SUMMARY

This report prepared for Eagle Plains Resources Ltd. summarizes exploration undertaken on the Drag claims in the 1999 season including surface sampling, magnetometer survey and a diamond drill program. The initial discovery of mineralized metasedimentary rocks on the south shore of Dragon Lake was made in 1945. B. Kreft acquired the prospect in 1996 and performed a hand trenching programs in 1996 and 1997, described in a report by the writer dated Nov. 30, 1997. Surface samples were consistently elevated in gold values with 29 of 81 samples assaying > 1gpt.

The DRAG 1-8, 13-44 (40 claims) cover 900 hectares, located south of Dragon Lake, 85 kilometers northeast of the town of Ross River and 10 kilometers west of the North Canol Road in the central Yukon Territory. A winter trail connects the property to the North Canol Road. Summer access is by helicopter or float plane from Ross River to the south shoreline of Dragon Lake. Charter aircraft and supplies are available from Ross River or alternately Whitehorse located, 255 kilometers to the south. The showings are situated 250-450 meters south of the lake shore on several rocky ridges and gullies in an area of moderate relief. Three small streams flow northward through the claims. Forest fires have killed most of the vegetation in the area, leaving fairly thick windfall and buckbrush.

The property is in the Selwyn Basin geological region, a thick sequence of Proterozoic and Paleozoic sedimentary rocks situated on the western edge of the North American craton. The Tintina Fault, the contact between the craton and accreted rocks is located southwest of the property marking the transition from the Selwyn Basin to the Yukon Tanana terrane. At Dragon Lake Proterozoic-Lower Cambrian quartzite, phyllite, quartz pebble conglomerate, sandstone, argillaceous limestone, marble and quartz mica schist of the Yusezyu Formation of the Hyland Group are intruded by Cretaceous syenitic to monzonitic stock. Limestone beds are variably replaced by actinolite skarn lenses and calc-silicte rocks containing disseminated and fracture filling pyrrhotite, pyrite and minor chalcopyrite, scheelite and arsenopyrite. These horizons are marked by heavy limonite and hematite staining.

The DRAG claims were staked on an old prospect originally worked by Kennco in 1960-1961 followed by Union Carbide and partners in 1980, Canamax in 1983 and Welcome North in 1988. Collectively the companies completed general surface exploration including geochemical and magnetometer surveys. Favorable copper, gold and silver values were found in two lenses about 600 meters apart and the better mineralized central zone (Main Zone) exhibited a strong Au-Ag-Cu soil geochemical response. Welcome North sampled three pods of mineralization at the Main Zone recording gold values of > 1 gpt in several 1 m chip samples with a high value of 12.7 gpt over 1 m. A small magnetometer survey outlined a magnetic high approximately 200 meters long and 100 meters wide. Grid lines were destroyed by a forest fire which burned through the claim group in the 1980's.

Prospector B. Kreft staked the DRAG claims in 1996 and the claims are presently held by Eagle plains Resources Ltd (EPL). B. Kreft relocated the Main Zone showings along a creek gully approximately 350 meters south of Dragon Lake. Samples collected by B. Kreft and Battle Mountain Canada in 1996 obtained gold values of > 1000 ppb in eleven of twenty-six samples. In 1997, 51 samples were collected in fourteen hand trenches from mineral occurrences along a 250 meter wide and 400 meter long section. The hand trenches exposed skarn zones up to 20 m wide that weather to form distinct gossans. Individual sulfide bands weather a dark blue-black color and are extremely hard Disseminated or banded to massive mineralization consists of fine-grained pyrrhotite with less magnetite, chalcopyrite, scheelite, arsenopyrite and pyrite in a silicified matrix. Galena, arsenopyrite and stibnite occur in narrow quartz veinlets and a few wider quartz veins. The writer visited the prospect on October 7, 1997 and collected another 10 chip samples from the various showings and hand pits. Of the 61 samples collected, 18 samples of 1 meter or more in width assayed > 1gpt gold.

