## EXECUTIVE SUMMARY

BMC Minerals (No.1) Ltd. (BMC) is proposing to develop the Kudz Ze Kayah (KZK) Project (the Project), which is located approximately 110 km southeast of Ross River, Yukon territory. BMC's Project Proposal for the Project and is currently undergoing a Screening Assessment by the Yukon Environmental and Socio-economic Assessment Board's (YESAB) Executive Committee, under the *Yukon Environmental and Socio-economic Assessment Act*. During the Adequacy stage of the Assessment, YESAB requested that BMC submit a number of updated water related reports, prior to YESAB preparing the draft Screening Report. Subsequently, this 2017 Hydrogeology Baseline report is an update to the 2016 Hydrogeology Baseline Report (AEG, 2017) that was submitted as Appendix D-3 of the Project Proposal (BMC, 2017). This report builds upon the hydrogeology baseline information collected by Tetra Tech EBA Inc. (EBA) during 2015 and reported in the document entitled *2015 Baseline Hydrogeology Assessment Kudz Ze Kayah, Yukon* (EBA, 2016).

New information presented in this update report includes:

- Data from quarterly groundwater sampling March, June, September, and November 2017 by AEG at 32 bedrock and overburden monitoring wells (total of four sampling events);
- Refined baseline water quality characterization using all water chemistry data collected during 2015, 2016, and 2017; and
- Evaluation of groundwater level elevations across the site using information from all three years of data collection.

The 2017 data were compiled by AEG and combined with data from the 2015 and 2016 field work presented in EBA (2016). Additionally, the data collected by Cominco Ltd. (Cominco) as part of the Initial Environmental Evaluation (Cominco, 1996) in the 1990's is also presented within this report.

The principal hydrogeologic units at KZK are bedrock and overburden. The overburden consists of two subunits:

- Fine-grained lower permeability sediments composed of silts and fine sands; and
- Coarse-grained higher permeability sands and gravels.

In the depth range of 10 m to 70 m below ground surface, the bedrock hydraulic conductivity generally ranges from  $1 \times 10^{-7}$  m/s to  $1 \times 10^{-5}$  m/s and does not appear to exhibit a trend of increasing or decreasing hydraulic conductivity with depth. The geometric mean of short-term tests conducted in bedrock is  $1.2 \times 10^{-6}$  m/s, which is similar to the results of a longer term bedrock pumping test ( $1.7 \times 10^{-6}$  m/s).

For tests conducted in the fine-grained overburden, the measured hydraulic conductivities have a geometric mean of  $5.2 \times 10^{-6}$  m/s. Based on two field tests, including a 2015 long-term pumping test conducted by EBA, the hydraulic conductivity of the coarse-grained overburden is about  $1.3 \times 10^{-4}$  m/s.

Continuous groundwater level monitoring was conducted in eight monitoring wells across the site from mid-November 2015 through November 2017. With varying levels of intensity, the water levels in both bedrock and overburden wells exhibited the following seasonal trends:

- Rising water levels through the summer months (approximately May to August);

- Peak water levels reached between August and September, depending on the year;
- Falling water levels through the winter months (approximately October to March); and
- Lowest levels reached between April and May, depending on the year.

In most monitoring wells, the maximum-minimum water level difference ranged between 2 m and 8 m; the maximum observed difference was 14 m.

Project wide, the groundwater field pH ranged from circumneutral to slightly alkaline (5.68 to 8.63, or an average value of 7.5) for both bedrock and overburden wells. Monitoring wells MW15-10S and MW15-10D had lower pH values compared to the average site pH, with a range of 5.8 to 6.46, and 5.82 to 6.43, respectively. These two wells are located near the KZ-9 east seep, which is also characterized by low pH water (pH 5.8 to 6.0), suggesting groundwater found in wells MW15-10S and MW15-10D are fed from the same source as this seep.

Water quality results were compared against the Yukon Contaminated Sites Regulation Standards, which indicated a few exceedances for dissolved cadmium and cobalt, and single exceedances of dissolved arsenic and zinc. Sulphate and fluoride concentrations were generally higher in the wells screened in bedrock compared to overburden; however, the concentrations of other anions, nutrients, and metals did not show marked differences between overburden and bedrock wells. Groundwater sampled in the ABM open pit area generally returned higher anion, nutrient, and metal concentrations than groundwater sampled elsewhere on the KZK property. Groundwater concentrations of cadmium, iron, and zinc were elevated in the ABM open pit area relative to the rest of the KZK property, likely due to the subsurface mineralization present in this area. Additionally, sulphate concentrations were typically more elevated within the pit area, likely due to the oxidation of the sulphidic minerals in the deposit.

## GLOSSARY

**Chain of Custody:** paperwork that chronologically documents the collection, transportation, processing, and analysis of a sample.

**Detection Limit:** the lowest quantity of a constituent that can be distinguished from the absence of that constituent using the analytical technique employed, generally at a 1% confidence limit (i.e. it is the smallest amount of a constituent that can be measured with a 99% certainty of detection).

**EQWin:** database management software that is used to archive and interrogate water quality data collected for the Kudz Ze Kayah Project.

**Initial Environmental Evaluation:** document produced by Cominco Ltd. in 1996 that summarizes baseline studies at the Kudz Ze Kayah property, describes the baseline information, Mine plan, waste material characterization, closure plan, environmental management, potential impacts and associated mitigation measures, and socio-economic impacts associated with the Project as it was defined in 1996.

**Oxidation-reduction Potential:** a measure of how oxidizing or reducing a water sample is and can shed light on the geochemical conditions of the water body from which the water sample was collected.

**Practical Quantification Limit:** defined here as five times the detection limit.

**Relative Percent Difference:** calculated as the difference between the constituent concentrations of two replicate samples divided by the average of the two constituent concentrations, expressed as a percentage.

**Theis Equation:** presented in Theis (1935) as a method for estimating the transmissivity and storativity of an aquifer using drawdown data from a pumping/recovery test.

## 1 INTRODUCTION

BMC Minerals (No.1) Ltd. (BMC) is proposing to develop the Kudz Ze Kayah (KZK) Project (the Project), which is located approximately 110 km southeast of Ross River, Yukon territory. BMC's Project Proposal for the Project and is currently undergoing a Screening Assessment by the Yukon Environmental and Socio-economic Assessment Board's (YESAB) Executive Committee, under the Yukon Environmental and Socio-economic Assessment Act. During the Adequacy stage of the Assessment, YESAB requested that BMC submit a number of updated water related reports, prior to YESAB preparing the draft Screening Report. Subsequently, this Hydrogeology Baseline report is an update to the 2016 Hydrogeology Baseline Report (AEG, 2017) that was submitted as Appendix D-3 of the Project Proposal (BMC, 2017).

The Project is located approximately 260 km northwest of Watson Lake and 110 km southeast of Ross River (Figure 1- 1). Access to the Project is via a 24 km long, all weather, single lane gravel Tote Road that connects the Project to the Robert Campbell Highway. The Project is in the northern foothills of the Pelly Mountains of the Yukon Plateau and in the Finlayson Creek watershed.

In March 2015, a gap analysis was undertaken by Tetra Tech EBA Inc. (EBA) to review the historic baseline groundwater quality data available. Based on the review of historical data and current regulatory requirements, a baseline water quality program was designed to update the dataset and fill in any data gaps. The baseline hydrogeology program was implemented in May 2015 and is ongoing. This report summarizes the data collected up to November 2017

Site activities performed to date for the Project have primarily been exploration activity and associated infrastructure (accommodation, offices, core storage, and equipment laydown areas). Subsequently, the baseline groundwater monitoring program documents the natural background chemistry of the groundwater and flow paths in the Project's local and regional study area.

