## Our Wildlife: Yukon Species at Risk

A “*species at risk*” is any naturally occurring plant or animal in danger of extinction or extirpation (disappearing from the territory). Most Yukon wildlife species are considered to be secure. However, nation-wide declines of the Barn Swallow, slow recovery of Bowhead Whale, and changes to habitats have raised concern about the future of some Yukon animals and plants. The recovery of the Trumpeter Swan and Peregrine Falcon are great examples of conservation achievements.

The Yukon Conservation Data Centre (YCDC) collects and shares information on plants, animals and ecological communities at risk in Yukon including those that have not been formally assessed.

The species in this booklet are those that have been assessed as at risk nationally.

Yukon is known to be home to at least 10,000 plant and animal species, some found nowhere else in Canada and several nowhere else in the world.

## How To Use This Guide

The purpose of this guide is to provide information on species assessed as at risk nationally that occur in Yukon. This publication will be updated periodically as both the federal *Species at Risk Act* (SARA) and the Committee on the Status of Wildlife in Canada (COSEWIC) list of species at risk change. For the most current list of species on Schedule 1 of SARA, visit: [www.sararegistry.gc.ca](http://www.sararegistry.gc.ca). For the most current COSEWIC list, visit: [www.cosewic.gc.ca](http://www.cosewic.gc.ca).

### Subheading Descriptions

#### Typical Habitat

The information in this section describes the typical habitat of the species in Yukon.

#### Potential Threats

Threats to a species can vary from region to region; for the most part, the information in this section only describes known threats to each species within Yukon's borders.

#### Did You Know?

The information in this section highlights interesting facts about the species.

#### Range Map

The range map shows the general distribution of each species in Yukon and adjacent jurisdictions. Please note that these distributions are approximate. The green colour represents the species' inferred breeding range.

## Contents

### Mammals

- 
- 4 **Bowhead Whale, Bering-Chukchi-Beaufort population**
  - 6 **Collared Pika**
  - 8 **Grey Whale, Eastern North Pacific population**
  - 10 **Grizzly Bear**
  - 12 **Little Brown Myotis**
  - 14 **Northern Myotis**
  - 16 **Polar Bear**
  - 18 **Wolverine**
  - 20 **Wood Bison**
  - 22 **Woodland Caribou**
  - 23 **Woodland Caribou, Boreal population**
  - 24 **Woodland Caribou, Northern Mountain population**

### Plants

- 
- 26 **Baikal Sedge**
  - 28 **Spiked Saxifrage**
  - 30 **Yukon Draba**
  - 32 **Yukon Podistera**

### Insects

- 
- 34 **Dune Tachinid Fly**
  - 36 **Gypsy Cuckoo Bumble Bee**
  - 38 **Western Bumble Bee, *mckayi* subspecies**
  - 40 **Yellow-banded Bumble Bee**

### Fish & Amphibians

- 
- 42 **Bering Cisco**
  - 44 **Bull Trout, Western Arctic population**
  - 46 **Dolly Varden (northern form)**
  - 48 **Squanga Whitefish**
  - 50 **Western Toad**

### Birds

- 
- 52 **Bank Swallow**
  - 54 **Barn Swallow**
  - 56 **Buff-breasted Sandpiper**
  - 58 **Canada Warbler**
  - 60 **Common Nighthawk**
  - 62 **Horned Grebe**
  - 64 **Olive-sided Flycatcher**
  - 66 **Peregrine Falcon**
  - 68 **Red-necked Phalarope**
  - 70 **Rusty Blackbird**
  - 72 **Short-eared Owl**

### 74 Species At Risk Resources

#### Please Note:

- The species in **red** are legally listed on the *Species at Risk Act*.
- The species in **blue** have been assessed by COSEWIC but not yet listed.

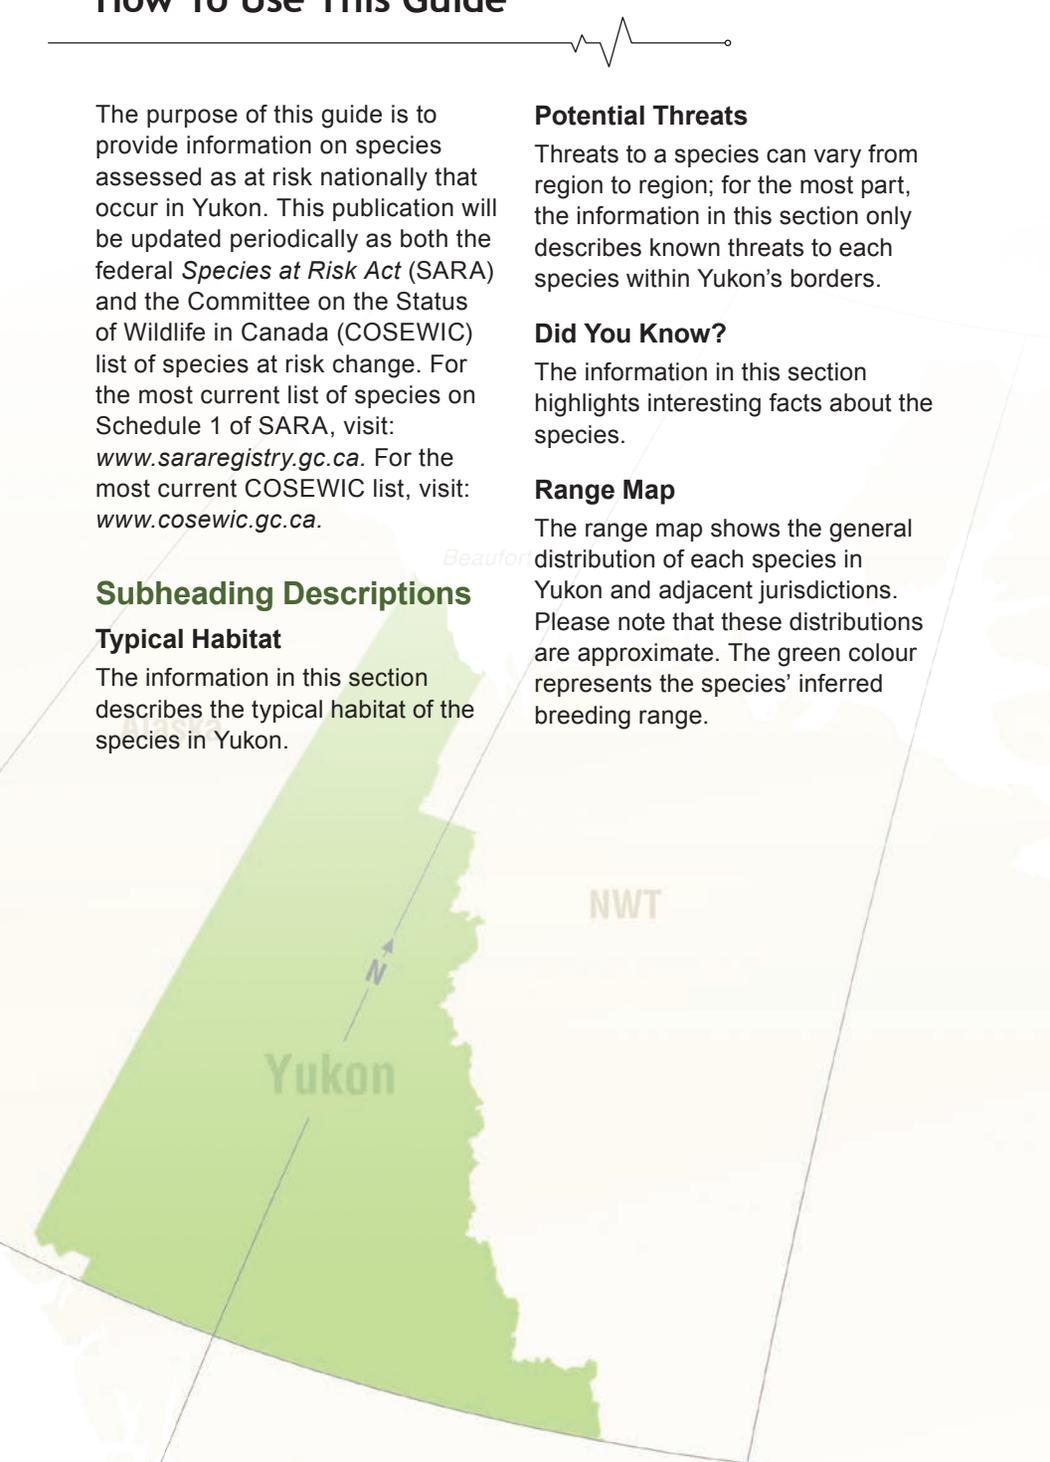

Photo: U.S. National Marine Mammal Laboratory

## Bowhead Whale, Bering-Chukchi-Beaufort population

*Balaena mysticetus*

### SPECIAL CONCERN (2009)

This population was severely reduced by commercial whaling from 1848 until about 1915. Since then, there has been very limited subsistence hunting by Aboriginal people in Alaska, Yukon and eastern Russia. In the absence of commercial whaling, it has recovered to an estimated population of 16,892 in 2011.

### Description

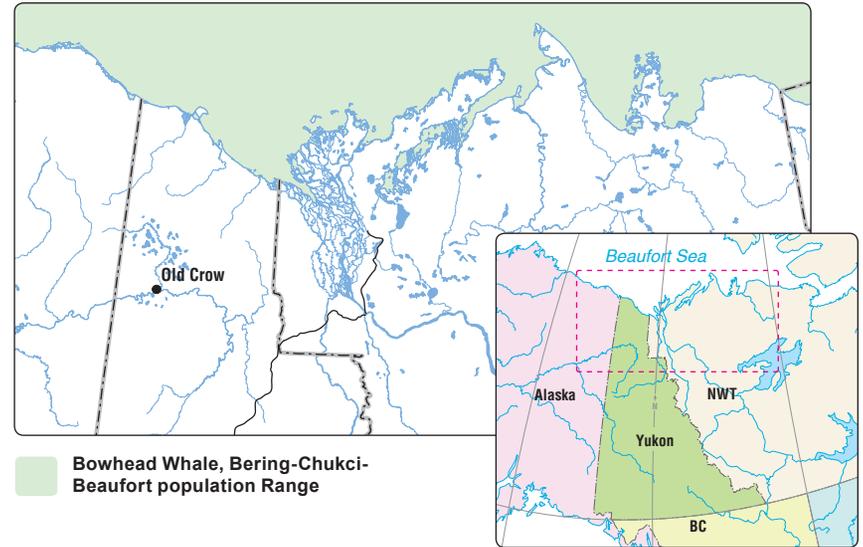

- Bowheads are stocky baleen whales without a dorsal fin. Adults can grow to 20 metres long and weigh up to 100 tonnes.

### Typical Habitat

- Bowhead Whales occur in the marine waters of the Beaufort Sea, in conditions ranging from open water to thick, extensive but broken pack ice.

### Potential Threats

- Long generation time and low natural reproduction and growth rates make Bowheads inherently vulnerable.
- Rapid changes in ice cover due to climate change are a major concern, although there is uncertainty about how Bowheads will respond to these changes.
- Increasing noise and disturbance from activities such as shipping and oil and gas exploration in the Arctic.
- Harvest of this population will require ongoing monitoring to ensure that it is sustainable.

*Bowhead Whales do not migrate to warmer waters like other whales—they spend their whole lives in the Arctic.*

### DID YOU KNOW?

- The Bowhead Whale has the largest mouth of any animal.
- By weight, the Bowhead is one of the largest whales, second only to the Blue Whale.
- Bowhead Whales take about 25 years to become mature and mothers give birth to a single calf about every 3-4 years.
- Bowhead Whales can live more than 200 years, making it one of the longest living mammals in the world.
- In Canada, Bowhead hunting is managed by Fisheries and Oceans Canada in collaboration with Wildlife Management Boards created under land claims agreements.
- Bowhead Whales do not migrate to warmer waters like other whales—they spend their whole lives in the Arctic.
- Bowheads feed on tiny copepod prey by swimming forward with their mouths open, continuously filtering water through their baleen.

Left photo: Ryan Agar. Top photo: Jared Hobbs. Bottom photo: Kieran O'Donovan

## Collared Pika

*Ochotona collaris*

### SPECIAL CONCERN (2011)

The Collared Pika is a small relative of rabbits. Its bleating calls are familiar to hikers who venture into rocky alpine country in Yukon. The Collared Pika is a species that evolved in unglaciated Beringia, and is restricted to northwestern North America. Close to 50% of their range is in Yukon. Pikas have been deemed “harbingers of climate change” because of their sensitivity to climate patterns, and may be adversely affected by high snowfall and late snowmelt.

### Description

Collared Pikas look like small, short-eared rabbits. They are about the size of a small squirrel, and are grey with paler grey patches on their napes and shoulders, which are

reminiscent of a collar around the neck.

### Typical Habitat

Collared Pikas are restricted to alpine talus slopes interspersed with small meadows. The talus-meadow combination offers access to both forage and shelter from predators and weather. Pikas typically do not stray more than 10 m from the edge of the talus slope when foraging.

### Threats

Because climate change in Yukon is predicted to bring a greater variability in precipitation, the pika's sensitivity to deep snowpacks and late snowmelt is of concern. This sensitivity, coupled with the fact that their alpine habitat will decline substantially in area as the climate warms, means that the potential for future population declines is substantial.

Collared Pika Range

### DID YOU KNOW?

- Even though they live above treeline in Yukon, Collared Pikas do not hibernate.
- Pikas eat plants, but collect two types of diets in the summer—the first they eat right away, while the second is stored in ‘haypiles’ within the talus rocks for consumption during winter.
- They are solitary animals and defend individual territories.
- Juveniles emerge to the surface at one month of age and disperse to a new territory within days. They reach near-adult size during their first summer and must establish their own haypile before winter.
- Pika are often heard before they are seen. Listen for their weak “meep” alarm call when near or crossing rock piles.

Photo: Sergio Martinez/PRIMMA

## Grey Whale, Eastern North Pacific population

*Eschrichtius robustus*

### SPECIAL CONCERN (2004)

The eastern North Pacific population of Grey Whale winters along the west coast of Mexico. Most individuals spend the summer feeding in the arctic waters of the Bering, Chukchi, and Beaufort seas. A small number migrate through the waters off the Yukon coast to reach feeding areas east of the Mackenzie Delta. On their arctic feeding grounds Grey Whales feed predominantly on amphipod crustaceans by scooping up sediment and straining it through their baleen. They are responsible for recirculating nutrients from the

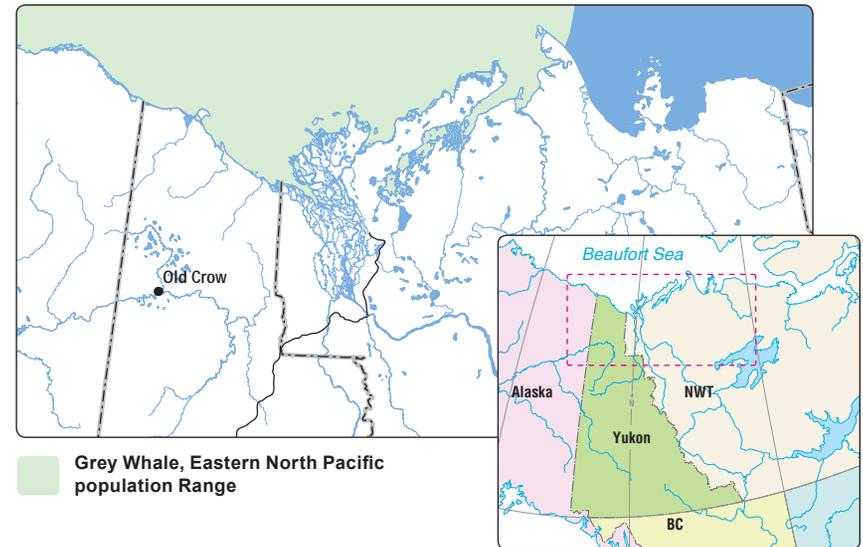

sediments into the water column, making them a keystone species in arctic marine ecosystems.