In 1999 a total of 50 chip and grab samples were collected from the skarn occurrences in July and another 22 samples were taken in August from the claims. Of the 72 samples collected in 1999, four were > 1gpt gold. A proton magnetometer survey over 7 km of gridline outlined a fairly flat magnetic response with several weak magnetic lows that correlate with some of the mineralized horizons. Weak magnetic highs indicate magnetite skarn lenses contain up to 2% chalcopyrite.

Four diamond drill holes totaling 301 m were drilled from three pads from August 11-21. The drill contractor Falcon Drilling Ltd. provided a helicopter portable hydraulic drill operated on a day shift. The dill program intersected thick bands of actinolite skarn and calc-silicate rock containing up to 5% pyrrhotite. Gold values in skarn were generally weakly elevated with a few spot highs but no consistent mineralization was intersected. The drill results outline variably mineralized zones which do not warrant any further drilling at this time.

INTRODUCTION

The Dragon Lake property consists of 40 claims located in the central Yukon Territory near Dragon Lake in the Macmillan River valley of the Pelly Mountains and the Whitehorse Mining District. The claims cover low-lying hills and ridges of moderate topography. The showings are located along creek gullies and on small rocky ridges that have an east-west orientation. The entire area has been burned by a forest fire and only a few isolated pockets of spruce forest remain. The most recent exploration completed on the prospect was a four hole (301m) diamond drill program in August 1999. This report reviews data provided by B. Kreft and diamond drill logs compiled by Chuck Downey, P.Geo. The report is prepared for assessment purposes at the request of B. Kreft for EPL, and it may be used for any other purposes normal to the business of these companies including filing with the Alberta Stock Exchange.

LOCATION AND ACCESS

The Dragon Lake property is located 85 kilometers northeast of the town of Ross River and 10 kilometers west of the North Canol Road midway along the south shore of Dragon Lake on NTS Map Sheet 105 J-12 at geographical co-ordinates 62° 37' N and 131° 33' W. The property was accessed by float plane from Whitehorse. Alternate access by boat is possible from the North Canol Road from a staging area at kilometer 110. Good camp sites are available on the shoreline of Dragon Lake in DRAG claims 1 & 2. Figures 1 and 2 show the property location. Logistically, Whitehorse, Ross River and Watson Lake provide supplies, accommodations and government services for the district and there is a government maintained airstrip at Ross River.

PHYSIOGRAPHY

Dragon Lake occupies a southeast-northwest trending valley surrounded by low hills sloping up to higher mountain peaks and upland plateau's to the south. Elevations range from 857 to 1060 meters (see Figure 3-Topographic Map). The claim area rises to the south and is incised by three narrow creek gullies. Most outcrop is located on ridges flanking the creek gullies and above depressions containing small ponds. Overburden depth is variable but averages 4 meters. Glaciation has left a few eskers along the north shoreline of Dragon Lake.

Vegetation consists of buck brush with thickets of small poplar trees. Otherwise, the forest fire has left mainly dead standing trees. The ground cover is fairly thick and any grid development would require linecutting. The district has a northern interior climate marked by long cold winters and moderate annual precipitation. Exploration on the property can be performed from May until October but is possible on a year round basis.

PROPERTY

The Dragon Lake property consists of 40 contiguous mineral claims, as shown in Figure 4 and listed in Table 1

TABLE 1

CLAIM DATA

Claim Name	Grant Number	Expiry Date (* applied for)
DRAG 1-4	YB67142-45	JUNE 28, 2006
DRAG 5-6	YB96313-14	SEPT. 20, 2006
DRAG 7-8	YB96608-09	SEPT. 30, 2006
DRAG 13-24	YC09170-81	Dec. 7, 2004
DRAG 25-44	YC18119-38	Aug 10, 2000

The original Drag 1-8 claims were staked in 1996 and recorded in the office of the district mining recorder in Whitehorse. The Drag 13-24 were staked in 1997 and the Drag 25-44 were staked in 1999. The claims are registered to Eagle Plains Resources Ltd. The writer examined some of the claim posts and claim lines in 1997 and found them to be staked in compliance with the Yukon Quartz Mining Act.

