Spiked Blank: A blank matrix sample to which a known amount of the analyte, usually from a second source, has been added. Used to evaluate method accuracy.

Method Blank: A blank matrix containing all reagents used in the analytical procedure. Used to identify laboratory contamination.

NC (Matrix Spike): The recovery in the matrix spike was not calculated. The relative difference between the concentration in the parent sample and the spike amount was too small to permit a reliable recovery calculation (matrix spike concentration was less than the native sample concentration)

NC (Duplicate RPD): The duplicate RPD was not calculated. The concentration in the sample and/or duplicate was too low to permit a reliable RPD calculation (absolute difference <= 2x RDL).

(1) Recovery or RPD for this parameter is outside control limits. The overall quality control for this analysis meets acceptability criteria.

**Remarks:**

Maxxam Analytics' laboratories are accredited to ISO/IEC 17025:2005 for specific parameters on scopes of accreditation. Unless otherwise noted, procedures used by Maxxam are based upon recognized Provincial, Federal or US method compendia such as CCME, MDDELCC, EPA, APHA.

All work recorded herein has been done in accordance with procedures and practices ordinarily exercised by professionals in Maxxam's profession using accepted testing methodologies, quality assurance and quality control procedures (except where otherwise agreed by the client and Maxxam in writing). All data is in statistical control and has met quality control and method performance criteria unless otherwise noted. All method blanks are reported: unless indicated otherwise, associated sample data are not blank corrected.

Maxxam Analytics' liability is limited to the actual cost of the requested analyses, unless otherwise agreed in writing. There is no other warranty expressed or implied. Maxxam has been retained to provide analysis of samples provided by the Client using the testing methodology referenced in this report. Interpretation and use of test results are the sole responsibility of the Client and are not within the scope of services provided by Maxxam, unless otherwise agreed in writing.

Solid sample results, except biota, are based on dry weight unless otherwise indicated. Organic analyses are not recovery corrected except for isotope dilution methods.

Results relate to samples tested.

This Certificate shall not be reproduced except in full, without the written approval of the laboratory.

Reference Method suffix "m" indicates test methods incorporate validated modifications from specific reference methods to improve performance.

\* RPDS calculated using raw data. The rounding of final results may result in the apparent difference.

(1) DOC present in the sample should be considered as non-purgeable DOC.

(2) The BC-MOE and APHA Standard Method require pH to be analysed within 15 minutes of sampling and therefore field analysis is required for compliance. All Laboratory pH analyses in this report are reported past the BC-MOE/APHA Standard Method holding time.

RDL = Reportable Detection Limit

(1) Duplicate RPD above control limit - (10% of analytes failure allowed). Matrix Spike outside acceptance criteria re-analysis yields similar results.

(2) Matrix Spike outside acceptance criteria due to sample matrix interference, re-analysis yields similar results.

## GENERAL COMMENTS

Sample RZ2886 [MW15-03S] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2887 [MW15-03D] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level).

Sample RZ2888 [MW15-04S] : Sample analyzed past method specified hold time for Carbon (DOC) - unfiltered/unpreserved . {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2889 [MW15-04D] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2890 [MW15-07D] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2901 [MW15-07S] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level).

Sample RZ2907 [MW15-09S] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2908 [MW15-10D] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2909 [DUP-1] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2910 [MW16-14D] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2911 [MW16-12D] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level).

Sample RZ2912 [MW16-16D] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2913 [MW16-17] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2914 [MW16-15D] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2915 [DUP-3] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2916 [MW16-15S] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2917 [MW15-01] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2918 [BH95G-2] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample received past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample received past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample received past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2919 [BH95G-15D] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2920 [BH95G-25D] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2921 [BH95G-32] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2922 [BH95G-131] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample analyzed for digested low level

metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2923 [BH95G-22] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2924 [BH95G-31] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2925 [FIELD BLANK] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Ion Balance: NC = Not Calculable due to low ion sum [< 0.4 meq/L].

Sample RZ2926 [BH95G-33D] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2927 [DUP-2] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2928 [TRIP BLANK] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.}

Sample RZ2929 [MW15-02] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2930 [BH95G-21] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2931 [MW15-11S] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2932 [BH95G-25S] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2933 [MW16-12S] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample

analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample RZ2934 [MW15-10S] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

#### **LOW LEVEL DISSOLVED METALS WITH CV HG (WATER) Comments**

Sample RZ2908 [MW15-10D] Elements by ICPMS Low Level (dissolved): RDL raised due to concentration over linear range, sample dilution required.

Sample RZ2911 [MW16-12D] Elements by ICPMS Low Level (dissolved): RDL raised due to concentration over linear range, sample dilution required.

Sample RZ2911 [MW16-12D] Elements by ICPMS Low Level (dissolved): RDL raised due to concentration over linear range, sample dilution required.

Sample RZ2933 [MW16-12S] Elements by ICPMS Low Level (dissolved): RDL raised due to concentration over linear range, sample dilution required.

#### **LOW LEVEL TOTAL METALS WITH CV HG (WATER) Comments**

Sample RZ2911 [MW16-12D] Elements by ICPMS Low Level (total): RDL raised due to concentration over linear range, sample dilution required.

#### **LL TOTAL METALS (DIGESTED) WITH CV HG Comments**

Sample RZ2886 [MW15-03S] Elements by ICPMS Digested LL (total): RDL raised due to concentration over linear range, sample dilution required.

Sample RZ2908 [MW15-10D] Elements by ICPMS Digested LL (total): RDL raised due to concentration over linear range, sample dilution required.

Sample RZ2916 [MW16-15S] Elements by ICPMS Digested LL (total): RDL raised due to concentration over linear range, sample dilution required.

Method Blank Elements by ICPMS Digested LL (total): Antimony blank outside acceptance criteria, detection limit adjusted accordingly

Sample RZ2923 [BH95G-22] Elements by ICPMS Digested LL (total): RDL raised due to concentration over linear range, sample dilution required.

Sample RZ2933 [MW16-12S] Elements by ICPMS Digested LL (total): RDL raised due to concentration over linear range, sample dilution required.

Sample RZ2934 [MW15-10S] Elements by ICPMS Digested LL (total): RDL raised due to concentration over linear range, sample dilution required.

Sample RZ2889, Elements by ICPMS Low Level (dissolved): Test repeated.

Sample RZ2910, Elements by ICPMS Low Level (dissolved): Test repeated.

Sample RZ2911, Elements by ICPMS Low Level (dissolved): Test repeated.

Sample RZ2916, Elements by ICPMS Low Level (dissolved): Test repeated.

Sample RZ2920, Elements by ICPMS Low Level (dissolved): Test repeated.

Sample RZ2927, Elements by ICPMS Low Level (dissolved): Test repeated.

Sample RZ2930, Elements by ICPMS Low Level (dissolved): Test repeated.

**Results relate only to the items tested.**

| 8768204  | Total Phosphorus (P)      | 2017/09/22 |              |           | 104          | 80 - 120  | <0.0020      | mg/L  |           |           |
| 8770210  | Dissolved Molybdenum (Mo) | 2017/09/25 |              |           | 99           | 80 - 120  | <0.000050    | mg/L  |           |           |
| 8770210  | Dissolved Zinc (Zn)       | 2017/09/25 |              |           | 104          | 80 - 120  | <0.00010     | mg/L  |           |           |

Duplicate: Paired analysis of a separate portion of the same sample. Used to evaluate the variance in the measurement.

Matrix Spike: A sample to which a known amount of the analyte of interest has been added. Used to evaluate sample matrix interference.

Spiked Blank: A blank matrix sample to which a known amount of the analyte, usually from a second source, has been added. Used to evaluate method accuracy.

Method Blank: A blank matrix containing all reagents used in the analytical procedure. Used to identify laboratory contamination.

NC (Matrix Spike): The recovery in the matrix spike was not calculated. The relative difference between the concentration in the parent sample and the spike amount was too small to permit a reliable recovery calculation (matrix spike concentration was less than the native sample concentration)

NC (Duplicate RPD): The duplicate RPD was not calculated. The concentration in the sample and/or duplicate was too low to permit a reliable RPD calculation (absolute difference <= 2x RDL).

(1) Dissolved greater than total. Reanalysis yields similar results.

(2) Recovery or RPD for this parameter is outside control limits. The overall quality control for this analysis meets acceptability criteria.

**Remarks:**

Maxxam Analytics' laboratories are accredited to ISO/IEC 17025:2005 for specific parameters on scopes of accreditation. Unless otherwise noted, procedures used by Maxxam are based upon recognized Provincial, Federal or US method compendia such as CCME, MDDELCC, EPA, APHA.

All work recorded herein has been done in accordance with procedures and practices ordinarily exercised by professionals in Maxxam's profession using accepted testing methodologies, quality assurance and quality control procedures (except where otherwise agreed by the client and Maxxam in writing). All data is in statistical control and has met quality control and method performance criteria unless otherwise noted. All method blanks are reported: unless indicated otherwise, associated sample data are not blank corrected.

Maxxam Analytics' liability is limited to the actual cost of the requested analyses, unless otherwise agreed in writing. There is no other warranty expressed or implied. Maxxam has been retained to provide analysis of samples provided by the Client using the testing methodology referenced in this report. Interpretation and use of test results are the sole responsibility of the Client and are not within the scope of services provided by Maxxam, unless otherwise agreed in writing.

Solid sample results, except biota, are based on dry weight unless otherwise indicated. Organic analyses are not recovery corrected except for isotope dilution methods.

Results relate to samples tested.

This Certificate shall not be reproduced except in full, without the written approval of the laboratory.

Reference Method suffix "m" indicates test methods incorporate validated modifications from specific reference methods to improve performance.

\* RPDS calculated using raw data. The rounding of final results may result in the apparent difference.

(1) DOC present in the sample should be considered as non-purgeable DOC.

(2) "Total Hardness" was calculated from Total Ca and Mg concentrations and may be biased high (Hardness, or Dissolved Hardness, calculated from Dissolved Ca and Mg, should be used for compliance if available).

(3) The BC-MOE and APHA Standard Method require pH to be analysed within 15 minutes of sampling and therefore field analysis is required for compliance. All Laboratory pH analyses in this report are reported past the BC-MOE/APHA Standard Method holding time.

RDL = Reportable Detection Limit

(1) Test repeated.

Dissolved greater than total. Reanalysis yields similar results.

## GENERAL COMMENTS

Each temperature is the average of up to three cooler temperatures taken at receipt

|           |       |
|-----------|-------|
| Package 1 | 1.0°C |
| Package 2 | 2.7°C |
| Package 3 | 3.0°C |
| Package 4 | 1.0°C |

Sample SK8985 [TRIP BLANK] : Ion Balance: NC = Not Calculable due to low ion sum [< 0.4 meq/L].