### Description

Grey Whales are medium-to-large (11-14 m) baleen whales that lacks a dorsal fin. They are dark grey, have mottled skin, and are often covered with patches of barnacles and other crustaceans.

### Typical Habitat

Grey Whales are usually found in shallow (< 60 m) water close to shore, although in Yukon they have only been reported off Herschel Island and may be transient in deeper waters here. On arctic feeding grounds, Grey Whales feed almost exclusively over mud or sand bottoms and avoid areas of heavy ice.

### Potential Threats

Industrial development of shallow marine areas (e.g. oil exploration and offshore mining) and the associated noise pollution (e.g. seismic exploration) can cause loss and deterioration of habitat. Ice cover on the arctic feeding grounds

limits the feeding season and thus affects mortality and calf production. In addition, Grey Whales are killed by entanglement in fishing gear and in collisions with ships, though these causes of mortality have not been reported in waters off the Yukon coast.

### DID YOU KNOW?

- Commercial whaling reduced the size of the eastern North Pacific population before they were protected in 1937.
- Grey Whales reach sexual maturity at approximately 8 years and may live up to 70 years.
- Grey Whales undertake one of the longest annual migrations of any mammal, travelling 15,000-20,000 km round trip.
- Grey Whales are the focus of an expanding whale-watching industry and are of significant economic value to coastal communities.
- The entrapment of three Grey Whales in sea ice near Barrow, Alaska, in October 1988 made international news and was the focus of a spectacular rescue involving a Russian icebreaker brought in to create an escape route for the whales.

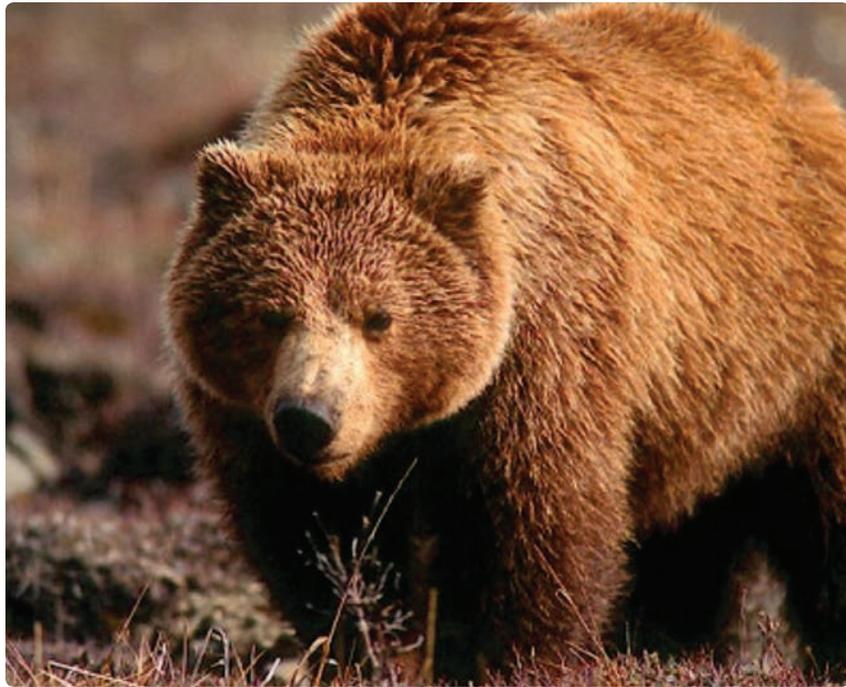

Photo: Jared Hobbs

## Grizzly Bear

*Ursus arctos*

### SPECIAL CONCERN (2012)

Yukon is home to healthy populations of grizzlies, but they are vulnerable to threats that have reduced or eliminated populations elsewhere. These bears are slow to reproduce; female grizzlies mature at 6-8 years of age, have small litter sizes (commonly 1 or 2 cubs), and have long intervals between cub births (3 to 5 years). These factors make it difficult for them to recover from population declines. Increasing conflicts between bears and humans will likely result in the death of more bears.

### Description

Typically, Grizzly Bears are larger than Black Bears and are more heavily built. They can be recognized by their prominent shoulder hump. Their colour varies from light gold to almost black.

### Typical Habitat

- Grizzlies are most common in open tundra and subalpine terrain, but also range through the boreal forest.
- Concentrations occur where salmon spawn, such as in the Fishing Branch and southern Klwane areas.

Grizzly Bear Range

### Potential Threats

- Increasing industrial development and expanding human habitation in Yukon could lead to an increase in bear-human conflicts. Bears are often relocated or killed in such situations.

### DID YOU KNOW?

- Bears are more powerful than people—learn to avoid conflicts with bears and always travel in groups.
- Grizzlies can travel long distances and use very large areas of habitat. One bear that was tracked with a radio transmitter traveled 471 km (292 miles) in 23 days.

Photo: Graham Forbes

## Little Brown Myotis

*Myotis lucifugus*

**ENDANGERED (2013)**

### Description

The Little Brown Myotis is likely the most common bat species in Canada. Yukoners will probably recognize these bats because they often use buildings as day-roosts and forage in open areas, such as over lakes. Maternal colonies have been studied in the communities of Whitehorse, Watson Lake, and Haines Junction.

### Typical Habitat

Little Brown Myotis are not yet known to hibernate in Yukon. Individuals arrive in late April and leave through September. They roost in buildings, rock crevices, tree

cavities, and under tree bark within the boreal forest zone, usually close to water.

### Potential Threats

White-nose Syndrome (WNS) is caused by a fungal pathogen (*Pseudogymnoascus destructans*) that likely was brought from Europe

Photo: Graham Forbes

Little Brown Myotis Range

and was first recorded in US in 2006 and in Canada in 2010. Since then, population declines of more than 90% in northeastern US and 94% in eastern Canada have been reported. Mixing of bats during autumn swarming events and transmission by people may help spread WNS

across the species' range. Rate of spread has averaged 200-250 km/yr and WNS is predicted to infect the entire Canadian range by 2026-2030. Other threats include wind turbines, colony eradication due to public concerns, and other conflicts and disturbances.

### DID YOU KNOW?

- Little Brown Myotis can live up to 34 years (the oldest known in Yukon is 12 years).
- The colonies in Yukon are some of the most northerly occurring bats in North America.

- They weigh about as much as a toonie.

For more information on Yukon bats see: [www.env.gov.yk.ca/publications-maps/documents/yukonbats\\_brochure.pdf](http://www.env.gov.yk.ca/publications-maps/documents/yukonbats_brochure.pdf)

Photo: Graham Forbes

## Northern Myotis

*Myotis septentrionalis*

**ENDANGERED (2013)**

### Description

Very little is known about the Northern Myotis in Yukon. It was first recorded from the LaBiche River in 2004 and from the Watson Lake area in 2007. Its range covers much of North America but is absent in the mid-western US and rare in the southeastern US. The species appears more common in the northern parts of its range.

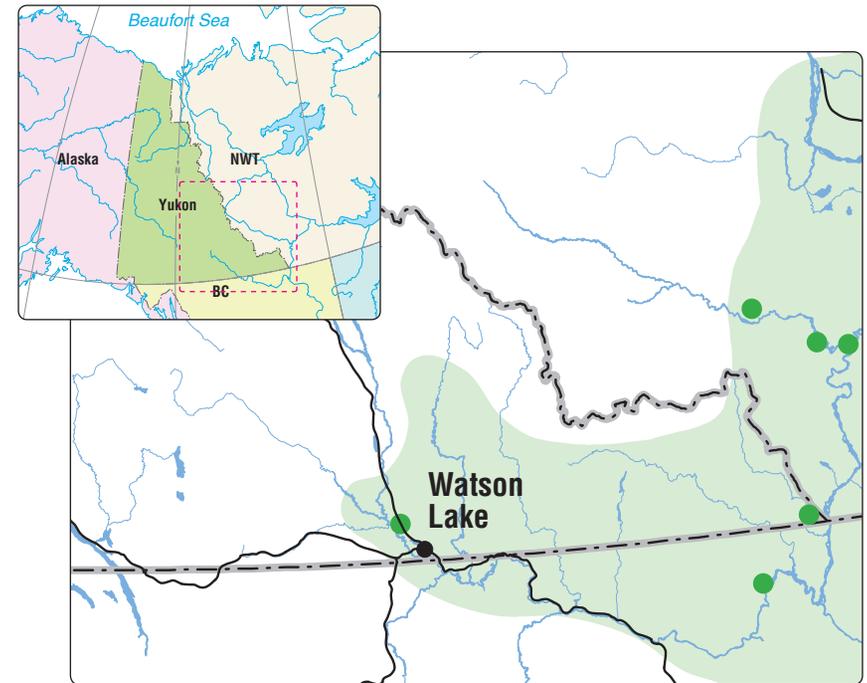

### Typical Habitat

Northern Myotis are not known to hibernate in Yukon. They are less cold tolerant than Little Brown Myotis. In Yukon, they have been found only in the Liard River

drainage in older White Spruce dominated forests. Northern Myotis rarely use human-made structures for roosting and are strongly associated with older trees. Maternity colonies in eastern Canada are usually in larger trees, ranging from 25-44 cm diameter.

### Potential Threats

White-nose Syndrome (WNS) is caused by a fungal pathogen (*Pseudogymnoascus destructans*) that likely was brought from Europe and was first recorded in US in 2006 and in Canada in 2010. Since then, population declines of more than 90% in northeastern US and 94% decline in hibernating populations of Myotis bats in hibernacula in Eastern Canada have been reported. Mixing of bats during autumn swarming events and

■ Northern Myotis Range ● Northern Myotis known Distribution

transmission by people may help spread WNS across species range. Rate of spread has averaged 200-250 km/yr and WNS is predicted to infect the entire Canadian range by 2025-2028. Other threats include wind turbines, colony eradication due to public concerns regarding disease transmission, and other conflicts and disturbances.

### DID YOU KNOW?

- Northern Myotis are rarely seen, even in areas where they are common, because they are generally solitary and prefer to stay within the forest canopy.
- This species is also known to feed by gleaning (taking insects directly off leaves and tree bark).

*This species is also known to feed by gleaning (taking insects directly off leaves and tree bark).*

Photo: Gordon Court

## Polar Bear

*Ursus maritimus*

### SPECIAL CONCERN (2008)

Recent scientific research suggests the Southern Beaufort Sea population of Polar Bears is likely declining. Reproductive rates vary among sub-populations of Polar Bears but all are relatively low. Females reach maturity at 4-6 years and have litters of no more than 1-2 cubs every 3 or so years. There is increasing concern over the effect of climate change on the availability of sea ice and the seals that Polar Bears prey upon.

### Description

Translucent hairs make polar bear fur appear white or off-white to yellow. Compared to Grizzly Bears,

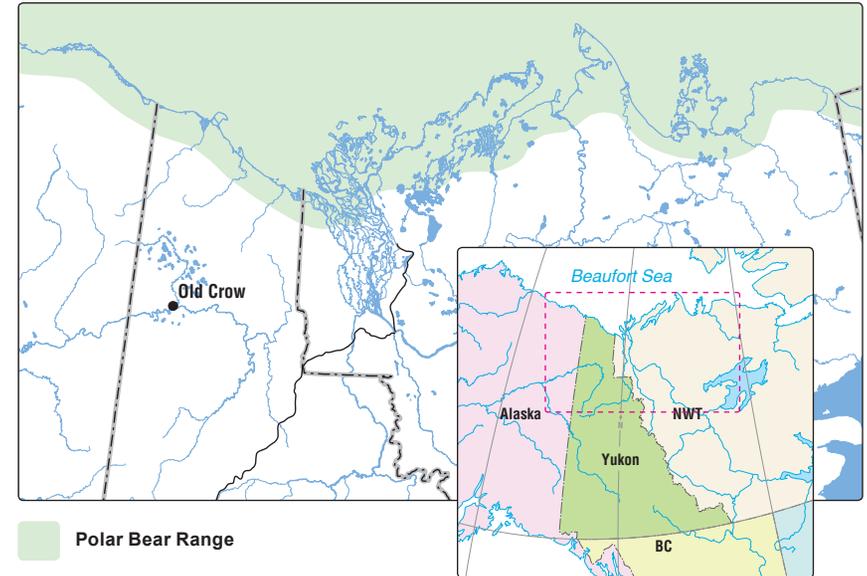

Polar Bears have shorter claws, a much longer neck, and no shoulder hump.

### Typical Habitat

- From early winter until sea ice break-up, Polar Bears prefer to hunt seals on the annual sea ice along coastlines, but they may range more than 200 km offshore.
- Maternal denning sites are usually located in snowdrifts on land near the coast, but they can also be in snow on sea ice.

### Potential Threats

- Climate warming is causing a reduction in the total amount of sea ice, and affect the timing of break-up and freeze-up—thus reducing the abundance of ice-dependent seals and the bears' ability to find them.

- Environmental contaminants (mainly organochlorines) and marine oil spills.
- Harvest of this population will require ongoing monitoring to ensure that it is sustainable.

*Compared to Grizzly Bears, Polar Bears have shorter claws, a much longer neck, and no shoulder hump.*

### DID YOU KNOW?

- Polar Bears evolved within the last 400,000 years to occupy the niche of hunting seals from a sea-ice platform.
- 60% of the world's Polar Bears live in Canada.
- Polar Bears can swim 100 kilometers.
- Polar Bear males can be 2 to 3 times as large as females - one of the greatest differences between sexes in mammals.
- Polar Bears can live 25-30 years.
- Polar Bear skin is black, which helps them retain heat from the sun.
- Polar Bear paws have thick fur between the toes to help insulate their feet.

Photo: Damian Power

## Wolverine

*Gulo gulo*

### SPECIAL CONCERN (2014) Western population

Wolverine populations in Yukon are believed to be stable. However, their low density and secretive nature make them difficult and expensive to inventory, so information on populations is limited. Elsewhere they have declined or even disappeared in the face of human expansion into wilderness. They are sensitive to disturbances, only breed every two years or more, have small litters, and juveniles and kits can have high mortality rates.

### Description

The Wolverine resembles a small, stocky bear. Colour varies from brown to black, often with a pale facial mask and a yellowish or tan

stripe running along the sides from the shoulders and crossing at the tail.

### Typical Habitat

- Wolverines can travel long distances (over 350 km) and use large areas of habitat. They also can live in a wide variety of habitats, from the boreal forest to alpine tundra and barren-lands, as long as they have large wilderness areas with adequate year-round food supplies.

