducted their monthly surveys, which included the annual maximum snowpack. This peak in terms of SWE measurement typically occurs between late-March to mid-April in the Yukon.

Snow surveys are conducted following the guidelines set out in the *Snow Survey Sampling Guide* (BC Ministry of Environment, 1981). At each site, 10 sampling locations along a transect were sampled for depth and snow water equivalent [SWE] using a Federal snow sampler, and then averaged. As summarized in previous annual reports, snow courses were established at the Project site to discern effects of aspect and elevation gain on local snow accumulation (Table 2-1 and Figure 2-1).

3. Climate Data Summary

Victoria
GOLD CORP

3 Climate Data Summary

3.1 Temperature

Air temperatures at the Project site are consistent with those throughout the Yukon interior. Mean annual air temperature at site is -3.2°C at the Camp station (782 m) and -3.8°C at the Potato Hills station (1420 m) over their respective periods of record.

Mean, maximum and minimum monthly (based on the daily average) temperatures are presented in Table 3-1 for both stations. At the Camp station, monthly average temperature ranges from -19.9°C in December to 13.2°C in July, and -15.2°C to 10.8°C at the Potato Hills station, for the same months. The minimum (maximum) recorded daily average temperatures were -43.8°C (22.0°C) and -36.6°C (22.8°C) at the Camp and Potato Hills stations, respectively. The minimum (maximum) recorded 15-minute temperatures were -46.4°C (31.6°C) and -37.6°C (31.7°C) at the Camp and Potato Hills stations, respectively.

The monthly mean temperatures signatures for both climate stations are shown in Figure 3-1, and the pattern is consistent with the larger regional picture. During the months of March to October inclusive, the standard lapse rate applies, with temperatures decreasing with rising elevation, and are approximately 3°C cooler at the upper station, on average. However, during the winter months of November to February, temperature inversions are common at the Project site, with temperatures roughly 2.5°C cooler on average in the valley bottom than at the height of land.

The spring/summer lapse rate of -4°C/1000 m is consistent with the saturated adiabatic lapse rate of -5.0°C/1000 m. This is likely due to the increased frequency of precipitation during the summer months, when a larger portion of the annual precipitation falls, resulting in warmer and wetter air masses at the Project site. The winter lapse rate of +4°C/1000 m is consistent with that reported by Wahl *et al.* (1987), which states that during a temperature inversion, lapse rates can range from 3-5°C/1000 m of elevation gain.

Table 3-1:
Project site monthly air temperature record.

Climate Station	Elevation (m asl)	Temperature (°C)

Notes:
1. Values are calculated from average daily temperatures.
2. Data is considered missing for a month when there are less than 25 days of data available for that month.
3. Monthly values in italics for the Potato Hills station, for the period of 2013 through 2015 have been infilled using monthly regression relationships with temperature data from the Camp station.
4. Monthly values in gray for the period of June 2014 to March 2015 and May through July 2016 were recorded by a standalone HOBO temperature sensor.
5. 'M' denotes data missing due to a sensor/datalogger malfunction.
6. Monthly temperature lapse rates presented in Section 3.1 are based on a comparison of monthly average temperature data from the Camp and Potato Hills stations.

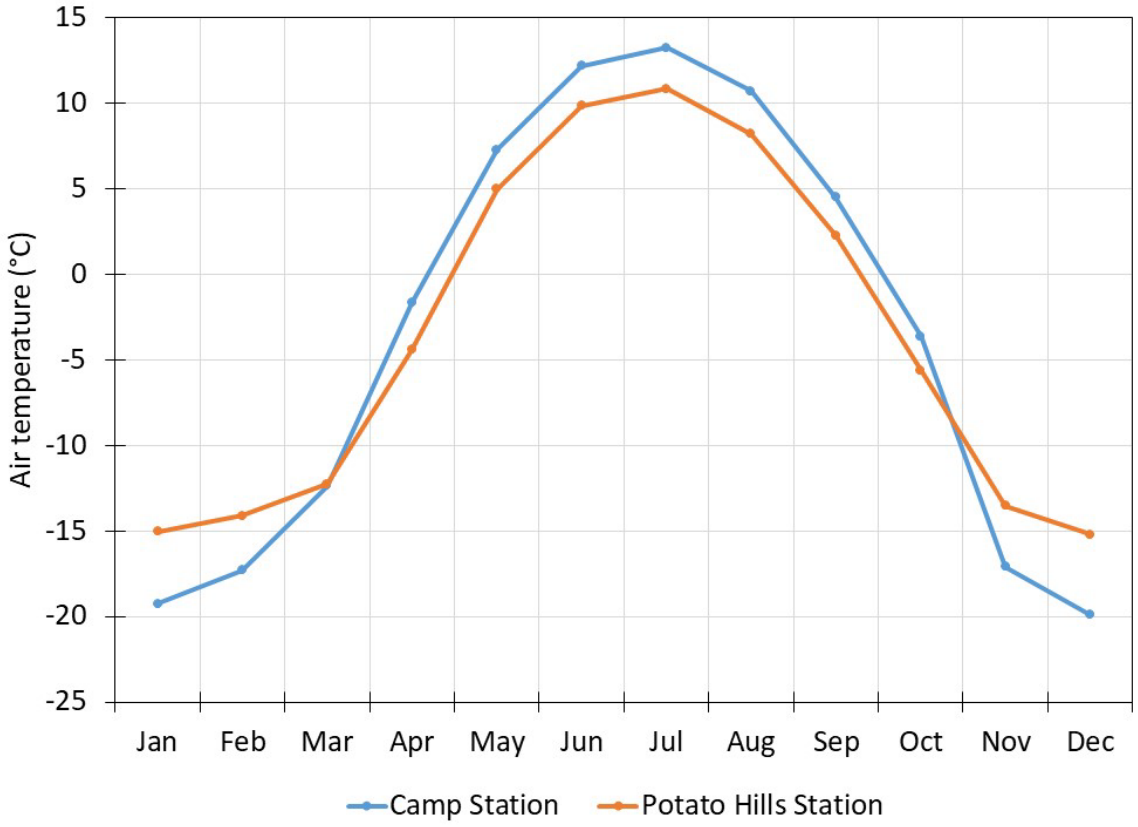

Figure 3-1: Monthly mean air temperature for the Project climate stations for the available period of record.

3.2 Rainfall

The precipitation data is collected at the Project site using tipping bucket rain gauges, which have not been adapted to measure snowfall. Therefore, the precipitation data presented in Table 3-2 is for rainfall only, collected between the months of March and October, inclusive. Generally, precipitation falls as snow from November through March, with precipitation falling as a mix of rain and snow in April and October. Rainfall data for March is included in the table below, where the temperature record indicates that precipitation would have fallen as rain (*i.e.*, daily average air temperature was above zero).

Table 3-2:
Project site monthly rainfall data.

			Minimum	S	S	0.2	0.2	9.6	23.0	12.6	18.2	4.0	*0.4*	S	S	162.6

Notes:
1. Winter precipitation data (October through April in many years) are unreliable due to the majority falling as snow. The months where no rainfall was recorded due to freezing conditions are denoted by an 'S'.
2. Data for the month of October are in italics, as rainfall is not measured for the entire month.
3. 'M' denotes data missing due to a sensor malfunction.
4. In August 2015, the primary rain gauge at the Potato Hills Station was replaced by a standalone tipping bucket rain gauge. The replacement gauge is deployed each spring (i.e., in April or May) then decommissioned in the autumn (October). Missing data at Potato Hills Station denoted by 'D' indicate time periods during which the standalone tipping bucket rain gauge was not deployed.

3.3 Snow Water Equivalent and Continuous Snow Depth Data

As discussed in Section 2.2, snow data have been collected at three snow courses[2] at the Project site since 2009. Furthermore, the annual maximum snow water equivalent (SWE) value generally occurs in late-March or early-April at the Project site. Field measurements from site show that snow density is generally lower earlier in the season, corresponding to colder temperatures, but increases through winter as the snow pack deepens, weathers and as snow melt progresses.

Project site snow survey data is summarized in Table 3-3 for period of record 2009 to 2018. Annual maximum SWE values range from 93 mm to 161 mm at the Camp snow course, 98 mm to 117 mm (shorter record) at the Ann Gulch snow course and from 190 mm to 410 mm at the Potato Hills snow course.

The Potato Hills snow survey was conducted in the immediate vicinity of the weather station from 2009 to 2011. However, due to the exposed location, snow redistribution resulted in variable measurements, and therefore the survey was moved to its current and more sheltered location in 2012, several hundred metres to the south-east (Figure 2-1). Note that high snowpacks did not allow access to the Potato Hills snow course in March 2012, and therefore the survey was conducted at Stewart Gulch (Snow Survey #2; see Figure 2-1).

[2] See Note 1 in Table 3-3.

Table 3-3:

Notes:

1. Snow survey data for Potato Hills collected on 2012-03-20 is from the Stewart Gulch survey (Snow Survey #2) at 995 m asl (see Figure 2-1).
2. No snow surveys were conducted at site in 2015.

3.3.1 Continuous Snow Depth Data

Continuous snow depth data is summarized for the Camp climate station in Figure 3-2.

The upper panel of Figure 3-2 shows the evolution of the snowpack for the 2012 to 2018 time-period, with pack depth showing initial and appreciable accumulation through the months of November and December, typically reaching maximum depth by mid-March each year. These data then show snow pack depth remains deep and relatively stable to April.

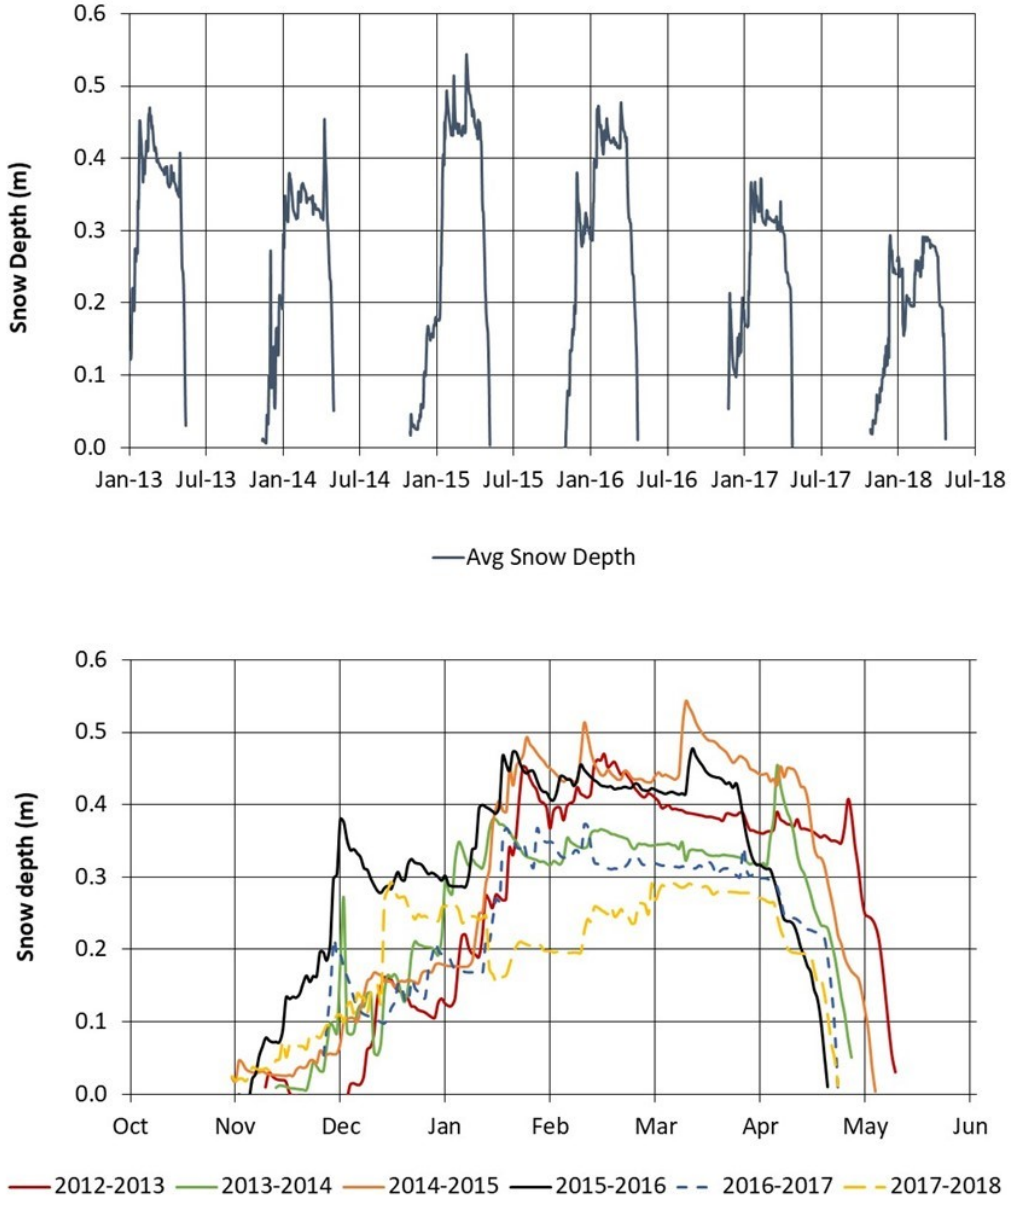

Figure 3-2: Summary of recent (2012-2018) continuous snow depth data for the Camp climate station.

The lower panel of Figure 3-2, illustrates the timing and rate of snowpack loss for the Camp climate station. While variable from year to year, these data show snowpack losses begin in earnest by mid- to late-April each year. Furthermore, the duration of snowmelt is short- and typically a 15-20 day process at this station elevation.

3.4 Barometric Pressure

Barometric pressure provides a measure of the weight exerted by the atmosphere on the earth's surface at a point and provides a direct indication of changes in the synoptic weather pattern (*e.g.*, dropping barometric pressure can indicate the approach of a warm front). As expected, barometric pressure decreases with elevation at site, and is generally elevated during the summer months in comparison to the winter season (Table 3-4). When the Potato Hills climate station experienced a malfunction between May 2014 and July 2015, Table 3-4 was populated with data recorded by a standalone HOBO temperature/pressure logger for this time period. Annual average barometric pressure is 91.8 kPa at the Camp station, and 84.9 kPa at the Potato Hills station.

Table 3-4:
Project site monthly average barometric pressure.

Climate Station	Elevation (m asl)	Barometric Pressure (kPa)												
		Year	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Annual

Notes:
1. Monthly values in gray for the period of June 2014 to March 2015 were recorded by a standalone HOBO barometric pressure sensor.
2. 'M' denotes data missing due to a sensor malfunction.

3.5 Relative Humidity

Relative humidity is a measure of the water vapour content of an air parcel, expressed as a percentage of the total water vapour required for the air to be fully saturated at a given temperature. Therefore, at colder temperatures, less water vapour is required to achieve a high relative humidity, and conversely at higher temperatures, more water vapour is required to obtain the same relative humidity value.

Given that air temperatures are well below zero during the winter, relative humidity values are elevated throughout the winter, and lower during the summer. With respect to monthly patterns for relative humidity, the annual minimum is expected to occur in the month of May. All monthly average relative humidity values from both climate stations are provided in Table 3-5 and Figure 3-3. Annual average relative humidity is 70% at the Camp station, and 77% at the Potato Hills station.

Table 3-5:
Project site monthly average relative humidity.

Notes:
1. 'M' denotes data missing due to a sensor malfunction.

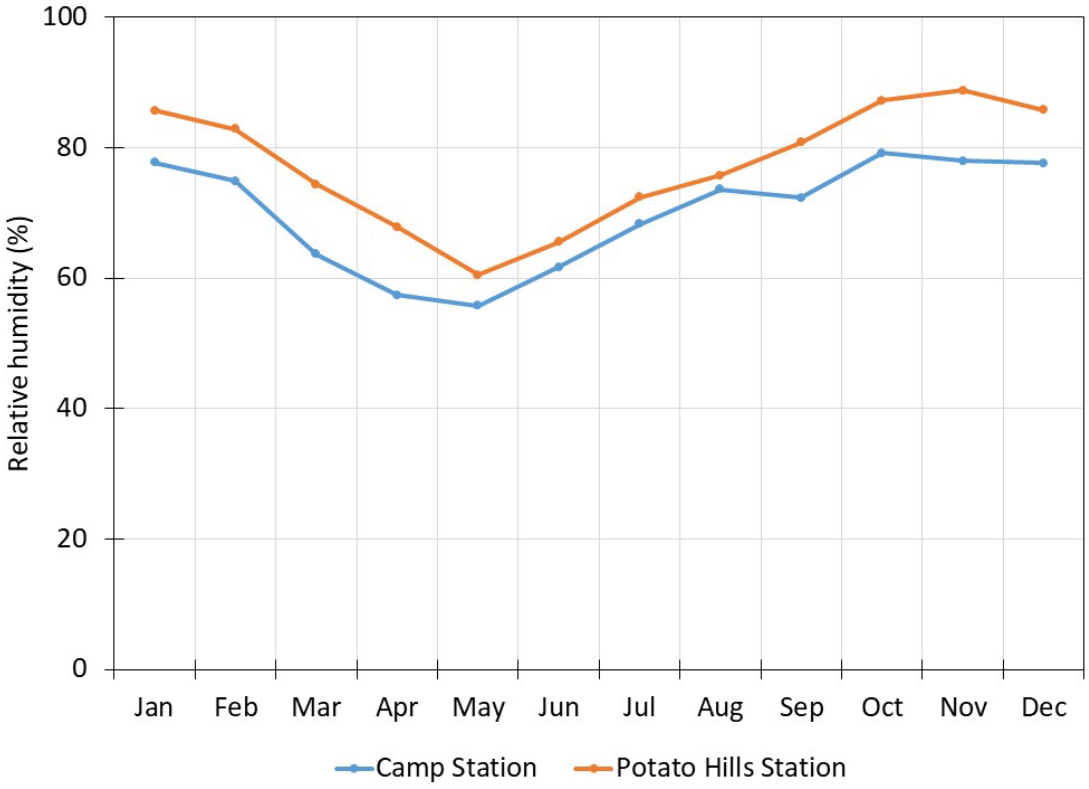

Figure 3-3: Project site average monthly relative humidity.

3.6 Wind Speed and Direction

The predominant wind direction at the site climate stations is north, and west-northwest, for the Camp and Potato Hills stations, respectively. Wind speeds average 1.2 m/s at the Camp station, and 2.4 m/s at the Potato Hills station, on an annual basis (Table 3-6; Figure 3-4). The maximum recorded gust speed at the Camp station was 23.5 m/s over a 15-minute interval (August 15, 2016). At the Potato Hills station, wind speeds averaged 23.5 m/s over a 1-hour period (November 3, 2010; 15-min maximum gust of 23.9 m/s), and during the same event, wind speeds in excess of 20 m/s were recorded for a 4.5-hour period. As shown in Table 3-6, the mean monthly wind speeds for both stations are higher in the spring, summer, and autumn months, and lower in the winter, with annual average monthly minimums occurring in December, and annual maximum winds in April and May.

Table 3-6:
Project site monthly average wind speeds.

Notes:
1. Zero value for January 2012 is likely due to icing of the wind sensor.
2. 'M' denotes data missing due to a sensor malfunction and R an indicator the wind sensor affected by rime.

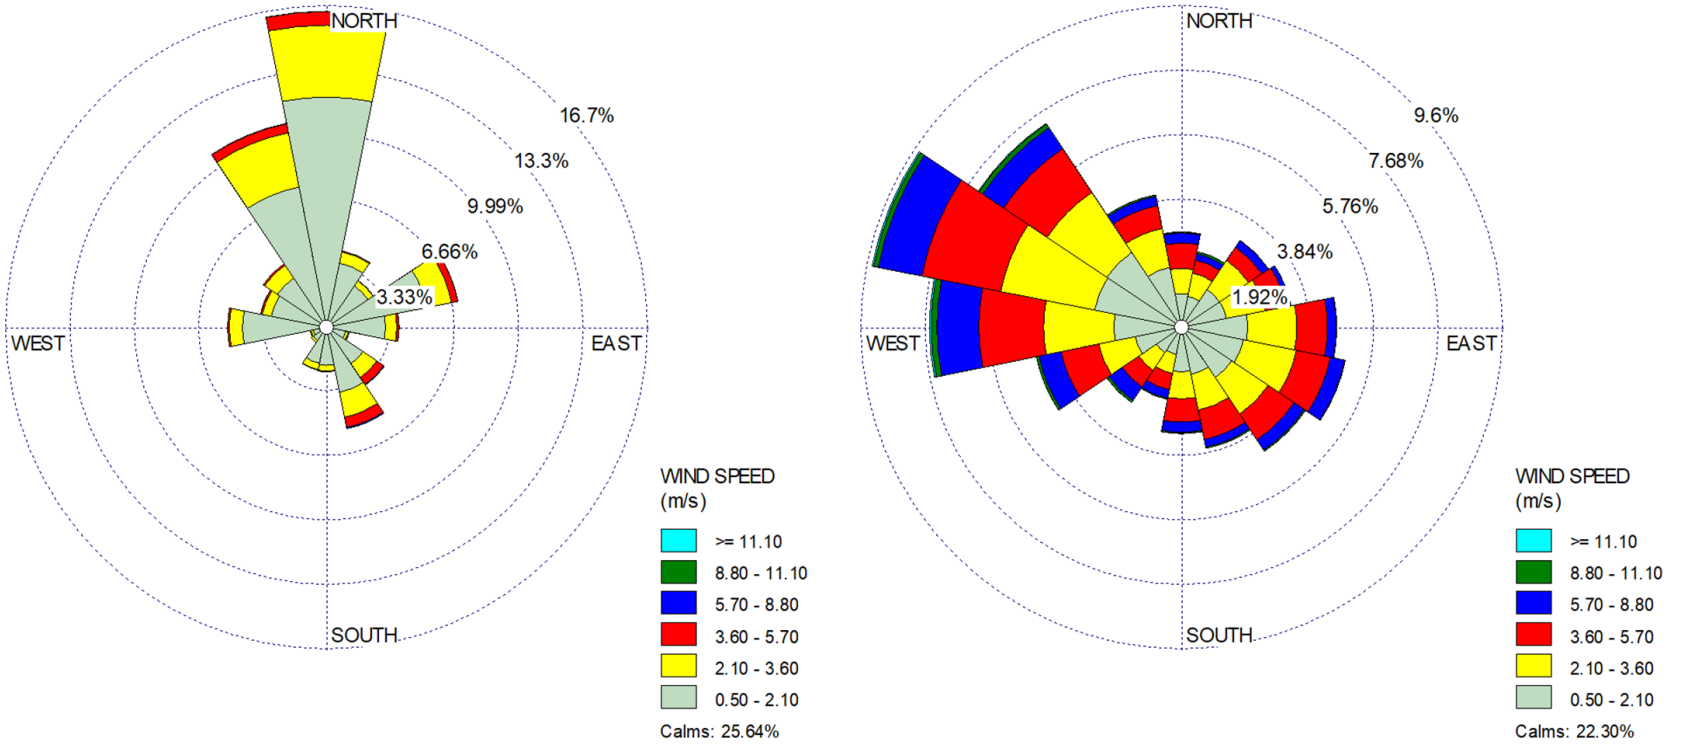

Figure 3-4: Project site wind roses for the Camp station (a) and the Potato Hills station (b). Wind roses are based on hourly averages of 15-minute readings of wind speed and direction.

3.7 Solar Radiation

Solar radiation (or solar irradiance) is a measure of the power per unit area provided by the Sun, in watts per square meter (W/m^2). Given the high-latitude location of the Project site, day length, and therefore solar radiation, fluctuate greatly on a seasonal basis. The average annual minimum of 1 W/m^2 (Camp station) and 3 W/m^2 (Potato Hills station) occur in the month of December, while the average annual maximum of 208 W/m^2 and 224 W/m^2 occur in May at the Camp and Potato Hills stations, respectively. The Camp station location in the valley bottom results in slightly lower incident solar radiation, presumably due to the shading effect of the surrounding terrain. The monthly average and maximum solar radiation values for both stations are presented in Table 3-7 for their periods of record.

Table 3-7:
Project site monthly maximum and average incoming solar radiation.

Climate Station	Elevation (m asl)	Maximum Solar Radiation (W/m²)

		Average	6	30	91	168	224	219	203	155	91	37	10	3	102

Notes:
1. Solar radiation is zero at night.
2. Maximum values are based on an hourly/sub-hourly recording interval.
3. Zero values are not included in the calculation of averages.
4. 'M' denotes data missing due to a sensor malfunction.

3.8 Potential Evaporation

15-minute potential evaporation rates were computed for the Camp station using available climate and the Ref-ET calculator - a compiled, stand-alone computer program that calculates reference evapotranspiration (ASCE, 2005). For the period of available record (Jan 2013 to Dec 2017), a 15-minute climate input file was prepared for the Eagle Gold site. The input variables required by Ref-ET are: maximum air temperature, minimum air temperature, relative humidity, incoming solar radiation, atmospheric pressure and wind speed.

From the assembled climate inputs, Ref-ET returned potential evaporation (PE) computations at daily time-step based on an array of evaporation models (*e.g.,* Penman-Monteith model, Priestley-Taylor formulation). Presented in Table 3-8 (monthly tabulations) are resulting outputs from Ref-ET for months March to October. May to end-September PE for the Camp station is estimated to range from 380-400 mm, with highest monthly rates of PE expected in May, June, July and August of each year.

Table 3-8:
Potential evaporation (PE) estimates for the Camp station.

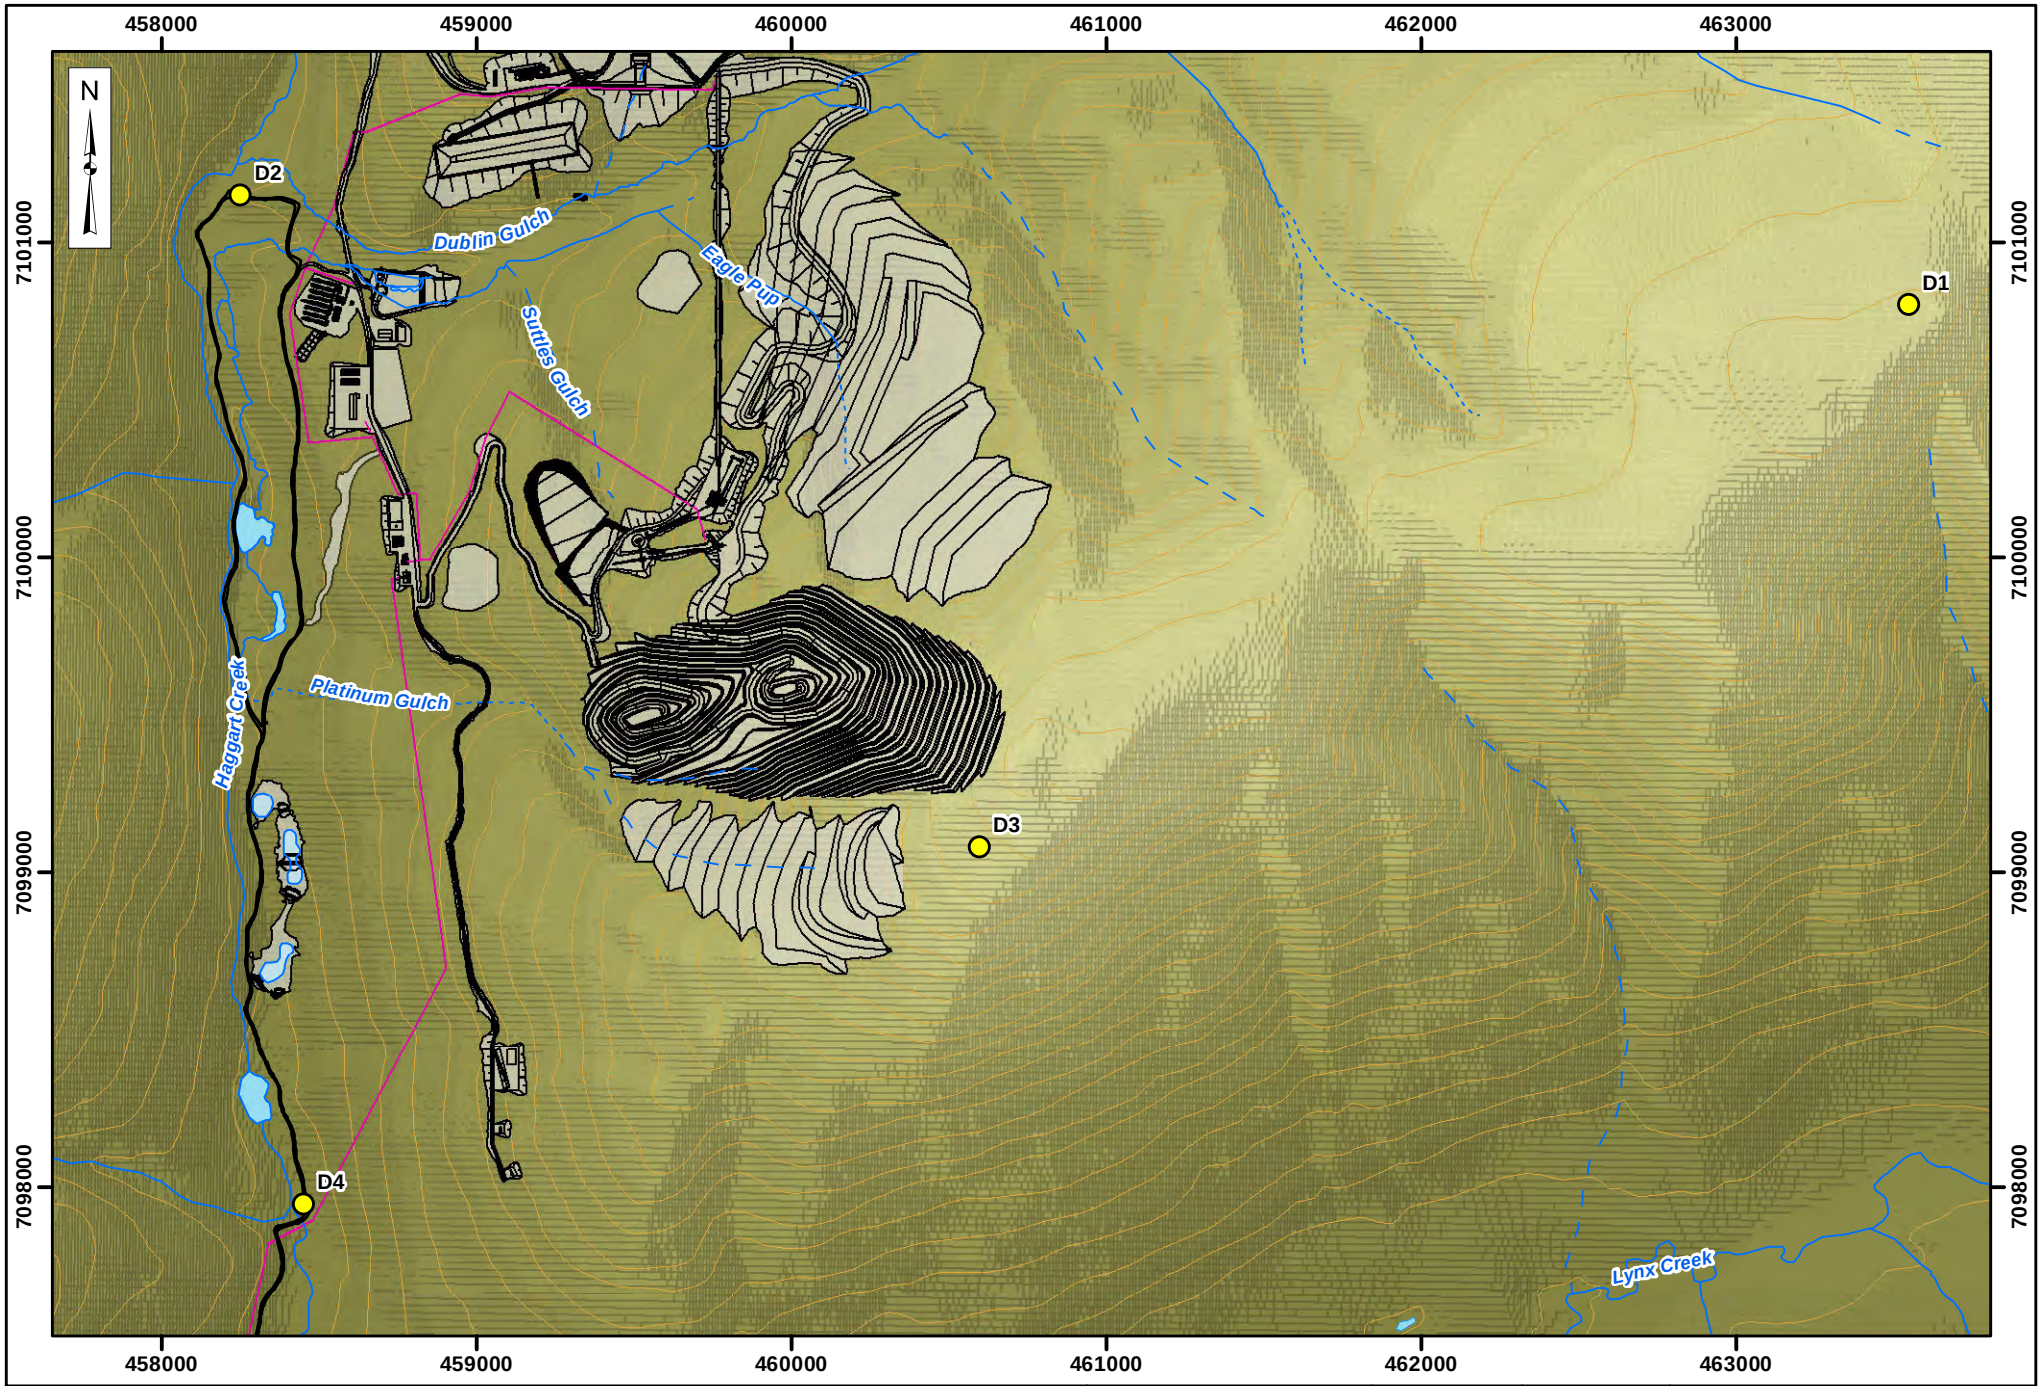
1.0 INTRODUCTION

The vegetation monitoring program has been designed to evaluate changes to vegetation during the construction phase of the Project. Specifically, metal burden in and on plant tissues is measured annually during the growing season in each year of the construction period to help identify whether any trends can be attributed to site activities. The 2018 survey is the first year of the program and represents baseline conditions.

The Environmental Monitoring, Surveillance and Adaptive Management Plan (EMSAMP), Version 2018-01, indicated four areas located in the Project area for the establishment of permanent vegetation plots. These sites are also the locations for the Soils Program and the dust fall installations.

2.0 METHODS



Four sites were established in each of the identified quadrants in early August 2018 and locations are detailed in Table 1 and displayed on Figure 1. The coordinates for each site represents the centre point of the site. Four corner points were then established in cardinal directions 10 metres from the centre. The plot layout is represented in Figure 2. Each of these five points were identified with fluorescent painted half-inch diameter rebar, 50 cm long. Circle plots of one-meter radius, were flagged around each rebar. The EMSAMP states that foliar samples of willow, sedge, bluejoint and northern rough fescue are to be collected within these two-meter diameter plots. As each of these four vegetation sites are located in different ecosystem units, not all species were present at each site.

TABLE 1 LOCATION AND DESCRIPTION OF VEGETATION SITES

Site #	NAD 83 Zone 8W		Aspect	Elevation (m)	Site Description
	Easting	Northing			
D 1	463550	7100803	level	1417	Potato Hills near climate station
D 2	458251	7101150	west	834	Upslope of the air quality station and the camp climate station
D 3	460598	7099079	south west	1356	Top of Eagle Pup near the over-the-top road
D 4	458450	7097945	level	757	On the west side of the access road just upstream of the Haggart Creek culverts, approx 3 km downwind of the Camp Climate Station

New disposable nitrile gloves were worn for each collection. Where possible, separate samples were collected for willow leaves and the current season's growth of twigs. Willow foliar samples were collected from each quadrant. Due to their presence at most of the plots, and the fact they also have reasonable surface area for dust deposits, dwarf birch leaves were also sampled. Sedge was only present and collected at one site, D4. Fescue biomass was low throughout the four sites; populations were high enough to warrant collections at D1 only. Bluejoint was only available for collection at D4.

Samples were placed in Ziplock® bags and kept cool until delivered to the ALS laboratory in Whitehorse, Yukon. After the samples were logged in, they were frozen and shipped to the lab in Burnaby, BC, for analysis. The foliar samples were homogenized and sub-sampled prior to hot-block digestion with nitric and hydrochloric acids, in combination with the addition of hydrogen peroxide. Metals were analyzed using collision cell inductively coupled plasma-mass spectrometry. Analysis for mercury was done by atomic fluorescence or atomic absorption spectrophotometry.

3.0 RESULTS

3.1 Description of the Vegetation Sites

The four roughly 200m^2 established sites lie within two ecological zones; the Subalpine Zone where the elevation is greater than 1225 masl and the Forested Zone which includes the treed areas on the mountain slopes and the valley bottoms (Stantec, 2011). D1 and D3 are located in the Subalpine Zone and D2 and D4 are in the Forested Zone.

D1

D1 is situated approximately 30 meters west of the Potato Hills Climate station. Stantec (2011) conducted ecosystem mapping throughout the Eagle Gold Project area in 2009. The polygon that contains D1 is classified as 50% Dwarf Birch and Lichen, 40% Dwarf Birch and Northern Rough Fescue and 10% Subalpine Fir, Dwarf Birch, Crowberry and Lichens (Stantec, 2011, Appendix 11, Part 1).

Within the 14 meter square boundary of D1, dwarf birch was the dominant species followed by willow. Tree species were solitary sporadic subalpine fir as well as one white spruce. There was exposed rock and talus throughout the site with the majority encrusted with lichen. A diversity of forbs was noted. The following plants were identified within D1:

Common Name	Scientific Name
Subalpine Fir	*Abies lasiocarpa*
White Spruce	*Picea glauca*
Dwarf Birch	*Betula glandulosa*
Willow	*Salix* sp
Diamond Leaf Willow	*Salix pulcha*
Willow	*Salix richardsonii*
Labrador Tea	*Rhododendron groenlandicum*
Low Bush Cranberry	*Vaccinium vitis-idaea*
Blueberry	*Vaccinium uliginosum*
Arctic White Heather	*Cassiope tetragona*
Crowberry	*Empetrum nigrum*
Colt's Foot	*Petasites frigidus* var. *sagittatus*
Lupine	*Lupinus arcticus*
Mountain Sagewort	*Artemisia norvegica*
Spike Trisetum	*Trisetum spicatum*
Northern Rough Fescue	*Festuca altaica*
Anemone	*Anemone narcissiflora*
Lousewort	*Pedicularis labradorica*
Red Hook Moss	*Drepanocladus revolvens*
Finger lichen	*Dactylina arctica*
Caribou lichen	*Cladina stellaris*
Club lichen	*Cladonia* spp
Rockstripe lichen	*Umbilicaria torrefacta*
Green crusticose lichen	*Aspicilia caesiocinerea*
Leaf lichen	*Peltigera aphthosa*
Caribou horn tumbleweed lichen	*Masonhalea richardsonii*

D2

D2 was established in the Forested Zone east of the camp weather station. Stantec (2011) classified the polygon where D2 is located as 80% Black spruce, Labrador Tea and Feathermoss and 20% Subalpine Fir, Crowberry and Lichen.

Tree species found within the boundary of site D2 consisted of Black Spruce, subalpine fir and paper birch. Willows and dwarf birch were the dominant shrub species. Feather moss was the dominant ground cover. Forbs and other shrubs were also present. Moose and rabbit scat were observed in the plot.

The following plants were identified at D2:

Common Name	Scientific Name
Subalpine Fir	*Abies lasiocarpa*
Black Spruce	*Picea mariana*
Alaska Birch	*Betula neoalaskana*
Willow	*Salix* sp
Diamond Leaf Willow	*Salix pulchra*
Scouler's Willow	*Salix scouleriana*
Dwarf Birch	*Betula glandulosa*
Labrador Tea	*Rhododendron groenlandicum*
Low Bush Cranberry	*Vaccinium vitis-idaea*
Blueberry	*Vaccinium uliginosum*
Crowberry	*Empetrum nigrum*
Kinnikinnick	*Arctostaphylosu uva-ursi*
Colt's Foot	*Petasites frigidus* var*. sagittatus*
Fireweed	*Chamerion angustifolium*
Horsetail	*Equisetum* sp
Polar Grass	*Arctagrostis latifolia*
Caribou lichen	*Cladina stellaris*
Pelt Lichen	*Peltigera canina*
Black hair lichen	*Bryoria* sp
Feather mosses	*Pleurozium schreberi*
Red Hook Moss	*Drepanocladus revolvens*

D3

D3 is located in a subalpine setting above Platinum Gulch accessed by the over-the-top road. The ecosystem classification in the polygon where D3 is situated is 50% Dwarf Birch and Northern Rough Fescue, 40% Dwarf birch and Lichen, and 10% Subalpine Fir, Dwarf Birch, Crowberry and lichens (Stantec, 2011).

Within the boundaries of D3, dwarf birch was the dominant species with scattered subalpine fir and white spruce. Willows, berry bushes, lichens and moss were also present.

The following plants were identified at D3:

Common Name	Scientific Name
Subalpine Fir	*Abies lasiocarpa*
White Spruce	*Picea glauca*
Grey-leaved Willow	*Salix glauca*
Diamond Leaf Willow	*Salix pulchra*
Dwarf Birch	*Betula glandulosa*
Low Bush Cranberry	*Vaccinium vitis-idaea*
Blueberry	*Vaccinium uliginosum*
Crowberry	*Empetrum nigrum*
Labrador Lousewort	*Pedicularis labradorica*
Anemone	*Anemone narcissiflora*
Arctic Bluegrass	*Poa arctica*
Woodrush	*Luzula parviflora*
Caribou lichen	*Cladina stellaris*
Caribou horn	*Masonhalea richardsonii*
Leaf Lichen	
Feather mosses	

D4

D4 is located in the Forested Zone in the floodplain area of Haggart Creek just upstream of the culverts at the access road crossing. Stantec (2011) has classified this area consisting mostly of rivers and large creeks and gravel bars with 20% as an ecosystem vegetation type of White Spruce and Horsetail.

The monitored site of D4 is generally a sedge covered open area with willows and alder interspersed throughout. Balsam Poplar was the only tree species although they were immature within D4. Horsetail and forbs were scattered within the site.

The following plants were identified at D4:

Common Name	Scientific Name
Balsam Poplar	*Populus balsamifera*
Alder	*Alnus crispa*
Diamond Leaf Willow	*Salix pulchra*
Sweet vetch	*Hedysarum alpinum*
Siberian Yarrow	*Achillea sibirica*
Grass of Parnassus	*Parnassia palustris*
Green Bog Orchid	*Platanthera hyperborea*
Eyebright	*Euphrasia subarctica*
Horsetail	*Equisetum* sp
Bluejoint Grass	*Calamagrostis canadensis*
Water Sedge	*Carex aquatilis* (dominant)
Golden Sedge	*Carex aurea*
Tiny orange crusticose lichens	*Caloplaca cerina*
Red Hook Moss	*Drepanocladus revolvens*

3.2 2018 Metals Data

Foliar samples were collected from each site and where possible from each of the five plots at each site. Willows were the only species that was collected from each of the four sites. The majority of the willows were *Salix pulchra*, diamond leaf willow, and this species was present at all of the sites. Dwarf birch (*Betula glandulosa*) was collected at three of the sites. Fescue (*Festuca altaica*), Bluejoint (*Calamagrostis canadensis*) and Sedges (*Carex aquatilis*) were collected at one site only. At some of the sites there wasn't enough biomass to create separate samples for willows and twigs so these were submitted as a single sample. There was insufficient biomass for individual samples of Bluejoint from each plot so grasses were collected throughout all of site D4. The following table depicts which samples were collected from each plot.

