SUMMARY

Environment Yukon has been conducting assessments of important fish stocks since 1991. Priority lakes are identified for survey based on accessibility, sensitivity, and management concern. Environment Yukon works with user groups, First Nations and Renewable Resources Councils to establish priorities for assessment. Assessments focus on lake trout, which is considered an indicator species of the health of northern aquatic ecosystems.

Wellesley Lake is a popular fly-in fishery, with a commercial lodge that has been operating since the 1970s. Surveys were done on this lake in 1997, 2002, and 2007 based on a 5-year survey rotation for lakes with important recreational harvests. The results of this work identified no change in lake trout numbers or average condition among the three surveys.

In 2002, because of concerns about possible over-exploitation of lake trout, new regulations were put in place for Wellesley Lake. The catch and possession limit of lake trout was reduced from 2 to 1 and the maximum size limit was set at 65cm.

While we detected no change as a result of implementing the new harvest limit on lake trout, the methods used in this study were only sensitive to measure large ($\pm 100\%$) responses. Future population assessments should use other methods that are better able to detect changes in the fish populations of Wellesley Lake. An alternate way to evaluate the response of the lake trout population to the 2002 regulation change would be to seek the experienced opinion of the lodge operator and examine catch records.

KEY FINDINGS

- Results of these surveys do not identify any management concerns for fish populations in Wellesley Lake.
- The lake trout population appeared stable between 1997 and 2007.
- Average condition of lake trout remained constant through survey years.
- Current methods are coarse; only large ($\pm 100\%$) changes in fish abundance can be detected.

INTRODUCTION

Since 1991, Environment Yukon has surveyed over 100 Yukon lakes using standardized methods. Lakes are chosen for assessment based on the level of the active commercial, recreational, or aboriginal subsistence fisheries, as well as the level of available fisheries information. Lakes with significant harvest pressure are surveyed on a regular basis. The survey consists of setting non-lethal gillnets at different locations around the lake and recording biological information about the catch. To allow comparison of results among years the same methods are used each time the survey is done. The survey typically determines:

- the relative abundance of lake trout and lake whitefish compared to past surveys;
- length and weight of individual lake trout and lake whitefish; and
- length and weight of other fish species caught.

We did fisheries surveys on Wellesley Lake in 1997, 2002, and 2007 and here we report on data from all 3 study years.

Study Area

Wellesley Lake is located on the Kluane Plateau about 50 km east of Beaver Creek (Figure 1). It is approximately 13.5 km long and 6.5 km wide and covers an area of 73.8 km². The lake has an average depth of 23.8 m and a maximum depth of 47.0 m. Wellesley Lake has a relatively small drainage basin and has no major in-flow streams. It is fed by small, unnamed streams and groundwater flow from the within the Wellesley Lake basin. Wellesley Creek drains the lake and flows northeast into the Donjek River.

In 2002, new regulations reduced the catch and possession limit in Wellesley Lake from 2 to 1 lake trout and set a maximum size limit of 65 cm (26 in). These management actions were expected to result in an increase in the lake trout population as measured by an increase in the catch per unit effort.

METHODS

We used commonly applied techniques (adapted from Lester *et al.* 1991) to catch fish in this study: we set small-mesh, multi-filament gill nets during the day. In small-mesh nets, lake trout tend to be caught by their teeth and jaws rather than by their gills and few fish are killed or injured using this method. Aiming to reach a net set density of 0.75 sets per square kilometre of lake surface area, we set gillnets at between 36 and 55 locations around the lakeshore (Table 1, Appendix 1).

Table 1. Sampling information for Wellesley Lake surveys.

Year	Dates	Number of Sets	Set Density (sets/km ²)	Water Temperature (°C)	
				Average	Range
2007	June 11 - 14	49	0.66	12	8 – 15
2002	June 24 - 27	36	0.49	10	9 – 12
1997	June 11 - 15	55	0.75	10	8 – 14

Each net set was made up of 3 panels. Each panel was 22.9 m wide and 2.4 m deep and had a mesh size of 3.8, 6.4, or 7.6 cm (in that order). Nets were set perpendicular to the shoreline with the near-shore end in at least 2.4 m water. The offshore end was sunk with heavy anchors to ensure the net ran along the bottom of the lake. We alternated between setting the small (3.8 cm) and large (7.6 cm) mesh panels closest to shore to address the issue of net configuration bias (Lester *et al.* 1991). We checked the nets after one hour. For each net set we recorded location, surface water temperature, and the depth of the offshore anchor.