Sample SK8986 [MW16-15D] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample received past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. Sample analyzed past method specified hold time for Total Phosphorus - Low Level Unpreserved. Sample received past method specified hold time for Total Phosphorus - Low Level Unpreserved. Sample received past method specified hold time for Nitrate+Nitrite (N) (low level). Sample received past method specified hold time for Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample SK8987 [MW15-11S] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample received past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. Sample analyzed past method specified hold time for Total Phosphorus - Low Level Unpreserved. Sample received past method specified hold time for Total Phosphorus - Low Level Unpreserved. Sample received past method specified hold time for Nitrate+Nitrite (N) (low level). Sample received past method specified hold time for Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample SK8988 [BH95G-21] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample received past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. Sample analyzed past method specified hold time for Total Phosphorus - Low Level Unpreserved. Sample received past method specified hold time for Total Phosphorus - Low Level Unpreserved. Sample received past method specified hold time for Nitrate+Nitrite (N) (low level). Sample received past method specified hold time for Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample SK8989 [MW16-17] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample received past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. Sample analyzed past method specified hold time for Total Phosphorus - Low Level Unpreserved. Sample received past method specified hold time for Total Phosphorus - Low Level Unpreserved. Sample received past method specified hold time for Nitrate+Nitrite (N) (low level). Sample received past method specified hold time for Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample SK8990 [BH95G-33D] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample received past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. Sample analyzed past method specified hold time for Total Phosphorus - Low Level Unpreserved. Sample received past method specified hold time for Total Phosphorus - Low Level Unpreserved. Sample received past method specified hold time for Nitrate+Nitrite (N) (low level). Sample received past method specified hold time for Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample SK8991 [MW15-02] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample received past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. Sample analyzed past method specified hold time for Total Phosphorus - Low Level Unpreserved. Sample received past method specified hold time for Total Phosphorus - Low Level Unpreserved. Sample received past method specified hold time for Nitrate+Nitrite (N) (low level). Sample received past method specified hold time for Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level).

Sample SK8992 [MW15-03D] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample analyzed past method specified hold time for Total Phosphorus - Low Level Unpreserved. Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level).

Sample SK8993 [BH95G-25S] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample analyzed past method specified hold time for Total Phosphorus - Low Level Unpreserved. Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample SK8994 [BH95G-25D] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample analyzed past method specified hold time for Total Phosphorus - Low Level Unpreserved. Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample SK8995 [DUP-1] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample analyzed past method specified hold time for Total Phosphorus - Low Level Unpreserved. Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample SK8996 [MW15-04S] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample analyzed past method specified hold time for Total Phosphorus - Low Level Unpreserved. Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample SK8997 [MW15-04D] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample analyzed past method specified hold time for Total Phosphorus - Low Level Unpreserved. Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample SK8998 [MW15-01] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample analyzed past method specified hold time for Total Phosphorus - Low Level Unpreserved. Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sample was analyzed past method specified hold time for Nitrite (N) (low level). Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample SK9000 [MW15-10D] : Sample analyzed for digested low level metals due to sediment in sample. This results in an increased reportable detection limit for Al B Ba Bi Cr Co Cu Fe Mn Ni P Pb Sb Si Ti U V and Zn.

Sample SK9001 [FIELD BLANK] : Sample analyzed past method specified hold time for Phosphorus-P (LL Tot, dissolved) - UF/UP. {Exceedance of hold time increases the uncertainty of test results but does not necessarily imply that results are compromised.} Sample analyzed past method specified hold time for Total Phosphorus - Low Level Unpreserved. Sample was analyzed past method specified hold time for Nitrate+Nitrite (N) (low level). Sam

## QUALITY ASSURANCE REPORT(CONT'D)

ALEXCO ENVIRONMENTAL GROUP INC.  
Client Project #: BMC-15-01  
Site Location: KUDZ ZE KAYAH  
Sampler Initials: CL

| QC Batch | Parameter           | Date       | Matrix Spike |           | Spiked Blank |           | Method Blank |       | RPD       |           |
|----------|---------------------|------------|--------------|-----------|--------------|-----------|--------------|-------|-----------|-----------|
|          |                     |            | % Recovery   | QC Limits | % Recovery   | QC Limits | Value        | UNITS | Value (%) | QC Limits |
| 8828439  | Dissolved Zinc (Zn) | 2017/11/14 |              |           | 105          | 80 - 120  | <0.00010     | mg/L  |           |           |

Duplicate: Paired analysis of a separate portion of the same sample. Used to evaluate the variance in the measurement.

Matrix Spike: A sample to which a known amount of the analyte of interest has been added. Used to evaluate sample matrix interference.

Spiked Blank: A blank matrix sample to which a known amount of the analyte, usually from a second source, has been added. Used to evaluate method accuracy.

Method Blank: A blank matrix containing all reagents used in the analytical procedure. Used to identify laboratory contamination.

NC (Matrix Spike): The recovery in the matrix spike was not calculated. The relative difference between the concentration in the parent sample and the spike amount was too small to permit a reliable recovery calculation (matrix spike concentration was less than the native sample concentration)

NC (Duplicate RPD): The duplicate RPD was not calculated. The concentration in the sample and/or duplicate was too low to permit a reliable RPD calculation (absolute difference <= 2x RDL).

(1) Recovery or RPD for this parameter is outside control limits. The overall quality control for this analysis meets acceptability criteria.

## TABLE OF CONTENTS

|  |          |
|--|----------|
| <b>1.0 INTRODUCTION</b>  | <b>1</b> |
| 1.1 Purpose and Objective .....  | 1        |
| 1.2 Scope of Work .....  | 2        |
| 1.3 Project Background .....   | 2        |
| <b>2.0 STUDY AREA</b>  | <b>4</b> |
| 2.1 Location .....   | 4        |
| 2.2 Access .....   | 4        |
| 2.3 Physiography .....   | 4        |
| 2.4 General Hydrology and Meteorology .....                            | 4        |
| 2.5 Geology.....   | 5        |
| 2.5.1 Surficial Geology.....   | 5        |
| 2.5.2 Bedrock Geology .....  | 6        |
| 2.5.3 Glacial History.....   | 6        |
| <b>3.0 SUMMARY OF HISTORICAL HYDROGEOLOGICAL DATA AND GAP ANALYSIS</b> | <b>7</b> |
| <b>4.0 METHODS</b>   | <b>9</b> |
| 4.1 Monitoring Well and Instrumentation Installation.....              | 9        |
| 4.1.1 Drilling .....   | 9        |
| 4.1.2 Monitoring Wells .....   | 9        |
| 4.1.3 205 mm Diameter Well Installation.....                           | 11       |
| 4.1.3.1 Well Locations .....   | 12       |
| 4.1.3.2 Well Installation – WW15-01.....                               | 12       |
| 4.1.3.3 Well Installation – WW15-02.....                               | 14       |
| 4.1.4 Vibrating Wire Piezometers .....                                 | 15       |
| 4.2 Hydraulic Well Testing .....                                       | 16       |
| 4.2.1 Packer Testing .....   | 16       |
| 4.2.2 Hydraulic Response Testing.....                                  | 17       |
| 4.2.3 Pumping Tests .....  | 18       |
| 4.2.3.1 Observation Wells.....   | 18       |
| 4.2.3.2 Regulations Relating to Water Discharge.....                   | 19       |
| 4.2.3.3 Pumping Test Program – WW15-01.....                            | 19       |
| 4.2.3.4 Step-drawdown Pumping Test .....                               | 19       |
| 4.2.3.5 Constant Rate Pumping Test .....                               | 20       |
| 4.2.3.6 Pumping Test Program – WW15-02.....                            | 20       |
| 4.2.3.7 Step-drawdown Pumping Test .....                               | 20       |
| 4.2.3.8 Constant Rate Pumping Test .....                               | 21       |
| 4.3 Groundwater Level Measurements.....                                | 21       |
| 4.4 Groundwater Sampling .....   | 21       |
| 4.4.1 Groundwater Sampling – Monitoring Wells .....                    | 21       |
| 4.4.2 Groundwater Sampling – WW15-01 and WW15-02.....                  | 22       |
| 4.5 Capping of Flowing Wells .....                                     | 22       |

## LIMITATIONS OF REPORT

This report and its contents are intended for the sole use of BMC Minerals (No. 1) Ltd. and their agents. Tetra Tech EBA Inc. (Tetra Tech EBA) does not accept any responsibility for the accuracy of any of the data, the analysis, or the recommendations contained or referenced in the report when the report is used or relied upon by any Party other than BMC Minerals (No. 1) Ltd., or for any Project other than the proposed development at the subject site. Any such unauthorized use of this report is at the sole risk of the user. Use of this report is subject to the terms and conditions stated in Tetra Tech EBA's General Conditions that are provided in Appendix A of this report.

## 1.0 INTRODUCTION

BMC Minerals (No. 1) Ltd. (BMC) is currently assessing the potential to develop the Kudz Ze Kayah Project (the KZK Project), a volcanic massive sulphide (VMS) deposit within the Finlayson VMS district, South Central Yukon. The KZK VMS deposit hosts zinc-rich polymetallic (zinc-lead-copper-silver-gold) massive-sulphide mineralization. The KZK Project is located in the northern Pelly Mountains, 135 km south of Ross River, Yukon. The KZK Property (the site) covers 23,000 hectares and is accessible by an all-weather tote road from the Robert Campbell Highway (Figure 1).

Tetra Tech EBA Inc. (Tetra Tech EBA) was retained by BMC to conduct a baseline hydrogeology assessment for the KZK Project in support of the preparation of a project proposal for assessment under the Yukon Environmental and Socio-economic Assessment Act (YESAA) and the subsequent application under the Waters Act for a Type A Water Use Licence.

This report presents the results of the hydrogeology baseline assessment for the KZK Project. The baseline assessment was based on information collected from a network of groundwater monitoring wells installed in the 1990s with additional wells installed in the summer of 2015. This report includes data collected during the first year of seasonal monitoring up until March 2016. Tetra Tech EBA understands that the seasonal groundwater monitoring has been continued and that additional monitoring wells were installed during the summer 2016 field program. However, any monitoring data collected after March 2016 and the details of the additional monitoring wells installed in 2016 are not included in this report but will be documented under separate cover.

### 1.1 Purpose and Objective

The purpose of this project was to review and evaluate existing hydrogeological information for Kudz Ze Kayah collected and documented as part of the baseline studies in 1994 and 1995 that were previously presented in the Initial Environmental Evaluation (IEE) (Cominco, 1996). The 2015/16 hydrogeology baseline program was then designed to fill data gaps that were observed in order to meet the current regulatory requirements. Groundwater information forms an essential part of the environmental baseline characterization that is required for a future assessment of the KZK mine project proposal under YESAA and a Type A Water Use Licence application as part of the mine permitting process.