TABLE 2 FOLIAR SAMPLES COLLECTED PER PLOT

The analytical report is presented in Appendix A. Samples were analyzed for a suite of 34 metals including mercury. The highest concentrations of many of the metals were documented in the tissue samples collected from D4. This site has the greatest impact from activities as it is located close to the access road and accumulated dust was apparent on the vegetation. The general suggested location of D4 in the EMSAMP was situated at the current location of the large equipment staging area and a more suitable site was chosen. Due to the topography of the area south of here, and zones of existing disturbance, the closest appropriate site was a flat area just upstream of the Haggart Creek culverts. This site was established as D4.

The range of concentrations of each parameter for all vegetation types per site is summarized in Table A-1 (in Appendix A). There are no guidelines regarding metal concentrations in vegetation with respect to wildlife consumption (e.g., moose and/or caribou). For reference, Stantec (2011) compared the 2009 Eagle Gold foliar data to the dietary tolerances for beef cattle. These toxic values have also been included in Table A-1. For the majority of the metals where there are toxic values, concentrations in the 2018 foliar samples were well below these levels. The exception to this was manganese where some concentrations exceeded the referenced toxicity of 2000 mg/kg but were less than 4000 mg/kg. This occurred in dwarf birch leaves collected from all of the plots in D1 and three of the plots in D3 (analytical report, Appendix A).

Potential emissions related to the gold recovery process include the metals arsenic, cadmium, chromium, mercury and lead (ENSAMP, 2018). These metals have been averaged per vegetation type for the five collection plots at each site (Table 3).

TABLE 3 SELECTED METAL CONCENTRATIONS (mg/kg) PER TISSUE TYPE

Site	Tissue Type	N	Arsenic	Cadmium	Chromium	Lead	Mercury
D4	Bluejoint	1	2.27	0.0224	0.181	0.438	ND
D1	Festuca	5	0.113	0.055	0.073	0.108	ND
D4	Sedge	4	2.608	0.103	0.327	0.593	ND
D1	Dwarf Birch Leaves	5	0.187	0.187	ND	0.055	0.0054
D2	Dwarf Birch Leaves	5	2.128	0.255	0.205	0.395	0.0060
D3	Dwarf Birch Leaves	5	0.410	0.188	ND	0.066	0.005
D1	Willow Leaves	5	0.187	1.758	ND	0.082	0.0
D2	Willow Leaves	4	2.015	2.700	0.158	0.381	0.0059
D3	Willow Leaves	1	0.551	1.05	ND	0.132	0.0055
D4	Willow Leaves	5	6.800	1.712	0.636	1.384	0.006
D2	Willow Leaves & Twigs	1	2.49	2.38	0.218	0.439	0.0067
D3	Willow Leaves & Twigs	4	0.460	2.065	0.051	0.083	0.006
D1	Willow Twigs	5	0.135	1.948	ND	0.154	ND
D2	Willow Twigs	4	0.612	2.490	0.100	0.188	ND
D3	Willow Twigs	1	0.311	1.03	0.068	0.102	ND
D4	Willow Twigs	5	1.848	1.501	0.225	0.429	ND

ND = not detected

Generally the highest concentrations of the selected metals occurred in the willow leaves. The highest concentration of arsenic was found in willow leaves collected from D4, however levels were not considered toxic (Table A-1). Arsenic concentrations were relatively high in the willow and dwarf birch leaves at D2, and in the Bluejoint and Sedge tissues, both collected at D4. Of the four sites, arsenic concentration in the soil at D2 was the highest (Laberge, 2018). Arsenic values in the soil exceeded the CCME and Yukon CSR guidelines for agriculture and parkland in the soil samples from all four plots (Laberge, 2018).

Cadmium concentration in the vegetation tissues was relatively similar in the willow leaves and in the willow twigs from each site. The highest concentrations were found in the willow leaves and twigs collected from D2. However, all levels were low and well below the referenced toxic level (Table A-1).

The greatest concentration of chromium was documented in the willow leaves collected from D4 followed by sedge from D4. Chromium was not detected in the willow leaves, willow twigs and dwarf birch leaves at D1, nor in the willow or dwarf birch leaves at D3.

Concentrations of lead were highest in the willow leaves and sedge collected from D4. Concentrations were generally low throughout and were well below the referenced toxic level (Table A-1).

Mercury levels were very low in the various vegetation types at all of the sites and were not detected in any of the willow twigs, sedge, bluejoint or fescue.

3.3 Previous Data

In 2009, Stantec (2011) had foliar tissues collected in the Eagle Gold study area analyzed for metal concentrations. Unfortunately, none of the nine sites sampled correlate to the sites established under the EMSAMP. Cantest completed the analysis and used much higher detection limits than the current study. The method detection limits (MDL) have decreased over time providing more precision for the lower concentrations of metals that are reported in the 2018 tables. Complete comparisons therefore cannot be made as non detected parameters in 2009 can now be detected in 2018. Of detected parameters in both studies, the greatest arsenic concentrations reported in the 2009 study occurred in grasses collected from a slope off the access road near Platinum Gulch, with a concentration of 0.4 mg/kg. This is much lower than the 2018 highest concentration of 6.80 mg/kg documented in willow leaves from D4. Reported cadmium levels were much lower in the tissues sampled in 2009 than in 2018.

4.0 DISCUSSION

The levels of metals found in the foliar samples collected in 2018 represent baseline levels and give a general idea of the metal burden (uptake in tissues as well as through dust deposition) in various species in different ecological zones. Arsenic is potentially a parameter of concern in the Eagle Gold Project area. The soil samples collected from each of the four sites indicates high ambient levels of arsenic in each of the areas. Arsenic is associated with the gold bearing anomalies in the district and these baseline concentrations reflect the natural mineralization of the Project area. As mentioned in Section 3.2, arsenic concentrations greatly exceeded the CCME and CSR guidelines, notably in the soil at D2 (Laberge, 2018). These high soil concentrations are not reflected in the plant tissues.

The toxicity of arsenic to biota depends upon the speciation with inorganic forms generally thought to be more toxic than organic forms. .Arsenate [As(V)] is the dominant form of arsenic in aerobic soils (Meharg et al, 2002). It is similar to the macronutrient phosphate and creates toxicity in plants by competing with phosphate. Processes within the plant convert arsenate to the more toxic arsenite [As(III)]. Trivalent arsenic (arsenite) is 5 to 10 times more toxic than pentavalent arsenic (arsenate). Elemental arsenic is non-toxic. There was no visible sign of stress in any of the vegetation in the plots. The arsenic concentration in the soil at D2 was 302 mg/kg (the guideline is 12 to 15 mg/kg) yet the plants at D2 appeared healthy with a broad range of biodiversity present. It is not known what species of arsenic are present in the Project's soils or the species present in the plant tissues. Investigations into the speciation of arsenic in plant tissues have shown more than one species present (Meharg et al, 2002). Therefore, the arsenic present in the soil may not be bioavailable to plants or the availability may be limited by the mycelium associated with the vegetation types, which effectively screen out toxins at the root hairs.

5.0 RECOMMENDATIONS

It is recommended that D4 be relocated for the 2019 sampling season. A suitable location could hopefully be located approximately 50 to 100 m downstream of the culverts and away from direct contact with the road. The results then will be more representative of dust deposition in the Haggart Creek Valley but will still be located downwind of the prevailing winds at the Camp meteorological station.

Reference Information

Qualifiers for Individual Parameters Listed:

Qualifier	Description
DLM	Detection Limit Adjusted due to sample matrix effects (e.g. chemical interference, colour, turbidity).

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
HG-200.2-CVAF-VA	Soil	Mercury in Soil by CVAAS	EPA 200.2/1631E (mod)

Soil samples are digested with hot nitric and hydrochloric acids, followed by CVAAS analysis. This method is fully compliant with the BC SALM strong acid leachable metals digestion method.

HG-DRY-CVAFS-N-VA	Tissue	Mercury in Tissue by CVAFS (DRY)	EPA 200.3, EPA 245.7

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Analysis is by atomic fluorescence spectrophotometry or atomic absorption spectrophotometry, adapted from US EPA Method 245.7.

MET-200.2-CCMS-VA	Soil	Metals in Soil by CRC ICPMS	EPA 200.2/6020A (mod)

This method uses a heated strong acid digestion with HNO3 and HCl and is intended to liberate metals that may be environmentally available. Silicate minerals are not solubilized. Dependent on sample matrix, some metals may be only partially recovered, including Al, Ba, Be, Cr, Sr, Ti, Tl, V, W, and Zr. Volatile forms of sulfur (including sulfide) may not be captured, as they may be lost during sampling, storage, or digestion. Analysis is by Collision/Reaction Cell ICPMS.

MET-DRY-CCMS-N-VA	Tissue	Metals in Tissue by CRC ICPMS (DRY)	EPA 200.3/6020A

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.

N-TOT-LECO-SK	Soil	Total Nitrogen by combustion method	CSSS (2008) 22.4

The sample is ignited in a combustion analyzer where nitrogen in the reduced nitrous oxide gas is determined using a thermal conductivity detector.

N2/N3-AVAIL-SK	Soil	Nitrate, Nitrite and Nitrate+Nitrite-N	APHA 4500 NO3F

Available Nitrate and Nitrite are extracted from the soil using a dilute calcium chloride solution. Nitrate plus Nitrite is quantitatively reduced to nitrite by passage of the sample through a copperized cadmium column. The nitrite (reduced nitrate plus original nitrite) is then determined by diazotizing with sulfanilamide followed by coupling with N-(1-naphthyl) ethylenediamine dihydrochloride. The resulting water soluble dye has a magenta color which is measured at colorimetrically at 520nm. Nitrite is determined on the same extract by following the same instrumental procedure without a cadmium column.
Reference: Recommended Methods of Soil Analysis for Canadian Prairie Agricultural Soils. Alberta Agriculture (1988) p. 19 and 28

PH-1:2-VA	Soil	pH in Soil (1:2 Soil:Water Extraction)	BC WLAP METHOD: PH, ELECTROMETRIC, SOIL

This analysis is carried out in accordance with procedures described in the pH, Electrometric in Soil and Sediment method - Section B Physical/Inorganic and Misc. Constituents, BC Environmental Laboratory Manual 2007. The procedure involves mixing the dried (at <60°C) and sieved (No. 10 / 2mm) sample with deionized/distilled water at a 1:2 ratio of sediment to water. The pH of the solution is then measured using a standard pH probe.

PO4/K-AVAIL-SK	Soil	Plant Available Phosphorus and Potassium	Comm. Soil Sci. Plant Anal, 25 (5&6)

Plant available phosphorus and potassium are extracted from the soil usng Modified Kelowna solution. Phosphorous in the soil extract is determined colorimetrically at 880 nm, while potassiumis determined by flame emission at 770 nm.

PSA-1-SK	Soil	Particle Size Analysis:Mini-Pipet Method	SSIR-51 Method 3.2.1

Dry, < 2 mm soil is treated with sodium hexametaphosphate to ensure complete dispersion of primary soil particles. The homogenized suspension is allowed to settle in accordance with Stoke's Law so that only clay particles remain in suspension.To determine the clay fraction, an aliquot of the clay suspension is removed, then dried and weighed. The sand fraction is determined by wet sieving the remaining suspension, then drying and weighing the sand retained on the sieve. The silt fraction is determined by calculation where % Silt = 100 - (%Sand+%Clay)

Reference Information

S-TOT-LECO-SK	Soil	Total Sulphur by combustion method	ISO 15178:2000

The air-dried sample is ignited in a combustion analyzer where sulfur in the reduced SO2 gas is determined using a thermal conductivity detector.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
SK	ALS ENVIRONMENTAL - SASKATOON, SASKATCHEWAN, CANADA
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

1 of 5 2 of 5 3 of 5 4 of 5 5 of 5

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.
mg/kg - milligrams per kilogram based on dry weight of sample.
mg/kg wwt - milligrams per kilogram based on wet weight of sample.
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.
mg/L - milligrams per litre.
< - Less than.
D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

1.0 INTRODUCTION

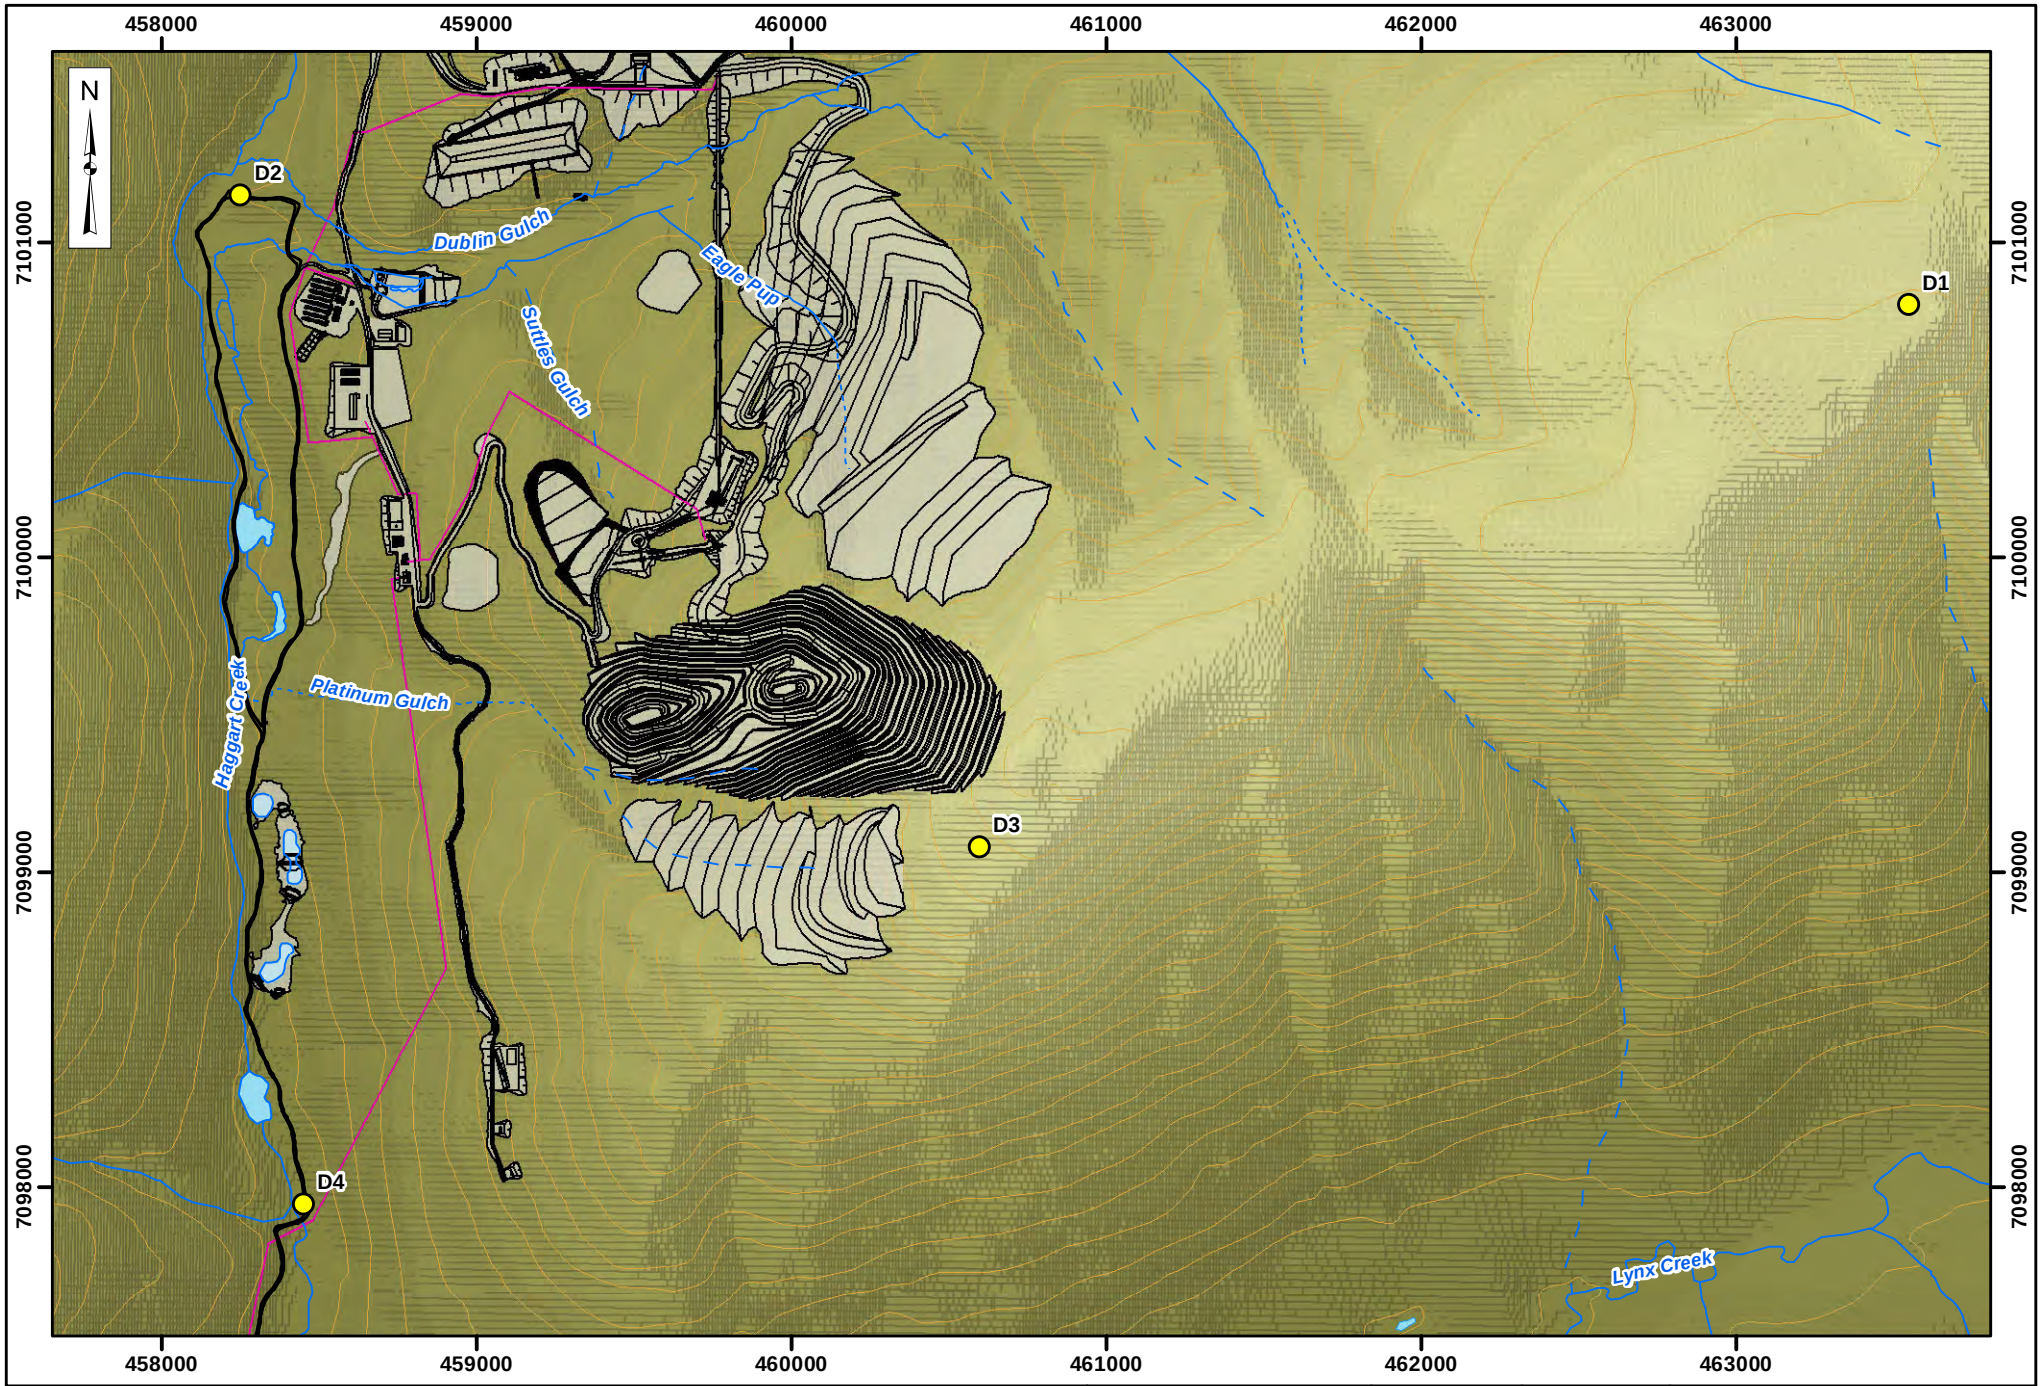
The soils monitoring program was designed to provide data to determine changes to metal and nutrient levels in soils adjacent to the mine as a result of dust deposition occurring via Project activities. The Environmental Monitoring, Surveillance and Adaptive Management Plan (EMSAMP), Version 2018-01, suggested four areas located in the Project area for the establishment of permanent plots. The soil monitoring program was undertaken in conjunction with the vegetation monitoring program conducted in early August 2018.

2.0 METHODS

Four sites for the vegetation monitoring were established in August 2018 in each of the suggested quadrants and are displayed on Figure 1. One soil sample was collected from each site, 2.5 m in from the north plot as indicated by "Year 1" on Figure 2. Sample locations are described in Table 1.

TABLE 1 LOCATION AND DESCRIPTION OF SOIL PLOTS

Plot #	Easting	Northing	Elevation (m)	Site Description
D 1	463557	7100803	1417	Potato Hills near climate station
D 2	458251	7101150	834	Upslope of the air quality station and the camp climate station
D 3	460598	7099079	1356	Top of Eagle Pup near the over-the-top road
D 4	458450	7097945	757	On the west side of the access road just upstream of the Haggart Creek culverts



Samples were collected with a stainless steel trowel from a depth of 0 to 0.5 m below the litter layer. Samples were transferred into clean glass jars for metal analysis and into ziplock plastic bags for the remaining analyses. New nitrile gloves were worn prior to sampling to prevent cross-contamination between sites. Samples were kept cool until delivered to the ALS lab/depot in Whitehorse, Yukon.

At the laboratory the following analyses were performed:

pH in Soil
Analysis was performed based on procedures described in the "Manual on Soil Sampling and Methods of Analysis" (1993) published by the Canadian Society of Soil Science. The test is performed using a deionized water leach with measurement by pH meter.

Silver, Arsenic, Cadmium, Selenium and Thallium
Inductively, Coupled Plasma Mass Spectrometry (ICP/MS).

Mercury–Cold Vapour Atomic Fluorescence.

Particle Size Analysis
The particle size distribution was determined in accordance with Methods of Soil Analysis Part 1-Physical and Mineralogical Methods (2nd Ed), UBC Methods Manual for Soil Analysis (1981) and Soil Sampling and Methods of Analysis (1993). The percentage gravel, sand, slit and clay was determined by a combination of a standard dry sieve, wet sieve and pipetting techniques. Particle size limits used to define size fractions are based according to Canadian Soil Survey Committee (CSSC) and U.S. Department of Agriculture (USDA) classification scheme. Soil texture is determined according to CSSC definition of texture. The size fractions that are analyzed are 2.0, 0.250, 0.125, 0.053 and 0.002 mm. The % Sand, % Slit and % Clay are based on the <2 mm fraction of the sample by weight.

Molybdenum
Acid digestion followed by determination using Inductively Coupled Plasma Mass Spectrometry (ICP/MS).

Strong Acid Leachable Metals in Soil
B.C. MOELP Method “Strong Acid Leachable Metals in Soil Version1.0”. The method involves drying the sample at 60 C, sieving using a 2 mm (10 mesh) sieve and digestion using a mixture of hydrochloric and nitric acids. Analysis is performed using inductively Coupled Argon Plasma Spectroscopy (ICAP) or by specific techniques as described.

Total Nitrogen and Sulfur
Combustion analyzer where nitrogen in the reduced nitrous oxide gas is determined using a thermal conductivity detector.

Available NO3 and Available NO2
Available Nitrate and Nitrite was extracted from the soil sample using a dilute calcium chloride solution. Nitrate was quantitatively reduced to nitrite by passage of the sample through a copperized Cadmium column. The nitrite (reduced nitrate plus original nitrite) was then determined by diazotizing with sulfanilamide followed by coupling with N-(1-naphthyl) ethylenediamine dihydrochloride. The resulting watersoluble dye has a magenta color which, is measured colorimetrically at 520 nm.

Available P and Available K
Plant available phosphorus and potassium were extracted from the soil using Modified Kelowna solution. Phosphorous in the soil extract is determined colorimetrically at 880 nm, while potassium is determined by flame emission at 770 nm.

3.0 RESULTS AND DISCUSSION

3.1 2018 Data

A total of four soil samples was collected and analyzed for a range of parameters. The analytical report is presented in Appendix A.

The soil samples were sieved and based on the distribution of grain sizes less than 2mm, texture was determined (Table 2). The texture of the soil at D-1 was sandy loam, sand at D-2, and silt loam at D-3 and D-4.

TABLE 2	PARTICLE SIZE AND TEXTURE			
Site	**D-1**	**D-2**	**D-3**	**D-4**
Date Sampled	1-Aug-2018	1-Aug-2018	2-Aug-2018	2-Aug-2018
% Sand (2.0mm - 0.05mm)	50.0	91.3	38.4	27.8
% Silt (0.05mm - 2um)	45.7	8.2	57.4	68.8
% Clay (<2um)	4.3	<1.0	4.2	3.4
Texture	Sandy loam	Sand	Silt loam	Silt loam

Nutrients and available plant nutrients were analyzed and summarized in Table 3.

TABLE 3	PLANT AVAILABLE NUTRIENTS			
Site	**D-1**	**D-2**	**D-3**	**D-4**
Date Sampled	1-Aug-2018	1-Aug-2018	2-Aug-2018	2-Aug-2018
Nutrients				
Total Nitrogen %	0.710	0.026	0.066	0.098
Plant Available Nutrients				
Nitrate+Nitrite-N (mg/kg)	<3.0	<2.0	<2.0	<2.0
Nitrate-N (mg/kg)	<3.0	<2.0	<2.0	<2.0
Nitrite-N (mg/kg)	<1.2	<0.40	<0.40	<0.40
Available Phosphate-P (mg/kg)	<2.0	2.3	2.0	<2.0
Available Potassium (mg/kg)	136	43	39	96

Soil at D-1 had the highest total nitrogen content at 0.710%. However, plant available nitrogen in the form of Nitrate+Nitrite, Nitrate and Nitrite were all below the method detection limits (MDL) in all soil samples. Available phosphate was just barely detected in the soils at D-2 and D-3. Available potassium was present in all samples and ranged from 39 mg/kg at D-3 to 136 mg/kg at D-1.

The soil samples were also analyzed for pH and a suite of 36 metals (Table A-1, Appendix A). The soils were somewhat acidic to near neutral ranging from 4.62 at D-1 to 6.42 at D-4. Boron, sulphur and tin were not detected in any of the samples.

The most recent Canadian Council of Ministers of the Environment (CCME) guidelines, which include new guidelines from 2018, and the Yukon Contaminated Sites Regulations for agriculture and parklands were tabulated and compared to the range of concentrations found throughout project area (Table 4). Arsenic was the only parameter that exceeded all of the recommended guidelines and occurred in all samples ranging from 15.1 mg/kg at D-1 to 302 mg/kg at D-2, highlighted in pink. The remaining elements met all of the guidelines.

Selected photographs of each site are provided in Appendix B.

TABLE 4 RANGE OF RESULTS COMPARED TO CCME AND YUKON AGRICULTURE AND PARKLAND GUIDELINES FOR METALS IN SOILS

Element	CCME (mg/kg)		Yukon CSR (mg/kg)		Range of Results (mg/kg)
	Agriculture	Parkland	Agriculture	Parkland	
Antimony (Sb)	20	20	20	20	2.00 to 9.03
Arsenic (As)	12	12	15	15	15.10 to 302.00
Barium (Ba)	750	500	750	500	124.00 to 205.00
Beryllium (Be)	4	4	4	4	0.38 to 0.55
Cadmium (Cd)	1.4	10	1.5	1.5	0.12 to 0.42
Chromium (Cr)	64	64	50	60	16.90 to 42.20
Cobalt (Co)	40	50	40	50	5.94 to 13.50
Copper (Cu)	63	63	90	90	18.00 to 28.90
Lead (Pb)	70	140	100	100	19.80 to 40.60
Mercury (Hg)	6.6	6.6	0.6	15	0.02 to 0.07
Molybdenum (Mo)	5	10	5	10	0.83 to 1.19
Nickel (Ni)	45	45	150	150	17.70 to 35.30
Selenium (Se)	1	1	2	1	0.25 to 0.37
Silver (Ag)	20	20	20	20	0.11 to 0.22
Thallium (Tl)	1	1	2	--	0.15 to 0.25
Tin (Sn)	5	50	5	50	ND
Uranium	23	23			1.12 to 1.75
Vanadium (V)	130	130	200	200	20.90 to 55.10
Zinc (Zn)	250	250	150	150	56.60 to 90.40

ND = not detected

3.2 Previous Data

In 2009 Stantec completed baseline soil surveys (Stantec, 2011). None of the 18 soil samples (surface soil samples and overburden samples) submitted for metal analysis coincided with the locations of the four soil samples collected in 2018. As with the current survey however, arsenic also exceeded the CCME and Yukon guidelines for agriculture and parkland.

SRK conducted analysis on metasediment samples collected from 2007, consisting primarily of drill core from the exploration program and from the 2009 geotechnical drilling programs (SRK, 2014). Arsenic concentrations ranged from 24 mg/kg to 740 mg/kg for 120 samples.

Arsenic is prevalent throughout the Eagle Gold Project area and the concentrations documented in the current study are a reflection of natural concentrations found in the undisturbed soils.

4.0 SUMMARY

The soils at the Eagle Gold Project are nutrient poor. The sampled soils were fairly acidic to near neutral, and with the exception of arsenic had low metal concentrations that met CCME and Yukon CSR guidelines for agriculture and parkland. Arsenic concentrations in all soil samples exceeded these guidelines. Arsenic is associated with the gold bearing anomalies in the district and these baseline concentrations reflect the natural mineralization of the Project area.

APPENDIX A

- **TABLE A-1**
- **ANALYTICAL REPORT, AUGUST 2018**

TABLE A-1 SUMMARY OF ANALYTICAL RESULTS, 2018

Site	D-1	D-2	D-3	D-4
Date Sampled	1-Aug-2018	1-Aug-2018	2-Aug-2018	2-Aug-2018
pH (1:2 soil:water)	4.62	5.78	4.85	6.42
Aluminum (Al)	15200	7440	15500	8340
Antimony (Sb)	2.00	6.13	6.21	9.03
Arsenic (As)	15.1	302	115	155
Barium (Ba)	134	124	205	138
Beryllium (Be)	0.47	0.40	0.55	0.38
Bismuth (Bi)	<0.20	0.69	0.64	0.64
Boron (B)	<5.0	<5.0	<5.0	<5.0
Cadmium (Cd)	0.123	0.402	0.258	0.421
Calcium (Ca)	1300	1980	1930	2930
Chromium (Cr)	26.2	16.9	42.2	18.3
Cobalt (Co)	5.94	11.6	11.0	13.5
Copper (Cu)	18.0	18.4	28.9	27.5
Iron (Fe)	21200	19800	28800	28500
Lead (Pb)	19.8	26.9	40.6	37.8
Lithium (Li)	13.4	15.9	19.7	14.5
Magnesium (Mg)	3880	3570	6050	3620
Manganese (Mn)	195	520	346	578
Mercury (Hg)	0.0543	0.0219	0.0239	0.0708
Molybdenum (Mo)	1.19	1.08	0.83	0.84
Nickel (Ni)	17.7	22.6	35.3	31.1
Phosphorus (P)	531	407	483	490
Potassium (K)	850	2590	1840	1060
Selenium (Se)	0.37	<0.20	0.25	0.36
Silver (Ag)	0.11	<0.10	<0.10	0.22
Sodium (Na)	86	162	91	82
Strontium (Sr)	13.2	19.9	17.0	26.2
Sulfur (S)	<1000	<1000	<1000	<1000
Sulfur (S)-Total	1500	600	700	1000
Thallium (Tl)	0.220	0.252	0.234	0.152
Tin (Sn)	<2.0	<2.0	<2.0	<2.0
Titanium (Ti)	514	717	727	242
Tungsten (W)	4.35	16.0	<0.50	3.58
Uranium (U)	1.75	1.46	1.12	1.47
Vanadium (V)	55.1	20.9	47.3	22.9
Zinc (Zn)	56.6	65.6	73.5	90.4
Zirconium (Zr)	<1.0	3.1	<1.0	1.7

Units for metals concentrations : mg/kg

Reference Information

Qualifiers for Individual Parameters Listed:

Qualifier	Description
DLM	Detection Limit Adjusted due to sample matrix effects (e.g. chemical interference, colour, turbidity).

Test Method References:

ALS Test Code	Matrix	Test Description	Method Reference**
HG-200.2-CVAF-VA	Soil	Mercury in Soil by CVAAS	EPA 200.2/1631E (mod)

Soil samples are digested with hot nitric and hydrochloric acids, followed by CVAAS analysis. This method is fully compliant with the BC SALM strong acid leachable metals digestion method.

HG-DRY-CVAFS-N-VA	Tissue	Mercury in Tissue by CVAFS (DRY)	EPA 200.3, EPA 245.7

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Analysis is by atomic fluorescence spectrophotometry or atomic absorption spectrophotometry, adapted from US EPA Method 245.7.

MET-200.2-CCMS-VA	Soil	Metals in Soil by CRC ICPMS	EPA 200.2/6020A (mod)

This method uses a heated strong acid digestion with HNO3 and HCl and is intended to liberate metals that may be environmentally available. Silicate minerals are not solubilized. Dependent on sample matrix, some metals may be only partially recovered, including Al, Ba, Be, Cr, Sr, Ti, Tl, V, W, and Zr. Volatile forms of sulfur (including sulfide) may not be captured, as they may be lost during sampling, storage, or digestion. Analysis is by Collision/Reaction Cell ICPMS.

MET-DRY-CCMS-N-VA	Tissue	Metals in Tissue by CRC ICPMS (DRY)	EPA 200.3/6020A

This method is conducted following British Columbia Lab Manual method "Metals in Animal Tissue and Vegetation (Biota) - Prescriptive". Tissue samples are homogenized and sub-sampled prior to hotblock digestion with nitric and hydrochloric acids, in combination with addition of hydrogen peroxide. Instrumental analysis is by collision cell inductively coupled plasma - mass spectrometry (modified from EPA Method 6020A).

Method Limitation: This method employs a strong acid/peroxide digestion, and is intended to provide a conservative estimate of bio-available metals. Near complete recoveries are achieved for most toxicologically important metals, but elements associated with recalcitrant minerals may be only partially recovered.

N-TOT-LECO-SK	Soil	Total Nitrogen by combustion method	CSSS (2008) 22.4

The sample is ignited in a combustion analyzer where nitrogen in the reduced nitrous oxide gas is determined using a thermal conductivity detector.

N2/N3-AVAIL-SK	Soil	Nitrate, Nitrite and Nitrate+Nitrite-N	APHA 4500 NO3F

Available Nitrate and Nitrite are extracted from the soil using a dilute calcium chloride solution. Nitrate plus Nitrite is quantitatively reduced to nitrite by passage of the sample through a copperized cadmium column. The nitrite (reduced nitrate plus original nitrite) is then determined by diazotizing with sulfanilamide followed by coupling with N-(1-naphthyl) ethylenediamine dihydrochloride. The resulting water soluble dye has a magenta color which is measured at colorimetrically at 520nm. Nitrite is determined on the same extract by following the same instrumental procedure without a cadmium column.
Reference: Recommended Methods of Soil Analysis for Canadian Prairie Agricultural Soils. Alberta Agriculture (1988) p. 19 and 28

PH-1:2-VA	Soil	pH in Soil (1:2 Soil:Water Extraction)	BC WLAP METHOD: PH, ELECTROMETRIC, SOIL

This analysis is carried out in accordance with procedures described in the pH, Electrometric in Soil and Sediment method - Section B Physical/Inorganic and Misc. Constituents, BC Environmental Laboratory Manual 2007. The procedure involves mixing the dried (at <60°C) and sieved (No. 10 / 2mm) sample with deionized/distilled water at a 1:2 ratio of sediment to water. The pH of the solution is then measured using a standard pH probe.

PO4/K-AVAIL-SK	Soil	Plant Available Phosphorus and Potassium	Comm. Soil Sci. Plant Anal, 25 (5&6)

Plant available phosphorus and potassium are extracted from the soil usng Modified Kelowna solution. Phosphorous in the soil extract is determined colorimetrically at 880 nm, while potassiumis determined by flame emission at 770 nm.

PSA-1-SK	Soil	Particle Size Analysis:Mini-Pipet Method	SSIR-51 Method 3.2.1

Dry, < 2 mm soil is treated with sodium hexametaphosphate to ensure complete dispersion of primary soil particles. The homogenized suspension is allowed to settle in accordance with Stoke's Law so that only clay particles remain in suspension.To determine the clay fraction, an aliquot of the clay suspension is removed, then dried and weighed. The sand fraction is determined by wet sieving the remaining suspension, then drying and weighing the sand retained on the sieve. The silt fraction is determined by calculation where % Silt = 100 - (%Sand+%Clay)

Reference Information

S-TOT-LECO-SK	Soil	Total Sulphur by combustion method	ISO 15178:2000

The air-dried sample is ignited in a combustion analyzer where sulfur in the reduced SO2 gas is determined using a thermal conductivity detector.

** ALS test methods may incorporate modifications from specified reference methods to improve performance.

The last two letters of the above test code(s) indicate the laboratory that performed analytical analysis for that test. Refer to the list below:

Laboratory Definition Code	Laboratory Location
SK	ALS ENVIRONMENTAL - SASKATOON, SASKATCHEWAN, CANADA
VA	ALS ENVIRONMENTAL - VANCOUVER, BRITISH COLUMBIA, CANADA

Chain of Custody Numbers:

1 of 5 2 of 5 3 of 5 4 of 5 5 of 5

GLOSSARY OF REPORT TERMS

Surrogate - A compound that is similar in behaviour to target analyte(s), but that does not occur naturally in environmental samples. For applicable tests, surrogates are added to samples prior to analysis as a check on recovery.
mg/kg - milligrams per kilogram based on dry weight of sample.
mg/kg wwt - milligrams per kilogram based on wet weight of sample.
mg/kg lwt - milligrams per kilogram based on lipid-adjusted weight of sample.
mg/L - milligrams per litre.
< - Less than.
D.L. - The reported Detection Limit, also known as the Limit of Reporting (LOR).
N/A - Result not available. Refer to qualifier code and definition for explanation.

Test results reported relate only to the samples as received by the laboratory.
UNLESS OTHERWISE STATED, ALL SAMPLES WERE RECEIVED IN ACCEPTABLE CONDITION.
Analytical results in unsigned test reports with the DRAFT watermark are subject to change, pending final QC review.

EXECUTIVE SUMMARY

Following advanced exploration activities and obtaining regulatory approvals, Victoria Gold Corp.'s Eagle Gold Mine (the Project) is advancing to the construction stage. As part of their operating licence terms and conditions, Victoria Gold is required to conduct annual winter moose surveys within 10 km of the Project footprint.

The primary objective of this study was to document the distribution and abundance of moose during the late-winter season to inform adaptive management strategies to mitigate Project effects on moose. The 2018 survey is the first construction phase survey completed at the Eagle Gold Mine and builds on the baseline/pre-construction studies conducted from 2011 to 2013.

The 2018 aerial survey was conducted in the late-winter on 5 and 6 March 2018. A total of 10.8 hours of flight time was required to complete the moose survey resulting in a survey intensity of 0.49 min/km² which is consistent with standard intensive stratification survey protocols required for adequate coverage. A total of 100 moose were observed during the survey of which 75 were observed within the study area boundary. Most moose were observed as individuals or pairs.

The number of moose observed within the survey area in 2018 was higher than in previous surveys Potential factors for the variation in moose numbers could include observer bias and seasonal variability in the regional distribution of moose. The latter can be influenced by annual and regional variations in snow characteristics such as depth and hardness and could also be the result of high wolf activity preceding the survey within or near habitats seasonally important to moose. Moose distribution also differed from previous surveys where moose were often located in moderate to low elevation habitats. In 2018, most moose were located in moderate elevation burns to subalpine shrubs and spruce. No moose were located in the South McQuesten River and Haggart Creek valleys where moderate to high densities of moose are usually located.

ACKNOWLEDGEMENTS

The 2018 Eagle Gold Project moose survey was completed with the assistance from Lindsay Rear (Victoria Gold Corp.), Stephan Walke (First Nation of Na-Cho Nyäk Dun), and Andrew Swenson (Alpine Aviation). Their professionalism, vigilance, and companionship during the survey were greatly appreciated.

AUTHORSHIP

1 BACKGROUND

Following advanced exploration activities and obtaining regulatory approvals, Victoria Gold Corp.'s (VIT) Eagle Gold Mine (the Project) is advancing to the construction stage. As part of their operating licence terms and conditions, Victoria Gold is required to conduct annual winter moose surveys within 10 km of the Project footprint. The Eagle Gold Mine will produce ore from a conventional open pit operation and gold recovery plant. The Project is located approximately 85 km by road from the village of Mayo and VIT has year-round road access to the site. The Eagle Gold Project has received all major permits required for construction and operations following the Environmental Assessment process.

As part of the environmental assessment completed under *YESAA*, VIT committed to conduct annual winter moose distribution surveys. Commitment #35 from Appendix A of the YESAB Screening Report and Recommendation (YOR 2010-0267-358-2) states:

> *VIT will implement annual aerial mapping of winter moose distribution within 5 km of the access road and mine site and in adjacent control areas. This will be conducted before construction (in 2011 and 2012), during construction, and during mine operations, to allow assessment of displacement and population reduction resulting from mine activities, and adaptive management measures if negative effects occur.*

Commitment #35 is re-iterated in the Final Screening Report and Recommendation issued by YESAB February 13, 2013. However, the YESAB recommendation specifies that the survey area be extended to 10 km from Project infrastructure. This recommendation was initially proposed August 24, 2011 by Environment Yukon's Environmental Programs Branch (YOR 2010-0267-197-1). It was recommended that the study design change to delineate a zone of influence (ZOI) extending 5 km from the Project area and access road and that a survey area extending from 5 km to 10 km beyond the ZOI be treated as the "control" area. This study design, referred to as before-after control-impact (BACI), is intended to detect changes in moose distribution near Project infrastructure due to unanticipated Project effects.

In their Screening Report and Recommendation issued on February 19, 2013, YESAB recommended to the Yukon Government that this commitment become a Term and Condition which was supported by the Yukon Government in their Decision Document (YOR 2010-0267-361-1). Term and Condition #99 states:

> *The Proponent shall, in cooperation with Government of Yukon, Department of Environment, design and conduct annual winter moose surveys consistent with methodology and study area (ten kilometres from infrastructure) used in 2011.*

Moose are the most common ungulate species in the region and occur in the Project area during all seasons. The most critical season for moose is late-winter (January–April) when availability and access to food is most limited. The Project area is identified as important moose habitat by local residents and contains some higher quality early successional and lower elevation winter habitat. Winter habitats of particular importance are the South McQuesten River and Haggart Creek valleys (Stantec Consulting Ltd. 2011b).

Studies examining the effects of disturbance on the distribution and behaviour of moose along access corridors found that these effects were limited to within 1000 m of the corridors (Colescott and Gillingham

1998, Yost and Wright 2001, Laurian et al. 2008, 2012, Shanley and Pyare 2011). If avoidance of habitat due to mining related activities was observed, this data would be useful in understanding moose distribution near and on the access road in order to implement additional mitigation measures to reduce traffic/moose interactions and potential of vehicle collisions.