We used the number of fish caught to estimate catch per unit effort (CPUE). CPUE is defined as the number of fish (of a certain species) caught per unit time. Using this method we cannot estimate the absolute abundance (number) of fish in a lake, but we can use CPUE as an index of abundance and use it to compare between years and to detect population trends (i.e., relative abundance).

For each fish caught we noted the size of mesh in which it was caught, species, length, and weight. We released all fish at or near the sampling location. For the few fish that died, we recorded sex and maturity, collected the stomach contents for diet analysis and the otoliths to determine age. Data on diet, age, sex and maturity are not reported here but can be obtained from Environment Yukon.

Although we targeted lake trout, these methods may also be applicable to lake whitefish if catches are consistent. However, as lake whitefish are under no harvest pressure in Wellesley Lake, no comparisons were made. Because we cannot consistently catch warm-water species such as Northern pike or schooling species like round whitefish with these methods we do not make statistical comparisons of CPUE for them.

Figure 1. Location of Wellesley Lake, Yukon.

Data Analysis

CPUE is calculated as: $CPUE = \text{number of fish caught} / \text{time}$ (standardized to 1 hour). The frequency distribution of CPUE data is heavily right-skewed with many data points at zero (Table 2). Because of the non-normality of the data, we used the non-parametric Kruskal-Wallis test to compare CPUE among years. The Kruskal-Wallis test does not directly compare the mean CPUE but ranks the data and then compares the mean ranks. To calculate the power of the Kruskal-Wallis test we used bootstrap methods; we re-sampled with replacement from each of the 3 years, and performed the test 1000 times. We then took the proportion of those 1000 tests that resulted in a significant change to represent the *power* of the test. *Statistical power* is the chance of detecting a change when it exists.

To estimate statistical power needed for future surveys we simulated possible catch distributions using a Poisson distribution and compared this distribution to the 2007 data. We used bootstrap methods to run the simulations 1000 times and to predict the power to detect a 50% increase, a 50% decrease, and a 100% increase in population size. We also examined the effect of increasing the sample size on the ability to detect change.

We used regression analysis to detect trends in CPUE over time. Because we had only the minimum number of data points (3 years) needed to do this analysis, the results provide limited statistical information but can be used to detect trends. However, limited weight is placed on the result of the regression analysis.

We used ANOVA to compare the length and weight of lake trout between years. The relationship between a fish's weight and length can be described as its *condition factor* (K) and is calculated as: $K = (\text{Weight (g)} / \text{Length (cm}^3)) \times 100$. The heavier a fish is at a given length, the better its condition. At the individual level, K can be a crude indication of fish health. We averaged K over the entire catch and used this as an indication of overall condition of lake trout within the population.

RESULTS and DISCUSSION

Lake Trout Catch and Effort

CPUE in 2007, 2002, and 1997 was 0.41, 0.36, and 0.47. We found no difference in CPUE between years (Kruskal-Wallis: $X^2_{(df=2)} = 0.180$, $P = 0.914$; Table 3) nor did we find any significant trend through time (b (slope) = -0.007, $r^2 = 0.001$, $F = 0.167$, $P = 0.684$). In other words, we did not detect a change in the relative abundance of lake trout over this 10-year period. Predicted power to detect change in future surveys at current sample size (50 sets) is 0.40 for a 50% increase in the population, 0.30 for a 50% decrease, and 0.79 for a 100% increase. The results of this power analysis suggest that we do not have sufficient statistical power to detect potential changes of less than a 100%

increase of CPUE between surveys. This is a fairly coarse scale at which to estimate population changes for management purposes; we would prefer to be able to detect changes of 50% or less with good power (0.80). In this context, a further CPUE survey in 5 years (regular rotation) is not recommended as we would likely be able to detect only very large changes in our population index. In addition, declines in populations of lake trout (e.g., due to overfishing, habitat loss, disease, etc.) may generally be observed over shorter time spans than increases in population. Population growth or recovery may only be apparent after 10 or 15 years because northern lake trout populations have slow growth and low reproductive rates.