The baseline groundwater information collected using the monitoring well network established at the site was used for the development of a conceptual hydrogeological model (CHM). The CHM demonstrates the understanding of the local groundwater regime, including a characterization of the hydrostratigraphic units encountered at the site, aquifer properties, recharge and discharge areas, general direction of groundwater flow, and groundwater-surface water interaction.

Groundwater samples collected in the areas of the proposed mine infrastructure was used to characterize baseline groundwater quality and identify spatial and temporal trends. A minimum of one year of seasonal groundwater data is typically required prior to a project proposal submission under YESAA and a minimum of two consecutive years of seasonal groundwater data is required for a Type A Water Licence application. In addition to some sporadically collected data in the 1990s, this report includes the results of four rounds of seasonal groundwater monitoring conducted in May, August/September, and November 2015, and March 2016, thus representing approximately one year of data. Seasonal groundwater monitoring is being continued at the site through 2016. The results of the ongoing groundwater monitoring will be presented in a supplementary report upon the completion of the 2016 of baseline groundwater monitoring.

## 1.2 Scope of Work

The scope of work for this baseline hydrogeology and groundwater quality assessment for the KZK Project included:

- Review of pertinent geological and hydrogeological background information;
- Review and evaluation of the historic hydrogeological information collected as part of the environmental baseline assessment for KZK in the 1990s (Cominco, 1996);
- Design of a field program to install groundwater monitoring wells and other subsurface instrumentation to re-initiate hydrogeological data collection and fill data gaps identified in the historic hydrogeological baseline data collected at KZK;
- Field oversight and coordination of monitoring well drilling and instrumentation installation;
- Design and field oversight for the installation of two test wells for conducting pumping tests in the area of the proposed open pit;
- Monitoring well development and groundwater sampling;
- Hydraulic testing including packer testing in select diamond drill holes, hydraulic response tests on monitoring wells, and two pumping tests in overburden and shallow bedrock within the area of the proposed open pit; and
- Comparison of the findings of the 2015/16 hydrogeology baseline assessment with the results of the historic baseline assessment (Cominco, 1996).

The hydrogeology baseline assessment provides a characterization of the groundwater regime in the vicinity of the proposed KZK mine site and addresses the following:

- Location and boundaries of hydrostratigraphic units identified within the study area;
- Estimated rate and direction of groundwater flow;
- Anticipated interaction of groundwater with surface water;
- Areas where permafrost may influence groundwater flow; and
- Groundwater quality of the overburden and bedrock aquifers.

The hydrogeology baseline assessment provides the basis for identifying potential effects on groundwater quantity and quality from the proposed mining activities. Where potential effects are identified, mitigation measures and contingency plans will be developed to minimize or eliminate potential effects that the proposed project may have on the groundwater resources in the vicinity and downgradient of the KZK Project.

## 1.3 Project Background

The KZK Property, which is 100% owned by BMC, hosts high grade zinc-copper- lead- gold-silver veins. The property was acquired by BMC in February 2015.

KZK environmental and socioeconomic baseline studies were conducted in the 1990s, along with an Environmental and Social Impact Assessment (under the Canadian Environmental Assessment Act). In 1999, a Type A Water User Licence (QZ97-026) was issued for the Project (valid until September 2018).

BMC is currently carrying out environmental and socioeconomic baseline studies at the KZK Project. These studies build on and add to the data collected by previous owners in the 1990's to support a project proposal submission to be made under YESAA. Subsequent to Yukon Environmental and Socio-economic Assessment Board (YESAB) approval, BMC intends to apply for a Quartz Mining License to allow for Project development and operation.

## 2.0 STUDY AREA

The study area (also referred to as the site) for the purpose of this hydrogeological baseline assessment encompasses the area of the main mineral deposit and conceptual open pit, Class A, B, and C storage areas, water management pond and polishing pond depicted on Figure 2. The Class A storage facility is proposed to contain dry-stack tailings and strongly potentially acid generating (SPAG) waste rock. The Class B storage facility will contain weakly potentially acid generating (WPAG) waste rock, and the Class C storage facility will contain potentially acid consuming (PAC) material.

### 2.1 Location

The KZK Project is located in southeastern Yukon, approximately 250 km northeast of Whitehorse. The proposed infrastructure has an approximate UTM/NAD83 location of 414700 E / 6816200 N in Zone 9N and lies on National Topography System (NTS) map sheet 105G/10.

### 2.2 Access

The site is road accessible by a 24 km long gravel tote road from the Robert Campbell Highway. The tote road joins the highway near Finlayson Lake airstrip, about 530 km by road northeast of Whitehorse.

### 2.3 Physiography

The study area is located in the northern foothills of the Pelly Mountains and within the Pelly Mountains ecoregion. The Pelly Mountains ecoregion is described as a rolling plateau topped by numerous mountain peaks and dissected in places by small rivers.

The relief in the study area is generally greater than 1,200 metres above mean sea level (m asl) on valley floors and up to 1,700 m asl at surrounding peaks. The Pelly Mountains ecoregion is the first major barrier to the flow of weather systems east of the St. Elias and Coast Mountains, so precipitation is relatively heavy. The higher elevations of this region result in cooler summers and less severe winters.

Throughout the Pelly Mountains ecoregion, permafrost can regularly be found in the alpine zone, but at lower elevations it is more variably distributed. In northern parts of the ecoregion, most valley floors are underlain by frozen ground, such as near Ross River and Finlayson Lake, where the base of permafrost is over 20 m below the ground surface (Smith et al., 2004). In these parts, only some south-facing slopes and river courses are permafrost-free (Smith et al., 2004).

With much of the ecoregion lying above treeline (between 1,350 and 1,500 m asl), shrub and dwarf shrub tundra dominate the vegetation at higher elevations. Coniferous, and sometimes mixed, forests mantle the slopes below 1,350 m asl. In the north of the ecoregion, while white spruce is the dominant tree species, black spruce is common on cool wet sites and paper birch can be a significant component of the canopy (Smith et al., 2004).

### 2.4 General Hydrology and Meteorology

The study area is drained by Geona Creek, which flows in a northerly direction along the valley that dissects the study area. At the southern end of the study area, Geona Creek flows across the sub-crop of the ABM deposit. To the north of the study area, Geona Creek flows into Finlayson Creek, which is a tributary of Finlayson River, a major regional drainage feature. A surface water divide exists immediately to the south of the ABM deposit.

The climatic conditions in the area of KZK were summarized by Geo-engineering Ltd. (2000) with additional data collected by Alexco Environmental Group (AEG) since 2015 (AEG, 2016a). The following presents a summary of key climate characteristics for Kudz Ze Kayah:

- The study area can be described as having a typical northern interior climate with daily mean temperatures ranging from around -25°C in January up to 15°C in July. Extreme temperatures range from -60°C in winter to 35°C in summer months.
- Total annual precipitation is estimated to be approximately 780 mm, with 290 mm falling as rain and 490 mm as snowfall (expressed as water equivalent). Annual lake evaporation is estimated to be approximately 330 mm. The snow pack generally peaks in early April although snow may continue to accumulate later in the year at higher elevations. Snow melt and ice breakup in streams generally occurs between late April and early May.
- Based on stream flow records, runoff is usually at its minimum in March and April prior to the snow-melt freshet. Runoff peaks in late May or early June due to snowmelt. Summer rainstorms can give rise to significant flood peaks between May and September, although these events are most likely to occur in June or July.
- Runoff was estimated to be about 63% of precipitation in the area of the KZK project.

## 2.5 Geology

The following sections provide a brief summary of the surficial and bedrock geology in the area of the Kudz Ze Kayah Property. More detailed discussion of the local geology and mineralization at Kudz Ze Kayah can be found in Geo-engineering (2000) and Golder (1996).

### 2.5.1 Surficial Geology

Regional 1:100 000 surficial geology maps (GSC Map 1797A, 1993) indicate that the ABM deposit area is underlain by a till veneer (less than 1 m thick or discontinuous) that may contain extensive areas of thin (less than 1 m) patchy colluvium (Figure 3). Till is described as morainal deposits; diamicton, mainly till, generally consisting of a silty sandy matrix containing pebbles, cobbles and minor boulders.

To the north of the deposit area, till is mapped as overlain by glaciofluvial deposits composed of sand, gravel, diamicton, and minor silts and clay. Geo-engineering (2000) noted that geotechnical investigations confirmed the presence of these deposits to over 40 m deep in the Geona Creek valley. South of the deposit area, till is overlain by alluvial fan sediments consisting of gravelly sand, silt and diamicton up to 10 m or more thick and colluvial apron sediments consisting of boulder diamicton, poorly sorted sands and gravels.

Borehole logs of subsurface conditions from drilling investigations undertaken in 1995 and 2015 generally concur with the mapped surficial geology, indicating that across the study area, overburden is primarily composed of till and glacial deposits ranging in thickness from a thin veneer on valley flanks, to more than 20 m near the centreline of the valley. Overburden deposits are commonly logged as consisting of an upper compact to dense brown sand with varying amounts of silt, gravel or cobble overlying a basal dense to very dense sand and gravel.

Bedrock exposures are encountered at higher elevations, steep slopes and in deep ravines where post-glacial erosion has removed the overburden mantle.

## 2.5.2 Bedrock Geology

The Pelly Mountains Ecoregion is within the Omineca Morphological Belt, an area of uplifted sedimentary, metamorphic and granitic rocks. The study area lies within a belt of metamorphosed rocks known as the Yukon-Tanana (also called Kootenay) terranes (YTT).

Geo-engineering (2000) describe the YTT in the study area as consisting of a layered sequence of metamorphosed sedimentary and volcanic rocks subdivided into three main assemblages: (1) a “lower unit” of pre Devonian Quartzite, pelitic schist and minor marble, (2) a “middle unit” of Late Devonian to lower Mississippian carbonaceous phyllite and schist with interbanded mafic and locally significant felsic volcanic units, and (3) an “upper unit” comprising Pennsylvanian marbles and quartzite. Volcanism in the “middle unit” was accompanied by the intrusion of two to three Late Devonian to Mississippian mafic to felsic metaplutonic suites. The ABM deposit is hosted within felsic volcanics of the “middle unit”.

Exploratory drilling programs in 1995 and 2015 have shown that bedrock in the vicinity of the ABM deposit mainly consists of felsic volcanics intersected with thick felsic tuff and sill/flow complexes that host the deposit. The host felsic volcanic sequence is described by Geo-engineering (2000) as underlying the extreme upper reaches of Geona Creek, Geona Lakes and South Lakes and extending east-west along strike. North of the ABM deposit, the study area is underlain by units of the metasedimentary sequence. These units occur on ridges east and west of Geona Creek (Figure 4).