### Potential Threats

- Wolverines avoid areas of human activity, especially near denning sites.
- Wolverines are reluctant to cross active roads; elsewhere, roads can form a significant barrier to movement and cause high mortality.
- Habitat loss and alteration.

Wolverine Range

### DID YOU KNOW?

- Track counts and aerial surveys in Vuntut National Park have documented a relatively dense population estimated at 9.6 animals/1000 square kilometres.
- Wolverine fur is frost- and ice-resistant, and highly valued for parka trim.
- Wolverines have large paws that help them move easily on top of crusted snow.
- Wolverines have strong jaws that allow them to crush bone and frozen food.

Photo: Syd Cannings

## Wood Bison

*Bison bison athabasca*

### SPECIAL CONCERN (2013)

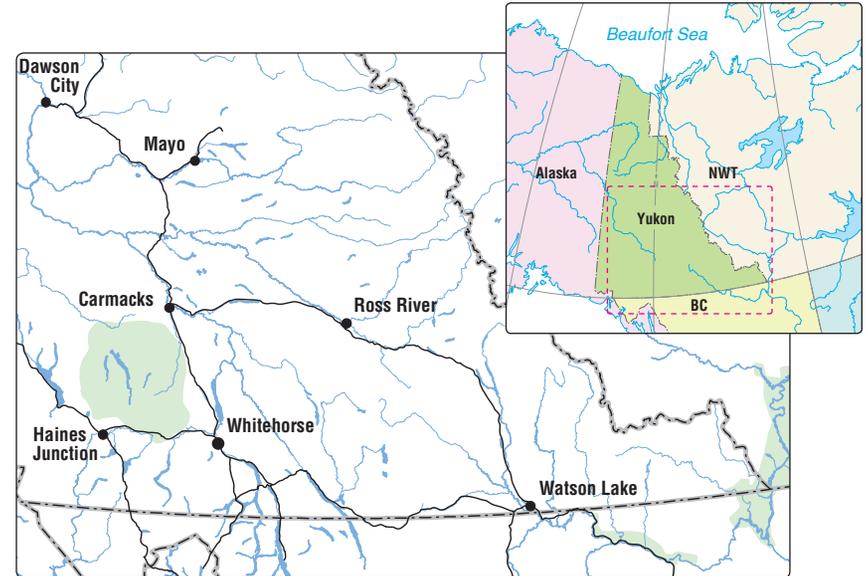

Between 1986 and 1992, 142 bison were brought to Yukon. They were released along the Nisling River west of Carmacks, but subsequently moved south into the Aishihik and Hutshi lake watersheds. The Aishihik herd numbers about 1,300. Other Wood Bison were released at Nahanni Butte, Northwest Territories—this herd has grown to 400 animals, and regularly crosses the border into the southeastern Yukon. Others were released in the Liard region of British Columbia—this herd, numbering about 140 animals, often ranges into Yukon near Contact Creek.

### Description

Wood Bison are dark brown with a very large head, distinct beard, and shoulder hump. They are larger than Plains Bison, and can be distinguished from them on a number of characters, including: the highest point of the hump is well forward of the front legs in Wood Bison; there are virtually no furry 'chaps' on the front legs in Wood Bison; and the cape grades smoothly back rather than ending abruptly behind the shoulders as it does in the Plains Bison.

### Typical Habitat

Wood Bison rely on a variety of grasses and sedges found on south-facing slopes, wetlands, open meadows, and alpine tundra.

Wood Bison Range

### Potential Threats

- Contact with livestock or other bison could introduce diseases such as anthrax, brucellosis, and tuberculosis.
- Collisions with traffic.
- Because the Wood Bison population was reduced to just a

few dozen individuals in the 1960s, the remaining genetic diversity is very low and the genetic diversity in the reintroduced populations is even more limited. This means a greater susceptibility to diseases and a potential decreased ability to adapt to a changing environment.

### DID YOU KNOW?

- Wood Bison are the largest land mammals in North America.
- Various forms of bison inhabited Yukon for perhaps as long as 700,000 years. Fossils indicate that changes in appearance and size happened quickly during the ice ages.
- The Aishihik herd in southwest Yukon is the largest disease-free, free-ranging Wood Bison herd in the world.
- Unlike most hoofed mammals that use their front feet to paw through snow, bison sweep their neck and head from side to side to clear snow from vegetation.

Photo: John Nagy

## Woodland Caribou

*Rangifer tarandus caribou*

Because they have different lifestyles and therefore face different threats, Woodland Caribou in Yukon have been divided into two population types under the *Species at Risk Act*: Northern Mountain and Boreal. Northern Mountain Caribou live in mountainous areas through the central and southern Yukon and have distinct elevational and seasonal migrations. They make up the bulk of Yukon's Woodland Caribou. Boreal Caribou, on the other hand, live in the forests east

of the Mackenzie Mountains and enter Yukon only in small numbers in the Peel River lowlands. They live in small groups, and prefer to stay within the forest all year. Recent research suggests Woodland Caribou populations in Yukon are stable overall.

### Description

Both types of Woodland Caribou look the same. They are larger and darker brown than Barren-ground Caribou (such as those of the Porcupine Caribou herd), and have thicker and broader antlers, and longer legs and faces.

## Woodland Caribou, Boreal population

*Rangifer tarandus caribou*

**THREATENED (2014)**

### Typical Habitat

- In general, the habitat of Woodland Caribou is lichen-rich, mature and old coniferous forest in a matrix with alpine/subalpine, subarctic taiga, peatlands, or lakeshores.
- Boreal Caribou range across the northern boreal forest and taiga, and require vast areas of land and the ability to move unhindered between various habitats.

### Potential Threats

- Loss or degradation of habitat as a result of resource exploration and development.
- Habitat changes that result in an increased risk of predation.
- Human disturbance (e.g. snow machines on winter range, increasing backcountry activity on summer range).
- Climate change threatens Woodland Caribou by causing an increase in the frequency and severity of forest fires, which eliminate winter forage habitat for 50 to 60 years.

*In general,  
the habitat of  
Woodland Caribou  
is lichen-rich,  
mature and old  
coniferous forest  
in a matrix with  
one or more of  
alpine/subalpine,  
subarctic taiga,  
peatlands, or  
lakeshores.*

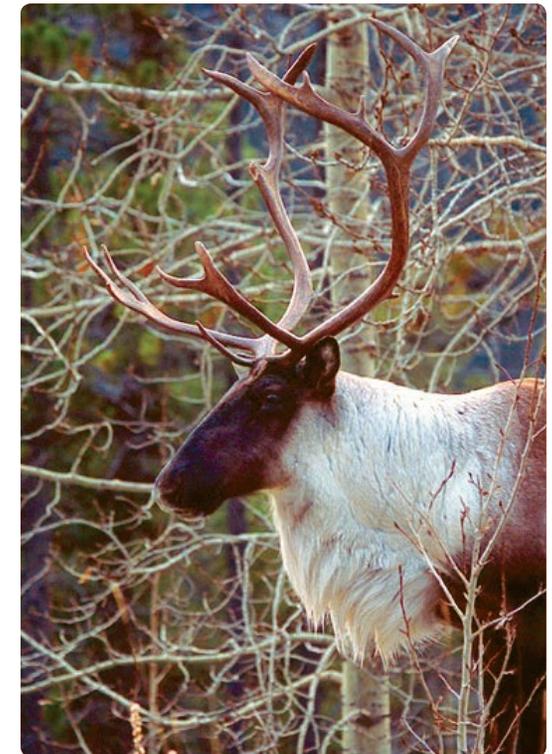

Photo: Jared Hobbs

## Woodland Caribou, Northern Mountain population

*Rangifer tarandus caribou*

**SPECIAL CONCERN (2014)**

### Typical Habitat

- In general, the habitat of Woodland Caribou is lichen-rich, mature and old coniferous forest in a matrix with one or more of alpine/subalpine, subarctic taiga, peatlands, or lakeshores.
- Northern Mountain Caribou spend the summer in alpine and upper subalpine ranges and in winter move down to the forest in lower areas where ground lichens are abundant and snow cover is relatively shallow.

### DID YOU KNOW?

- Caribou are the only members of the deer family where both sexes grow antlers.
- Twenty-six Northern Mountain Caribou Herds occur at least partially within Yukon. The Finlayson Herd may be the largest.
- Historically Woodland Caribou inhabited the forests of the northern US states from Maine to Washington. The last herd in the southern US has been reduced to 35 animals that live in the Selkirk Mountains of northern Washington and Idaho.

### Potential Threats

- Loss or degradation of habitat as a result of rural land use and industrial development.
- Habitat changes that result in an increased risk of predation or hunting, as well as unregulated hunting itself.
- Human disturbance (e.g. snow machines, exploration).
- Highway collisions are a threat for some herds.
- Climate change threatens Woodland Caribou in several ways:
  1. It may cause an increase in the frequency and severity of forest fires, eliminating winter forage habitat for 50 to 60 years;
  2. It will cause shrinkage of summer alpine tundra habitat; and
  3. It may cause spring icing events.

Photo: Randi Mulder

## Baikal Sedge

*Carex sabulosa*

### THREATENED (2005)

Until 2009, Baikal Sedge was known in North America from only four dune complexes in Yukon (Carcross, Robinson Roadhouse, upper Takhini River, and the Alsek River) and at the Nogahabara Dunes in Alaska. Recent surveys have discovered several smaller sites in the area of Whitehorse, Champagne, and Dezadeash Lake. Historically, there was also a small population at Christmas Bay on Kluane Lake. As its name suggests, it also lives in the Lake Baikal region of eastern Asia.

### Description

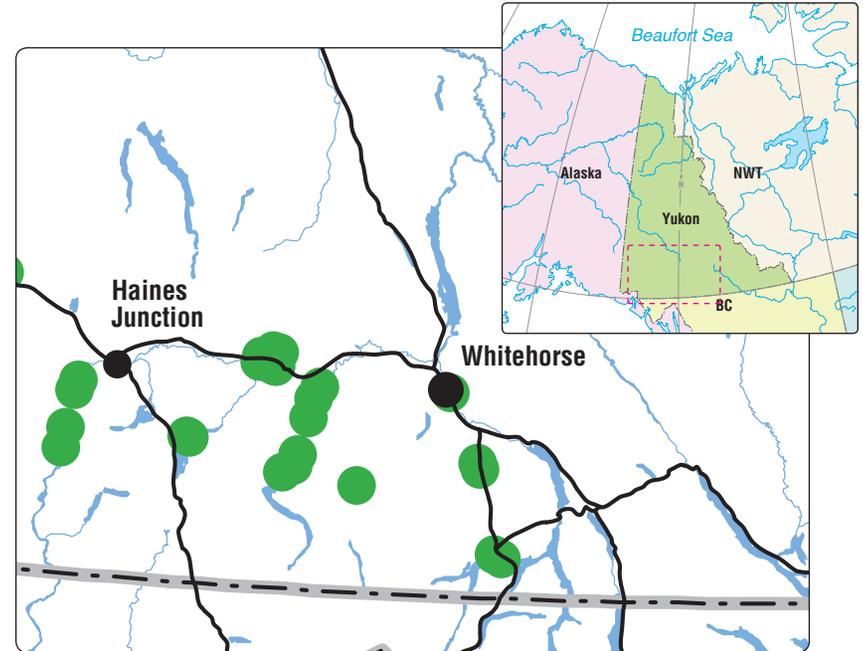

The Baikal Sedge is a grass-like perennial with a drooping, club-shaped flowering head; long, mostly underground, reddish leaf sheaths; and curled basal leaves.

### Typical Habitat

Occurs only on active or semi-stabilized dunes.

### Potential Threats

- Natural dune stabilization—air photos show a reduction in dune area of 15-20% over the last 50 years at Carcross due to the encroachment of trees and other vegetation.
- Recreational (all-terrain vehicle) use at Carcross and the Takhini dunes.
- Loss of habitat.
- Invasive species.

● Baikal Sedge Distribution

### DID YOU KNOW?

- The root system of the Baikal Sedge is 10 to 20 times as massive as the above-ground plant.
- A smut fungus that destroys developing seeds has been found at most Yukon populations. It is unclear how large an impact this fungus has on the sedge.
- Baikal Sedge was likely much more widespread during the last ice age, when aeolian dunes and steppe habitat were common on the landscape. Natural plant succession has resulted in dunes across southern Yukon becoming overgrown with forest communities.

Photo: Syd Cannings

Photo: Syd Cannings

## Spiked Saxifrage

*Micranthes spicata*

### SPECIAL CONCERN

Spiked Saxifrage is restricted to the unglaciated portions of Alaska and Yukon. It was first reported in Yukon from near the mouth of the Indian River in 1899, but was not seen again for over a century. After its rediscovery along a small tributary of the Yukon River in 2009, targeted inventories found it to be an extremely sparse inhabitant of the Klondike region. Recently, however, it has been found in the Beaver Creek area--there it not only grows along creeks, but in the moist alpine zone of mountains south of the community of Beaver Creek.

### Description

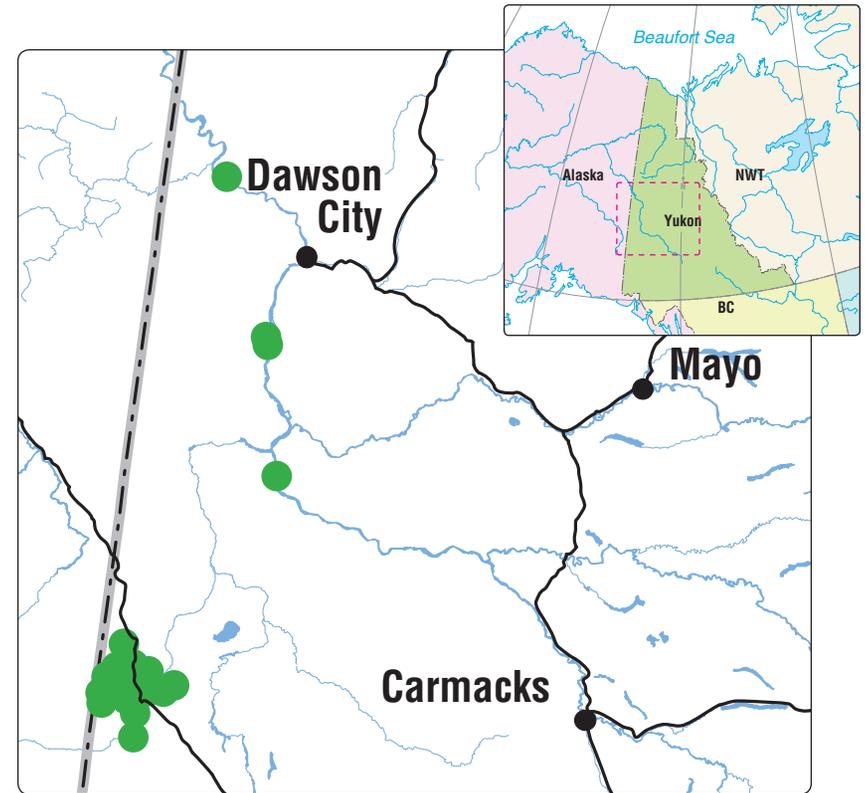

Spiked Saxifrage is a tall (up to at least 70 cm high), striking plant with large, round, toothed leaves and a spike of small, cream-coloured flowers.