ENVIRONMENT

No special environmental concerns are known for this area. The Department of Indian and Northern Affairs has implemented mining land use regulations that are described in various government publications Land use permits may be required prior to commencing exploration on a claim group. It is recommended that mining land use applications for work programs should be submitted at least 90 days prior to mobilization

Land Use Permits are also necessary for access via the winter trail Movement of heavy equipment onto the claims for drilling or trenching purposes is best achieved in the winter.

REGIONAL GEOLOGY

The rocks underlying the Dragon Lake district are mainly metasedimentary and include argillites, phyllites, limestones, cherts, slates, schists and quartzites of the Proterozoic to Lower Cambrian Hyland Group of the Selwyn Basin. Conformable lenses and sills of greenstone, probably Triassic in age, occur in profusion in places in the metasediments and a few narrow lamprophyre and quartz-porphyry sills, probably Jurassic or younger, are present locally. Granitic bodies of Cretaceous age intrude the sediments, metasediments and greenstones at several places. Porphyry copper-molybdenum style mineralization occurs within the intrusives and characteristic skarn zones are developed in calcareous metasedimentary rocks around the granitic intrusions. In the late Mesozoic extensive thrust faulting accompanied the emplacement of Carboniferous and Permian dark green aphanitic basalt, dunite, peroxinite, peridotite, serpentinized equivalents and quartz carbonate rock.

The claims lie north of the Tintina Fault, a large transcurrent Late Cretaceous to Tertiary fault system that caused at least 450 km of displacement. During the Eocene volcanism and sedimentation deposited sequences of basalt, rhyolite, felsic tuff and conglomerate in the Tintina depression. Late Tertiary uplift and faulting preserved Eocene volcanoclastic rocks in structurally complex grabens. Epithermal style gold and silver mineralization occurs at fault intersections in these grabens.

South of the Selwyn Basin the Yukon Tanana terrane is the focus of exploration for volcanogenic massive sulfide deposits The increase in general interest in the region has led to a re-evaluation of prospects in the Selwyn Basin in particular mineralization occurring in association with Cretaceous intrusions and volcanic rocks Metasedimentary units in the Dragon Lake area strike 120° and dip 45-65° northeast. The most recent geological map of the area was compiled by Templeman-Kiuit as Map 12-1961. Figure 5 shows the area geology and the Table of Formations is presented in Table II.

HISTORY

The Ross River area was first explored by Robert Campbell of the Hudsons Bay Company who descended the Pelly River in 1840. A trading post was established by the HBC at Francis Lake in the 1850's. Prospectors entered the country via the Liard River system around 1880 looking for placer gold deposits. Minor amounts were found along bars in the Finlayson River. Lode prospecting began in the 1950's and intensified in the 1960's with the discovery of the Anvil Pb-Zn deposit at Faro. Most of the mineral occurrences in the district were found at this time. Several staking rushes in the Ross River, Finlayson and Pelly River areas targeted massive sulfide mineralization in volcanogenic and replacement style deposits. The latest rush in the mid 1990's resulted in the discovery of the Kutz ze Kayah and Wolverine massive sulfide deposits

The dramatic increase in the level of exploration around Ross River has led to a re-evaluation of many mineral occurrences including those associated with Cretaceous intrusives in the Selwyn Basin. The original discovery of mineralization in the area of the DRAG claims is credited to a GSC field party in 1945, while regional mapping. Kennco staked the showing in 1960, completing preliminary mapping and soil sampling but had difficulties due to a lack of outcrop. Later work by Canamax and Welcome North included magnetometer surveys and soil geochemistry. The mineralized zones responded well to the magnetometer but the surveys were of limited extent and it is difficult to position the anomalies. Unfortunately the historical geophysical data is incomplete and can not be used to plan future exploration. Grid soil geochemistry by Canamax outlined several small coincidental gold and copper anomalies, mainly located in the gullies where overburden is thinner. The anomalies trend northwest-southeast and correlate well with mineralized horizons. The Main Zone consists of three pyrrhotite rich skarn lenses and coincident geochemical anomalies located in the central portion of the claims. A second area of gossan zones and pyrrhotite mineralization is situated in the northwest corner of the claim block (Northwest Zone).