Bedrock is assumed to be relatively competent, but with a highly fractured zone about two metres thick at the upper contact with the overlying sediments (Golder, 1995). Several northeast-southwest trending faults are mapped as intersecting the deposit area, including the East Fault, Northwest Fault and Fault Creek. Grain size analyses of fault gouge associated with these fault zones indicate that the gouge is comprised primarily of sand and gravel-sized material with a minor fine grained fraction.

Mineralization within the ABM deposit, which consists of the ABM and Krakatoa Zones, occurs as a stratabound body of massive sulphide up to 39 m thick, with a 700 m strike length and 400 m down-dip extent. Massive sulphide is not exposed at surface but subcrops beneath 2-20 m of overburden and dips 35 degrees to the north. A flexure at approximately 200 m depth flattens the dip to 15 degrees for the remaining 200 m. Host rocks to the mineralization are dominated by felsic volcanic and volcaniclastic rocks. Minor amounts of mudstone are intermingled with rhyolitic material or locally form discrete horizons up to several meters thick. A distinct mafic sill occurs in the footwall to the ABM deposit and is locally weakly mineralized.

## 2.5.3 Glacial History

Deposits left by Cordilleran ice sheets during the last two glaciations are found within the Pelly Mountains Ecoregion, including within the study area. During the postglacial period, streams incised into glacial sediments deposited alluvial fans and cut alluvial terraces. Intense mechanical weathering and mass wasting created colluvial mantles on mountain slopes. Rock glaciers advanced from cirques and from below precipitous slopes during the Little Ice Age (about 1550 to 1850 AD). These rock glaciers remain active in many areas (Jackson, 1994).

## 3.0 SUMMARY OF HISTORICAL HYDROGEOLOGICAL DATA AND GAP ANALYSIS

In 1995/96, Golder Associates Ltd. (Golder, 1996a and 1996b) conducted feasibility level geotechnical and hydrogeological site investigations for the KZK Project to support the overall project feasibility evaluation and the design for the tailings impoundment, waste rock storage facilities, mill site and open pit at the site.

The proposed design criteria for the pit slopes were based upon field investigations undertaken in association with the exploration drilling program in 1994 and additional drilling in 1995, as well as specific field investigations in the proposed Class B and C storage areas and a limited laboratory testing program. The focus of the field investigation was to gather information on the hydrogeological regime in the vicinity of the planned open pit, Class B and C storage areas and tailings dam options and to source a possible water supply for potable and process make-up water.

During the investigations, the following monitoring wells were installed to target proposed site infrastructure, including:

- Class B Storage Area – two monitoring wells (BH95G-32 and BH95G-33);
- Class C Storage Area – two monitoring wells (BH95G-30 and BH95G-31);
- South of Open Pit – one monitoring well (BH95G-29);
- Tailings dam sites A (not being considered in current mine plan) – five monitoring wells (BH95G-6, BH95G-7, BH95G-8, BH95G-9 and BH95G-10);
- Tailings dam sites B (not being considered in current mine plan) – four monitoring wells (BH95G-2, BH95G-3, BH95G-4, and BH95G-5);
- Tailings dam site C (not being considered in current mine plan) – one monitoring well (BH95G-12);
- Tailings dam site D (not being considered in current mine plan) – seven monitoring wells (BH95G-13, BH95G-14, BH95G-15, BH95G-17, BH95G-18, BH95G-19, BH95G-21);
- Open Pit area – thirteen monitoring wells (BH95G-20, BH95G-21, BH95G-22, BH95G-23, BH95G-24, BH95G-25, BH95G-26, BH95-129, BH95-131, BH95-135, BH95-146, BH95-148, and BH95-150);
- Mill Site (location changed in current mine plan) – four monitoring wells (BH95G-35, BH95G-36, BH95G-37 and BH95G-20M); and
- Water supply exploration well (not being considered in current mine plan) – one monitoring well (BH95G-27).

Hydraulic conductivity tests (falling and rising head tests) were conducted to estimate the hydraulic conductivity of the overburden (BH95G-21S, BH95G-22, BH95G-23, BH95G-24, BH95G-25S, BH95G-26, BH95G-29), fractured bedrock (BH95G-15D, BH95G-21D, BH95G-20, BH95G-21, BH95G-25S, BH95G-33) and competent bedrock (BH95-131, BH95-129) (Golder, 1996b). Hydraulic conductivity of the overburden and fractured bedrock varied between  $1 \times 10^{-6}$  m/s to  $1 \times 10^{-5}$  m/s, whereas the competent bedrock had lower inferred hydraulic conductivity values ranging between  $2.5 \times 10^{-7}$  m/s and  $2.6 \times 10^{-8}$  m/s.

The conceptual hydrogeological model created by Golder expected the groundwater table to generally mimic topography, with the groundwater table located near surface in the valley bottom and greater than 200m below the

mountains. They anticipated the groundwater table to be within the competent and fractured bedrock on the valley flanks and in the overburden in the valley bottoms. They found that the groundwater flows from the mountains to the valley bottoms. Artesian conditions encountered in the valley bottom indicated discharging groundwater, which is the result of the steep topography and upward hydraulic gradients.

The purpose of the mining geotechnical investigation was to address open pit slope design criteria and pit wall stability. The investigations also addressed mine dewatering requirements based on the groundwater conditions encountered in the area of the ABM deposit.

The hydrogeological data collected by Golder (1996a and 1996b) formed the basis for the updated baseline hydrogeology assessment presented in this report. However, changes to the regulatory regime and more stringent data requirements for the environmental assessment of proposed mining projects in the Yukon required the installation of additional monitoring wells and seasonal groundwater monitoring to supplement the data collected by Golder in 1995/96. Also, many of the existing monitoring wells were found to be in poor condition with no steel protective casing and very short PVC pipe stick-ups.

As part of the work plan development for the baseline hydrogeology assessment, Tetra Tech EBA designed a monitoring well network based on the historical mine plan (Cominco, 1996) that was aimed to satisfy the requirements of a project proposal review under YESAA. The monitoring well network was designed to provide groundwater information from all main aquifers in the area of each major piece of proposed mine infrastructure that may have an impact on groundwater quantity and/or quality during mine construction, operation, remediation, or post closure. The proposed monitoring well network consisted of:

- Historical monitoring wells that were able to be upgraded with proper stick-ups and steel protective casings for long-term use; and
- New monitoring wells in areas that were not covered by historical monitoring wells, or where historical monitoring wells were damaged beyond repair.

Table 1 presents the monitoring well network used for the baseline hydrogeology assessment for KZK Project, along with the date of construction and completion details for each monitoring well. The well logs of all monitoring wells used as part of this assessment are included in Appendix B1. Further details on the historical monitoring wells can be found in Golder (1996a and 1996b). The following sections provide additional detail on the new monitoring wells installed as part of the 2015 hydrogeology field program.

## 4.0 METHODS

The following sections describe the methods used for the field program and data analysis.

### 4.1 Monitoring Well and Instrumentation Installation

#### 4.1.1 Drilling

All drilling was completed using diamond drill rigs with NQ and HQ-size tools which produced a borehole diameter of 75.7 mm and 96.1 mm, respectively. Drilling was conducted by Geotech Drilling Services Ltd. of Prince George, BC. Drill water was taken from local creeks and lakes, and water was continuously pumped from the creek to a water tank located at the drill rig (as per the exploration permit). Excess and return water was drained to a sump at each drill site.

The diamond drill holes (DDHs) were drilled using a polymer-based drilling mud when required for borehole stability. Drillers were directed to use as little drilling polymer as possible. The borehole was flushed with water until there was no visible polymer in the return water prior to conducting a packer test or installing a monitoring well.

Table A presents the location, depth, and dip angle for the exploration drill holes used as part of the hydrogeological investigations. Figure 2 shows the location of the exploration drill holes where VWP<sub>s</sub> were installed, and where packer tests were conducted, as well as where monitoring wells were installed.

All monitoring wells and exploration hole collars were surveyed by Challenger Geomatics using professional surveying equipment. The vertical accuracy of the survey is about ±3 cm.

Drill logs are included in Appendices B1 through B3. The geological logging was completed by Equity Exploration Consultants Ltd. (Equity) geologists.

#### 4.1.2 Monitoring Wells

Groundwater monitoring wells were installed in 2015 at 11 locations on site, eight of which are nested installations. These wells are located within the areas of the ABM deposit and proposed mine infrastructure, and are to be used for the ongoing assessment of groundwater elevations and quality. At most locations, a “deep” well was installed in the bedrock aquifer and a “shallow” well was installed within the shallow overburden aquifer where present. Well logs for all monitoring wells are included in Appendix B1.

Tetra Tech EBA observed the drilling of each borehole as the drilled depth approached the anticipated groundwater depth. The following procedures were employed in the determination of whether groundwater had been intercepted and the interval the deep groundwater monitoring well was to be screened over:

- When drilling close to the expected groundwater depth, drilling was halted, water switched off and water levels were monitored. Where water levels were observed to be rising, the depth to water was recorded several times in order to estimate the recovery rate. Water was then added to the borehole in small volumes (to accelerate recovery) until the water level was observed to be falling.
- The driller was asked to note any increases in water returns (an increase in return may indicate interception of groundwater). Artesian conditions were encountered at several locations across the site and an increase in return was noted at several locations.

**Table A: Exploration drill holes used for hydrogeological investigations and monitoring wells**

| Hole ID | Alternate Hole ID | Borehole Diameter | Easting <sup>1</sup> | Northing <sup>1</sup> | Ground Elevation   | Length             | Azimuth | Dip     |

**Packer tests**

**Monitoring well**

**Pumping test well**

<sup>1</sup> Collar Coordinates; UTM NAD 83, Zone 09N

<sup>2</sup> m asl – metres above mean sea level

<sup>3</sup> m bgs – metres below ground surface

Deep monitoring wells were constructed in accordance with the following general protocol:

- A minimum of 0.1 m of 10-20 filter sand was placed at the base of the borehole.
- A screened section of 10-slot (0.010") 32 mm (1.25") diameter (nominal) Schedule 40 polyvinyl chloride (PVC) pipe was placed in the borehole annulus to span the desired depth interval. Screen lengths were either 9.1 m or 12.2 m (30 or 40 ft).
- Above the screened section, the PVC standpipe was completed to surface using solid lengths of 32 mm (1.25") diameter (nominal) Schedule 40 PVC pipe.
- 10-20 filter sand was added to about 0.9 m above the top of the screened section.