### Typical Habitat

- Occurs along cool, shady creeks in the permafrost zone
- In the Beaver Creek area, it also occurs in moist, rocky alpine and open subalpine areas.
- Prefers shallow soils over rock or wood debris.

### Potential Threats

- Placer and hard-rock mining and exploration in the Klondike and Beaver Creek regions.

● Spiked Saxifrage Distribution

- Climate change, which may increase the frequency of fires, landslides, and scouring floods, and over the long term may cause changes to subalpine and alpine habitats.
- Human-caused wildfires.

### DID YOU KNOW?

- Spiked Saxifrage is reported as a food used by aboriginal peoples.
- The Yukon population harbours gene variants not found in Alaska, and may be important in contributing genetic diversity to the species.

Left photo: Martin Owen (YG). Top photo: Syd Cannings. Bottom photo: Yukon Government.

## Yukon Draba

*Draba yukonensis*

### ENDANGERED (2011)

Yukon Draba is a relict species of Beringia, known globally from grassland sites in southwestern Yukon: one just outside of Kluane National Park and the rest near Sekulumun, Hutshi and Aishihik lakes.

### Description

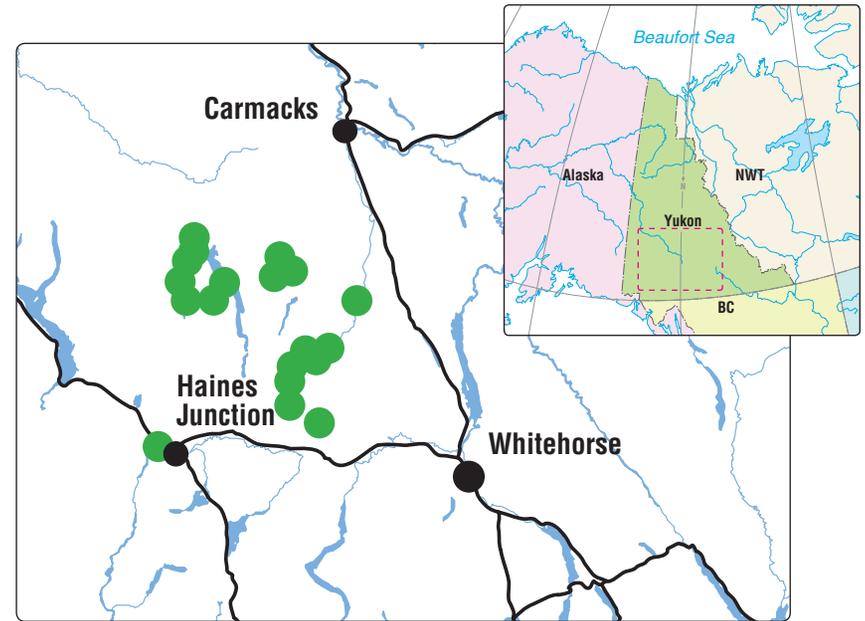

Yukon Draba is 2-20 cm tall, with small, 4-petaled, white flowers. It is a herbaceous wildflower in the mustard family. Individual plants have a small taproot, one or more rosettes of leaves and one or more flower-bearing stems. The untoothed leaves are covered with distinctive, stiff, unforked hairs.

### Typical Habitat

- Dry, grassland sites.
- At the Haines Junction site, Yukon Draba grows on almost flat, well-drained meadows situated on ancient sandy beaches.
- Often most dense on the tops of low ridges, bumps, road berms, and Arctic Ground Squirrel mounds.

### Potential Threats

- The Haines Junction site is threatened by increased traffic and road expansion associated with mining exploration.
- Invasive species that are well adapted to dry meadows are expanding rapidly in southern Yukon.

● Yukon Draba Distribution

### DID YOU KNOW?

- Yukon Draba is one of four mustards found only in Southwest Yukon and nowhere else in the world.
- Yukon Draba has been collected by botanists in the meadows near

- Haines Junction since the 1940's. Other sites were found between 2011 and 2014.
- Yukon is home to 35 of Canada's 54 species of Draba.

Photo: Yukon Government

Photo: Syd Cannings

## Yukon Podistera

*Podistera yukonensis*

### SPECIAL CONCERN (2014)

This rare member of the carrot family is restricted globally to the west-central Yukon and a small piece of adjacent Alaska. After an intensive survey over the past few years, 22 sites are now known in Canada; these are found in two separate regions of unglaciated Beringia: a northern group centred in the southern Ogilvie Mountains and a southern one in the Dawson and Ruby ranges.

### Description

Yukon Podistera is a perennial that grows in clumps from a stout, elongate taproot. Blue-green pinnate

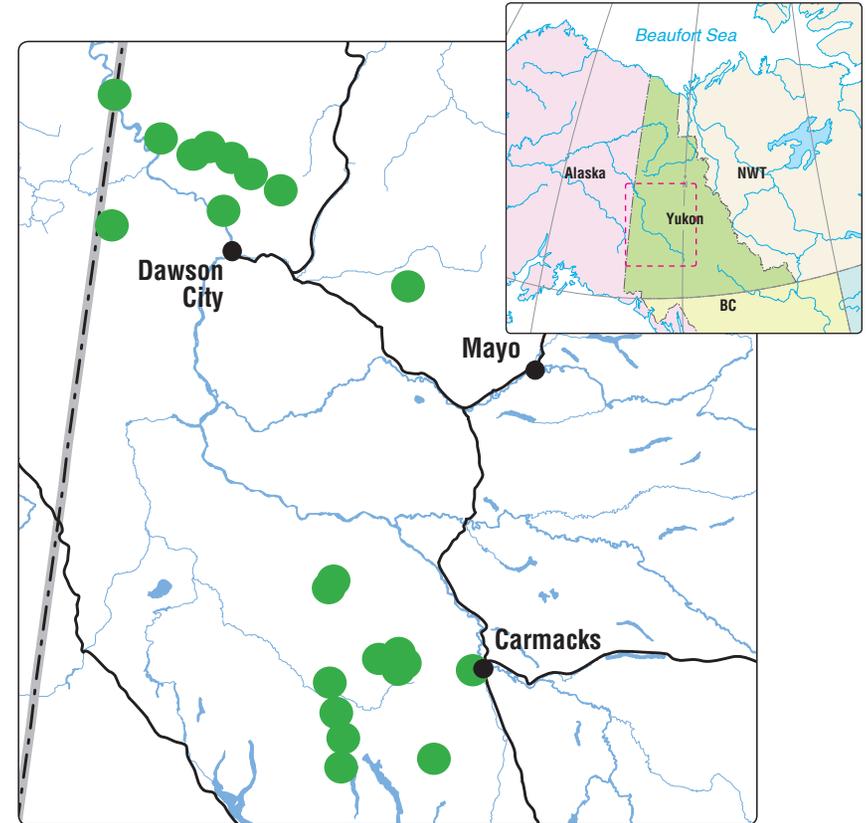

leaves grow below leafless stems that bear umbels of small flowers. The flowers are bright yellow when young, but soon fade to white.

### Typical Habitat in Yukon

- Open, rocky areas with shallow soil; stable talus slopes, scree and tors.
- Dry, sunny, windswept ridges that have little snow cover and are clear early in the spring.
- Primarily in the low alpine, but also occasionally on steep faces lower down.

### Potential Threats in Yukon

- Climate change that results in shrubs and other plants taking over open habitats.
- Mining and mineral exploration.

● Yukon Podistera Distribution

### DID YOU KNOW?

- The Yukon Podistera begins flowering early in the spring, usually in mid-to late May.
- These plants grow slowly and live a long life, perhaps at least 15 years.
- The closest relatives of Yukon Podistera live in the southern Rocky Mountains and Sierra Nevada of the United States.

Photos: Shannon Henderson, Agriculture and Agri-food Canada

## Dune Tachinid Fly

*Germaria angustata*

### SPECIAL CONCERN (2011)

In Canada, the Dune Tachinid Fly is restricted to a few active dunes in southwestern Yukon. It is presumed to be a parasite of the larva of a dune moth. This fly is just one of a group of species that are found only in these dunes at the edge of unglaciated Beringia—others include the Baikal Sedge, a small gelechiid moth, a stiletto fly, and other tachinid flies.

### Description

The Dune Tachinid Fly is a black, bristly, medium-sized fly (about 9 mm long). The second segment of the antennal branch (arista) has a distinctive elbowed appearance.

### Typical Habitat

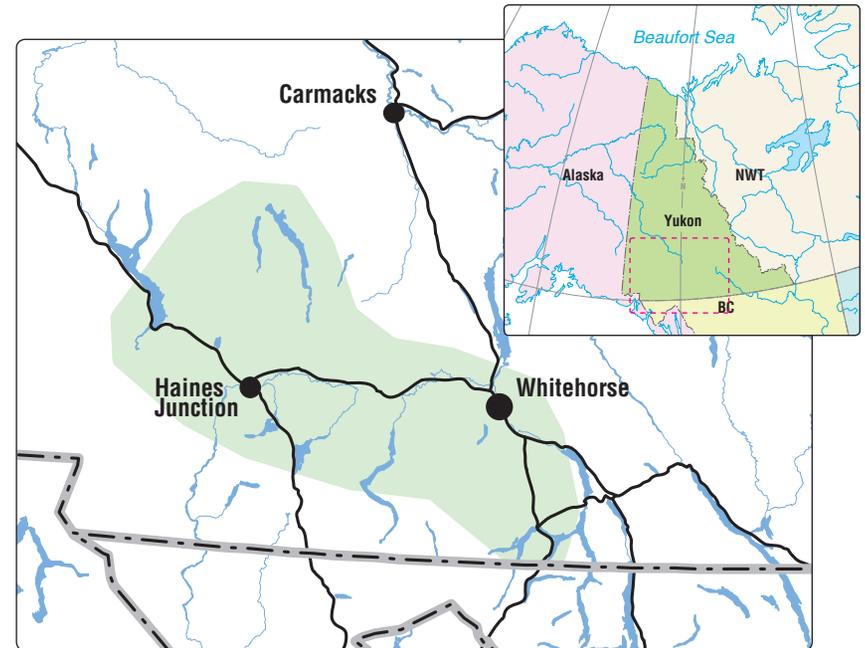

- Active or semi-stabilized dunes or smaller sand blowouts with scattered grasses, sedges, and other vegetation.
- In Yukon, the habitat always includes some grass or grasses.

### Potential Threats

- At the Carcross dunes, increasing recreational all-terrain vehicle use has caused a decline in habitat by eliminating grasses in heavy use areas.
- The Carcross Dune habitat is also threatened by residential housing and road developments.
- A potential, but significant threat is invasive species that have the ability to quickly stabilize dunes—for example, Altai Wild Rye and White Sweet-clover.
- Natural succession will probably continue to eliminate more open dune area, especially at the large Alsek dunes in Kluane National Park Reserve.

Photo: Syd Cannings

Dune Tachinid Fly Range

### DID YOU KNOW?

- All tachinid fly larvae are parasitic on other insects, usually moth caterpillars.
- The fly family name Tachinidae comes from the Greek tachys, meaning “fast,” a reference to the speedy flight of these flies.

Photo: Syd Cannings

Photo: Sheila Colla

## Gypsy Cuckoo Bumble Bee

*Bombus bohemicus*

### ENDANGERED (2014)

This bumble bee, formerly relatively common across a broad swath of northern North America, has virtually vanished in recent years—despite recent intensive bee inventories, it hasn't been seen in Yukon since the 1980s. It is an obligate nest parasite of particular bumble bees, among them the Western Bumble Bee and Yellow-banded Bumble Bee.

### Description

A medium-sized bumble bee with a gold band across the thorax and a white tip on an otherwise black abdomen. This rare bee can be distinguished from worker and queen Western Bumble Bees by

the absence of broad, concave pollen baskets on the hind leg and an abdomen that is distinctly more curved.

### Typical Habitat in Yukon

- Require open areas with abundant flowers through the summer.
- Areas where their host bees occur: Western and Yellow-banded bumble bees inhabit lowland meadows and open woodlands.
- May also parasitize Cryptic Bumble Bees, which in Yukon occur from the valley bottom up into subalpine shrub tundra.

### Potential Threats in Yukon

- Declines of host bees.
- Introduced pathogens from managed bees in greenhouses.
- Pesticide and other chemical use in agriculture.

### DID YOU KNOW?

- Queens invade other bumble bee colonies, disable or kill the host queen, and lay their eggs. After they hatch, the larvae are reared by the host workers.
- Cuckoo Bumble Bee queens are built for battle: their bodies are armoured with extra thick chitin and their abdomens are curled beneath them, ready to sting their host queens.

Photo: Syd Cannings

## Western Bumble Bee, *mckayi* subspecies

*Bombus occidentalis mckayi*

### SPECIAL CONCERN (2014)

This northern subspecies of the Western Bumble Bee ranges in Canada from northern British Columbia through the southern Yukon and the westernmost Northwest Territories. Recent surveys suggest that it is still relatively common. However, its southern relatives are experiencing a serious, apparently northward-moving decline, and the northern subspecies faces an uncertain future.

### Description

A medium-sized bumble bee with a short head. In Yukon, these bees usually have a transverse band of golden hair across the front of the

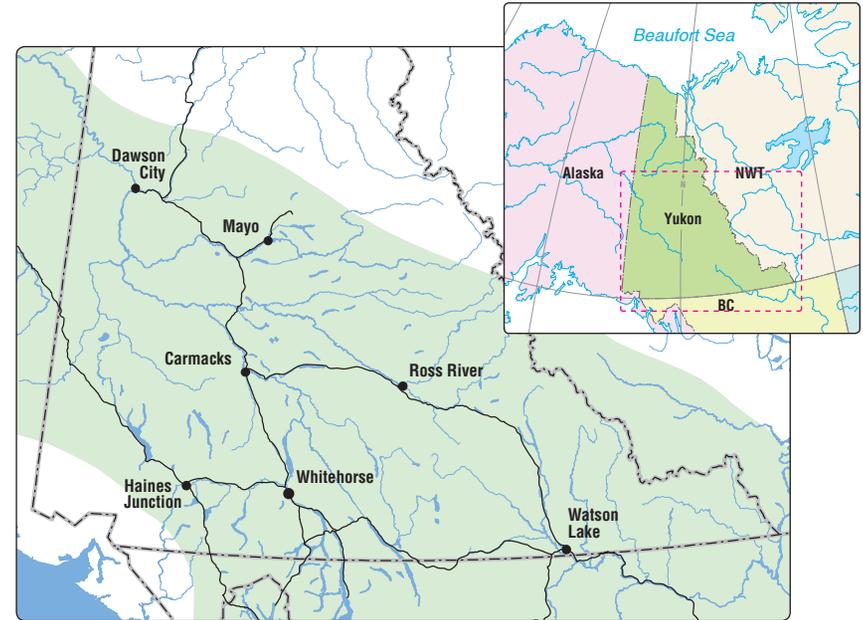

thorax, a golden stripe across the third segment of the abdomen, and a whitish tip to the abdomen.

### Typical Habitat in Yukon

- A bumble bee of the valleys, where it inhabits mixed woodlands and montane meadows.
- Requires nectar and pollen from a wide variety of flowers throughout the spring and summer, including willows, Kinnikinnick, sweet vetches and white sweet-clover.
- Nests underground in abandoned rodent burrows.