In consultation with Environment Yukon, VIT agreed to conduct late-winter moose distribution monitoring relative to the Project infrastructure for a total of five years including 2 years pre-construction, 2 years of construction phase, and the first year of operations (email communication with Mark O'Donoghue, Northern Tutchone Regional Biologist, on 5 August 2010). The study was designed by Environment Yukon to monitor moose distribution within the ZOI of the proposed mine site (0 to 1 km), and to include a control area well outside of the ZOI (5 to 10 km). If no effects were observed after five years of monitoring, the parties agreed that the frequency of this monitoring could be reduced during subsequent years of the operations phase (email communication with Mark O'Donoghue, Northern Tutchone Regional Biologist, on 5 August 2010).

To date, moose surveys were conducted in early-March of 2011, 2012, and 2013. The 2011 baseline moose distribution survey was conducted in March 2011 by Stantec (Stantec Consulting Ltd. 2011a) using a 10 km buffer from the Project and access road footprints. The 2012 and 2013 surveys were conducted by EDI Environmental Dynamics Inc. (EDI) using the 2011 survey methodology and study area as per Term and Condition #99 (EDI Environmental Dynamics Inc. 2012, 2013). However, in consultation with the Environment Yukon Regional Biologist for the Northern Tutchone Region, EDI made some slight modifications to the survey methodology to improve efficiency, moose detection rates, and crew safety while maintaining the same survey intensity.

This report presents and compares the results of the 2018 late-winter moose distribution survey with those of previous surveys. The 2018 survey follows the three baseline/pre-construction and represents the first construction phase survey upon which subsequent surveys will be compared to evaluate potential changes in moose distribution and abundance in the survey area.

2 METHODS

2.1 SURVEY AREA

The Project is located approximately 45 km north of Mayo. In 2011, a 1,130 km² survey area was generated by applying a 10 km buffer to the proposed mine site and the access road footprints. In 2012, the size of the survey area was increased by 10 km² to accommodate a modified Project footprint. In 2013, a survey grid comprised of 5 minutes longitude by 2 minutes latitude blocks (approximately 4 x 4 km at this latitude) was developed to guide survey intensity. This method also aligns with the methods used by the Yukon Government for moose stratification (distribution) surveys (Environment Yukon 2010, O'Donoghue et al. 2014). The addition of blocks at the edge of the survey area increased the size of the survey area from 1,140 km² to 1,320 km². The 2018 survey followed the same survey design as the 2013 survey (Map 1).

Most of the survey area is suitable moose habitat except for small portions of rock cliffs and scree on Mount Haldane and other hill tops as well as a few small lakes. The Silver Trail Highway, which extends from Mayo to Keno City, cuts across the southeast corner of the study area. Major geographic features of the area include the valley and riparian flats of the South McQuesten River as well as Mount Haldane, a prominent mountain in the region.

The survey area lies entirely within the Yukon Plateau North ecoregion (Yukon Ecoregions Working Group 2004). The survey area consists of rolling highlands with a generally northeast-southwest orientation dissected by numerous small creeks. Vegetation cover is predominantly boreal but ranges from boreal to alpine. Alpine environments are characterized by low ericaceous shrubs, small willows (*Salix sp.*), and lichens. Subalpine environments are typically vegetated with willow and shrub birch (*Betula glandulosa*) with scattered white spruce (*Picea glauca*) and subalpine fir (*Abies lasiocarpa*). At lower elevations, black spruce (*P. mariana*) and white spruce forests grow over moist sites. Trembling aspen (*Populus tremuloides*), lodgepole pine (*Pinus contorta*), and white spruce stands grow in warmer and better-drained sites. Some nearly pure deciduous stands comprised primarily of birch and aspen can be found on south aspect slopes in southeastern portions of the study area. A riparian flat approximately 3 km wide dominated by a mix of shrub lands, grasslands, and black spruce can be found along the South McQuesten River.

The survey area is located near the Tintina Trench, which has a high incidence of thunderstorms. Consequently, the study area has a complex and diverse forest fire history contributing to the high diversity of forest covers. These burned areas have variable habitat suitability for moose depending on their age, elevation, and intensity of the burn. Two large fires have occurred recently in the study area. The most recent is a 2005 fire that burned 55 km² of forest in the headwaters of Shanghai Creek north of the South McQuesten River and that extended west to the Project area. A 1998 fire that burned 71 km² of forest from Hanson Lake to Skate Creek only partially overlaps with the study area. Other smaller fires, mainly from the mid-1990s, are scattered throughout the area.

Mean annual temperatures are –5°C, but temperatures vary widely by season and elevation. Mean January temperatures range from below -30°C in the lower valleys to above -20°C over higher terrain. This gradient

shifts in July when mean temperatures are 15°C in the valley bottoms and 8°C over higher terrain. Rain and snowfall is moderate in the region and annual precipitation amounts range from 300 to 600 mm. Winds are usually light, and only moderate to strong in thunderstorms or unusually active weather systems.

2.2 SURVEY DETAILS

The survey took place 5 and 6 March 2018. Surveyors included Andrew Swenson (pilot, Alpine Aviation), Alain Fontaine (navigator, EDI), Lindsay Rear (observer, VIT) and Stephan Walshe (observer, FNNND). The survey was completed with a Cessna 206 (C-FBVA) flown at 120–150 km/hr and an elevation of 100–200 m above ground level.

The design of the 2011 moose survey included forty east-west transects spaced at 1 km intervals (Stantec Consulting Ltd. 2011a). Flight lines followed the planned transects to the extent possible based on flight and terrain conditions. In 2012, EDI adjusted the survey methods used in the 2011 survey to increase their efficiency, moose sightability, and safety in mountainous terrain while maintaining the same survey intensity. The method used the same transect spacing (1 km) but did not restrict the survey crew to predetermined east-west transect lines. Instead, the survey crew flew linear transects (generally east-west) when flying over terrain with moderate topography but adjusted transects to follow contour lines over terrain with more relief and topography. This allowed the aircraft to fly at a more consistent height and speed and minimized crew discomfort which generally improves ungulate detection rates.

In 2013 and 2018, survey blocks were used to guide survey intensity while providing flexibility to fly according to terrain. This alteration in methodology improves comparability among years and with other moose surveys conducted by Environment Yukon (Environment Yukon 2010). Blocks were used to confirm that a minimum of four passes were flown through each block, which is equivalent to 1 km transect spacing and similar to previous surveys. As per the 2012 survey, linear north-south and east-west transects were flown over terrain with moderate topography while terrain guided transects in areas with more relief. A limitation of moose distribution surveys is a sightability bias toward open habitat. Moose are more easily observed in open habitat compared to dense cover and open habitat are often composed of early seral stage vegetation (i.e., burns) that contain higher browse quality (i.e., shrubs). Furthermore, monitoring of moose distribution via annual aerial surveys provides a snapshot in time of moose abundance and distribution that can be influenced by weather, snow conditions, and predation risk.

During the survey, observers recorded all moose and fresh moose track observations as well as any incidental wildlife sightings. All moose tracks and observations were recorded as waypoints using a handheld GPS (Garmin GPSMAP 64). Wildlife observations documented the species and number of animals in the group and, when possible, the age class (adult/calf) and sex of the animals. However, it is generally difficult to classify animals by age and sex during moose distribution surveys given the speed and elevation of fixed-wing aircraft. Therefore, most moose were unclassified. We estimated the distance and direction of animals relative to the position of the plane when the waypoint was recorded to correct the spatial location. Only fresh tracks that crossed directly under the flight path of the aircraft were recorded during the survey.

Consequently, tracks did not require spatial correction. The track recording protocol is consistent with methods developed by Environment Yukon for collecting moose track data (Environment Yukon 2011). The observed tracks were categorized as one, two, several (three to five), or many (more than five) track sets to indicate the relative number of animals.

2.3 SURVEY CONDITIONS

Survey conditions in 2018 were ideal for aerial wildlife surveys (Table 1). Weather conditions were consistent throughout the survey; winds were calm, clouds were high with low to moderate cover, light conditions were generally bright which helped to detect and assess the relative age of moose tracks (fresh vs old), and temperatures ranged from -10°C to -20°C. Light snow and low ceilings delayed the start of the survey on 6 March but conditions were clear by the time we started the survey. Survey conditions were also ideal for aerial wildlife surveys in 2012 and 2013 but old snow and flat light during afternoons in 2011 made it more difficult to sight moose (Table 1).

Table 1. Survey conditions during the 2011-2013 and 2018 late-winter moose distribution surveys at the Eagle Gold Project.

Survey Conditions	2011	2012	2013	2018
Date	7-9 March	7-8 March	4-6 March	5-6 March
Snow Condition	Old (> 2 weeks)	Lots of fresh snow prior to survey	~10 days old	Some fresh snow prior to survey and on morning of 6 March
Cloud Cover	Clear in morning changing to overcast by late afternoon on all days	Clear to slightly overcast on 8 March	Clear	Clear on 5 March; clear in morning changing to slightly overcast by mid-afternoon on 6 March
Light	Bright in morning to flat by late afternoon	Bright	Bright	Bright
Wind	Light to moderate	Calm	Calm	Calm
Temperature	-35°C to -17°C	-30°C to -10°C	-27°C to -10°C	-20°C to -10°C
Comment	Old snow and flat afternoon light made it difficult to sight moose	Considerable snow fall in days prior to survey	Delayed both mornings due to low fog	Light snow and low ceiling delayed start of survey on second day

3 RESULTS AND DISCUSSION

A total of 12.0 hours of flight time was required to complete the survey of which 10.8 hours was spent surveying moose and 1.2 hours was needed to ferry between the survey area and Mayo. In addition, approximately 3 hours of ferry time was required to mobilize and demobilize the aircraft between Whitehorse and Mayo.

Survey intensity was consistent across years and ranged from 0.49 min/km² in 2018 to 0.53 min/km² in 2011 (Table 2). A survey intensity of 0.4 to 0.5 min/km² is required for adequate coverage of the study area and for consistency in comparing survey results between years and with other surveys across Yukon (Environment Yukon 2010). In total, 100 moose were observed during the survey of which 75 were observed within the study area boundary (Table 2). Most moose were observed as individuals or pairs with few observations of groups of three or four moose.

The number of moose observed within the survey area in 2018 was much higher than in previous surveys (Table 2). Potential factors for the variation in moose numbers could include observer bias and a change in the regional distribution of moose. The latter can be influenced by annual and regional variations in snow characteristics such as depth and hardness and could also be the result of high wolf activity preceding the survey within or near habitats seasonally important to moose.

Table 2. Survey intensity and moose observations within the survey area for the 2011-2013 and 2018 late-winter moose distribution surveys at the Eagle Gold Project.

Year	Survey Intensity (min/km²)	Study Area (10 km buffer)	Total Moose Observed[1]
2011	0.53	26	31
2012	0.52	48	61
2013	0.50	39	74
2018	0.49	75	100

[1]Inlcudes moose observed just outside study area, within the survey grid (2013 and 2018), and incidental moose observations in transit to and from Mayo.

Typically in Yukon, as winter progresses and snow depth increases, moose move from subalpine habitats to valley bottoms (O'Donoghue 2005, O'Donoghue et al. 2014). Local knowledge and results from Environment Yukon surveys confirm that moose in this region exhibit this typical seasonal movement from higher to lower elevation as winter advances (Stantec Consulting Ltd. 2011b, O'Donoghue et al. 2014). Although moose are well adapted to snow environments, characteristics of snow such as temperature, density, hardness, and depth, influence moose movement and habitat use (Peek 2007). Snow depth is the most frequently studied variable and depths of 70 to 99 cm have been shown to restrict moose movement (Kelsall 1969, Telfer 1970, Peek 2007).

However, despite snow depth in the range typical of those restricting moose movement (Table 3), at the time of the survey moose did not follow this pattern of altitudinal migration in 2018. High concentrations of

moose were observed on moderate and higher elevation burned plateaus on the eastern side of the survey area, namely within the 2005 Shanghai Creek drainage burn (blocks 34, 35, and 44) and in the portion of the 1998 Hanson Lake burn that overlaps the northeastern corner of the study area (blocks 19 and 27; Map 1). We also observed small clusters of moose in the small mid-1990's burns along the southern boundary of the study area. A relatively high concentration of moose was observed in a series of high elevation ridges running predominantly southwest-northeast between Haggart Creek and Red Mountain. In this broad area, moose were observed in mixed shrub and spruce in subalpine or near subalpine areas. Moose and/or fresh tracks were observed throughout the survey area; however, very few fresh moose tracks were observed near creek bottoms or river valleys. We saw no moose and few fresh tracks within the South McQuesten River flats and the Haggart Creek valley; both valleys are reported to be important for moose in late-winter (Stantec Consulting Ltd. 2011b) and are overlapped in part by a moose late-winter key area (Map 1).

We present moose densities rather than the total number of moose observed within each distance buffer to provide a better basis for comparison because the area of each buffer gets progressively larger as they get further away from the Project footprint. Selecting a moose density relative to a 100 km² area rather than per 1000 km² as they are generally reported by Environment Yukon maintained the densities relatively close to the total numbers we observed since the area covered by the buffers ranged from 104 to 130 km².

Moose densities of 0 moose per 100 km² were observed within 1 km of the proposed Project footprint along the Haggart Creek Access Road and existing advanced exploration camp in 2018, compared to 11.2 moose per 100 km² in both 2013 and 2012, and 6.1 moose per 100 km² in 2011 (Figure 1). The Haggart Creek valley contains abundant browse and cover that moose select for winter habitat. Human disturbance adjacent to the Haggart Creek Access Road has created similar high-quality habitat because of clearing associated with the road right of way and historic placer mining operations. Moose are likely to continue to use these areas as late-winter habitat; however, the intensity of use appears to be highly variable between years. Human activity along the access road and at the Project site during the winter 2018 survey was similar to that of previous surveys; construction activities occurred from August to October 2017 and were started again in April 2018. Therefore, construction activities did not influence moose distribution in early-March 2018.

The distribution of moose observed within the survey area changed throughout all survey years (Map 2). However, some important areas are noticeably important across survey years such as the 2005 Shanghai Creek burn, the 1998 Hanson Lake burn, the high elevation ridges between Red Mountain and Haggart Creek, and small burns along the southern edge of the study area. Moose made greater use of low elevation habitats during the 2011 to 2013 surveys; few moose were observed at low elevation during the 2018 survey. During the 2011 survey, moose were observed scattered throughout the survey area with the majority of animals occurring at mid to lower elevations east and south-east of the mine site between Lynx Creek and the South McQuesten River. During the 2012 survey, moose continued to be observed using the mid to low elevations, but were primarily observed in old burns, and west of the Haggart Creek Access Road and the existing advanced exploration camp operated by VIT. In 2013, moose were again observed in mid to low

elevation areas; however, most observations were east of the Haggart Creek Access Road and the camp in the moderate elevation burns (Map 2).

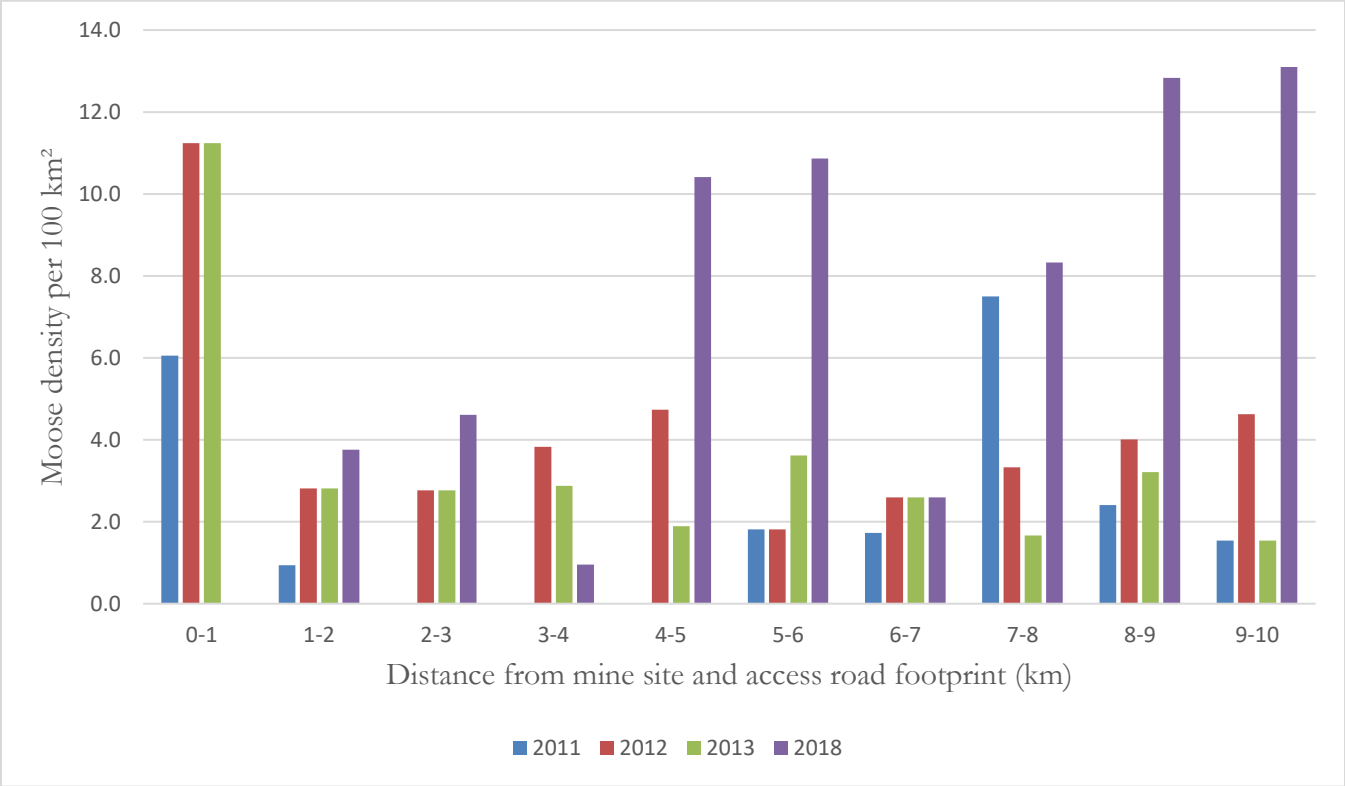

Figure 1. Moose density per 100 km² at 1 km intervals within 10 km of the Eagle Gold Project infrastructure during late-winter 2011, 2012, 2013, and 2018 moose surveys.

Yearly variation in the distribution of large ungulates is common. Food availability, snow depth, and risk of predation affect late-winter moose distribution (Dussault et al. 2005). Food availability is assumed to be constant year over year because there have not been major changes to moose habitat in the survey area during the survey years. We obtained snow depth data from the Water Resources Branch, Environment Yukon, for the snow course survey stations nearest to the Project (Mayo A, Mayo B, and Calumet). Snow depth was also measured at two climate stations within the Project area: Potato Hills (alpine) and Camp (valley bottom); however, the snow sensors at these two locations were not functioning at the time of the survey in 2013.

Snow depth at the end of February was 83 cm at the Calumet snow station (elevation 1310 m; Table 3) and 90 cm at VIT's Potato Hills meteorological station. The Calumet snow station is generally more representative of snow conditions in the Project area than the Mayo A and B snow stations; the latter are at lower elevations and are subject to wind scour and human disturbance related to airport activities (Email communication on 27 April 2018 with Steve Therriault, Energy, Mines and Resources, and Jonathan Kollot,

Environment Yukon). Regionally, snow depth in 2011, 2012, and 2013 was above average while 2018 was average for the region (Table 3). Furthermore, snow depth at stations located at higher elevations (Potato Hill, Calumet) was much deeper than those recorded at stations located at lower elevations (Camp, Mayo A and B; Table 3). This higher than average snow depth from 2011 to 2013, especially at higher elevations, might explain the greater use of moderate to low elevation habitats by moose in earlier surveys relative to 2018. However, snow depth in all years were higher than those reported to affect moose distribution.

Table 3. Snow depth for 2011, 2012, 2013, 2014, and 2018 at weather stations within or near the Eagle Gold Project.

Year	VIT Camp (cm)	VIT Potato Hills (cm)	YG Mayo Airport A (cm)[1]	YG Mayo Airport B (cm)[1]	YG Calumet (cm)[1]
2011	55	105	55	55	88
2012	50	126	51	64	94
2013	n/a[2]	n/a[2]	62	60	87
2014	57	98	53	55	82
2018	54[3]	90[3]	40	46	83
2009-2018 Average	n/a	n/a	50.1	52.2	82.7
1987-2018 Average	n/a	n/a	50.7	52.0	85.5

[1]Snow depth data for the Mayo A, Mayo B, and Calumet snow course stations were obtained from the Water Resources Branch, Environment Yukon.
[2]The snow sensors at the Camp and Potato Hills climate station were not functioning at the time of the 2013 survey.
[3]Data recorded on 3-4 April 2018.

3.1 INCIDENTAL OBSERVATIONS

Caribou cratering (i.e., digging in snow for forage and mineral rich water) was observed in a wetland complex along the South McQuesten River approximately 14 km southeast of the Project. The tracks and cratering in the snow were old since they had been snowed over on a few occasions prior to the observation but appeared to be from a moderate size group of animals (i.e., 8 to 12 caribou). A snow covered east-west travel trail from around the same time period based on snow deposition and thought to be from a group of caribou was observed on the ridge line between the South McQuesten River and the Project.

Caribou or caribou tracks were not observed during the 2011 and 2012 late-winter surveys. However, a group of five woodland caribou was observed in 2013 in an alpine area on Red Mountain which is located on the western edge of the survey area approximately 10 km from the Haggart Creek Access Road. In the Terrestrial Wildlife Environmental Baseline Report submitted to the Executive Committee as part of the Project Proposal, local knowledge indicated that caribou were known to occur in the Red Mountain area (Stantec Consulting Ltd. 2011b). However, based on the distribution of herd ranges in the region, caribou are expected to be an uncommon occurrence in the study area. The closest woodland caribou herd to the survey area is the Clear Creek caribou herd located approximately 8.5 km to the west of the study area boundary. A 2001 survey estimated the herd to be composed of 900 caribou (Environment Canada 2012).

We did not observe any wolves during the 2018 survey. However, wolf tracks, fresh and old, were common throughout the lower elevation creek and river valleys. The flats along the South McQuesten River had high densities of wolf tracks especially in the blocks west of the access road. This area also had high densities of old moose tracks but few fresh tracks were observed. No wolves were observed in 2011 and 2012; however, three packs were observed in 2013 (EDI Environmental Dynamics Inc. 2013). Two of the packs observed in 2013 were in the vicinity of the South McQuesten River area where we observed high densities of wolf tracks in 2018. Survey notes from 2013 also indicate that the survey crew observed high densities of wolf tracks in the South McQuesten River and Haggard Creek valleys.

4 CONCLUSIONS

The data collected as part of the 2011–2013 moose surveys were intended to reflect the baseline pre-construction distribution of moose in the study area while those of the 2018 survey were collected near the end of a 5-month halt during the construction phase. A potential effect of mine construction and operation activities may be sensory disturbance which could result in the avoidance of habitat within a zone of influence (ZOI) around the mine site and access road.

Slight changes in distribution and density were expected among years as a result of dynamic habitat variables and predation risk. However, although some areas appear to hold higher moose densities, overall moose distribution to date has been highly variable between years. No moose were observed within 1 km of the Project footprint in 2018 during a 5-month halt in construction activities and unmaintained road access conditions. If the 2018 survey had occurred during ongoing construction activities or the operation phase, a potentially erroneous conclusion could have been drawn that disturbance due to Project activities or facilitated harvest due to improved road access had led to complete avoidance or depletion of the population within 1 km of the Project footprint.

Data obtained from the surveys will be used to inform adaptive management measures to mitigate the potential effects of the Project on moose.

SPILL RESPONSE PLAN

Version 2019-01

MARCH 2019

THIS PAGE INTENTIONALLY LEFT BLANK

DOCUMENT CONTROL

Submission History

Version Number	Version Date	Document Description and Revisions Made
2013-01	Apr 2013 (draft)	Submission of preliminary draft
2013-01	Sep 2013	Original submission to the Department of Energy, Mines and Resources in support of an application for a Quartz Mining Licence allowing for preliminary construction activities and submitted to the Yukon Water Board in support of the application to amend Type B Water Use License QZ11-013. The amendment application considered the use of water and deposit of waste associated with preliminary construction activities and included the construction and operation of the Dublin Gulch Diversion Channel.
2014-01	Jun 2014	Revisions made in support of an application to the Yukon Water Board for a Type A Water Use License for the full Construction, Operation and Closure of the Project. Version 2014-01 was also submitted to the Department of Energy, Mines and Resources in support of an application for a Quartz Mining Licence allowing the full Construction, Operation and Closure of the Project.
2016-01	Feb 2016	Revisions made in support of an application to the Yukon Water Board for a renewal of the Type B Water Use Licence.
2017-01	Mar 2017	Revisions made to address comments received during the adequacy review of the application to the Yukon Water Board for a Type A Water Use Licence and to address the conditions of the Quartz Mining Licence QML-0011. Version 2017-01 was submitted to the Department of Energy, Mines and Resources and the Yukon Water Board to satisfy SGC's annual reporting requirements.
2017-02	Jul 2017	Revisions made to reflect the current site general arrangement and submitted as part of a consolidated application for *Environment Act* permits.
2019-01	Mar 2019	Revisions made in accordance with Clause 8 of QZ14-041 and with Paragraph 2.5 of Schedule C, Part 2 of QML-0011, which require an annual review of the Spill Response Plan.

Version 2017-02 of the Spill Response Plan (the Plan) for the Project has been revised in March 2019 to update Version 2017-02 submitted in July 2017. The table below is intended to identify modifications to the Plan and provide the rationale for such modifications

Version 2019-01 Revisions

Section	Revision/Rationale
Section 2.2 Reportable Spills	▪ Updated the description of site personnel roles and responsibilities for reporting spills.
Table 2.2-1 Reportable Spill Thresholds	▪ Updated to indicate that any amount of antifreeze released into a water course is reportable.

Section	Revision/Rationale
Section 2.3 Non-Reportable Spills	▪ Updated to include reference to the Spill report Form used to track both reportable and non-reportable spills and describe roles and responsibilities of site personnel.
Section 3.0	▪ Updated to differentiate between small and large spill response and site personnel roles and responsibilities.
Section 3.1 Spill Response Equipment	▪ Updated to describe roles and responsibilities of site personnel.
Table 3.2-1 Position and Responsibilities of Personnel Involved in Spill Response	▪ Updated to include responsibility for additional external reporting, if required.
Section 3.6	▪ Updated description of the land treatment facility
Section 4.0 Internal and External Reporting	▪ Updating external reporting responsibilities to include reporting to the Yukon Water Board Waterline online registry and FNNND (if required)
Appendix B	▪ Updated Spill Report Form.

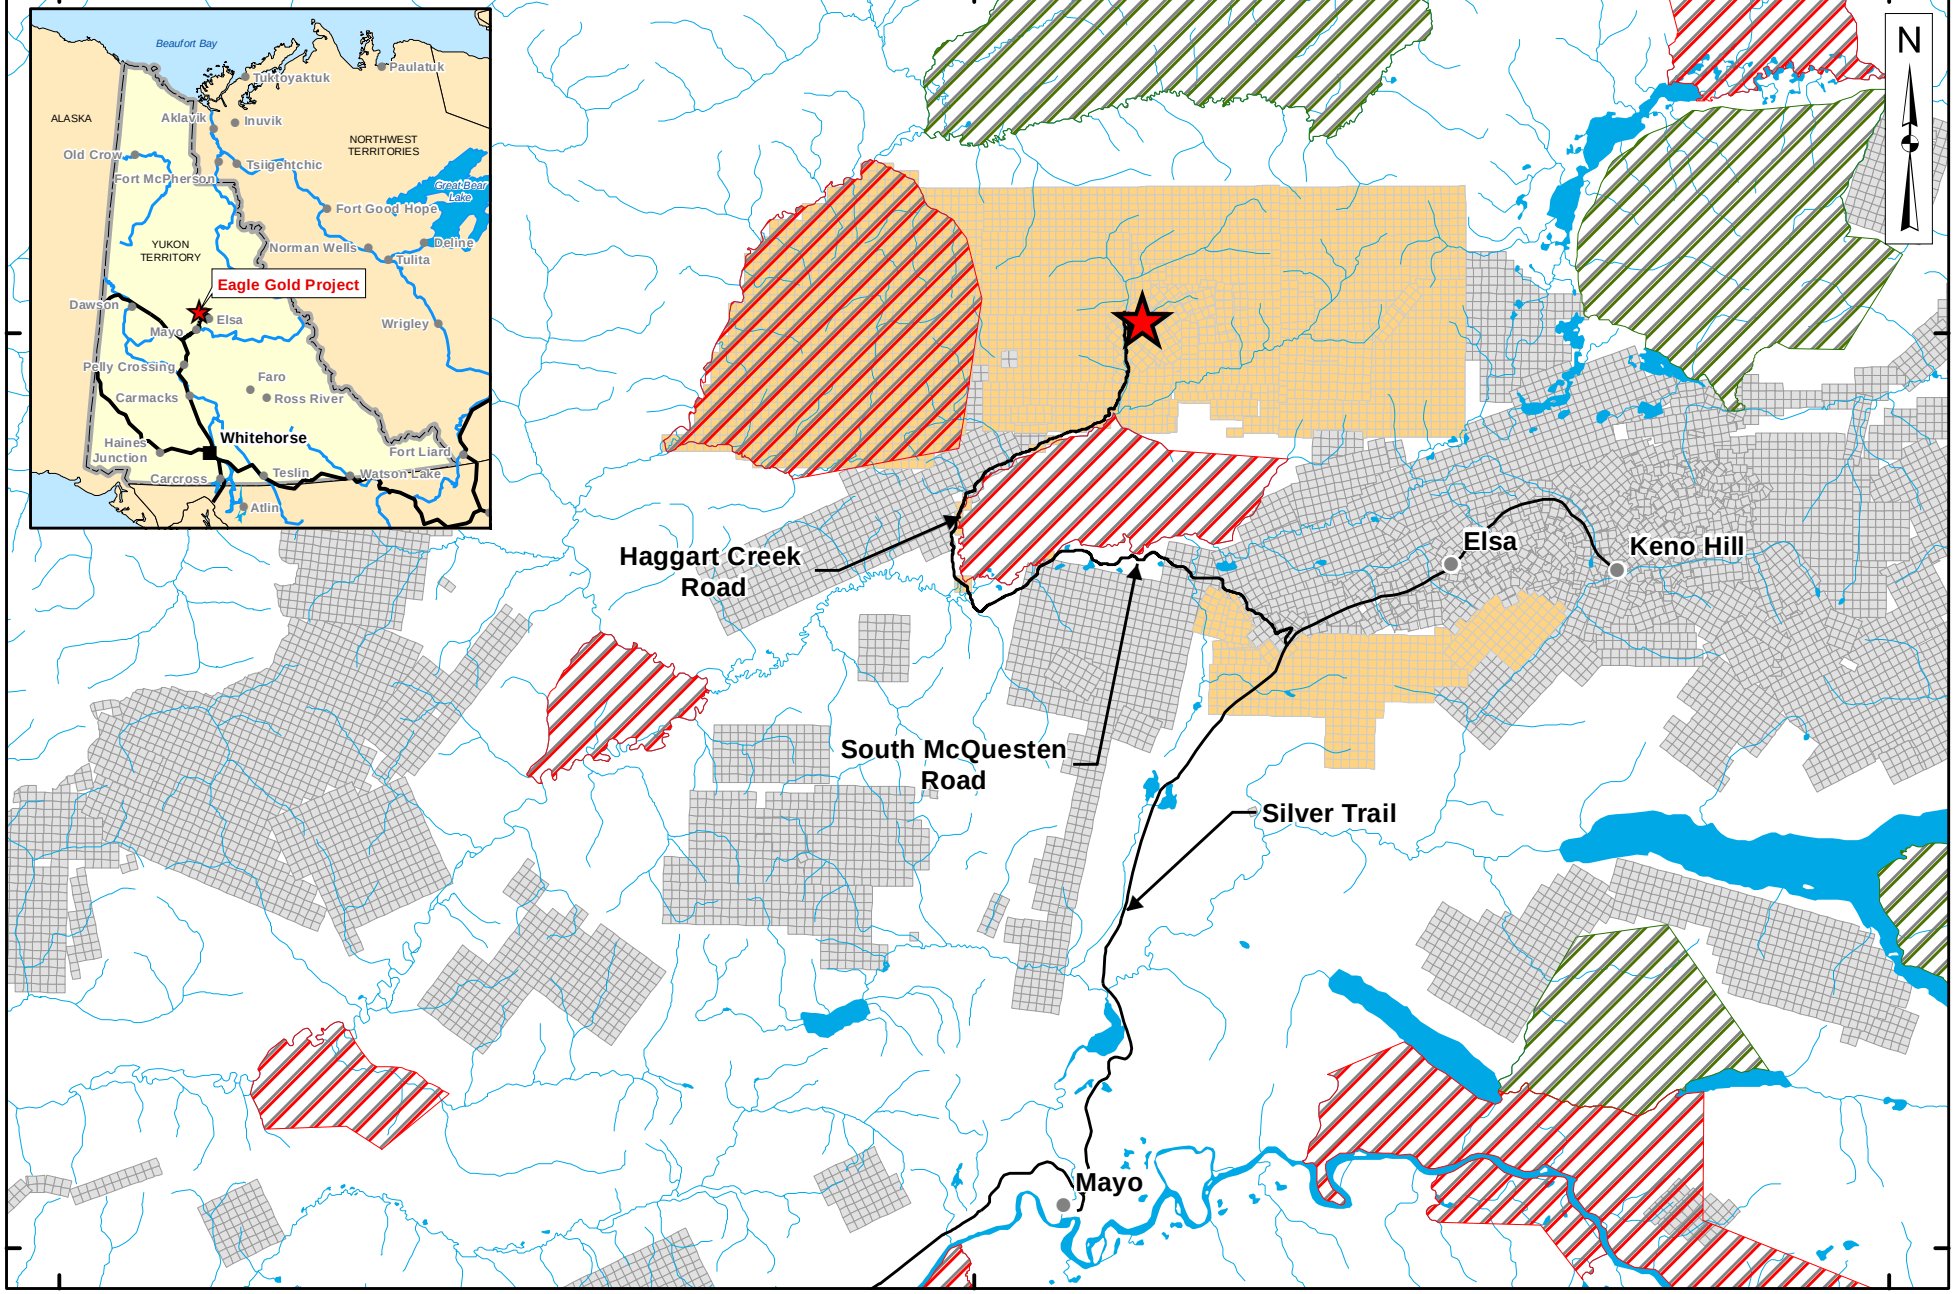
1 INTRODUCTION



StrataGold Corporation (SGC), a directly held-wholly owned subsidiary of Victoria Gold Corp., has proposed to construct, operate, close and reclaim a gold mine in central Yukon. The Eagle Gold Project ('the Project') is located 85 km from Mayo Yukon using existing highway and access roads (Figure 1.1-1). The Project will involve open pit mining and gold extraction using a three stage crushing process, heap leaching, and a carbon adsorption, desorption, and recovery system over the mine life.

SGC is committed to exploring for, building, operating and closing mines in an environmentally, socially and financially responsible manner. SGC will endeavor to protect the environment in which it operates by providing a safe, responsible and efficient operating atmosphere through the development, and implementation of corporate policies as well as development and operational plans.

The purpose of this Spill Response Plan (the Plan) is to enable timely and effective responses to spills throughout the life of the Project. The Plan provides measures to prevent spills from occurring, and response measures to be implemented in the event of a spill.

This plan was informed by the guidelines provided by Government of Yukon's Department of Energy, Mines and Resources and the Yukon Water Board in the Plan Requirement Guidance for Quartz Mining Projects (August 2013), the Terms and Conditions of Recommendation, Proponent Commitments and Proponent Mitigations specified in the Final Screening Report and Recommendation (Yukon Environmental and Socio-economic Assessment Board Project Assessment 2010-0267), and the regulatory approvals issued for the Project

Appendix A summarizes the requirements pertaining to spill prevention and response outlined in the Final Screening Report and Recommendation and other licenses and permits issued to date.

2 SPILL DEFINITION AND CATEGORIES

2.1 SPILL DEFINITION

A spill is defined under Section 132 of the *Yukon Environment Act* ("the Act") as a "release of a substance into the natural environment; from or out of a structure, vehicle or other container; and that is abnormal in quantity or quality in light of all the circumstances of the release; or in excess of an amount specified in the regulations". For the purposes of the *Act*, a "substance" means a hazardous substance, pesticide, contaminant or special waste.

2.2 REPORTABLE SPILLS

Schedule A of the *Yukon Spills Regulations* defines reportable spill quantities in reference to hazardous material classes defined under the *Transportation of Dangerous Goods Regulations*. The release into the environment of a hazardous material above the reportable quantities or any release into a watercourse is a reportable spill under the *Yukon Spills Regulations* and SGC is required immediately notify the 24-hour Yukon Spill Report line at:

867-667-7244

All reportable spills must be reported as soon as possible, within 24 hours. The reporting should be performed by the Environmental Coordinator or their designate. If the Environmental Coordinator is not on site, the Site Services Manager should perform the reporting. If there is uncertainty regarding the volume or type of material that has been spilled, it is advised that a report be made to the Spill Hotline.

Spill Reporting Forms will be completed for all spills (Appendix B).

Reporting thresholds for all substances including hazardous materials, pesticide, contaminant or special waste used or stored at the Project are provided in Table 2.2-1, Table 2.2-2 and Appendix C.

A list of emergency contact numbers is provided in Appendix D.

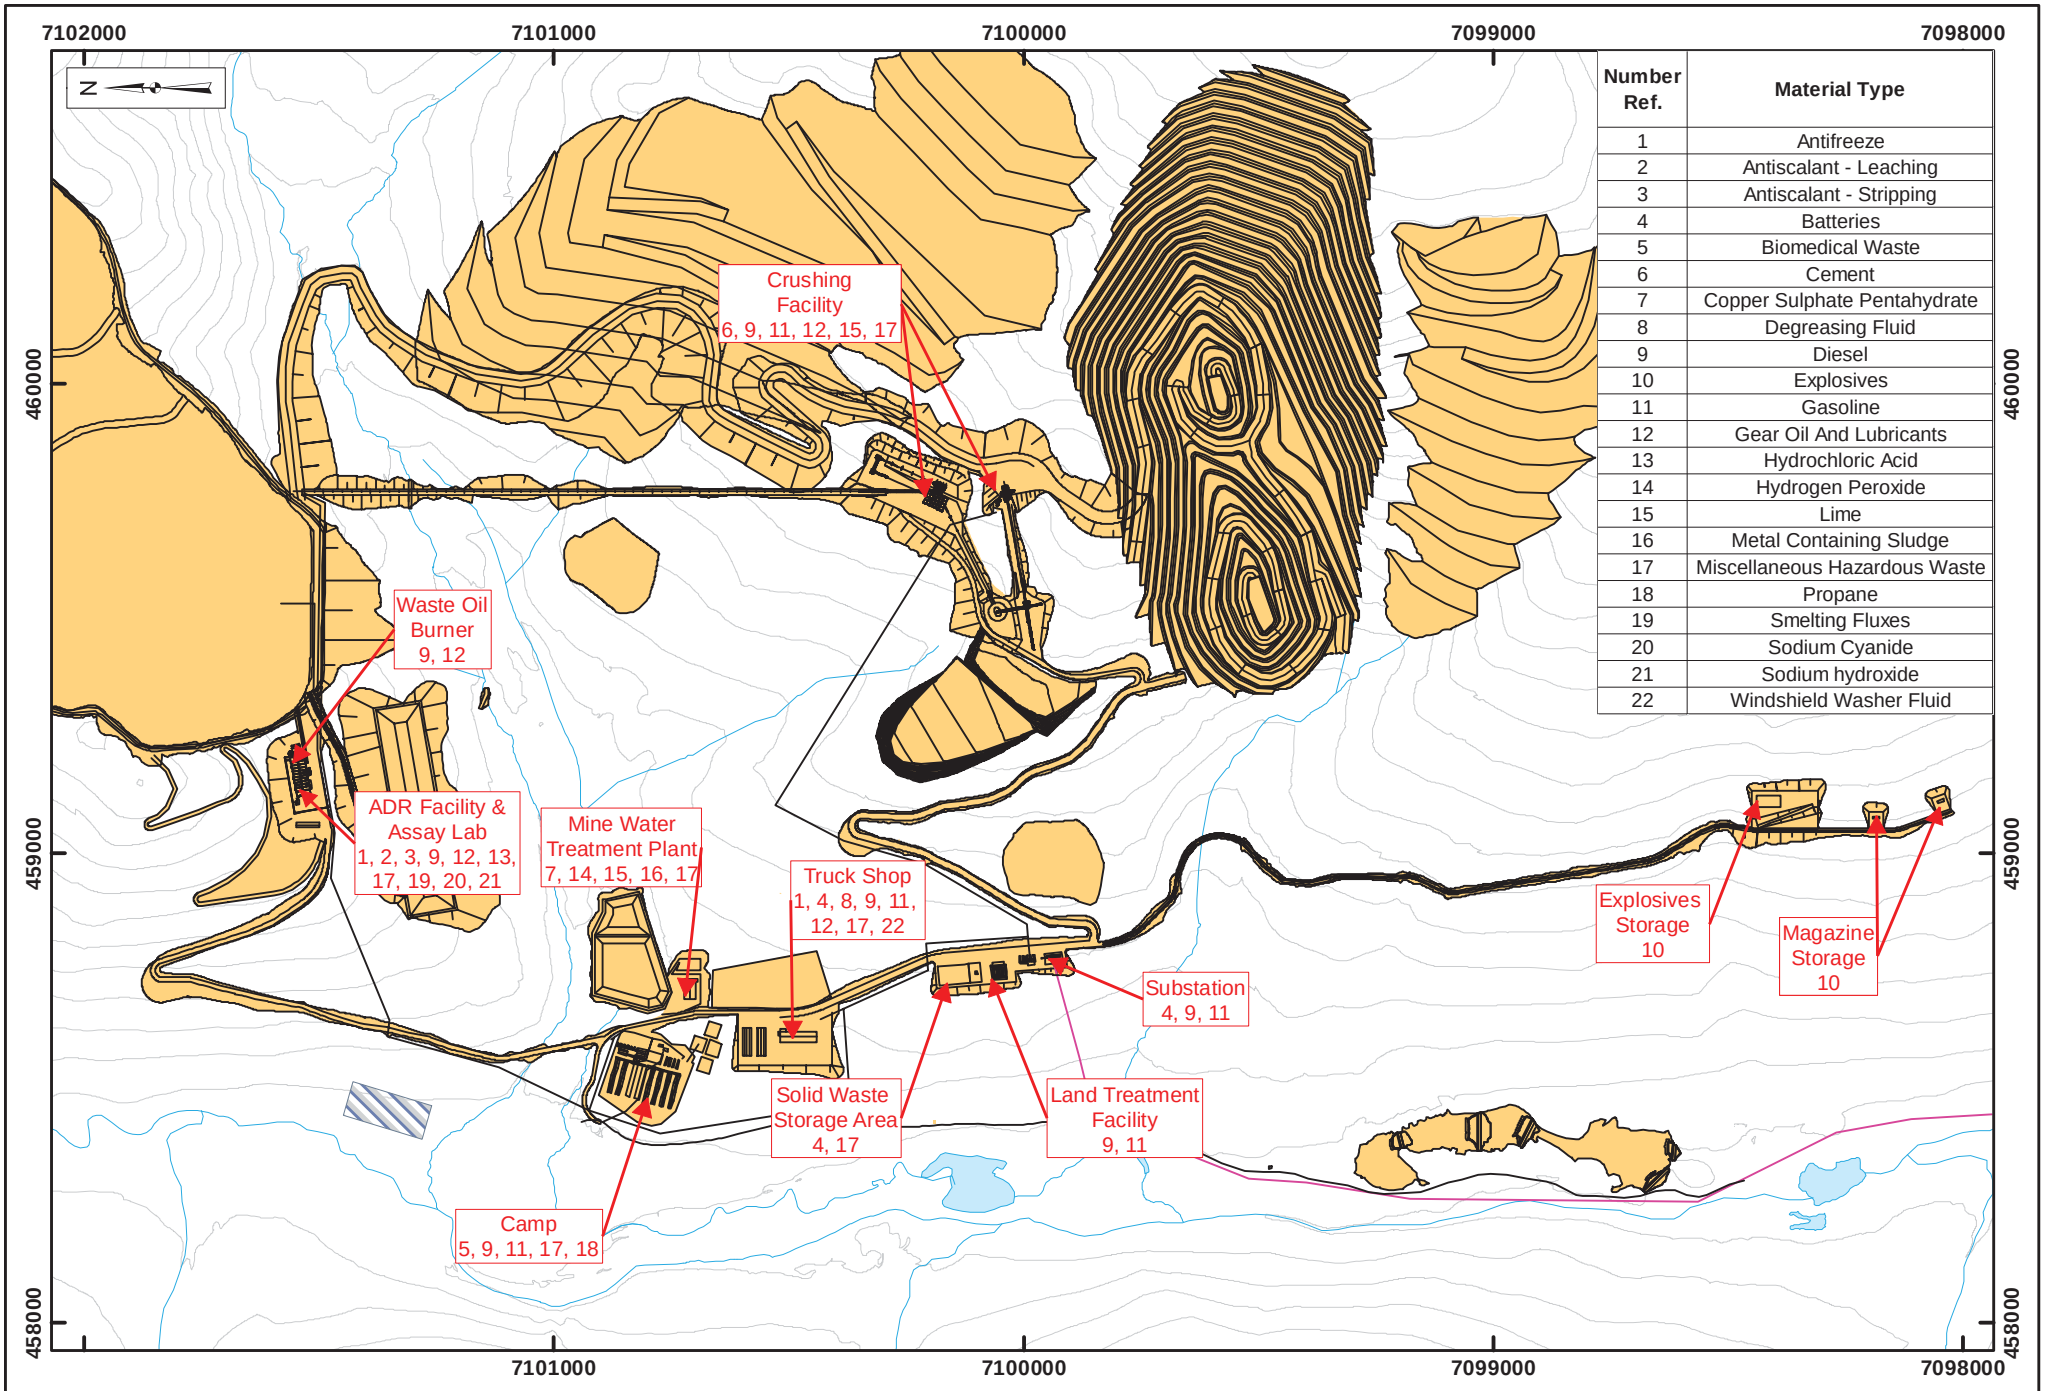
Material Safety Data Sheets (MSDS) for all hazardous substances used for the Project at risk of spills are provided in Appendix E.