RECENT EXPLORATION 1996-1997

Sampling programs were undertaken in 1996 and 1997. The initial visit in August, 1996 included sampling of known occurrences finding promising gold values ranging from 1312-6116 ppb in 5 of 14 samples. Mr. Kreft returned to the prospect in August, 1997 and hand trenched fourteen sites on and around the Main Zone. Another 51 samples were collected and 12 returned gold values of > 1gpt. The writer examined and sampled six of the sites marked as T-1, T-2, T-9, T-11, T-12 and T-14 during the property visit confirming good gold values.

TABLE II - TABLE OF FORMATIONS

Sst-Siltstone
1a-Quartzite-pale grey to white-weathering with minor interbedded phyllite
1b-Phyllite and chert-thinley laminated black to grey sediments
1c-Marble, limestone-light grey to white, hematite and limonite staining
1d-Calc-silicate rock, diopside skarn and hornfels-black rusty weathering horizons, banded to disseminated pyrrhotite

PROPERTY GEOLOGY AND MINERALIZATION

The rocks exposed on the DRAG claims are Hyland Group clastic and metasedimentary rocks of the Selwyn Basin overlain and intruded by volcanic flows and dykes of undetermined age, in turn intruded by Cretaceous or younger syenite to monzonite stock The Hyland Group, Yusezyu Group sediments consist of coarse clastic units, ranging from quartz-pebble conglomerate to fine sandstone and siltstone separated by less extensive beds of limestone, dark grey limestone and silty limestone. The sediments are variably metamorphosed to graphitic and calcareous phyllite, chert, calc-silicate rock, skarn, marble and quartzite Small cliffs of quartzite along the creek gullies are highly fractured with hematite and pyrrhotite in the fractures. The units generally strike 120° and dip 45-65° northeast Actinolite skarn occurrences extend along many of the limestone beds. Replacement style mineralization consisting of fine grained disseminated pyrrhotite and pyrite, minor chalcopyrite and sulphide lenses are commonly found in patchy skarn along limestone beds

Structurally the sedimentary units are folded and fractured by uplift, normal faults and thrust faulting Figure 6 shows the property geology and the following units were identified;

- Syenite to monzonite (Ks, Km)· fine to medium-grained body of biotite plagioclase syenite, outcrops at the northwest end of the claims
- Quartz pebble conglomerate (Qpc)
- Sandstone (Ss) and siltstone (Sst)·
- Quartzite (1a) typically bedded light grey and white, glassy, fine to medium grained quartzite, locally gritty and recrystallized, contains sericite, minor pyrite and pyrrhotite on fracture faces Prominent white cliffs of quartzite are fractured containing rusty weathering pyrrhotite and hematite on fractures. A few white quartz veins contain galena, arsenopyrite and stibnite
- Phyllite and chert (1b) fine grained light to dark gray siliceous calcareous bedded sediments with disseminated to patchy pyrite and pyrrhotite, graphitic fracture faces, locally brecciated with minor white quartz and carbonate veining, weak to heavy limonite staining
- Limestone and marble (1c) bedded grey-white, locally silicified containing minor cubic pyrite Some diopside-magnetite-sulfide skarn development in limy units
- Calc-silicate, skarn rock (1d). black fine-grained metasediment with banded and disseminated pyrrhotite, rusty red weathering, forms gossans in creek gullies.