### Potential Threats in Yukon

- High natural parasite load, particularly the intercellular, parasitic, fungus *Nosema bombi*.
- Pesticide and other chemical use in agriculture.
- Habitat loss.

Western Bumble Bee Range

### DID YOU KNOW?

- Bumble bees are essential to the pollination of certain flowers that require a serious shaking to release their pollen; blueberries and low-bush cranberries are good examples.
- The *mckayi* subspecies of Western Bumble Bee probably originated in the unglaciated region of Beringia, when the northern populations were isolated from their southern cousins by the vast ice sheets that covered British Columbia and southern Yukon.

Photo: Leif Richardson

## Yellow-banded Bumble Bee

*Bombus terricola*

### SPECIAL CONCERN

The Yellow-banded Bumble Bee is a widespread species across eastern northern North America, and reaches the northwestern limit of its range in southeastern Yukon. In recent decades, its numbers have declined significantly in southern Canada, probably as a result of a number of cumulative threats, including pathogens from managed bumble bees used in greenhouses, pesticide use associated with agriculture (including neonicotinoids), climate change, and habitat loss within urban and agricultural areas. Little is known of population trends or the species' status in Yukon, but it seems to be reasonably common in its restricted range.

### Description

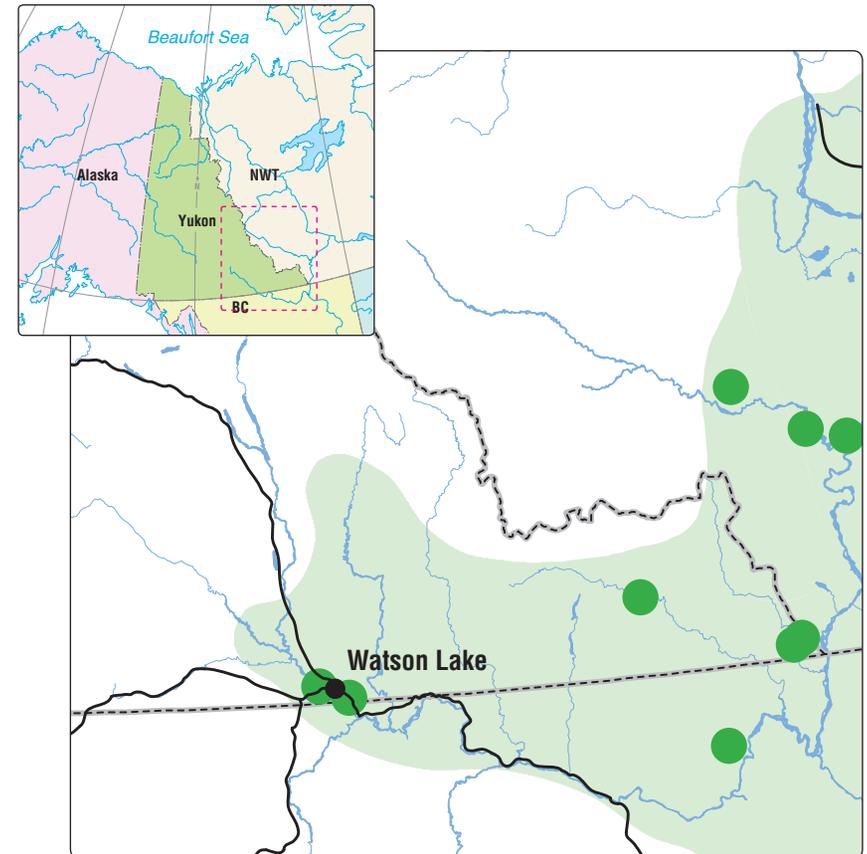

The Yellow-banded Bumble Bee is a medium-sized bumble bee, distinguished by a narrow yellow band behind the head and a broad yellow band on the second and third segments of the abdomen. The tip of the abdomen is white.

### Typical Habitat in Yukon

- Open, flower-rich areas in the lowlands of southeastern Yukon.
- Requires nectar and pollen from a wide variety of flowers throughout the spring and summer.

### Potential Threats in Yukon

- There are few known threats in the wilds of the southeastern Yukon, although parasites and diseases may be limiting factors.

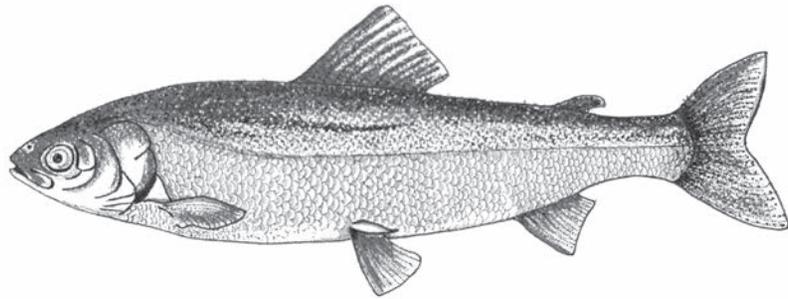

Yellow-banded Bumble Bee Range ● Yellow-banded Bumble Bee Migration Records

### DID YOU KNOW?

- Bumble bees live in small colonies of female workers and a single queen. Late in the summer, reproductive males and females emerge and mate. The fertilized queens disperse and overwinter on their own, and start a new colony the following spring.
- Bumble bees are close relatives of the introduced Honey Bee. Like

that species, they make honey to rear their larvae, but because they don't maintain their colonies over the winter, they make only small amounts.

- The Yellow-banded Bumble Bee is the eastern sibling of the Western Bumble Bee, another Special Concern species in Yukon.

Drawing: Nancy Lewis-de Graff

## Bering Cisco

*Coregonus laurettae*

### SPECIAL CONCERN (2004)

Bering Cisco are common in the Yukon River system in Alaska, but only a few reach Canadian waters as far upstream as Dawson City. However, traditional knowledge suggests that the distribution is more widespread than currently documented. Recent research indicates that a number spawn in the Yukon River system upstream of Dawson. Spawning migrations spans late spring or early summer through fall, with peak spawning activity occurring in October.

### Description

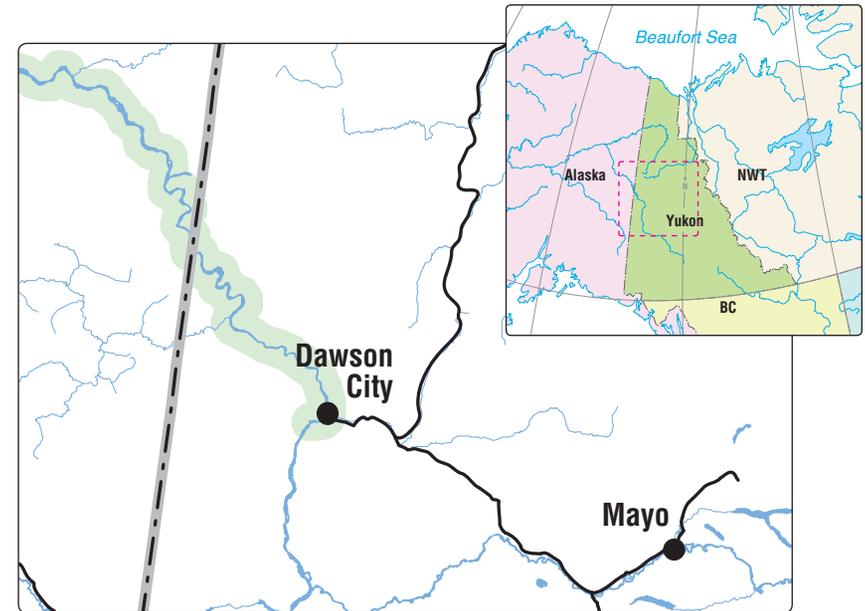

Bering Cisco resemble large, plump herring, with silver-coloured bodies and moderately sized scales. The average fork length of migrating fish is about 37 cm. The species is distinguished from other cisco by the pale, almost colourless pelvic and pectoral fins and 18 to 25 gill rakers on the lower portion of the first gill arch.

### Typical Habitat

- Long annual migrations are made to spawning areas in the mainstem portions of large rivers; in Yukon they are restricted to the lower Yukon River drainage. Bering Cisco spawn in fast-flowing water near beds of loose gravel where eggs are broadcast over the substrate.
- Outside Yukon, they are found in river estuaries and brackish lagoons along coastal Alaska.

### Potential Threats

- No urgent threats are known, but the small numbers of fish restricted to one main river in Canada (the Yukon River) make it sensitive in that system.
- The migratory behaviour of Bering Cisco makes the species susceptible to obstructions such as causeways and dams.
- The reduction of water flow or alteration in discharge or water quality in those rivers where they are known to spawn could be a limiting factor and a future threat.
- Incidental by-catch and a potential for over-harvest in the subsistence fishery.

Bering Cisco Range

### DID YOU KNOW?

- These small but powerful travelers battle against currents for over 2100 kilometres in their migratory upriver path from the Bering Sea through the Yukon River.
- In Alaska, Bering Cisco are targeted by coastal fishers who value them for their high oil content.

Photo: Syd Cannings

Photo: Yukon Government

## Bull Trout, Western Arctic population

*Salvelinus confluentus*

### SPECIAL CONCERN (2012)

Because Bull Trout are highly sensitive to habitat changes. They are an indicator species of general ecosystem health. There is no evidence of decline of Bull Trout in Yukon or the Northwest Territories; but in recent decades Bull Trout declined in abundance, including localized extinctions, across their southern range. Bull Trout populations depend on the availability of more pristine and cooler environments of the northerly regions.

### Description

Bull Trout are difficult to distinguish from Dolly Varden (*Salvelinus malma*) but the two species generally occupy different

geographic ranges. Where their ranges overlap, measurements or genetic studies are needed to separate them. Bull Trout have larger, broader, and flatter heads than Dolly Varden, with bodies that are more slender and ventrally flattened. Pale round spots along their sides and backs that are pink, lilac, yellow-orange or red distinguish them from other types of trout such as Rainbow and Cutthroat.

### Typical Habitat

This cold water species' strict habitat requirements vary across life history stages. Bull Trout require habitat that is cold, clean, complex, and connected. Structurally complex habitat provides cover for shelter and the right requirements for breeding and rearing young, while connected habitat allows this migratory species to move between the areas it needs to complete its life cycle.

Bull Trout, Western Arctic population Range

### Potential Threats

- Their voracious appetite and habit of congregating during spawning make Bull Trout susceptible to over-harvest by anglers particularly in spawning congregations.
- Barriers including dams, roads, and hanging culverts.
- Habitat change including forest harvest, mining, oil and gas developments, and increasing wildfire events.

### DID YOU KNOW?

- Its head and jaws are unusually large for a salmonid, leading to its common name "bull".
- In the US Bull Trout is listed as Threatened.
- Both freshwater and anadromous (ocean run), populations are known although only freshwater populations occur in Yukon.

Photo: US Fish and Wildlife Service

## Dolly Varden (northern form)

*Salvelinus malma malma*

### SPECIAL CONCERN (2010)

Two subspecies of Dolly Varden are recognized in Canada, a southern form and a northern form. The northern form is found north of Bristol Bay in Alaska, along the north slope of Alaska and Yukon, east to the lower Mackenzie River, including the Peel River and its tributaries. Some isolated populations have found their way over low passes and entered the headwater systems of Yukon River tributaries such as the Klondike, Hess, and Rackla rivers.

### Description

Dolly Varden are characterized by a pattern of pale orange or reddish spots on a dark background. Anadromous (sea-run) northern

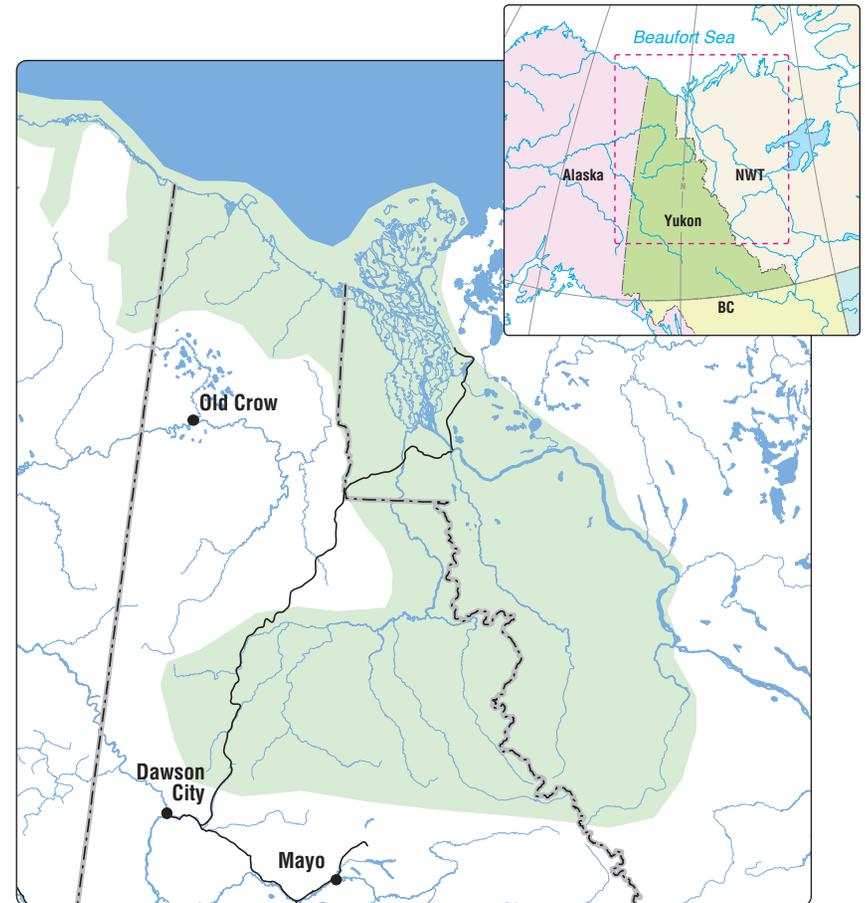

form Dolly Varden reach more than 35 cm in length; other adults are usually less than 30 cm. Non-anadromous adults retain the parr marks of the juveniles whereas anadromous individuals lose them. Spawning anadromous males develop a hooked lower jaw and are strikingly coloured; all other individuals have a more muted colouration.

### Typical Habitat

- All types of the northern form of Dolly Varden spawn and overwinter in freshwater associated with perennial groundwater springs.

### Potential Threats

- Low water and low groundwater flow in freshwater habitats at spawning and overwintering grounds, correlated with climate warming.
- Over-harvesting.

Dolly Varden (northern form) Range

### DID YOU KNOW?

- Dolly Varden are a valued part of the Gwich'in and Inuvialuit diet.
- Dolly Varden get their name from a character in the novel *Barnaby Rudge* by Charles Dickens—a woman known for her colourful dresses, one of which was green with pink polka-dots.
- Dolly Varden and their close cousins, the Arctic Char and Bull Trout, have confused scientists for many years, and have been the subject of many studies regarding biogeography and evolution.