Table 2.2-1: Reportable Spill Thresholds

Substance Name	Type	TDGA Class	Reportable Threshold
Propane	Petroleum product	2	Any amount of gas from a container larger than 100 L, or where the spill results from equipment failure, error, or deliberate action or inaction
Acetylene	Petroleum product	2	Any amount of gas from a container larger than 100 L, or where the spill results from equipment failure, error, or deliberate action or inaction
Oxygen	Gas	2	Any amount of gas from a container larger than 100 L, or where the spill results from equipment failure, error, or deliberate action or inaction

Substance Name	Type	TDGA Class	Reportable Threshold
Gasoline	Petroleum product	3	200 L (any amount if spilled into a watercourse)
Diesel	Petroleum product	3	200 L (any amount if spilled into a watercourse)
Jet A & B Aviation Fuel	Petroleum Product	3	200 L (any amount if spilled into a watercourse)
Antifreeze	Solvent	9	5 L (any amount it spilled into a watercourse)
Lubricating and Hydraulic Oils	Lubricating oil	n/a	200 L (any amount if spilled into a watercourse)

Table 2.2-2: Reportable Spill Thresholds for Special Waste



Substance Type	Time period	Reportable Threshold
Special Waste that may cause an adverse effect	N/A	Any amount
Solid Special Waste	24 hours	500 g
	30 days	5 kg
Liquid Special Waste	24 hours	500 ml
	30 days	5 L
Mixture of Solid and Liquid Waste	24 hours	500 g or 500 ml whichever is less
	30 days	5 kg or 5 L whichever is less

2.3 NON-REPORTABLE SPILLS

Spilled materials which are below the reporting thresholds are not required to be reported externally; however, all spills (whether reportable externally or not) must be reported internally to the SGC Environmental Department, and the SGC Environmental Department will maintain a record of all spills. The SGC Spill Report Form (Appendix B) should be used by all contractors and Victoria Gold employees who first observe a spill. Non-reportable spills will be handled according to the Spill Response Procedure described in Section 3 of this Plan. After any non-reportable spill is controlled and cleaned up, the Environmental Department will complete the Spill Response Form and perform an inspection of the area as required. Spill cleanup supplies used for the response must be replenished by area supervisors.

2.4 STORAGE LOCATIONS AND USE OF HAZARDOUS MATERIALS

Hazardous materials used on site and storage locations are described in the Solid Waste and Hazardous Materials Management Plan and shown on Figure 2.4-1. SGC will ensure that spill kits compatible with the type and volume of material stored and used are available at sites where hazardous materials are stored and used.

Number Ref.	Material Type
1	Antifreeze
2	Antiscalant - Leaching
3	Antiscalant - Stripping
4	Batteries
5	Biomedical Waste
6	Cement
7	Copper Sulphate Pentahydrate
8	Degreasing Fluid
9	Diesel
10	Explosives
11	Gasoline
12	Gear Oil And Lubricants
13	Hydrochloric Acid
14	Hydrogen Peroxide
15	Lime
16	Metal Containing Sludge
17	Miscellaneous Hazardous Waste
18	Propane
19	Smelting Fluxes
20	Sodium Cyanide
21	Sodium hydroxide
22	Windshield Washer Fluid

Storage Areas for Hazardous Materials

3 SPILL RESPONSE PROCEDURE

The immediate priority in the event of a spill is to ensure the safety of any personnel in the immediate vicinity and to minimize the potential impact to the environment due to a sustained release of hazardous material. The implementation of spill containment measures and site cleanup and remediation will only be undertaken when safety is assured and the source of the release has been controlled.

In the case of a small spill, for example an overturned drip tray or a small coolant leak noticed under equipment, the first observer should immediately try to contain the spill. This can be done by using a drip tray, or placing absorbent pads under the leak.

Before responding to any large spill, it is important to first STOP and THINK:

- Identify hazards
- Assess Risks
- Control Risks

The priority sequence for spill response is as follows:

1. **ENSURE SAFETY**
    - Identify the spilled material (if not possible, assume dangerous)
    - Use Personal Protective Equipment (PPE)
    - Ensure the safety of nearby personnel
    - Remove all ignition sources – no smoking
2. **FIRST AID**
    - Call for assistance if necessary
    - Attend to the injured
    - Begin first aid immediately as required by following the guidelines from MSDS for the substance released
3. **STOP THE FLOW (IF POSSIBLE)**
    - Close valves, shut off pumps and plug holes or leaks (if safe to do so)
4. **NOTIFY YOUR SUPERVISOR AND/OR SPILL RESPONSE TEAM**
    - Provide basic information of spill – What, Who, Where, When and How
    - Activate Spill Response Team
5. **SECURE THE AREA**
    - Limit access to the spill area and prevent unauthorized entry

6. CONTAIN THE RELEASE

- Block off and protect drains, culverts, and other drainage structures which are not designated for spill management
- Use dykes, berms, trenches, ditches or sorbent material from spill kits to control the spilled substances

7. CLEAN-UP

- Under the direction of the Spill Response Team or Environmental Personnel, begin clean-up activities

8. REPORT THE SPILL

- The Environmental Manager, or designate, will report the spill to the appropriate agencies.

9. CONDUCT INCIDENT INVESTIGATION

- Undertake appropriate corrective and preventative action and document all activities on the Spill Report Form

3.1 SPILL RESPONSE EQUIPMENT

Spill kits will be available at all hazardous materials storage sites and transfer areas shown in Figure 2.4-1. Spill kits will also be available in hazardous material transporters, heavy equipment and light trucks. Spill kits will contain booms, sorbent materials, shovels and PPE, and fire extinguishers will be located in close proximity to assist in responding to a possible spill incident involving flammable materials. Spill kits will also contain a kit inventory sheet to assist with monthly inspections and the replenishment of spent supplies and equipment. The SGC Environmental Department will be responsible for monthly spill kit inspections. The area supervisors will be responsible for the replenishment of spent supplies and equipment, and ensuring that their worksite is equipped with a fully stocked 50 Gallon Spill Response Kit. Spare spill response supplies will be maintained on site to replenish spill kits and to be deployed to other locations in the event of a spill requiring additional equipment or as a replacement until spent, location specific, kits can be replenished.

If there is a risk of spills on open water, surface booms will be available for deployment.

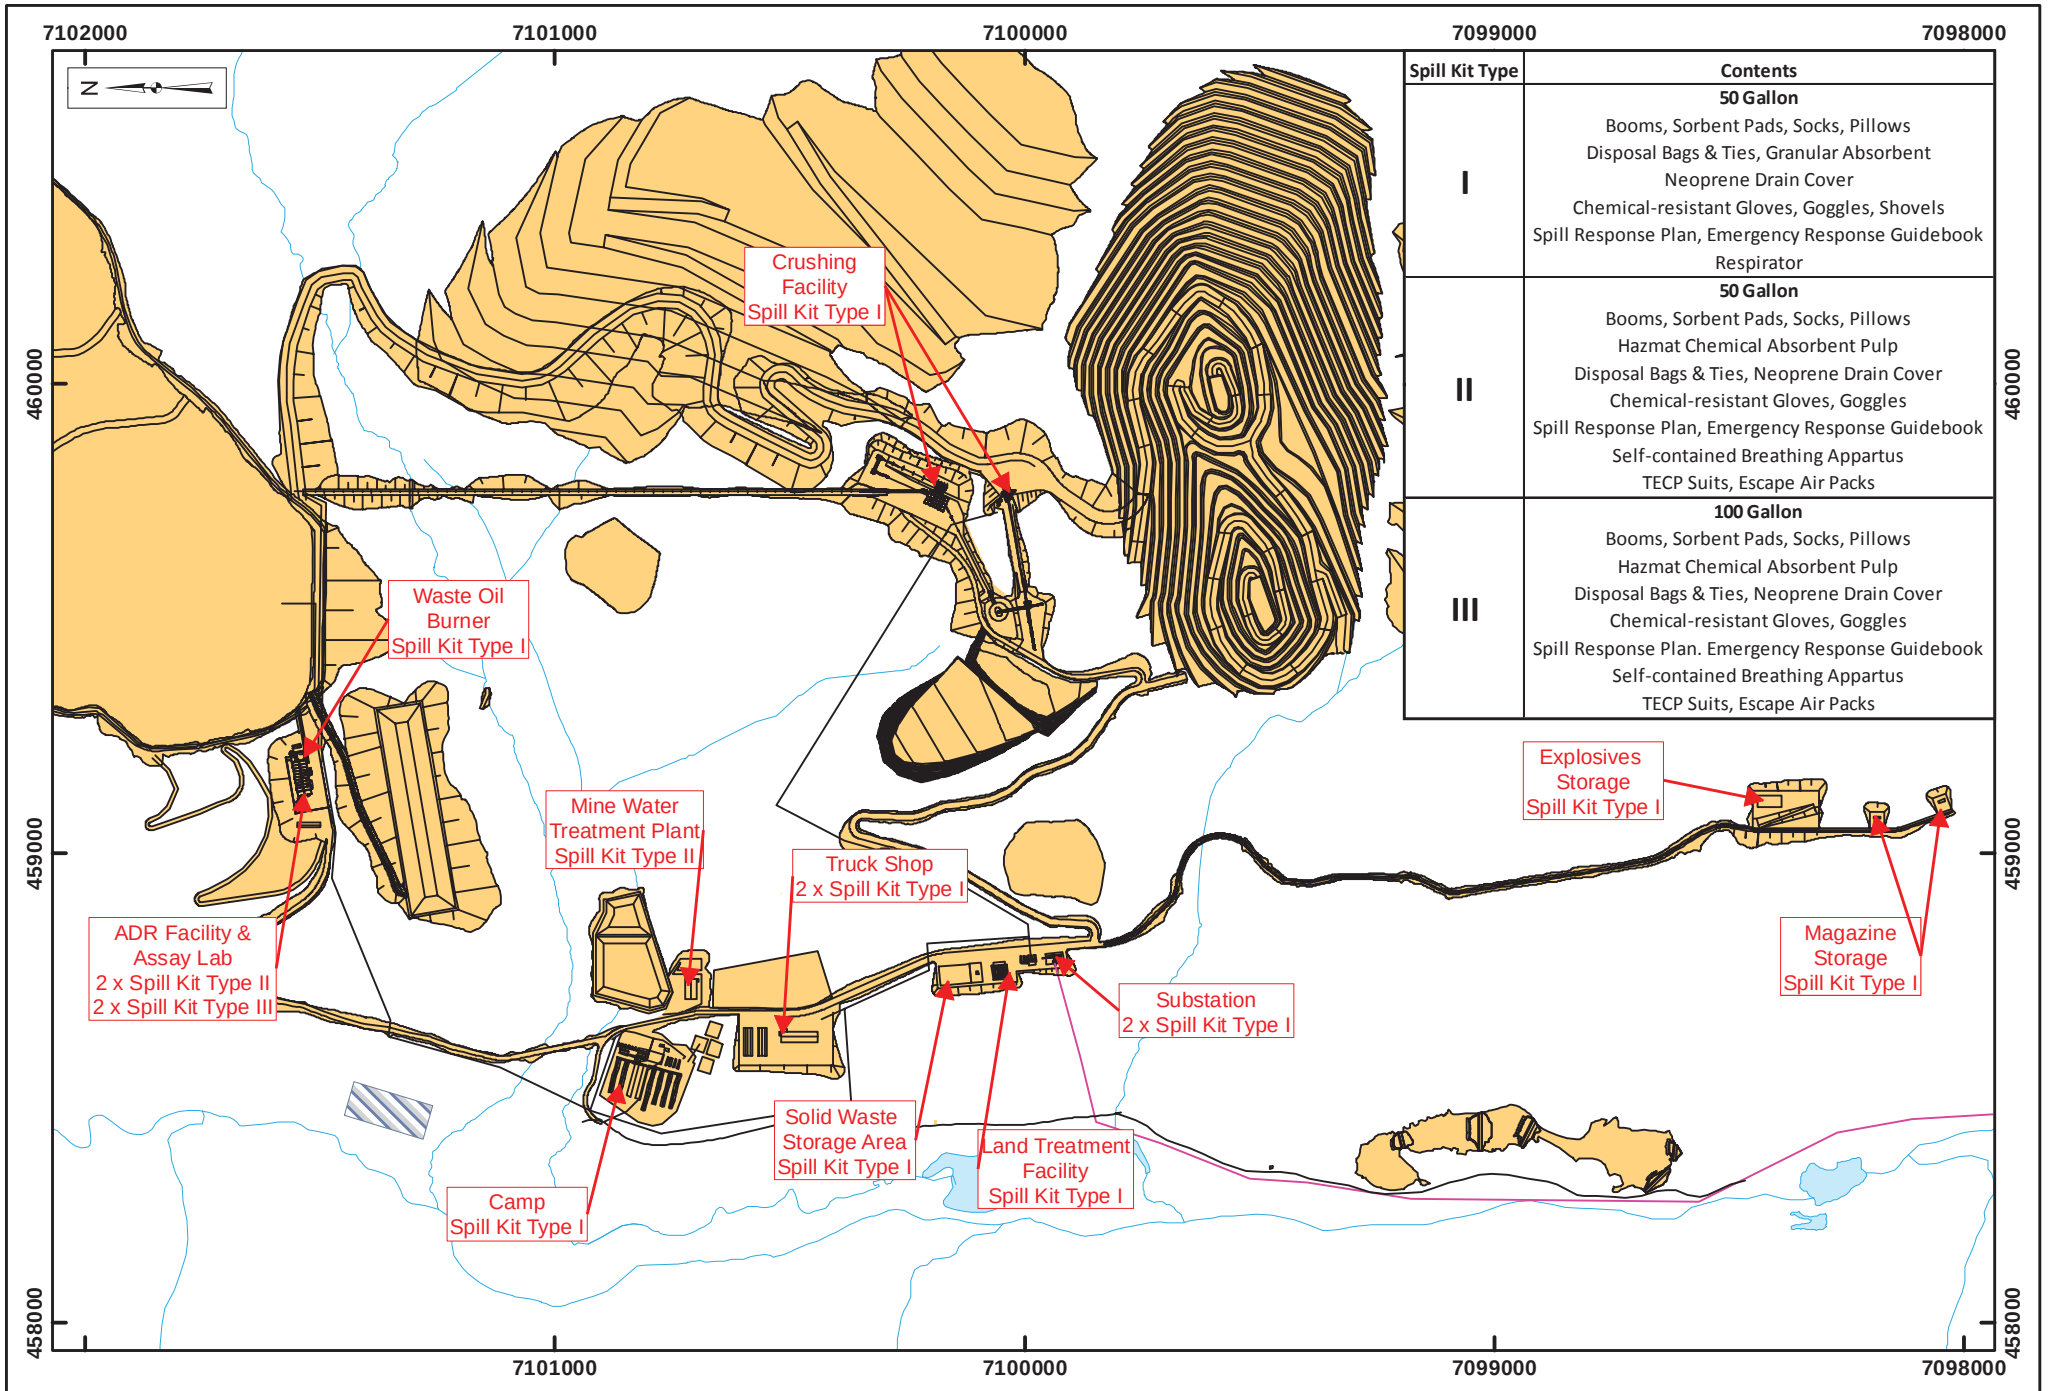
All spill kits will include the 2016 Emergency Response Guidebook which has been developed jointly by Transport Canada (TC), the U.S. Department of Transportation (DOT), the Secretariat of Transport and Communications of Mexico (SCT) and with the collaboration of CIQUIME (Centro de Informaciòn Quìmica para Emergencias) of Argentina, for use by fire fighters, police, and other emergency services personnel who may be the first to arrive at the scene of a transportation incident involving dangerous goods.

The Emergency Response Guidebook is a guide to aid first responders in quickly identifying the specific or generic hazards of the material(s) involved in the incident, and protecting themselves and the general public during the initial response phase of the incident.

Figures 3.1-1 and 3.1-2 provide the location of Spill Response Equipment and Table 3.1-1 provides an inventory of anticipated Spill Response Equipment located around the Project Site. Area

supervisors are responsible for ensuring spill response equipment is sufficient for the substances and tasks being performed at their respective locations.

Table 3.1-1: Inventory of Spill Response Equipment Planned for the Project



Location	Type of Equipment
ADR Facility and Assay Lab – Reagent Storage area	2X100 Gallon Spill response carts containing: ▪ Booms, sorbent pads, socks, dikes, pillows ▪ Hazmat Chemical Absorbent Pulp ▪ Disposal bags and Ties ▪ Neoprene Drain Cover ▪ Spill Response Plan ▪ Emergency Response Guidebook ▪ Chemical-resistant gloves ▪ Goggles This location will also be equipped with the following: ▪ Self-contained breathing apparatus ▪ Totally-Encapsulating Chemical Protective (TECP) suits ▪ Escape air packs (10 minute)
ADR Facility and Assay Lab– At each reagent handling area	2X50 Gallon Spill kits containing: ▪ Sorbent Pads, Socks, Pillows ▪ Disposal Bags and Ties ▪ Hazmat Chemical Absorbent Pulp ▪ Neoprene Drain Cover ▪ Chemical-resistant Gloves ▪ Goggles ▪ Spill Response Plan ▪ Emergency Response Guidebook This location will also be equipped with the following: ▪ Self-contained breathing apparatus ▪ Totally-Encapsulating Chemical Protective (TECP) suits ▪ Escape air packs (10 minute)
Mine water treatment plant	1X100 Gallon Spill response carts containing: ▪ Booms, sorbent pads, socks, dikes, pillows ▪ Hazmat Chemical Absorbent Pulp ▪ Disposal bags and Ties ▪ Chemical-resistant Gloves ▪ Goggles ▪ Neoprene Drain Cover ▪ Spill Response Plan ▪ Emergency Response Guidebook This location will also be equipped with the following: ▪ Self-contained breathing apparatus ▪ Totally-Encapsulating Chemical Protective (TECP) suits ▪ Escape air packs (10 minute)

Location	Type of Equipment
Truck shop	2 X 50 Gallon Spill kits containing: ▪ Booms, Sorbent Pads, Socks, Pillows ▪ Disposal Bags and Ties ▪ Granular Absorbent ▪ Neoprene Drain Cover ▪ Chemical-resistant Gloves ▪ Goggles ▪ Shovels ▪ Spill Response Plan ▪ Emergency Response Guidebook This location will also be equipped with the following: ▪ Respirators
Crushing and screening plants	1 X 50 Gallon Spill kits containing: ▪ Booms, Sorbent Pads, Socks, Pillows ▪ Disposal Bags and Ties ▪ Granular Absorbent ▪ Neoprene Drain Cover ▪ Chemical-resistant Gloves ▪ Goggles ▪ Shovels ▪ Spill Response Plan ▪ Emergency Response Guidebook This location will also be equipped with the following: ▪ Respirators
Agglomerator Building	1 X 50 Gallon Spill kits containing: ▪ Booms, Sorbent Pads, Socks, Pillows ▪ Disposal Bags and Ties ▪ Granular Absorbent ▪ Neoprene Drain Cover ▪ Chemical-resistant Gloves ▪ Goggles ▪ Shovels ▪ Spill Response Plan ▪ Emergency Response Guidebook This location will also be equipped with the following: Respirators
Fuel storage areas	1 X 50 Gallon Spill kits containing: ▪ Booms, Sorbent Pads, Socks, Pillows ▪ Disposal Bags and Ties ▪ Granular Absorbent ▪ Neoprene Drain Cover ▪ Chemical-resistant Gloves ▪ Goggles

Location	Type of Equipment
	▪ Shovels ▪ Spill Response Plan ▪ Emergency Response Guidebook This location will also be equipped with the following: ▪ Respirators
Explosives storage facility	1 X 50 Gallon Spill kits containing: ▪ Booms, Sorbent Pads, Socks, Pillows ▪ Disposal Bags and Ties ▪ Granular Absorbent ▪ Neoprene Drain Cover ▪ Chemical-resistant Gloves ▪ Goggles ▪ Shovels ▪ Spill Response Plan ▪ Emergency Response Guidebook This location will also be equipped with the following: ▪ Respirators
Explosives magazine	1 X 50 Gallon Spill kits containing: ▪ Booms, Sorbent Pads, Socks, Pillows ▪ Disposal Bags and Ties ▪ Granular Absorbent ▪ Neoprene Drain Cover ▪ Chemical-resistant Gloves ▪ Goggles ▪ Shovels ▪ Spill Response Plan ▪ Emergency Response Guidebook This location will also be equipped with the following: ▪ Respirators
Camp	1 X 50 Gallon Spill kits containing: ▪ Booms, Sorbent Pads, Socks, Pillows ▪ Disposal Bags and Ties ▪ Granular Absorbent ▪ Neoprene Drain Cover ▪ Chemical-resistant Gloves ▪ Goggles ▪ Shovels ▪ Spill Response Plan ▪ Emergency Response Guidebook This location will also be equipped with the following: ▪ Respirators
Solid Waste Storage Area	1 X 50 Gallon Spill kits containing: ▪ Booms, Sorbent Pads, Socks, Pillows

Location	Type of Equipment
	▪ Disposal Bags and Ties ▪ Granular Absorbent ▪ Neoprene Drain Cover ▪ Chemical-resistant Gloves ▪ Goggles ▪ Shovels ▪ Spill Response Plan ▪ Emergency Response Guidebook This location will also be equipped with the following: ▪ Respirators
Substation	2 X 50 Gallon Spill kits containing: ▪ Booms, Sorbent Pads, Socks, Pillows ▪ Disposal Bags and Ties ▪ Granular Absorbent ▪ Neoprene Drain Cover ▪ Chemical-resistant Gloves ▪ Goggles ▪ Shovels ▪ Spill Response Plan ▪ Emergency Response Guidebook This location will also be equipped with the following: ▪ Respirators
Inside mine vehicles: Fuel carts Utility vehicles Explosive transport vehicles Emergency response vehicles	Vehicle spill kits containing: ▪ Sorbent Pads, Socks and Pillows ▪ Disposable Bags and Ties ▪ Granular Absorbent ▪ Neoprene Drain Cover ▪ Chemical-resistant Gloves ▪ Goggles ▪ Shovels ▪ Spill Response Plan ▪ Emergency Response Guidebook
Strategic locations along access road	1 X 50 Gallon Spill kits containing: ▪ Booms, Sorbent Pads, Socks, Pillows ▪ Disposal Bags and Ties ▪ Granular Absorbent ▪ Chemical-resistant Gloves ▪ Goggles ▪ Shovels ▪ Spill Response Plan ▪ Emergency Response Guidebook

An inventory of spill kits will be maintained and monthly inspections will be carried out to ensure that they are suitably stocked. MSDS will be available for the substances used in the area serviced by the kit.

Spill Kit Type	Contents
I	**50 Gallon** Booms, Sorbent Pads, Socks, Pillows Disposal Bags & Ties, Granular Absorbent Neoprene Drain Cover Chemical-resistant Gloves, Goggles, Shovels Spill Response Plan, Emergency Response Guidebook Respirator
II	**50 Gallon** Booms, Sorbent Pads, Socks, Pillows Hazmat Chemical Absorbent Pulp Disposal Bags & Ties, Neoprene Drain Cover Chemical-resistant Gloves, Goggles Spill Response Plan, Emergency Response Guidebook Self-contained Breathing Appartus TECP Suits, Escape Air Packs
III	**100 Gallon** Booms, Sorbent Pads, Socks, Pillows Hazmat Chemical Absorbent Pulp Disposal Bags & Ties, Neoprene Drain Cover Chemical-resistant Gloves, Goggles Spill Response Plan. Emergency Response Guidebook Self-contained Breathing Appartus TECP Suits, Escape Air Packs

3.2 DUTIES AND RESPONSIBILITIES

To ensure human safety and limit potential environmental effects resulting from a spill, all site personnel will have specific responsibilities when responding to a spill. The responsibilities for spill response are summarized in Table 3.2-1 and depicted in Figure 3.2-1.

Table 3.2-1: Position and Responsibilities of Personnel Involved in Spill Response

Position	Responsibilities
All Personnel (Discoverer)	▪ Assess the initial severity of the spill and safety concerns ▪ Identify the source of the spill ▪ Ensure the safety of nearby personnel ▪ Begin first aid immediately as required ▪ Report all spills to Supervisor and Environmental Coordinator as soon as possible ▪ Determine the size of the spill and, if safe to do so, stop or contain it ▪ Remove all ignition sources if safe to do so ▪ Participate in spill response as a member of cleanup crew under the direction of the Spill Response Team
Supervisors	▪ Contact the Mine Manager ▪ Report to the site of the spill ▪ Gather information on the spill (substance, location, approximate area/quantity, in water, etc.) ▪ Participate in spill response as a member of cleanup crew under the direction of the Spill Response Team
Emergency Response/Spill Response Team	▪ Report to the site of the spill ▪ Assume primary role for first aid (Emergency Response Team) ▪ Stop or contain the spill ▪ Remove all ignition sources ▪ Take appropriate response measures – deploy booms, absorbents, and other equipment and materials as required ▪ Continue cleanup as directed by Mine Manager or Environmental Coordinator
Mine Manager	▪ Report to the site of the spill or Incident Command Centre (if Emergency Response Team has been deployed) ▪ Coordinate initial and ongoing response efforts ▪ Ensure source of spill has stopped and contain spill ▪ Record spill information ▪ Ensure a log book of all spill or unauthorized discharge occurrences is maintained ▪ Ensure coordination of equipment and personnel as needed ▪ Oversee the cleanup operation until it is satisfactorily completed ▪ Decide with the Environmental Coordinator if mobilization of additional equipment, resources or personnel is warranted
Environmental Manager /Coordinator	▪ Report to the site of the spill ▪ Report the spill to the Yukon 24-Hour Spill Report Line and Energy Mines and Resources - Client Services and Inspections ▪ Ensure timely response and cleanup of spill site and impacted areas

Position	Responsibilities
	▪ With the Mine Manager, decide if additional equipment, resources or personnel is required for containment and remedial activities ▪ Notify senior management ▪ With the Mine Manager and senior management, discuss and implement additional external reporting if it is required ▪ Oversee completion and distribution of Spill Report ▪ Ensure investigation identifies measures to prevent similar spills
Executive Vice President	▪ Communicate with the media for large spills when required. ▪ Ensure that all press releases are accurate and in accordance with policy ▪ Make financial decisions on major expenses during large spill response ▪ Oversee preventative measures to ensure risk of a similar incident is mitigated

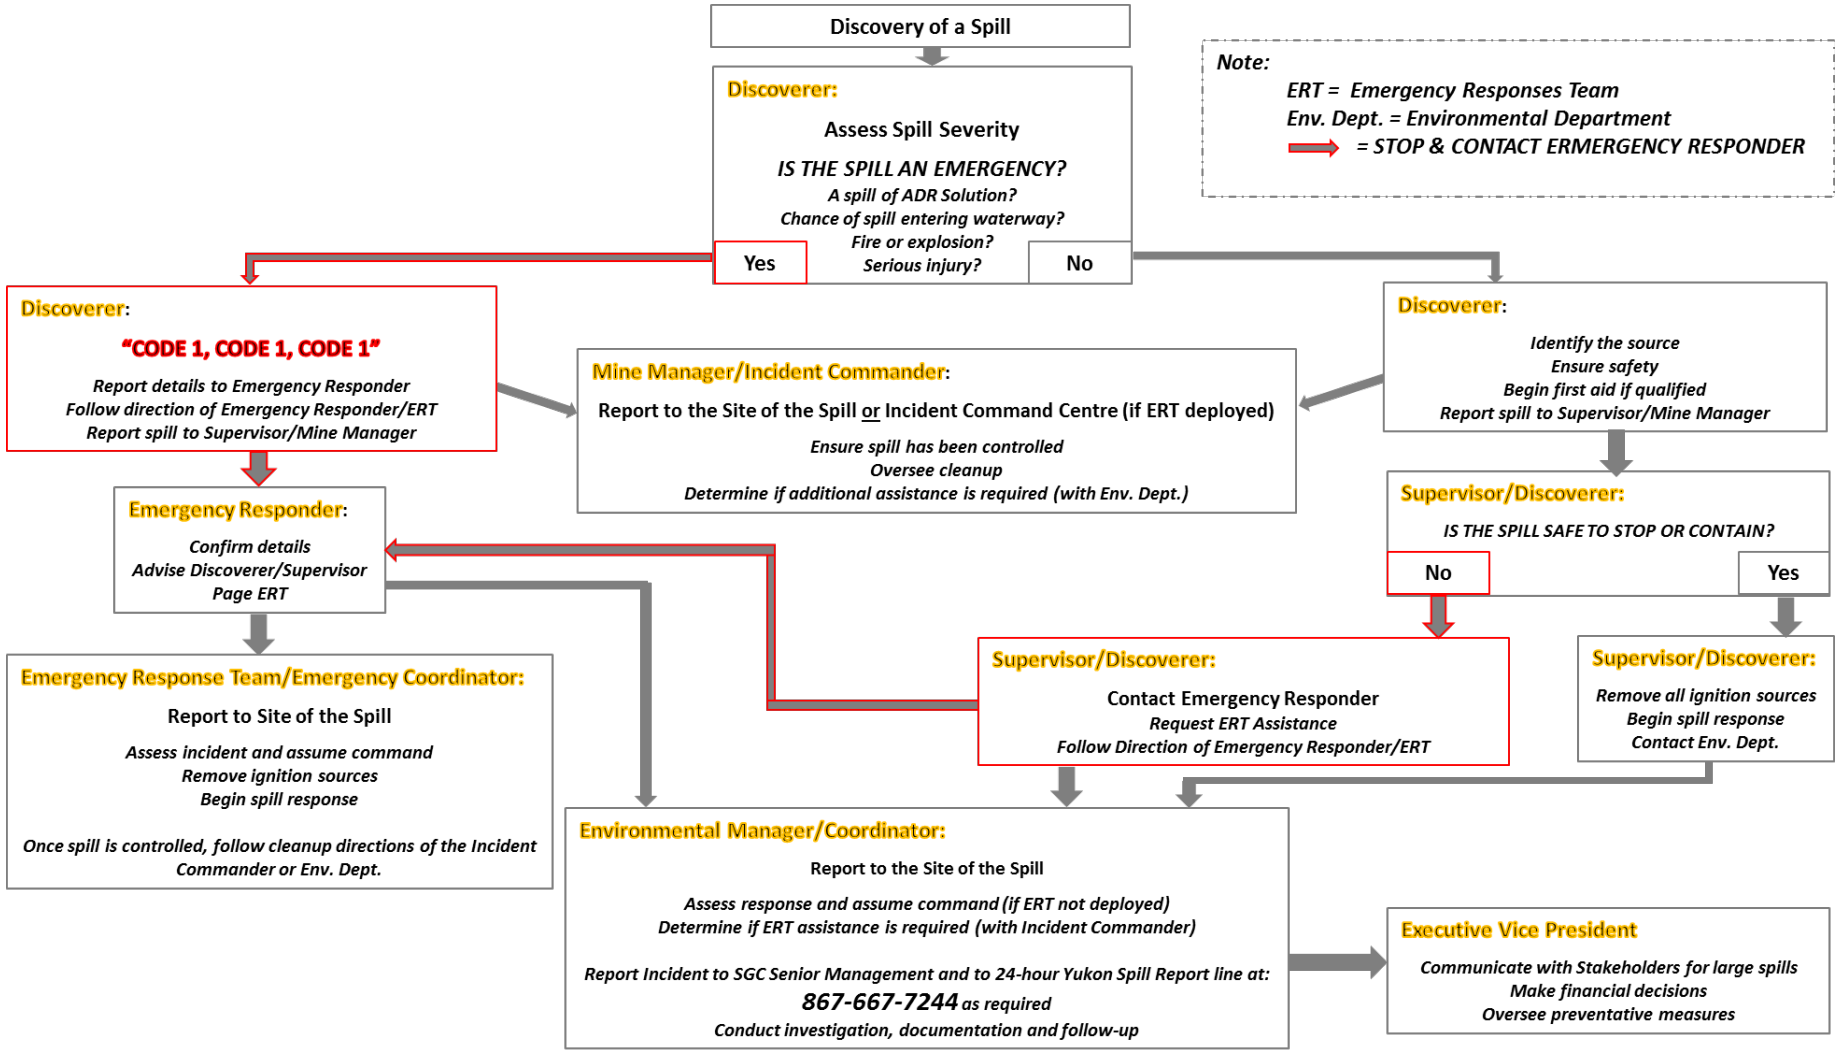

Figure 3.2-1: Spill Response Procedure

3.3 CONTAINMENT AND CLEANUP PROCEDURES

Containment methods for spills vary depending on the substance, size of the spill, location (inside buildings or outside), terrain and soil type, proximity to watercourses, climatic conditions and the availability of equipment and personnel.

Spill containment and response steps for each substance that could be spilled are summarized in Table 3.3-1 and Appendix C.

Table 3.3-1: Spill Containment Procedures by Substance

Substance Name	Type	TDGA Class	PPE required for Spill Response	Cleanup or disposal method
Propane	Petroleum product	2	Insulated gloves, safety glasses, respirator if there is a possible of oxygen reduction (confined spaces with poor ventilation)	Shut off flow and remove ignition sources if safe to do so and evacuate area. Consult supplier if container needs disposal.
Acetylene	Petroleum product	2	Insulated gloves, safety glasses, respirator	Shut off flow and remove ignition sources if safe to do so and evacuate area. Consult supplier if container needs disposal.
Oxygen	Gas	2	Insulated gloves, safety glasses	Allow gas to dissipate. Consult supplier if container needs disposal.
Gasoline	Petroleum product	3	Chemical-resistant impervious gloves, safety glasses, respirator if ventilation is inadequate	Approach from upwind, contain and collect spillage with sorbents from spill kits and/or sand and gravel. Pump free liquid into containment. Arrange for transport of material to an approved facility.
Diesel	Petroleum product	3	Chemical-resistant impervious gloves, safety glasses	Approach from upwind and contain and collect spillage with sorbents from spill kits and/or sand and gravel. Pump free liquid into containment. Arrange for transport of material to an approved facility.
Jet A & B Aviation Fuel	Petroleum Product	3	Chemical resistant gloves, safety glasses	Use sorbents, pump free liquid into containment. Arrange for transport of material to an approved facility.
Antifreeze	Solvent	9	Chemical-resistant impervious gloves, safety glasses	Approach from upwind, contain and collect spillage with sorbents from spill kits and/or sand and gravel. Pump free liquid into containment. Arrange for transport of material to an approved facility.
Lubricating and Hydraulic Oils	Lubricating oil	n/a	Chemical-resistant gloves, safety glasses.	Approach from upwind, contain and collect spillage with sorbents from spill kits and/or sand and gravel. Pump free liquid into containment. Arrange for transport of material to an approved facility.

Various practical methods of containment and recovery have been proven and effective for use in northern climates on land, snow ice or in open water. These methods are summarized in Table 3.3-2.

Table 3.3-2: Spill Containment Procedures by Location

Spill location	Response Actions	Containment Methods	Limitations	Required resources
Snow and Ice	▪ Stop spill source ▪ Eliminate ignition sources ▪ Block entry to waterways with snow dyke or other barrier ▪ Trench or ditch to intercept or contain spill ▪ Compact snow around spill to increase retention ▪ Contain or collect contaminated snow	Snow or Ice dykes	▪ Best suited for flat areas in winter ▪ Requires sufficient snow or ice	▪ Shovels ▪ Heavy equipment
		Snow or Ice trench	▪ Requires sufficient snow or ice ▪ Only applicable when ice is >1m thick ▪ Generally requires mechanical equipment for construction on ice	▪ Shovels ▪ Heavy equipment ▪ Ice chain saws
		Sorbent berm	▪ Requires sufficient, readily available sorbent material ▪ Impractical for larger spills	▪ Sorbents
Land	▪ Stop spill source ▪ Eliminate ignition sources ▪ Block entry to waterways with sand or gravel dyke ▪ Trench or ditch to intercept or contain spill ▪ Deploy sorbents ▪ Recover liquids with pumps or vacuum equipment	Sand or gravel dykes	▪ Best suited for flat areas ▪ Requires sufficient, easily excavated material if hand tools are being used	▪ Shovels ▪ Heavy equipment ▪ Sandbags or liner material if available ▪ Pump out equipment
		Land trench	▪ Can be difficult to excavated if soil is frozen ▪ Not conducive to areas with shallow bedrock	▪ Shovels ▪ Heavy equipment ▪ Pump out equipment
		Sorbent berm	▪ Requires sufficient, readily available sorbent material ▪ Impractical for larger spills	▪ Sorbents
Open Water	▪ Stop spill source ▪ Eliminate ignition sources ▪ Deploy sorbent booms or containment booms to control spread of substance	Sorbent boom	▪ Requires sufficient, readily available sorbent material ▪ No suitable for fast moving watercourses	▪ Sorbents
		Containment boom	▪ Requires sufficient, readily available sorbent material	▪ Sorbents

An effective way of controlling spills on land is through the construction of trenches or berms using sand and gravel. Small spills may be contained manually using shovels. More substantial spills may require the use of heavy equipment to dig trenches or place berm material.

Since snow has absorbent and containment properties, snow can be very effective for containing spills. Liquid spills typically become immobile within the snow pack and can be easily removed for transport

and disposal. Snow will be used to its advantage in the construction of snow dykes, and whenever possible, the snow pack will be left in place to avoid contaminating the underlying substrate. For spills on ice, the methods of containment are similar to those used on land.

Spills occurring on open water (e.g. water retention ponds) will spread very rapidly, and therefore, initial preventative measures such as those described in Table 3.3-1 will be taken to minimize the potential for spills to enter open water. In the event of a petroleum product spills on open water, booms will be deployed immediately to limit the spread of the product and to facilitate recovery, by absorbents or by pumping.

3.4 OFF-SITE RESOURCES

With the exception of medical aid incidents, external resources will be authorized only by the Mine Manager or designate, or those with a higher level of responsibility. Key municipal, territorial and federal services and contact numbers are provided in Table 3.4-1.

Table 3.4-1: Municipal, Territorial and Federal Services and Contact Numbers

Name	Office	Location
Canutec – Emergency Response for TDG spill	**613-996-6666** or ***666 on a cellular phone**	Ottawa
Mayo Nursing Station	867-996-4444	Mayo
Mayo Fire & Rescue	867-996-2222	Mayo (Volunteer Responders)
Mayo RCMP	Emergency: 867-996-5555 Admin: 867-996-2677	Mayo
Whitehorse Regional Hospital - Emergency and Admissions	867-393-8700	Whitehorse
Environment Yukon Conservation Officer – Debra Morris	867-996-2202	Mayo
Environment Yukon Conservation Officer Services Branch	867-667-8005	Whitehorse
First Nation of Nacho Nyäk Dun	867-996-2265	Mayo

Fisheries and Oceans Canada	867-393-6722	Whitehorse
Yukon Energy Corporation	867-996-2387	Mayo

Name	Office	Location
Yukon Energy Corporation	1-800-676-2843	After hours Whitehorse
Yukon Workers' Compensation Health and Safety Board, Chief Mines Safety Officer, Occupational Health & Safety Branch - Michael Henney	867-667-8739	Whitehorse
Yukon Workers' Compensation Health and Safety Board 24-Hour Emergency Line for Reporting Serious Workplace Incidents and Injuries	867-667-5450	Whitehorse

3.5 FIRE SUPPRESSION

The Fire Response Procedure in the Emergency Response Plan must be implemented in the event of a fire.

Fire suppression equipment will be located at all hazardous materials storage, transfer and dispensing areas. If a spill of a flammable substance occurs and is ignited, firefighting efforts may be required prior to spill containment and cleanup. Personnel will be made aware of substance specific dangers prior to conducting fire suppression activities.

Any individual discovering a fire is responsible for attempting to control it and notifying his or her supervisor (Note: Any attempt to control the fire should be made without exposing oneself to risk or injury).

An individual should never enter a smoke-filled environment without self-contained breathing apparatus, appropriate protective clothing and proper training. If a fire is not immediately extinguished and poses an active threat to human health or the environment, then a 'Code 1' call that describes the size and location of the fire must be activated. Immediately notify the Mine Manager in such an event.

In the event that the Mine Manager deems that site wide evacuation is necessary, all personnel must gather at the appropriate muster station so that transport from the site can be arranged, and all mine personnel can be accounted for.

The Mine Manager or designate must:

- Take and remain in charge of firefighting activities until the fire is extinguished
- Ensure all personnel not involved are evacuated to a safe zone and instructed to be on standby for deployment on firefighting duties
- Identify all fire extinguishers used in the firefighting effort and ensure they are serviced, tested, re-charged, and returned for re-use.

3.6 CONTAMINATED SOIL

If cleanup material contains hazardous materials, it will be prepared for transport and taken to an approved offsite facility. Caution will be taken with reactive chemicals to make sure disposal of the material does not create additional danger through potential reaction with other materials.

Hazardous materials that cannot be re-used or recycled will be handled in accordance with SGC's Solid Waste and Hazardous Materials Management Plan.

A land treatment facility will be constructed for the progressive treatment and remediation of hydrocarbon contaminated soils as and when required. The land treatment facility will be located adjacent to the landfill area and will consist of two, geo-membrane lined cells. The area will be leveled and sloped such that run-off from the area can be contained and treated prior to release to the receiving environment.

Hydrocarbon contaminated soils will be stored within the land treatment facility and remediated by regular tilling (aeration) and standard northern bioremediation practices. Runoff from the facility will be collected in a sump and treated via an oil water separator in the sump prior to discharge to ground. The construction of dual cells will allow the treatment of contaminants in cell 1 while soils are added to cell 2, remediation treatment will occur in summer months only. Contaminated soils will be tested for hydrocarbons prior to treatment and will be tested for F1/F2/F3/F4 (one test per 50 cubic meters).

4 INTERNAL AND EXTERNAL REPORTING

Any spill for which external reporting is required, as described in Section 2.2, will be reported to the 24-hour Yukon Spill Report Line. The reporting sequence below will be followed to allow for an efficient and effective response, completion of an accurate spill report, and timely notification of SGC management, government agencies, and First Nations.