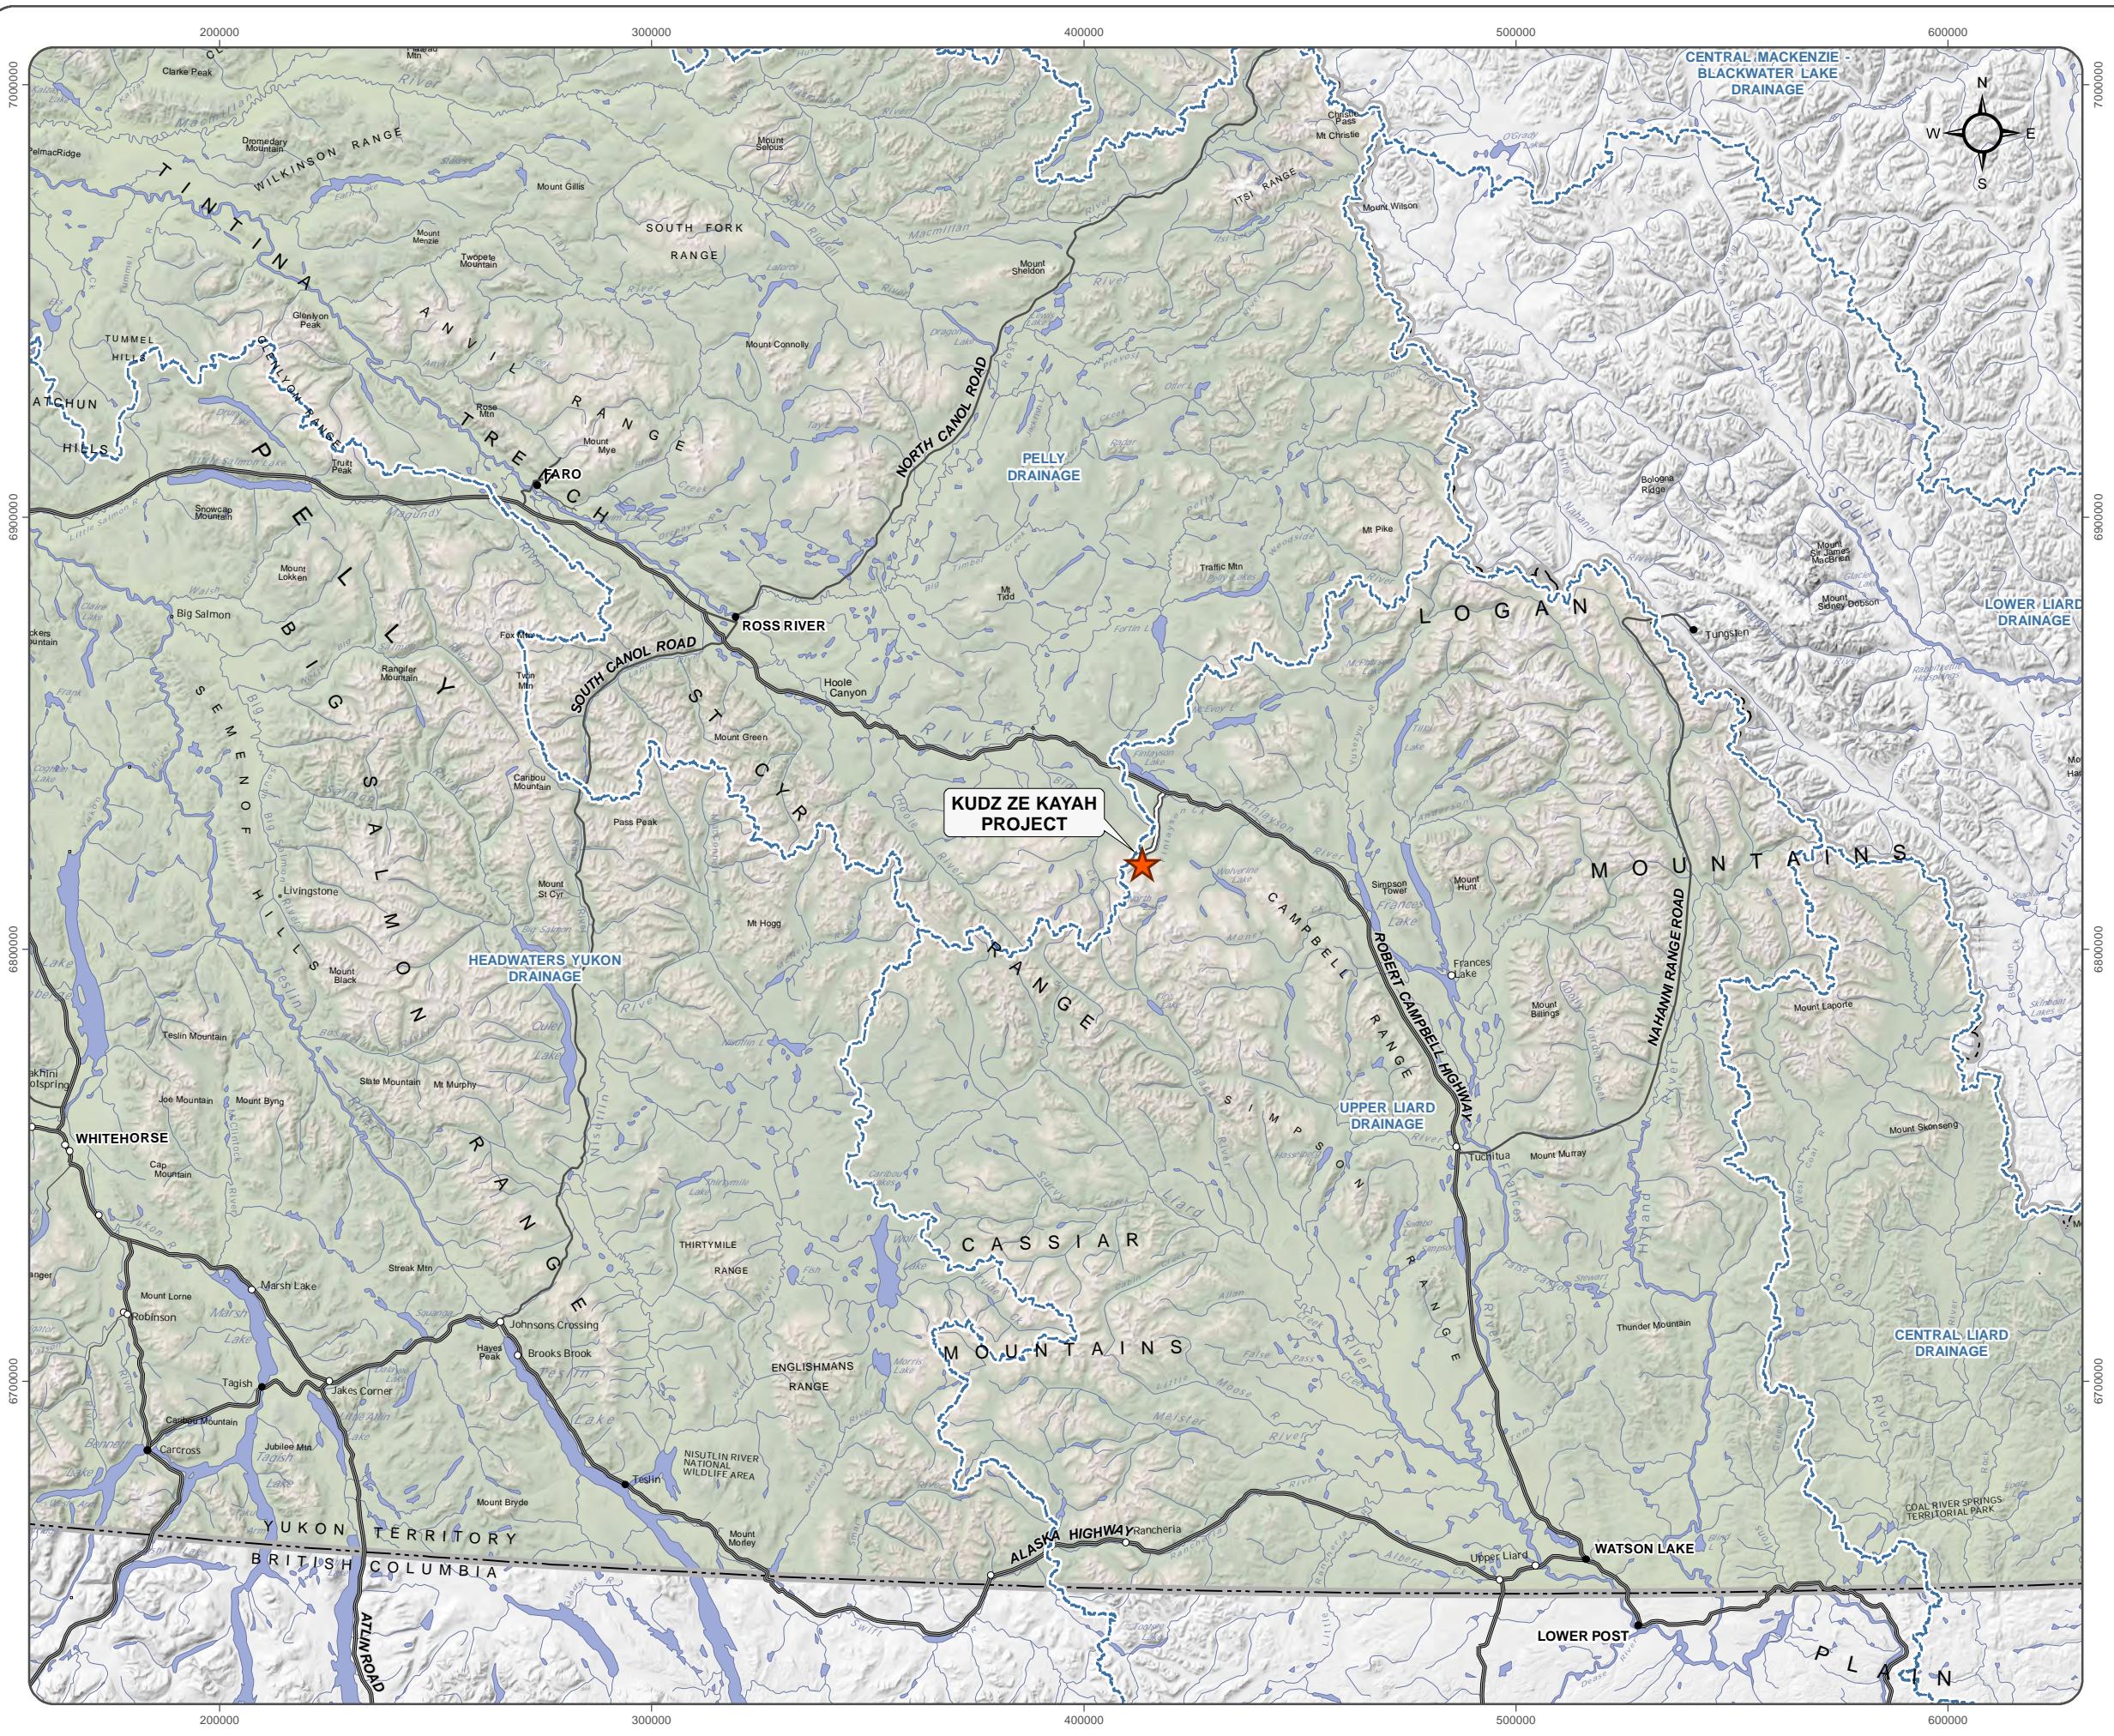

### 1.1 SCOPE OF 2017 BASELINE PROGRAM

Groundwater monitoring at KZK was initiated in 1995 by Cominco Ltd. (Cominco) through the installation of 40 groundwater piezometers. During September 1995, Cominco performed water level monitoring in the piezometers and some open exploration boreholes, and minor water quality sampling at 11 wells. These results are summarized in Section 1.2, which is based on the information provided in Section 3 of the Initial Environmental Evaluation Kudz Ze Kayah Project, Yukon Territory (Cominco Ltd., 1996). During 2015/2016, EBA performed hydraulic testing and groundwater sampling (May, August, September, November 2015 and March 2016. The 2015 Baseline Hydrogeology Assessment Kudz Ze Kayah, Yukon (EBA, 2016) also includes the 1995 Cominco data. AEG took over sampling in May 2016 and the program is ongoing.

The scope and purpose of this AEG report is to update to the AEG 2016 baseline report (AEG 2017) and EBA baseline report (EBA, 2016) with 2017 data to support BMC's Project Proposal submission to YESAB.

The 2017 scope of work included the following:

- Quarterly groundwater sampling in March, June, September, and November 2017 by AEG at 32 bedrock and overburden monitoring wells (total of seven sampling events);
- Update and refine the baseline water quality characterization using all water chemistry data collected during 2015 to 2017; and
- Evaluate groundwater level elevations across the site.

## 1.2 HISTORICAL DATA

During 1995 a geotechnical and hydrogeological site investigation was conducted by Golder Associates Ltd. (Golder) with the purpose of characterising the hydrogeology around the proposed open pit, Class B Storage Facility, Class C Storage Facility, and four optional tailings dam locations. The investigation also addressed mine dewatering requirements for the ABM open pit and identified a process water source (Golder, 1996a, 1996b).

### 1.2.1 1995 Hydrologic Investigation

Forty piezometers, listed in Table 1-1, were installed to target the originally proposed site infrastructure. Water levels were measured in the piezometers, as well as selected open exploration boreholes.

**Table 1-1: 1995 Piezometer Installations**

During (or shortly after) the drilling of select boreholes, single-well rising and falling head slug tests were performed by Golder to characterize the hydraulic conductivity of overburden, upper fractured bedrock, and deeper massive bedrock. Table 1-2 presents a summary of the 1995 test results (Golder, 1996a).

**Table 1-2: 1995 Hydraulic Conductivity Testing by Golder Associates**

| Soil/Rock Type          | Borehole ID | Hydraulic Conductivity (K) <sup>1</sup><br>m/s | Soil/Rock Description                    | Geometric Mean       |
|-------------------------|-------------|--|--|----------------------|
| Overburden              | BH95G-21S   | $8.35 \times 10^{-7}$                          | Silty SAND some gravel (TILL)            | $4.1 \times 10^{-6}$ |

<sup>1</sup> Depth of hydraulic testing, methodology of test and subsequent analysis, and raw data were unavailable to confirm results. These results are as reported in Feasibility Level Mining Geotechnical Design Criteria for the ABM Deposit (Golder, 1996a).

In the 2015 *Baseline Hydrology Assessment, Kudz Ze Kayah, Yukon* (EBA, 2016), EBA provides the following summary of the Golder conceptual model:

*The conceptual hydrogeological model created by Golder expected the groundwater table to generally mimic topography, with the groundwater table located near surface in the valley bottom and greater than 200 m below the mountains. They anticipated the groundwater table to be within the competent and fractured bedrock on the valley flanks and in the overburden in the valley bottoms. They found that the groundwater flows from the mountains to the valley bottoms. Artesian conditions encountered in the valley bottom indicated discharging groundwater, which is the result of the steep topography and upward hydraulic gradients.*

### 1.2.2 1995 Groundwater Quality Investigation

In 1995, a single round of groundwater sampling was conducted on September 4<sup>th</sup> to characterise the baseflow of Geona Creek and South Creek (Cominco, 1996). Groundwater was sampled at 11 sites, from a combination of wells and exploration boreholes (Table 1-3 and Table 1-4). A complete description of the 1995 groundwater quality program and results is summarized by EBA in the 2015 *Baseline Hydrogeology Assessment, Kudz Ze Kayah, Yukon* (EBA, 2016) and is provided below:

*One piezometer below the proposed tailings dam (BH95G-13D), and two in the area of the proposed open pit (BH95G-26 and BH95G-29) were sampled, and analyzed for a range of non-metal "general parameters" as well as total and dissolved metals. The general parameters included pH, conductivity, suspended solids, dissolved solids, hardness, alkalinity, nitrogen species, phosphorous and sulphate. Three other piezometers, located on the north and south sides of the open pit (BH95G-21 and BH95G-23), and west of the proposed Class C Storage Area (95G-31) were also sampled. These samples were analyzed for total and dissolved metals only. Flowing exploration boreholes were sampled including one each on the north and south sides of the open pit (T94-23 and T94-49). These samples were analyzed for general parameters and total and dissolved metals. Three other borehole samples (T94-14, T94-26 and T94-30) were analyzed for total and dissolved metals only. All of the exploration boreholes were cased through the overburden, and are open for the remaining length of the borehole in bedrock.*

*Analytical results showed that groundwater chemistry was similar to surface water chemistry (Table [1-3]). The groundwater pH was similar to that of surface water. Alkalinity, total dissolved solids and hardness were slightly higher in groundwater than in surface water. Sulphate concentrations were variable, with two wells (one shallow, one deep) having sulphate concentrations more than double the concentrations in surface water and the remaining three having similar concentration to surface water. Concentrations of nitrate, nitrite and ammonia were generally low except for a moderate level of nitrate-N (0.13 mg/L) in shallow well BH95G-26. The two shallow*

overburden wells (BH95G-26 and BH95G-29) had phosphorus concentrations an order of magnitude or more above those measured in surface water. Metal concentrations in both shallow and deep groundwater were low. In particular, copper and lead concentrations in all groundwater samples were equal to or lower than the concentrations in surface water. Exceptions to the pattern of low metals were elevated concentrations of arsenic and iron in the three deep bedrock wells within the orebody (T94-49, T94-30 and T94-13) and elevated arsenic, iron, cadmium and zinc in one overburden well.

The deep well (T94-49) with the highest arsenic and iron concentrations (170 µg/L and 4300 µg/L, respectively) also had elevated sulphate (71.4 mg/L) and the lowest pH and alkalinites of any of the wells measured. Zinc was also somewhat elevated (160 µg/L). Sulphate, pH and alkalinity were not measured in the shallow well that had elevated arsenic, iron, cadmium and zinc (BH95G-23).

**Table 1-3: Historical Water Quality Summary**

| Borehole  | Location        | Well Screen<br>(mbgs) | Flowing | Analyses              |        | Field Measurements <sup>1</sup> |                 |              |              |

<sup>1</sup> Data from Cominco (1996)

## 2 METHODOLOGY

### 2.1 MONITORING WELLS

Through 2015 and 2016 there were 44 groundwater wells in the Project monitoring network. In 2017 this was reduced to 32 wells to reflect the change in the proposed Project footprint, as well as removing wells that were inoperable. The current well network is made up of a combination of wells installed by Cominco in 1995 (now refurbished), and new wells installed in 2015 by EBA and 2016 by Knight Piésold Ltd. (KP). The 1995 wells are constructed with unthreaded 1¼ inch schedule 80 PVC pipe and the 2015/2016 wells are constructed with unthreaded 1¼ inch schedule 40 PVC pipe. The PVC well screens are slotted and have lengths ranging from 1.70 m to 14.6 m. The wells have sand packs, bentonite pellet seals, and above-ground steel well protectors. The well casings are sealed with either J-plugs or pressed-on PVC caps. Twelve wells are dual completions with a bentonite seal between two screened intervals. The well completion information is summarized Table 2-1, and well locations are shown on Figure 2-1.

## 2.2 FIELD METHODOLOGY

### 2.2.1 Well Development

All wells were developed using the following methodology:

1. Waterra tubing, equipped with a foot valve, was inserted into the well and pulled up from the bottom approximately 0.5 m;
2. The tubing was connected to an inertial Waterra pump, fixed to the well protector;
3. Water was pumped from the well at the maximum operating speed of the pump;
4. A minimum of five to seven well volumes were removed from the well;
5. Field chemical parameters (pH, specific conductance, oxygen reduction potential (ORP), dissolved oxygen, and temperature) were measured at regular time intervals during pumping;
6. Turbidity (water clarity) was visually observed throughout development; and
7. Development was deemed complete when the field parameters had stabilized and there was minimal visual turbidity. Development generally continued until the pumped water was clear; however, if this was not possible, additional water volumes were purged until there was no visible change in turbidity.

### 2.2.2 Groundwater Level Measurements

As part of monitoring program, water-level measurements were made in all monitoring wells. In most wells, the depth-to-water (in metres below top of PVC casing) was measured using an electric water-level sounder. Based on the surveyed top-of-casing elevations, the depth-to-water measurements were converted to piezometric (hydraulic head) elevations in metres above sea level (masl). These measurements were performed prior to any groundwater collection disturbances such as purging or sampling.

In eight wells, water levels were continuously monitored using submerged pressure transducers and dataloggers. The accuracy of these measurements was corroborated by periodic hand measurements. Two boreholes (K15-200 and K15-248) were completed with multiple *grouted-in* vibrating wire pressure transducers that were positioned at different depths to provide vertical piezometric profiles (that is, hydraulic head elevation versus depth below ground surface). Dataloggers for the submerged transducers and vibrating wire transducers were downloaded during each field trip and the data were transferred to spreadsheets to generate water-level hydrographs expressed in masl.

As described in EBA (2016), all 2015 monitoring wells and exploration hole collars were surveyed by Challenger Geomatics using professional surveying equipment with an absolute vertical accuracy of about  $\pm 0.03$  m. The coordinates of the monitoring wells installed during 2016 were located by KP using a real-time kinematic differential GPS unit with an accuracy of  $\pm 4.0$  m. Elevations were then taken from a topographic map with 1.0 m contours provided by BMC in February 2016.

Groundwater sample collection procedures at all monitoring wells followed the AEG established *Standard Data Collection Protocol for Groundwater Monitoring Well Sampling*, which conforms to the Yukon Environment's Contaminated Sites Regulation, Protocol #7 (YG, 2011). An overview of the sampling process is presented in this section.

Prior to sampling, the static water level is measured in the well using an electric sounder. Groundwater quality samples are collected after a minimum of three well volumes have been purged from the well. Field parameters (pH, specific conductance,

oxidation reduction potential (ORP), dissolved oxygen, and temperature) are measured after each well volume have been removed using a YSI Professional Plus multimeter and then compared to previous measurements to assess water chemistry stabilization.

After the field parameters have stabilized, the groundwater samples are collected. In order to maintain the chemical integrity of the samples, AEG employs quality assurance/quality control (QA/QC) practices during collection. This includes wearing clean, disposable nitrile gloves during collection and placing the water sample in laboratory grade bottleware provided by the analytical laboratory specific to the analyte(s) being tested. Dissolved mercury and dissolved organic carbon parameter water samples are filtered using a 45 µm filter in the field at the time of sample collection. Dissolved metals are collected in falcon tubes and are filtered and preserved by the laboratory. Preservatives are added to bottled samples for measuring total mercury, dissolved mercury, dissolved organic carbon, and nutrients as directed by the laboratory. The samples are packed on ice in a cooler and shipped to the laboratory via courier with an accompanying chain of custody (COC) form specifying the analyte(s) to be tested.

### **2.2.3 Hydraulic Well Testing**

Short-term pumping/recovery tests were performed by AEG in seven new monitoring wells installed during 2016. The following test procedure was followed at each well:

- The depth-to-water was measured using an electric sounder;
- A Solinst M2 levelogger was set to a one second measurement interval and submerged below water in the well. The levelogger hung securely from stainless steel cable;
- Waterra tubing equipped with a foot valve was installed down the well and positioned just above the levelogger;
- The Waterra Powerpack inertial pump was installed at the top of the protective well casing, and the tubing was secured;
- The equipment was left untouched for a minimum of five minutes to allow the water level in the well to recovery back to static;
- The pump was turned on and operated at its maximum flow rate for 20 to 30 minutes;
- During pumping the discharge rate was measured every five minutes by measuring the time to fill a 500 mL measuring cup;
- The pump was then shut off and without removing any equipment from the well, water level recovery was monitored by the levelogger for approximately 20 minutes; and
- All equipment was removed from the well and the levelogger data were downloaded to a laptop computer.

During the 2016 drilling of geotechnical test holes, KP performed 52 single- and straddle-packer injection tests in bedrock open boreholes. The procedures used to perform these tests and the associated data analyses are provided in KP (2016).

## **2.3 WATER CHEMISTRY ANALYSIS**

Groundwater samples were collected between May of 2015 and November of 2017. Samples were analyzed for the following field and laboratory parameters:

Field parameters

- pH;
- Specific conductance;
- Temperature;
- ORP;
- Dissolved oxygen; and
- Turbidity.

#### Laboratory parameters

- pH;
- Specific conductance;
- Major anions (chloride, fluoride, sulphate, nitrate, nitrite, phosphate)
- Alkalinity and acidity;
- Ammonia;
- Dissolved organic carbon (DOC);
- Hardness; and
- Metals package - dissolved concentrations (including phosphorous and mercury).

A subset of field duplicates was collected during each sampling event to evaluate replication of sampling procedures and laboratory accuracy. All laboratory analyses were performed by Maxxam Analytics International Corp. (Maxxam). Maxxam is an accredited International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC) 17025 testing laboratory located in Burnaby, British Columbia. Maxxam is certified by the Canadian Association for Environmental Analytical Laboratories (CAEAL). The certificates of analysis provided by Maxxam for the 2017 samples are provided in Appendix F. The certificates of analysis for 2015/2016 are located in EBA (2016) and AEG (2017). A summary of the laboratory analysis technique used for each parameter is presented in Table 2-2.

**Table 2-2: Analytical Methods used in the Laboratory**

| Parameter                                   | Analytical Method  | Source Method  |
|---|--|--|
| Acidity                                     | Titration  | 2310 B (Rice et al., 2012)   |
| Alkalinity                                  | Titration  | 2320 B (Rice et al., 2012)   |
| Dissolved Organic Carbon                    | Persulphate Oxidation  | 5310 C (Rice et al., 2012)   |
| Chloride                                    | Automated Colourimetry   | 4500-Cl- G (Rice et al., 2012)                                     |
| Fluoride                                    | Ion Specific Electrode   | 4500-F C (Rice et al., 2012)                                       |
| Sulphate                                    | Automated Colourimetry   | 4500-SO42- E (Rice et al., 2012)                                   |
| Phosphorus                                  | Ascorbic Acid Method (Colourimetry)  | 4500-P E (Rice et al., 2012)                                       |
| Nitrite-N                                   | Cadmium Reduction Flow Injection   | 4500-NO3- I (Rice et al., 2012)                                    |
| Nitrate-N                                   |  | 4500-NO3- I (Rice et al., 2012)                                    |
| Ammonia-N                                   | Automated Phenate (Colourimetry)   | 4500-NH3- G (Rice et al., 2012)                                    |
| Dissolved Metals (34 elements) <sup>1</sup> | Major elements using Inductively Coupled Plasma – Optical Emission Spectrometry (ICP-OES), and Trace elements using Collision Reaction Cell Inductively Coupled Plasma – Mass Spectrometry (CRC ICP- MS) | CRC ICP-MS USEPA Method 6020 ICP-OES EPA Method 6010 (USEPA, 2007) |
| Dissolved Mercury                           | Cold Vapour Atomic Fluorescence  | BCMOE (2013)   |

<sup>1</sup>: CRC ICP-MS scan includes: Al, Sb, As, Ba, Be, Bi, B, Cd, Ca, Cr, Co, Cu, Fe, Pb, Li, Mg, Mo, Ni, P, K, Se, Si, S, Ag, Na, Sr, Tl, Sn, Ti, U, V, Zn, & Zr.