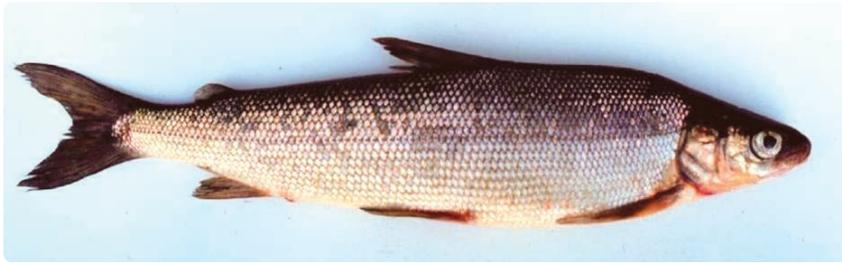

Photo: Louis Bernatchez

## Squanga Whitefish

*Coregonus sp.*

### SPECIAL CONCERN (1987)

The Lake Whitefish is a common species in Yukon, but in five Yukon lakes, two forms of the species coexist and act as separate species. One is the 'typical' Lake Whitefish that feeds on bottom-dwelling invertebrates; the second is a distinct form that feeds on plankton in open water. The one ecological feature that the five lakes have in common is the absence of plankton-feeding Least Cisco, so it appears that the plankton-feeding form of Lake Whitefish has evolved to take advantage of this open ecological niche.

These whitefish, unofficially named the Squanga Whitefish after the lake in which they were first found, probably evolved independently within each watershed. In fact, genetic evidence indicates that the pattern is best explained by two distinct populations of whitefish colonizing the lake on separate occasions; one securing the rich

bottom-feeding niche and the other doing the best it can to survive in the open water. This pattern is found in a number of lake systems across Canada.

### Description

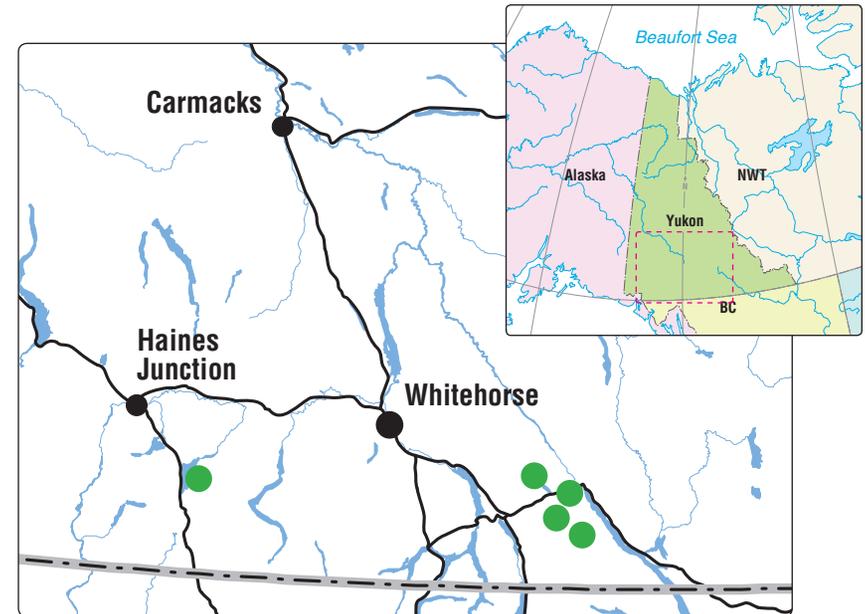

To the casual observer, the Squanga Whitefish looks just like the Lake Whitefish. In the hand, it can be distinguished from Lake Whitefish by higher gill raker numbers. Other differences include greater gill raker length, distance between gill rakers, size of the head, and length of the fins relative to the size of the body.

### Typical Habitat

- Lakes that are relatively shallow and productive with well-developed, meandering creek channels for spawning adjacent to the lake.

### Potential Threats

- Habitat loss due to lakeside developments (Little Teslin Lake).
- Introduction of exotic fish, including trout.
- Over-harvesting

● Squanga Whitefish Range

### DID YOU KNOW?

- The Squanga Whitefish is known from only five lakes in Yukon: Dezadeash Lake in the southwest, and Squanga, Seaforth, Little Teslin and Teenah lakes in the south-central region. A similar form also existed in Hanson Lake in central Yukon, but was poisoned along with all other fish species there to

prepare this lake for Rainbow Trout stocking.

- Similar fish have evolved from Lake Whitefish elsewhere, including Dragon Lake near Quesnel, British Columbia. Like those in Hanson Lake, that species was also poisoned to extinction before trout were introduced to the lake.

Photo: Randi Mulder

Photo: Jared Hobbs

## Western Toad

*Bufo boreas*

### SPECIAL CONCERN (2012)

Western Toads have severely declined in the southern half of their range since the late 1970s—the centre of the world's distribution of Western Toads has shifted north from the U.S. to British Columbia. The cause for the decline is uncertain but a number of factors including diseases are thought to play a part. In Yukon, they are confined to the southeastern corner of the territory, although their range in northwestern British Columbia reaches Atlin and parts of White and Chilkat pass regions.

### Description

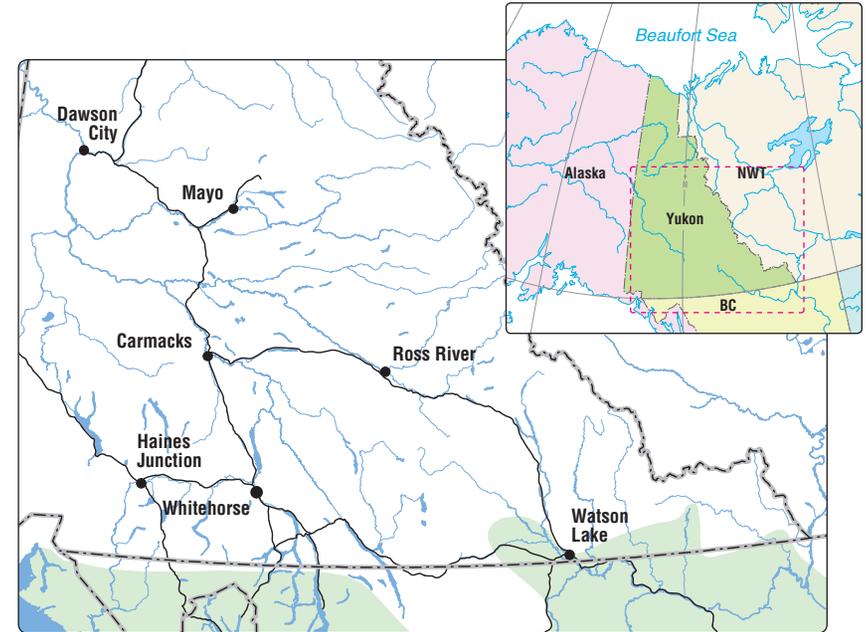

Western Toads are usually green or brown with a light stripe down the middle of the back, and have reddish-brown warts. Newly hatched tadpoles and toadlets are black.

### Typical Habitat

- Congregate and breed in shallow silty or sandy ponds, springs, lake margins, and streamside flood pools.
- Summer habitats include shrubby, forested areas; wet shrublands; and meadows.
- Over-winter in areas of high snow cover by burrowing underground to a layer deep enough (up to 1.3 m) to prevent freezing, and moist enough to prevent their skin from getting too dry.

### Potential Threats

- Loss of breeding habitat.
- Drought.
- Fluctuating winter temperatures, freezing rain, low snow cover.
- Disease (e.g. ranaviruses and chytrid fungus).
- Fish stocking

Western Toad Range

### DID YOU KNOW?

- Western Toads return to the same breeding sites year after year.
- They are one of the few amphibians that live in alpine areas.
- They can travel up to 7 km in less than a day, and prefer to walk or crawl rather than hop.
- They are nocturnal and difficult to find outside the spring breeding season.

Photo: Syd Cannings

Photo: Cameron Eckert

## Bank Swallow

*Riparia riparia*

### THREATENED (2013)

This widespread species has shown a severe long-term decline of 98% of its Canadian population (now estimated at 1.4 million) over the last 40 years. As with many other aerial insectivores, the decline continues, albeit at a slower rate since the 1980s. Data from 2001-2011 indicate a potential loss of 31% of the population during that 10-year time period.

### Description

The Bank Swallow is the smallest swallow in the Americas. Total body length averages 12 cm and they weigh 10-18 g. Sexes are similar in size and plumage. Bank Swallows have a grey-brown head, a pale

forehead, white underparts, a distinctive brown upper breast-band, and a long notched tail. In flight, the Bank Swallow is best distinguished by its small size, distinctive breast-band, and its quick and flicking wing-beats.

### Typical Habitat

The Bank Swallow breeds in a wide variety of natural and artificial sites with vertical banks, including riverbanks, lake and ocean bluffs, aggregate pits, road cuts, and stockpiles of soil. Sand-silt substrates are preferred for excavating nest burrows. Breeding sites tend to be somewhat ephemeral because of bank erosion. Breeding sites are often situated near open habitat used for aerial foraging (e.g., grasslands, meadows, rivers or lakes). Large wetlands are used as communal

Bank Swallow Range

nocturnal roost sites during post-breeding and migration periods.

### Potential Threats

The reasons for the declines are not well understood, but are likely driven by the cumulative effects of several threats. These include loss of breeding and foraging habitat, destruction of nests during aggregate excavation, collision

with vehicles, widespread pesticide use affecting prey abundance, and impacts of climate change.

### DID YOU KNOW?

- The Bank Swallow has an extensive global distribution, occurring on every continent except Australia and Antarctica.
- In Yukon, Bank Swallows are among the most numerous birds encountered by river travellers.

Photo: Gord Court

## Barn Swallow

*Hirundo rustica*

### THREATENED (2011)

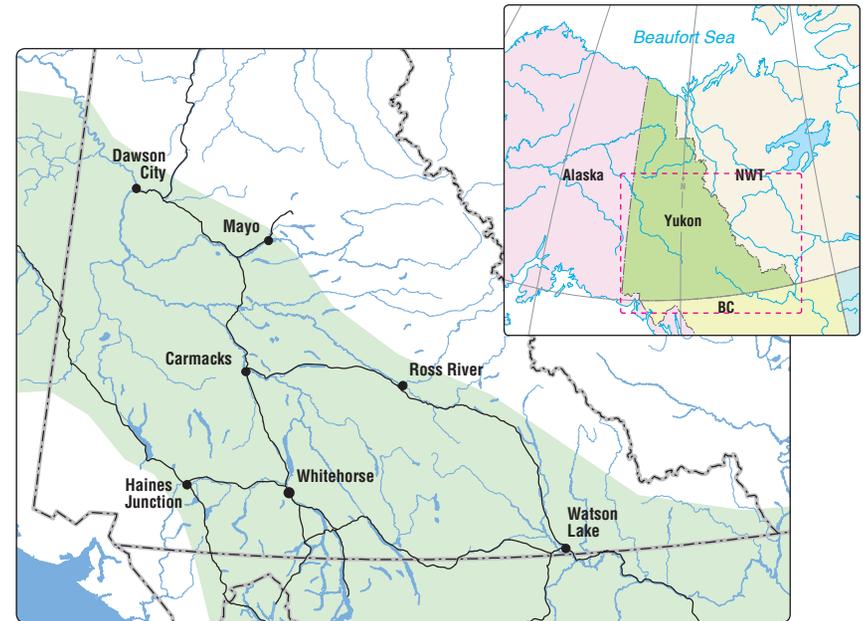

The Barn Swallow is the most widespread species of swallow in the world, and has become closely associated with human rural settlements. Despite its cosmopolitan distribution and close ties with humans, it has suffered recent, significant declines that began somewhat inexplicably in the mid 1980s. In the last ten years alone, populations have declined about 30% in Canada. Causes of this decline are not clearly understood, but the Barn Swallow is an insectivorous, long-distance migrant, and may be suffering primarily from troubles on its tropical wintering ground and migration routes.

### Description

The Barn Swallow is a small, slender bird easily recognized by its steely-blue back, cinnamon belly, chestnut throat and forehead, and by its deeply forked 'swallow' tail.

### Typical Habitat

- Following European settlement, nesting sites of Barn Swallows have shifted almost completely from natural sites (caves and crevices in cliff faces) to manmade structures. Structures most commonly used include barns and other outbuildings, garages, houses, bridges, and road culverts.
- Barn Swallows prefer various types of open habitats for foraging, including grassy fields, wetlands, farmyards and croplands, lake and river shorelines, cleared rights-of-way, sand dunes, and alpine tundra.

Barn Swallow Range

### Potential Threats

- Nests may be lost through intentional or incidental destruction on buildings and bridges.
- Yukon's Barn Swallows may also be threatened during their migration by loss of foraging habitat, and exposure due to pesticides at tropical wintering grounds.

### DID YOU KNOW?

- The Barn Swallow is perhaps the only Yukon breeding bird that occasionally breeds in South America during the boreal winter.
- The Barn Swallow is found on every continent except Antarctica.
- Scientific studies have shown that female Barn Swallows prefer males with longer, more symmetrical tails.

Photo: Trish Loretz

## Buff-breasted Sandpiper

*Tryngites subruficollis*

### SPECIAL CONCERN (2012)

The Canadian Arctic supports about 87% of the Buff-breasted Sandpiper's North American breeding range, and about 75% of this shorebird's global population. The species was once common and historically perhaps even abundant, but it suffered severe declines from intensive market hunting in the late 1800s and early 1900s. By the 1920s, it was thought to be on the brink of extinction. Its population has grown since hunting of the species was banned in North America, but numbers have never fully recovered. There is evidence for population decline in recent decades, and many conservation organizations consider the species to be of concern throughout its range. However, this species is difficult to monitor effectively, and population trend information is currently lacking.

### Description

The Buff-breasted Sandpiper is a medium-sized shorebird with a buff-coloured face and underparts, and brown to black speckling on its wings and back.

### Typical Habitat

In Yukon, Buff-breasted Sandpipers breed on the tundra on the North

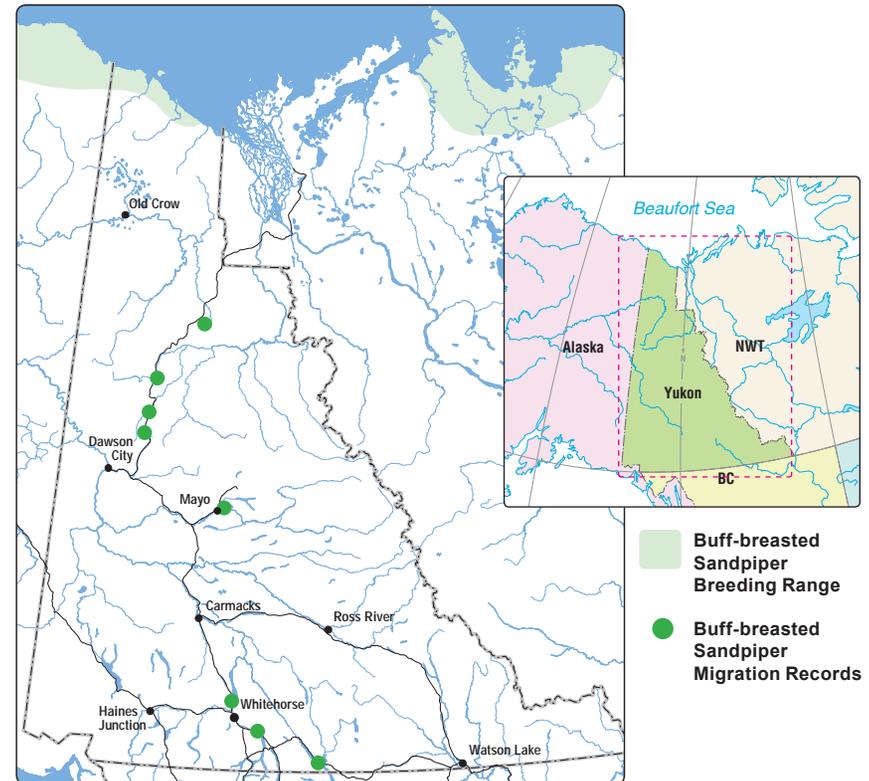

Photo: Cameron Eckert

Slope. On migration and during the winter, they occur primarily in grasslands. Nowadays, they use a variety of human-altered sites for stopovers, such as crop fields, golf courses, airport runways, sod farms, and pastures. Buff-breasted Sandpipers winter mainly on the South American Pampas, where livestock grazing maintains their preferred short-grass habitat structure.