- The First Observer (the person who discovers the spill) will identify the source and report to his/her direct supervisor.
- The supervisor will gather spill information and provide to the Mine Manager and Environmental Manager or designate.
- The Environmental Manager or designate will record the information regarding the spill and forward it to the Mine Manager.
- The Environmental Manager or Environmental Coordinator will report the spill to SGC senior management and the 24-hour Spill Report Line and the Department of Energy, Mines and Resources - Client Services and Inspections, and to the Yukon Water Board Waterline online registry, as well as overseeing the completion and distribution of spill-related information.
- The Environmental Manager and senior management will determine responsibility for reporting to the FNNND within 24 hours if required.

5 TRAINING REQUIREMENTS

All personnel on site involved with the handling, use, storage and transportation of hazardous substances will be trained in the procedures for responding to and reporting of spills. Training topics will include:

- Workplace Hazardous Materials Information System (WHMIS) – renewed every 3 years and mandatory for all new hires
- Transportation of Dangerous Goods
- Hazmat training will be delivered to Emergency Response Team members

The following spill related topics will be covered during site orientation for all relevant personnel:

- Responsibilities of personnel
- Causes of spills and preventative measures
- Control, containment and cleanup methods for various spill locations
- Emergency contact information and location
- Storage and disposal of materials used on site
- Reporting requirement and procedure
- Overview of Spill Response Plan
- PPE requirements for handling potential spill materials

6 BEST MANAGEMENT PRACTICES

SGC will incorporate best management practices (BMPs) into all work procedures and plans. BMPs relating to spills are outlined below.

6.1 HEALTH AND SAFETY

SGC will implement a system of workplace inspections to ensure that procedures put in place to prevent incidents and accidents relating to hazardous materials are followed. This system will identify levels of hazard, which will trigger immediate work stoppages, and levels of hazards, which will trigger notification of management. This system will ensure that work does not continue with inadequate provisions for health and safety and those personnel are empowered to address unsafe or potentially unsafe scenarios.

Specifically in relation to hazardous materials, the following will be provided:

- Engineering controls and engineered hazardous material handling mechanisms to ensure that manual handling and ergonomic issues do not exacerbate the risk associated with working with hazardous materials.
- Monitoring systems for detection of hazardous solution and gaseous leaks.
- PPE designed for use in handling the various types of hazardous materials.
- Communication systems with emergency response capabilities.
- MSDS for all hazardous materials will be readily available anywhere these products are stored or used.
- A copy of the MSDSs will be accessible in the site offices.
- Emergency contact information will be posted and kept current.

6.2 SPILL PREVENTION

All relevant personnel that will use or handle hazardous materials will receive WHMIS training and will be trained in proper handling, spill response, and PPE use specific to their job tasks.

No lubrication, refueling or maintenance of equipment is permitted to occur within 30 m of watercourses or wetlands. All fueling and lubrication of equipment will be conducted in a manner that minimizes the possibility of spills with containers, hoses and nozzles kept free of leaks and all fuel nozzles equipped with functional automatic shutoffs.

Sodium cyanide will be mixed with water in a well-ventilated area and maintained at a high pH to prevent the evolution of hydrogen cyanide gas.

The following mitigation measures will be implemented to minimize the potential for transportation incidents that could result in a hazardous substance spill:

- SGC will work with the Department of Highways and Public Works to ensure the access road is properly maintained.
- Speed limits will be strictly enforced for all Project vehicles.
- SGC will ensure trucking and hauling contractors have appropriate driver training, radio contact capabilities, properly maintained vehicles, and spill response capabilities.
- SGC will ensure all hazardous materials are transported and handled in accordance with the *Transportation of Dangerous Goods Act.*
- Signage will be posted along the access road to the Project to ensure non-Project traffic is aware of radio protocols.
- Wildlife migration corridors and crossings along the access road will be identified and signage provided in high risk areas.
- Wildlife crossing and escape points will be plowed in the access road snow banks.
- SGC will have on-site personnel with emergency first aid training to provide primary care in the event of an accident, and will implement the appropriate components of the Emergency Response Plan for the Project.

6.3 SPILL RESPONSE

All site personnel will be familiar with SGC's Spill Response Plan, and their duties and responsibilities. Storage sites will be well labeled, and MSDS are accessible in storage areas. This Spill Response Plan will be kept current, and made available to all personnel. SGC will ensure that suitable spill kits are used for spill response and that personnel are trained in using the spill response equipment.

6.4 STORAGE OF HAZARDOUS MATERIALS

The Solid Waste and Hazardous Materials Management Plan, describes the method of storage of hazardous materials for the Project. SGC will ensure that all hazardous materials are stored with secondary containment structures, either in the form of concrete foundations with curbed sides or double walling of the primary container. Hazardous material storage areas will be well labeled and access to the storage areas will be restricted.

Spill response equipment will be available at hazardous materials storage locations and will be inventoried, maintained and inspected monthly. Signage will be clearly visible in storage, dispensing and transfer areas. Fire extinguishers and/or fire suppression systems will be located at all hazardous material storage locations. Fuel and lubrication materials will be stored a minimum of 30 m from natural watercourses.

6.5 FUEL TRANSFER PROCEDURES

All personnel responsible for transfer, storage, transportation or handling of fuel will be trained in safe work practices for fuel and lubricants.

Caches of spill response materials will be placed along the South McQuesten Road and the Haggart Creek Road, including at the Haggart Creek crossing. Project personnel will have appropriate emergency response and spill contingency training and knowledge; equipment, materials and procedures will be maintained to limit consequences of releases of fuel or oil to the terrestrial or aquatic environment through prompt containment and clean-up.

6.5.1 Spill Protection and Prevention

Spill prevention will be undertaken through ensuring that accepted standard operating procedures are employed for the safe and secure transfer of hazardous materials from product transporters and within the Project site. Hazardous materials will be stored in areas that have containment structures such as concrete foundations with curbed sides. Hazardous material handling will be undertaken within the concrete foundations. Equipment handling hazardous materials will be inspected regularly and any inadequacies will be reported to maintenance personnel and repaired prior to continuation with work.

Spills will be responded to using the methods described in this Plan, according to what type of substance and what surface they occur on, as described in Section 3.3 and Appendix C. Routine inspections and maintenance will be conducted at hazardous material storage and transfer areas. Storage areas will be kept clean through good housekeeping practices.

6.5.2 Dispensing

Storage containers will be stored properly, and will not be over filled. Operating procedures will be established to minimize the potential for fuel spills during dispensing. All personnel handling fuel will be trained on these procedures.

6.6 ROUTINE MONITORING

Monitoring and maintenance is essential in the prevention of spills, and the effective handling of potential spills.

6.6.1 Maintenance

Maintenance procedures will be posted in applicable service areas. Maintenance personnel will be trained and familiar with the procedures. Regular checks will be performed on storage and dispensing equipment to identify any potential problems. If the regular checks identify issues, repairs are to be made prior to continued use of the piece of equipment. Spill response equipment will be kept stocked and maintained, and maintenance logs will be kept.

6.6.2 Perimeter Assessment

The following outlines items that will be identified during inspection:

- Signs of leakage from storage containers, loss of material, cracks, holes etc.
- Signs of inadequacy of secondary containment structures

- Unexpected solution or gaseous emissions will be thoroughly investigated to determine the source and nature of the emissions.
- Discoloration, oily discharges or any unusual odours.

6.6.3 Hazardous Material Storage and Transfer Areas

The following outlines items that will be identified during inspection:

- Spills or stains on the ground.
- Losses of material from storage containers.
- Cracks or damage to storage containers.
- Emergency shut off systems in place, functioning and clearly marked.
- Spill kits are available, adequate and accessible.
- Procedures posted for reference, MSDS are available

APPENDIX A

Assessment, Licence and Permit Requirements for Spill Prevention and Response

THIS PAGE INTENTIONALLY LEFT BLANK

Assessment, Licence and Permit Requirements for Spill Prevention and Response

Document, License or Permit	Section Number	Requirement
Final Screening Report and Recommendation: Terms and Condition of Recommendation	11	As proposed, the Proponent shall ensure a certified cyanide transporter is used and appropriate driver training, radio contact capabilities, vehicle maintenance, and emergency clean-up kits will be on trucks carrying NaCN. Furthermore, the Proponent shall ensure that emergency clean-up kits include equipment to contain NaCN as well and material to protect from, and respond to, cyanide toxicity in spill responders.
Final Screening Report and Recommendation: Terms and Condition of Recommendation	23	The proponent shall ensure that the following communication elements are in the ERP: a) Notification to management, regulatory agencies, outside response providers and medical facilities of the cyanide emergency. b) Notification to potentially affected communities of the cyanide related incident and any necessary response measures. c) Communication protocols with the media.
Final Screening Report and Recommendation: Proponent Commitments	97	SGC will implement the following to maximize road and transport safety: a) Ensure trucking/hauling contractors have appropriate driver training, radio contact capabilities, vehicle maintenance requirements, and spill response capabilities b) Ensure all hazardous materials are transported and handled in accordance with the Transport of Dangerous Goods Act and Regulations
Final Screening Report and Recommendation: Proponent Commitments	98	SGC commits to the following spill prevention and response measures: a) If there is any doubt regarding the size of a spill, material involved, and whether it is reportable, SGC will err on the side of caution and report the spill. b) Caches of spill response materials will be placed along the access road as required by the Spill Contingency Plan, including the Haggart Creek Crossing. c) Project staff will have appropriate emergency response and spill contingency training and knowledge. Equipment, materials, and procedures will be maintained to limit the consequences of releases to the environment through prompt containment and clean-up. d) Fuels, hydrogen peroxide, and other hazardous liquids will be transferred from tanker trucks to storage tanks by enclosed lines, hoses, and pumps equipped with pressure transducers and volume counters to ensure tanks cannot be overfilled. e) No lubrication, refuelling or maintenance of equipment will occur within 30 m of wetlands or watercourses. f) All fuelling and lubrication of construction equipment will be carried out in a manner that minimizes the possibility of spills. All containers, hoses, and nozzles will be free of leaks and all fuel nozzles equipped with functional automatic shut-offs. g) Where stationary equipment cannot be relocated more than 30 m from a watercourse, it will be situated in a designated area that has been bermed and lined with an impermeable barrier with a holding capacity equal to 125% of the largest tank within the berm. h) Equipment operators will be appropriately trained in spill response procedures and carry spill kits capable of handling spills on land and water.

Assessment, Licence and Permit Requirements for Spill Prevention and Response

Document, License or Permit	Section Number	Requirement
Final Screening Report and Recommendation: Proponent Commitments	110	SGC is committed to developing and implementing Environmental Management Plans with the following components: a) Spill Contingency Plan
Final Screening Report and Recommendation: Proponent Commitments	112	The ERP will include the following commitments: a) Resource inventories of personnel, equipment, first aid kits, spill kits, and clean-up materials will be maintained on-site and updated regularly. These inventories will also contain information on external resources available off-site (e.g., RCMP, fire department, other mining establishments in the vicinity). b) All staff on site will receive basic training, including environmental awareness, general emergency response, spill contingency measures, and communication procedures. Truck drivers transporting hazardous materials will also receive additional training on spill response, hazardous material handling, and emergency driving techniques. All security personnel will be trained in first aid.
Final Screening Report and Recommendation: Proponent Mitigations	26	Prevent and respond to all potential spills.
Final Screening Report and Recommendation: Proponent Mitigations	59	Fuel, hazardous material and explosives will be managed according to industry standards including; storage in appropriate containers; containment areas sized to hold the larger of 110% of the largest tank or 10% of the total maximum volume of all tanks in the facility; and storage of explosives in separate buildings away from the rest of the mine activities.
Quartz Mining License QML-0011	10.3	The Licensee must immediately implement the environmental management system if a spill or release of dangerous or hazardous substance or material occurs at the mine.
Class 4 Mining Lands Approval LQ00303	6	All spills must be reported immediately to the 24-Hour Yukon Spill Reporting Ling (867) 667-7244 and to the Mining Inspections Division (867) 456-3882.
Class 4 Mining Lands Approval LQ00303	37	A spill contingency plan for petroleum products and other hazardous waste must be prepared and posted in the camp and at all fuel handling locations used in carrying out the exploration program. The spill plan shall include reporting to EMR-CSI Mining Inspections and the Chief to ensure compliance with spill reporting requirements.
Class 4 Mining Lands Approval LQ00303	38	All spill clean-up equipment and material must be maintained in a state of readiness sufficient at all times to contain and clean-up any hazardous material spills.
Class 4 Mining Lands Approval LQ00303	39	If a spill occurs, the spill contingency plan must be immediately implemented and notice given to the 24-hour Yukon Spill Report Line. As soon as practicable, an inspector must be contacted. Whatever remedial action is required to clean-up the spill and reclaim the affected land and water must be taken.
Class 4 Mining Lands Approval LQ00303	40	Routine maintenance areas where heavy equipment is serviced or repaired should be inspected regularly for minor spills and stored waste hydrocarbons.
Class 4 Mining Lands Approval LQ00303	41	Any contaminated soils should be excavated and contained for eventual land farm treatment at an approved facility.
Type B Water Use Licence QZ16-	19	Where a spill or an unauthorized discharge occurs, that is of a reportable quantity under the Yukon Spills

Assessment, Licence and Permit Requirements for Spill Prevention and Response

Document, License or Permit	Section Number	Requirement
006		Regulations, the Licensee shall immediately contact the 24-hour Yukon Spill Report number, (867) 667-7244 and implement the Spill Contingency Plan. A detailed written report on any such event including, but not limited to, dates, quantities, parameters, causes and other relevant details and explanations, shall be submitted to the Board not later than 10 days after the occurrence.
Type B Water Use Licence QZ16-006	20	The Licensee shall apply the relevant procedures in the Spill Contingency Plan. The Licensee shall review the Spill Contingency Plan annually and shall provide a summary of that review, including any revisions to the plan, as a component of the annual report.
Type B Water Use Licence QZ16-006	21	The Licensee shall maintain a log book of all spill or unauthorized discharge occurrences, including spills that are less than the reportable quantities under the Yukon Spills Regulations. The log book shall be made available at the request of an Inspector. The log book shall include, but not necessarily be limited to the: a) date and time of the spill or unauthorized discharge occurrence; b) substance spilt or discharged; c) approximate amount spilt or discharged; d) location of the spill; e) distance between the spill or discharge and the nearest Watercourse; and f) remedial measures taken to contain and clean-up the spill area or to cease the unauthorized discharge.
Type B Water Use Licence QZ16-006	22	The Licensee shall include a summary of all spills or unauthorized discharges that occurred during the year reported, as part of the annual report.
Type B Water Use Licence QZ16-006	23	All personnel shall be trained in procedures to be followed and the equipment to be used in the containment of a spill.
Type B Water Use Licence QZ16-006	24	Prior to the commencement of construction. the Licensee shall update the Spill Contingency Plan and provide the updated plan to the Board.
Type B Water Use Licence QZ16-006	25	The Spill Contingency Plan shall be posted on site for the duration of the works.
Type B Water Use Licence QZ16-006	26	Ten days prior to construction, the Licensee shall submit material safety data sheets to the Board for all petroleum products and/or hazardous materials that are to be present during this undertaking.
Type B Water Use Licence QZ16-006	13	Fuel, lubricants, hydraulic fluids, coolants and similar substances shall be stored and/or transferred a minimum of 30 metres from the Natural Boundary of any Watercourse, in such a way that said substances are not deposited in or allowed to be deposited in waters.
Type A Water Use Licence QZ14-041	8	The Licensee shall apply the relevant procedures in the Spill Contingency Plan. The Licensee shall review the Spill Contingency Plan annually and shall provide a summary of that review, including any revisions to the plan, as a component of the annual report.
Type A Water Use Licence QZ14-041	9	The Licensee shall maintain a log book of all spill or unauthorized discharge occurrences, including spills that are less than the reportable quantities under the Yukon Spills Regulations. The log book shall be made available

Assessment, Licence and Permit Requirements for Spill Prevention and Response

Document, License or Permit	Section Number	Requirement
		at the request of an Inspector. The log book shall include, but not necessarily be limited to the: g) Date and time of the spill; h) Substance spilt or discharged; i) Approximate amount spilt or discharged; j) Location of the spill; k) Distance between the spill or discharge and the nearest Watercourse; and l) Remedial measures taken to contain and clean-up the spill area or to cease the unauthorized discharge.
Type A Water Use Licence QZ14-041	10	The Licensee shall include a summary of all spills or unauthorized discharges that occurred during the year reported, as part of the annual report.
Type A Water Use Licence QZ14-041	11	All relevant personnel shall be trained in procedures to be followed and the equipment to be used in the containment of a spill.
Type A Water Use Licence QZ14-041	12	Prior to the commencement of Development, the Licensee shall update the Spill Contingency Plan and provide the updated plan to the Board.
Type A Water Use Licence QZ14-041	13	The Spill Contingency Plan shall be posted on site for the duration of the works.
Type A Water Use Licence QZ14-041	14	Ten days prior to Development, the Licensee shall submit material safety data sheets to the Board for all petroleum products and/or hazardous materials that are to be present during the Project.
Type A Water Use Licence QZ14-041	15	Fuel, lubricants, hydraulic fluids, coolants and similar substances shall be stored and/or transferred a minimum of 30 meters from the Natural Boundary of any Watercourse, in such a way that said substances are not deposited in waters.

Reportable Spill Thresholds

THIS PAGE INTENTIONALLY LEFT BLANK

Reportable Spill Thresholds, Personal Protective Equipment and Clean-up Method by Substance FOR UNUSED PRODUCTS

Substance Name	Type	TDGA Class	Reportable Threshold	PPE required for Spill Response	Cleanup or disposal method
Propane	Petroleum product	2	Any amount of gas from a container larger than 100 L, or where the spill results from equipment failure, error, or deliberate action or inaction	Insulated gloves, safety glasses, respirator if there is a possible of oxygen reduction (confined spaces with poor ventilation)	Shut off flow and remove ignition sources if safe to do so and evacuate area. Consult supplier if container needs disposal.
Acetylene	Petroleum product	2	Any amount of gas from a container larger than 100 L, or where the spill results from equipment failure, error, or deliberate action or inaction	Insulated gloves, safety glasses, respirator	Shut off flow and remove ignition sources if safe to do so and evacuate area. Consult supplier if container needs disposal.
Oxygen	Gas	2	Any amount of gas from a container larger than 100 L, or where the spill results from equipment failure, error, or deliberate action or inaction	Insulated gloves, safety glasses	Allow gas to dissipate. Consult supplier if container needs disposal.
Gasoline	Petroleum product	3	200 L (any amount if spilled into a watercourse	Chemical-resistant impervious gloves, safety glasses, respirator if ventilation is inadequate	Approach from upwind, contain and collect spillage with sorbents from spill kits and/or sand and gravel. Pump free liquid into containment. Arrange for transport of material to an approved facility.
Diesel	Petroleum product	3	200 L (any amount if spilled into a watercourse)	Chemical-resistant impervious gloves, safety glasses	Approach from upwind and contain and collect spillage with sorbents from spill kits and/or sand and gravel. Pump free liquid into containment. Arrange for transport of material to an approved facility.
Jet A & B Aviation Fuel	Petroleum Product	3	200 L (any amount if spilled into a watercourse)	Chemical resistant gloves, safety glasses	Use sorbents, pump free liquid into containment. Arrange for transport of material to an approved facility.
Antifreeze	Solvent	9	5 L	Chemical-resistant impervious gloves, safety glasses	Approach from upwind, contain and collect spillage with sorbents from spill kits and/or sand and gravel. Pump free liquid into containment. Arrange for transport of material to an approved facility.
Lubricating and Hydraulic Oils	Lubricating oil	n/a	200 L (any amount if spilled into a watercourse)	Chemical-resistant gloves, safety glasses.	Approach from upwind, contain and collect spillage with sorbents from spill kits and/or sand and gravel. Pump free liquid into containment. Arrange for transport of material to an approved facility.

Reportable Spill Thresholds, Personal Protective Equipment and Clean-up Method by Substance
FOR USED/WASTE PRODUCTS

Substance Type	Time period	Reportable Threshold
Special Waste that may cause an adverse effect	N/A	Any amount
Solid Special Waste	24 hours	500 g
	30 days	5 kg
Liquid Special Waste	24 hours	500 ml
	30 days	5 L
Mixture of Solid and Liquid Waste	24 hours	500 g or 500 ml whichever is less
	30 days	5 kg or 5 L whichever is less

Reportable Spill Response Forms and Photos

EAGLE GOLD PROJECT
SPILL RESPONSE FORM

Name (first observer):	Cliff Ruth, Kevin Raymond	**Company/Department:**	Summit Camps
Date of spill:	March 23, 2018	**Time of spill:**	750am
Location of spill:	Eagle Camp Dorm B	**Site conditions (temperature, wind, precipitation, etc.):**	-4C to -16C; sunny
Distance to nearest watercourse:	>400 m		
Photos (append):	**Y / N, Attached File VIC_CA202 Pictures**		
List safety hazards (Fire, explosive substance, etc.):	Small amount of smoke was observed from electrical line to heat trace due to malfunction. Electrical current to line was immediately shut off.		
Substance spilled:	Black water (sewage)		
Volume of spill (Liters or kilograms):	100-150 L		
Machinery/equipment involved:	Sewage discharge line on "B" dorm		
Cause of spill (Equipment malfunction, vehicle accident, etc.):	Heat trace on sewage discharge line malfunctioned, causing line to freeze and break.		
Environmental areas affected (watercourse, soil, wetland, etc.):	N/A		
Containment actions taken:	The spill was contained in a localized area within the excavation of the lift station at Dorm B. The spill was not absorbed by any soils, as the area around the lift station is frozen.		
Disposal method and location:	The liquid effluent was removed using the site vacuum truck, and surrounding snow/ice was also removed and disposed of in the existing camp septic field.		
Samples taken:	**Y / N, list**		
Further actions required:	None – follow up conducted with Yukon Government as per spill reporting regulations. Currently reviewing heat trace installation throughout site.		
Name of Supervisor informed:	Shawn Wilson, Summit Supervisor		
Spill externally reportable:	**Y / N**	**Name of other personnel informed (Environment Dept):**	Lindsay Rear, VIT

SPILL RESPONSE FORM

StrataGold Corporation

Name (first observer):	Mike Sanborn	**Department:**	Camp Construction.
Date of spill:	2018 04 04	**Time of spill:**	0800
Location of spill:	Between A+B	**Site conditions (temperature, wind, precipitations, etc.):**	-20, calm.
Distance to nearest watercourse	>1Km		
Photos: please list & append	Attached		
Safety hazards identified (Fire, explosive substance, etc.):	N/A		
Substance spilled:	Blackwater		
Estimated volume of spill (Liters or kilograms):	1 L		
Cause of spill (Equipment malfunction, vehicle accident, etc.)	Frozen Blackwater line.		
Environmental areas affected (watercourse, soil, wetland, etc.)	Soil		
Containment actions taken:	Pipe replaced, spill removed & disposed of in septic tank.		
Disposal method and location:	"		
Samples taken:	N/A		
Further actions required:	Repair & Replace Blackwater pipe - Complete ff.		
Supervisor reported to:	Ishan F.

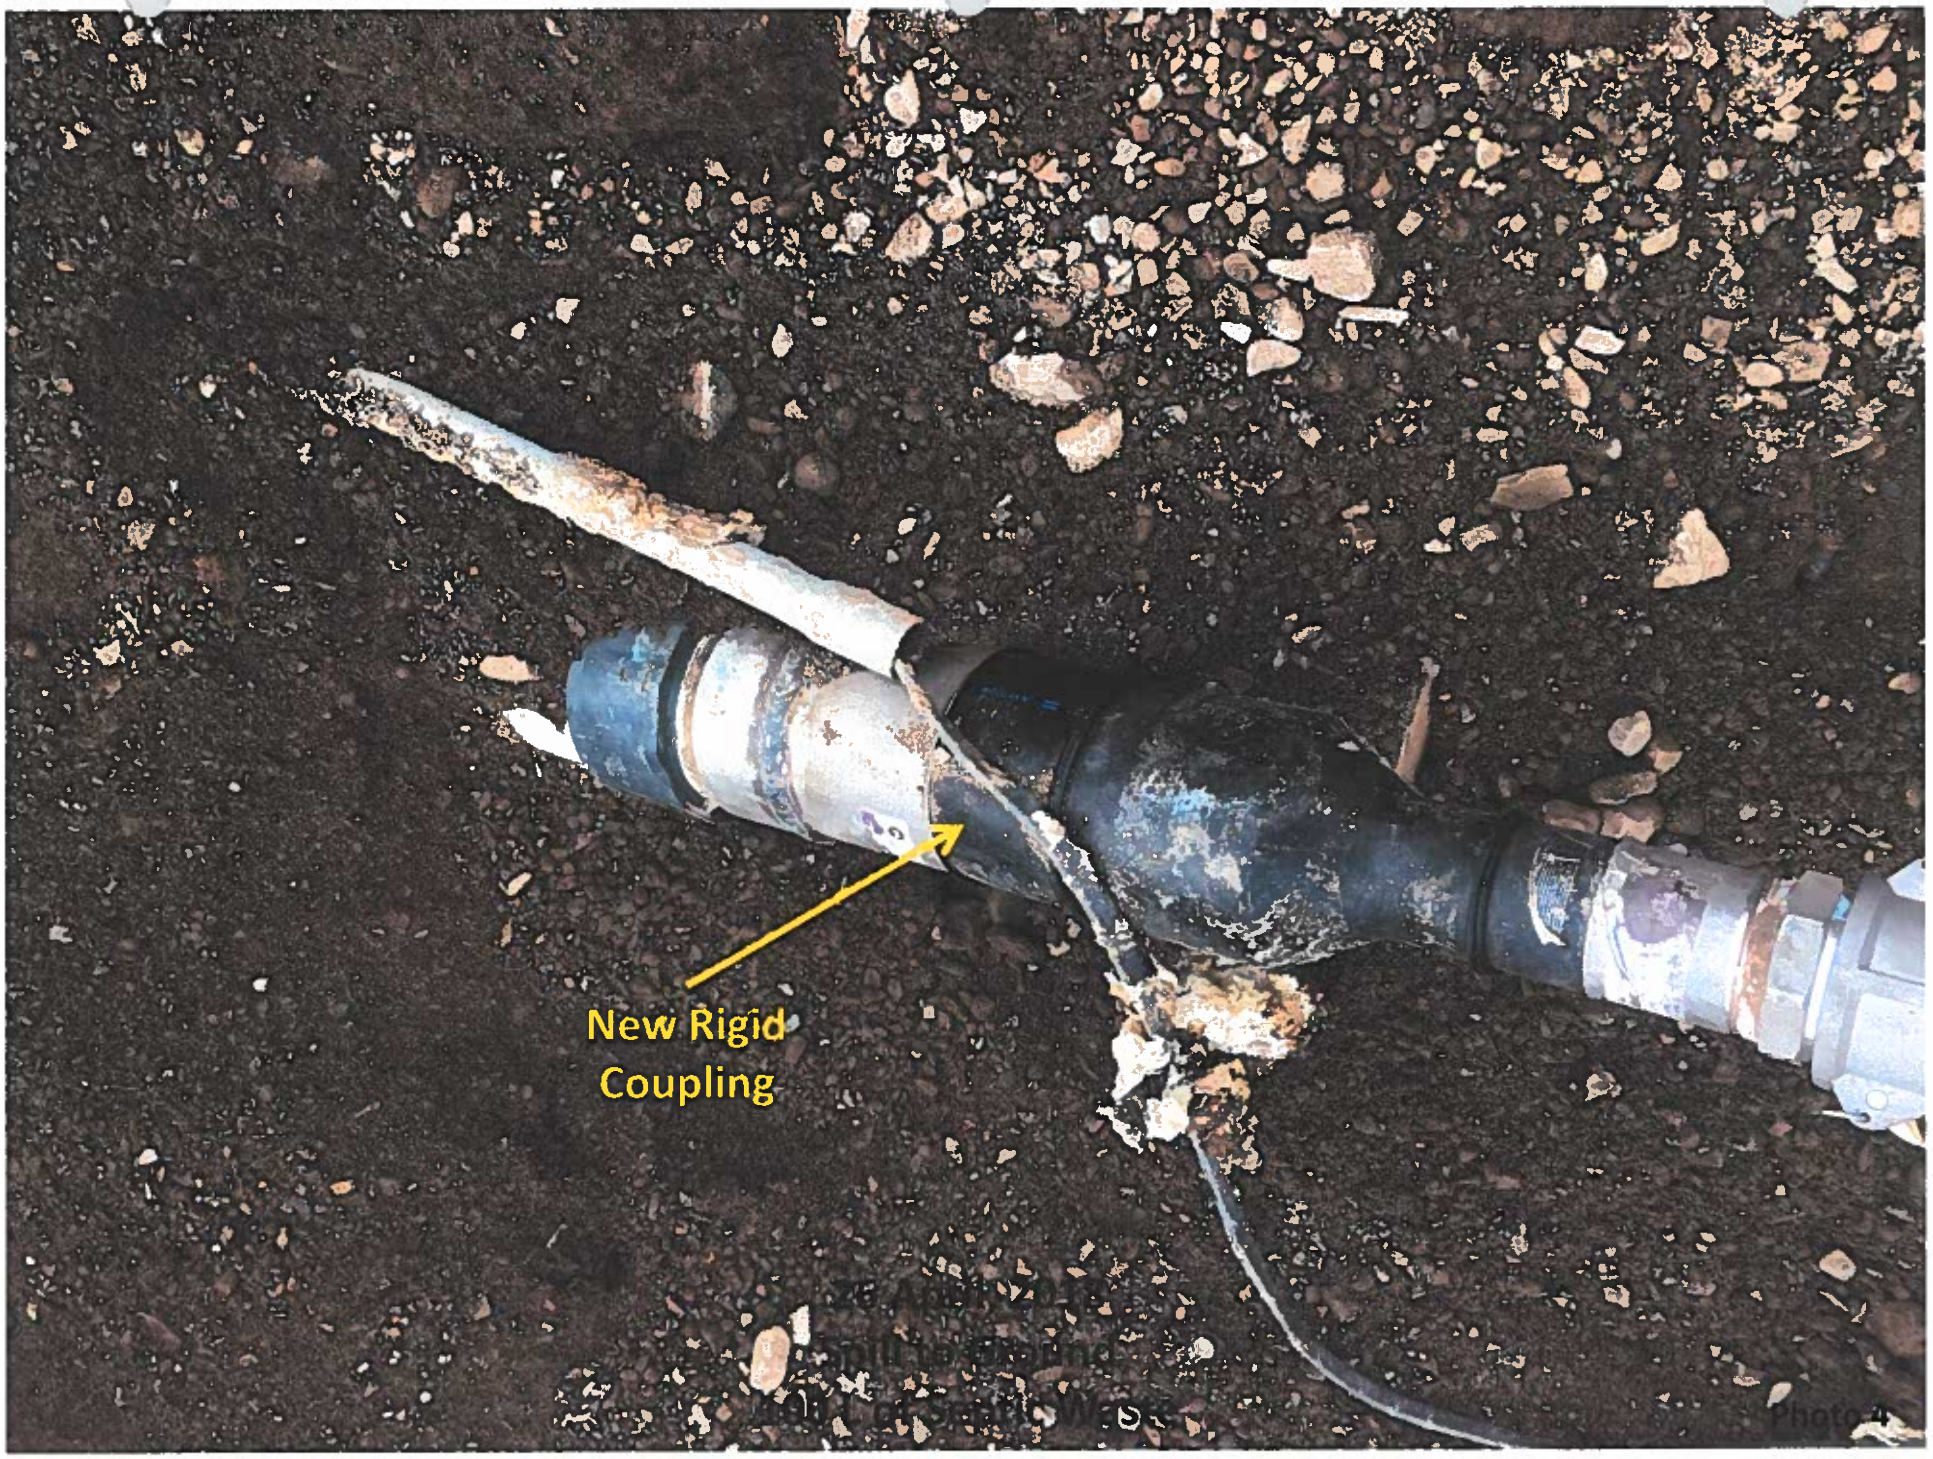
EAGLE GOLD PROJECT
SPILL RESPONSE FORM



StrataGold Corporation

Name (first observer):	Shayne Whipp	**Department:**	Site Services
Date of spill:	26 April 2018	**Time of spill:**	6:30 am
Location of spill:	North end of septic field	**Site conditions (temperature, wind, precipitations, etc.):**	-2C / No wind
Distance to nearest watercourse	>500 meters		
Photos: please list & append	Photo #1 - As discovered, Photo #2 - Post clean-up, Photo #3 - Failed flexible coupling, Photo #4 - New ridged coupling		
Safety hazards identified (Fire, explosive substance, etc.):	None		
Substance spilled:	Septic waste		
Estimated volume of spill (Liters or kilograms):	100 liters		
Cause of spill (Equipment malfunction, vehicle accident, etc.)	The addition of septic waste at a volume in excess of what the system can accommodate, over pressured the system resulting in a failure of the flexible coupling on the pressure side.		
Environmental areas affected (watercourse, soil, wetland, etc.)	Unvegetated sand and gravel associated with #1 Septic field #2 Parking lot		
Containment actions taken:	Shoveled into loader bucket and transported to the septic field. The impacted ground was sprayed with a diluted water-bleach solution		
Disposal method and location:	Impacted sand and gravel was spread over septic field and additional clean fill material was placed over contaminated material to cover.		
Samples taken:	N/A		
Further actions required:	None. Replaced the flexible coupling with a new ridged coupling. Communicated with site services not to pump additional septic waste into septic system in order to prevent over filling/pressurizing the capabilities of the system.		
Supervisor reported to:	Larry LeBlanc		
Is the Spill Reportable	Yes	**Who was it reported to?**	Lindsay Rear (Victoria Gold)

Name (first observer):	Romney Duncan	**Company/Department:**	Walters Construction
Date of spill:	7/06/2018	**Time of spill:**	~ 4:00
Location of spill:	By septic tank	**Site conditions (temperature, wind, precipitation, etc.):**	Clear
Distance to nearest watercourse:	150 m		
Photos (append):	(Y) / N, list		
List safety hazards (Fire, explosive substance, etc.):	None		
Substance spilled:	Sewage		
Volume of spill (Liters or kilograms):	Un/known		
Machinery/equipment involved:	Septic		
Cause of spill (Equipment malfunction, vehicle accident, etc.):	Pipe cracked releasing approx. 20 liters into septic field		
Environmental areas affected (watercourse, soil, wetland, etc.):	None		
Containment actions taken:	Self contained within septic field		
Disposal method and location:	Self contained within the septic field		
Samples taken:	Y / (N) list		
Further actions required:	None - Repair piping		
Name of Supervisor informed:	Ishan		
Spill externally reportable:	Y / N	**Name of other personnel informed (Environment Dept):**

Corrected Form

Name (first observer):	Stephane with Summit	**Company/Department:**	Summit
Date of spill:	June 17, 2018	**Time of spill:**	~6:10AM
Location of spill:	Between A & B Dorms	**Site conditions (temperature, wind, precipitation, etc.):**	Sunny, warm morning, low wind
Distance to nearest watercourse:	~800 meters		
Photos (append):	**Yes**		
List safety hazards (Fire, explosive substance, etc.):	N/A		
Substance spilled:	Grey and black water (sewage)		
Volume of spill (Liters or kilograms):	~15 Liters		
Machinery/equipment involved:	Lift station		
Cause of spill (Equipment malfunction, vehicle accident, etc.):	Lift station high level alarm, pump / shut off malfunction		
Environmental areas affected (watercourse, soil, wetland, etc.):	Soil around the lift station/pump. Was contained in the sump		
Containment actions taken:	Deployed vacuum truck to suck up contaminated water and soil at 6:45 AM		
Disposal method and location:	**Pumped into new septic field**		
Samples taken:	**No**		
Further actions required:	Once the lift station pump is repaired, the soil around the area will be sprayed with a bleach solution as per correct practice		
Name of Supervisor informed:	Blair Laurila (JDS) and Stephane (Summit)		
Spill externally reportable:	**Yes**	**Name of other personnel informed (Environment Dept):**	Alex Therriault and Dean Wold

Name (first observer):	Pacesetter Driver	**Company/Department:**	Pacesetter Petroleum
Date of spill:	27 June, 2018	**Time of spill:**	12:05
Location of spill:	Access Road Km 34	**Site conditions (temperature, wind, precipitation, etc.):**	Rain, overcast
Distance to nearest watercourse:	300 m		
Photos (append):	**Y / N, list**		
List safety hazards (Fire, explosive substance, etc.):	None		
Substance spilled:	Antifreeze (radiator fluid)		
Volume of spill (Liters or kilograms):	20.0 L (maximum, based on amount required to refill)		
Machinery/equipment involved:	North 60 Petro truck #19544 hauling diesel for Pacesetter		
Cause of spill (Equipment malfunction, vehicle accident, etc.):	Radiator hose failure		
Environmental areas affected (watercourse, soil, wetland, etc.):	Gravel/roadbed material associated with the Access Road, non-vegetated, no impact to water		
Containment actions taken:	Truck engine immediately shut off, spill pads immediately put down under engine compartment and where it had contacted the road		
Disposal method and location:	Spill pads and impacted roadbed material collected and placed into large, yellow, hazardous waste bags and taken to the hazardous waste storage area by the Shop; the impacted spill pads and roadbed material will remain segregated from hydrocarbon-bearing waste		
Samples taken:	**Y / N, list**		
Further actions required:	A qualified mechanic replaced the hose, tested it for pressure, and the truck was deemed fully repaired and left the incident scene at 13:47		
Name of Supervisor informed:	Larry Leblanc (JDS), Brent Hartshorne (Pacesetter)		
Spill externally reportable:	**Y / N** No	**Name of other personnel informed (Environment Dept):**	Terry Goodwin (JDS HSE) Crystal Beaudry (Vit Gold)

Corporation

Name (first observer):	Robert Seminiuk	**Company/Department:**	Site operations
Date of spill:	August 26, 2018	**Time of spill:**	07:15
Location of spill:	ADR Wash Car	**Site conditions (temperature, wind, precipitation, etc.):**	Sunny, +8C
Distance to nearest watercourse:	500 meters		
Photos (append):	Yes		
List safety hazards (Fire, explosive substance, etc.):	Potential for biohazards (sewage)		
Substance spilled:	Gray water		
Volume of spill (Liters or kilograms):	5L		
Machinery/equipment involved:	Wash car trailer		
Cause of spill (Equipment malfunction, vehicle accident, etc.):	Gray water tank shifted or settled pipe came out of tank. Shifting of ground below wash car.		
Environmental areas affected (watercourse, soil, wetland, etc.):	Gravel near gray water tank		
Containment actions taken:	Contaminated gravel shoveled and placed into pails		
Disposal method and location:	Pails of contaminated gravel taken down to waste management area near JDS shop. Ground area sprayed with diluted bleach solution.		
Samples taken:	No		
Further actions required:	No – Wash car was repaired immediately by re-attaching pipe		
Name of Supervisor informed:	Robert Seminiuk – Larry Leblanc		
Spill externally reportable:	**Yes**	**Name of other personnel informed (Environment Dept):**	Alex Therriault – VIT Environmental

EAGLE GOLD PROJECT
ENV MONITORING

Name (first observer):	Blair Laurila	**Company/Department:**	JDS/ Site Services
Date of spill:	September 14, 2018	**Time of Spill:**	Unknown. Noticed at 16:00
Location of spill:	Camp parking lot	**Site conditions (temperature, wind, Precipitation, etc.):**	Warm, sunny, light breeze
Distance to nearest watercourse:	200m		
Photos (append):	**Yes**		
List safety hazards (fire, explosive, etc.):	Sewage effluent- contact with people		
Substance spilled:	Sewage effluent		
Volume of spill (litres, kilograms, etc.):	100L		
Machinery/equipment Involved:	Piping on old septic field was not capped and effluent leaked		
Cause of spill (equipment malfunction, vehicle accident, etc.):	Hygiene products are being flushed down the toilets and causing the pumps to stop working.		
Environmental areas affected (watercourse, soil, wetlands, etc.):	Piping on old septic field was not capped, pump breakers went and effluent back up and spilled out of pipe and into the parking lot ditch		
Containment actions taken:	Material was scrapped up and worked into the septic field.		
Disposal method and location:	**On septic field**		
Samples taken:	**No**		
Further actions required:	Currently site services will be checking the area twice a day until a suitable warning system can be installed		
Name of supervisor informed:	Blair Laurila		
Spill externally reportable:	**Yes**	**Name of other personnel informed (Environment Dept.):**	Phil Emerson

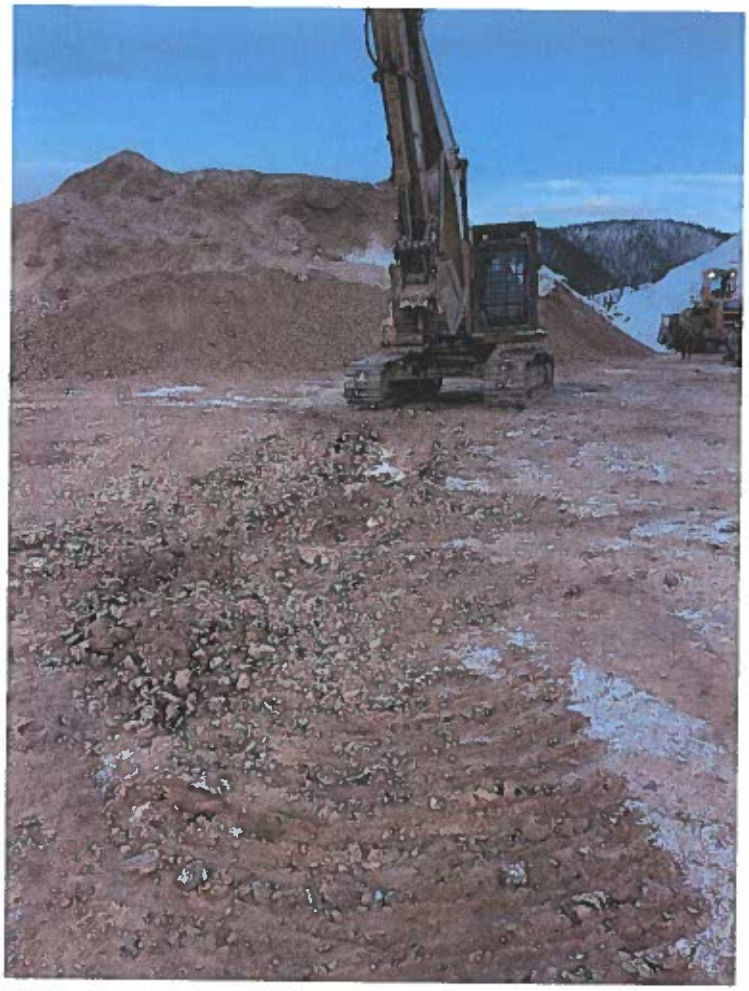
FIRST OBSERVER			
Name & Company:	Colin Kabanak. Ewing Transport		
Date & Time Observed:	December 8, 2018 11:48am		
Location of Spill:	Victoria Gold mine site at the 4 inch stockpile, north of secondary		
Distance to Waterbody:	1.8km	**Photos Taken?**	☒ Yes ☐ No
Estimated Spill Volume:	40 L	**Reported to:**	JDS Safety, VIT Environmental

COMPANY RESPONSIBLE	
Supervisor/Investigator:	Dick Ewing
Date of Spill:	December 8, 2018
Substance Spilled:	Coolant
Equipment Involved:	Cat 980 Wheel loader
Volume of Contaminated Material:	1.5 cubic meters of material
Personnel Contacted for Disposal (Name):	Paul Medvid
Cause of Spill: (Equipment Failure, vehicle accident, foreign object, etc.)	Equipment failure - Failed heater hose
Spill Response Actions Taken: (Containment and/or absorbent materials used, equipment required for clean-up, Pre-trip attached, etc.)	Spill was reported to supervisor immediately, Soaker pads and spill tray was used for containment. Hose line was fixed and the equipment was moved. An excavator was used to clean up the majority of the spill and a track shovel was used to finish cleaning the area.