- The annulus between the PVC standpipe and borehole wall was backfilled with bentonite (coated bentonite pellets, bentonite pellets and bentonite chips) from the top of the sand pack to the ground surface at MW15-01 and MW15-02 and to the bottom of the sand pack of the shallow installation at all nested monitoring wells.

Shallow monitoring wells were constructed in accordance with the following general protocol:

- A minimum of 0.6 m of clean 10-20 filter sand was placed on top of the lower bentonite plug.
- A 3.0 m screened section of 10-slot (0.010") 32 mm (1.25") diameter (nominal) Schedule 40 PVC was placed at all shallow monitoring wells except at MW15-09S, which had a 6 m screened section, in the borehole annulus at the desired depth.
- The PVC standpipe was completed to surface using 32 mm (1.25") diameter (nominal) Schedule 40 PVC solid lengths.
- 10-20 filter sand was added to about 0.5 m above the top of the screened section.
- The borehole annulus was backfilled from the top of the sand to 0.3 m below ground surface (bgs) with bentonite (coated bentonite pellets, bentonite pellets and bentonite chips).
- The borehole was completed to slightly above surface with concrete (to minimize water pooling around the well), then a protective steel casing placed over the PVC and set in concrete.
- Once the protective steel casing was installed, the solid 32 mm (1.25") diameter (nominal) Schedule 40 PVC standpipe was extended from ground surface to an accessible point within the casing.

During the deep monitoring well construction, the following procedures were employed to ensure sand and bentonite intervals were placed at the correct intervals and to minimize the risk of bridging in the borehole annulus during addition:

- Sand and bentonite was added slowly to the well to minimize the risk of bridging in the borehole annulus.
- Coated bentonite pellets (which have a delayed swelling response when submerged in water) were used below the water table to ensure they would reach the base of the borehole.
- Settled depths were recorded regularly to limit the possibility of overfilling the annulus to above the desired interval.
- When placing the sand and bentonite into the borehole annulus, the drill rods were left in place to keep the borehole annulus open and prevent collapsing in order to best place the materials within the annulus. The depth of the drill rods were measured and compared to the top of the settled materials within the borehole. The drill rods were slowly lifted to ensure that material was not settling within the drill rods to prevent jacking of the monitoring wells.

#### **4.1.3 205 mm Diameter Well Installation**

Two large diameter (205 mm) groundwater wells were installed in the vicinity of the proposed mine pit at the southern end of the mine site in July and August, 2015. This phase of the drilling program was conducted in recognition of the key objectives of completing multipurpose wells that could be used for:

1. Long term pumping tests to infer bulk hydraulic conductivity of the overburden and bedrock aquifers;

2. Assessment of groundwater quality; and
3. Potential use as future dewatering/extraction wells.

#### **4.1.3.1 Well Locations**

Figure 2 shows the locations of WW15-01 and WW15-02. Each well was located in consultation with BMC and Equity representatives to ensure the wells were located outside of the footprint of the proposed pit and other planned site developments.

Tetra Tech EBA note that both WW15-01 and WW15-02 were proposed to be located to the north of the proposed pit location. However, during the drilling of WW15-02, bedrock was observed to be close to surface (approximately 3.0 m bgs) and there was no overburden aquifer present at this location. Following review of existing well logs and consultation with BMC and Equity representatives, the location of WW15-01 was amended to the south of the proposed pit location where an overburden aquifer was expected to be present.

#### **4.1.3.2 Well Installation – WW15-01**

WW15-01 was drilled and constructed by Midnight Sun Drilling Inc. (Midnight Sun) of Whitehorse, Yukon, under the direction of Tetra Tech EBA on August 1 and 2, 2015. WW15-01 was designed and constructed to monitor and test overburden aquifer conditions, with the base of the well screen contacting the top of the underlying bedrock.

A well log describing the depth and thickness of geologic materials encountered during drilling is provided in Appendix B2. In summary, a sand and gravel fill was encountered from surface to 3.7 m bgs. The fill was underlain by natural gravels, some sand to 5.2 m bgs. From 5.2 m bgs to 11.0 m bgs, a damp silt, sand and gravel unit was logged. A sand and gravel unit was encountered from 11.0 m to 15.2 m bgs. This unit was generally uniform in composition, other than a 0.4 m layer from 12.2 m to 12.6 m bgs, where a medium to coarse sand was encountered. The borehole was drilled to 15.2 m bgs, the depth at which bedrock was intercepted.

Groundwater was encountered at 11.0 m bgs, in the sand and gravel unit immediately below the base of the silt, sand and gravel unit.

Field particle size analysis was conducted on samples obtained from 12.2 m and 14.0 m bgs to design an appropriate well screen for the aquifer encountered from 11.0 m to 15.2 m bgs. Particle size distribution results from these samples are included in Appendix B2 and indicate that the primary aquifer material is medium to coarse grained sand and fine gravel.

The well screen assembly was designed based on the results of field particle size analysis on the sample collected at 14.0 m bgs (using a 50% passing rate). A summary of WW15-01 construction details is provided in Table B and detailed on its well log in Appendix B2.

WW15-01 was developed on August 1 and 2, 2015 by air lifting and jetting. The well was not surged during development as the driller was concerned that surging would create excessive downhole pressure that could blow water to the surface on the outside of the casing. To minimise potential environmental effects of discharging groundwater to Geona Creek, all water removed from WW15-01 during development was directed to and stored in a temporary sump which had been excavated adjacent to the well (Figure A). Water in the sump infiltrated into the ground within approximately 12 hours of the cessation of development. Approximately 156,000 L was removed from WW15-01 during development. The visual clarity and turbidity measurements of the development water were considered acceptable to stop development after 2.75 hours. Detailed well development records are provided in Appendix B2.

**Table B: Well Construction Summary (WW15-01)**

| Well Detail | Interval      | Internal Diameter (m) | Slot Size (in) | Screen Open Area Length | Notes   |
|-------------|---------------|-----------------------|----------------|-------------------------|---|
|             | m bgs         |                       |                | m                       |   |
| Casing      | -0.64 to 11.6 | 0.205                 | -              | -                       | Standard 8" steel water well casing   |
| K-packer    | 11.2 to 11.3  | 0.176                 | -              | -                       | K-packer friction fitted to casing.<br>Fitted to top of riser with female threaded fitting.<br>Top of K-packer is unthreaded. |

| Well Screen | 12.0 to 15.2  | 0.176                 | 0.080          | 3.0                     | Veriperm telescopic wire wrapped well screen, (0.1905 m (7.5 in) OD)  |

**Figure A: Sump adjacent to WW15-01 used to store development water.**

Following development, a surface seal was installed to minimise the potential for surface water ingress and impact from potential surficial contaminants. The surface seal was installed by overdrilling around the 205 mm (8") casing with 279 mm (11") casing to a depth of 4.3 m bgs. A neat Portland cement grout was injected into the annulus between the 203 mm (8") well casing as the 279 mm (11") casing was removed from the ground, leaving an approximate 38 mm (1.5") surface seal around the 203 mm (8") casing. The well was completed by welding on a flat steel plate to the top of the 203 mm (8") casing.

#### **4.1.3.3 Well Installation – WW15-02**

WW15-02 was drilled and constructed by Midnight Sun under the direction of Tetra Tech EBA on July 30, 2015. This well was designed and constructed to target the shallow bedrock aquifer.

WW15-02 was drilled by advancing 203 mm casing through the overburden and into competent bedrock to a depth of 3.4 m bgs (to establish a seal between the overburden and bedrock units). Open hole drilling was continued in bedrock to a total depth of 38.1 m bgs. In accordance with the drilling work plan, drilling was halted at 38.1 m bgs as there had been no clear increase in water returns between 25.9 m and 38.1 m bgs, indicating competent and relatively unfractured bedrock had been intercepted. A well log describing the depth and thickness of geologic materials encountered during drilling is provided in Appendix B2.

The following points are noted in regards to observations of groundwater flow and yield during the drilling program:

- Groundwater was first noted in returns at 23.8 m bgs.
- Yield from the well at a depth of approximately 26 m bgs was estimated by the driller to be approximately 1 to 2 L/s. There was no observable increase in yield as the borehole depth was increased from 26 m to 38.1 m bgs.
- After the drill rods were tripped out of the borehole, groundwater was visually observed (through looking down the borehole with a flashlight) flowing into the borehole at four points approximately 13 m bgs. The rate of flow was estimated by the driller and Tetra Tech EBA to be approximately 0.3 L/s.

After the drill string was removed from the borehole a PVC liner was placed in the well to provide protection to equipment placed in the well (i.e. pump and monitoring equipment) from borehole collapse. As there was no observable increase in water returns during drilling from 26 m to 38.1 m bgs (and therefore inferred to be no major water bearing fractures in this interval), the liner was constructed with a 3.1 m solid section at the base of the borehole (35.0 to 38.1m bgs) to act as a sump to collect sediment and debris. A screened section was placed from 22.9 to 35 m bgs, and a second solid section from 22.9 m bgs to 0.76 m above ground. A summary of the well construction details is provided in Table C and detailed on the well log in Appendix B2.

WW15-02 was developed on July 30, 2015 by air lifting and jetting. The well was not surged during development as the driller was concerned that surging would create excessive downhole pressure that could blow water to the surface on the outside of the casing. To minimise potential environmental effects of discharging groundwater to Geona Creek, all water removed from WW15-02 during development was directed to and stored in a temporary sump, which had been excavated adjacent to the well. Water in the sump infiltrated to ground within approximately 12 hours of the cessation of development. A total of approximately 3,300 L was removed from WW15-02 during development. The visual clarity and turbidity measurements of the development water were considered acceptable to stop development after 35 minutes.

Following development, a surface seal was installed to minimise the potential for surface water ingress and impact from potential surficial contaminants. The surface seal was installed by overdrilling around the 203 mm (8") casing with 279 mm (11") casing to a depth of 2.6 m bgs. A neat portland cement grout was injected into the annulus between the 203 mm (8") well casing as the 279 mm (11") casing was removed from the ground, leaving an

approximate 38 mm (1.5") surface seal around the 203 mm (8") casing. The well was completed by welding on a flat steel plate to the top of the 203 mm (8") casing.

**Table C: Well Construction Summary (WW15-02)**

| Well Detail  | Interval                      | Internal Diameter | Slot Size | Screen Open Area Length | Notes  |
|--------------|-------------------------------|-------------------|-----------|-------------------------|--|

#### 4.1.4 Vibrating Wire Piezometers

Vibrating Wire Piezometers (VWPs) are used to measure piezometric levels and temperatures in boreholes. The sensing element of the VWP is a high strength steel wire attached to a diaphragm. The wire is excited by two coil magnets set around the connecting over tube. External pressure on the diaphragm will move the diaphragm a very small amount changing the tension on the vibrating wire. This tension change is directly proportional to the resonant frequency at which the wire will vibrate. The current resonant frequency of the wire is measured using a readout unit that connects to the cable at the surface. The resonant frequency is then converted into a pressure reading using the individual calibration record for each instrument. The calibration sheets for the VWPs installed at KZK are included in Appendix C.

