

Figure 51. Schematic structural transect of the project area southwest of Tintina fault. The same allochthonous rocks rest above autochthonous strata, but different features are present in the northeast and southwest regions. In the northeast the allochthonous slice rests on an imbricated, but unmetamorphosed, stratigraphic stack. To the southwest the allochthonous rocks structurally overlie metamorphosed and intruded autochthonous strata, and are deformed with them [original figure].