ENVIRONMENTAL DEPARTMENT USE ONLY

1 BACKGROUND

In September, 2018, Allnorth Consultants Limited (Allnorth) was retained by Victoria Gold Corp. (VGC) to conduct a visual physical stability assessment for their Eagle Gold mining operation located in Mayo Mining District, Yukon, Canada in support of Quartz Mining License QML-0011. Rod Keetch P. Eng. and James Garner EIT of Allnorth conducted the inspection on September 25th, 26th, and 27th, 2018. The inspection was limited to visual inspection and did not include any specific geotechnical or structural testing or evaluation. Visual inspection generally consisted of traversing the structures on foot, and viewing the structures in their entirety from accessible vantage points. Any issues that were discovered were investigated and documented with detailed notes and photographs. Allnorth inspectors were given complete freedom in determining what to look at, and were not permanently restricted for access to any locations within the site.

The mining project is currently under construction and is not currently extracting, storing, processing or refining ore at the time of inspection. As the project is in the early stages, there is no stability instrumentation monitoring program in place, nor are there historical records for survey data, or photographs to review and compare. This will likely become part of the physical stability assessment in the future.

2 SCOPE

This report outlines the findings of the physical stability assessment conducted from September 25th-27th of 2018. This report documents the findings of the physical stability assessment and makes recommendations for remediation, additional inspection or monitoring of the issues identified. The following structures were included in the assessment:

- Lower Dublin South Pond and outfall,
- Stockpile B,
- Stockpile A,
- 90 Day Stockpile,
- Heap Leach Facility,
- Cut and fill slopes of the primary and secondary crushers including MSE walls,
- Cut and fill slopes of the Adsorption, Desorption and Recovery Plant.

The purpose of the inspection is to identify any visual indicators associated with instability of mass earth structures, including but not limited to tension cracking, bulging, pooled water above the slope or near the toe of the slope, falling material, indications of creep, slumps, deposits of debris, or cracking in bedrock. Additionally, constructed slopes were reviewed for slope angles and compared against the recommend slope angles for known material types on site.

3 LOWER DUBLIN SOUTH POND (LDSP)

3.1 Spillway

No issues to note.

3.2 1500mm Spillway Outlet Culvert

1. At the inlet of the 1500mm spillway culvert that crosses under the process plant service road there is a depression with exposed soil. Water is pooling in the depression. Additionally, a very small amount of moving water is flowing from ditching adjacent to the camp road to the spillway. The flow is below the riprap, but above the geotextile. This water is not passing through the 1500mm culvert, therefore it is likely that the low volume flow is passing through the granular subgrade of the culvert.

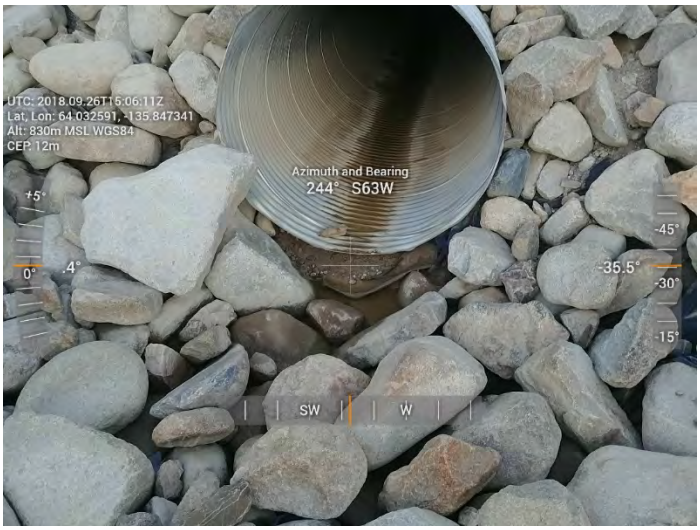

Figure 1: LDSP - 1500mm Culvert with depression and pooling at inlet.

3.3 Lower Dublin South Dam

1. Tension cracking, 0.3m deep by 5.0m long, is present on the Lower Dublin South Dam possibly associated with the settlement of new construction.

Figure 2: LDSP - Tension cracking on south dam.

3.4 Cut slopes

1. A significant amount of water and sediment is entering the collection pond and fore bay from the southern side. Some of the water and sediment is not intercepted by the fore bay prior to entering the collection pond. The water appears to be directed from a berm at a higher elevation. Erosion can be seen at the edge of the collection pond liner, in the cut slopes above the pond and fore bay, and in the bench. Comments on site indicate that a plan is already in place to address drainage in the area.

Figure 3: LDSP - Erosion at the southern side near the fore bay berm.

Figure 4: LDPS - Erosion at liner.

2. On the northeast corner of the pond water is flowing out of a culvert of unknown size. VGC staff have indicated that the culvert was uncovered during construction and is a relic from historic placer mining. The outlet is damaged, and the flow is currently captured by a diversion ditch.

Figure 5: LDSP – Water flow from damaged culvert on northeast corner of pond.

3. Groundwater with unknown origin has previously caused erosion on the West slope of the fore bay. No ground water flows were observed at the time of inspection.

Figure 6: LDSP - Erosion on west slope of fore bay.

4. A small elevated pond above the East slope of the fore bay has trapped some water. A PVC pipe is in place to drain the pond, however, the elevation of the PVC pipe to too high to fully drain the pond. Leaving perched water storage above a soil structure is non-typical. VGC staff have indicated that the pond was created to mitigate erosion of the east fore bay slope and that the pond is periodically pumped to the exfiltration sump when threshold levels in the pond are reached.

Figure 7: LDSP - Elevated Pond above Eastern side of fore bay

3.5 Low Level Outlet Channel

1. In the pond outlet area, surface water from the roadway is flowing down slope causing minor erosion. The exclusion ditching appears inadequate around pond above the v-notch weir to avoid further erosion.

Figure 8: LDSP - Erosion at low level outlet pond.

2. The channel has appropriately sized riprap, but the armour does not meet typical minimum thickness in many locations.

Figure 9: LDSP - Exposed liner in low level outlet channel.

3.6 LDSP Fore bay

1. The fore bay has a reduced capacity due to large quantities of material entering the pond from the South and West slopes. VGC staff have indicated that plans are currently in place to excavate the sedimentation pond and restore additional capacity.

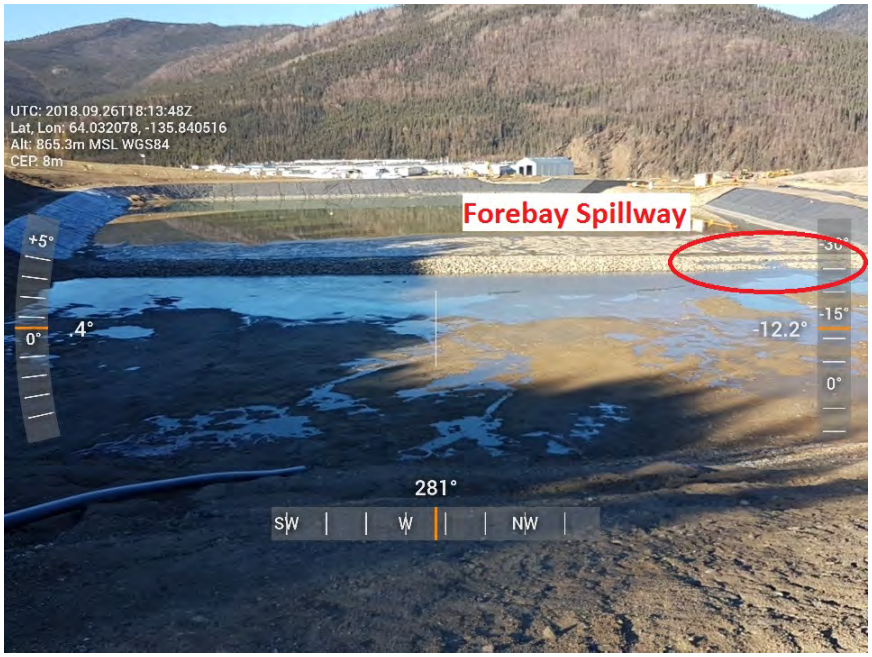

Figure 10: LDSP - Sediment Nearing the top of the fore bay spillway.

3.7 Collection Pond

1. The under drains below the LDSP storage appear to be operating as planned. There is water at the outlet, and outlet flow has stayed fairly constant since their install, according to site staff.

Figure 11: LDSP - Low level outlet pond.

2. Water and sediment has been carried into the pond and onto the liner at the southwest corner of the pond.

Figure 12: Sediment carried onto collection pond liner.

4 PRIMARY CRUSHER

1. The support slope for the Primary Crusher access road is over steepened at 50%, however, this appears to be for a temporary access. (No Photo).

2. The slope immediately behind the primary crusher is rip-able rock with knobs of rock that would require blasting. Measurements taken on site indicates slopes here meet recommendations and range between 50% and 64%.

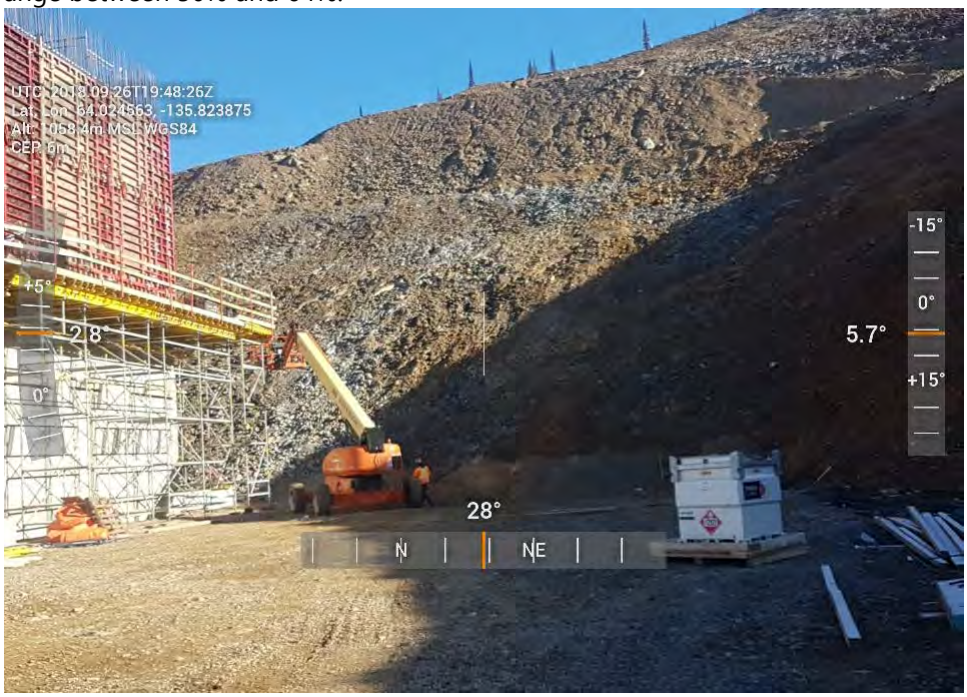

Figure 13: Slope behind primary crusher.

3. Road ditching is in place along the primary crusher access road which restricts over land flow from eroding the slope. (No Photo).

5 SECONDARY CRUSHER + MSE WALL (SC MSE)

1. Very minor ponding is present at the base of the MSE wall due to inadequate grading in some sections.

Figure 14: SC MSE - Minor ponding at base of MSE wall.

2. Drain outlets for the MSE wall are not visible at the face. Site staff have indicated the drain system is in place, installation has been recorded in as-built records and will be day lighted as part of the final site grading. (No Photo).

3. Construction on the MSE wall is ongoing and appears to be well compacted and placed during our inspection.

Figure 15: SC MSE - Equipment used for MSE wall construction.

4. Backfill behind the MSE wall varies to a maximum recorded angle of 64% and appears to be type 2 rock and blastable rock.

Figure 16: SC MSE - Slope behind secondary crusher MSE wall.

5. The slope below the MSE wall is well offset from both the wall and the Secondary Crusher foundations. The slope was measured at 22%-25%.

Figure 17: SC MSE - Slope below secondary crusher pad.

6. The MSE wall has inadequate set back and uneven layers at the bottom of the wall. This has been addressed by the owner and the wall manufacturer according to site personnel.

Figure 18: SC MSE - Secondary crusher MSE wall.

6 90 DAY STOCKPILE

1. Portions of the 90 day stockpile has been developed at this time, and the area below the current pad has been stripped of trees in preparation of the second phase. (No Photo)
2. The outside edge of the current pad development appears to have access and some evidence of recent dumping/placement in an attempt to further construct the pad, though no active dumping or earth moving was witnessed during the inspections. The placed material requires dozing and grading to deal with drainage run off in isolated locations, but there were no features identified that would store significant runoff or melt volume.

Figure 19: 90 Day Stockpile - Ungraded material.

3. The current 90 day stockpile fill slopes meet a 50% maximum grade where measured although there is little in the way of benching. (No Photo)

4. There are perched boulders on the fill above an access road on the south east corner of the stockpile, only a relatively narrow band of vegetation and trees separates the toe of the stockpile from the road.

Figure 20: 90 Day Stockpile - perched boulders.

Figure 21: 90 Day Stockpile - perched boulders.

5. Portions of the 90 Day Stockpile footprint have not yet had complete stripping of the organics, and there appears to be limited locations where the new placement is being completed on some built up organics near the west edge. It is unclear if this is an acceptable part of the foundation of the stockpile, or if the stripping program is complete at this time.

Figure 22: 90 Day Stockpile – Organic layer near west edge.

Figure 23: 90 Day Stockpile - Organics in phase 2 foundation (typical).

7 ADSORPTION, DESORPTION AND RECOVERY PLANT(ADR)

1. Vegetation is perched near to the top of the ADR Slope, though an explicit measurement was not possible due to access considerations. There is adequate space at the base of the slope to accommodate any materials that may fall, though during construction some of that space is being used as a laydown.

Figure 24: ADR - Perched vegetation.

2. The established slope behind the ADR building appears stable and well constructed on the face with only minor accumulation at the toe of small rock and gravels.

Figure 25: ADR - Minor accumulation of gravel at base of cut slope.

3. There is additional borrow happening around the corner from the ADR facility. The slope is under construction/excavation, and there does not appear to be any adverse affects to the already constructed slope above the ADR building. The final excavation should be reviewed to ensure that any altered drainage isn't directed onto critical infrastructure, or the slopes above them, or is accounted for.

Figure 26: ADR – Borrow area.

4. There is a temporary stockpile perched on the outside of slope on this area. The stockpile exceeds the recommended slopes for long term stability for a common fill material. The stockpile should be shaped to meet requirements if it is a long term storage solution.

Figure 27: ADR - Common material stockpile with over steepened slopes.

Figure 28: ADR - Common material stockpile with over steepened slopes.

8 HEAP LEACH FACILITY (HLF)

1. Phase 1 of the HLF is under construction. The confining embankment is nearly complete, and the liner is being installed. A drainage collection ditch has been constructed above current liner and is approximately 1m deep by 3m wide at the top. The measured faces of the constructed slopes were measured at an acceptable 38% grade.

Figure 29: HLF – Collection ditch.

Figure 30: HFL - Confining embankment construction.

Figure 31: HLF - Construction (facing south).

Figure 32: HLF - Construction (facing north).

2. Clearing and stripping has begun for the phase 1B areas. Slopes have been graded to approximately 33%.

Figure 33: HLF - Phase 1B northwest slope.

3. A small amount of water has ponded above the collection ditch. VGC staff have indicated that this will be eliminated as construction of the HLF proceeds.

Figure 34: HLF - Ponded water above collection ditch.

Figure 35: HLF - Pooling above collection ditch.

4. The free face of the HLF confining embankment is benched with some heaped material and perched rock. Typically these exposed faces are smoothed and sealed to help prevent erosion of the face once in operation, it is not clear if that is part of the final design. Perched rock does not appear to be located above any construction, infrastructure, or roadways at the time of inspection.

Figure 36: HLF - Free face with heaped material and perched rock.

Figure 37: HLF - Free face with heaped material and perched rock.

5. There is some water directed near, but not onto the HLF construction. This is west of the structure, but there does not appear to be any management plan in place for the concentration of water directed by a terminated haul road.

Figure 38: HLF - Erosion and material flows west of confining embankment.

9 EVENT POND

1. This area is under construction. Temporary excavations in rock meet the suggested slopes as laid out by the specifications provided, and determined by the geotechnical consultants in mine planning.

Figure 39: Event pond (facing east) – rock cuts.

2. There are some small over steepened stockpile material above the rock cuts, but there is no equipment or active work below the face.

Figure 40: Event pond (facing west) – over steepened material.

3. Some tension cracking and sloughing block failures can be seen in material consisting of common fill and mixed stripping organics at the SE corner of the current works. The area does not have any active drainage but is under construction. The short runout for any minor sloughing does not threaten any infrastructure. (No Photo).

10 STOCKPILE A

1. The Stockpile is currently being excavated with the material being used for road fill in a culvert installation on the road adjacent. There is very little stockpiled material present at the time of inspection.

Figure 41: Stockpile A.

2. The rear slopes of the stockpile area are composed of placed rock and engineered fill at 50% below a bench and a rock face above the bench at 65%.

Figure 42: Stockpile A - upper slope.

Figure 43: Stockpile A - upper slope.

3. The temporary faces of the remaining stockpile material are well supported and set at 50% when benching setbacks are included.

Figure 44: Stockpile A - lower slopes.

11 STOCKPILE B

1. Edges of the stockpile are extending past stripping, this could be an issue if there is a required base/foundation preparations for future loading.

Figure 45: Stockpile B - Toe of slope encroaching on organics.

Figure 46: Stockpile B - Toe of slope encroaching on organics.

2. The west portion of the stockpile is primarily organics and topsoil. Tension cracking up to 1m deep and 30m long was found on the west edge behind some slowly failing material caving off in sloughing block sections. There is no infrastructure or active work nearby, therefore, if a small failure were to occur the consequences would be very low.

Figure 47: Stockpile B - West end tension cracking.

Figure 48: Stockpile B - West end tension cracking.

Figure 49: Stockpile B - West end tension cracking.

3. The new material being moved to the stockpile varies significantly in material composition and moisture content. The north edge of the dump has significantly saturated soils at the time of inspection.

Figure 50: Stockpile B - North side saturated soils

4. There is a small failure at the north west edge of the stockpile. While the mechanism is not completely clear, it appears to be linked to a stockpile deposit of mixed ice and earth that was excavated for other works. The material failed in a flow mechanism, and the run out does not extend more than 20m past the toe of the existing stockpile. The toe of the flow is composed of ice chunks and fractured rock mixed with fines. Work is not taking place below the stockpile, but there is an active haul road accessing the stockpile adjacent to the failure path. It is unclear if any ice remains in the stockpile.

Figure 51: Stockpile B - Northwest material flow.

Figure 52: Stockpile B - Northwest material flow.

Figure 53: Stockpile B - Ice found in northwest material flow.

5. Sloping of the outside faces of the stockpile was found to be supported at 90% to 100%.

Figure 54: Stockpile B - Outside slope (Typical).

12 RECOMMENDATIONS

12.1 General

1. VGC should assign a qualified, on site, individual to be responsible for monitoring and documentation of any mass earth structures that have significant risks in the case of a failure. The individual should develop a standard operating procedure for the monitoring and risk management of these structures. This individual should be responsible for coordination with a qualified professional to review monitoring data for concerns and trends, if they are not qualified themselves.

2. All stockpiles, material storage areas, and other mass earth structures should all have formal foundation and construction designs completed by a qualified professional. Design and base preparation have been completed and documented for much of the work in progress. VGC should continue to assign individuals to document and be responsible for the monitoring and construction review to determine if such structures are constructed in accordance with design. Any variations between design documents and final construction should be included in final record drawings.

3. Any finalized construction of mass earth structures should include a final construction report that includes any operational and maintenance requirements (if any) to ensure stability of the structure.

4. VGC should consider a monitoring program to assist in early warning and detection of any movements in mass earth structures. Such a program might use permanent survey points, slope

inclinometers, piezometers, or other tools to measure internal/external movements and pore water pressures. Such a monitoring program should be developed with the assistance of and be implemented with the oversight of a qualified professional.

12.2 LDSP

1. Extend the existing berm along the south side of the pond further to the east to direct water into the fore bay / siltation pond, where there is no liner to disturb and where the facility is designed to capture eroded material.

12.3 Primary Crusher

1. No specific recommendations at this time.

12.4 Secondary Crusher and MSE Wall

1. No specific recommendations at this time.

12.5 90 Day Stockpile

1. Mitigate risks associated with perched rocks throughout the slope. Boulders should be removed in a controlled manner, or have a machine press (or bury) the boulders into the existing fill so they have a more stable base, and are less likely to become dislodged. Care should be taken during this work to ensure that critical infrastructure, workers and equipment are restricted from the fallout path, or other appropriate mitigation measures are put in place.

12.6 ADR

1. Reduce the outside slope of material in the stockpile above the ADR Access Road. The stockpile West Northwest of the ADR Building is composed of a mix of several materials with unknown compaction and possibly over steepened outside slopes. It is recommended that the stockpile be shaped within geotechnical design specifications, or that the location of the pile is adjusted so that there is a bench between the crest of the adjacent slope, and the toe of the stockpile. If the stockpile is to remain long term, the structure should have a design completed by a qualified professional.
2. At the time of inspection, there appeared to be over-steepened temporary cut slopes created adjacent to short term haul roads used for construction access in the area. Cut back slopes adjacent to haul roads that do not meet geotechnical specifications for the site, or have recommendations in place for temporary slopes during construction.

12.7 HLF

1. No specific recommendations at this time.

12.8 Event Pond

1. No specific recommendations at this time.

12.9 Stockpile A

1. No specific recommendations at this time.

12.10 Stockpile B

1. This stockpile should be graded on top to eliminate or seal tension cracking.
2. The extent (volume and location) of ice and other frozen materials in the stockpile should be determined based on site records and information from site staff available. A record of the resulting instability should be noted.
3. Have a qualified professional determine if ice and other frozen materials are an acceptable material for construction of a mass earth structure, and if they are, how they should be placed or incorporated in an overall stockpile design to ensure that there are no localized failures as a result.

13 CONCLUSION

The structures reviewed in this inspection generally show little evidence of movement or risk indicators. Where risk of movement was identified, there risk is typically low and the consequence of a small instability is managed by minimizing exposure to workers, infrastructure or high value natural resources.

Slopes reviewed meet the recommendations for slope angles in most locations except where the slopes are temporary in nature and will later be cut back under final design, this is typical in construction on major projects.

The lack of previous stability review reports due to the age of the project and no requirement for previous completion, the fact that current infrastructure is currently incomplete and in construction, and the lack of any established survey or instrumentation monitoring program leaves little baseline data for comparison, but will improve with subsequent reviews.

There are some minor erosional and stability concerns within the project, that can be addressed with some minor planning and maintenance as construction continues in order to moderate or eliminate the associated risks.

We trust this report satisfies your requirements at this time and thank you for the opportunity to work with you on the project. If you have questions or concerns do not hesitate to contact our office.

Yours truly,

EXECUTIVE SUMMARY

NND EBA Land Protection Corp. operating as NELPCo Limited Partnership (NELPCo) was retained by Victoria Gold Corp. (Victoria Gold) to provide consulting services for a geotechnical permafrost investigation program at the Eagle Gold Project (the Project) site. The Project is located in the Dublin Gulch area of central Yukon Territory approximately 45 km (85 km via road) north-northeast of Mayo and 370 km (485 km by road) north of Whitehorse. A primary focus of the spring 2018 investigation was to acquire geotechnical and permafrost data, including frozen and unfrozen overburden soil and bedrock conditions, that would provide important data and information for input to the design of mine infrastructure, in particular to support the final design of the mine waste rock storage areas (WRSA): Eagle Pup WRSA, Platinum Gulch WRSA, the 90 Day Storage area, and the potential run-of-mine (ROM) stockpile area.

This data report has been prepared by Tetra Tech Canada Inc. (Tetra Tech), NELPCo's engineering service provider.

Several previous geotechnical site investigations were carried out by BGC Engineering Inc. (BGC) in 2009, 2010, 2011, and 2012. The previous site investigations were comprehensive and included numerous geotechnical drillholes, test pits, and subsequent laboratory testing programs. Based on a detailed review of the previous investigations (BGC 2009; 2010; 2011a,b; and 2012b,c) it was determined that additional information was necessary to confirm the characteristics and extent of permafrost (including frozen materials with excess ice) within the WRSA and ore stockpile footprints. The spring 2018 geotechnical investigation was designed specifically to augment the previous investigations by characterizing permafrost conditions in foundation areas critical to physical stability of the facilities.

The 2018 geotechnical site investigation program was carried out from April 5 to 15, 2018 and consisted of coring and testing frozen and unfrozen overburden soil and bedrock. A total of 13 boreholes with depths ranging from 7.9 m to 21.3 m were sonic-drilled and logged at the mine site facility locations.

An important objective of the spring 2018 program was to characterize permafrost conditions, including ground temperatures and ground ice contents (e.g., excess ice). Cores were logged according to appropriate geotechnical and permafrost standards. A total of six multi-bead ground temperature (thermistor) cables (GTCs) and seven single-bead thermistor strings were installed in the completed boreholes. GTCs were installed to 15 m to 20 m depths while single-bead thermistor strings to 8 m to 9 m depths.

This report presents the most recent geotechnical and permafrost data collected during the spring 2018 investigation, including borehole logs, geotechnical laboratory test results, GTC, and single-bead thermistor string readings collected from newly installed ground temperature monitoring instrumentation. This report is not intended to be a comprehensive summary of all geotechnical information used as the basis of the WRSA and ore stockpile designs. The BGC 2010, 2011 and 2012 site geotechnical investigation reports should be referenced for details regarding information collected from those investigations. Subsurface conditions at the WRSAs: the 90 Day Storage area, and the potential ROM stockpile area are summarized from the new data.

The new permafrost data was used to update the permafrost distribution map of the project area which was originally developed based on the previous BGC investigations and detailed air photo analysis by Tetra Tech in 2017. A discussion regarding the review of previous investigations and preparation of the initial permafrost map can be found in Tetra Tech's October 6, 2017 technical memo (issued for review) entitled "Permafrost Distribution Mapping within the Dublin Gulch Area" (Tetra Tech 2017).

ROM	Run-of-Mine
RQD	Rock Quality Designation
SBTS	Single-Bead Thermistor String
Tetra Tech	Tetra Tech Canada Inc.
UCS	Unconfined Compressive Strength
UTM	Universal Transverse Mercator
Vc	Perennially frozen soil with excess ice visible as ice coating on particles
Victoria Gold	Victoria Gold Corp.
Vr	Perennially frozen soil with excess ice visible as random or irregularly oriented ice formations
Vs	Perennially frozen soil with excess ice visible as stratified or distinctly oriented ice formations
Vu	Perennially frozen soil with excess ice visible as ice formations uniformly distributed throughout
Vx	Perennially frozen soil with excess ice visible as individual ice crystals or inclusions
WRSA	Waste Rock Storage Area

GLOSSARY OF TERMS

ACTIVE LAYER – the top layer of ground that is subject to annual thawing and freezing in areas underlain by permafrost. The thickness of the active layer varies from year to year, depending on such factors as the ambient air temperature, vegetation, drainage, soil and rock type, water content, snow cover, slope degree, and aspect.

CRYOSTRUCTURE – the structural characteristics of frozen earth materials determined by the amount and distribution of pore ice and lenses of segregated ice. Can be described as massive, layered, reticulate etc.

DEPTH ALONG AXIS (m) – depth measured along the borehole axis from its collar.

DEPTH OF ZERO ANNUAL AMPLITUDE (*depth of zero seasonal temperature variations*) – the distance from the ground surface downward to the level beneath which there is practically no annual fluctuation in ground temperature (NRCC 1988).

EXCESS ICE – the volume of ice in the ground that exceeds the total pore volume that the ground would have under natural unfrozen conditions (NRCC 1988).

GROUND ICE – a general term referring to all types of ice (segregated, intrusive, vein etc.) formed in freezing and frozen ground. Occurs in pores, cavities, voids, cracks, fractures, and other openings in soil or rock.

ICE + SOIL TYPE (ICE and SILT etc.) – ice with soil inclusions: discrete visible ice formations in frozen soils that are greater than 50% by volume. Frozen core interval that contains more ice (>50% by volume of visible ice) than soil particles.

ICE COATINGS – discernible layers of ice found on or below the larger soil particles in a frozen soil mass.

ICE CONTENT – the amount of ice contained in frozen or partially frozen soil or rock. Ice content is normally expressed in one of two ways:

- On a dry-weight basis (gravimetric), as the ratio of the mass of the ice in a sample to the mass of the dry sample, expressed as a percentage; or
- On a volume basis (volumetric), as the ratio of the volume of ice in a sample to the volume of the whole sample, expressed as a percentage.

ICE LENS – a dominantly horizontal, lens-shaped body of ice ranging in thickness from hairline to 0.3 m. Ice layers more than 0.3 m in thickness are better termed massive ice beds.

ICE WEDGE – a massive, generally wedge-shaped body of foliated or vertically banded, commonly white, ground ice with its apex pointing downward.

MASSIVE ICE – A comprehensive term used to describe large masses of ground ice, including ice wedges, pingo ice, buried ice, and predominantly horizontal beds of segregated ice. Massive ice layers have a minimum thickness of 0.3 m. Ice layers less than 0.3 m in thickness are better termed ice lenses. Some massive ice beds are more than 40 m thick and extend several kilometres laterally (Mackay 1973; NRCC 1988; Tetra Tech WM4102).

MASSIVE ICE BED – a predominantly horizontal layer of ground ice with a minimum thickness of 0.3 m, a minimum lateral extent of at least 10 m, and an ice content of at least 250% (on an ice-to-dry-soil weight basis). If the ice content is less than 250%, the beds are termed "**massive icy beds**". The largest ice beds exceed 1 km^2 in area and are more than 40 m thick. Massive ice beds show every possible gradation from icy muds to pure ice (Mackay 1973; NRCC 1988; Tetra Tech WM4102).

PERMAFROST – ground (soil and/or rock) that remains at or below 0ºC for at least two consecutive years. Permafrost is defined exclusively on the basis of temperature. It does not necessarily contain ground ice.

PERMAFROST BASE – the lower boundary surface of permafrost, above which temperatures are perennially below 0°C and below which temperatures are perennially above 0°C.

PERMAFROST, ICE-RICH – permafrost containing excess ice.

PERMAFROST TABLE – the upper boundary of permafrost.

SUPRAPERMAFROST WATER – water occurring in the active layer above the permafrost table.

SUBPERMAFROST WATER – water occurring in the unfrozen ground below the permafrost base.

TALIK – a layer or body of unfrozen ground in a permafrost area. Several types of taliks can be distinguished on the basis of their relationship to the permafrost: closed, open, lateral, isolated etc. (NRCC 1988).

TRUE DEPTH (m) – depth measured from the borehole collar perpendicular (normal) to the ground surface.

LIMITATIONS OF REPORT

This report and its contents are intended for the sole use of Victoria Gold Corp. and their agents. Tetra Tech Canada Inc. (Tetra Tech) does not accept any responsibility for the accuracy of any of the data, the analysis, or the recommendations contained or referenced in the report when the report is used or relied upon by any Party other than Victoria Gold Corp., or for any Project other than the proposed development at the subject site. Any such unauthorized use of this report is at the sole risk of the user. Use of this document is subject to the Limitations on Use of this Document attached in the Appendix or Contractual Terms and Conditions executed by both parties.

1.0 INTRODUCTION

NND EBA Land Protection Corp. operating as NELPCo Limited Partnership (NELPCo) was retained by Victoria Gold Corp. (Victoria Gold) to provide consulting services for a geotechnical permafrost investigation program at the Eagle Gold Project (the Project) site. The Project is located in the Dublin Gulch area of central Yukon Territory approximately 45 km (85 km by road) north-northeast of Mayo and 370 km north of Whitehorse (485 km by road) (Figure 1; "Figures" Section of this report).

This data report has been prepared by Tetra Tech Canada Inc. (Tetra Tech), NELPCo's engineering service provider.

Several previous geotechnical site investigations were carried out in the Project area by BGC Engineering Inc. (BGC) in 2009, 2010, 2011, and 2012. The previous site investigations were comprehensive and included numerous geotechnical drillholes, test pits, and subsequent laboratory testing programs. Based on a detailed review of the previous investigations (BGC 2009; 2010; 2011a,b; and 2012b,c) it was determined that additional information was necessary to confirm the characteristics and extent of permafrost (including frozen materials with excess ice) within the WRSA and ore stockpile footprints. The spring 2018 geotechnical investigation was designed specifically to augment the previous investigations by characterizing permafrost conditions in foundation areas critical to physical stability of the facilities. Specifically, the final toes and first few years of interim toes were targeted.

The 2018 geotechnical investigation program consisted of coring and testing of frozen and unfrozen overburden soil and bedrock. Although BGC (2012a) defines the overburden soil as including completely weathered bedrock, for the purpose of this report, overburden soil is described as all soils above bedrock, including organic and/or inorganic (mineral) soils in both frozen and unfrozen states.

An important objective of the spring 2018 program was to characterize the permafrost conditions as accurately as possible, including ground temperatures and ground ice contents (percent by volume of visible ice). Cores were logged according to appropriate geotechnical and permafrost standards (ASTM D4083; WM4102; WM4105; WM4400). Every completed borehole was instrumented by either a multi-bead ground temperature (thermistor) cable (GTC) installed to 15 m to 20 m depth or a single-bead thermistor string (SBTS) installed to 8 m to 9 m depth.

This report presents the most recent geotechnical and permafrost data collected during the spring 2018 site investigation, including borehole logs, geotechnical laboratory test results, ground temperatures measured with GTC and SBTS. Subsurface conditions at the two proposed WRSA locations, the 90 Day Storage area, and potential ROM stockpile area are summarized from the data collected from this study only. This report is not intended to be a comprehensive summary of all geotechnical information used as the basis for the WRSA and ore stockpile designs. The BGC 2010, 2011, and 2012 geotechnical site investigation reports (BGC 2009; 2010; 2011a,b; and 2012b,c) and the waste rock storage design report (BGC 2012a) should be referred to for details regarding information collected from the previous investigations.

The new permafrost data was used to update the permafrost distribution map of the project area. The updated map is provided as the background for Figure 2. The permafrost map was originally developed by using data from the previous BGC investigations (BGC 2009; 2010; 2011a,b; and 2012b,c) and detailed air photo analysis by Tetra Tech (Tetra Tech 2017). It has now been further refined with the subsurface data collected as part of this study.

This report incorporates and is subject to Tetra Tech's Limitations on Use of this document, which are included in Appendix A.

2.0 GEOTECHNICAL INVESTIGATION

2.1 General

The spring 2018 geotechnical site investigation program was completed from April 5 to 15, 2018 and was managed by Dr. Vladislav E. Roujanski, P.Geol., a senior project geologist-geocryologist based in Tetra Tech's Edmonton office. Field core logging, sampling, and on-site geotechnical soil core testing was conducted by Dr. Roujanski, Mr. Ernest Palczewski, P.Geo., and Mr. Ryan Okkema, E.I.T. (all based in Tetra Tech's Edmonton Office).

Technical support for the field program was provided by Mr. Kevin Jones, P.Eng., Tetra Tech's Vice President for Arctic Development, while logistical support for the field program was provided by Mr. Chad Cowan, Tetra Tech's Yukon Geotechnical Manager based in Tetra Tech's Whitehorse Office.

Victoria Gold had representatives on site helping to coordinate the drilling program. Midnight Sun Drilling Ltd. (MSD) was the drilling contractor.

Existing site roads were plowed and cleared of snow by a bulldozer where necessary to allow access to the drill pad locations. Drill pads were cleared and flattened by an excavator prior to rig mobilization. Crew access to the drill pad locations was provided by light vehicles. Construction of drill pads often required cut and fill to make a level surface for the sonic drill to move into position. To recover representative core samples of the uppermost ground layer and install thermistor cables within undisturbed terrain, the drill rig was positioned on the edge of the pad, when possible, to drill into the undisturbed native ground. However, due to space and accessibility constrains, Boreholes GT18-05, GT18-09, and GT18-10 required drilling through fill material, advancing into the cut on the original slope or otherwise previously disturbed ground.

2.2 Borehole Locations

To characterize the WRSA foundation materials, 20 borehole locations were initially selected for the spring 2018 program based on permafrost distribution maps and mine development plans. Thirteen boreholes were drilled as seven of the originally proposed borehole locations were inaccessible due to deep snow cover, slope steepness, or other challenging ground conditions (e.g. accumulations of large boulders).

The project area is located within Zone 8 of the Universal Transverse Mercator (UTM) Grid. The horizontal datum for this project is the North American Datum 1983 (NAD83).

Survey control for the geotechnical site investigation was provided by Tetra Tech field personnel using a handheld GPS unit (Garmin GPSMAP 62) to locate and verify the borehole locations that were staked by Victoria Gold prior to the investigation. The coordinates, depth to bedrock, and completion depth for each of the boreholes are presented on borehole logs in Appendix B and are summarized in Table 1 below. Borehole locations are also presented on Figure 2.

Table 1: Borehole Information Summary

Site Infrastructure	Borehole	UTM Zone			Depth to Bedrock (m)	Completion Depth (m)
		Northing (m)	Easting (m)	Elevation (m)		
Eagle Pup WRSA	GT18-01	7,100,952	459,831	913.0	4.8	21.3
	GT18-02	7,100,945	459,925	932.0	2.1	7.9
	GT18-04	7,100,787	459,854	961.0	2.1	9.0
	GT18-05	7,100,814	460,006	944.0	3.5	21.0
	GT18-06	7,100,852	460,088	968.0	3.8	12.0
	GT18-07	7,100,709	460,139	965.0	12.0	21.0
Platinum Gulch WRSA	GT18-08	7,099,141	459,517	990.0	N/A	17.4
	GT18-09	7,098,981	459,925	1,117.0	9.5	21.0
	GT18-10	7,098,851	459,968	1,175.0	9.0	12.0
	GT18-11	7,098,964	460,080	1,181.0	10.0	12.0
Potential ROM Stockpile Area	GT18-15	7,100,583	459,597	961.0	18	21.0
	GT18-16	7,100,308	459,607	982.0	3.5	9.0
90 Day Storage	GT18-17	7,100,290	459,263	944.0	5.5	9.0

2.3 Drilling and Coring Methodology

Thirteen completed boreholes were drilled using a Compact Crawler TerraSonic CC150 Sonic drill rig operated by MSD (Photo 1). A sonic drill was selected for the program due to its ability to consistently recover high percentages of samples in the overburden. Sonic drilling is not particularly effective in coring bedrock but this was not a concern given that the program was designed with the primary focus of soil and permafrost sampling. Bedrock was already well sampled and characterized using diamond core drilling during the previous BGC investigations (BGC 2009; 2010; 2011a,b; and 2012b,c). The maximum depth drilled by the sonic drill was 21.25 m. Overburden soil and bedrock core samples were recovered using an HQ bit (4” ID and 4.75” OD) for all boreholes.

Photo 1: Compact crawler TerraSonic CC150 Drill Rig, Borehole GT18-05 site. Eagle Pup WRSA, looking north. Photo taken April 9, 2018

Overburden soil recovery ranged from 90% to 100%, but in some cases, core was thermally and mechanically disturbed from the drilling process. Holes were typically only drilled far enough into bedrock to confirm that competent bedrock had been reached. Rock core recovery was variable, depending on the use of water to aid in the drilling process. Rock core recovery ranged from 90% to 100% without the use of water and decreased to 10% to 20% recovery with water aided drilling.

2.4 Geotechnical Logging and Sampling

Frozen and unfrozen overburden soil and bedrock core examination and logging was conducted immediately following core recovery to ensure that there was minimal thermal disturbance to the frozen core samples. This allowed accurate identification, logging, and sampling of frozen and unfrozen overburden core.

Overburden soils were logged according to the Modified Unified Soil Classification System guidelines (Appendix B) and Tetra Tech's methodology for logging frozen and unfrozen overburden, which includes soil composition, particle shape, moisture, colour, and consistency of soil (WM4400 – see Appendix E) and classify frozen soil based on whether ice is visible or not (WM4102 – see Appendix E).

All recovered core samples were placed in wooden core boxes and photographed immediately upon recovery, prior to sample removal. Close-up photographs were taken of ground ice formations and cryostructures where present. Photographs of the recovered core samples are included in the "Photographs" Section of this report, as are selected photographs (Photos 1 to 48) of the recovered overburden soil and bedrock core.

Representative disturbed soil samples were placed in plastic bags, double-bagged for moisture preservation, and transported to the onsite geotechnical laboratory.

Representative undisturbed frozen core samples were wrapped in several layers of plastic wrap and aluminum foil. The wrapped samples were temporarily stored at the drill sites in insulated coolers with ice packs to maintain their frozen undisturbed state until they were transferred to a freezer located at the Eagle Camp.

2.5 Geotechnical Laboratory Testing

2.5.1 General

Eight samples were tested in the onsite laboratory located at the camp, which was equipped with a microwave oven, electronic scale, and other basic testing equipment. On-site laboratory testing included measurements of excess ground ice content, moisture content, and porewater salinity. The remainder of the frozen core samples were shipped to Whitehorse and Edmonton for testing and storage at Tetra Tech's geotechnical laboratories. The off-site testing included natural moisture and excess ice contents, grain size analysis, bulk densities, and direct shear tests.

The testing results are summarized below in Tables 2 and 3. The results are also presented in Appendix C and are detailed on the borehole logs in Appendix B.

2.5.2 Classification Laboratory Testing

On-site Moisture Content, Excess Ice Content, and Salinity Analysis

On-site excess ice content analyses were completed on eight samples, as these samples showed potential for the presence of excess ice. Five of the selected eight samples were also tested on-site for moisture content. Salinity analysis was completed on one sample. The results are summarized in Table 2.

Table 2: Summary of On-site Laboratory Test Results

Borehole No.	Sample No.	Depth		Moisture Content (%)	Excess Ice Content (% by volume)	Porewater Salinity (ppt)
		From (m)	To (m)			
GT18-02	S1	0.47	0.64	29.0	0.0	-
GT18-05	S1	0.40	0.55	48.1	0.0	-
	S2	0.80	0.90	23.0	0.0	-
	S5	1.35	1.50	29.0	0.0	-
GT18-08	S2	0.70	0.75	139.4	>0.0*	-
	S5	3.45	3.50	-	15.6	0
GT18-17	S1	0.60	0.75	-	52.2	-
	S4	2.30	2.40	-	0.0	-

*Organic material present in the sample expanded in volume on thawing and absorbed excess water lowering the actual excess ice content (% by volume) compared to that estimated visually in the field.

Off-site Moisture Content, Bulk Density, Excess Ice Content, and Particle Size Analysis

Moisture content testing was completed on 32 samples from 12 boreholes. Hydrometer (particle size) analyses were completed on 12 samples, bulk density analysis was performed on 4 samples, and a wash sieve analysis was completed on 13 samples. The number of samples selected for testing and their locations along the vertical borehole profile depends on the variability of the overburden materials encountered during drilling. The intent of the laboratory

testing program was to fill in information gaps and provide sufficient geotechnical characterization of the overburden soils. The test results are summarized in Table 3.

Table 3: Summary of Off-site Laboratory Test Results

Borehole No.	Sample No.	Depth		Moisture Content (%)	Bulk Density (kg/m^3)	Excess Ice Content (% by volume)	Clay (%)	Silt (%)	Sand (%)	Gravel (%)

2.5.3 Geomechanical Laboratory Testing

Direct Shear Testing

Direct shear tests were carried out at Tetra Tech's Edmonton geotechnical laboratory on four test specimens reconstituted from seven samples following ASTM D3080. Samples GT18-01-S1 and GT18-04-S2 and samples

GT18-02-S2, GT18-06-S2, and GT18-07-S2 were reconstituted together to produce two separate test specimens. A test specimen was reconstituted from disturbed sample GT18-08-S4, and another test specimen was trimmed from sample GT18-08-S6. The samples were selected based on a high percentage of fines and high excess ice contents.

Table 4 presents a summary of the direct shear test results. The sample ring and thickness of all the test specimens was 18.92 mm.