## 2.4 QUALITY ASSURANCE/QUALITY CONTROL (QA/QC)

### 2.4.1 Groundwater Sampling QA/QC

QA/QC practices in the groundwater monitoring program follow the methods described in AEG's Protocols and in *Standard Methods for Examination of Water and Wastewater* (Rice et al., 2012). The monitoring program includes a comprehensive QA/QC program to ensure validity of the data collected including the establishment of data quality objectives and documentation of sample variability due to natural variability and analytical variability. The QA/QC program includes the following:

- All field staff are familiar with and follow work methods for groundwater monitoring and sample collection that are based on generally accepted best industry practices (Rice et al., 2012). The sampling procedures include measures to avoid sample contamination in the field during sample collection, as well as during sample handling and shipping;
- Blind field duplicates are collected at a rate of one duplicate per 10 samples collected. The field duplicates are clearly linked to one of the monitoring wells on sampling logs and field notes, but not on the chain of custody forms;
- A field and travel blank are collected for each monthly sampling event;
- All samples are sent to Maxxam in Burnaby, BC, a Canadian Association for Laboratory Accreditation member, for analysis. The laboratory also conducts an internal QA/QC program, including split duplicates (one per 10 samples); and
- Following each sampling event, AEG conducts a review of all analytical results and QA/QC results received from the laboratory to ensure data quality and to flag any potential issues (e.g., data quality issues from the information provided by the lab, conduct an ion balance for each sample – typically ≤10% is acceptable, etc.). Additionally, the QA/QC program includes a review of the relative percent difference in duplicates and parameters measured in field blanks and trip blanks to assess data quality.

Relative Percent Difference (RPD) was used to determine field variability and is equal to the difference between the sample and duplicate value, divided by the average of the sample and duplicate value, and expressed as a percent. When RPD was greater than 25%, a subsequent check was performed against the laboratory detection limit (DL) to establish if the practical quantitation limit (PQL) was met. The PQL is five times the DL and is defined as the minimum concentration that can be measured within specified limits of precision and accuracy. Both results need to be above the PQL for the analyte to be considered to be 'meeting the PQL'. If one result from the sample or duplicate is  $>5\times$  DL and one result is  $<5\times$  DL, then the 'PQL is not met'. An analyte with results below the PQL indicates that the parameter being analyzed is not present in a sufficient amount to be reliably quantified. Typically, as parameters approach their detection limit, higher variability is more likely to occur. A RPD  $>25\%$  is flagged for further comment or consideration.

## **2.4.2 Laboratory Quality Control Sample Analysis**

Overall quality control sample analysis from method blanks, laboratory duplicates, matrix spikes, and blank spikes met the Maxxam acceptability criteria and consequently the data were issued.

## **2.4.3 Field Variability**

During the 2017 monitoring program field duplicates were collected to measure field variability between simultaneous grab samples. A total of nine field duplicates were collected during the quarterly sampling events between March 2017 and November 2017. For all nine field duplicates, analytes with RPD  $>25\%$  and meeting the PQL are provided in Table 2-3, while analytes that were  $>25\%$  and did not meet the PQL are listed in Table 2-4. In general, relative to each other the simultaneous grab samples have low variability. Dissolved trace metals and ammonia exceeded the 25% RPD threshold in between one and three of the nine duplicate samples. In general, these RPD exceedances were not excessive (typically 27% to 47% RPD; Table 2-3) and were not restricted to any particular constituent, sampling event or monitoring well, suggestive of natural variability at any given sampling location. That one third of the ammonia-N duplicate results returned an RPD  $>25\%$  might suggest that this parameter may have more marked natural variation than other analytes; however, only 10% of the 20 duplicates collected during the 2016 sampling program returned ammonia-N concentrations that had an RPD  $>25\%$  and met the PQL (AEG, 2017).

**Table 2-3: Duplicate Analytes with RPD  $>25\%$  and Meeting the PQL**

| Analyte                  | Number of times RPD $>25\%$ and PQL met | RPD           | Analyte                   | Number of times RPD $>25\%$ and PQL met | RPD       |
|--------------------------|---|---------------|---------------------------|---|-----------|
| Aluminum (Al), dissolved | 2                                       | 44%, 88%      | Lead (Pb), dissolved      | 1                                       | 32%       |
| Ammonia (N)              | 3                                       | 35%, 39%, 44% | Manganese (Mn), dissolved | 1                                       | 37%       |
| Antimony (Sb), dissolved | 1                                       | 27%           | Nickel (Ni), dissolved    | 1                                       | 28%       |
| Copper (Cu), dissolved   | 2                                       | 29%, 47%,     | Zinc (Zn), dissolved      | 2                                       | 32%, 106% |

**Table 2-4: Duplicate Analytes with RPD >25% and Not Meeting the PQL**

| Analyte                  | Number of times RPD >25% and PQL not met | Analyte                        | Number of times RPD >25% and PQL not met |
|--------------------------|--|--------------------------------|--|
| Aluminum (Al), dissolved | 3  | Cyanide, Weak Acid Dissociable | 1  |
| Ammonia (N)              | 3  | Dissolved Organic Carbon       | 1  |
| Antimony (Sb), dissolved | 3  | Fluoride                       | 4  |
| Arsenic (As), dissolved  | 1  | Phosphorus (P), dissolved      | 3  |
| Chloride                 | 2  | Thallium (Tl), dissolved       | 2  |
| Cobalt (Co), dissolved   | 2  | Total Acidity                  | 2  |
| Copper (Cu), dissolved   | 1  | Zinc (Zn), dissolved           | 1  |

#### 2.4.4 Field and Travel Blanks

Additional field quality control samples include field blanks and trip blanks, where de-ionized water is handled, processed and analyzed in the same manner as the site water samples. Blanks can provide an indication of sample contamination occurring in the field (field blank) or lab (method blanks) and at any point in between (trip blanks). Concentrations of parameters should not be detectable, though a PQL of >2 times the reportable detection limit allows for slight “noise” around the detection limit.

Field blanks were processed by taking de-ionized water (analyte free media) to the sample station, opening it and exposing it to ambient air and ‘collecting’ it in the sample bottles. These samples were treated the same as the actual water samples, preserved and filtered as necessary, and their analysis can provide an indication of contamination that may be affecting the actual samples.

Four field blanks were collected between March 2017 and November 2017. Field blank analytes with concentrations >2 times the DL are shown in Table 2-5. Dissolved antimony, nitrate, and nitrite were detected at 2.8 to 3.1x their respective detection limits in the field blanks. These results are not considered concerning given the concentrations detected were only marginally above the 2x threshold and were limited to very few parameters. Furthermore, the trip blank concentrations detected (i.e. ≤3.1 times the detection limit) are so low that they are unlikely to materially affect the interpretation of the groundwater sample data.

**Table 2-5: Field Blank Analytes >2x DL**

| Analyte                   | Result / DL (where >2) | Month Analyte was > 2x DL |
|---------------------------|------------------------|---------------------------|
| Antimony (Sb), dissolved  | 2.8                    | September 2017            |
| Nitrate (N)               | 3.1                    | June 2017                 |
| Nitrite and Nitrate, as N | 3.1                    | June 2017                 |

Trip blanks (sample of de-ionized water) are supplied and prepared by the lab and are meant to accompany the sample bottles provided by the lab for the monitoring program. The trip blank travels with the sample bottles to the sample stations and is returned unopened back to the lab with the collected samples. The purpose of the trip blank is to identify any potential contamination (e.g., cross contamination from other samples or ambient air conditions) to which the samples may be exposed. Four trip blanks were analyzed between March 2017 and November 2017. Of these, three analytes had a

concentration >2 times the DL: total lead, which was 10 times the detection limit, alkalinity, bicarbonate HCO<sub>3</sub> at 2.3x DL, and barium at 3x DL. The corresponding March 2017 field blank did not have elevated lead concentrations, nor did any of the samples collected during this event. Such contamination is likely related to the bottles, preservative, and/or laboratory handling, as the bottles were not opened in the field or during transport; however, sporadic contamination during fieldwork cannot be ruled out.

Since laboratory method blanks showed no notable results >2 times the DL, it can be assumed that the original lab water is not a source of contamination. For the purposes of this data quality assessment, periodic field and trip blank results >2 times the DL do not call sample results into question; rather the relevance and potential for actual sample results to have been affected have been considered when interpreting results.

## 2.5 GUIDELINES

Groundwater quality samples results were compared to the Yukon Contaminated Sites Regulation (YCSR) Schedule 3 Generic Numerical Water Standards for groundwater (YG, 2002). The standard values are dependent on the applicable primary water use, of which there are four: aquatic life, irrigation, livestock, and drinking water. Aquatic life (column II) for freshwater was selected as the primary use at the KZK site. The YCSR Standards or applicable formulas to calculate the standard are provided in Table 2-6. Although the YCSR Standards for the protection of freshwater aquatic life have been used for comparison to groundwater concentrations, it is noted that the quality of groundwater at KZK is reflective of natural conditions.

Groundwater samples results were also compared to the Federal Interim Groundwater Quality Guidelines (FIGWQG) (FCSAP, 2012) for those constituents which do not have a YCSR standard (pH, chloride, aluminum and iron). The FIGWQG are intended to be used as an interim measure until Canadian Environmental Quality Guidelines (CEQG) for groundwater are developed by the Canadian Council of Ministers of the Environment (CCME). The guidelines are primarily risk-based numerical guidelines set at levels at which it is believed that unacceptable adverse effects on environmental or human health will not occur (FCSAP, 2012). There are three tiers to the guidelines and Tier 1 was used as it allows for direct application of the generic numerical guideline. Furthermore, there are different values for different land uses; agricultural, residential/parkland, commercial and industrial. Industrial was selected as the land use most comparable. The FIGWQG values or applicable formulas to calculate the guideline are listed below in Table 2-6.

**Table 2-6: Summary of YCSR Standards and FIGWQG Guidelines Used for Comparative Purposes**

| Parameter                  | YCSR Schedule 3 Column II Standards (Aqueous Life)   | FIGWQG Industrial Tier 1 Guidelines            |
|----------------------------|--|--|
| pH (field)                 | -  | 6.5-9 pH units                                 |
| Chloride                   | -  | 120 mg/L                                       |

## 2.6 DATA QUALITY ASSESSMENT

All water quality data has been compiled into an EQWin® software database. This continually growing database allows for the assessment of water quality trends for specific parameters of interest. Water quality data are reviewed after each monitoring event in comparison to the previously collected data. Results that show variance from historical data are reviewed in detail to determine if lab rechecks may be required or if they are representative of the station water quality. Following a lab recheck, the data point(s) may be removed if there is compelling evidence to do so (e.g., field notes regarding potential sample contamination or well integrity issues etc.). To date, limited variance has been observed in the 2017 sample data compared to the historical dataset and no data have been removed from the database.

During the data assessment it was noticed that dissolved iron concentrations within the pit area were not consistent between the 2015 and 2016 data. In general, the 2016 dissolved iron concentrations were markedly lower than the 2015 dataset. This is ascribed to different sampling approaches employed for the dissolved samples collected in 2015 versus 2016. In 2015, the samples were filtered and preserved in the field; however, in order to achieve low level detection limits, Maxxam advised AEG not to filter and preserve in the field. Instead, the 2016 samples for dissolved metals were submitted to Maxxam unfiltered and unpreserved for filtration and acidification in the laboratory. Field filtering and preserving was restarted in November 2016 for all future sampling events. The lower dissolved iron concentrations observed in the 2016 samples is most likely due to precipitation of iron-bearing phases during transit to Maxxam, removing a portion of dissolved iron from the sample prior to processing in the laboratory. This would be most prominent in samples collected from anoxic wells where the majority of dissolved iron would be present as Fe(II). Upon exposure to the atmosphere, the Fe(II) would oxidize quickly at the circumneutral to mildly alkaline pH of the groundwaters, and the resulting Fe(II) would hydrolyse to precipitate iron (oxyhydr)oxides. Given the uncertainty associated with the dissolved iron dataset, the dissolved iron results from May to July 2016 and September to November 2016 have been removed from the dataset.

Otherwise, the duplicate, field and trip blank data and variance analysis suggest the sample dataset is suitable for use.

### 3 RESULTS AND DISCUSSION

#### 3.1 BOREHOLE HYDRAULIC TESTING COMPILATION

During 2015, borehole hydraulic conductivity tests were conducted by EBA, and the associated methodologies and test analyses are reported in EBA (2016). These tests included two long-term pumping tests at water wells, slug tests in completed monitoring wells, and bedrock packer injection tests in open boreholes. Results of the 2015 slug and packer tests are summarized in Table 3-1.

**Table 3-1: 2015 Slug Tests and Packer Tests**

| Drillhole ID | Slug Tests        |                                |                                   |                              | Packer Tests      |                                  |                                     |                                    |

(a) Mean of individual hydraulic conductivity, K, results

(b) Storativity cannot be reliably measured from pumping well data

(c) Storativity cannot be measured from Theis recovery analysis

(d) Artesian storage coefficient

During 2016, KP performed packer injection tests in 16 drill holes to evaluate the hydraulic conductivity of bedrock at multiple depths along each open hole to create a profile of the hydraulic properties. The packer tests were conducted in locations of proposed infrastructure, such as the storage facilities and pit to support the geotechnical evaluation for the Prefeasibility Study Report (KP, 2016b). The methodology, data, and results are provided in the *2016 Geotechnical Site Investigation Data Report* (KP, 2016a). These results are summarized in Table 3-3. The locations of these wells are shown on Figure 2-1.

**Table 3-3: 2016 Bedrock Packer Test Results**

bgs Vertical depth below ground surface.

- 1 Pressure applied during testing exceeded the maximum allowable injection pressure ( $P_{MAX}$ ).  $P_{MAX}$  is calculated in the literature as the vertical distance from the ground surface to the top of the test interval multiplied by a factor of safety of 0.98 PSI/m - 1.64 PSI/m (Read and Stacey, 2009). Test results do not appear to have been affected by the high pressure applied as they are consistent with other testing.
- 2 Estimated hydraulic conductivity less certain because injected flow not well constrained during testing.
- 3 Shut-in pressure and artesian flow recorded only.
- 4 Water level at or below transducer (top of test interval) based on plotted transducer data. Initial water level assumed to be at the mid-point of the test interval for analysis. Hydraulic conductivity estimated provided for qualitative purposes only as the initial water level assumed and testing methodology/analysis valid only for saturated conditions.
- 5 Estimate of hydraulic conductivity less certain because of small head applied during testing.

AEG performed short-term (low flow rate) pumping tests in seven new monitoring wells that were installed in 2016, and these test results are summarized in Table 3-4. The eighth well installed (MW16-13) was not tested as the well froze shortly after installation. The well locations are shown on Figure 2-1, and associated data plots, equations, and inputs used to estimate hydraulic conductivity are provided in Appendix A.

No additional pumping or packer tests were conducted in 2017 or 2018.

**Table 3-4: 2016 Short-Term Pumping Tests**

| Well ID  | Geologic material | Top of test interval <sup>(a)</sup> | Bottom of test interval <sup>(a)</sup> | Saturated test interval length <sup>(a)</sup> | Pumping duration | Average pumping rate | Specific capacity transmissivity | Theis recovery transmissivity | Best estimate transmissivity <sup>(g)</sup> | Best estimate hydraulic conductivity <sup>(b)</sup> |

bgs Vertical depth below ground surface

a Test interval length is generally from the top to the bottom of the sand pack. If the static water level is below the top of sand pack, the test interval is from the static water level to the bottom of the sand pack.

b Average hydraulic conductivity of geologic materials within the test interval.

c Three brief intermittent pumping periods over a total duration of 34.7 minutes.

d Cannot be analyzed due to oscillations and discontinuous pumping.

e Recovery too rapid for reliable analysis.

f Insufficient drawdown; analysis provides lower-bound transmissivity.

g Average of specific capacity and Theis recovery transmissivities if both values calculated.