Vibrating wire piezometers were installed to assess the vertical hydraulic gradient within the deeper bedrock aquifer in the area of the proposed open pit. The VWPs were installed in exploration boreholes K15-200 and K15-248 located to the west and east of Geona Creek, respectively. These two locations allow the vertical hydraulic gradient and subsurface temperatures in the deeper bedrock aquifer to be assessed on either side of Geona Creek which is believed to be a local groundwater discharge feature.

The vibrating wire instrument measures absolute pressure; subsequently measurements should be corrected for temperature and barometric pressure to calculate the actual piezometric pressure or hydraulic head. Each instrument includes a thermistor, which measures the temperature of the transducer and its surroundings. This temperature information is used to provide temperature correction to the output pressure readings. Barometric pressure readings from the KZK weather station were used to compensate the VWP data for barometric pressure changes.

Fresh water was brought to each site at least one day prior to VWP installation to allow water to equilibrate to local atmospheric conditions. VWPs were submerged in water and soaked before installation. The VWPs were installed in exploration boreholes with three VWPs installed in each borehole at various depths below the anticipated groundwater table. The VWPs were attached to the outside of a 25.4 mm (1-inch) diameter Schedule 80 PVC pipe that was lowered downhole through the open hole or drill rods depending on borehole stability. The PVC pipe was

then used as a tremie pipe to grout the VWPs in place. Each hole was tremie-grouted using a cement-bentonite grout until grout return was observed through the surface casing. The surface casing was then removed and the well was completed with a protective steel casing secured in concrete. As recommended by Mikkelsen (2002), the cement-bentonite grout mix presented in Table D was used for the installation of the VWPs.

**Table D: Cement-bentonite Mix**

| Material        | Weight                        | Ratio by Weight |
|-----------------|-------------------------------|-----------------|
| Water           | 30 gallons                    | 2.5             |
| Portland Cement | 94 lbs (~2 bags)              | 1               |
| Bentonite       | 25 lbs (1/2 bag, as required) | 0.3             |

## 4.2 Hydraulic Well Testing

Hydraulic well testing consisted of packer, hydraulic response and pumping tests. Each of these tests is described in this section.

### 4.2.1 Packer Testing

Packer tests are used to infer the in situ hydraulic conductivity of a rock mass over a specific interval. All packer tests were conducted as constant head injection tests, i.e., water was injected at specific pressure steps and the resulting injection rate is recorded when flow has reached a quasi-steady state condition.

Packer tests were conducted in seven selected exploration drill holes (see Table A). The test holes were selected to provide a reasonable spatial coverage of the area of the proposed open pit. Golder (1996a) had identified a number of faults in the area of the ABM deposit. The packer test holes were also selected based on their likelihood to intersect those faults identified during previous exploration and geotechnical investigations.

A packer test system is composed of:

- A downhole assembly of two or three inflatable “packer” glands used to isolate the target interval within the DDH;
- A packer inflation system utilizing nitrogen (inert gas) to inflate the packer system and seal the test section; and,
- A water pressure system (in this case utilizing the drill mud pump and a clear water tank) to facilitate water injection at a constant pressure (head) into the tested interval with the ability to measure flow rate.

The packer tests were conducted after the drill had penetrated a specified depth or encountered a target test zone. A static water level measurement is important to determine the excess pressure ( $P_W^{max}$ ) to apply over the specific test interval. This is calculated as follows:

$$P_W^{max} = \sigma_v' = \gamma_s'(z_s) + \gamma_r'(z_{tz} - z_s)$$

Where  $\gamma_s'$  is the submerged unit weight of the overburden deposits;  $\gamma_r'$  is the submerged unit weight of the bedrock;  $z_s$  is the thickness of the overburden deposits; and  $(z_{tz} - z_s)$  is the thickness of bedrock over the tested interval. If the water pressure is too high, hydraulic fracturing or opening of fissures may alter the rock mass hydraulic

conductivity. CANMET (1977) recommends a maximum excess water pressure ( $P_W^{max}$ ) of 700 kPa. Therefore, the excess pressure was not allowed to exceed 700 kPa to avoid potential hydraulic fracturing of the bedrock. The packer inflation pressures ensure that the tested interval is properly sealed to prevent leakage of flow, slippage and damage to packers.

After the drill had reached the specified testing depth, the hole was flushed with clear water to remove any drill mud or cuttings, then the drill rods were pulled back to allow the water level to stabilize. Water for testing was pumped from a separate clean water tank. The downhole assembly was attached to the wireline and lowered through the drill rods with the bottom packer(s) extending through the drill bit into the open drill hole. The packer glands were then inflated using nitrogen gas to the calculated inflation pressure and the water pressure assembly was attached to the drill mud pump (pumping from the clean water tank). Water was then injected into the bedrock interval isolated by the packers under a constant pressure. The injection rate (flow rate) was measured by recording readings of total flow at regular time intervals. The packer tests were conducted in stages where the excess pressure was increased from 33% to 67% to 100% of  $P_W^{max}$  to a maximum pressure of 700 kPa.

Data from these tests were then analyzed to determine the hydraulic conductivity of the bedrock interval tested. The results were interpreted using the Thiem solution and the following assumptions were made:

- Steady-state condition was reached during the test;
- Laminar flow applies; and,
- Radius of influence of the test did not exceed 10 m.

The hydraulic conductivity  $K$  of the rock mass over the test zone is inferred from the field data using the following modified Thiem equation (e.g., Doe et al., 1980):

$$K = \frac{Q}{2\pi LH} \cdot \ln\left(\frac{L}{r}\right)$$

Where  $K$  is the hydraulic conductivity,  $Q$  is the flow rate ( $\text{m}^3/\text{s}$ ),  $L$  is the vertical length of the test zone (m),  $H$  is the excess head applied to the test zone (m water column), and  $r$  is the radius of the test zone (borehole radius) (m).

#### 4.2.2 Hydraulic Response Testing

Hydraulic response tests were conducted to evaluate the hydraulic conductivity of the aquifer in the vicinity of the monitoring wells. Hydraulic response tests involve the instantaneous injection or withdrawal of a slug of water or solid cylinder of a known volume which cause a sudden change of the well water level. The slug injection causes an instantaneous increase in water level and a subsequent recovery phase during which the water level drops back to the static water level. This test is also referred to as a falling head test. In contrast, slug withdrawal causes an instantaneous drop in water level followed by a recovery phase with the water level rising back to the static water level. This test is also referred to as a rising head test. The recovery phase of the well water level is recorded by manual measurements and/or automatic pressure transducer readings. The recovery data can then be analyzed to infer the hydraulic conductivity of the aquifer material in the vicinity of the test well.

A series of falling and/or rising head tests were conducted on all test wells if the recovery was reasonably fast (i.e., less than 30 min). Only one or two tests were conducted on monitoring wells completed in low hydraulic conductivity formations with an associated slow recovery of the well water level during the hydraulic response test.

All hydraulic response test data were analyzed using the methods presented in Appendix D that are implemented in the software AquiferTest Pro Version 2014.1.

#### 4.2.3 Pumping Tests

Pumping tests (12 hours in overburden and 24 hours in shallow bedrock) were undertaken at WW15-01 and WW15-02 in order to estimate the bulk hydraulic conductivities of the different hydrostratigraphic units (permeable overburden and shallow fractured bedrock) to better determine anticipated dewatering rates for a possible future open pit. The pumping tests also provided the opportunity to identify aquifer boundaries that may be present given the topography in the vicinity of the proposed open pit and collect groundwater quality samples.

Temporary submersible pumps were installed in WW15-01 and WW15-02 at the depths specified in Table E.

**Table E: Submersible Pump Placement (WW15-01 and WW15-02)**

| Well ID | Pump Inlet Placement (m bgs) | Notes   |
|---------|------------------------------|---|
| WW15-01 | 9.4                          | <ul style="list-style-type: none"><li>▪ Inlet placed approximately 2.6 m above the top of the screen</li></ul>  |
| WW15-02 | 31.4                         | <ul style="list-style-type: none"><li>▪ Inlet placed approximately 3.6 m above the base of the screened section of liner in order to provide sufficient flow over the pump motor for cooling.</li></ul> |

At each well, a pressure transducer and logger was installed within a one-inch sounding tube to monitor water level response during each pumping test. Manual water level data were also collected during the testing program using a manual water level sounder. A barologger was placed at each wellhead to monitor the barometric pressure for the duration of testing so that water level data could be corrected for changes in atmospheric pressure.

Flow rates were controlled using a ball valve and rates monitored using a digital flow meter and confirmed throughout the testing program through manual measurements. Tetra Tech EBA measured temperature and field water quality parameters of discharge water at each well through the duration of the pumping test program.

##### 4.2.3.1 Observation Wells

Select wells in the vicinity of WW15-01 and WW15-02 were identified for use as observation wells, with groundwater elevations measured in the wells over the course of the pumping test program. A summary of observation wells is provided in Table F and the locations of observation wells shown in Figure 2.

**Table F: Observation Wells**

| Pumping Well ID | Observation Well | Unit Observation Well Completed In                      | Distance From Pumping Well (m) | Direction From Pumping Well |
|-----------------|------------------|---|--------------------------------|-----------------------------|
| WW15-01         | BH95-23          | Overburden (considered to be same unit as pumping well) | 24                             | Southeast                   |
| WW15-02         | BH95-21          | Bedrock   | 132                            | South Southwest             |
|                 | BH95-22          | Bedrock   | 97                             | East Southeast              |
|                 | ABM16            | Bedrock   | 190                            | South Southwest             |

#### **4.2.3.2 Regulations Relating to Water Discharge**

BMC currently holds a Type A Water Licence No. QZ97-026 (the Licence) for the KZK Project that was issued on November 2, 1999 and expires on September 28, 2018. Under this Licence, the licensee is authorized to dewater the overburden and bedrock in the area of the proposed open pit and discharge the water to Geona Creek (Part D.43, p. 10).

Both test wells WW15-01 and WW15-02 are located in the area of the proposed open pit and were completed so they can potentially be used as dewatering wells. Tetra Tech EBA, in consultation with BMC, therefore determined that the pumping tests can be completed under the existing Type A Water Licence.

Even though the Licence permits direct discharge of groundwater from the overburden and bedrock aquifers within the open pit area into Geona Creek, all groundwater produced during the drilling, development and pumping tests was discharged into the ground and returned to the same aquifers it was extracted from to minimize or eliminate any potential environmental impact.