Silicified calc-silicate horizons host the disseminated to banded semi-massive pyrrhotite mineralization. The sulfide mineral content of the gold bearing samples average 5-7%. The Main Zone is three exposures of limonitic calc-silicate rock around a quartzite unit. The longest exposure at pit T-9 is a rusty weathering zone of mineralization that assayed an average of 1208 ppb gold over 15.3 meters in a series of six chip samples taken in 1997. The Creek showing is a 3.5 meter thick calc-silicate horizon containing massive pyrrhotite bands that outcrops in an open cut (T-11) on the east side of the creek gully The mineralization is locally well-layered, but typically is disseminated and fine-grained. Two pits expose mineralization, the upper pit was sampled by the writer (1997) in a 3 meter chip sample that assayed 1106 ppb gold (see Fig. 6 for sample sites).

About 150 m west of the T-11 showing, pit T-12 uncovers banded pyrrhotite in a limey phyllite layer underlain by limestone. A chip sample taken by the writer (1997) assayed 1569 ppb gold over 3 meters.

The main zone, T-9, T-11, T-12, and T-13 were suggested as drill targets in the 1997 report or by C Shulze.

1999 ROCK SAMPLING

A rock sampling program was performed from July 13-19 and Aug. 1, 1999 including 50 samples collected by B. Kreft and another 22 samples taken by C Shulze. The sample locations are shown on Figures 7 and 8. Rock sample descriptions are listed in Appendix I and Certificates of Analysis are in Appendix III.

Carl Shulze reports in a July 1999 Progress Report " Mineralization extends across the property, primarily confined to calc-silicate altered limestone members Lenses of bedding-controlled massive to banded pyrrhotite and pyrite with minor chalcopyrite extend up to 100 m in length and 10 m in width. Numerous showings of this nature were identified during this program, particularly in extreme eastern areas, along the main east-west trend, and in southwestern areas, the latter associated with up to 3% chalcopyrite. Mineralization and associated alteration is typical of retrograde "skarn" occurrences, although garnet development to the east suggests otherwise Several occurrences display a strong NNW trending lineation in central areas, with mineralization extending at least 25 m along this orientation This suggests that mineralization is structurally controlled along several NNW bands Mineralization in the clastic sediments occurs within small joint controlled quartz veins, locally sheeted containing arsenopyrite. More intense fracture controlled quartz stringer and stockwork veining associated with minor pyrite boxwork and limonitic staining occurs along the NNW trending structures. Minor joint controlled sheeted quartz-arsenopyrite veining with moderate argillic alteration and silicification occurs near the small stock in the western portion of the property."

DIAMOND DRILLING

In mid August a Falcon Drilling Ltd. Hydrocore S-1 diamond drill was flown by helicopter to the Drag claims from the Canol Road. Four drill holes totalling 301 m were drilled from three drill pads, targeting the surface showings at the main zone. The pad locations are shown in Figure 8 and drill logs with drill core sample results are provided in Appendix II.

Drill hole D 99-1 intersected mixed quartz-pebble conglomerate, quartzite, limestone and skarn bands. Gold assays from 49.3-50.5 m at 2142 ppb and from 106.6-107.8 at 3664 ppb were the best results of the drill program. These sections have approximately 5% pyrrhotite however other similar sections produced lower gold values.

Drill hole D 99-2 intersected mixed skarn and hornfels units and clastic sedimentary beds with variable sulphide mineralization and weak quartz sulphide veining. Several breccia and shear zones were evident in the core. Gold values were low in all samples.

Drill hole D 99-3 intersected mixed skarn, hornfels and sheared sedimentary rocks with patchy pyrrhotite mineralization. Gold values were weakly elevated to background.

Drill hole D 99-4 intersected quartzite with weak skarn and hornfels bands. Minor pyrrhotite in microfractured sections and shear zones assayed background gold values.