Table 2. Number of lake trout caught per set net in Wellesley Lake in 1997, 2002, and 2007.

Number caught	2007		2002		1997	
	Number of sets	Percent	Number of sets	Percent	Number of sets	Percent
0	34	69%	27	75%	39	71%
1	12	24%	5	14%	11	20%
2	2	4%	4	11%	3	5%
3						
4	1	2%			1	2%
5					1	2%
Total	49	100%	36	100%	55	100%

Biological Characteristics of Lake Trout

Lake trout length ranged from 330 to 875 mm in 1997, 495 to 770 mm in 2002, and 548 to 835 mm in 2007. Lake trout caught in 2007 were neither longer nor heavier than lake trout caught in previous years (ANOVA: $F_{(2,55)} = 0.38$, $P = 0.69$ and $F_{(2,55)} = 0.83$, $P = 0.44$ respectively). Similarly, the average condition factor (K) did not change between years (ANOVA: $F_{(2, 55)} = 0.12$, $P = 0.89$; Table 3).

Table 3. Morphological data for lake trout from Wellesley Lake.

Year	Total Catch	Average length (mm)	Average weight (g)	Average Condition Factor (K)	% of Catch by Weight
2007	20	634	2808	1.03	20.17
2002	13	626	2654	1.06	18.88
1997	26	655	3362	1.03	22.02

Other Fish Species

Most of the total catch in all years was lake whitefish followed by round whitefish, lake trout, and Northern pike (Table 4). We also caught one burbot in 1997.

Table 4. Summary of catch data from Wellesley Lake.

Species	Year	Total Number of Sets	Total Catch	Average length (mm)	Average weight (g)	CPUE (# fish caught per hour net set)	Proportion of Total Catch
Lake trout	2007	49	20	634	2808	0.41	0.15
	2002	43	13	626	2654	0.36	0.07
	1997	55	26	655	3362	0.47	0.12
	Average	49	20	641	3022	0.41	0.11
Burbot	2007	49	-	-	-	-	0.00
	2002	43	-	-	-	-	-
	1997	55	1	800	4500	0.02	-
	Average	49	-	-	-	-	-
Lake whitefish	2007	49	81	494	1622	1.65	0.61
	2002	42	122	392	938	2.40	0.68
	1997	55	154	539	1609	2.80	0.68
	Average	49	119	474	1383	2.61	0.66
Northern pike	2007	49	27	732	2924	0.55	0.20
	2002	43	10	765	2760	0.28	0.06
	1997	55	20	744	2685	0.36	0.09
	Average	49	19	742	2811	0.40	0.12
Round whitefish	2007	49	4	279	225	0.08	0.03
	2002	43	35	244	177	0.97	0.19
	1997	55	25	228	138	0.45	0.11
	Average	49	21	240	165	0.50	0.11

Factors Affecting Results

Catch can vary within a lake when netting is done under different environmental conditions. To be comparable, it is important that all surveys are done when fish are equally susceptible to being caught.

Surveys are done in the spring, when lake trout are using shallow, cool water habitats along the lakeshore. If average surface water temperatures exceed threshold levels (often cited as 13°C) then lake trout move to deeper, colder water and are less likely to be caught in near-shore nets. Surface temperature averages were below this threshold level in all 3 surveys, but maximum temperature recorded did exceed this on occasion (Table 1). We do not consider temperature to have affected the results of this study.

CPUE results cannot be extrapolated to the entire lake. Because net sets were not distributed randomly across the lake results cannot be scaled up to give an estimate of absolute abundance of fish. However, because our methods are identical from year to year we can compare results through time on a single lake.