### **3.1.1 Overburden Hydraulic Conductivity**

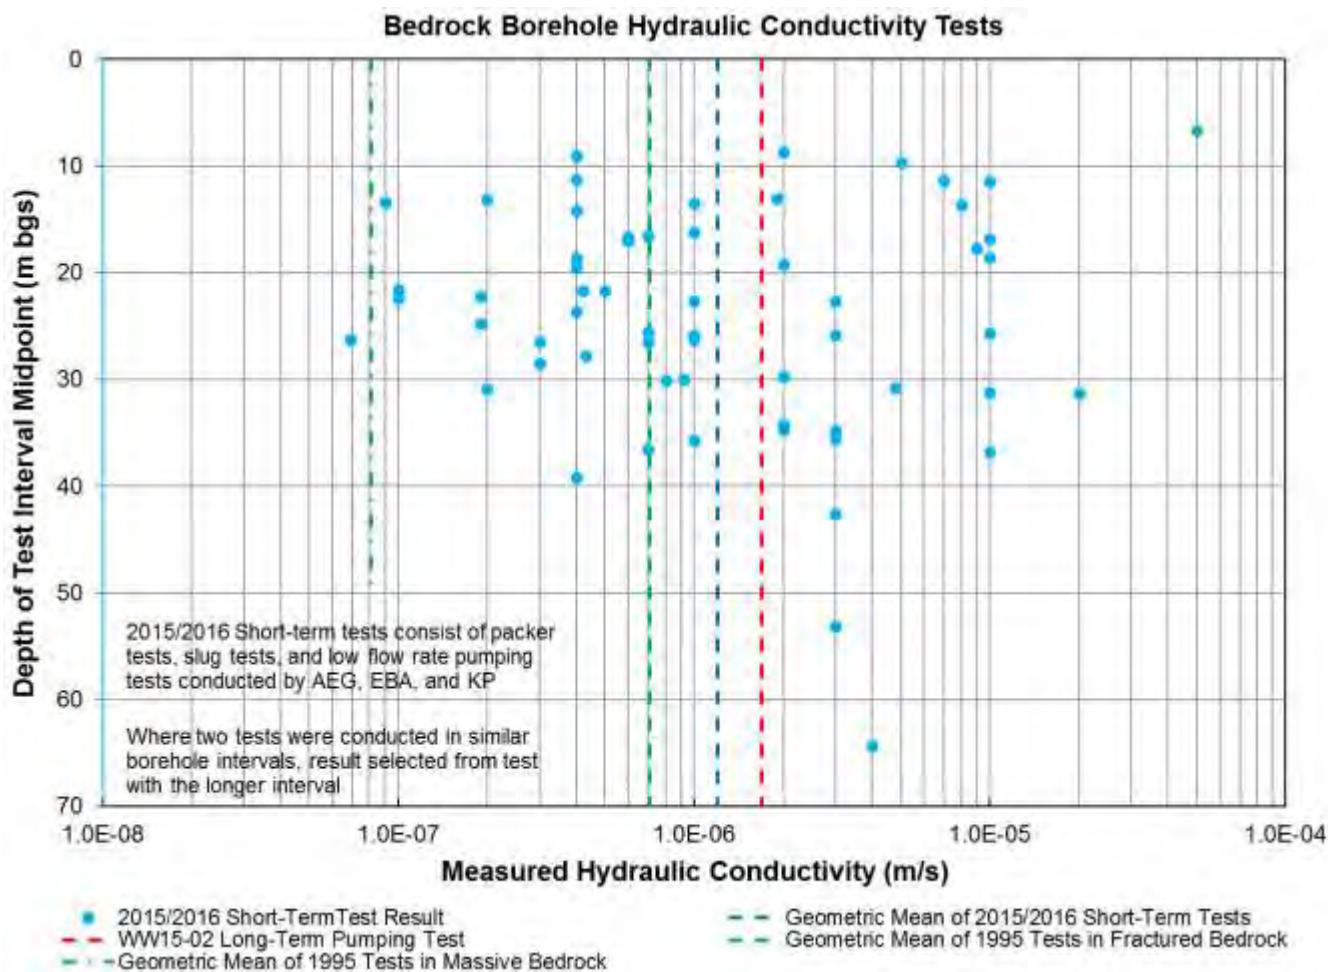

Overburden at the KZK site generally consists of two material types:

- Fine-grained lower permeability sediments composed of silts and fine sands; and
- Coarse-grained higher permeability sands and gravels.

Results of the ten 2015/2016 tests conducted in the overburden are bimodal, reflecting the presence of these two material types. Eight tests were conducted in wells completed in the fine-grained overburden, and the geometric mean of hydraulic conductivities measured by these tests is  $5.2 \times 10^{-6}$  m/s. The two tests conducted in sands and gravels have a geometric mean of  $1.3 \times 10^{-4}$  m/s (or 25 times greater than the fine-grained tests). For comparison, the geometric mean of the 1995 tests conducted in "overburden" was  $4.1 \times 10^{-6}$  m/s, which is similar to, but somewhat lower than, the geometric mean of the coarse-grained geometric mean of the 2015/2016 tests.

### **3.1.2 Bedrock Hydraulic Conductivity**

Based on borehole tests conducted during 2015/2016, Figure 3-1 presents a plot of measured bedrock hydraulic conductivity versus the depth of the test interval midpoint. The short-term tests consist of the packer tests, slug tests, and low flow rate pumping tests presented in previous sections. In many open boreholes, a series of packer tests was performed at different depths to create a vertical profile of bedrock hydraulic conductivity. Many of these holes were subsequently completed as monitoring wells and tested for hydraulic conductivity using well testing methods. At seven locations, a tested monitoring well had a completion interval that was similar to the borehole interval previously packer tested, resulting in two hydraulic conductivity values for essentially the same depth interval. To avoid double-counting these occurrences on Figure 3-1, the plotted point is the hydraulic conductivity value that was measured for the longest of the two test intervals, regardless of the test methodology. As shown on Figure 3-1, most of the bedrock hydraulic conductivities lie within a range of  $1 \times 10^{-7}$  and  $1 \times 10^{-5}$  m/s. For the depth range of 10 to 70 m below ground surface, there is no apparent trend of increasing or decreasing hydraulic conductivity with depth. The geometric mean of the plotted tests is  $1.2 \times 10^{-6}$  m/s, which is similar to the result of the long-term bedrock pumping test conducted in water well WW15-02 by EBA ( $1.7 \times 10^{-6}$  m/s). For comparison, the plot shows the geometric mean of 1995 tests conducted in "upper fractured bedrock" ( $7.1 \times 10^{-7}$  m/s), which is similar to, but somewhat lower than, the geometric mean of the 2015/2016 tests. Also shown is the geometric mean of two 1995 tests performed in relatively unfractured "massive bedrock" ( $8.1 \times 10^{-8}$  m/s), which is at the low end of the 2015/2016 values.

**Figure 3-1: Measured Bedrock Hydraulic Conductivity versus Depth**

### 3.2 GROUNDWATER ELEVATIONS

Groundwater elevation was continuously measured using Solinst M10 levelloggers installed in eight monitoring wells across the site. These wells are BH95G-2, BH96G-22, BH95G-33D, BH95G-131, MW15-01, MW15-04D, MW15-04S, and MW15-07S. A barometric pressure logger was installed at BH95G-131 to provide data for correcting the water level readings to account for variable atmospheric pressure. Levelloggers were installed during October/November 2015 for most wells, and during May 2016 for MW15-04D and MW15-04S. No new levelloggers were installed in 2017. Plots of the data logger elevations and manual water readings are presented in Figure 3-2 through Figure 3-9 (data are presented up to November 2017). The plots of all the water levels collected across the site are provided in Appendix B. Comparison of the levellogger and manual readings show good correspondence.

The continuously monitoring wells exhibited the following seasonal general trends:

- Rising water levels through the summer months (approximately May to August);
- Peak water levels reached between August and September, depending on the year;
- Falling water levels through the winter months (approximately October to March); and

- Lowest levels reached between April and May, depending on the year.

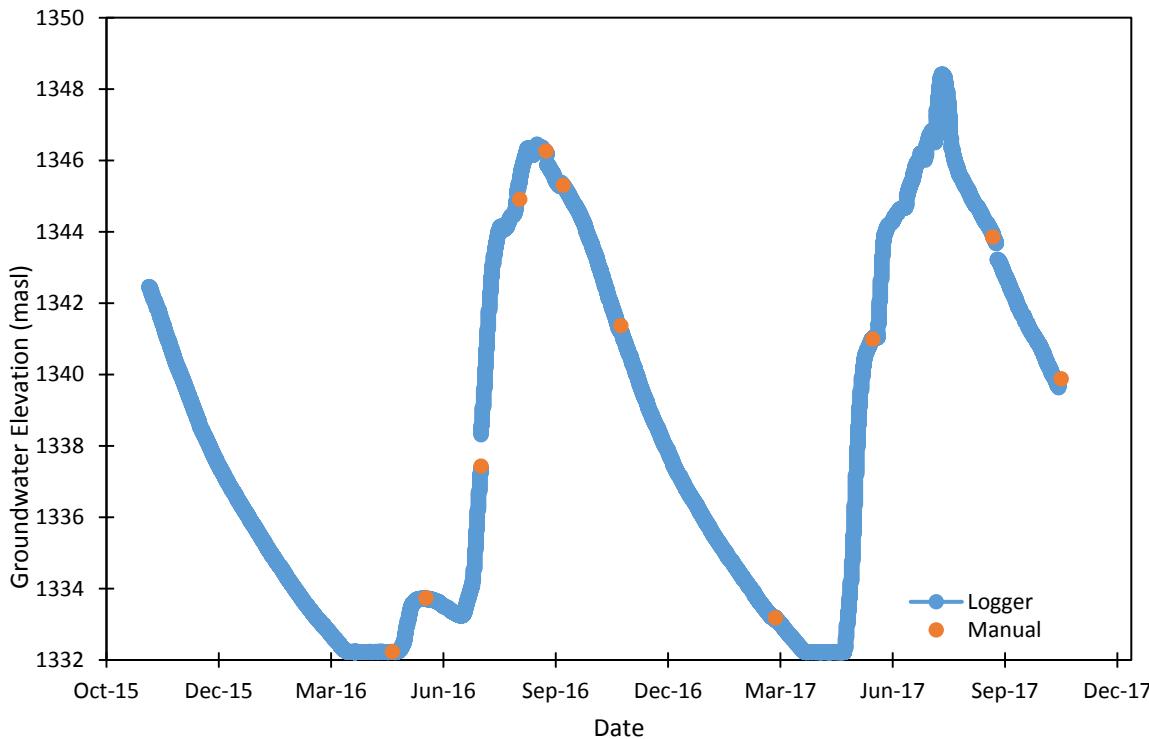

In most wells, the minimum and maximum water levels differed by 2 m to 8 m. However, there was a 16 m water level difference in BH95G-2 and approximately 1.5 m difference in MW15-07S. The BH95G-2 data show an extended horizontal line during April and May 2016, and again in 2017, when it is assumed that the water level briefly dropped below the logger level.

For well BH95G-131 (Figure 3-5), the anomalous raw data in June 2016 was affected by the sampling event and as such was removed (~1 day). The anomalous data in August 2016 was potentially affected by activity on site, such as exploration drilling, and as such was removed (less than 2 days).

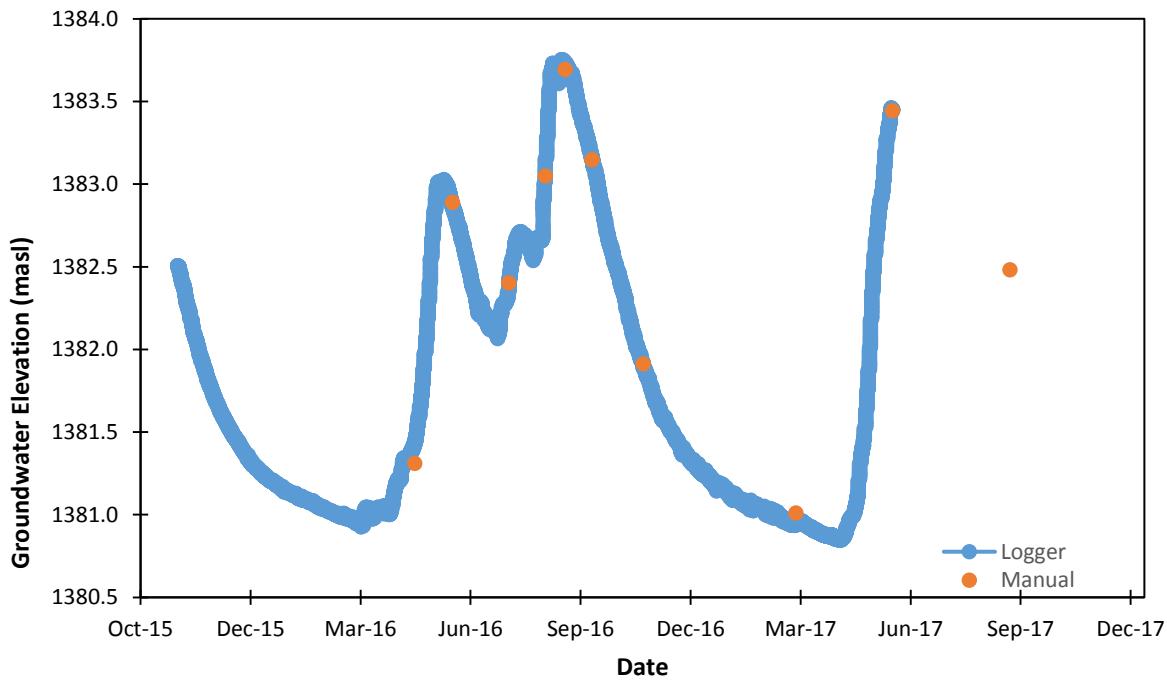

The levellogger data for MW15-01 are more complex, showing gross trends similar to the general trends discussed above, but with large superimposed fluctuations during the open-water months of April to September (Figure 3-6). This trend seems consistent between 2016 and 2017, and is likely due to this shallow water table being heavily influenced by snow melt and rain events.

MW15-07S was frozen during November 2017 so the hydrograph ends in September 2017. The gross trends in the levellogger data are similar to the general trends discussed above, but with several superimposed fluctuations during the fall of 2016 (Figure 3-9).

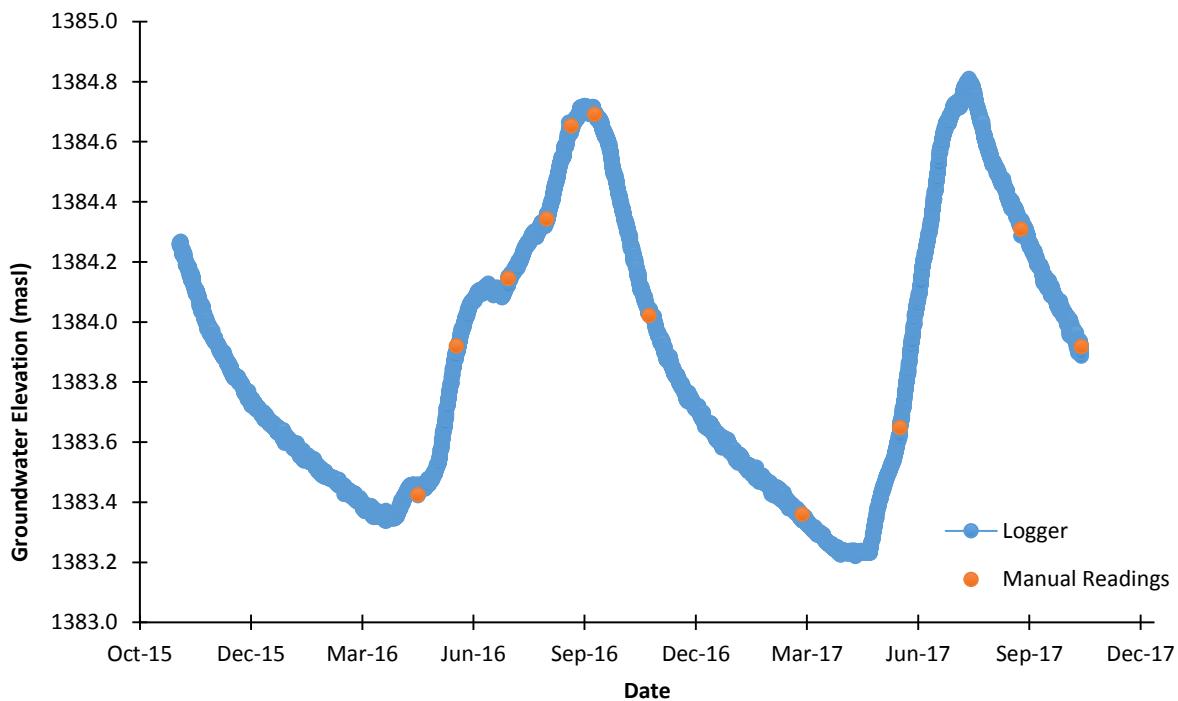

BH95G-22 was frozen in November 2017, so data are only available up to June 2017 (Figure 3-3).