### Potential Threats

- Climate change may impact Buff-breasted Sandpipers in several ways. Northward advancement of shrub cover will dramatically alter its tundra breeding habitat. Rising sea levels and increased rainfall could flood the birds' coastal habitat on both breeding and wintering grounds. More frequent and intense storms could increase mortality of juveniles migrating along the Atlantic coast.

- Habitat loss, fragmentation and degradation are likely the primary threats to the Buff-breasted Sandpiper, particularly within its specialized grassland habitat, both on its wintering grounds in South America and along its migration routes. Throughout much of the migration and winter range, native grasslands have largely disappeared, and the species have been forced to switch to using human-altered habitats.
- In the Arctic, breeding habitat overlaps areas of mineral and energy extraction although in Yukon these activities have not

taken place in the species' known breeding area.

### DID YOU KNOW?

- This is the only North American shorebird with a lek mating system (similar to Sage and Sharp-tailed grouse), in which males congregate to display to females during courtship.
- Buff-breasted Sandpipers are known to be extremely tame, and to return to wounded flock members.

Photo: Larry Master

Despite their diminutive size, Canada Warblers are long-distance migrants, flying to and from the northern Andes each year.

## Canada Warbler

*Wilsonia canadensis*

### THREATENED (2008)

In the heart of their breeding range to the southeast of Yukon, Canada Warblers apparently declined almost 5% per year between 1968 and 2006, which amounts to a loss of 85% of the population during that period. But because their Yukon breeding grounds are far from the nearest road, there is no information on declines in the territory. The factors responsible for the decline have not been confirmed, but habitat loss, particularly on the wintering range, is thought to be the most likely factor. In Yukon, Canada Warblers only nest in the far southeast, in the valleys of the Beaver and La Biche rivers.

### Description

Canada Warblers are small, brightly coloured songbirds. The male (pictured above) is a handsome slate grey above and bright yellow below, with a black face and a necklace of black spots. The female is similar but duller in colour, without a necklace.

### Typical Habitat

- Canada Warblers nest in Yukon in the interior of old-growth forests with dense, shrubby understories.
- Nests are hidden on the ground under dense cover.

### Potential Threats

- Habitat loss in old-growth forests of the southeast.
- Sour gas escapement from wells in the La Biche valley.
- Insecticide and herbicide use on their wintering grounds.

Photo: Cameron Eckert

### DID YOU KNOW?

- Despite their diminutive size, Canada Warblers are long-distance migrants, flying to and from the northern Andes each year.
- Perhaps because they must travel such a long distance between wintering and breeding grounds, Canada Warblers arrive in their namesake country late in the spring, and are among the first songbirds to head south in summer.
- Many other insect-eating long-distance migrants are also declining in numbers, including Common Nighthawks, Olive-sided Flycatchers, and Barn Swallows.

Photo: John Meikle

## Common Nighthawk

*Chordeiles minor*

### THREATENED (2007)

Despite their 'common' name, declines approaching 50% have been recorded for Common Nighthawks across Canada in the last ten years. Substantial threats likely occur at the southern edge of their breeding range, and on their winter range in South America.

They are late migrants, usually arriving in Yukon in the first week of June. Two eggs are laid directly on soil, sand, gravel or bare rock. Nestlings remain in the nest until late summer.

### Description

Common Nighthawks are medium-sized birds, with mottled, dark brown plumage. They have long, slender wings and a long tail. The head is

large and broad, with large eyes and a wide mouth. In flight, adults show a white patch on the wings.

### Typical Habitat

- Common Nighthawks nest in a variety of habitats such as mature pine forests, old burned forests, open forests, and wetlands.
- Wetlands, lakes and rivers can be an important source of abundant flying insects.
- They are also known to nest on sand dunes and beaches, forest clearings including recently logged areas, rocky outcrops, peatlands, marshes, lakeshores, river banks, gravel roads and quarries, and the open areas around airstrips.

### Potential Threats

- Reductions in insect prey due to pesticides.
- Habitat loss and degradation.

Common Nighthawk Range

- Human activities that result in increased numbers of predators such as domestic cats, ravens, gulls, and foxes.
- Collisions with motor vehicles, particularly on gravel roads.

### DID YOU KNOW?

- Common Nighthawks actively pursue flying insects in the long summer twilight.
- The sexes can be distinguished by the colour of their throat: white in males and buff in females.
- Common Nighthawks are long-distance migrants, wintering in South America.
- During the breeding season, males perform an aerial courtship display. They dive straight down from a great height, then pull up—the air rushing through their wingtips at the bottom of the dive makes a deep booming sound.

Photo: Donna Dewhurst, USFWS

## Horned Grebe

*Podiceps auritus*

### SPECIAL CONCERN (2009)

Although limited trend information is available from Yukon, Horned Grebes have suffered a 30% decline across Canada between 1986 and 2006, and a significant decline of 65% has been reported for Alberta. Horned Grebes are still relatively common on small lakes and wetlands in southern Yukon, but become less common as one travels north. Early migrants arrive in late April, but numbers quickly rise, peaking in the second week of May—up to 250 have been seen on Swan Lake, near Whitehorse. Between one and six eggs are laid in closely-guarded, floating nests. Horned Grebes feed on aquatic insects and small fish and frogs. The

last fall migrants have usually left the territory by the end of October.

### Description

The Horned Grebe is a small waterbird with striking breeding plumage: bright golden feathers flare out behind the startlingly red eye, contrasting with a chunky, black head and back. The underparts are a rich, rusty brown.

### Typical Habitat

- Horned Grebes nest on ponds and small lakes with marshy margins. The adults dive for food in open water, but the floating nests are anchored in shallow water in the midst of dense stands of sedge, reeds, or horsetails.

### Potential Threats

- Wetland loss and degradation.

Horned Grebe Range

### DID YOU KNOW?

- Unlike ducks, grebes do not have fully webbed feet; instead, each toe has its own lobe of skin that helps the grebe swim through the water.
- Baby Horned Grebes have striking, black-and-white zebra stripes on their heads and necks.
- Horned Grebes are aggressive

defenders of their nesting territories, so they usually nest as single pairs. But if the lake is large enough or food plentiful enough, several pairs may share the shoreline.

- Breeding Horned Grebes engage in a series of complex and spectacular ceremonial displays.

Photo: Ted Murphy-Kelly

## Olive-sided Flycatcher

*Contopus cooperi*

### THREATENED (2007)

Like the Common Nighthawk, the Olive-sided Flycatcher is an insectivorous bird that makes long migrations between Canada and South America. For unknown reasons, but perhaps related to its migratory or wintering habitat, it has shown a widespread population decline over the last 30 years; the Canadian population is estimated to have declined by 79% from 1968 to 2006.

### Description

This large flycatcher is between a bluebird and robin in size. It has a dark face and back, and dark olive sides on its chest.

### Typical Habitat

- Found in a wide variety of open forests and woodlands, especially along edges of burns or peatlands with standing dead trees.

### Potential Threats

- Fire suppression can create closed forests that these birds avoid.
- Clearcut logging removes breeding habitat.
- Habitat alteration and loss on the wintering grounds of this migratory bird may also pose serious threats to these birds' populations.

Photo: Ted Murphy-Kelly

Olive-sided Flycatcher Range

### DID YOU KNOW?

- The Olive-sided Flycatcher is one of the very few Yukon songbirds that migrate as far south as South America—others in this exclusive club include Swainson's Thrush, Blackpoll Warbler, and Cliff, Barn, and Bank swallows.
- The male's loud, ringing song has been transcribed as "Quick, three

- beers!" or the shorter "Free beer!" A "pip-pip-pip" call is believed to be given in close proximity to the nest.
- Although they attack many flying insects, the most common prey recorded in a central Alaska study were yellowjacket wasps and small dragonflies.

Photo: Gordon Court

## Peregrine Falcon

*Falco peregrinus*

### SPECIAL CONCERN (2007)

The Peregrine Falcon was one of the first species assessed by COSEWIC. It was initially evaluated as three subspecies. In the late 1940s, their populations suffered a rapid decline reducing the populations by 80-90% by the mid-1970s. Following the ban of organochlorine pesticides, populations have recovered to near historical numbers.

### Description

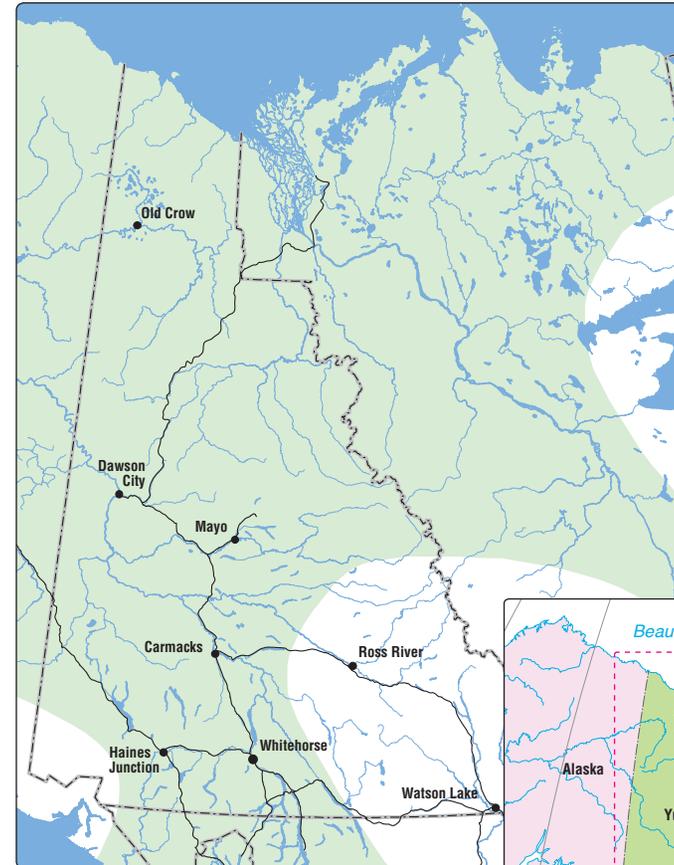

Peregrine Falcons are about the size of a small hawk, with long, pointed wings. They have black cheek patches and dark “cap” on the top of their head.

### Typical Habitat

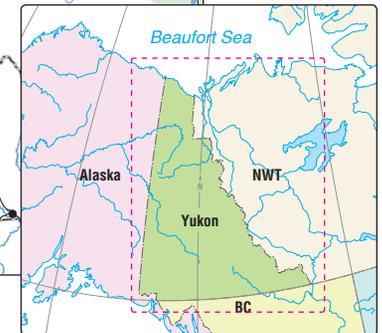

- Peregrines primarily hunt waterfowl and shorebirds, so require healthy wetlands, lakes, rivers and oceans to survive. In Yukon, most nest on protected cliff ledges or crevices near water.

### Potential Threats

- Because of their long migrations through a number of countries, peregrines remain highly susceptible to organochlorine pesticide contamination (causes a softening of the eggs and widespread reproductive failure).
- Human disturbance at nest sites.
- Loss or degradation of foraging habitat and decline of prey populations.
- Loss of habitat.

Peregrine Falcon breeding Range

### DID YOU KNOW?

- Yukon’s *Wildlife Act* protects all raptor (predatory bird) eggs, nests and individuals. Therefore it is illegal in Yukon to hunt or possess live Peregrines, possess whole or parts of dead Peregrines, or export individuals, their eggs or parts of peregrine without a permit.
- Peregrines can reach speeds of more than 320 kph when diving or ‘stooping’ at their prey.
- “Peregrine” means traveler. They are long-distance migrants - most Yukon Peregrines apparently cross the Gulf of Mexico in migration and will occasionally reach places as far south as Argentina.
- The Peregrine Falcon is one of the most widely distributed bird species in the world.

Photo: Cameron Eckert

## Red-necked Phalarope

*Phalaropus lobatus*

### SPECIAL CONCERN (2014)

The Red-necked Phalarope has declined across the continent over the past 40 years. In Yukon declines have been noted particularly at Herschel Island, Shingle Point, and Old Crow Flats. In Yukon, it breeds primarily in the north, but can be found on ponds throughout most of the territory. Red-necked Phalaropes spend the winter in large flocks at sea, primarily at upwellings off Peru, eating surface zooplankton.

### Description

A small shorebird; in breeding season blue-grey and white, easily recognized by the brick-red colour of the sides and base of the neck. Females are larger and more brightly-coloured than males.

Outside the breeding season, Red-necked Phalaropes are white below and around the face, with a dark eye stripe, crown and back.

### Typical Habitat in Yukon

- Breeds in low Arctic and subarctic wetlands; near ponds, lakes, or streams.
- Open areas near wetlands are required for nesting.

### Potential Threats in Yukon

- The likely greatest local threat is a rapidly changing climate with associated habitat and food-web effects.
- Threats during the non-breeding season include changes in ocean temperature, salinity and currents as a result of climate change; chronic oiling and point-source oil spills; and ingestion of microplastics.

Red-necked Phalarope Range

### DID YOU KNOW?

- All phalaropes exhibit gender-role reversal: unlike most other birds, females are larger and more brightly coloured than the males.
- Shortly after egg-laying, females desert the nest and leave to search for other mates.
- Males incubate the eggs and care for the young when they are small.
- Unlike other shorebirds, phalaropes have lobed feet and swim on the surface of ponds and lakes.

Photo: Cameron Eckert

## Rusty Blackbird

*Euphagus carolinus*

### SPECIAL CONCERN (2006)

Rusty Blackbirds live in boreal forest wetlands across North America, from Alaska to Newfoundland. In Yukon, they can be found right up to the tundra's edge. Not much is known about their numbers in Yukon, but there has been a 90% reduction in the overall North American population over the last 30 years.

### Description

Females are brownish-grey with no gloss; males are glossy black. Both sexes have white eyes. In August, both sexes moult into their winter plumage, which is brown and black

*In August, both sexes moult into their winter plumage, which is brown and black due to the rusty and beige feather edges, which wear off by spring.*

due to the rusty and beige feather edges, which wear off by spring.

### Typical Habitat

- Present in Yukon from April to October, Rusty Blackbirds live throughout the boreal forest in brushy wetland areas.

### Potential Threats

- Many Rusty Blackbirds have been killed during control programs for Red-winged Blackbirds in agricultural areas in southern agricultural areas.

Rusty Blackbird Range

### DID YOU KNOW?

- Rusty Blackbirds usually nest alone or in small, loose colonies, and pair with the same mate every year.
- Blackbirds are some of the few migratory birds (along with pelicans, cormorants, and raptors) not protected by the *Migratory Birds Convention Act*.

