### INTRODUCTION

In November and December, 1985 Freegold Venture (FV) submitted 3885 soil sample splits for 30 element ICP analysis at Chemex Labs in North Vancouver. The samples were collected from grids on FV's Idaho Creek, Nit, Maloney and Stoddart properties and were previously analyzed for gold. Sampling techniques and gold results were discussed at some length in the 1985 Freegold Venture Final Report. The ICP analyses were performed to obtain information for common pathfinder metals, principally silver, arsenic, lead, zinc and copper, which have been used elsewhere in the Dawson Range to better define potential source areas and to infer the probable deposit type from which the metals were derived.

### IDAHO CREEK PROPERTY

Approximately 50% of the samples from Idaho Creek were analyzed by ICP in fall, 1985 and the results were discussed in the Final Report. The fill-in analyses better defined and amplified some of the earlier anomalies but in general the sizes and shapes are little changed. Figures I 10 to 14 in the pocket show complete, recontoured results for silver, arsenic, lead, zinc and antimony, respectively. Appendix I contains the ICP results, while Figure I 9 in the Final Report shows sample locations. Table 1 on the following page is a revision of Table 4 from the Final Report that summarizes the anomalies.

<u>Anomaly</u>	<u>Dimensions</u>	<u>Principal Metals</u>	M a x i m u m V a l u e s					<u>Comments</u>	
			<u>Au</u> <u>ppb</u>	<u>Ag</u> <u>ppm</u>	<u>Pb</u> <u>ppm</u>	<u>Zn</u> <u>ppm</u>	<u>As</u> <u>ppm</u>		<u>Sb</u> <u>ppm</u>
A	varies from metal to metal but relatively contiguous over 1200 x 600 m	polymetallic	258	122.0	3302	1010	1500	1110	Shape of anomaly suggests dispersion from 2 or more NNE-trending zones and possibly ENE-trending zone; quartz veins occur in part of this anomaly
B	varies from metal to metal but relatively contiguous over 1000 x 400 m	polymetallic	1490	11.2	1256	1210	690	20	same as A
C	two or more clusters within 800 x 400 m	Au,As	6550	1.8	178	900	2300	10	As and Au values coincide with porphyry dykes and ENE-trending linears
D	scattered clusters within 1000 x 300 m	Au,As	918	10.2	264	470	1000	10	Anomalous values follow ENE trend developed in the hanging wall of the porphyry dyke and major linear

Table 1: Geochemical Anomalies, Idaho Creek Property

Based on all available geological and geochemical data, it is probable that the metals in the Idaho Creek soils were derived from a series of veins cutting Mid-Cretaceous granitic rocks. This property remains the most promising of the Freegold Venture claim groups.

NIT PROPERTY

Seven hundred and seventy-seven of the 960 soil samples collected on the ITN grid have undergone ICP analysis. Figures T7 to T11 in the pocket illustrate contoured silver, arsenic, lead, zinc and copper results. Complete ICP results are presented in Appendix II, while sample locations are shown on Figure T12, also in the pocket.

Silver and lead are closely correlated to gold; thus the highest values are clustered in the three anomalies previously outlined by gold geochemistry. Arsenic and zinc show broader dispersion and less direct correlations to gold, but once again the highest values are clustered in the three main anomalies. Copper values are low with only 23 of the 777 samples exceeding 25 ppm. Table 2 below summarizes the geochemical signatures of the anomalies.

TABLE 2

<u>Anomaly</u>	<u>Characteristic Metals</u>	<u>Au ppb</u>	<u>Ag ppm</u>	<u>As ppm</u>	<u>Pb ppm</u>	<u>Zn ppm</u>	<u>Cu ppm</u>
A	Au,As,Ag,Pb,Zn	1020	14.0	770	414	550	121
B	Au,As,Pb,Ag	850	5.2	980	464	570	51
C	Ag,Au,Pb,As,Zn	193	54.0	880	1550	420	27

Geological data on the property is scant but suggests potential for bulk tonnage deposits associated with feldspar porphyry dyking or higher grade mineralization related to faults. Pathfinder geochemistry best supports the vein fault model as this combination of metals and metal ratios is associated with epithermal veins elsewhere in the Dawson Range. The high gold and silver values and silver-to-lead ratios obtained from Anomaly C, coupled with its exposure on the ridge crest and known geological control, make it the logical target for the next stage of property evaluation.