### 3.3 GROUNDWATER QUALITY

To simplify the discussion of water quality data, results are delineated by geography in terms of areas around proposed Project areas being:

- ABM open pit area;
- Class A Storage Facility (Area A);
- Class B Storage Facility (Area B); and
- and Class C Storage Facility (Area C).

The in situ parameters and anions (sulphate, chloride, fluoride, nitrite, nitrate) and nutrients (ammonia, phosphorus) are discussed for each area. There was no exceedance of the YCSR standards for anions and nutrients at any of the wells.

The groundwater trace element discussion is also presented by area and is largely focussed on constituents that exhibited YCSR standard exceedances and major and trace elements that may be related to ABM mineralization (i.e., aluminum, arsenic, cadmium, copper, iron, lead, selenium, and zinc). Of the 44 monitoring wells, only six wells exceeded the YCSR standards for dissolved metals, primarily dissolved cadmium.

All summary statistics tables are based on the water quality dataset collected between May 2015 and November 2017. Where results were below laboratory detection levels, one half the detection limit was used in the calculation of summary statistics

as well as presented on graphs. Figures that display the temporal changes in the concentration of metals of interest are presented in Appendix C, the summary statistics of all the wells by area are provided in Appendix D, all the raw data are provided in Appendix E, and the laboratory Certificates of Analysis are provided in Appendix F.

As a comparison to the current data set (2015-2017), the September 4<sup>th</sup>, 1995 data are presented where available, as only select parameters were analysed during the 1995 sampling event, as discussed in Section 1.2.2. Additionally, fewer metals were analysed in 1995, of which cadmium, copper, lead, and selenium had detection limits that were too high to be suitable for comparison with the 2015-2017 dataset. Nine of the eleven samples were collected from the ABM open pit area, five of which were from flowing, open boreholes. Of the other two samples from that period, one well is in the Class C Storage Facility area, and the other was in a location of proposed mine workings that are not part of the current mine plan.

### 3.3.1 ABM Open Pit Area

#### 3.3.1.1 Setting

The ABM open pit area contains the proposed ABM open pit and Krakatoa underground (Figure 2-1). It also includes the Fault Creek drainage and the headwater ponds of Geona Creek. The ABM open pit area is in the south end of the KZK property in a broad valley. Fourteen monitoring wells populate this area, which comprise a combination of wells screened in overburden (six wells) and bedrock (eight wells). Four of these wells are frozen for most of the year (BH95G-21, BH95G-29, MW15-11D, MW15-11S). Wells BH95G-23 and BH95G-24 each have a single data point in August 2015; however, further sampling was not possible due to ice and frost heaving resulting in pinched or frozen wells.

#### 3.3.1.2 Physical Parameters and Nutrients

The bedrock and overburden wells in the ABM open pit area were generally pH circumneutral (pH range 5.98 to 8.07, as shown in Table 3-5, Table 3-6, and the in situ parameter summary table provided in Appendix D-1. Only one sample returned a pH measurement (pH 5.98 in well BH95G-22) that was outside the FIGWQG pH range of 6.5 to 9.0; the YCSR standards do not have a defined pH range. The average pH from ABM open pit area wells sampled on 4 September 1995 data was slightly alkaline with an average of 7.97, which is just higher than the maximum recorded pH within the 2015-2017 dataset (8.07). Well water dissolved oxygen levels ranged from 2 to 104% saturation, suggesting the groundwater ranged from suboxic/anoxic to oxic. Temperature varied seasonally between -0.1 and 10°C, and five of the fourteen wells were frozen for most or all of the year.

No anions or nutrients within the ABM open pit area wells exceeded YCSR standards; the plots of these parameters for the pit area wells can be found in Appendix C. Overall, fluoride appears to be the parameter that fluctuates the least in any given well, with relatively consistent concentrations in each well. The highest concentrations of fluoride were in monitoring well BH95G-146, which ranged from 0.28 to 0.31 mg/L, and the next highest were in BG95G-129 which ranged from 0.18 to 0.22 mg/L. These were followed by MW15-11S and MW15-11D, which had similar concentrations to each other (0.14 to 0.19 mg/L). The trends for the all the monitoring wells in terms of fluoride concentrations were fairly constant over the period of record, with little to no seasonality apparent.

The range of sulphate concentrations observed for the pit area was 32.6 to 279 mg/L, well below the YCSR standard (1000 mg/L). There was a distinct split in sulphate concentrations between monitoring wells: higher sulphate concentrations (170 to 280 mg/L) were observed in samples collected from wells BH95G-131, BH95G-146, BH95G-25D, and BH95G-25S, which are located towards the centre of the ABM Pit area (Figure 2-1). The remainder of the wells had dissolved sulphate

concentrations that were typically less than 100 mg/L. These relatively elevated sulphate concentrations may be related to leaching of the orebody and/or sulphidic rocks proximal to the mineralization. Three of the four wells with dissolved sulphate concentrations in excess of 100 mg/L were bedrock wells: BH95G-146 typically had the highest dissolved sulphate concentrations, ranging from 232 to 279 mg/L, followed by BH95G-25D, ranging from 220 to 260 mg/L, and BH95G-131, ranging from 215 to 247 mg/L. Well BH95G-25S was the fourth well that consistently exceeded the FIGWQG, with concentrations ranging from 167 to 212 mg/L, but it is a shallow overburden well.

Two samples collected from MW15-11S returned sulphate concentrations greater than 100 mg/L, at 128 mg/L and 138 mg/L respectively, but were less than 100 mg/L for the rest of the events in 2016 and 2017 (the lowest concentration was 61.5 mg/L). BH95G-24 has a single data point recorded in August 2015 (135 mg/L sulphate) but samples could not be collected from this well for the rest of 2015, 2016 or 2017, as the well was either broken or frozen. BH95G-129, a deep bedrock well, had relatively consistent dissolved sulphate concentrations ranging between 33.4 mg/L and 54.6 mg/L, which also encompassed the dissolved sulphate range for wells BH95G-21, BH95G-22 and BH95G-29. The average sulphate concentration for samples collected from the wells in the open pit area on 4<sup>th</sup> September 1995 (57.5 mg/L) was within the minimum and maximum range of the 2015 to 2017 data (32.6 to 279 mg/L), but below the 2015 to 2017 average (123 mg/L).

Ammonia-N concentrations did not exceed the YCSR ammonia guideline (1.31 to 18.4 mg/L) in any well over the period of record, which ranged between 0.009 and 1.2 mg/L. Ammonia-N concentrations in individual wells were often variable; for example, concentrations fluctuated by an order of magnitude over the period of record in wells BH95G-21 (0.019 to 0.27 mg/L), BH95G-22 (0.011 to 0.51 mg/L), MW15-11S (0.048 to 0.64 mg/L), BH95G-29 (0.06 to 1.2 mg/L), and BH95G-146 (0.022 to 0.78 mg/L). Ammonia-N levels in the remaining monitoring wells displayed more limited variation. The average data on 4 September 1995 from the open pit wells for ammonia-N (0.018 mg/L) was within the minimum and maximum range of the 2015 to 2017 data (0.009 to 1.2 mg/L), but well below the 2015 to 2017 average (0.12 mg/L).

### 3.3.1.3 Metals

The only parameters that exceeded the YCSR standards in the ABM open pit area were dissolved cadmium, arsenic, and zinc (Table 3-7 and Appendix D-1). The YCSR exceedances were in three wells: BH95G-23, BH95G-24 and MW16-15S; dissolved cadmium exceeded YCSR (0.0001 to 0.0006 mg/L) in all samples from these wells while dissolved arsenic and zinc concentrations exceeded YCSR (0.05 mg/L for arsenic and 0.075 to 2.4 mg/L for zinc) only in BH95G-23. It should be noted that only one sample was collected from each of BH95G-23 and BH95G-24 wells.

Dissolved cadmium concentrations in well MW16-15S consistently exceeded the YCSR standard, with dissolved cadmium concentrations that ranged between 0.0017 mg/L and 0.0021 mg/L. The sole samples collected from wells BH95G-23 (0.0017 mg/L) and BH95G-24 (0.0038 mg/L) also both exceeded both the YCSR standards. The monitoring well with the next highest concentrations of dissolved cadmium was BH95G-22 (0.00007 to 0.00019 mg/L), which was an order of magnitude lower than MW16-15S. The majority of dissolved cadmium concentrations measured in the other wells were well below 0.0001 mg/L.

The wells that displayed the highest dissolved cadmium concentrations also returned the highest dissolved zinc levels, suggesting a common source for these two elements in the ABM open pit area (i.e., buried mineralization). Only the single sample from well BH95G-23 returned a zinc concentration (2.0 mg/L) that exceeded the YCSR standard. The sole sample from well BH95G-24 (0.85 mg/L) was the next highest recorded dissolved zinc concentration, followed by well MW16-15S (0.096 to 0.16 mg/L). The majority of the remaining well samples were below 0.01 mg/L. Groundwater samples collected from wells BH95G-131, BH95G-146, and BH95G-22 appeared to have dissolved zinc concentrations that followed a muted water elevation change, with similar concentration patterns over the period of record. All the zinc concentrations in waters abstracted from these wells were below the FIGWQG. The average zinc concentration from the 4<sup>th</sup> September 1995 dataset was 0.484 mg/L, which is within the minimum and maximum ranged collected in the 2015 to 2017 dataset (<0.0001 to 2.03 mg/L).

Dissolved arsenic exceeded the YCSR standard (0.05 mg/L) for the single sample collected from well BH95G-23 (0.075 mg/L). The next highest dissolved arsenic concentrations were observed in well MW16-15D (0.012 to 0.019 mg/L). Dissolved arsenic concentrations in the remainder of the wells were below 0.01 mg/L and exhibited limited variation. The lowest dissolved arsenic levels were observed in well BH95G-22, ranging from 0.00002 to 0.0003 mg/L. The average arsenic concentration

from the 4<sup>th</sup> September 1995 dataset was 0.033 mg/L, within the minimum and maximum ranged collected in the 2015-2017 dataset (0.000024 to 0.075 mg/L).

Within the ABM open pit area there were no exceedances of the FIGWQG for dissolved aluminum (0.1 mg/L if pH ≥6.5, 0.005 mg/L if pH <6.0). Note that there is no YCSR standard for dissolved aluminum. Overall, the range of aluminum concentrations varied by two orders of magnitude between all the pit wells. Samples collected from wells MW15-11S, BH95G-21, BH95G-22, and BH95G-131 ranged by an order of magnitude each within the period of record. The highest concentration recorded was in MW15-11S in November 2015 (0.046 mg/L), but otherwise had lower concentrations between 0.00077 and 0.0030 mg/L. Well BH95G-22 had two sampling events with higher dissolved aluminum concentrations in May 2015 (0.038 mg/L) and November 2015 (0.03 mg/L), but generally ranged between 0.00089 and 0.013 mg/L. MW16- 15D, a new well in the pit area with nine samples, generally had consistent concentrations ranging between 0.0026 and 0.013 mg/L. Samples collected from wells BH95G-131, and BH95G-25S were below the detection limit (0.0005 mg/L) for most of the samples recorded. The average aluminum concentration from the 4<sup>th</sup> September 1995 dataset was 0.013 mg/L, within the minimum and maximum ranged collected in the 2015 to 2017 dataset (<0.0005 to 0.046 mg/L).

Dissolved copper concentrations were generally highest in well MW16-15S (0.0033 to 0.0055 mg/L), which also exhibited elevated cadmium and zinc concentrations. Samples from well BH95G-22 generally had the next highest dissolved copper concentrations (0.00055 to 0.0064 mg/L). The dissolved copper concentrations in the remainder of the samples were generally well below 0.001 mg/L.

The concentrations of dissolved iron within the ABM open pit area monitoring wells spanned three orders of magnitude, from 0.0034 mg/L to 7.62 mg/L. BH95G-25S returned the highest dissolved iron concentration and, apart from well BH95G-23 which only yielded one sample (6.48 mg/L dissolved iron), had the highest average concentration (5.75 mg/L). Wells BH95G-22 and MW16-15S returned the lowest dissolved iron concentrations with average concentrations of 0.0309 and 0.0209 mg/L, respectively. These were the only wells for which dissolved iron concentrations were consistently below the FIGWQG (0.3 mg/L; there is no YCSR standard for iron). Overall, there was no distinction between overburden and bedrock wells.

The highest dissolved selenium concentrations were observed in wells MW16-15S (0.0023 and 0.0032 mg/L) and BH95G-22 (0.00046 to 0.00088 mg/L). Aside from a sporadic concentration of 0.0014 mg/L in well MW15-11S, the dissolved selenium concentrations observed in the remainder of the wells were less than 0.0002 mg/L. Dissolved lead concentrations were highest in BH95G-131 and varied by an order of magnitude over the period of record (0.000084 mg/L to 0.0019 mg/L). Dissolved lead concentrations in BH95G-22 well waters also spanned an order of magnitude over the period of record (<0.00005 mg/L to 0.00027 mg/L).

There was no evidence of a distinction between the bedrock and overburden wells in terms of groundwater quality with the three years of baseline data collected. The pit area had higher sulphate concentrations than the other areas around the KZK site, likely due to the mineralization.

**Table 3-7: Summary Statistics for Metals ABM Open Pit Area**

| Metal (dissolved) | Al      | As       | Cd            | Cu        | Fe     | Pb        | Se       | Zn        |
|-------------------|---------|----------|---------------|-----------|--------|-----------|----------|-----------|
|                   | mg/L    | mg/L     | mg/L          | mg/L      | mg/L   | mg/L      | mg/L     | mg/L      |

### 3.3.2 Class A Storage Facility Area

#### 3.3.2.1 *Setting*

The Class A Storage Facility area, defined for the purposes of characterizing the groundwater quality across the KZK site, contains the proposed Class A Storage Facility, water management ponds, and camp, as shown on Figure 2-1. The Class A Storage Facility is on the western slope of the valley with Geona Creek flowing through the bottom of the valley. Thirteen monitoring wells characterize this area, a combination of wells screened in overburden (four wells) and bedrock (nine wells). Of the 13 monitoring wells, two were damaged due to ice and frost heaving such that sampling was not possible in 2017 (MW15-09D and MW15-08D) and six wells were frozen for all or part of the year (MW15-09S, MW15-08S, MW15-07S, MW15-07D, MW16-14D, and MW16-13).

#### 3.3.2.2 *Physical Parameters and Nutrients*

The bedrock and overburden wells in the Class A Storage Facility area were generally circumneutral (pH range 7.22 to 8.63; Table 3-8; Appendix D-2), with the exception of three wells. Samples from well MW15-09D (5.68 pH, only one sample collected as well was broken) and paired wells MW15-10S (pH 5.82 to 6.24) and MW15-10D (pH 5.8 to 6.17) returned pH measurements below the FIGWQG pH range of 6.5 to 9.0. These lower pH wells are located proximal to the KZ-9 east seep, which is characterized by low pH water (pH 5.8 to 6.0) (AEG, 2017); this suggests groundwater found in wells MW15-10S and MW15-10D also feeds this seep. Well water dissolved oxygen levels ranged from 6 to 95% saturation, suggesting the groundwaters ranged from sub-oxic/anoxic to oxic. The dissolved oxygen content of waters from well MW15-10S were on the lower end of this dissolved oxygen range (19 to 36% saturation) and overlapped that for the KZ-9 East Seep (21 to 54% saturation) (AEG, 2017), compatible with the hypothesis that this seep is supplied by groundwater sampled by well MW15-10S. Temperature varied seasonally between -0.1 and 5.9°C, and six of the thirteen wells were frozen for most or all the year.

No YCSR standard for anions or nutrients were exceeded in any wells within the Class A Storage Facility area; the plots of these parameters for the Class A Storage Facility area wells can be found in Appendix C. Fluoride were highest in monitoring well MW15-10D, ranging from 1.2 mg/L to 1.4 mg/L. The lowest concentrations were observed in wells BH95G-2 (0.04 to 0.063 mg/L) and MW15-08S (0.084 to 0.093 mg/L). The remainder of the wells returned fluoride concentrations between 0.16 and 0.73 mg/L. Overall, fluoride concentrations were very stable over the period of record in all the monitoring wells, with no seasonality apparent. In general, fluoride concentrations were higher in bedrock wells than shallow wells with the exception of well BH95G-2.

All samples collected from the Class A monitoring wells returned ammonia-N concentrations that were below the YCSR standard. The highest concentrations were typically observed in the paired monitoring wells MW15-10S (0.033 to 0.67 mg/L; average 0.39 mg/L), and MW15-10D (0.18 to 0.30 mg/L; average 0.25 mg/L). The remainder of the wells in the Class A Storage Facility area returned ammonia-N concentrations that were generally between 0.01 mg/L and 0.1 mg/L. This is consistent with the September 1995 sample from well BH95G-13D, which returned an ammonia-N concentration of 0.01 mg/L.