Table 4: Direct Shear Test Results

Borehole and Sample Number	Sample Depth (m)	Sample ID	Wet Density (Mg/m^3)	Dry Density (Mg/m^3)	Normal Stress (kPa)	Shear Stress (kPa)	Inferred Shear Strength Parameters – Peak	
							Cohesion Intercept (kPa)	Shearing Resistance Angle (°)
GT18-01-S2 & 04-S2	1.50–2.50, 0.95–1.25	DS-1	2.220	1.989	500	368	71.0	32.0

2.6 Ground Temperature Cable Instrumentation Installations

Six multi-bead GTCs were installed to determine ground temperatures in locations where there is no or limited ground temperature data. GTCs were installed in the following boreholes: GT18-01 (TT# 2665), GT18-05 (TT# 2666), GT18-07 (TT# 2663), GT18-08 (TT# 2668), GT18-09 (TT# 2669), and GT18-15 (TT#2667).

The GTC boreholes were drilled to a minimum target depth of 21.0 m. A 25 mm I.D. flush couple threaded watertight PVC pipe with a bottom cap was threaded and glued together and lowered into the borehole. The annulus between the 25 mm PVC pipe and the borehole wall was backfilled with clean, dry sand to hold the PVC pipe in place. Several bags of bentonite chips were used to backfill the annulus at intervals within the sand to create a plug, preventing water from flowing down the borehole causing possible thermal irregularities along the thermistor string. GTCs were inserted inside the watertight PVC pipes at depth where the first thermistor bead is 0.5 m below ground level (BGL). An exception is Borehole GT18-08 where the drill bit hit refusal on hard granite boulders at 17.4 m depth, 3.6 m short of the minimum required depth. Therefore, GTC at this location was placed to a depth of 15.15 m, with the first thermistor bead below ground surface being the eighth thermistor bead on the string at 0.65 m BGL). Backfill was not used inside of PVC pipes. A 50 mm I.D. PVC pipe with a metal housing cabinet attached at the top was set over the 25 mm PVC pipe to protect the GTC lead. Metal housings were attached to two 2” by 4” by 4’ wood planks to provide stability. GTC cable installation reports are provided in Appendix D.

Initial GTC readings were taken immediately after installation to confirm that all the thermistor beads were working properly. Ground temperature readings were taken again several days after installation. Two subsequent sets of readings were taken by Victoria Gold site personnel on May 15 and June 8, 2018. The measured ground

temperatures at the depth of zero annual amplitude appear to have reached equilibrium and show either very warm permafrost with ground temperatures ranging from approximately 0°C at GT18-15 (Potential ROM Storage Area) to -0.5°C at GT18-08 (Platinum Gulch WRSA) or non-permafrost conditions with ground temperatures above the freezing point. Ground temperature profiles showing changes in temperatures with depth are presented in Appendix D.

Sacrificial SBTSs were installed in the remaining seven completed boreholes to depths ranging from 7.9 m to 9.0 m BGL to confirm the ground thermal condition, i.e. the presence or absence of permafrost. Borehole numbers, thermistor bead depths, installation dates, and the most recent ground temperature readings collected on June 8, 2018 are given in Table 5. Manual ground temperature readings from SBTSs were collected three times, i.e. several days after installation and again on May 15 and June 8, 2018.

Table 5: Single Bead Thermistor Readings

Borehole No.	Single Bead No.	Northing (m)	Easting (m)	Elevation (m)	Bead Depth (m)	Date Installed	Most Recent Date Measured	Ground Temperature (°C)
GT18-02	14	7,100,945	459,925	932.0	7.9	7-Apr-18	8-Jun-18	1.21
GT18-04	18	7,100,787	459,854	961.0	8.5	10-Apr-18	8-Jun-18	1.32
GT18-06	13	7,100,852	460,088	968.0	9.0	8-Apr-18	8-Jun-18	0.21
GT18-10	10	7,098,851	459,968	1,175.0	8.5	14-Apr-18	8-Jun-18	-0.08

2.7 Permafrost Distribution Mapping

The subsurface data collected during the spring 2018 geotechnical drilling program, as well as continued monitoring of the site ground thermal regime with GTCs and SBTSs installed in April 2018 have been used to update a preliminary map of permafrost distribution in the Dublin Gulch area that was compiled by Dr. Roujanski and Dr. McCuaig (Tetra Tech 2017). The map is provided as the background for Figure 2.

3.0 SUBSURFACE CONDITIONS

3.1 General

Observed terrain conditions are discussed in the following sections. The discussions are based on the drill site terrain observations and the data collected during the drilling, logging, field and laboratory testing phases of the investigation. Subsurface conditions are not uniform; it is expected that conditions between and surrounding the boreholes may vary from the subsurface conditions identified within the boreholes described in this report. However, the borehole data does give a general indication of the range of subsurface properties to be expected in the area.

Based on data from previous site investigations (BGC 2009; 2010; 2011a, b; and 2012b,c), the results of the current geotechnical investigation and updated permafrost distribution mapping, we find that permafrost generally occurs on north-facing slopes, and on some west- and east-facing slopes at higher elevations, and within poorly-drained

areas lower in the valleys. The distribution of permafrost is highly variable within the project area – changing from patchy occurrence and permafrost-free areas on south-facing slopes to more prevalent presence on north-facing slopes. More data is needed to refine the permafrost distribution patterns within the project area.

Permafrost conditions are very warm, even at higher elevations – hovering close to 0°C (Table 5 and Appendix D).

3.2 Eagle Pup WRSA

Six boreholes (GT18-01, GT18-02, GT18-04, GT18-05, GT18-06, GT18-07) were drilled within the footprint of the proposed Eagle Pup WRSA (Figure 2). These boreholes were drilled along and adjacent to the Eagle Pup Gulch.

The general terrain and subsurface conditions of the proposed Eagle Pup WRSA footprint are discussed in the following sections and are summarized in Table 6.

Table 6: Overburden Soil Condition Summary, Eagle Pup WRSA

Borehole No.	Overburden Thickness (m)	Organic Layer Thickness (m)	Major Overburden Soil Types	Active Layer Thickness (m)*	Permafrost Conditions
GT18-01	4.2 (not including 0.6 m fill)	0.22	Peat; Sand and Gravel; Cobble	~2.5; (a seasonally frozen layer)	Permafrost-free with a seasonally frozen layer (Vx up to 5%)
GT18-02	2.1	0.3	Sand and Gravel; Cobble	~1.5 to 2.0; (a seasonally frozen layer)	Permafrost-free with a seasonally frozen layer Vx 15-20%
GT18-04	2.1	N/A	Sand and Gravel	~2.0 to 2.5; (a seasonally frozen layer)	Permafrost-free with a seasonally frozen layer (Nbn)
GT18-05	3.15 (not including 0.35 m fill)	0.45	Sand and Gravel, Silt	~2.0; (a seasonally frozen layer)	Permafrost-free with a seasonally frozen layer (Vx, Vc, Vs up to 10%)

GT18-07	12.0	0.6	Sand and Gravel, Silt	~2.3; (a seasonally frozen layer)	Permafrost-free with a seasonally frozen layer (Vx 1-3%)

* - measurements of the active layer thickness are based on interpretation of the ground temperature data and examination of the core immediately after its recovery.

3.2.1 General

The terrain of the proposed Eagle Pup WRSA was observed and drilled between April 7 to 10, 2018. Its footprint lies within a drainage basin with an overall northerly aspect. The drainage basin converges into Eagle Pup which drains into Eagle Creek.

Boreholes GT18-01, GT18-02, GT18-06, and GT18-07 are located on the eastern side of Eagle Pup, where the slope has a southwesterly to westerly aspect. Vegetation consists of relatively healthy aspen, pine, and spruce trees and shrub birch and willow. Boreholes GT18-04 and GT18-05 are located on the southwestern slope, where

the slope has a northern to northeastern aspect. Vegetation here lacks aspen trees and consists of moderately sparse pine, black spruce trees and shrubs.

The slope of Eagle Pup stream is on average 3° to 5°. The slope northeast of it dips 15° to 25° where the boreholes are (but more steeply above them), while the southwestern slope is mainly 15° but slope angle increases farther up the incline.

3.2.2 Overburden Soils

The organic layer consists mainly of dark brown to black fibrous peat up to 0.3 m thick. A trace of rootlets were found up to 0.6 m BGL into till material.

Poorly to well graded, grey to dark brown silt, sand and gravel mixtures with cobbles disseminated throughout make up the bulk of the colluvial overburden. Any of these may be the dominant soil component. Rubble zones of angular gravel and cobble make up the coarse component.

Gravimetric moisture content of the overburden material varied from 4.0% in gravel and sand at a depth of 4.0 m in GT18-07 to 48.1% at a depth of 0.4 m in GT18-05 (Tables 2 and 3).

Frozen conditions with visible excess ice (Vx, Vc, Vs, Vr) were observed in the upper 3.0 m of the overburden in four out of six boreholes. Thermistor cables installed in these boreholes confirmed non-permafrost conditions below the seasonally frozen layer (Appendix D and Table 5). Therefore, visible ice observed in these boreholes is seasonal ice present within the active layer.

3.2.3 Bedrock

Bedrock in all six boreholes consisted of metasedimentary rock with varying levels of oxidation. Due to the heavily mechanically disturbed condition of the recovered rock core from the Sonic drilling process, RQDs, fracture frequencies, and strength designations could not be determined. As previously discussed, RC drilling is not particularly effective at coring bedrock. Bedrock has previously been well characterized in the Eagle Pup WRSA area during the BGC 2010 and 2011 geotechnical field investigations (BGC 2010 and 2011a,b).

3.3 Platinum Gulch WRSA

Four boreholes (GT18-08, GT18-09, GT18-10, GT18-11) were drilled within the proposed footprint for the Platinum Gulch WRSA (Figure 2).

The general terrain and subsurface conditions of the Platinum Gulch WRSA are discussed in the following sections and are summarized in Table 7.

Table 7: Overburden and Bedrock Condition Summary, Platinum Gulch WRSA

Borehole No.	Overburden Thickness (m)	Organic Layer Thickness (m)	Major Overburden Soil Types	Active Layer Thickness (m)*	Permafrost Conditions
GT18-08	>17.4	1.1	Peat; Sand and Gravel; Cobble; boulders	Undetermined	Permafrost (Vs up to 15%)
GT18-09	9.5	0.5	Sand and Gravel	~3.0 (a seasonally frozen layer)	Permafrost-free with a seasonally frozen layer (Nbn)
GT18-10	7.9 (not including 1.1 m of fill)	N/A	Sand and Gravel	Undetermined	Permafrost (Vx 1%)
GT18-11	10.0	0.4	Sand and Gravel	Undetermined	Permafrost Confirmed by thermistor (-0.1°C)

* - measurements of the active layer thickness are based on interpretation of the ground temperature data and examination of the core immediately after its recovery.

3.3.1 General

The proposed Platinum Gulch WRSA was drilled on April 11, 13, and 14, 2018. Its footprint lies within a watershed with an overall northerly and westerly aspect. The watershed narrows into the Platinum Gulch outlet that feeds into Haggart Creek.

Borehole GT18-08 is located at the west end of the proposed footprint, just north of Platinum Gulch stream. A granite boulder field is located 20 m south of the borehole location on the opposite bank of Platinum Gulch stream. Vegetation near the bottom of the gulch is sparse black spruce trees.

Boreholes GT18-09, GT18-10, and GT18-11 are located farther up the gulch, east of borehole GT18-08. The surrounding vegetation includes dense pine and spruce forest, but aspen dominates the west-facing slopes.

3.3.2 Overburden Soils

The organic layer in the area consists of dark red to brown to black fibrous peat up to 0.3 m thick. Borehole GT18-09 and GT18-10 were drilled on previously disturbed ground, resulting in removed or altered organic material. A trace of rootlets were found up to 0.6 m BGL into the till material.

Poorly to well graded, grey to dark brown silt, sand and gravel mixtures with cobbles disseminated throughout make up the bulk of the colluvial overburden. Any of these may be the dominant soil component. Angular gravel and cobble make up the coarse component.

Borehole GT18-08 encountered granite boulders at 17.4 m depth into overburden material, which caused refusal for the drill. A drill rod, shoe, and bit were damaged, so drilling at this location was terminated before the planned depth of 21.0 m could be reached.

Borehole GT18-09 was positioned on the edge of an old access road that appeared to have been unused for years. Fill material for the road contributed to the top 0.5 m of the core, with root systems, moss, and young vegetation growing in the road surface, which can be defined as native overburden for this report.

Gravimetric moisture content of the overburden material varied from 4.5% at a depth of 2.0 m in GT18-09 to 29.6% at a depth of 0.55 m in GT18-08.

Permafrost conditions with visible excess ice (Vx, Vc, Vs, Vr) were confirmed in two of the four boreholes. Excess ice contents found in GT18-08 ranged from 0.0% to 15.6%, with no excess ice measured in the remaining boreholes. Permafrost conditions were confirmed using GTC and SBTSs in boreholes GT18-08, GT18-10, and GT18-11 (Appendix D and Table 5).

3.3.3 Bedrock

Bedrock consisted of metasedimentary rock with varying levels of oxidation. Due to the heavily mechanically disturbed condition of the recovered rock core as part of the Sonic drilling process, RQDs, fracture frequencies, and strength designations could not be determined. As previously discussed, RC drilling is not particularly effective at coring bedrock. Bedrock has previously been characterized in the Platinum Gulch WRSA area during the BGC 2010 and 2011 geotechnical field investigations (BGC 2010 and 2011a,b).

Bedrock in borehole GT18-08 was not reached due to refusal on granite boulders.

3.4 90 Day Storage Area

Borehole GT18-17 was drilled within the proposed footprint for the 90 Day Storage (Figure 2).

The general terrain and subsurface conditions of the proposed 90 Day Storage area are discussed in the following sections and are summarized in Table 8.

Table 8: Overburden and Bedrock Condition Summary, 90 Day Storage Area

Borehole No.	Overburden Thickness (m)	Organic Layer Thickness (m)	Major Overburden Soil Types	Active Layer Thickness (m)*	Permafrost Conditions
GT18-17	5.5	0.3	Peat; Sand and Silt; Sand and Gravel	Undetermined	Ice-Rich Permafrost (ICE + Soil, Vx 3-5%, Nbn)

* - measurements of the active layer thickness are based on interpretation of the ground temperature data and examination of the core immediately after its recovery.

3.4.1 General

The proposed 90 Day Storage area was investigated on April 12, 2018. Its footprint lies on a slope that dips towards Suttles Gulch and has an overall northerly aspect.

Suttles Gulch is densely forested with spruce, pine, and dense shrubs. Trees on the western slope of Suttles Gulch are noticeably more stunted and withered compared to trees on the eastern side of the gulch. Both slopes range from 10° to 20° in slope angle.

Borehole GT18-17 is located at the northeast corner of the 90 Day Storage area footprint, on the west bank of Suttles Gulch.

3.4.2 Overburden Soils

The organic layer consists of a 0.3 m thick dark brown to black peat layer with interspersed rootlets and moss. Well graded, light brown to grey silt, sand and gravel mixtures make up the bulk of the colluvial overburden. Sand is the dominant soil component, while angular gravel makes up the coarse component. The colluvium is underlain by boulders.

Gravimetric moisture contents of the overburden material varied from 10.9% in frozen silty sand with some gravel at a depth of 3.7 m to 76.6% in frozen silty, gravelly sand at a depth of 1.1 m.

Warm permafrost conditions (-0.1°C) with excess ice (Vx, Vc, Vs, Vr) were observed in the borehole and were confirmed by SBTS installed at a depth of 8.5 m (Table 5). A layer of ice with sand and silt approximately 1.3 m thick was observed at a depth of 0.3 m BGL (Photo 2). The ice mass was clear to cloudy. It is believed that this ice is a result of the borehole being located within a depression on the slope face that channels runoff, resulting in higher than normal water content. Ice coatings and inclusions (Vc, Vx 21%) were observed in silty sand with some gravel from 1.6 m to 1.8 m. Excess ice (Vx 3.0% to 5.0%) was logged in sand and gravel from 1.8 m to 2.5 m. Well-bonded permafrost (Nbn) was observed in sand and gravel from 2.5 m to the top of bedrock, which was encountered at a depth of 5.5 m.

Photo 2: Ice and sand, silty between 1.05 m and 1.2 m in GT18-07.

3.4.3 Bedrock

Bedrock in this borehole consists of metasedimentary rock. Due to the heavily mechanically disturbed condition of the recovered rock core due to the Sonic drilling process, RQDs, fracture frequencies, and strength designations could not be determined. As previously discussed, RC drilling is not particularly effective at coring bedrock. Bedrock has previously been characterized in the 90 day Storage Area during the BGC 2009 and 2011 geotechnical field investigations (BGC 2009 and 2011a,b).

3.5 Potential ROM Stockpile Area

Two boreholes (GT18-15, GT18-16) were drilled within the potential ROM Stockpile Area. An actual footprint for the ROM stockpile has not been developed yet in the mine facility design, therefore it is not shown on Figure 2.

The general terrain and subsurface conditions of the Potential ROM Stockpile Area are discussed in the following sections and are summarized in Table 9.

Table 9: Overburden and Bedrock Condition Summary, Potential ROM Stockpile Area

Borehole No.	Overburden Thickness (m)	Organic Layer Thickness (m)	Major Overburden Soil Types	Active Layer Thickness (m)*	Permafrost Conditions
GT18-15	18.0	0.4	Sand; Sand and Gravel; Silt; Cobble	~2.0	Permafrost (Vx 1-3%, Nbn)
GT18-16	3.5	0.3	Peat; Sand and Gravel	Undetermined	Permafrost-free with a seasonally frozen layer (Nbn)

* - measurements of the active layer thickness are based on interpretation of the ground temperature data and examination of the core immediately after its recovery.

3.5.1 General

The potential ROM Stockpile area lies east of the 90 Day Storage area, within the Suttles Gulch drainage area. Suttles Gulch is densely forested with spruce, pine, and dense shrubs. Trees situated on the west slope of Suttles Gulch are noticeably more stunted and withered compared to trees on the east side of the gulch. The slopes on either side of Suttles Gulch range from 10° to 20° in angle.

Boreholes GT18-15 and GT18-16 were drilled on the eastern slope of the gulch on April 10 and 11, 2018.

3.5.2 Overburden Soils

The organic layer consists of 0.3 m brown peat with rootlets down to 0.4 m into the underlying sand and gravel. Overburden consists of well to poorly graded, brown to dark grey sand and angular gravel, with increasing silt and clay content at depth in GT18-15. This material is interpreted as colluvium.

Gravimetric moisture contents of the overburden material varies from 7.7% in frozen silt and sand at a depth of 1.0 m to 14.5% in frozen sand with some silt and gravel at a depth of 8.8 m in GT18-15.

Permafrost conditions were confirmed in one of the two completed boreholes. In GT18-15, visible ice (up to 3% by volume) was observed in the frozen active layer, with well-bonded permafrost (Nbn) below. GTC installed in GT18-15 confirmed very warm permafrost conditions (0°C to -0.1°C; Appendix D), while SBTS installed in GT18-16 revealed non-permafrost ground (Table 5).

3.5.3 Bedrock

Bedrock encountered in these two boreholes comprises metasedimentary rock. Due to the heavily mechanically disturbed condition of the recovered rock core because of the Sonic drilling process, RQDs, fracture frequencies, and strength designations could not be determined. As previously discussed, RC drilling is not particularly effective at coring bedrock. Bedrock has previously been well characterized in the ROM Stockpile area during the BGC 2009, 2010, 2011, and 2012 geotechnical field investigations.

4.0 CLOSURE

We trust this report meets your present requirements. If you have any questions or comments, please contact the undersigned.

TETRA TECH does not accept any responsibility for the accuracy of any of the data, analyses, recommendations or other contents of the Professional Document when it is used or relied upon by any party other than the Client, unless authorized in writing by TETRA TECH.

Any unauthorized use of the Professional Document is at the sole risk of the user. TETRA TECH accepts no responsibility whatsoever for any loss or damage where such loss or damage is alleged to be or, is in fact, caused by the unauthorized use of the Professional Document.

Where TETRA TECH has expressly authorized the use of the Professional Document by a third party (an "Authorized Party"), consideration for such authorization is the Authorized Party's acceptance of these Limitations on Use of this Document as well as any limitations on liability contained in the Contract with the Client (all of which is collectively termed the "Limitations on Liability"). The Authorized Party should carefully review both these Limitations on Use of this Document and the Contract prior to making any use of the Professional Document. Any use made of the Professional Document by an Authorized Party constitutes the Authorized Party's express acceptance of, and agreement to, the Limitations on Liability.

The Professional Document and any other form or type of data or documents generated by TETRA TECH during the performance of the work are TETRA TECH's professional work product and shall remain the copyright property of TETRA TECH.

The Professional Document is subject to copyright and shall not be reproduced either wholly or in part without the prior, written permission of TETRA TECH. Additional copies of the Document, if required, may be obtained upon request.

1.2 ALTERNATIVE DOCUMENT FORMAT

Where TETRA TECH submits electronic file and/or hard copy versions of the Professional Document or any drawings or other project-related documents and deliverables (collectively termed TETRA TECH's "Instruments of Professional Service"), only the signed and/or sealed versions shall be considered final. The original signed and/or sealed electronic file and/or hard copy version archived by TETRA TECH shall be deemed to be the original. TETRA TECH will archive a protected digital copy of the original signed and/or sealed version for a period of 10 years.

Both electronic file and/or hard copy versions of TETRA TECH's Instruments of Professional Service shall not, under any circumstances, be altered by any party except TETRA TECH. TETRA TECH's Instruments of Professional Service will be used only and exactly as submitted by TETRA TECH.

Electronic files submitted by TETRA TECH have been prepared and submitted using specific software and hardware systems. TETRA TECH makes no representation about the compatibility of these files with the Client's current or future software and hardware systems.

1.3 STANDARD OF CARE

Services performed by TETRA TECH for the Professional Document have been conducted in accordance with the Contract, in a manner consistent with the level of skill ordinarily exercised by members of the profession currently practicing under similar conditions in the jurisdiction in which the services are provided. Professional judgment has been applied in developing the conclusions and/or recommendations provided in this Professional Document. No warranty or guarantee, express or implied, is made concerning the test results, comments, recommendations, or any other portion of the Professional Document.

If any error or omission is detected by the Client or an Authorized Party, the error or omission must be immediately brought to the attention of TETRA TECH.

1.4 DISCLOSURE OF INFORMATION BY CLIENT

The Client acknowledges that it has fully cooperated with TETRA TECH with respect to the provision of all available information on the past, present, and proposed conditions on the site, including historical information respecting the use of the site. The Client further acknowledges that in order for TETRA TECH to properly provide the services contracted for in the Contract, TETRA TECH has relied upon the Client with respect to both the full disclosure and accuracy of any such information.

1.5 INFORMATION PROVIDED TO TETRA TECH BY OTHERS

During the performance of the work and the preparation of this Professional Document, TETRA TECH may have relied on information provided by persons other than the Client.

While TETRA TECH endeavours to verify the accuracy of such information, TETRA TECH accepts no responsibility for the accuracy or the reliability of such information even where inaccurate or unreliable information impacts any recommendations, design or other deliverables and causes the Client or an Authorized Party loss or damage.

1.6 GENERAL LIMITATIONS OF DOCUMENT

This Professional Document is based solely on the conditions presented and the data available to TETRA TECH at the time the data were collected in the field or gathered from available databases.

The Client, and any Authorized Party, acknowledges that the Professional Document is based on limited data and that the conclusions, opinions, and recommendations contained in the Professional Document are the result of the application of professional judgment to such limited data.

The Professional Document is not applicable to any other sites, nor should it be relied upon for types of development other than those to which it refers. Any variation from the site conditions present, or variation in assumed conditions which might form the basis of design or recommendations as outlined in this report, at or on the development proposed as of the date of the Professional Document requires a supplementary investigation and assessment.

TETRA TECH is neither qualified to, nor is it making, any recommendations with respect to the purchase, sale, investment or development of the property, the decisions on which are the sole responsibility of the Client.

1.7 ENVIRONMENTAL AND REGULATORY ISSUES

Unless stipulated in the report, TETRA TECH has not been retained to investigate, address or consider and has not investigated, addressed or considered any environmental or regulatory issues associated with development on the subject site.

1.8 NATURE AND EXACTNESS OF SOIL AND ROCK DESCRIPTIONS

Classification and identification of soils and rocks are based upon commonly accepted systems and methods employed in professional geotechnical practice. This report contains descriptions of the systems and methods used. Where deviations from the system or method prevail, they are specifically mentioned.

Classification and identification of geological units are judgmental in nature as to both type and condition. TETRA TECH does not warrant conditions represented herein as exact, but infers accuracy only to the extent that is common in practice.

Where subsurface conditions encountered during development are different from those described in this report, qualified geotechnical personnel should revisit the site and review recommendations in light of the actual conditions encountered.

1.9 LOGS OF TESTHOLES

The testhole logs are a compilation of conditions and classification of soils and rocks as obtained from field observations and laboratory testing of selected samples. Soil and rock zones have been interpreted. Change from one geological zone to the other, indicated on the logs as a distinct line, can be, in fact, transitional. The extent of transition is interpretive. Any circumstance which requires precise definition of soil or rock zone transition elevations may require further investigation and review.

1.10 STRATIGRAPHIC AND GEOLOGICAL INFORMATION

The stratigraphic and geological information indicated on drawings contained in this report are inferred from logs of test holes and/or soil/rock exposures. Stratigraphy is known only at the locations of the test hole or exposure. Actual geology and stratigraphy between test holes and/or exposures may vary from that shown on these drawings. Natural variations in geological conditions are inherent and are a function of the historic environment. TETRA TECH does not represent the conditions illustrated as exact but recognizes that variations will exist. Where knowledge of more precise locations of geological units is necessary, additional investigation and review may be necessary.

1.11 PROTECTION OF EXPOSED GROUND

Excavation and construction operations expose geological materials to climatic elements (freeze/thaw, wet/dry) and/or mechanical disturbance which can cause severe deterioration. Unless otherwise specifically indicated in this report, the walls and floors of excavations must be protected from the elements, particularly moisture, desiccation, frost action and construction traffic.

1.12 SUPPORT OF ADJACENT GROUND AND STRUCTURES

Unless otherwise specifically advised, support of ground and structures adjacent to the anticipated construction and preservation of adjacent ground and structures from the adverse impact of construction activity is required.

1.13 INFLUENCE OF CONSTRUCTION ACTIVITY

There is a direct correlation between construction activity and structural performance of adjacent buildings and other installations. The influence of all anticipated construction activities should be considered by the contractor, owner, architect and prime engineer in consultation with a geotechnical engineer when the final design and construction techniques are known.

1.14 OBSERVATIONS DURING CONSTRUCTION

Because of the nature of geological deposits, the judgmental nature of geotechnical engineering, as well as the potential of adverse circumstances arising from construction activity, observations during site preparation, excavation and construction should be carried out by a geotechnical engineer. These observations may then serve as the basis for confirmation and/or alteration of geotechnical recommendations or design guidelines presented herein.

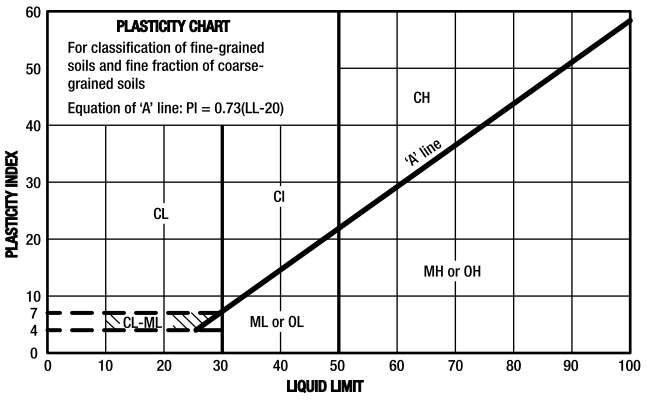
1.15 DRAINAGE SYSTEMS

Where temporary or permanent drainage systems are installed within or around a structure, the systems which will be installed must protect the structure from loss of ground due to internal erosion and must be designed so as to assure continued performance of the drains. Specific design detail of such systems should be developed or reviewed by the geotechnical engineer. Unless otherwise specified, it is a condition of this report that effective temporary and permanent drainage systems are required and that they must be considered in relation to project purpose and function.

1.16 BEARING CAPACITY

Design bearing capacities, loads and allowable stresses quoted in this report relate to a specific soil or rock type and condition. Construction activity and environmental circumstances can materially change the condition of soil or rock. The elevation at which a soil or rock type occurs is variable. It is a requirement of this report that structural elements be founded in and/or upon geological materials of the type and in the condition assumed. Sufficient observations should be made by qualified geotechnical personnel during construction to assure that the soil and/or rock conditions assumed in this report in fact exist at the site.

1.17 SAMPLES



TETRA TECH will retain all soil and rock samples for 30 days after this report is issued. Further storage or transfer of samples can be made at the Client's expense upon written request, otherwise samples will be discarded.

APPENDIX B

BOREHOLE LOGS

MODIFIED UNIFIED SOIL CLASSIFICATION

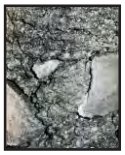
MAJOR DIVISION			GROUP SYMBOL	TYPICAL DESCRIPTION	LABORATORY CLASSIFICATION CRITERIA
COARSE-GRAINED SOILS More than 50% retained on 75 µm sieve*	GRAVELS 50% or more of coarse fraction retained on 4.75 mm sieve	CLEAN GRAVELS	GW	Well-graded gravels and gravel-sand mixtures, little or no fines	Classification on basis of percentage of fines (GW, GP, SW, SP, GM, GC, SM, SC Borderline Classification requiring use of dual symbols; Less than 5% Pass 75 µm sieve, More than 12% Pass 75 µm sieve, 5% to 12% Pass 75 µm sieve): $C_U = D_{60}/D_{10}$ Greater than 4; $C_c = \frac{(D_{30})2}{D_{10} \times D_{60}}$ Between 1 and 3
			GP	Poorly graded gravels and gravel-sand mixtures, little or no fines	Not meeting both criteria for GW
		GRAVELS WITH FINES	GM	Silty gravels, gravel-sand-silt mixtures	Atterberg limits plot below "A" line or plasticity index less than 4
			GC	Clayey gravels, gravel-sand-clay mixtures	Atterberg limits plot above "A" line or plasticity index greater than 7
	SANDS More than 50% of coarse fraction passes 4.75 mm sieve	CLEAN SANDS	SW	Well-graded sands and gravelly sands, little or no fines	$C_U = D_{60}/D_{10}$ Greater than 6; $C_c = \frac{(D_{30})2}{D_{10} \times D_{60}}$ Between 1 and 3
			SP	Poorly graded sands and gravelly sands, little or no fines	Not meeting both criteria for SW
		SANDS WITH FINES	SM	Silty sands, sand-silt mixtures	Atterberg limits plot below "A" line or plasticity index less than 4
			SC	Clayey sands, sand-clay mixtures	Atterberg limits plot above "A" line or plasticity index greater than 7
					Atterberg limits plotting in hatched area are borderline classifications requiring use of dual symbols
FINE-GRAINED SOILS (by behavior) 50% or more passes 75 µm sieve*	SILTS Liquid limit <50		ML	Inorganic silts, very fine sands, rock flour, silty or clayey fine sands of slight plasticity	
	SILTS Liquid limit >50		MH	Inorganic silts, micaceous or diatomaceous fine sands or silts, elastic silts	
	CLAYS Above "A" line on plasticity chart negligible organic content; Liquid limit <30		CL	Inorganic clays of low plasticity, gravelly clays, sandy clays, silty clays, lean clays	
	CLAYS Liquid limit 30-50		CI	Inorganic clays of medium plasticity, silty clays	
	CLAYS Liquid limit >50		CH	Inorganic clays of high plasticity, fat clays	
	ORGANIC SILTS AND CLAYS Liquid limit <50		OL	Organic silts and organic silty clays of low plasticity	
	ORGANIC SILTS AND CLAYS Liquid limit >50		OH	Organic clays of medium to high plasticity	
HIGHLY ORGANIC SOILS			PT	Peat and other highly organic soils	

* Based on the material passing the 75 mm sieve

† ASTM Designation D 2487, for identification procedure see D 2488 USC as modified by PFRA

SOIL COMPONENTS

FRACTION	SIEVE SIZE PASSING	SIEVE SIZE RETAINED	DEFINING RANGES OF PERCENTAGE BY MASS OF MINOR COMPONENTS: PERCENTAGE	DESCRIPTOR
GRAVEL				
coarse	75 mm	19 mm	>35 %	"and"
fine	19 mm	4.75 mm	21 to 35 %	"y-adjective"
SAND				
coarse	4.75 mm	2.00 mm	11 to 20 %	"some"
medium	2.00 mm	425 µm		
fine	425 µm	75 µm	>0 to 10 %	"trace"
SILT (non plastic) or CLAY (plastic)	75 µm		as above but by behavior	



OVERSIZE MATERIAL

Rounded or subrounded	
COBBLES	75 mm to 300 mm
BOULDERS	> 300 mm
Not rounded	
ROCK FRAGMENTS	>75 mm
ROCKS	> 0.76 cubic metre in volume

GROUND ICE DESCRIPTION

VISIBLE ICE LESS THAN 50% BY VOLUME

GROUP SYMBOL	SYMBOL	SUBGROUP DESCRIPTION	SKETCH	PHOTOGRAPH
V	Vx	Individual ice crystals or inclusions		
	Vc	Ice coatings on particles		
	Vr	Random or irregularly oriented ice formations		
	Vs	Stratified or distinctly oriented ice formations		
	Vu	Ice formations uniformly distributed throughout frozen soil		

ICE NOT VISIBLE

GROUP SYMBOL	SYMBOL	SUBGROUP DESCRIPTION	SKETCH	PHOTOGRAPH
N	Nf	Poorly-bonded or friable		
	Nbn	No excess ice, well-bonded		
	Nbe	Excess ice, well-bonded		

LEGEND: Soil ☐ Ice ■

NOTES:

1. Dual symbols are used to indicate borderline or mixed ice classifications.
2. Visual estimates of ice contents indicated on borehole logs ± 5%
3. This system of ground ice description has been modified from NRC Technical Memo 79, Guide to the Field Description of Permafrost for Engineering Purposes.

VISIBLE ICE GREATER THAN 50% BY VOLUME

GROUP SYMBOL	SYMBOL	SUBGROUP DESCRIPTION	SKETCH	PHOTOGRAPH
ICE	ICE + Soil Type	Ice with soil inclusions (greater than 25 mm thick)		
	ICE	Ice without soil inclusions (greater than 25 mm thick)

PARTICLE SIZE ANALYSIS REPORT

ASTM D7928 & C136

Project:	Eagle Gold – Spring 2018 Geotech. Invest.	Sample No.:	S2
Project No.:	ENG.EARC03103-02	Material Type:	-
Site:	Eagle Gold Mine, Yukon	Sample Loc.:	GT18-16
Client:	Victoria Gold Corp.	Sample Depth:	2.5 - 2.8 m
Client Rep.:	Dr. Stephen Wilbur	Sampling Method:	Grab
Date Tested:	May 18, 2018 By: AH	Date Sampled:	April 11, 2018
Soil Description[2]:	SILT - gravelly, sandy	Sampled By:	Tetra Tech Canada
		USC Classification:	- Cu: #N/A
Moisture Content:	10.3%		Cc: #N/A

Particle Size (mm)	Percent Passing

APPENDIX E

TETRA TECH WORK METHODS

WM4400 GEOTECHNICAL SOIL CLASSIFICATION

CATEGORY:	Field Testing/Sampling	**REVISION NO.:**	03	**PAGE:**	1 of 15
SUBCATEGORY:	Geotechnical	**REVISION DATE:**	July 2013	**APPROVED DATE:**	June 2009
				EXPIRY DATE:	July 2017

1.0 PURPOSE

1.1 To define the responsibilities and procedures to be used when classifying soils for geotechnical purposes. It is acknowledged that for some projects a variation from this method may be necessary. In these cases, authorization from the Manager (after consultation by the Manager with the Chief Engineer) should be obtained and documentation of the differences should be included in the report and project file.

2.0 SCOPE

2.1 This work method applies to classification of soils based on inspection of samples recovered from ground investigations and laboratory testing. Soils are typically logged in the field, (generally in accordance with ASTM D2488), and then laboratory classification tests are used to confirm the description (generally in accordance with ASTM D2487-93). This work method is intended as a supplement to those standards.

2.2 This work method is intended to provide Tetra Tech Canada (EBA OU)[1] employees with guidelines to carry out Geotechnical Soil Classification (WM4400). Significant deviation from this work method should be in collaboration with your Manager and/or a Quality Council (QC) Representative. Any variance should be documented and placed in the project file.

3.0 DEFINITIONS

3.1 **EBA OU** – EBA Operating Unit of Tetra Tech Canada Inc. (Tetra Tech).

3.2 **Boulders:** particles of rock (rounded or sub-rounded) that will not pass a 300 mm square sieve opening.

3.3 **Cobbles:** particles of rock (rounded or sub-rounded) that will pass a 300 mm square sieve opening and be retained on a 75 mm sieve.

3.4 **Gravel:** particles of rock that will pass a 75 mm sieve and be retained on a 4.75 mm sieve, with the following subsections:

- Coarse – passes a 75 mm sieve and is retained on a 19 mm sieve.
- Fine – passes a 19 mm sieve and is retained on a 4.75 mm sieve.

[1] Please note that as of January 1, 2017, our legal operating name changed from Tetra Tech EBA Inc. to Tetra Tech Canada Inc.

3.5 **Sand:** particles of rock that will pass a 4.75 mm sieve and be retained on a 0.0750 mm sieve with the following subsections:

- Coarse – passes a 4.75 mm sieve and is retained on a 2 mm sieve.
- Medium – passes a 2 mm sieve and is retained on a 0.425 mm sieve.
- Fine – passes a 0.425 mm sieve and is retained on a 0.075 mm sieve.

3.6 **Silt:** soil which passes a 0.075 mm sieve that is non-plastic or very slightly plastic (Plasticity Index <4 or plots below A line (Attachment 7.1)) and that exhibits little or no strength when air dry.

3.7 **Clay:** soil passing a 0.002 mm sieve that exhibits plasticity (Plasticity Index >4 and plots on or above A line (Attachment 7.1)) and has considerable strength when air dry.

4.0 RESPONSIBILITIES AND AUTHORITIES

4.1 Manager

- Ensure that the project team is qualified to classify soils according to these methods.
- Ensure that the safety procedures/methods are understood and followed by project team.
- Ensure that the project team has sufficient project budget and schedule, and is aware of and meets these requirements.

4.2 Project Engineer

- Ensure that the field personnel and testing laboratory staff are qualified to complete the tests and classify the soils according to these methods.
- Designate the testing laboratory.
- Ensure that the field personnel have all necessary resources for the soil characterization.
- Be available for timely consultation with the field personnel and the testing laboratory.
- Review the soil classification report (borehole logs and laboratory test results) and provide timely input.
- Develop the laboratory testing program in consultation with field personnel.

4.3 Field Personnel

- Be familiar with this work method.
- Classify soils based on the inspection of samples recovered from geotechnical investigations and the results of laboratory testing.
- Have the equipment and supplies available to carry out the appropriate tests.
- Assist the Project Engineer in developing the laboratory testing program.

5.0 WORK METHOD

The following method identifies the soil properties that shall be recorded for a complete geotechnical soil description. There are two phases to the classification of soils: the initial description prepared in the field; and the refinement of the description completed after laboratory testing.

5.1 Soil Classification in the Field

5.1.1 General

Soil can generally be divided into three main groups:

- Coarse-grained soils (e.g., fluvial deposits);
- Fine-grained soils (e.g., lacustrine deposits); and
- Organic soils (e.g., topsoil).

It is the intent of this work method to make sure that the classifications of soils correlate in a general way with the engineering behaviour of soils.

Coarse-grained: the description's behaviour is confirmed in the laboratory with a Gradation Analysis.

Fine-grained: the description's behaviour is confirmed in the laboratory with the Atterberg Limits Test.

Organic soils: the description's behaviour is confirmed in the laboratory with Organic Content Test and Gradation Analysis.

When presented with a soil sample, the first task is to assess which of these three categories it is likely to fall into:

- If the sample contains visible organics, is dark brown or black, and has an organic smell, it will likely fall into the organic soil category (refer to Section 5.1.1.3);
- If it displays cohesion, such as a sample of till, it is likely to be a fine-grained material (refer to Section 5.1.1.2); and
- If it is non-plastic, such as pit-run granular, it is a coarse-grained soil (refer to Section 5.1.1.1).

5.1.1.1 Coarse-grained Soils: The behaviour is influenced mainly by sand and gravel sized particles and shall be described in the following sequence.

5.1.1.1.1 **Coarse-grained Principal Soil Constituent** is the soil component with the highest percentage by mass. This soil constituent shall be capitalized in the soil description:

Example: 52% sand, 34% silt, 12% gravel, 2% clay.

In this example, SAND will be the principal soil constituent since it has the highest percentage.

SAND, silty, some gravel and trace clay.

The percentage of cobbles and boulders in the original sample should be estimated and included in the description (e.g., 5% cobbles). Provide the maximum size of the boulder(s) evident (e.g., up to ---mm in diameter).

5.1.1.1.2 **Coarse-grained Minor Soil Constituents** include all remaining soil components that are found in the soil mass. These constituents are described according to the amount, by mass, of each component. They are described in the following manner and are listed in decreasing order of significance:

- >35% "and" (soil constituent in capital letters, e.g., …and SAND) (Note that the use of the qualifier "and" is not to be applied to SILT/CLAY Principal constituents)

- 21 to 35% “y – adjective” (e.g., silty, clayey)
- 10 to 20% “some” (soil constituent, e.g.. some sand)
- >0 to 10% “trace” (soil constituent, e.g.. trace gravel)
- “occasional” use for noting presence of isolated occurrences

Example: 40% sand, 36% silt, 21% gravel, 3% clay shall be called SAND and SILT, gravelly, trace clay

5.1.1.1.3 **Coarse-grained Grading** shall describe the particle size distribution. In general, soils with predominantly one particle size are poorly graded, while soils with a range of particle sizes are well graded.

5.1.1.1.4 **Coarse-grained Particle Size** shall further describe the size of particles of the principal soil constituent in coarse-grained soils. The principal soil constituent shall be described as any, some, or all of the following:

- *fine* and *coarse* for gravel; and
- *fine*, *medium*, and *coarse* for sand.

Note: these descriptions can also be used if the granular soils are a minor constituent.

5.1.1.1.5 **Coarse-grained Angularity/Particle Shape** shall describe the angularity and shape of the principal soil constituent in coarse-grained soils.

The angularity of coarse-grained soils shall be described as one or more of the following: *angular*, *sub-angular*, *sub-rounded*, *rounded*.

Particle shape shall be described as one or more of the following: *flat*, *elongated* (see Attachment 7.2 for a more complete description).

Note: these descriptions can also be used if the granular soils are a minor constituent.

5.1.1.1.6 **Coarse-grained Moisture** shall describe the wetness of the soil mass. The following terms shall be used to describe moisture:

- *dry* – no moisture can be seen or felt
- *damp* – a slight dampness to the touch when handling the soil
- *moist* – soil is moist to the touch but there is no free water
- *wet* – a film of water is visible around the particles
- *very wet* – there is free water, the water is separated from the soil particles

5.1.1.1.7 **Coarse-grained Consistency** shall describe the in situ density of granular soils. It is determined during drilling with Standard Penetration Testing, Dynamic Cone Penetration Testing, Becker Penetration Testing, or Cone Penetration Testing. The consistency of the soil shall be described using the following terms: *very loose*, *loose*, *compact*, *dense*, *very dense* (see Attachment 7.3 for the relationship between SPT N - index and Consistency).

5.1.1.1.8 **Coarse-grained Colour** shall describe the overall colour of the moist soil mass as well as any staining or mottling that may be present. If the colour provided in the description is for the dry soil, this should be noted. The Munsell Soil Colour Chart will be used as a reference.

5.1.1.1.9 **Coarse-grained Odour** shall describe any odour that is emitted from the soil mass. This may include a decaying smell that would indicate the presence of organics or a petroleum or chemical smell that may signal an area of contamination.

5.1.1.1.10 **Coarse-grained Inclusions** shall describe any other material that is present within the soil mass. Examples of inclusions include, but are not limited to, roots, metal pieces, glass, concrete, and precipitates.