DISCUSSION AND RECOMMENDATIONS

The Dragon Lake property has numerous gold bearing showings in surface pits however diamond drill core from the skarn and calc-silicate zones assayed weakly elevated gold values with a few spot highs. The weak drill results compared to strong gold values from surface pits suggests that some surface enrichment is present. Weathering and oxidation of the bedrock at surface probably cause this enrichment.

There is potential to find more consistent gold bearing skarn mineralization in the area around the intrusive. Grid geochemistry and geophysical surveys are the best method for identifying larger targets.

CERTIFICATE

I, GRAHAM DAVIDSON, of the City of Whitehorse in the Yukon Territory, HEREBY CERTIFY:

1. That I am a consulting geologist and that I visited the Drag claims on October 7, 1997 and reviewed assessment documents and sample data provided by B. Kreft. in the preparation of this report.

2. That I am a graduate of the University of Western Ontario (H. BSc., Geology, 1981).

3. That I am registered as a Professional Geologist by the Association of Professional Engineers, Geologists and Geophysicists of Alberta (No.42038).

4. That I have been engaged in mineral exploration for fourteen years in the Yukon, the Northwest Territories and British Columbia and that I do not hold any interest in the Drag claims or in Eagle Plains Resources Ltd.

SIGNED at Whitehorse, Yukon, this 30 day of November, 1999.

G.S. DAVIDSON, P. Geol.

SAMPLE DESCRIPTIONS (CARL SCHULZE), DRAG PROPERTY

Sample No.	Type	Width	Setting	Location (Grid)	Description
DL-CS 1	Chip	0 8m	Outcrop	604W + 249S	Massive - disseminated pyrite +/- pyrrhotite skarn, strong actinolite development 15% Py +/- nonmag. pyrrhotite, 1/2% chalcopyrite
DL-CS 2	Chip	1 4m	Outcrop	603W + 248S (60 cm NE of DL-CS 1	10% Pyrite +/- pyrrhotite, trace chalcopyrite, fracture controlled, disseminated to semi-massive Strong actinolite development.
DL-CS 3	Chip	0 4m	Outcrop	680W + 230S (creekside)	Quartz-pebble conglomerate - sandstone, 25% quartz veins, moderate quartz flooding, argillic alteration 1 - 2% disseminated pyrite
DL-CS4	Grab		Talus	682W + 230S	Quartz-pebble conglomerate, moderate argillic alteration, weak phyllic alteration.
DL-CS 5	Chip	1.7m	Outcrop	470W + 113S	Quartz-pebble conglomerate (QPC), approx. 10% quartz veins, tr Arsenopyrite, silicified, weak argillic alteration Veins parallel jointing at 280 - 45.
DL-CS 6	Chip	1 7m	Outcrop	470W + 101S	Silicified QPC to sandstone, moderately fractured with fracture controlled trace arsenopyrite + scorodite. 3% limonite after sulphides.
DL-CS 7	Chip	1 1m	Outcrop	470W + 100S (adjacent to DL-CS 6)	Similar QPC to DL-CS 6, 10% fine fracture controlled quartz to chalcedony veins, trace arsenopyrite? Trace limonite, pyrite
DL-CS 8	Chip	1.3m	Outcrop	415W + 167S	Strongly developed actinolite skarn, 10% disseminated and fracture controlled pyrrhotite, strongly limonitic. Most of sample reduced to fine fragments, but with strongly resistive, competent unit
DL-CS 9	Chip	1 7m	Outcrop	385W + 254S	QPC - sandstone; strongly fractured to brecciated, 10% quartz-carbonate veins and stringers, moderate fracture controlled limonite
DL-CS 10	Chip	0 5m	Outcrop	473W + 267S	Siltstone to phyllite (Road River Group?), foliated, 5% fine grained disseminated and banded pyrrhotite, trace pyrite (hornfelsed?), silicified. Foliation at 305 - 80, jointing at 200 - 85
DL-CS 11	Chip	1.0m	Outcrop	495W + 228S	Massive sulphide "skarn" showing, 30% pyrite, 2% chal, weakly silicified strongly developed actinolite skarn.
DL-CS 12	Chip	0 7m	Outcrop	493W + 227S (2m NE of DL-CS 11)	Actinolite "skarn", 5% pyrrhotite, 3-4% pyrite, 2-3% disseminated and fracture controlled chalcopyrite, moderately silicified
DL-CS 13	Chip	1.5m	Outcrop	502W + 233S (7m SW of DL-CS 11)	Massive sulphide actinolite skarn, 30% pyrite, 3-4% chalcopyrite, minor pyrrhotite Open to NE, probably contiguous mineralization with DL-CS 11 Foliation at 30 - 80