**Table 3-8: Summary Statistics for In situ Parameters Class A Storage Facility Area**

|              | Number of Samples | pH (field)       | Specific Conductance (lab) | Temperature (field) | Dissolved Oxygen (field) | Dissolved Oxygen (field) | ORP (field)          |

### 3.3.2.3 Metals

Only the YCSR Schedule 3 standards for dissolved cadmium and cobalt were exceeded in Class A Storage Facility area wells (Table 3-10 and Appendix D-2). Dissolved cadmium concentrations in excess of the YCSR standard (hardness dependent; 0.0001-0.0006 mg/L) were observed in all 15 samples from BH95G-2 (0.0012 to 0.0017 mg/L) and five of seven samples from MW15-10S (0.00087 to 0.0014 mg/L). The YCSR standard for cobalt (0.009 mg/L) was only exceeded in one sample from MW15-10S (0.0122 mg/L in June 2016).

Dissolved cadmium concentrations in the Class A Storage Facility area monitoring wells varied by nearly three orders of magnitude. The highest concentrations were observed in wells BH95G-2 (0.0012 to 0.0017 mg/L) and MW15-10S (0.00087 to 0.0014 mg/L), which exhibited YCSR standard exceedances for 100% and 71% of samples, respectively. Dissolved cadmium concentrations varied between below detection (<0.000005 mg/L) and 0.00017 mg/L in the other wells in the Class A Storage Facility area, and generally exhibited an order of magnitude range in concentration. All samples collected in wells MW15-07D and MW-16-17 were either at or below the detection limit. Similarly, the dissolved cadmium concentration in the September 1995 sample from well BH95G-13D was below detection (<0.00001 mg/L).

Overall, the Class A Storage Facility area had dissolved aluminum concentrations that varied by nearly four orders of magnitude between all the monitoring wells. The highest concentrations were generally observed in well MW15-10D (0.0095 to 0.44 mg/L), consistent with its mildly acidic pH range (5.8 to 6.2) which increases aluminum solubility. All the samples collected from this well exceeded the FIGWQG (there is no YCSR standard for aluminum). The FIGWQG dissolved aluminum guideline was also exceeded in samples from the other two wells that exhibited mildly acidic pH – the sole sample from well MW15-09D (0.17 mg/L) and three of the seven samples collected from well MW15-10S (0.0013 to 0.016 mg/L). The

highest dissolved aluminum concentration was observed in a single sample collected from well MW15-09S (1.5 mg/L), but this was significantly higher than the concentration range observed for other samples collected from this well (<0.0005 to 0.0085 mg/L). The dissolved aluminum concentration in the majority of samples collected from the remainder of the wells were below 0.01 mg/L. The September 1995 sample from well BH95G-13D was also in the lower range with a dissolved aluminum concentration of 0.007 mg/L.

Concentrations of dissolved arsenic ranged between 0.00001 and 0.012 mg/L for all the samples collected in the Class A Storage Facility area. The highest concentrations were observed in wells MW15-10S (0.0021 to 0.012 mg/L), MW16-14D (0.0031 to 0.0041 mg/L), MW15-07S (0.0011 to 0.0051 mg/L), the two samples from MW15-08D (0.0026 and 0.0050 mg/L), and the sole samples from MW15-09D (0.0085 mg/L). The dissolved arsenic concentrations in samples collected from the remaining wells were below 0.002 mg/L, consistent with the single sample collected from well BH95G-13D in September 1995 (0.00026 mg/L).

The highest dissolved copper concentrations that approached the hardness-dependent YCSR standard (0.009 mg/L based on median hardness of 255 mg/L for the Class A Storage Facility area wells) were observed for single samples collected from wells MW15-10S (0.036 mg/L) and MW15-09S (0.021 mg/L). However, these were between one and two orders of magnitude above the next highest dissolved copper concentration observed for these wells. The majority of well water samples returned dissolved copper levels between the detection limit (i.e., <0.00005 mg/L) and 0.001 mg/L. The dissolved copper concentration for the September 1995 sampling event at well BH95G-13D (0.0002 mg/L) is consistent with this range.

Like copper, a sporadically high dissolved lead concentration was observed for one sample from well MW15-09S (0.018 mg/L) which was the highest lead concentration observed for all the Class A Storage Facility area wells and two orders of magnitude higher than the other samples collected from this well. The next highest dissolved lead concentrations were generally in samples from well MW15-10D, although these varied by two orders of magnitude (0.000008 to 0.00035 mg/L). The dissolved lead concentrations in the majority of samples collected from the remainder of the wells were below 0.0001 mg/L; the September 1995 sample from well BH95G-13D was below detection (<0.0001 mg/L).

Although the guideline was not exceeded for any samples collected to date, the dissolved selenium concentrations in samples from three monitoring wells within the Class A Storage Facility area were within an order of magnitude of the YCSR threshold (0.01 mg/L): BH95G-2 had the highest concentrations (0.0014 /L to 0.0073 mg/L), followed by MW15-10S (0.0017 to 0.0024 mg/L) and MW15-08S (0.0014 to 0.0022 mg/L). Well MW15-09S (0.00063 to 0.0020 mg/L) also returned occasional samples that were within tenfold of the YCSR standard. In general, dissolved selenium concentrations showed very little fluctuation over the period of record within the Class A Storage Facility area groundwater monitoring wells. The exceptions to this were MW15-08D (only two data points available of <0.00004 and 0.0003 mg/L) and MW15-07S (<0.00004 to 0.00085 mg/L). The remainder of the wells in the Class A Storage Facility area ranged from <0.00004 to 0.0002 mg/L. The dissolved selenium concentration in the September 1995 sample from well BH95G-13D was below detection (<0.00005 mg/L).

Dissolved zinc concentrations ranged between <0.0001 and 0.050 mg/L in wells located in the Class A Storage Facility area. Although the highest concentration was recorded in the October 2016 sample in MW16-14D (0.050 mg/L), the other four samples collected from this well ranged between 0.00037 and 0.0048 mg/l, over an order of magnitude lower. Dissolved zinc concentrations measured in samples collected from well BH95G-2 exhibited little fluctuation and generally returned the highest concentrations for each sampling event, ranging from 0.015 to 0.028 mg/L. Well MW15-09S had a single spike in dissolved zinc concentrations relative to the rest of the sampling sites in June 2016 when the concentration was 0.028 mg/L, but otherwise ranged from below the detection limit (<0.0001 mg/L) to 0.0017 mg/L. Samples from the paired wells MW15-10S (0.0049 to 0.019 mg/L) and MW15-10D (0.0020 to 0.022 mg/L) shared a similar dissolved zinc concentration span.

The remainder of the monitoring wells in the Class A Storage Facility area generally had dissolved zinc concentrations below 0.001 mg/L. The September 1995 sample was similarly low, returning 0.002 mg/L dissolved zinc.

Dissolved iron concentrations exceeded the FIGWQG guideline (0.3 mg/L; there is no YCSR for iron) in all samples collected from four wells: MW15-10D, MW15-09D, MW15-10S, and MW15-08S. The highest dissolved iron concentrations were observed in MW15-10D (24.4 to 36.6 mg/L; average 28.0 mg/L), the lone sample from MW15-09D (12.3 mg/L) and MW15-10S (2.15 to 4.25 mg/L; average 3.01 mg/L). All three of these wells also returned the lowest pH range (5.7 to 6.2), which likely helped maintain iron in solution. Overall, the majority of the monitoring wells in the Class A Storage Facility area had relatively stable dissolved iron concentrations; however, there were a few exceptions. Dissolved iron concentration spanned two orders of magnitude in wells BH95G-2 (<0.001 to 0.0244 mg/L), MW15-09S (0.0114 to 1.31 mg/L) and MW16-17 (0.0078 to 0.247 mg/L). Dissolved iron concentrations in BH95G-15D were below the detection level (i.e., <0.001 mg/L) and MW15-08S returned a relatively very low maximum concentration of 0.0045 mg/L. The dissolved iron concentration from the September 1995 sampling of well BH95G-13D (0.32 mg/L) was in the mid-range of the 2015 to 2017 dataset for the Class A Storage Facility area. There was no apparent difference in iron concentrations between the overburden and bedrock wells.

Within the Class A Storage Facility area there was no evidence of a distinction between the bedrock and overburden wells in terms of trace element water quality with the three years of baseline data collected.

**Table 3-10: Summary Statistics for Metals in Class A Storage Facility Area**

| Metal (dissolved) | Al      | As       | Cd            | Cu        | Fe      | Pb        | Se       | Zn        |

### 3.3.3 Class B Storage Facility Area

#### 3.3.3.1 Setting

The Class B Storage Facility area contains the proposed Class B Storage Facility, Process Plant, and the Run of Mine (ROM) and the Low Grade Ore (LGO) stockpiles, as shown on Figure 2-1. The Class B Storage Facility is on the western slope of the valley with Geona Creek flowing through the bottom of the valley. Seven monitoring wells characterise this area; a combination of wells screened in overburden (two wells) and bedrock (five wells). Of the seven monitoring wells, BH95G-33s is dry, and three of the wells (MW15-02, MW16-12S, and MW16-12D) were frozen part of the years.

#### 3.3.3.2 Physical Parameters and Nutrients

The bedrock and overburden wells in the Class B Storage Facility area were generally circumneutral to mildly alkaline (pH range 6.27 to 8.50), as shown in Table 3-11, Table 3-12 and the in situ summary table provided in Appendix D-3. All the well water samples were within the FIGWQG pH range of acceptability (6.5 to 9.0) with the exception of two of the five samples collected from well MW16-12D, which had a pH range of 6.27 to 6.83. Well water dissolved oxygen levels ranged from 4 to 100% saturation, suggesting the groundwaters ranged from sub-oxic/anoxic to oxic. Temperature varied seasonally between -0.2 and 8°C, and three of the seven wells were frozen for most or all of the years monitored.

No wells from within the Class B Storage Facility area returned exceedances of YCSR standards for anions or nutrients. The plots of these parameters for the Class B Storage Facility area wells can be found in Appendix C. Fluoride concentrations were highest in samples collected from the paired wells MW16-12S (0.72 to 1.1 mg/L) and MW16-12D (0.01 to 1.1 mg/L). Fluoride concentrations in the remainder of the wells were an order of magnitude lower (0.032 to 0.12 mg/L). The trends for all the monitoring wells in terms of fluoride concentrations were fairly constant over the period of record, with little to no seasonality apparent over the period of record.

In the Class B Storage Facility area, no wells had dissolved sulphate concentrations greater than the YCSR standard (1000 mg/L). Sulphate concentrations in most wells ranged between 32 and 138 mg/L. The lowest concentrations were observed in the paired wells MW16-12S (<0.5 mg/L to 11.9 mg/L) and MW16-12D (all samples were below the detection limit <0.5 mg/L). Overall, sulphate concentrations showed limited fluctuations over the period of record.

No wells in the Class B Storage Facility area exceeded the YCSR standard for ammonia-N. Concentrations ranged between <0.005 and 0.4 mg/L, with the highest concentrations observed in the paired wells MW16-12D (0.27 to 0.40 mg/L) and MW16-12S (0.085 to 0.38 mg/L). The majority of samples collected in the remainder of the wells were below 0.1 mg/L and approximately two orders of magnitude lower than the YCSR standard.

**Table 3-11: Summary Statistics for In situ Parameters Class B Storage Facility Area**

## - ## is the minimum and maximum range for the well for 2015-2016 data

(##) is the average concentration, concentrations less than the DL were taken as ½ DL values

Range of sample numbers due to lack of temperature, % dissolved oxygen, and ORP measurements for 2015 sampling

### 3.3.3.3 Metals

The only exceedance of YCSR – Schedule 3 standards within Class B Storage Facility Area wells was for dissolved cobalt (Appendix D-4), which was elevated relative to the YCSR standard (0.009 mg/L) in the MW16-12S well only and exceeded in each of the four samples (ranging from 0.026 to 0.072 mg/L).

Water quality results were also compared to the FIGWQGs for dissolved aluminum and iron owing to an absence of YCSR standards for these metals – dissolved aluminum and iron FIGWQG exceedances were observed for at least one sampling event for monitoring wells located in the Class B Storage Facility area.

The highest dissolved iron concentrations were found in wells MW16-12S (17.2 to 101 mg/L; average 59.1 mg/L) and MW16-12D (3.57 to 4.1 mg/L; average 3.88 mg/L), which all exceeded the FIGWQG guideline (0.3 mg/L). Dissolved iron concentrations in the remainder of the wells (<0.001 to 0.17 mg/L) were between one to three orders of magnitude lower and were all below the FIGWQG threshold.

Within the Class B Storage Facility Area there was one exceedance of the FIGWQG for dissolved aluminium concentrations (0.1 mg/L if pH ≥6.5, 0.005 mg/L if pH <6.5). MW16-12D exceeded the FIGWQG in a single event in August 2016 (0.012 mg/L). This well is compared to the lower FIGWQG, as pH in this well ranged from 6.27 to 6.53. MW16-12D had four additional sampling events which ranged between 0.0017 to 0.0107 mg/L. The pH measured in the other Class B wells was >6.5. The aluminum FIGWQG at this pH is 0.1 mg/L; all the dissolved aluminum concentrations were lower than the FIGWQG by an order of magnitude or more (observed range of <0.0005 to 0.0142 mg/L).

The highest dissolved arsenic concentrations were recorded in two samples from well MW16-12S (0.026 and 0.0034 mg/L), which were one to two orders of magnitude higher than the other two samples collected from this well (0.00019 and 0.00021 mg/L). The dissolved arsenic concentration in the majority of samples from the other wells in the Class B Storage Facility area ranged between 0.0001 and 0.001 mg/L, except for well MW16-12D, which returned samples with the lowest dissolved arsenic content (0.00001 to 0.00006 mg/L).

Samples from two monitoring wells regularly returned dissolved selenium concentrations that were within an order of magnitude of the YCSR standard (0.01 mg/L): BH95G-33D (0.0038 to 0.0079 mg/L; average 0.0055 mg/L) and MW15-02 (0.00037 to 0.0020 mg/L; average 0.0016 mg/L). Wells BH95G-32 and MW15-01 abstracted groundwaters with dissolved selenium concentrations that varied between 0.00026 and 0.0015 mg/L, whereas the lowest concentrations were observed in the paired wells MW16-12D and MW16-12S, which were typically below detection (<0.00004 mg/L). Overall, dissolved selenium concentrations had very little fluctuation in concentrations over the period of record within the Class B Storage Facility area monitoring wells.

Dissolved zinc concentrations were generally highest in the samples collected from well MW16-12S (0.016 to 0.10 mg/L), although the highest concentration recorded for the Class B Storage Facility area was in a single sample collected from the paired deep well MW16-12D (0.24 mg/L). Dissolved zinc concentrations in the remainder of the samples varied between <0.0001 and 0.005 mg/L.

Dissolved copper concentrations in samples collected within the Class B Storage Facility area were below 0.001 mg/L, and at least two orders of magnitude below the hardness-dependent YCSR standard. Well MW15-01 had dissolved copper concentrations that ranged from 0.00007 to 0.0007 mg/L, and changed by an order of magnitude over the period of record. Samples collected from well BH95G-32 had a similar range with dissolved copper concentrations that varied between 0.00008 and 0.0006 mg/L. Well BH95G-33D also ranged by an order of magnitude over the period of record with dissolved copper

---

concentrations that ranged from 0.00007 to 0.0009 mg/L. The remainder of the wells generally had concentrations below 0.0001 mg/L.

Samples collected from well BH95G-32 had the highest dissolved cadmium concentrations over the period of record, ranging from 0.00002 to 0.00013 mg/L. Dissolved cadmium concentrations in well MW16-12S ranged from 0.000012 to 0.000038 mg/L and those in well MW15-01 ranged from below the detection limit (<0.000005 mg/L) to 0.000025 mg/L. The remainder of the wells all had dissolved cadmium concentrations that were generally below 0.00001 mg/L.

The highest dissolved lead concentration was recorded for the MW15-01 June 2017 sample (0.00024 mg/L), which otherwise ranged between <0.000005 and 0.000025 mg/L. For most sampling events, BH95G-32 generally had the highest concentrations of dissolved lead, ranging from below the detection limit (<0.000005 mg/L) to 0.00014 mg/L. The remainder well water samples ranged from <0.000005 to 0.00004 mg/L.

Overall, for metals there was no evidence of a distinction between the bedrock and overburden wells in terms of water quality with the three years of baseline data collected. Although there was significant fluctuation in some metal concentrations, the data collected to date do not indicate distinct seasonal trends.

**Table 3-13: Summary Statistics for Metals in Class B Storage Facility Area**

| Metal (dissolved) | Al      | As      | Cd            | Cu        | Fe          | Pb        | Se       | Zn        |
|-------------------|---------|---------|---------------|-----------|-------------|-----------|----------|-----------|
| Station Name      | mg/L    | mg/L    | mg/L          | mg/L      | mg/L        | mg/L      | mg/L     | mg/L      |
| YCSR – Schedule 3 |         | 0.05    | 0.0001-0.0006 | 0.02-0.09 |             | 0.04-0.16 | 0.01     | 0.075-2.4 |

### 3.3.4 Class C Storage Facility Area

#### 3.3.4.1 Setting

The Class C Storage Facility area contains the proposed Class C Storage Facility, the overburden stockpile and associated water collection ponds, as shown on Figure 2-1. The Class C Storage Facility is on the eastern slope of the valley with Geona Creek flowing through the bottom of the valley. A small tributary flows into Geona Creek through the proposed location of the Class C Storage Facility. Ten monitoring wells characterise this area; a combination of wells screened in overburden (four wells) and bedrock (six wells). Of the ten monitoring wells, MW15-05s is dry, and three of the wells (BH95G-30, BH95G-31, and MW15-06) were frozen part of the years that were monitored.