Additionally, pumping tests were designed to minimize the amount of groundwater extracted during each of the tests. The maximum extraction rate was 191 m<sup>3</sup>/day for both pumping tests conducted, i.e., below the threshold of 300 m<sup>3</sup>/day for the requirement of a water licence for water use associated with a quartz mining undertaking. A Schedule 3 notice (Notification of Water Use Without a Licence) was deemed to be not required as BMC holds a valid Type A Water Licence.

#### **4.2.3.3 Pumping Test Program – WW15-01**

Hydraulic testing was conducted from October 4 to 6, 2015 by Arctic Sky Welding under the supervision and direction of an onsite Tetra Tech EBA hydrogeologist.

Water pumped from the well during the pumping test program was directed to ground approximately 40 m from WW15-01 via lay flat hosing to a vegetated and low lying area to the north of the well. This was considered far enough from the pumping and observation wells for re-circulation of the pumped water into the aquifer not to be of concern. This location also maximised the distance to nearby surface water bodies (the closest lake is approximately 200 m north of WW15-01), allowing for higher pumping rates with less chance of overland flow reaching the lake. Overland flow was noted to be passive throughout the pumping test program and there was no observable transportation of particulate matter (i.e. silt, sand, or organic matter) between the discharge point and the maximum observed extent of flow.

Further information on the discharge of water to ground during the pumping test program is included in Tetra Tech EBA's November 2015 Technical Memo titled "Pumping Test Program – WW15-01 and WW15-02, Kudz Ze Kayah, October 2015" and included in Appendix E.

#### **4.2.3.4 Step-drawdown Pumping Test**

A step-drawdown pumping test consisting of four 1-hour steps of approximately 2.4, 4.7, 9.5 and 15.8 L/s (37.5, 75, 150 and 250 USgpm) was undertaken at WW15-01 on October 4, 2015. The maximum drawdown during the 15.8 L/s (250 USgpm) step was 5.09 m (16.7 ft) below the static water level, at which point the water level was drawn down to the pump inlet. This occurred approximately two minutes into the 15.8 L/s (250 USgpm) step and the test was halted at this point.

After completing the step-drawdown test, Tetra Tech EBA determined that the well could be pumped at 4.4 L/s (70 USgpm) for a 12 hour constant rate test.

#### **4.2.3.5 Constant Rate Pumping Test**

A constant rate pumping test was conducted on October 5, 2015 after the well had recovered to 96% of the pre-test static water level. The well was pumped at 4.4 L/s (70 USgpm) for 12 hours and the maximum drawdown during this test was 3.49 m (11.5 ft) below the pre-pumping static water level.

Following the completion of the constant rate pumping test, the groundwater level had recovered to 91 percent of drawdown (from static) after 11.5 hours, at which point the pump and associated pipework was removed from the well.

#### **4.2.3.6 Pumping Test Program – WW15-02**

Hydraulic testing was conducted at WW15-02 from October 7 to 11, 2015 by Arctic Sky Welding under the supervision and direction of Tetra Tech EBA.

Prior to the commencement of the pumping test program, the static water level at WW15-02 was measured at 0.94 m above grade (level with the top of the steel casing) and was frozen within the casing. Water in the casing was thawed using a tiger torch applied to the outside of the steel casing. Following thawing and water level recovery, water was observed to be flowing over the top of the casing, indicating the static elevation is above the top of casing.

Water pumped from the well during the pumping test program was directed via lay flat hosing to a vegetated area approximately 60 m to the southeast of WW15-02. This was considered sufficient distance from the pumping and observation wells for re-circulation of the pumped water into the aquifer not to be of concern. This location also maximised the distance to nearby surface water bodies (the closest creek on the valley floor is approximately 200 m east of WW15-02), allowing for higher pumping rates with less chance of overland flow reaching the creek. Over the course of the pumping test program, overland flow was noted to be passive and there was no observable transportation of particulate matter (i.e. silt, sand, or organic matter) between the discharge point and the maximum observed extent of flow.

Further information on the discharge of water to ground during the pumping test program is included in Tetra Tech EBA's November 2015 Technical Memo titled "*Pumping Test Program – WW15-01 and WW15-02, Kudz Ze Kayah, October 2015*", included in Appendix E.

#### **4.2.3.7 Step-drawdown Pumping Test**

A step-drawdown test was conducted at WW15-02 on October 7, 2015. During the first step of this test, Tetra Tech EBA observed that the contractor's flow meter was not reading flows accurately with the actual flow rate (based on flow into a 5 gal pail) on the order of three to four times the target flow rate. Due to the inaccurate flow meter readings, Tetra Tech EBA requested the contractor halt the test at the completion of the first step.

Following delivery to site of a flow meter capable of measuring low flow rates, a second step-drawdown pumping test consisting of four 1-hour steps of 0.13, 0.25, 0.76 and 1.9 L/s (2, 4, 12 and 30 USgpm) was undertaken at WW15-02 on October 9, 2015. The maximum drawdown during the 1.9 L/s (30 USgpm) step was 24.4 m (80 ft) below the static water level. At approximately 3.5 minutes into the fourth step, the drawdown increased rapidly and the pumping rate dropped below 1.9 L/s (30 USgpm), even with the discharge valve fully open. As the water level dropped, the pumping rate decreased further as the pump worked to overcome the increasing head. The step-drawdown test was halted after 18 min into the fourth step as useful data was no longer being collected.

After completing the step-drawdown, Tetra Tech EBA determined, based on the data collected from the step rate test that the well could be pumped at 0.7 L/s (11 USgpm) for the 24-hour constant rate test.

#### 4.2.3.8 Constant Rate Pumping Test

A constant rate pumping test was conducted on October 9, 2015 after the well had recovered to 91% of the pre-test static water level. The well was pumped at 0.7 L/s (11 USgpm) for two hours, at which point the water level had drawn down approximately 28 m (92 ft). This was a markedly different response to being pumped at this rate than what had been observed during the step-drawdown test. With drawdown showing no signs of stabilising and the water level nearing the pump inlet, the test was halted after two hours.

The well was left to recover to 92% of the pre-test static water level and a second constant rate test commenced on October 10, 2015. The well was pumped at 0.19 L/s (3 USgpm) for a 24 hour period and the maximum drawdown during this test was 5.73 m (18.8 ft) below the pre-test static water level.

The groundwater level had recovered to 63% of drawdown (from static) after 6 hours, at which point the pump and associated pipework was removed from the well.

### 4.3 Groundwater Level Measurements

Groundwater levels were recorded at each monitoring well using an electronic water level sounder as part of each round of groundwater monitoring. Groundwater levels were measured prior to disturbance by purging and sample collection.

All groundwater levels were measured relative to the top of the PVC well casing. The depth-to-water measurements were converted into piezometric elevations in m asl using the survey data.

### 4.4 Groundwater Sampling

The following sections describe the methods used for groundwater sample collection.

#### 4.4.1 Groundwater Sampling – Monitoring Wells

The groundwater monitoring wells installed at the site were purged and sampled using field methods in accordance with internal work methods that form part of Tetra Tech EBA's Quality Management System. The work methods are based upon generally accepted industry best practices and is in general accordance with applicable ASTM standards. Groundwater monitoring and sampling was completed by qualified Tetra Tech EBA hydrogeologists.

Prior to sampling, the static water level was measured in each well, using an electric measuring tape. Wells were then purged and sampled using an inertial pump. The monitoring wells were purged by removing a minimum of three well volumes (where possible) using a Waterra inertial pump prior to a sample being obtained. Where purge rates were high and required purged volumes low (i.e. less than 15 to 20 L), up to six holding volumes were purged prior to sample collection. Field parameters were recorded after approximately the first litre was purged from the well and then at regular intervals to sample collection.

As described above, while purging, physicochemical parameters (pH, temperature, electrical conductivity, and dissolved oxygen) were measured and recorded. All field measurements were conducted in a 1 L-bottle that was also used as a flow cell. The field parameters were measured using a YSI Professional Plus Multimeter. The pH probe was calibrated using a two-point calibration with pH 7 and pH 10 calibration solutions. The electrical conductivity probe was calibrated using a one-point calibration with a 1,413 µS/cm standard. The pH and electrical conductivity readings were checked every day while in the field using pre-made calibration solutions and found to have drifted very little from calibrated values.

After each monitoring well was purged, samples were collected for analysis of low-level total and dissolved metals, acidity, alkalinity, anions, dissolved organic carbon, electrical conductivity, hardness, ammonia, total phosphorus, pH, total dissolved solids, dissolved orthophosphate and total Kjeldahl nitrogen.

In addition to the monitoring wells, two flowing artesian wells (designated ART-3 and ART-4) in the area of the ABM deposit were sampled prior to being capped. The two wells are located at 414798 E / 6815481 N (ART-3) and 414947 E / 6815750 N (ART-4). Both wells are located in the western portion of the proposed open pit.

Each sample was labelled with the location ID, project number and the date. New, clean sample containers and appropriate preservatives for each suite of tests were provided by the laboratory. Samples were appropriately preserved in the field and the majority of dissolved metals and dissolved organic carbon samples field filtered using a 0.45 um filter. Samples were stored in coolers containing ice packs and delivered to the laboratory (Maxxam Analytics in Burnaby, BC) under chain of custody control within the appropriate holding times. The Maxxam laboratory is an accredited ISO/IEC 17025 testing laboratory.

#### **4.4.2 Groundwater Sampling – WW15-01 and WW15-02**

One sample was collected from WW15-01 by Tetra Tech EBA on October 5, 2015 immediately prior to the completion of the 12 hour constant rate pumping test and one sample was collected from WW15-02 by Tetra Tech EBA on October 11, 2015 immediately prior to the completion of the 24 hour constant rate pumping test.

Both samples were analyzed for total dissolved solids, alkalinity, electrical conductivity, pH, total organic carbon, total suspended solids, major ions (bicarbonate, carbonate, hydroxide, chloride, sulphate, and fluoride), dissolved metals, total metals, biological oxygen demand, and turbidity.

Samples were collected in laboratory supplied sample bottles in accordance with laboratory sampling protocols. All samples were stored on ice and shipped to Whitehorse via road then by air cargo to Maxxam Analytics, an accredited ISO/IEC 17025 testing laboratory located in Burnaby, BC.

#### **4.5 Capping of Flowing Wells**

At the request of BMC, Tetra Tech EBA and Arctic Sky Welding attended and capped a number of flowing artesian boreholes across the Project area. This work was conducted in conjunction with the October 2015 pumping test program. Male threaded NQ (60 mm ID) and NW (76.2 mm ID) size borehole caps made from machined aluminum were fitted directly into the female threaded borehole steel casing.