## Short-eared Owl

*Asio flammeus*

### SPECIAL CONCERN (2008)

Short-eared Owls are owls of open country that are active in the daytime, especially at dawn and dusk. In Yukon, breeding is tied to population cycles of lemmings and voles, causing their distribution and numbers to change markedly from year to year. In southern Canada, large-scale destruction of native prairie grasslands has been particularly hard on them, and natural wetland drainage, urban expansion and increasingly intensive farming have contributed to their decline. They are exposed to danger from predators and agricultural machinery because they nest on the ground. Shooting, collisions with aircraft, trains, cars, barbed wire and farm machinery are added factors.

### Description

Short-eared Owls are medium-sized, long-winged owls with small, feather “ear tufts”, and black bands that frame their yellow eyes. Females are larger and darker with heavier streaking than males.

### Typical Habitat

- Nesting on the ground in grasslands, tundra, bogs, marshes and other open forest areas with abundant small mammals.

### Potential Threats

- There are limited threats to Short-eared Owls in Yukon. Their primary limiting factor is loss of their native habitat to agricultural crops or pastureland. However, these owls are sensitive to human disturbances during egg laying and incubation as females easily desert the nest if disturbed.

- The collision of adults with vehicles, utility lines and barbed-wire fences, may also contribute to population decline.
- Concentrations of pesticides, particularly organochlorines, have been detected in Short-eared Owl eggs; the effects of these contaminants are not yet well known.

### DID YOU KNOW?

- One of the best ways to identify a Short-eared Owl is to watch its distinct moth-like flight when hunting (deep wing-beats, occasional hovering, and cutting low over patches of grassland or marsh).
- Short-eared Owls are the only owls that build their own nests.
- They typically search for food during dusk and dawn.

## Why Do Species Become At Risk?

In the past, over-hunting and over-fishing were among the prime causes of wild species' declines—the stories of the beaver, the bison, and the great whales are all prime examples of this. But today, with better wildlife management, the main cause of the decline and disappearance of animals and plants **is the destruction and degradation of their habitats.**

Although Yukon's environment has been more fortunate than areas elsewhere in this regard, we have a real opportunity to learn from the lessons learned to the south.

**“Invasive” animals and plants** are another potentially serious problem to native wildlife. These are species that, for the most part, have come from other continents and have been introduced into Canada through human activity. Although many such exotic species

don't move much beyond parking lots or roadsides, some invade the territories of native wildlife species and replace them, or substantially alter and degrade their habitat. Yukon again has been fortunate to see very few of these exotic species so far.

Some animals are taking up and concentrating the **chemical contaminants** in their habitat or food. Still others face the threat of **exotic diseases and parasites.**

**Global climate change** is now acknowledged as real and accelerating, especially in Arctic regions. The effects are already apparent in the north, through permafrost melting and the disappearance of Arctic sea ice. Many Yukon species will be affected as the climate and environment change rapidly around them.

*“Invasive” animals and plants are another potentially serious problem to native wildlife.*

*In Yukon, a number of the unique species that thrived in the ice-free lands of Beringia during the Ice Ages had their habitats and ranges shrink drastically during the extreme climatic changes following that period.*

**Boreal Glasswort.** Photo: Bruce Bennett (YG)

Finally, some species are at risk because, for historical reasons, they are already very rare. In Yukon, a number of the unique species that thrived in the ice-free lands of Beringia during the Ice Ages had their habitats and ranges shrink drastically during the extreme climatic changes following that period. For example, the Baikal Sedge now lives only in a handful of dunes, and Yukon *Draba* lives only in a few meadows both only in southwest Yukon. These species were likely once more widespread, but now could be accidentally wiped out by human activity.

**Salt flats are home to a unique Boreal Glasswort.** Photo: Syd Cannings

## Why Should We Be Concerned?

Species extinction has occurred since life first appeared on Earth. When organisms are unable to adapt to changes in their natural environment, they die and others, better adapted to the new situation, take over. Why then should we be concerned about the disappearance of wildlife species today if extinction is the outcome of a natural process? The answer is twofold: first, it is happening at an alarming rate, and second, human-caused changes are largely to blame.

*An ecosystem is a natural community—like a forest, a grassland, or a marsh—in which all the species depend on one another and their environment. When one component of the ecosystem is modified, the entire balance of the community changes.*

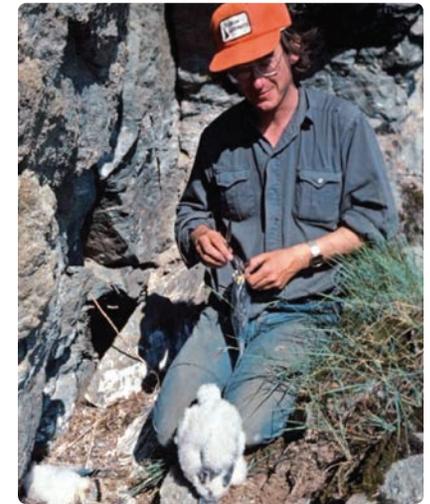

In the short term, there are also practical reasons for conserving wildlife species:

- Many Yukoners count on wildlife species for food, clothing, and as a source of spiritual inspiration.
- Wild animal and plant species are an important source of basic ingredients for traditional remedies and pharmaceutical formulations. Many plants have healing properties.
- Some Yukoners depend on the income they earn from activities like hunting, fishing, trapping, and nature tours that are closely tied to wild animals and plants.
- Plants, animals, and micro-organisms all play essential roles in the natural processes that keep Earth's atmosphere, climate, landscape, and water in balance. Humans depend upon ecosystems, too.
- The gene pool of wildlife species continues to provide basic materials often used to improve livestock and food crops. In genetic diversity is the strength to adapt and survive.
- Nature is beautiful and interesting. Our lives are enriched by it. Our artists and writers are inspired by it. We all lose when such beauty is lost.

## Peregrine Falcon - A Yukon Success Story

All is not doom and gloom—the status of certain species has improved, in some cases in a dramatic fashion. In the 1970s, things were not looking good for the Peregrine Falcon. This bird of prey had been declining as a result of the use of pesticides such as DDT, which had been banned in Canada since 1969. In 1975 it was estimated that only 34 breeding pairs remained in Canada. In 1978, the southern (*anatum*) subspecies of the Peregrine Falcon was designated Endangered by COSEWIC.

Dave Mossop, biology instructor at Yukon College and former ornithologist with the Yukon government, was closely involved with the work to save Peregrine Falcons. Dave saw the lowest number in Yukon between 1975 and 1980, when only one bird was found along the Yukon River. But in 1971, the Canadian Wildlife Service established a captive-breeding facility in Wainwright, Alberta. Chicks from these birds were then placed in the nests of breeding pairs of wild falcons, a technique called fostering. In 1978, the first

Gavin Johnston banding a young peregrine.  
Photo: Dave Mossop

captive-raised peregrine chicks were placed in nests in Yukon. Over the years, more than 1550 chicks were raised in captivity and released into the wild across Canada.

In 1995, only seventeen years after the first Yukon release, a survey conducted by 30 volunteers estimated that about 200 pairs of peregrines nested in the Peel River and Yukon River watersheds!

In 1999, the southern (*anatum*) subspecies was reclassified by COSEWIC as Threatened, a lower risk category. Then, in 2007, after examining the differences between the southern and tundra forms of peregrines, COSEWIC combined them and reassessed them together as Special Concern, a still lower risk category.

## Species Assessed As Not At Risk

### Mammals

- Beluga Whale, Eastern Beaufort Sea population (2004)
- Bearded Seal – Data Deficient (2007)
- American Black Bear (1999)
- Canada Lynx (2001)
- Northern Grey Wolf (1999)
- Ringed Seal (1989)

### Plants

- Narrow-leaved Wallflower (1993)
- Wood's Sagebrush (1997)
- Yukon Aster (1996)
- Yukon Goldenweed (1997)

### Fish & Amphibians

- Blackline Prickleback - Data Deficient (2003)
- Bull Trout, Upper Yukon Watershed population - Data Deficient (2012)
- Spoonhead Sculpin (1989)
- Columbia Spotted Frog (2000)

### Birds

- American Coot (1991)
- Bald Eagle (1984)
- Boreal Owl (1995)
- Common Loon (1997)
- Double-crested Cormorant (1978)
- Golden Eagle (1984)
- Great Grey Owl (1996)
- Gyrfalcon (1987)
- Merlin (1985)
- Northern Goshawk, atricapillus subspecies (1995)
- Northern Harrier (1993)
- Northern Hawk Owl (1992)
- Red-necked Grebe (1982)
- Red-tailed Hawk (1995)
- Rough-legged Hawk (1995)
- Sharp-shinned Hawk (1997)
- Snowy Owl (1995)
- Trumpeter Swan (1996)

**Data Deficient (DD)** - A category that applies when the available information is insufficient (a) to resolve a wildlife species' eligibility for assessment or (b) to permit an assessment of the wildlife species' risk of extinction.

**Not At Risk (NAR)** - A wildlife species that has been evaluated and found to be not at risk of extinction given the current circumstances.

(date of last assessment)

## Assessment History

- Bering Cisco – Data Deficient 1990, Special Concern 2004
- Bowhead – Assessed Endangered 1980, 1986, reassessed Special Concern 2005, 2009
- Caribou, Boreal Population – Threatened 2000, 2002, 2014
- Caribou, Northern Mountain population – Not At Risk 2000, Special Concern 2002, 2014
- Grey Whale – Not At Risk 1987, reassessed Special Concern 2004
- Grizzly Bear – Not At Risk 1979, Special Concern 2000, 2002, 2012
- Little Brown Myotis – Endangered 2012, 2013
- Northern Myotis – Endangered 2012, 2013
- Peregrine Falcon – Endangered 1978, Threatened 1999, 2000, Special Concern 2007
- Polar Bear – Not At Risk 1986, Special Concern 1991, 1999, 2002, 2008
- Short-eared Owl – Special Concern 1994, 2008
- Western Toad – Special Concern 2002, 2012
- Wood Bison – Endangered 1978, Threatened 1988, 2000, Special Concern 2013

## Get Involved!

*Stewardship is the management of spaces and species to ensure that they will be preserved for future generations of Canadians. It encompasses all kinds of habitat restoration and conservation initiatives.*

Everyone can help species at risk. First Nations and communities can get involved with stewardship and conservation efforts, while anyone can help by reporting sightings.

Yukon is a big place—everyone who gets out in the backcountry can add to our information base on the whereabouts and status of these Yukon species at risk.

You can use the form provided on the following page to record your sightings. Make sure you report them to:

Yukon Conservation Data Centre  
10 Burns Road  
Whitehorse, Yukon Y1A 4Y9

Ph. (867) 667-5331  
Fax. (867) 393-6263  
Toll - Free 1-800-661-0525 ex. 5331

Email: [yukoncdc@gov.yk.ca](mailto:yukoncdc@gov.yk.ca)

For more information on species at risk in Yukon,  
go to: [www.env.gov.yk.ca/sar](http://www.env.gov.yk.ca/sar)

## The Accord for the Protection of Species at Risk

In October 1996, federal, provincial and territorial ministers responsible for wildlife signed the *Accord for the Protection of Species at Risk* that lays out basic principles of national cooperation on species conservation as well as a number of strong commitments to monitor, assess, and protect species at risk. Under the Accord, the ministers recognized that intergovernmental cooperation is crucial to the conservation and protection of species at risk, that they must play a leadership role, and that complementary legislation and programs are essential to provide effective protection for species at risk and their habitats throughout the country. In September 1998, the ministers strengthened provisions of the Accord by placing greater emphasis and recognition on stewardship.

*The federal Species at Risk Act lists species extirpated (extinct in Canada but occurring elsewhere), endangered, threatened, or of special concern.*

### The federal Species at Risk Act

The federal *Species at Risk Act* lists species Extirpated (extinct in Canada but occurring elsewhere), Endangered, Threatened, or of Special Concern. Under the *Species at Risk Act*, species can receive protection for their residences (e.g. nest or den) and their critical habitats. Species listed as species of Special Concern have their habitats managed through development and implementation of management plans.

The purposes of the *Species at Risk Act* are:

- 1) to prevent wildlife species from becoming extinct or extirpated;
- 2) to help recover extirpated, endangered and threatened species; and
- 3) to ensure that species of special concern do not become endangered or threatened.

For more information visit:  
[www.sararegistry.gc.ca](http://www.sararegistry.gc.ca).

## Who Decides Which Wildlife Are “At Risk” in Canada? (The Listing Process)

On the national stage, there are two steps involved in determining whether a species is “at risk” under the *Species at Risk Act*.

1. **Assessment:** The Committee on the Status of Endangered Wildlife in Canada (COSEWIC) is a group of scientists and traditional knowledge specialists that assesses the biological status of species and assigns each one a conservation status. COSEWIC makes a recommendation on risk level to the Canadian (federal, provincial and territorial) ministers responsible for fish and wildlife who, in turn, advise the federal minister on a course of action.

All species recommended by COSEWIC to be listed as at risk or of special concern make up the **COSEWIC list**.

2. **Legal Listing:** After receiving COSEWIC’s recommendations and consulting with stakeholders, the federal minister decides whether or not to add species to the legal list of species at risk in Canada under the *Species at Risk Act (SARA)*.

This booklet highlights both **SARA** and the **COSEWIC** list of species found in Yukon. The full list is on page 3.

Yukon Wild Buckwheat (*Eriogonum flavum* var. *aquilium*) is only known from Yukon and Alaska. It will be assessed by COSEWIC in 2017. Photo: Adolf Ceska

## Categories Of Species At Risk

Species at risk are listed in one of seven primary categories:

**Extinct:** a wildlife species that no longer exists anywhere in the world

**Extirpated:** a wildlife species that no longer exists in the wild in Canada, but exists elsewhere

**Endangered:** a wildlife species that is facing imminent extirpation or extinction

**Threatened:** a wildlife species likely to become an endangered species if nothing is done to reverse the factors leading to its extirpation or extinction

**Special Concern:** a wildlife species that may become a threatened or an endangered species because of a combination of biological characteristics and identified threats

**Data Deficient:** a wildlife species for which the available information is insufficient to resolve the species' eligibility for assessment or to permit an assessment of its risk of extinction.

**Not At Risk:** a wildlife species that has been evaluated and found to be not at risk of extinction given the current circumstances

## Funding Programs

The federal government has funding programs to assist communities and organizations with species at risk issues.

### Habitat Stewardship Program

The Habitat Stewardship Program for Species at Risk ([www.recovery.gc.ca/hsp-pih](http://www.recovery.gc.ca/hsp-pih)) provides funding to non-governmental organizations, aboriginal organizations, communities, individuals, the private sector, and government to support the conservation and recovery of species at risk and their habitats.

### Aboriginal Funds for Species at Risk

The Aboriginal Funds for Species at Risk ([www.recovery.gc.ca/AFSAR-FAEP](http://www.recovery.gc.ca/AFSAR-FAEP)) helps build capacity in Aboriginal communities and organizations for their participation in the implementation of the Species at Risk Act, and to support Aboriginal involvement in activities that protect or conserve habitats for species at risk.

### A SUCCESS STORY

*From a breeding population of less than 200 birds in 1933, the Trumpeter Swan was delisted as Not At Risk in 1996.* Photo: Yukon Government