#### 3.3.4.2 Physical Parameters and Nutrients

The bedrock and overburden wells in the pit areas were generally circumneutral to mildly alkaline (pH range 6.06 to 8.1; Table 3-14), Table 3-15 and the in situ summary table provided in Appendix D-4. One sample from well MW15-03S returned a pH 6.06 which was below the lower FIGWQG boundary (pH 6.5). Well water dissolved oxygen levels ranged from 6 to 102% saturation, suggesting the groundwaters ranged from sub-oxic/anoxic to oxic. Temperature varied seasonally between -0.2 and 9.6°C, and three of the ten wells were frozen for most or all the years monitored.

Within the Class C Storage Facility area, no monitoring well samples exceeded the YCSR standards for the measured anions or nutrients (Table 3-15). The plots of these parameters for the Class C Storage Facility area wells can be found in Appendix C. Except for two low concentration outliers for single samples from wells MW16-16D (<0.01 mg/L) and BH95G-31 (0.011 mg/L), fluoride concentrations ranged between 0.054 and 0.24 mg/L. The highest fluoride concentrations were observed in samples collected from MW15-04D (0.20 to 0.24 mg/L), followed by MW15-03D (0.14 to 0.17 mg/L), and BH95G-30 (0.13 to 0.14 mg/L). Overall, fluoride concentrations showed limited variation in samples collected from each well over the period of record, with no seasonality apparent. With the exception of BH95G-31, higher fluoride concentrations were generally observed in the bedrock wells.

Sulphate concentrations also exhibited a relative narrow concentration range (8.5 to 42 mg/L) in wells located in the Class C Storage Facility area relative to the other areas (i.e., the ABM open pit and Class A and B Storage Facility areas). The highest concentrations were recorded in samples collected from wells MW16-16D (35 to 39 mg/L; average 37 mg/L) and MW15-05D (29 to 42 mg/L; average 32 mg/L), whereas the lowest concentrations were typically reported in wells MW15-03S (9.8 to 33 mg/L; average 15 mg/L) and MW15-04S (8.5 to 11 mg/L; average 9.7 mg/L). Overall, the sulphate concentrations in each well showed minimal variation over the period of record.

The ammonia-N concentrations for all samples ranged between <0.005 and 0.30 mg/L and were at least one order of magnitude below the pH-dependent YCSR standard. Concentrations were often highest for each sampling event in well MW15-03D (0.04 to 0.30 mg/L). Ammonia-N concentrations in each well were variable and generally spanned an order of magnitude over the sampling record for each well.

### 3.3.4.3 Metals

Metals concentrations within the Class C Storage Facility area were generally quite low with no exceedances of YCSR standards. Dissolved aluminium and iron, which have no YCSR standards, exceeded their FIGWQG (Table 3-16 and Appendix D-4) in one or more samples.

Dissolved iron concentrations were generally lower in the Class C Storage Facility area than in other areas at the KZK site. The highest average dissolved iron concentration was in well MW15-03D (0.577 mg/L), from which the majority of samples exceeded the FIGWQG guideline (0.3 mg/L), whereas BH95G-30, MW15-05D and MW15-06 wells returned average dissolved iron concentrations less than 0.01 mg/L. Sporadic FIGWQG guideline exceedances were also observed in single samples collected from wells MW15-04S and MW16-16D; however, the dissolved iron concentrations observed in these wells spanned two to three orders of magnitude. There was no obvious correlation between dissolved iron concentration in overburden or bedrock wells.

Within the Class C Storage Facility area there was a single exceedance of the FIGWQG for dissolved aluminium (0.1 mg/L if pH > 6.5, 0.005 mg/L if pH < 6.5), which occurred in March 2016 at MW15-03S. Concentrations in MW15-03S, ranged from 0.0018 to 0.0266 mg/L, followed by MW15-03D, ranging from 0.00057 to 0.0144 mg/L. BH95G-30 had a spike in September 2015 of 0.013 mg/L, but ranged from 0.0005 to 0.0010 mg/L. The highest concentration recorded was in BH95G-31, which had a peak of 0.085 mg/L (November 2015), but otherwise ranged from 0.002 to 0.005 mg/L. The aluminum concentration from the 4<sup>th</sup> September 1995 data point was 0.015 mg/L, within the minimum and maximum ranged collected in the 2015 to 2017 dataset (0.0005 to 0.0852 mg/L).

Concentrations of dissolved arsenic were generally quite low, ranging between 0.000028 and 0.0033 mg/L for all wells and well below the YCSR standard (0.05 mg/L). The highest dissolved arsenic concentrations were generally encountered in wells MW15-03D and MW15-04D, which had very similar concentrations and trends over time with averages of 0.0019 and 0.0015 mg/L, respectively. The six samples collected from MW16-16D returned dissolved arsenic concentrations that ranged from 0.0001 to 0.00054 mg/L. Monitoring wells MW15-04S, MW15-03S, MW15-05D, and BH95G-31 had similar dissolved arsenic concentrations over the period of record, ranging from 0.00004 to 0.0003 mg/L with the exception of the MW15-04S September 2017 sample (0.0026 mg/L). The remainder of the wells were generally under 0.0001 mg/L. The arsenic concentration from the 4<sup>th</sup> September 1995 data point was 0.000006 mg/L, within the minimum and maximum range collected in the 2015 to 2017 dataset (0.0000025 to 0.00024 mg/L).

The September 2017 sampling event at well MW14-04S returned the highest dissolved copper concentration within the Class C Storage Facility area throughout the period of record (0.014 mg/L); dissolved copper levels in samples from this well otherwise ranged from <0.00005 to 0.0012 mg/L. A few wells had dissolved copper concentrations above 0.001 mg/L:

- BH95G-31 had a concentration of 0.0013 mg/L in November 2015;
- MW15-04S had a concentration of 0.0012 mg/L in November 2015;
- MW15-03S had a concentration of 0.0020 mg/L in March 2016;
- MW15-05D had a concentration 0.0017 mg/L in May 2016; and
- MW15-03D had a concentration of 0.0016 mg/L in August 2016.

Otherwise all dissolved copper concentrations were below 0.001 mg/L. The copper concentration from the 4th September 1995 data point was 0.0007 mg/L, within the minimum and maximum range collected in the 2015 to 2017 dataset (0.000025 to 0.002 mg/L).

Overall dissolved selenium concentrations had very little fluctuation in concentrations over the period of record within the Class C Storage Facility area, but displayed a wide span between <0.00004 and 0.0029 mg/L. Four monitoring wells within the Class C Storage Facility area consistently exceeded 0.001 mg/L with very similar concentration ranges (0.0010 to 0.0029 mg/L): BH95G-30, BH95G-31, MW15-05D, and MW15-06. MW15-04S dissolved selenium levels ranged from 0.00070 to 0.00085 mg/L, and were generally an order of magnitude higher than its companion nested bedrock well MW15-04D (0.00002 to 0.0004 mg/L). The same pattern occurred for nested wells MW15-03S and MW15-03D, where the shallow well returned dissolved selenium concentrations that ranged from 0.00017 to 0.00032 mg/L, whereas concentrations in the deeper MW15-03D well were an order of magnitude lower, ranging from 0.00002 to 0.00026 mg/L.

Monitoring wells BH95G-30 and MW15-06 are bedrock and overburden paired wells, respectively, that had the highest dissolved cadmium concentrations, ranging from 0.000095 to 0.00018 mg/L. The remainder of the Class C Monitoring wells had dissolved cadmium concentrations below 0.0001 mg/L.

Within the Class C Storage Facility area, dissolved zinc concentrations were at least two orders of magnitude below the hardness-dependent YCSR standard. Samples collected from well BH95G-30 generally had the highest and most consistent concentrations of dissolved zinc, ranging from 0.007 to 0.009 mg/L. MW15-05D had a higher concentration than BH95G-30 for one event in May 2016, and fluctuated by over an order of magnitude over the period of record (0.00053 to 0.011 mg/L). MW15-03S and MW15-04S also fluctuated significantly over the period of record with a range of 0.00005 to 0.0106 mg/L, and 0.00005 to 0.018 mg/L, respectively. The remainder of the Class C monitoring wells were generally below a dissolved zinc concentration of 0.001 mg/L. The zinc concentration from the 4<sup>th</sup> September 1995 data point was 0.003 mg/L, within the minimum and maximum range collected in the 2015 to 2017 dataset (0.00005 to 0.011 mg/L).

All dissolved lead concentrations were less than 0.003 mg/L except for MW15-04S in September 2017 with a concentration of 0.007 mg/L. Samples collected from well MW15-05D typically had the highest concentrations in the Class C Storage Facility area, ranging from 0.000008 to 0.00022 mg/L. BH95G-31 had a peak in November 2015 with a dissolved lead concentration of 0.00026 mg/L, but otherwise ranged from 0.000012 to 0.000047 mg/L. MW15-04D and MW15-03S had similar concentrations, ranging from below the detection limit (<0.000005 mg/L) to 0.00027 mg/L. BH95G-30 ranged from 0.000006 to 0.000084 mg/L. The remainder of the monitoring wells in the Class C Storage Facility area generally had dissolved lead concentrations below 0.00001 mg/L.

There was no evidence of a clear distinction between the bedrock and overburden wells in terms of water quality with the three years of baseline data collected. Higher concentrations in metals were more closely related to location and redox regime, over the difference between overburden and bedrock.

**Table 3-16: Summary Statistics for Metals in Class C Storage Facility Area**

| Metal (dissolved) | Al      | As       | Cd            | Cu        | Fe     | Pb        | Se      | Zn        |
|-------------------|---------|----------|---------------|-----------|--------|-----------|---------|-----------|
| Station Name      | mg/L    | mg/L     | mg/L          | mg/L      | mg/L   | mg/L      | mg/L    | mg/L      |
| YCSR – Schedule 3 |         | 0.05     | 0.0001-0.0006 | 0.02-0.09 |        | 0.04-0.16 | 0.01    | 0.075-2.4 |
| BH95G-30          |         |          |               |           |        |           |         |           |

### 3.3.5 Site Groundwater Quality Observations

#### 3.3.5.1 Physical Parameters and Nutrients

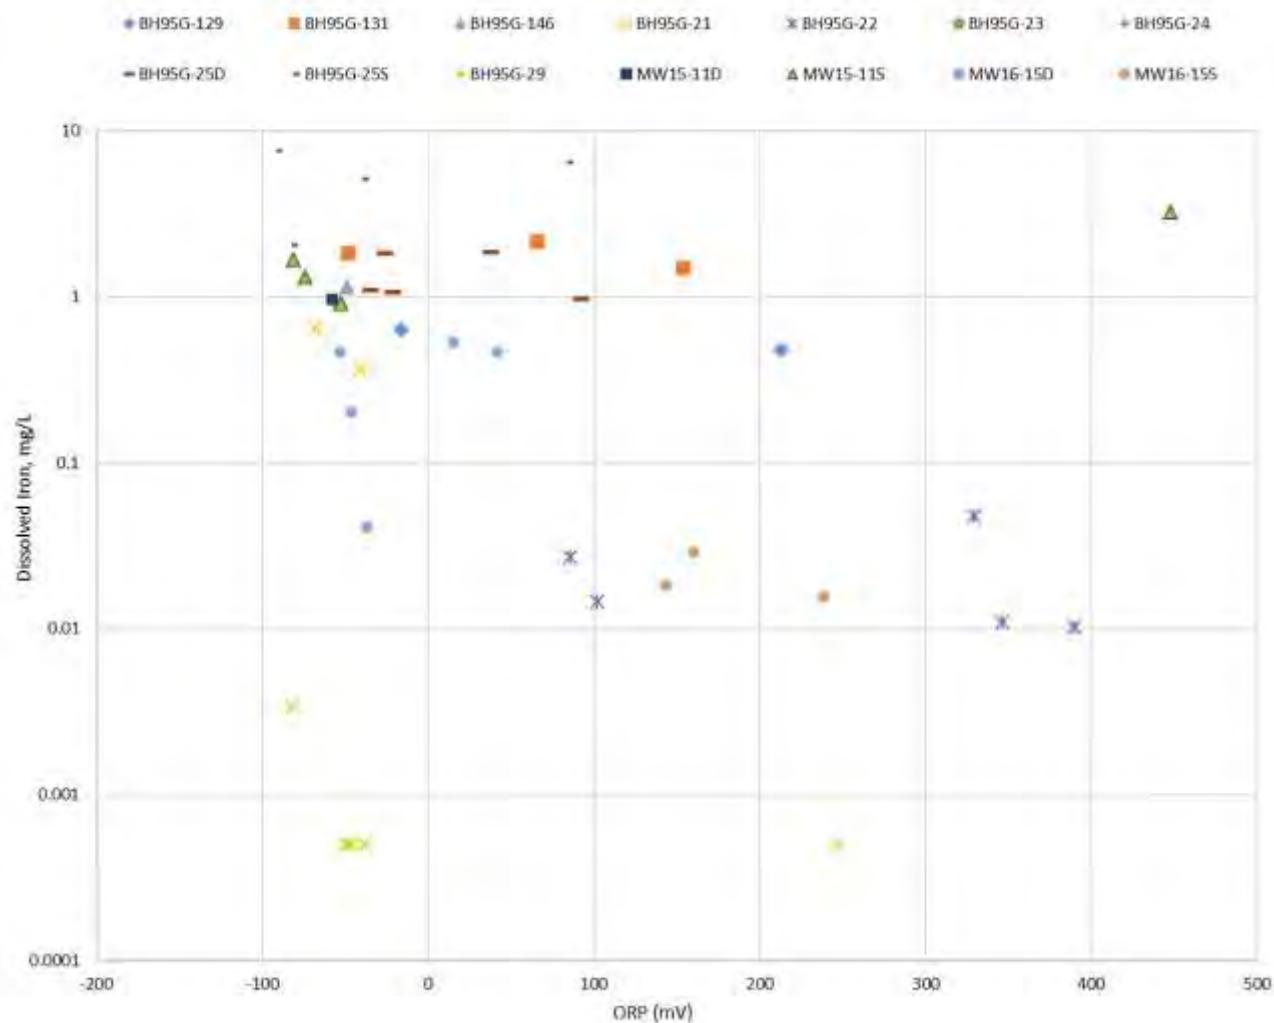

Throughout the KZK Project area field pH values ranged from 5.7 to 8.63, with an average pH value of 7.5, for both bedrock and overburden wells (Table 3-17). Field measured oxidation and reduction potential ranged from -115 mV to +448 mV indicating that some wells are screened in material with reducing conditions and others in oxidizing conditions. The higher dissolved iron concentrations in the ABM open pit area groundwater tended to occur at lower redox potential, as shown on Figure 3-10, suggesting the reducing conditions were responsible for the elevated iron levels observed.

Sulphate concentrations were generally much higher in the ABM open pit area, with maximum concentration of 280 mg/L and an average of 123 mg/L, relative to the rest of the Project area, which averaged 31 mg/L. Higher sulphate concentrations in the vicinity of the ABM open pit area is likely due to the oxidation of the sulphidic minerals in the deposit. Sulphate concentrations did seem to vary between overburden and bedrock wells across the site with deep wells tending to have slightly higher concentrations than shallow wells.

Ammonia was elevated in several wells spread across the entire KZK Project area and was not specific to a particular area, although the concentrations observed were generally higher in the ABM open pit area. Fluoride was elevated in many wells across the site, and was one of the few parameters to indicate a difference between bedrock and overburden concentrations, primarily in the Class A and Class C Storage Facility areas. Bedrock wells tended to have higher fluoride concentrations than the overburden wells likely reflecting the water-rock interaction and the leaching of fluoride from host rock minerals, such as mica. Fluoride concentrations across the site were the most consistent with little fluctuation relative to the other general parameters and metals.

#### 3.3.5.2 Metals

Many of the parameters summarized above fluctuated significantly over the period of record. There was very little indication that metals varied from bedrock wells compared to overburden wells. Dissolved cadmium, arsenic, zinc and cobalt were the only elements to exceed a YCSR – Schedule 3 standard; of these metals, cadmium exceeded most frequently (29 samples from five wells). Cadmium, arsenic, selenium, and zinc were also consistently elevated above the FIGWQG across the KZK site and are considered constituents of potential interest (COPI) for the KZK Project. Geochemical testing and the water quality modelling conducted for the site also indicate that these elements are COPI for meeting long term water quality objectives.