#### MALONEY PROPERTY

Two hundred and three of the 669 samples that were collected and analyzed for gold were reanalyzed for 30 other elements by ICP. All of the reanalyzed samples came from the eastern half of the property where the anomalous gold values were concentrated. Figures M5 to 9 inclusive illustrate silver, arsenic, lead, zinc and copper results, respectively. Complete ICP results are presented in Appendix III and sample locations are shown on Figure M10.

Comparison of ICP and gold results indicates two sets of associated metals: (1) gold + copper; and, (2) arsenic + zinc + gold + silver + copper. Table 3 below lists maximum values for the various metals obtained from each anomaly type.

TABLE 3

<u>Anomaly Type</u>	<u>Au ppb</u>	<u>Ag ppm</u>	<u>As ppm</u>	<u>Pb ppm</u>	<u>Zn ppm</u>	<u>Cu ppm</u>
gold + copper	1270	1.2	30	20	50	656
multi-element	532	8.6	2700	2162	5170	132

The gold + copper anomaly occurs near the centre of the property in the area that was previously explored as a porphyry copper target. In general, the highest gold values flank the copper-rich core and are underlain by argillically altered quartz diorite and quartz porphyry breccia. Although old drill holes that tested the copper produced several intersections grading 100 to 250 ppb Au over 3 m width, gold values from the adjacent soil were low, ranging from 3 to 56 ppb Au.

Two multi-element anomalies are present along an east-west trending ridge in the southern portion of the property. The eastern anomaly is relatively weak and lacks good precious metal response but the western anomaly is more intense and contains two high gold values (532 and 177 ppb) plus a high silver value (8.6 ppm). These anomalies are generally underlain by Pelly Gneiss metamorphic rocks that are cut by prominent, north-trending topographic linears.

Considering available geological and geochemical data, the property may host either a bulk tonnage deposit of the Nucleus-type or narrow veins similar to the Huestis or Webber vein at Mt. Nansen. However, the geochemical anomalies are not as intense or well clustered as those on the other properties. This may be due in part to poor sampling conditions and low sample density but for now the property is assigned a low priority relative to other FV prospects.

#### STODDART PROPERTY

All 610 samples FV collected from the EYM grid and 55 of the samples taken by earlier projects from the Northwest Zone were reanalyzed by ICP. Figures F3 to 7 inclusive illustrate silver, arsenic, lead, zinc and copper results, respectively. Appendix IV contains complete ICP results and sample locations are shown on Figure F8.

Results from this property are unusual in that the anomalous gold values form clusters but show little direct correlation with other metals, except arsenic within the Northwest Zone. Arsenic values within this zone are strongly anomalous typically in the range of 100 to 500 ppm and up to 1440 ppm. There is good correlation between silver, lead and zinc with the best values (11.0 ppm Ag, 282 ppm Pb, and 570 ppm Zn) occurring along the ridge crest immediately east of the Northwest Zone. Copper shows a weak correlation with gold in the Castle Zone but little correlation with other metals anywhere on the property.

There is very little bedrock exposure on the Stoddart property; thus it is difficult to speculate on the probable source of the metals. However, the geochemical data for the Northwest and Castle Zones resembles the signature at Nucleus except that the copper response is weaker in the Northwest Zone and the arsenic weaker in the Castle Zone. The presence of high lead, zinc and silver values in some samples east of the Northwest Zone suggests that small silver-lead veins similar to the nearby Red Fox Vein may also be present. The size and intensity of the gold and arsenic response from the Northwest Zone make it the logical target for follow-up trenching.

Respectfully submitted,

ARCHER, CATHRO & ASSOCIATES (1981) LIMITED

Semi quantitative multi element ICP analysis

Nitric-Aqua-Regia digestion of 0.5 gm of material followed by ICP analysis. Since this digestion is incomplete for many minerals, values reported for Al, Sb, Ba, Be, Ca, Cr, Ga, La, Mg, K, Na, Sr, Tl, Ti, W and V can only be considered as semi-quantitative.

COMMENTS :  
ATTN: WILL HALLERAN