DL-CS 14	Chip	1 3m	Outcrop	503W + 234S (adjacent to DL-CS 13)	Similar to DL-Cs 13, 5% nonmagnetic - weakly magnetic pyrrhotite, open to SW
DL-CS 15	Chip	1 3m	Outcrop	606W + 252S (4m SW of DL-CS-1)	Semi-massive actinolite "skarn"; 15% pyrite, 1-2% chalcopyrite, trace non-magnetic pyrrhotite? Fractured, partly strongly silicified, incl 40 cm of strongly decrepitated rubblecrop
DL-CS 16	Chip	1 4m	Outcrop	491W + 227S (2m E of DL-CS 12)	Actinolite "skarn", locally silicified, 15% pyrrhotite, 20% pyrite, 1-2% chalcopyrite; incl 15 cm wide zone of argillically altered fractured sediments Sample largely strongly decrepitated, open to E + W
DL-CS 17	Chip	1 5m	Outcrop	234W + ,183S	Limestone, minor coarse sandstone, strongly silicified, 3-4% fine grained disseminated pyrrhotite +/- pyrite
DL-CS 18	Chip	0 8m	Outcrop (poss. large boulder?)	338W + 232S	QPC to sandstone, strongly fractured, minor quartz-carbonate veining, weak argillic alteration, 25% pyrite, 2% chalcopyrite, disseminated and fracture controlled.
DL-CS 19	Chip	0.6m	Outcrop	598W + 237S	Actinolite skarn in limestone, strongly silicified, 5% Py tr pyrrhotite, trace chalcopyrite in most resistive areas,
DL-CS 20	Chip	2.0m	Outcrop	465W+38N	QPC to sandstone, jointed, moderately silicified, 6-7% quartz veins, 1% sheeted Qz-arseno veins, moderate limonite after sulphides, fractured, moderate argillic alteration Qz-arseno veins along joints at 180-70
DL-CS 21	Chip	1.5m	Outcrop	436W+30N	QPC, moderately fractured, minor quartz veining, trace Pyrite boxwork, moderately limonitic, weak argillic alteration
DL-CS 22	Chip	1 5m	Outcrop	352W+21N	Coarse sandstone, minor quartz veining, wk silicification, local moderate argillic alteration, limonitic

LEGEND & SYMBOLS

CRETACEOUS

Kg — Buff to grey dykes, sills and small plugs of aplite and biotite granite; locally quartz, feldspar and/or biotite phyric; minor arsenopyrite

PROTEROZOIC - Lower Cambrian
Hyland Group

1a — Quartzite-pale grey to white-weathering with minor interbedded phyllite

1b — Phyllite and chert-thinly laminated black to grey sediments

1c — Marble, limestone-light grey to white, hematite and limonite staining

1d — Calc-silicate rock, diopside skarn and hornfels-black rusty weathering horizons, banded to disseminated pyrrhotite

- Geological contact
- Fault
- Replacement mineralization
- Au soil anomaly, >40 ppb
- ⊗T-3 — Sample pit
- 1000 — Elevation contour interval, (20 metres)
- Stream, creek, lake
- 4-wheel drive trail
- Claim group boundary (approximate)
- Claim line
- 6 YB96315 — Claim no., grant no.