**Figure 3-10: ORP vs Dissolved Iron Concentration within the ABM Open Pit area**

Dissolved arsenic was slightly more elevated in the ABM open pit area, with an average concentration of 0.0038 mg/L, compared to the rest of the KZK Project area, with an average of 0.0009 mg/L. Dissolved zinc concentrations were higher in the ABM open pit area as well as in the wells that were located in the bottom of the valley beside Geona Creek, downgradient of the proposed ABM open pit. Similar to zinc, total iron was elevated in the ABM open pit area, as well as in the bottom of the Geona Creek valley. Cadmium and lead concentrations had similar concentrations in the pit compared to the rest of the Project area. Dissolved selenium was elevated across the KZK Project in numerous wells; however, concentrations in select wells were much higher in the Class A and B areas.

The concentrations of zinc within the pit area, are likely elevated compared to the rest of the KZK Project site due to the mineralization of this area. Elevated iron in the pit area may be related to oxidation of iron sulphide minerals in and around the mineral deposit, but are most likely governed by reducing conditions in these circumneutral groundwaters.

## 4 SUMMARY AND CONCLUSIONS

The main conclusions from the groundwater monitoring program are as follows:

- The hydraulic properties of the KZK were assessed as overburden and bedrock. Overburden at the KZK site generally consists of two material types:
  - Fine-grained lower permeability sediments composed of silts and fine sands; and
  - Coarse-grained higher permeability sands and gravels.

For bedrock, hydraulic conductivities generally range between  $1 \times 10^{-7}$  to  $1 \times 10^{-5}$  m/s. Bedrock at the depth range of 10 m to 70 m below ground surface does not appear to have increasing or decreasing hydraulic conductivities with depth. The geometric mean of these tests is  $1.2 \times 10^{-6}$  m/s, which corresponds to the long-term bedrock pumping test conducted by EBA ( $1.7 \times 10^{-6}$  m/s).

- Groundwater elevations across the site generally had a seasonality trend in both bedrock and overburden wells with varying levels of intensity. The seasonal patterns observed are:
  - Rising water levels through the summer months (approximately May to August);
  - Peak water levels reached between August and September, depending on the year;
  - Falling water levels through the winter months (approximately October to March); and
  - Lowest levels reached between April and May, depending on the year.

Water elevations fluctuated in most monitoring wells between 2 to 8 m. However, there is a 16 m water level difference in BH95G-2 and less than 1.5 m difference in MW15-07S.

- Project wide the field pH ranged from circumneutral to slightly alkaline, 5.68 to 8.63, with an average pH value of 7.39, for both bedrock and overburden wells.
- MW15-10S and MW15-10D, had lower pH values relative to the rest of the KZK Project monitoring wells, with a range of 5.80 to 6.46, and 5.82 to 7.38, respectively. These lower pH wells are located nearby the KZ-9 east seep, which is also characterized by low pH water (pH 5.8 to 6.0), suggesting groundwater found in wells MW15-10S and MW15-10D are fed from the same source as this seep.
- Sulphate concentrations were typically more elevated within the pit area, with a maximum sulphate concentration of 279 mg/L and an average of 123 mg/L. The remainder of the KZK Project site had average sulphate concentrations of 31 mg/L. Higher concentrations in the pit area is likely due to the oxidation of the sulphidic minerals in the deposit.
- Generally, concentrations of nutrients, anions, and metals did not vary between overburden and bedrock wells; with the exception of sulphate and fluoride. In both cases deeper wells had higher concentrations.
- No YCSR standard exceedances were observed for anions or nutrients in any KZK wells.
- Ammonia was elevated in wells throughout KZK Project area and was not specific to a particular area, although the concentrations observed were generally higher in the pit area.
- Cadmium, arsenic, zinc and cobalt were the only metals to exceed YCSR – Schedule 3 standards. Dissolved arsenic, zinc and cobalt exceedances were sporadic while dissolved cadmium was elevated in five wells in the ABM open pit and Class A Storage Facility area and exceeded its YCSR standard in 29 samples.

- Concentrations of iron and zinc were elevated in the pit area relative to the rest of the KZK Project. This is likely due to the mineralization of pit area. Elevated iron in the pit area may be related to oxidation of iron sulphide minerals in and around the ABM deposit, but are most likely governed by reducing conditions in these circumneutral groundwaters.

- (a) Test interval length is generally from the top to the bottom of the sand pack. If the static water level is below the top of sand pack, the test interval is from the static water level to the bottom of the sand pack.  
 (b) For typical well completions, the shape factor normally ranges from 5.4 to 6.2; a value of 5.8 is reasonable for practical application  
 (c) Three brief pumping periods over a total duration of 34.7 minutes  
 (d) Cannot be analyzed due to oscillations and discontinuous pumping  
 (e) Recovery too rapid for reliable analysis  
 (f) Insufficient drawdown for reliable analysis  
 (g) Average of specific capacity and Theis recovery transmissivities if both values calculated  
 (h) Average hydraulic conductivity of geologic materials within the test interval  
 bgs Below ground surface

Specific Capacity Analysis

$$T = \frac{Q F}{2 \pi s_p}$$

Theis Recovery Analysis

$$T = \frac{2.303 Q}{4 \pi \Delta s_{10}}$$

Hydraulic Conductivity

$$K = \frac{T}{L}$$

**Remarks:**

Maxxam Analytics' laboratories are accredited to ISO/IEC 17025:2005 for specific parameters on scopes of accreditation. Unless otherwise noted, procedures used by Maxxam are based upon recognized Provincial, Federal or US method compendia such as CCME, MDDELCC, EPA, APHA.

All work recorded herein has been done in accordance with procedures and practices ordinarily exercised by professionals in Maxxam's profession using accepted testing methodologies, quality assurance and quality control procedures (except where otherwise agreed by the client and Maxxam in writing). All data is in statistical control and has met quality control and method performance criteria unless otherwise noted. All method blanks are reported: unless indicated otherwise, associated sample data are not blank corrected.

Maxxam Analytics' liability is limited to the actual cost of the requested analyses, unless otherwise agreed in writing. There is no other warranty expressed or implied. Maxxam has been retained to provide analysis of samples provided by the Client using the testing methodology referenced in this report. Interpretation and use of test results are the sole responsibility of the Client and are not within the scope of services provided by Maxxam, unless otherwise agreed in writing.

Solid sample results, except biota, are based on dry weight unless otherwise indicated. Organic analyses are not recovery corrected except for isotope dilution methods.

Results relate to samples tested.

This Certificate shall not be reproduced except in full, without the written approval of the laboratory.

Reference Method suffix "m" indicates test methods incorporate validated modifications from specific reference methods to improve performance.

## CERTIFICATE OF ANALYSIS – REVISED REPORT

**MAXXAM JOB #: B721752**

**Received: 2017/03/23, 11:50**

\* RPDS calculated using raw data. The rounding of final results may result in the apparent difference.

(1) DOC present in the sample should be considered as non-purgeable DOC.

(2) The BC-MOE and APHA Standard Method require pH to be analysed within 15 minutes of sampling and therefore field analysis is required for compliance. All Laboratory pH analyses in this report are reported past the BC-MOE/APHA Standard Method holding time.

RDL = Reportable Detection Limit

N/A = Not Applicable

(1) Detection limits raised due to dilution to bring analyte within the calibrated range. Sample preserved to extend hold time.

(2) Sample preserved to extend hold time.

(3) Sample analysed past recommended hold time.

RDL = Reportable Detection Limit

N/A = Not Applicable

(1) Detection limits raised due to dilution to bring analyte within the calibrated range. Sample preserved to extend hold time.

(2) Sample preserved to extend hold time.

(3) Sample analysed past recommended hold time.

## GENERAL COMMENTS

Each temperature is the average of up to three cooler temperatures taken at receipt

|           |       |
|-----------|-------|
| Package 1 | 2.0°C |
| Package 2 | 6.0°C |
| Package 3 | 1.7°C |
| Package 4 | 1.0°C |
| Package 5 | 1.0°C |
| Package 6 | 1.0°C |
| Package 7 | 1.0°C |

Revised Report V2 (M\_S, 2017/04/05): Sample comment added for Trip Blank Total Lead result.

All samples were received at analytical lab past recommended hold time or on day of expiry for nitrate and nitrite.

Sample QT8718 [BH95G-22] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample QT8719 [MW15-03S] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample QT8721 [MW15-04S] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample QT8722 [MW15-04D] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample QT8723 [MW15-05D] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample QT8724 [MW16-15D] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample QT8725 [BH95G-2] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample QT8726 [BH95G-15D] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample QT8727 [BH95G-25S] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample QT8728 [BH95G-25D] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample QT8729 [BH95G-32] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample QT8730 [BH95G-33D] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample QT8731 [MW16-16D] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sampler Initials: MH

Sample QT8740 [MW16-17] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample QT8741 [DUP 1] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample QT8756 [DUP 2] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample QT8757 [FIELD BLANK] : Ion Balance: NC = Not Calculable due to low ion sum [< 0.4 meq/L].

Sample QT8758 [TRIP BLANK] : Ion Balance: NC = Not Calculable due to low ion sum [< 0.4 meq/L].

**LL TOTAL METALS (DIGESTED) WITH CV HG Comments**

Sample QT8719 [MW15-03S] Elements by ICPMS Digested LL (total): RDL raised due to sample matrix interference.

Sample QT8727 [BH95G-25S] Elements by ICPMS Digested LL (total): RDL raised due to sample matrix interference.

Sample QT8719, Elements by ICPMS Low Level (dissolved): Test repeated.

Sample QT8721, Elements by ICPMS Low Level (dissolved): Test repeated.

Sample QT8723, Elements by ICPMS Low Level (dissolved): Test repeated.

Sample QT8726, Elements by ICPMS Low Level (dissolved): Test repeated.

Sample QT8727, Elements by ICPMS Low Level (dissolved): Test repeated.

Sample QT8741, Elements by ICPMS Low Level (dissolved): Test repeated.

**Results relate only to the items tested.**

N/A = Not Applicable

Duplicate: Paired analysis of a separate portion of the same sample. Used to evaluate the variance in the measurement.

Matrix Spike: A sample to which a known amount of the analyte of interest has been added. Used to evaluate sample matrix interference.

Spiked Blank: A blank matrix sample to which a known amount of the analyte, usually from a second source, has been added. Used to evaluate method accuracy.

Method Blank: A blank matrix containing all reagents used in the analytical procedure. Used to identify laboratory contamination.

NC (Matrix Spike): The recovery in the matrix spike was not calculated. The relative difference between the concentration in the parent sample and the spike amount was too small to permit a reliable recovery calculation (matrix spike concentration was less than the native sample concentration)

NC (Duplicate RPD): The duplicate RPD was not calculated. The concentration in the sample and/or duplicate was too low to permit a reliable RPD calculation (absolute difference <= 2x RDL).

(1) Recovery or RPD for this parameter is outside control limits. The overall quality control for this analysis meets acceptability criteria.

**Remarks:**

Maxxam Analytics' laboratories are accredited to ISO/IEC 17025:2005 for specific parameters on scopes of accreditation. Unless otherwise noted, procedures used by Maxxam are based upon recognized Provincial, Federal or US method compendia such as CCME, MDDELCC, EPA, APHA.

All work recorded herein has been done in accordance with procedures and practices ordinarily exercised by professionals in Maxxam's profession using accepted testing methodologies, quality assurance and quality control procedures (except where otherwise agreed by the client and Maxxam in writing). All data is in statistical control and has met quality control and method performance criteria unless otherwise noted. All method blanks are reported: unless indicated otherwise, associated sample data are not blank corrected.

Maxxam Analytics' liability is limited to the actual cost of the requested analyses, unless otherwise agreed in writing. There is no other warranty expressed or implied. Maxxam has been retained to provide analysis of samples provided by the Client using the testing methodology referenced in this report. Interpretation and use of test results are the sole responsibility of the Client and are not within the scope of services provided by Maxxam, unless otherwise agreed in writing.

Solid sample results, except biota, are based on dry weight unless otherwise indicated. Organic analyses are not recovery corrected except for isotope dilution methods.

Results relate to samples tested.

This Certificate shall not be reproduced except in full, without the written approval of the laboratory.

Reference Method suffix "m" indicates test methods incorporate validated modifications from specific reference methods to improve performance.

\* RPDS calculated using raw data. The rounding of final results may result in the apparent difference.

(1) DOC present in the sample should be considered as non-purgeable DOC.

(2) The BC-MOE and APHA Standard Method require pH to be analysed within 15 minutes of sampling and therefore field analysis is required for compliance. All Laboratory pH analyses in this report are reported past the BC-MOE/APHA Standard Method holding time.

RDL = Reportable Detection Limit

N/A = Not Applicable

(1) Sample arrived to laboratory past recommended hold time.

(2) Detection limits raised due to dilution to bring analyte within the calibrated range. Sample arrived to laboratory past recommended hold time.

RDL = Reportable Detection Limit

N/A = Not Applicable

(1) Detection limits raised due to dilution to bring analyte within the calibrated range.

(2) Sample arrived to laboratory past recommended hold time.

(3) Sample analysed past recommended hold time.

(4) Detection limits raised due to dilution to bring analyte within the calibrated range. Sample analysed past recommended hold time.

RDL = Reportable Detection Limit

N/A = Not Applicable

(1) Ion balance out of optimal range due to high measurement uncertainty at this level (Ion Sum < 0.4 meq/L for both cations and anions).

(2) Sample analysed past recommended hold time.

(3) Detection limits raised due to dilution to bring analyte within the calibrated range. Sample analysed past recommended hold time.

## GENERAL COMMENTS

Each temperature is the average of up to three cooler temperatures taken at receipt

|           |       |
|-----------|-------|
| Package 1 | 6.7°C |
| Package 2 | 6.0°C |
| Package 3 | 8.3°C |
| Package 4 | 8.0°C |
| Package 5 | 7.7°C |

Samples collected on June 5th and June 6th were received at analytical lab past recommended hold time for Nitrate, Nitrite, Dissolved Phosphorus and Total Phosphorus. Sample collected on June 7th arrived at analytical lab on date of expiry for Nitrate, Nitrite, Dissolved Phosphorus and Total Phosphorus, samples ewre analyzed past recommended hold time.

Sample RG5766 [MW15-03S] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RG5767 [MW15-03D] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RG5768 [MW15-04S] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RG5769 [MW15-04D] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RG5771 [MW15-07S] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RG5772 [MW15-09S] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RG5773 [MW15-10D] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RG5774 [DUP-1] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RG5775 [MW16-14D] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RG5778 [MW16-17] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RG5779 [MW16-15D] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RG5780 [DUP-3] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RG5781 [MW16-15S] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RG5782 [MW15-01] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RG5783 [BH95G-02] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RG5784 [BH95G-15D] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RG5785 [BH95G-25D] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RG5786 [BH95G-32] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RG5788 [BH95G-22] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RG5789 [BH95G-31] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RG5790 [FIELD BLANK] : Sample was reanalyzed for Total Metals and Nitrate+Nitrite, re-analysis yields similar results.

Sample RG5791 [BH95G-33D] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RG5792 [DUP-2] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

#### **LOW LEVEL DISSOLVED METALS WITH CV HG (WATER) Comments**

Sample RG5773 [MW15-10D] Elements by ICPMS Low Level (dissolved): RDL raised due to sample matrix interference.

Sample RG5774 [DUP-1] Elements by ICPMS Low Level (dissolved): RDL raised due to sample matrix interference.

#### **LL TOTAL METALS (DIGESTED) WITH CV HG Comments**

Sample RG5768 [MW15-04S] Elements by ICPMS Digested LL (total): RDL raised due to sample matrix interference.

Sample RG5772 [MW15-09S] Elements by ICPMS Digested LL (total): RDL raised due to sample matrix interference.

Sample RG5773 [MW15-10D] Elements by ICPMS Digested LL (total): RDL raised due to sample matrix interference.

Sample RG5774 [DUP-1] Elements by ICPMS Digested LL (total): RDL raised due to sample matrix interference.

Sample RG5781 [MW16-15S] Elements by ICPMS Digested LL (total): RDL raised due to sample matrix interference.

Sample RG5786 [BH95G-32] Elements by ICPMS Digested LL (total): RDL raised due to sample matrix interference.

Sample RG5788 [BH95G-22] Elements by ICPMS Digested LL (total): RDL raised due to sample matrix interference.

Sample RG5789 [BH95G-31] Elements by ICPMS Digested LL (total): RDL raised due to sample matrix interference.

Sample RG5767, Elements by ICPMS Low Level (dissolved): Test repeated.

Sample RG5768, Elements by ICPMS Low Level (dissolved): Test repeated.

Sample RG5769, Elements by ICPMS Low Level (dissolved): Test repeated.

Sample RG5784, Elements by ICPMS Low Level (dissolved): Test repeated.

Sample RG5790, Elements by ICPMS Low Level (total): Test repeated.

**Results relate only to the items tested.**

N/A = Not Applicable

Duplicate: Paired analysis of a separate portion of the same sample. Used to evaluate the variance in the measurement.

Matrix Spike: A sample to which a known amount of the analyte of interest has been added. Used to evaluate sample matrix interference.