Comparisons of results among lake must be done cautiously. Lake productivity (the amount of food available for fish) can vary greatly among lakes. Fish abundance considered low for one lake may be moderate or high for another based on each lake's potential for fish production. Our methods are

identical from lake to lake, but care needs to be exercised when making comparisons between lakes.

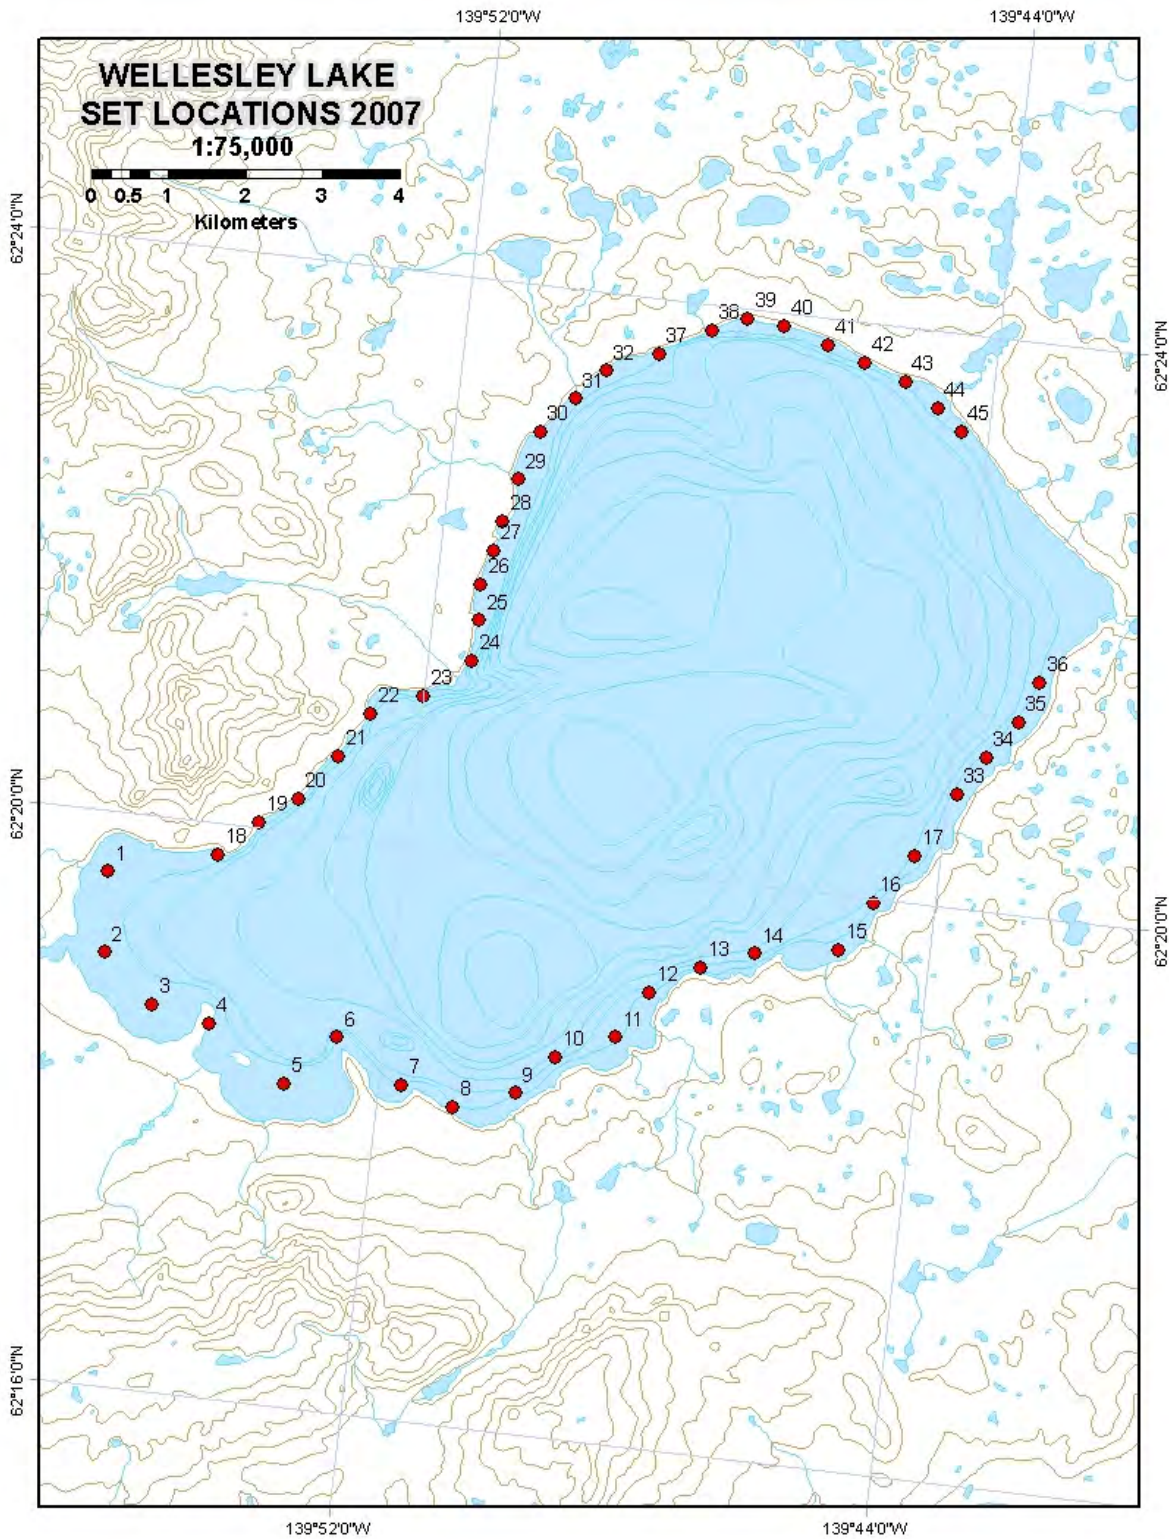

Recommendations

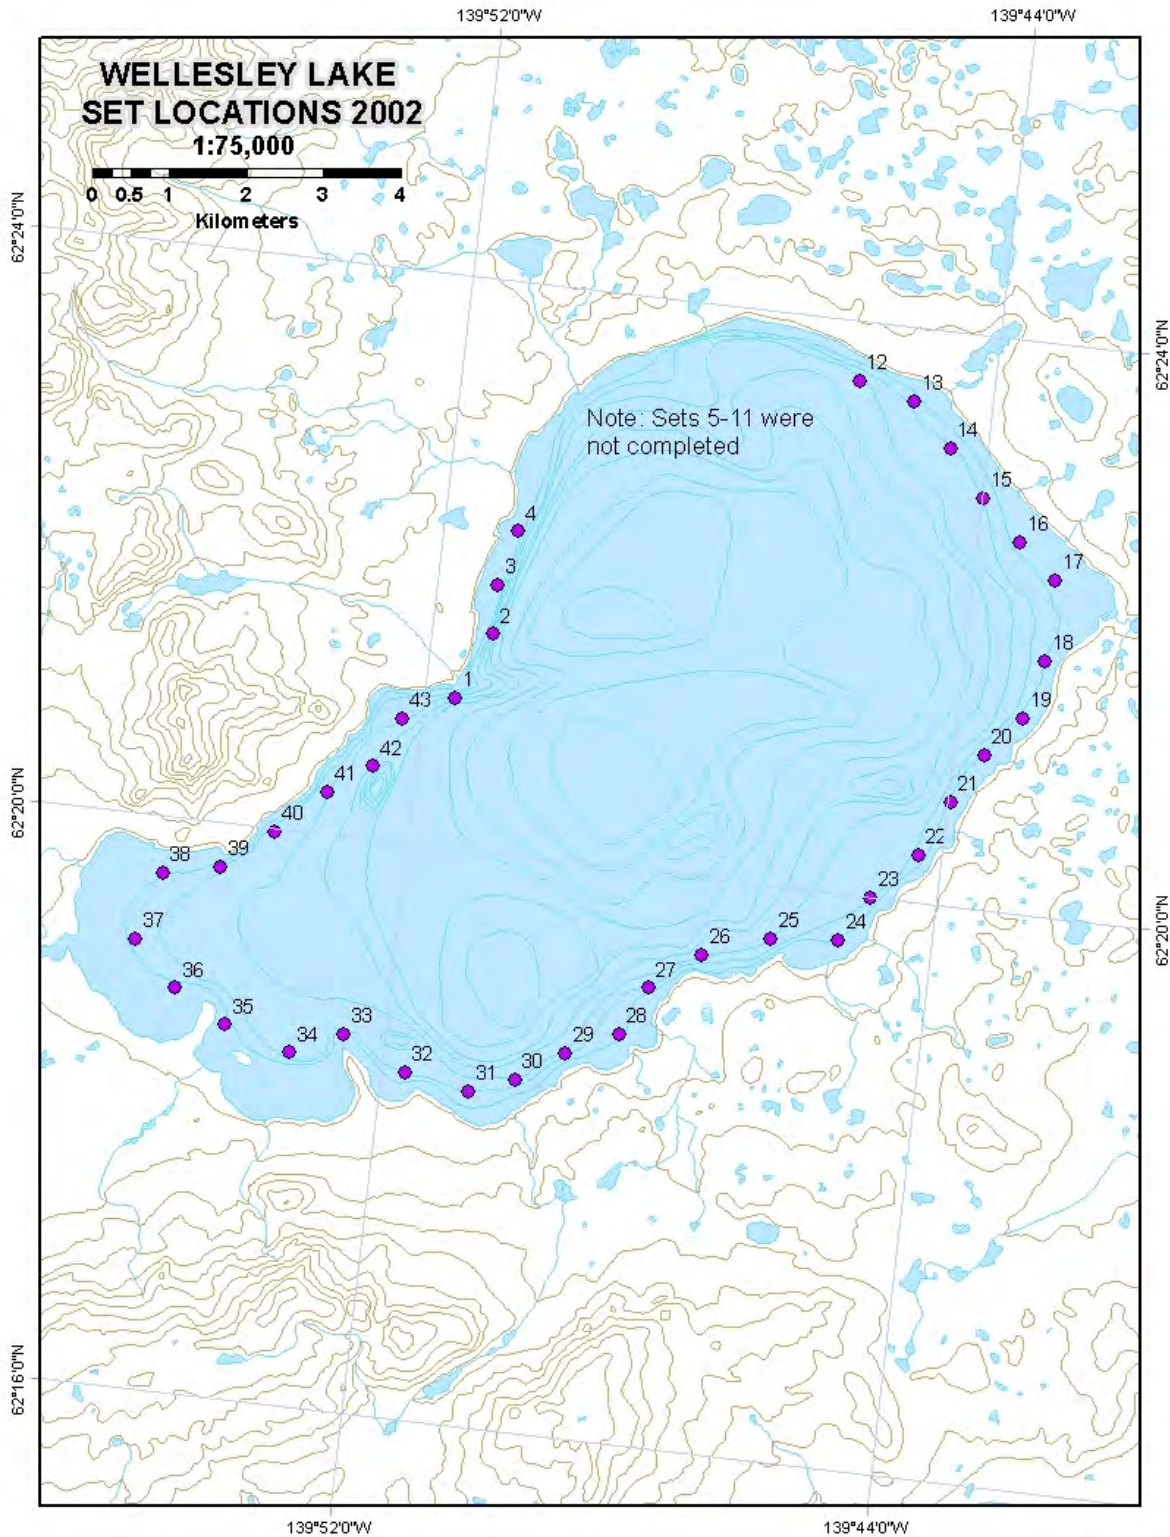

Because of the ambiguous results of this and previous surveys, I recommend that the survey scheduled for 2012 not be done. To obtain more robust data on lake trout and other fish populations in Wellesley Lake a more statistically robust study design should be developed. The downside to changing the survey method will be our inability to understand the effects of the 2002 regulation changes on the lake trout population through direct comparisons with existing information. In absence of survey data the catch records combined with the experienced opinion of the lodge operator could help identify any changes in the lake trout population.