5.1.1.1.11 **Coarse-grained Origin** shall be the geologic or anthropologic source of the deposit. This descriptor should be capitalized and bracketed, e.g., (GLACIAL TILL) or (FILL), and shall be inserted after the Principal Component, e.g. SAND (TILL)…

5.1.1.1.12 **Coarse-grained Example** of a complete soil description is as follows:

- SAND (ALLUVIUM), silty, some gravel, trace clay, occasional boulders and shell fragments, well graded, damp, compact, grey; fine to medium sand; fine to coarse rounded gravel; boulders up to 2000 mm diameter

5.1.1.2 **Fine-grained** soil behaviour is influenced mainly by silt and clay sized particles. It must be stressed that the final (i.e., laboratory results based) description of fine-grained soil is based strictly on behaviour, not the grain size distribution. They shall be described in the following sequence:

5.1.1.2.1 **Fine-grained Principal Soil Constituent** shall be described as above for Coarse-grained Principal Soil Constituent. The principal soil constituent should describe the engineering behaviour of the soil mass.

The following field tests shall be performed to determine if the soil behaves as a SILT or as a CLAY in fine-grained soils:

- dilatancy, dry strength, toughness, thread roll test (see Attachment 7.4 for a complete description of these tests)

Example: 50% silt, 27% clay, 20% sand, and 3% gravel.

In this example, although silt is the principal soil constituent (by size/mechanical analysis), the soil will behave as a clay due to clay content. As a general rule, clay contents over about 20% dominate soil behaviour.

CLAY, silty, some sand, trace gravel.

Note: for fine-grained soils the description should be either Clay or Silt but not Clay and Silt.

5.1.1.2.2 **Fine-grained Minor soil constituents** include all remaining soil components that are found in the soil mass. These constituents are described according to the amount, by mass, of each component. They are described in the following manner and are listed in decreasing order of significance:

- >35% “and” (soil constituent in capital letters, e.g., …and SAND) (Note that the use of the qualifier “and” is not to be applied to SILT/CLAY Principal constituents, i.e., SILT and CLAY).
- 21 to 35% “y-adjective” (e.g., silty, clayey)
- 10 to 20% “some” (soil constituent, e.g., some sand)
- >0 to 10% “trace” (soil constituent, e.g., trace gravel)
- “occasional” use for noting presence of isolated inclusions

5.1.1.2.3 **Fine-grained Structure** describes the features that are found throughout the soil mass if any. Structure can be an indication of the process of deposition or geologic history. Examples of structures include stratification, layering, and lamination.

5.1.1.2.4 **Fine-grained Moisture** shall be described as above in Section 5.1.1.1.6 with the following changes:

- *wet* – the soil can be easily smeared or remolded between fingers
- *very wet* will not be used to describe fine-grained soils

5.1.1.2.5 **Fine-grained Consistency** shall describe the stiffness of the soil mass. The tests mentioned in Section 5.1.1.1.7 can be used to approximate the consistency of the soil. Since soil samples are usually disturbed, a lower bound estimate of the consistency can be made from the stiffness of the sample. Consistency of fine-grained soils shall be described using the following terms: *very soft*, *soft*, *firm*, *stiff*, *very stiff*, *hard*

Note: for silt, the consistency can be described as above if it displays plasticity, or as described in Section 5.1.1.1.7 if it is very low to non-plastic (see Attachment 7.5 for a more detailed description of these terms).

5.1.1.2.6 **Fine-grained Plasticity** shall describe the ability of a soil to undergo deformation without cracking or crumbling. Plasticity can be determined by performing a thread roll test in the field. The plasticity of fine grained soils shall be described using the following terms: *non-plastic*, *low plastic*, *medium plastic*, *high plastic* (see Attachment 7.6 for a more detailed description of these terms).

5.1.1.2.7 **Fine-grained Colour** shall be described as above in Section 5.1.1.1.8.

5.1.1.2.8 **Fine-grained Odour** shall be described as above in Section 5.1.1.1.9.

5.1.1.2.9 **Fine-grained Inclusions** shall be described as above in Section 5.1.1.1.10.

5.1.1.2.10 **Fine-grained Example** of a complete soil description is as follows:

- CLAY (LACUSTRINE), silty, some sand, trace gravel, occasional shell fragments, moist, firm, low plastic, brown fine sand; rounded, fine gravel.

5.1.1.3 Organic Soils These soils can generally be divided into three categories: transition soils, peat, and organic silt or clay.

Transition soils are topsoil and 'B' horizon soils that are typically the result of weathering of surficial soils and decay of vegetation.

Peat comprises negligible inorganic content and should be described by the method provided in P3401 – Classification of Peat.

Organic silt or clay is fine-grained soil where the organic content dominates the behaviour of the deposit. Due to the complexity of the composition of organic matter, there are no definitive guidelines as to the percentage of organics that will result in this behaviour. The organic content can influence plasticity, shrinkage, compressibility, permeability, and strength. When presented with a sample of fine-grained soil for a field description, if it is dark brown to black, lightweight, has an organic smell, and displays sponginess, it should be noted as such and the appropriate laboratory test completed to make a determination.

5.1.1.3.1 **Organic Principal Soil Constituent** shall be modified by adding the word ORGANIC in front of the Principal Component.

PEAT shall be used as the Principal Component if the soil contains negligible inorganic contents. Refer to P3401 - Classification of Peat.

5.1.1.3.2 **Organic Minor Soil Constituents** shall be described as above in Section 5.1.1.2.2.

5.1.1.3.3 **Organic Texture** shall describe the feel of the organic soil. The soil shall be described as either amorphous for fine-grained peat or fibrous for woody peat (refer to P3401).

5.1.1.3.4 **Organic Moisture** shall be described as above in Section 5.1.1.2.4.

5.1.1.3.5 **Organic Consistency** shall be described as above in Section 5.1.1.2.5.

5.1.1.3.6 **Organic Colour** shall be described as above in Section 5.1.1.1.8.

5.1.1.3.7 **Organic Odour** shall be described as above in Section 5.1.1.1.9.

5.1.1.3.8 **Organic Inclusions** shall be described as above in Section 5.1.1.1.10.

5.1.2 Soil Class

The Modified Unified Soil Classification System provides a number of classes of soil (e.g., SM, CH). These are very useful but often do not provide sufficient information for the project engineer/designer. For example, they do not convey any information regarding consistency, colour, etc. Therefore, although the soil class can be used, it must be supplemented by the description as discussed in Sections 5.1.1.1, 5.1.1.2, and 5.1.1.3.

5.2 Soil Sampling

5.2.1 Once the soil has been classified, a representative sample shall be bagged and labelled with the project number, location of the sample, and date of sampling. The bag shall be sufficiently sealed so that moisture and air cannot be transferred in or out of the sample. The sample may be sent to the laboratory for testing at the discretion of the Project Director and Project Engineer.

5.3 Laboratory Testing and Presentation of Laboratory Test Results

5.3.1 Laboratory testing shall be carried out following ASTM standards and shall be used to refine the soil classification. Grain Size and Hydrometer Analysis shall be carried out following ASTM Standard D422. Plasticity testing to determine Atterberg Limits shall be carried out following ASTM Standard D4318. Preparation of soil samples for the above laboratory testing shall be carried out following ASTM Standard D2217.

For Grain Size analysis testing, an estimate of the percentage of cobbles/boulders by mass shall be recorded before they are removed from the sample for the test. The description shall include the estimate of oversize materials if it is not evident on the grain size curve.

5.3.2 Presentation of Laboratory Data

5.3.2.1 Grain Size Analysis

5.3.2.1.1 Percentages of each soil constituent by mass shall be recorded on the laboratory sheet; this shall include the following:

- Cobbles, Gravel, Sand, Fines (Silt and Clay)

5.3.2.1.2 Grain size analysis graphs shall include the sieve sizes in millimetres as well as the corresponding soil constituent size boundaries on the top 'x' axis. Boundaries separating the different grain sizes of each coarse-grained constituent will also be included. The following soil boundaries shall be included on the grain size analysis graphs:

- Cobbles, Gravel (fine and coarse), Sand (fine, medium, coarse), Fines (Silt and Clay)

5.3.2.2 Hydrometer Analysis

5.3.2.2.1 Percentages of each fine-grained soil constituent (Silt and Clay) shall be provided on the laboratory report.

5.3.2.2.2 Hydrometer graphs shall include particle sizes in millimetres as well as the corresponding particle size boundaries (Silt and Clay).

5.3.3 Classification Using Laboratory Results

5.3.3.1 Soil Constituents

The grain size analysis can be used to confirm the percentages of the constituent materials. Care must be taken to include particles (cobbles and boulders) not represented by the sample.

The grain size analyses can also be used to provide the particle size within the constituents, i.e., fine, medium, and coarse sand or fine and coarse gravel.

5.3.3.2 Grading

A more accurate description of the grading can be undertaken by using the following relationships:

- Coefficient of Uniformity $Cu = D_{60}/D_{10}$
- Coefficient of Curvature $Cc = (D_{30})^2 / (D_{10} \times D_{60})$

Where D_{10}, D_{30}, and D_{60} are the particle sizes diameters corresponding to 10%, 30%, and 60% passivity on the cumulative particle size distribution curve.

5.3.3.3 Moisture Content

The results of the moisture content test will give an indication of the wetness of the soil and can be compared to the Atterberg Limits to estimate behaviour characteristics for fine-grained soils.

5.3.3.4 Plasticity

Fine-grained soils will be classified by how they plot on a plasticity chart; refer to Attachment 7.1.

Attachment 7.1 – Modified Unified Soil Classification

MODIFIED UNIFIED SOIL CLASSIFICATION

MAJOR DIVISION			GROUP SYMBOL	TYPICAL DESCRIPTION	LABORATORY CLASSIFICATION CRITERIA
COARSE-GRAINED SOILS More than 50% retained on 75 µm sieve*	GRAVELS 50% or more of coarse fraction retained on 4.75 mm sieve	CLEAN GRAVELS	GW	Well-graded gravels and gravel-sand mixtures, little or no fines	$C_u = D_{60}/D_{10}$ Greater than 4; $C_c = \frac{(D_{30})^2}{D_{10} \times D_{60}}$ Between 1 and 3
			GP	Poorly graded gravels and gravel-sand mixtures, little or no fines	Not meeting both criteria for GW
		GRAVELS WITH FINES	GM	Silty gravels, gravel-sand-silt mixtures	Atterberg limits plot below "A" line or plasticity index less than 4
			GC	Clayey gravels, gravel-sand-clay mixtures	Atterberg limits plot above "A" line or plasticity index greater than 7
	SANDS More than 50% of coarse fraction passes 4.75 mm sieve	CLEAN SANDS	SW	Well-graded sands and gravelly sands, little or no fines	$C_u = D_{60}/D_{10}$ Greater than 6; $C_c = \frac{(D_{30})^2}{D_{10} \times D_{60}}$ Between 1 and 3
			SP	Poorly graded sands and gravelly sands, little or no fines	Not meeting both criteria for SW
		SANDS WITH FINES	SM	Silty sands, sand-silt mixtures	Atterberg limits plot below "A" line or plasticity index less than 4
			SC	Clayey sands, sand-clay mixtures	Atterberg limits plot above "A" line or plasticity index greater than 7
FINE-GRAINED SOILS (by behavior) 50% or more passes 75 µm sieve*	SILTS	Liquid limit <50	ML	Inorganic silts, very fine sands, rock flour, silty or clayey fine sands of slight plasticity	For classification of fine-grained soils and fine fraction of coarse-grained soils. PLASTICITY CHART
		Liquid limit >50	MH	Inorganic silts, micaceous or diatomaceous fine sands or silts, elastic silts	
	CLAYS Above "A" line on plasticity chart negligible organic content	Liquid limit <30	CL	Inorganic clays of low plasticity, gravelly clays, sandy clays, silty clays, lean clays	
		Liquid limit 30-50	CI	Inorganic clays of medium plasticity, silty clays	
		Liquid limit >50	CH	Inorganic clays of high plasticity, fat clays	
	ORGANIC SILTS AND CLAYS	Liquid limit <50	OL	Organic silts and organic silty clays of low plasticity	
		Liquid limit >50	OH	Organic clays of medium to high plasticity	
HIGHLY ORGANIC SOILS			PT	Peat and other highly organic soils	

*Based on the material passing the 75 mm sieve
Reference: ASTM Designation D2487, for identification procedure see D2488. USC as modified by PFRA

SOIL COMPONENTS					OVERSIZE MATERIAL
FRACTION	SIEVE SIZE		DEFINING RANGES OF PERCENTAGE BY MASS OF MINOR COMPONENTS		Rounded or subrounded
	PASSING	RETAINED	PERCENTAGE	DESCRIPTOR	COBBLES 75 mm to 300 mm; BOULDERS > 300 mm
GRAVEL					Not rounded
coarse	75 mm	19 mm	>35 %	"and"	ROCK FRAGMENTS >75 mm; ROCKS > 0.76 cubic metre in volume
fine	19 mm	4.75 mm	21 to 35 %	"y-adjective"	
SAND					
coarse	4.75 mm	2.00 mm	16 to 20 %	"some"	
medium	2.00 mm	425 µm			
fine	425 µm	75 µm	>0 to 10 %	"trace"	
SILT (non plastic) or CLAY (plastic)	75 µm		as above but by behavior

TETRA TECH

Attachment 7.2 – Angularity and Particle Shape of Coarse-grained Particles

Angularity:

Description	Criteria
Angular	Particles have sharp edges and relatively plane sides with unpolished surfaces.
Sub-angular	Particles are similar to angular description but have rounded edges.
Sub-rounded	Particles have nearly plane sides but have well-rounded corners and edges.
Rounded	Particles have smoothly curved sides and no edges.

Particle Shape:

The particle shape shall be described as follows where length, width, and thickness refer to the greatest, intermediate, and least dimensions of a particle, respectively.

Description	Criteria
Flat	Particles with width/thickness >3
Elongated	Particles with length/width >3
Flat and Elongated	Particles meet criteria for both flat and elongated

Reference:

ASTM (1998). Standard Practice for Description and Identification of Soils (Visual-Manual Procedure). Test Designation D2487 and D2488. 1998 Annual Book of ASTM Standards, American Society for Testing and Materials, Philadelphia, Vol. 04.08.

Attachment 7.3 – Consistency of Coarse-grained Soils

Description	SPT N-Index (blows per 0.3 m)
Very loose	0 to 4
Loose	4 to 10
Compact	10 to 30
Dense	30 to 50
Very Dense	Over 50

Note:

To be of practical value, the split-spoon sampling method of indirectly determining the compactness of cohesionless soil must satisfy three conditions:

1. The SPT N-index must be independent of the operator and the boring method;
2. The correlation between the SPT N-index and the compactness condition must be accurate to within acceptable limits; and
3. The same correlation between the SPT N-index and the compactness condition must be used by all.

Attachment 7.4 – Field Tests for Estimating Proportions of SILT and CLAY

Dilatancy (reaction to shaking):

After removing particles larger than sand sizes, prepare a pat of moist soil with a volume of about 10 cm^3. If necessary, add enough water to make the soil soft but not sticky. Then, place the pat in the open palm of one hand and shake horizontally, striking vigorously against the other hand several times. A positive reaction consists of the appearance of water on the surface of the pat, which changes to a livery consistency and becomes glossy. When the sample is squeezed between the fingers, the water and gloss disappear from the surface, the pat stiffens, and finally cracks or crumbles. The rapidity of appearance of water during shaking and of its disappearance during squeezing assist in identifying the character of the fines in a soil. Very fine, clean sands give the quickest and most distinct reaction, whereas a plastic clay has no reaction. Inorganic silts, such as a typical rock flour, show a moderately quick reaction.

Dry Strength (crushing characteristics):

After removing particles larger than sand sizes, mould a pat of soil to the consistency of putty, adding water if necessary. Allow the pat to dry completely by sun, or air drying, (when in the field) and then test its strength by breaking and crumbling between the fingers. This strength is a measure of the character and quantity of the clay fraction contained in the soil. The dry strength increases with increasing plasticity.

High dry strength is characteristic for inorganic clays of high plasticity. A typical inorganic silt possesses only very slight dry strength. Silty fine sands and silts have about the same slight dry strength, but can be distinguished by the feel when powdering the dried specimen. Fine sand feels gritty, whereas a typical silt has the smooth feel of flour.

Toughness (consistency near plastic limit):

After removing particles larger than sand sizes, a specimen of soil about 10 cm^3 is moulded to the consistency of putty. If too dry, water must be added and, if sticky, the specimen should be spread out in a thin layer and allowed to lose some moisture by evaporation. Then the specimen is rolled out by hand on a smooth surface or between the palms into a thread about 3 mm in diameter. The thread is then folded and rolled repeatedly. During the manipulation, the moisture content is gradually reduced and the specimen stiffens, until it is no longer malleable and crumbles. This indicates that the plastic limit has been reached. After the thread has crumbled, the pieces should be lumped together and a slight kneading action continued until the lump crumbles. The tougher the thread near the plastic limit and the stiffer the lump when it finally crumbles, the more active is the colloidal clay fraction in the soil. Weakness of the thread at the plastic limit and quick loss of coherence of the lump below the plastic limit indicate either inorganic clay of low plasticity, or materials such as kaolin-type clays and organic clays

Attachment 7.5 – Consistency of Fine-grained Soils

Description	Field Identification	UCS kPa	SPT – Value (N)
Very soft	Easily penetrated several centimetres by the fist.	<25	0-2
Soft	Easily penetrated several centimetres by the thumb.	26-50	3-4
Firm	Can be penetrated several centimetres by the thumb with moderate effort.	51-100	5-8
Stiff	Readily indented by the thumb but penetrated only with great effort.	101-200	9-15
Very stiff	Readily indented by the thumbnail.	201-400	16-30
Hard	Indented with difficulty by the thumbnail.	>400	>30

Reference:

Canadian Geotechnical Society (2006) *Canadian Foundation Engineering Manual 4th Edition*, Richmond, British Columbia.

Attachment 7.6 – Plasticity of Fine-grained Soils

From observations made during the toughness test (Attachment 7.4), plasticity shall be defined as below:

Description	Criteria
Non-plastic	A 3 mm thread cannot be rolled at any water content.
Low	The thread can barely be rolled and the lump cannot be formed when drier than the plastic limit.
Medium	The thread is easy to roll and not much time is required to reach the plastic limit. The thread cannot be re-rolled after reaching the plastic limit. The lump crumbles when drier than the plastic limit.
High	It takes considerable time rolling and kneading to reach the plastic limit. The thread can be re-rolled several times after reaching the plastic limit. The lump can be formed without crumbling when drier than the plastic limit.

TETRA TECH

WORK METHOD

ISSUED FOR USE

WM4102 LOGGING OF PERENNIALLY FROZEN SOILS AND GROUND ICE FOR ENGINEERING PURPOSES

CATEGORY:	Field Testing/Sampling	**REVISION NO.:**	04	**PAGE:**	1 of 34
SUBCATEGORY:	Arctic	**REVISION DATE:**	July 2018	**APPROVED DATE:**	December 2009
				EXPIRY DATE:	July 2023

1.0 PURPOSE

1.1 This work method provides a suggested procedure for identifying and describing perennially frozen soils and ground ice (if present) for engineering purposes based on visual examination and simple physical testing.

2.0 SCOPE

2.1 This work method is intended to be used in conjunction with Tetra Tech Canada (EBA OU)1 work methods WM4400 Geotechnical Soil Classification and WM3403 Geotechnical Logging of Rock Core.

2.2 This work method is based on ASTM Standard D4083-89 (2007): Standard Practice for Description of Frozen Soils (Visual-Manual Procedure) and the Guide to Field Description of Permafrost for Engineering Purposes, National Research Council of Canada (NRCC, 1963) and Tetra Tech's in-house field manuals and procedures for logging frozen overburden.

2.3 This work method is intended primarily for use by geotechnical engineers, geologists, and technicians in the field, where the soil cross-section or samples from it may be observed in a relatively undisturbed frozen state.

2.4 It may also be used in the laboratory to describe the condition of relatively undisturbed soil samples that have been maintained in a frozen condition following their acquisition in the field.

2.5 This work method is intended to provide Tetra Tech employees with guidelines to carry out Logging of Perennially Frozen Soils and Ground Ice for Engineering Purposes (WM4102). Significant deviation from this work method should be in collaboration with your Manager and/or a Quality Council (QC) Representative. Any variance should be documented and placed in the project file.

3.0 DEFINITIONS

3.1 **EBA OU** – EBA Operating Unit of Tetra Tech Canada Inc. (Tetra Tech).

3.2 **Active Layer** – The top layer of ground that is subject to annual thawing and freezing in areas underlain by permafrost.

3.3 **Ataxitic (Suspended) Cryostructure –** Develops in fine-grained soils and is represented predominantly by ice (up to 90% by volume) with randomly oriented soil inclusions (Photo 1).

3.4 **Basal Cryostructure** – Develops in coarse-grained soils and in fractured rock. It is represented predominantly by ice (greater than 50% by volume) that fills in voids and open fractures.

3.5 **Buried Ice** – Ice formed or deposited on the ground surface and later covered by sediments.

3.6 **Candled Ice** – Ice that has rotted or otherwise formed into long columnar crystals, very loosely bonded together.

3.7 **Clear Ice** – Ice that is transparent and contains only a moderate number of air bubbles.

3.8 **Cloudy Ice** – Ice that is translucent or relatively opaque due to the content of air (or other reasons), but which is essentially sound and impervious.

3.9 **Cryogenic Structure (Cryostructure)** – The structural characteristics of frozen earth materials. The structure of frozen soil may be described as massive, lenticular, layered, reticulate or ataxitic (or their combinations) based on the type and distribution of ice in the soil (Photos 1 to 5).

3.10 **Cryopeg** – A layer of unfrozen ground that is perennially cryotic (forming part of the permafrost), in which freezing is prevented by freezing-point depression due to the dissolved-solids content of the pore water.

3.11 **Cryotic Ground** – Soil or rock at temperatures of 0ºC or lower.

3.12 **Cryoturbation** – Irregular structures formed in earth materials by deep frost penetration and frost action processes, and characterized by folded, broken, and dislocated beds and lenses of unconsolidated deposits, including organic horizons and even bedrock.

3.13 **Dry Permafrost** – Permafrost containing neither free water nor ice.

3.14 **Epigenetic permafrost** – permafrost that formed after the deposition of the soil material in which it occurs.

3.15 **Excess Ice** – The volume of ice in the ground, which exceeds the total pore volume that the ground would have under natural unfrozen conditions.

3.16 **Foliated Ice** – Ground ice (usually wedge ice) with parallel inclusions of soil particles and/or air bubbles.

3.17 **Friable** – A condition under which the material is easily broken up under light to moderate finger pressure.

3.18 **Friable Permafrost** – Ice-bearing permafrost in which the soil particles are not held together by ice.

3.19 **Frost Action** – The process of alternate freezing and thawing of moisture in soil, rock and other materials, and the resulting effects on materials and on structures placed on, or in, the ground.

3.20 **Frost Heave** – The upward or outward movement of the ground surface (or objects on, or in, the ground) caused by the formation of ice in the soil.

3.21 **Frost Jacking** – Cumulative upward displacement of objects embedded in the ground, caused by frost action.

3.22 **Frost Shattering** – The mechanical disintegration of rock by the pressure of the freezing of water in pores and along grain boundaries.

3.23 **Frost Table** – The frozen surface, usually irregular, that represents the level to which thawing of seasonally frozen ground has penetrated.

3.24 **Frost Weathering** – The disintegration and break up of soil or rock by the combined action of frost shattering, frost wedging, and hydration shattering.

3.25 **Frost Wedging** – The mechanical disintegration, splitting or break-up of rock by the pressure of the freezing of water in cracks, crevices, pores, joints, or bedding planes.

3.26 **Frozen Ground** – Soil or rock in which part or all of the porewater consists of ice.

3.27 **Granular Ice** – Ice composed of coarse, more or less equidimensional, crystals weakly bonded together.

3.28 **Ground Ice** – A general term referring to all types of ice formed in freezing and frozen ground.

3.29 **Ice-Bearing Permafrost** – Permafrost that contains ice.

3.30 **Ice-Bonded Permafrost** – Ice-bearing permafrost in which the soil particles are cemented together by ice.

3.31 **Ice Coatings on Particles** – Discernible layers of ice found on or below the larger soil particles in a frozen soil mass.

3.32 **Ice Content** – The amount of ice contained in frozen or partially frozen soil or rock.

Ice content is normally expressed in one of two ways:

1. On a dry-weight basis (gravimetric), as the ratio of the mass of the ice in a sample to the mass of the dry sample, expressed as a percentage.

2. On a volume basis (volumetric), as the ratio of the volume of ice in a sample to the volume of the whole sample, expressed as a percentage.

3.33 **Crystal** – A very small individual ice particle visible in the face of a soil mass. Crystals may be present alone or in combination with other ice formations.

3.34 **Ice Lens** – A dominantly horizontal, lens-shaped body of ice ranging in thickness from hairline to 0.3 m (Photos 1 to 5). Ice layers more than 0.3 m in the thickness are better termed massive ice beds (Photos 7 to 10). Ice lenses occur essentially parallel to each other, generally normal to the direction of heat loss, and commonly in repeated layers.

3.35 **Ice-Rich Permafrost** – Permafrost containing excess ice.

3.36 **Ice Segregation** – The formation of segregated ice as distinct lenses, layers, veins, and masses in mineral or organic soils (i.e., the growth of ice within soil in excess of the amount that may be produced by the in-place conversion of the original void moisture to ice). Segregated ice formations are commonly, but not always, oriented normal to the direction of heat flow.

3.37 **3.37 Ice Vein** – A permafrost feature caused by frost action; an ice-filled crack or fissure in the ground.

3.38 **Ice Wedge** – A permafrost feature caused by frost action; a massive, generally wedge-shaped body with its apex pointing downward, composed of foliated or vertically banded, commonly white, ice. It is usually associated with frost cracks in frozen ground.

3.39 **Icing** – A sheet-like mass of layered ice formed on the ground surface, or on river or lake ice, by freezing of successive flows of water.

3.40 **Intrusive Ice** – Ice formed from water injected into soils or rocks.

3.41 **Layered Cryostructure** – Represented by distinctly oriented horizontal or inclined layers of ice alternating with soil layers that have massive cryostructure (Photos 1 to 4).

3.42 **Lenticular Cryostructure** – Formed by discrete ice lenses that may (or may not) form continuous ice layers with soil inclusions (Photos 1 and 2).

3.43 **Massive Cryostructure** – Characterized by the predominant presence of non-visible pore ice and by a relatively low total ice content (Photo 1).

3.44 **Massive Ice** – A comprehensive term used to describe large masses of ground ice, including ice wedges, pingo ice, buried ice, and predominantly horizontal beds of segregated ice (Photos 6 to 9). Massive ice beds typically have an ice content of at least 250% (on an ice-to-dry-soil weight basis). If the ice content is less than 250%, the beds are better termed “massive icy beds”. Massive ice beds have a minimum thickness of 0.3 m. Ice layers less than 0.3 m in thickness are better termed ice lenses. Some massive ice beds are more than 40 m thick and extend several kilometres horizontally (Photos 7 and 8).

3.45 **Micro-Lenticular Cryostructure** – Formed by thin and short ice lenses in perennially frozen soil matrix characterized by massive cryostructure (Photo 1).

3.46 **Perennially Frozen Soils** – Soils, which include ground ice (visible and/or non-visible), that remain frozen for at least two years due to natural climatic conditions.

3.47 **Permafrost** – Ground (soil or rock and included ice and organic material) that remains at or below 0°C for at least two years due to natural climatic conditions. Permafrost is defined exclusively on the basis of temperature. It is not necessarily frozen.

3.48 **Permafrost Aggradation** – A naturally or artificially caused increase in the thickness and/or areal extent of permafrost.

3.49 **Permafrost Table** – The upper boundary of permafrost.

3.50 **Pingo Ice** – Massive ice forming the core of a pingo.

3.51 **Poorly-Bonded** – A condition in which soil particles are weakly held together by ice so that the frozen soil has poor resistance to chipping and breaking (i.e., is characterized by low unconfined compressive strength).

3.52 **Pore Ice** – Ice occurring in the pores of soils and rocks.

3.53 **Porous Ice** – Ice that contains numerous voids, usually interconnected and usually resulting from melting of ice with air bubbles or along crystal interfaces from the presence of salt or other materials in the water, or from the freezing of saturated snow. Though porous, the mass retains its structural unity.

3.54 **Reticulate Cryostructure** – Represented by lenses and layers of ice that form a random net in perennially frozen soil matrix characterized by massive cryostructure (Photos 1, 2, and 5).

3.55 **Syngenetic Permafrost** – permafrost that formed more or less simultaneously with the deposition of the soil material in which it occurs.

3.56 **Talik** – A layer or body of unfrozen ground in permafrost.

3.57 **Thawed Ground** – Previously frozen ground in which all ice has melted.

3.58 **Total Moisture Content** – The total amount of water (unfrozen water plus ice) contained in soil or rock.

3.59 **Unfrozen Ground** – Soil or rock that does not contain any ice.

3.60 **Vein Ice** – A type of ground ice occupying cracks in permafrost.

3.61 **Wedge Ice** – A type of ground ice occurring in an ice wedge; comprises a series of ice veins formed at the same location over a period of time.

3.62 **Well-Bonded** – A condition in which soil particles are strongly held together by ice, so that the frozen soil possesses relatively high resistance to chipping or breaking (i.e., characterized by medium to high unconfined compressive strength).

3.63 **Work Method (WM)** – A document setting out the specific scope of work, method, and sequence of activities and organizational responsibilities relevant to a particular part of the practice.

4.0 RESPONSIBILITIES AND AUTHORITIES

4.1 Manager

- Establishes the terms of reference and project parameters with client, including contract terms;
- Confirms the project team has sufficient resources to carry out the site investigation;
- Confirms all safety procedures/methods are understood and followed by the project team;
- Confirms the project team is aware and meets the project objectives, budget and schedule requirements; and
- Reviews Issued for Use Report and authorizes it with his/her professional seal.

4.2 Project Engineer/Geologist

- Confirms the site investigation is appropriate for the site-specific conditions, available equipment, and proposed scope of work;
- Organizes and manages all logistical support, including subcontractors;
- Confirms field personnel have suitable qualifications and training for conducting fieldwork;
- Confirms the field personnel are aware of the objectives of the site investigation;

- Confirms field personnel are aware of their authority to adjust the site investigation;
- Is available for consultation with field personnel during the site investigation; and
- Confirms all safety procedures/methods are adhered to.

4.3 Technical Reviewer

- Provides timely technical input during the planning, conducting and reporting stages of the site investigation.

4.4 Field Engineer/Geologist

- Understands the site investigation goals and objectives;
- Is familiar with the drilling/excavating, coring, logging, and sampling methods to be used;
- Understands and accepts the authority to adapt the field program as needed;
- Informs a driller on borehole requirements or an excavator operator for test pitting or trenching requirements;
- Conducts the logging of permafrost and soil and collects the data in accordance with the procedures outlined in this work method;
- Keeps the Project Engineer/Geologist informed of any unusual conditions, such as occurrence of large bodies of massive ice, etc., or unusual performance of the equipment;
- Fosters on-site communication and team building between the Project Engineer/Geologist, the subcontractor, and the owner's representative;
- Supervises operation of field laboratory (if applicable);
- Carries out basic field testing of samples of perennially frozen soils;
- Keeps comprehensive records including quality photographs of frozen core and equipment; and
- Ensures all safety procedures/methods are followed.

5.0 WORK METHOD

Required Apparatus and Supplies for Core Logging

- Tetra Tech forms (borehole logs, sample inventory, bulk density)
- Butcher's knife, large pocket knife, or small spatula
- Hatchet
- 5 m measuring tape (steel)
- Low-power magnifying hand lens
- Graduated beakers (for excess ice content determination)
- Weigh scale with accuracy of 0.1 g (for measuring bulk density)
- Caliper (for measuring diameter of a core sample when doing bulk density calculations)
- Digital camera, memory cards, color scale chart and tripod if necessary
- A single-bead thermistor string or thermometer that can measure temperatures below 0°C
- Ohm-meter with a switch box for reading multi-bead ground temperature cables

- Permanent markers
- Pencils
- Clipboards
- White board and dry erase markers
- Field note books
- Pails
- Insulated core box
- Heavy duty coolers
- Freezer (ice) packs
- Industrial towels or rags
- Sample bags and sample tags
- Saran wrap (rolls)
- Foil (rolls)

Useful Auxiliary Apparatus and Supplies

- Small bottle of dilute hydrochloric acid
- Small test tube and stopper
- Munsell Soil Colour Chart or Rock Colour Chart
- Flashlight

5.1 Logging of Perennially Frozen Soils and Ground Ice

The system for describing and classifying perennially frozen soils and ground ice involves three steps: Parts I, II and III. Part I consists of a description of the soil composition (lithology), i.e., gravel, sand, silt, etc., and its classification independent of the frozen state. Part II describes the frozen state of the soil. Part III consists of a description of characteristic ice strata found in the soil.

5.1.1 Part I: Description of Soil Phase

The soil phase, whether thawed or frozen, is described independently of the frozen state according to the Modified Unified Soil Classification (MUSC) system (Appendix A) and Tetra Tech Work Method (WM4400).

5.1.2 Part II: Description of Frozen Soil

The perennially frozen soil is described according to the NRCC Ground Ice Classification system (1963) (Appendix A). This system is based on whether ice in the frozen soil is visible or not. Accordingly, frozen soils are divided into two major groups: soils in which ice is not visible to the unaided eye (N), and soils in which segregated ice is visible (V) (Photos 1 and 2).

5.1.2.1 Frozen Soils with Non-Visible Ice

Frozen soils in which ice is not visible to the unaided eye are divided into two main subgroups: poorly bonded or friable material (Nf), and well-bonded frozen soil (Nb). The Nf condition exists when the degree of saturation is low.

The Nb soils are further divided into two subtypes: Nbn (no excess ice) and Nbe (excess ice uniformly distributed throughout the frozen soil) (Photo 1).

The Nbe condition may occur in very fine sands, silty sands or coarse silts where excess ice is present but is so uniformly distributed that it is not easily identifiable by the unaided eye. However, on close examination, the presence of ice within the soil pores may be identified by crystalline reflections or by a sheen on trimmed surfaces. It can also be verified by placing some frozen soil in a graduated beaker, allowing it to melt, and observing the quantity of supernatant water as a percentage of the total volume.

5.1.2.2 Frozen Soils with Visible Ice (less than 50% by volume)

Frozen soils in which ice is visible to the unaided eye as discrete ice inclusions of measurable dimensions comprising less than 50% by volume are designated by the symbol V. These are divided into five subgroups: Vx (frozen soils, which contain individual ice crystals or inclusions); Vc (frozen soils with ice coatings on larger particles); Vr (frozen soils with random or irregularly oriented ice formations); Vs (frozen soils with stratified or distinctly oriented ice formations); and Vu (visible ice uniformly distributed throughout frozen soil) (Photos 1 to 5).

In addition to using the above symbols on the borehole logs, descriptions of cryostructures (massive, lenticular, layered, etc.) that are characteristic of perennially frozen soils should be described. Cryostructures are useful for determining the nature of the freezing process. Cryostructures are also helpful for determining the permafrost (i.e., syngenetic vs. epigenetic) and the conditions under which the sediments accumulated. The main types of cryogenic structures are defined in Section 3.0 and illustrated in Photos 1 to 5.

When logging an ice-rich frozen soil, multiple symbols may be used to indicate borderline or mixed classifications, e.g., Vr, Vc, Vx 30% (see BH 11580-TRD03, Appendix B); Vs, Vr 40% to 50% (see BH 11580.093-03, Appendix B). The percentage of volumetric ice content should be given only for visible ice symbols. It is important to include a more detailed description of the ice formations along with the ice classification. For example, Vs 10% - 2 mm thick ice lenses regularly spaced at 25 mm intervals.

Volumetric ice content of the ice-rich frozen soil should be estimated using Charts for Estimating Proportions (Appendix C) or measured if possible. A simple field test (suggested by Linell and Kaplar (1963) and Kokelj and Burn (2005)) should be conducted on frozen soil core samples to more accurately determine volumetric ice content of the ice-rich frozen soil. The test consists of placing an approximately 10 cm long frozen soil core sample into a graduated glass beaker and allowing it to thaw. The beaker should be covered with plastic wrap to prevent evaporation. The thawed saturated soil in the beaker should be thoroughly mixed and allowed to settle for 12 hours or more (Photo 6). Volumes of sediment and supernatant water are recorded to estimate excess ice content in percent (I_c) of the sample using the following formula:

$$I_c = [(W_v*1.09)/(S_v + (W_v*1.09))]*100$$

Where W_v is the volume of supernatant water (cm^3), multiplied by 1.09 to estimate the equivalent volume of ice, and S_v is the volume of saturated sediment (cm^3).

It is strongly recommended to test this same thawed sample for moisture content to compare volumetric ice content with total water content. Visual estimates of volumetric ice content as indicated on borehole logs should be within ± 5%.

Since proportions of ice and soil may vary widely, it may sometimes be difficult to decide without the excess ice beaker test whether a given material falls, for example, in the category of frozen soil or of ice with soil inclusions. Material containing as much as 80% ice by volume and 20% soil can sometimes give the appearance of being mostly soil (Linell and Kaplar 1963).

Soil and ice classifications and percentages may be altered on the field borehole logs after the laboratory testing results (moisture contents, grain size analyses, Atterberg Limits, and bulk densities) are complete.

5.1.2.3 Simplified Logging of Frozen Soils with Non-Visible or Visible Ice

In those cases, when recovered frozen soil samples are disturbed and it's difficult to divide main groups of frozen soils (N and V) into subgroups (Nbn vs. Nbe and Vx, Vc, Vs, Vr or Vu) it would be satisfactory to use Nb designation without breakdown into Nbn or Nbe categories, or it might even be sufficient to use only the N and V major group designations to indicate whether or not ground ice is visible, as suggested by Linell and Kaplar (1963). However, it is important to collect such disturbed frozen soil samples and conduct an excess ice beaker test to determine their volumetric ice content.

5.1.3 Part III: Description of Ice Formations

Discrete visible ice formations in frozen soils that are greater than 50% by volume are designated by the symbol ICE and are divided into two subgroups: ICE + Soil Type and ICE (see BH 11580-TRD03, Appendix B; (Photos 1, 9 and 10).

If the ice formation contains soil inclusions, it is designated as ICE + Soil Type. If the ice formation contains no soil inclusions, it is designated simply as ICE (Photo 1, 9 and 10).

Description of various forms of ground ice in permafrost should preferably be made using undisturbed core samples collected by coring with a CRREL dry auger, diamond drill or sonic drill. The description should include structure (clear, cloudy, porous, candled, granular, or stratified), colour (colourless, gray, blue), and the presence of air bubbles or any soil or organic inclusions.

When appreciable masses of ice are encountered in perennially frozen ground, they are termed massive ice (see Section 3.47 for definition of massive ice). It is recommended that these ice formations be designated as ICE or ICE + Soil Type and described as "massive ice bed" or "massive icy bed", respectively, if the layer in question has a minimum thickness of 0.3 m (Photos 7, 8, 9, and 10).

5.2 Logging and Sampling of Frozen Core Obtained by Diamond Drilling

5.2.1 In the case of diamond drilling, which is often used for Tetra Tech's site investigations in permafrost regions, the recovered core is extruded into a core box. The core box should be kept at a temperature below 0°C during logging and sampling to prevent thawing of the frozen core. A measuring tape should

be placed along the edge of the core and the amount of recovery noted (e.g., 1.2 m/1.5 m). A hatchet, a butcher's knife and a hammer can be used to break or split pieces of core for close examination. The ice formations in the frozen soil should be studied on the basis of observations from several directions. The Munsell Soil Colour Chart should be used to correctly describe colour of the soil phase. The core must be cleaned and wetted prior to describing the colour. When a core box is full, core photographs should be taken prior to covering the core box with a lid and removing it from the drill site.

5.2.2 After the core is logged and photographed, several representative core samples should be taken from the entire borehole, or run, wrapped in saran and foil, double-bagged, labelled (project number, borehole number, and depth) and ideally kept frozen (i.e., stored outside if weather permits or in an insulated core box if air temperature is above 0°C). Ultimately, the project will dictate how much of the recovered core is retained.

5.2.3 If both visible and non-visible ice is present in the frozen core, two samples of a representative frozen core interval should be acquired:

- The first sample should include both mineral layers and ice lenses. If layered or reticulate cryogenic structure is present, the sample should contain at least three ice lenses of each orientation. The weight of the sample may range from 1 kg to 3 kg. This sample will allow a total moisture content measurement to be made for frozen soil that includes visible ice formations, non-visible pore ice and unfrozen water.
- The second sample should comprise mineral soil between ice lenses that does not include visible ice. Its weight should range from 15 g to 50 g. This sample will allow moisture content of the mineral portion of the core interval to be determined.

5.2.4 Several representative sections of the core (at least 150 mm long) should be set aside for bulk density measurements. The sections must remain frozen prior to testing. These sections should be undisturbed, perfectly cylindrical, and well preserved. It is recommended that bulk density measurements be carried out in the field since the condition of the frozen core may deteriorate when shipped to a geotechnical laboratory.

5.2.5 Each sample should be recorded on a Sample Inventory Form (Appendix D). The sample interval and sample type should be recorded on the borehole log.

Re: **Update on Peso Vegetation Plots**

The sixth and final annual assessment of the vegetation plots at the Peso mine site was conducted on July 31st, 2018. A report outlining the complete project from commencement in 2012 to the wrap up assessment in the summer of 2018 is currently under preparation. In the interim, a summary of the Peso Project is presented below.

Revegetation trials were established at the Peso Mine site which had last been actively mined in the 1960s. After initial soil sampling, two sites were chosen for the experimentation; a trenched area and the waste rock dump below the adit. Plots were designed, seeded with native grasses and locally collected alder seeds, and prepared with various amendments including biochar, compost, leonardite and dolomite. Both sites were acidic; the trench with a pH of 5 to 6 and the waste rock dump with a pH of 2 to 3. Three blocks of plots were set up at each site.

The plots were assessed annually from 2013 to 2018. The percentage of vegetative cover, species composition and overall health were observed for each plot. In 2018, soil samples, foliar tissue samples and measurements on rooting length and depth were also undertaken.

The plots that were seeded but received no amendments supported very little, if any, growth over the six years. This is consistent with the general area as the acidic and mineral soils here have been very slow to colonize the disturbed areas. The other plots with the different amendments sustained various levels of growth over time. By year two most of the treated plots supported relatively healthy growth of the assorted grass species. Alder seeds that were also added to the plots began noticeably growing in years two and three. In year four grasses were gradually dying back and shrubs, mainly alder, were taking over. Willow, dwarf birch, Labrador tea, blueberry and paper birch were also beginning to colonize some of the plots, all of which are present in the neighbouring forest.

Soil analysis indicated that the growth medium is acidic, nutrient poor and mineralized with very high concentrations of several metals. It appeared biochar was sequestering some metals in the treated plots. Although metal concentrations were extremely high (i.e arsenic, antimony and lead), these metals were not taken up in large amounts by the plants. Concentrations in the tissues appear similar to those collected at other Yukon mine sites and at other locations at Dublin Gulch. Greater detail will be provided in the report.

In conclusion, a successful revegetation project at the Peso site would require amendments and at a minimum, biochar and compost. Biochar provides high surface area for moisture retention and metal sequestration; however it does not provide anything in the way of nutrients. Thus some form of fertilization will be required to get the growth initiated. After six years of growth on the treated plots, leaf litter and nitrogen addition through the fixation and decomposition of alder, was gradually building up the soil allowing for continued growth of the plants.

Generally, the shrubs growing at the treated plots were healthy and alder were reproducing in the final year (2018) as seed cones were observed on several of the plants. Many plots also supported healthy volunteer shrubs – willows, dwarf birch, Labrador tea etc. Initial seeding with native grasses, although not the dominant life form in the surrounding environment, served a useful purpose as they germinate quickly, assist in retaining moisture and help to build up the soil.

Volunteer spruce and shrubs growing with the alder on a plot at the Waste Rock Dump.

Alders producing seed cones on one of the Trench plots.