Where casing was corroded or out of shape, caps were fitted and secured using pipe and chain wrenches. These boreholes will likely require similar tools to remove the caps if access is needed in the future. If seepage was still evident following capping, the cap was removed and electrical tape was wrapped around the cap thread to enhance the seal.

Table G provides a summary of the capping work conducted. Tetra Tech EBA notes that ten borehole locations were attended by Arctic Sky Welding and their work was not viewed or verified.

#### **4.6 Ground Temperature Monitoring**

Ground temperatures were monitored using the VWPs installed at two locations within the area of the ABM deposit (K15-200 and K15-248; see Section 4.1.4). In addition, Knight Piesold (2016) installed four additional observation wells in early 2016 with ground temperature cables across the KZK Project area. Table H shows the location and completion details of the ground temperature observation wells. Figure 2 shows the location of the four ground temperature observation wells. The ground temperature observation wells were completed with 25 mm (1")

diameter PVC standpipes grouted in place. The thermistor cables were installed inside the PVC standpipe filled with silicone oil. Each of the observations wells is equipped with a datalogger collecting two measurements of ground temperatures per day.

**Table G: Borehole Capping Program (October 2015)**

| Hole ID | Casing Size | Well Capped | Capped/Attended by                    | Notes  |
|---------|-------------|-------------|---------------------------------------|--|
| K94021  | NW          | Yes         | Tetra Tech EBA                        | Sealed using electrical tape around cap thread   |
| K97172  | NW          | No          | Tetra Tech EBA                        | Could not cap as PVC casing extending out of steel casing. Will need to be revisited with tool appropriate to internally cut PVC (i.e. a dremel), then capped  |
| K95161  | NW          | Yes         | Arctic Sky Welding and Tetra Tech EBA | Sealed using electrical tape around cap thread   |
| K94026  | NW          | Yes         | Arctic Sky Welding                    | Capped and sealed  |
| K98190N | NW          | No          | Arctic Sky Welding                    | Two boreholes were understood to be at this location, only one could be located. Cap fitted to this borehole.  |
| K98190S | NQ          | Yes         | Arctic Sky Welding                    | Capped and sealed  |
| K95170  | NQ          | No          | Arctic Sky Welding                    | Two boreholes were understood to be at this location, only one could be located. The casing of this borehole was too big for NQ or NW cap. Is possibly HQ size (77.9 mm ID)?   |
| K95170  | NW          | No          | Arctic Sky Welding                    |  |
| K98194N | NQ          | Yes         | Arctic Sky Welding                    | Capped and sealed  |
| K98194S | NW          | Yes         | Arctic Sky Welding                    | Capped and sealed  |
| K98195N | NQ          | Yes         | Arctic Sky Welding                    | Capped and sealed  |
| K98195S | NW          | Yes         | Arctic Sky Welding                    | Capped and sealed  |
| K98191  | NW          | Yes         | Arctic Sky Welding                    | Borehole identified by adjacent stake as K98191. This borehole was not on original list to be capped. Capped following conversation between Arctic Sky Welding and Equity Exploration representative (Kelli Bergh) where Equity Exploration directed Arctic Sky Welding to cap any additional flowing boreholes noted. |

**Table H: Ground Temperature Observation Wells**

| Final Drillhole ID | UTM NAD83 Zone 09N |              |                   | Thermistor Cable ID | Datalogger ID | Thermistor Cable Length (m) | Depth of Thermistor Nodes (m bgs) |
|--------------------|--------------------|--------------|-------------------|---------------------|---------------|-----------------------------|-----------------------------------|
|                    | Easting (m)        | Northing (m) | Elevation (m asl) |                     |               |                             |                                   |

## 5.0 RESULTS AND DISCUSSION

### 5.1 Monitoring Well Completion

A total of 19 groundwater monitoring wells were installed at 11 locations to study the hydrogeological regime at the site. All monitoring wells were installed as nested pairs with the exception of MW15-01, MW15-02 and MW15-06. Figure 2 shows the locations of the newly installed monitoring wells.

Table 1 (attached) presents the well completion details for the monitoring wells installed as part of this project. Well logs indicating the lithologies encountered and well completion details are included in Appendix B1. Depth to groundwater and groundwater elevations are summarized in Table 2 (attached).

Issues were encountered during the monitoring well installation at MW15-05 and MW15-06. While installing the bentonite seal above the sand pack, the driller lost count of the number of drill rods that had been pulled. Consequently, bentonite chips were poured in the annulus between the drill rods and the monitoring wells. When removing another drill rod, the monitoring wells jacked. The shallow well, MW15-05S, lifted approximately 0.6 m resulting in the screened section being above the top of the sand pack. The deep well, MW15-05D, did not appear to be damaged but when confirming the depth to bottom within the well, the measurement taken after the well jacked was shallower than before. As bentonite was also noted within the well, it appears as though MW15-05D was damaged during the installation.

While installing the surface seal at MW15-06, the PVC standpipe broke approximately 0.6 m below ground. The PVC was extended using a coupler, however, some bentonite and sand entered the well. During the well development, some of the bentonite and sand were removed from the well.

No other issues were encountered during the drilling and monitoring well installations.

### 5.2 Vibrating Wire Piezometers

VWPs were installed into two exploration boreholes, ABM16/K15-200 and ABM50/K15-248 within the area of the proposed open pit. Table I summarizes the completion details of the two nested VWP installations including the depths of installation.

The pressure readings from the VWP were converted into piezometric elevations based on the elevation at which the instrument was installed. The raw and reduced data from the VWPs are presented in Appendix C. Inferred piezometric elevations are also summarized in Table J. The depths below ground presented in Table I should be considered approximate as the values do not take into account elevation changes between the drill collar and the actual location of the VWPs based on the azimuth and dip of the borehole.

#### 5.2.1 Inferred Piezometric Elevations

Groundwater piezometric elevations were inferred from the pore pressure measurements with the VWPs and direct measurements of the depth to groundwater in the deep monitoring wells. The depth to groundwater and groundwater elevation measurements collected at KZK are presented in Table 2 (attached) and Appendix C, and summarized in Table J below. The pore pressure measured by the VWPs is usually significantly affected by the disturbance due to drilling and grouting of the well and depending on the permeability of the formation and grout, it may take a considerable period of time for the pore pressures to re-equilibrate. The observed pore pressure readings from the VWPs (see Appendix C) suggest that the pore pressures have mostly returned to pre-disturbance conditions. However, additional readings from the VWPs are required to verify this observation.

The shallow monitoring wells MW15-03S through MW15-11S were installed within the overburden aquifer. The piezometric elevations measured in the shallow monitoring wells therefore reflect the shallow groundwater table within the overburden. Piezometric elevations observed in the shallow monitoring wells are summarized in Table K.

**Table I: VWP Installation Details**

| Area                               | VWP ID   | Well ID       | Azimuth | Dip | VWP No. | Depth Along Hole (m) | Depth (m bgs) | VWP S/N |

UTM coordinates are measured in NAD83 and Zone 9V

<sup>1</sup> – Artesian conditions observed at this well. Groundwater elevation is assumed to be at the top of the PVC pipe.

<sup>2</sup> – Groundwater elevations measured on September 5, 2015.

<sup>3</sup> – Groundwater elevations measured on November 7, 2015.

## 5.3 Hydraulic Well Testing

The following sections present the results of the hydraulic well tests conducted to infer the hydraulic conductivity of the bedrock aquifer at KZK.

### 5.3.1 Packer Testing Results

This section presents the results of the packer tests that were employed to collect data for determining the bedrock hydraulic conductivity in the areas of the main mineralized zones at KZK. The results of the individual packer tests are presented in Tables 3A and 3B (attached). The raw data and analysis for each packer test are included as Appendix F.

In addition to the packer tests conducted by Tetra Tech EBA, Knight Piesold also conducted packer tests on geotechnical drill holes in December 2015 using a similar method as described in Section 4.2.1 (Knight Piesold, 2016). The results of the packer tests conducted by Knight Piesold are also presented in Table 3B. However, as Tetra Tech EBA was not involved with conducting and analyzing of these packer tests, we cannot confirm the quality and accuracy of the data and rely on the information provided by Knight Piesold.

The packer tests were conducted at selected depth intervals deemed representative for both intersected bedrock sequences and structural features encountered as observed in the drill core. All test intervals were chosen over intervals expected to be below the groundwater table.

To assess the validity of the packer test data with respect to the assumptions implied by the analytical method of Thiem for inferring the aquifer hydraulic conductivity, the observed flow rate is plotted against the injection pressure for each pressure step (Figures 5a to 5g; attached). Ideally the flow rate should increase linearly with increasing injection pressure. However, deviation from the linear behaviour is often observed in packer test data and can be caused by a variety of reasons including, but not limited to, the following:

- Washing out of gouge material from fractures causing increased permeability;
- Fracture dilation or hydraulic fracturing due to excessive pressure;
- Clogging of fractures by transported material with a decrease in permeability; and,
- Turbulent (non-Darcian) flow due to excessive flow rate.

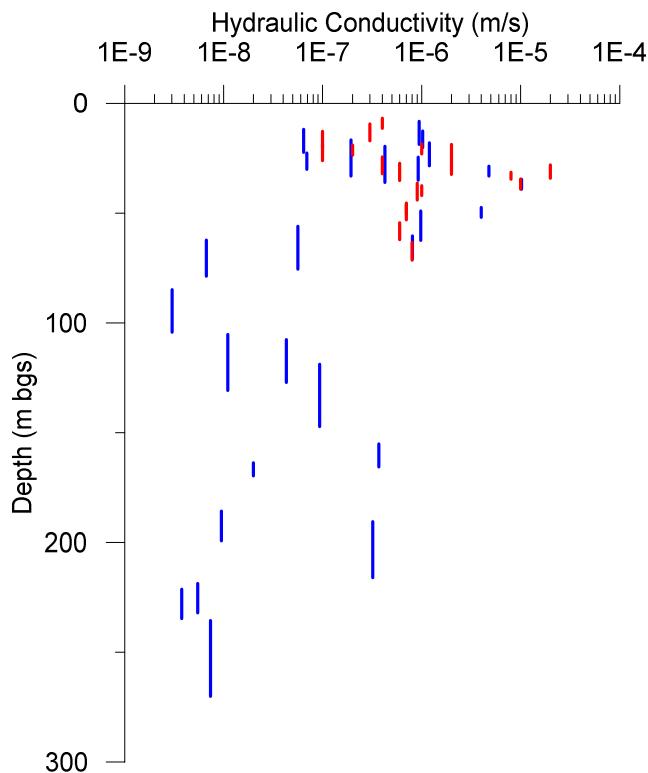

Tables 4A and 4B (attached) summarize the results of the diagnostic plot analysis and presents a data quality assessment. Packer tests with ideal linear flow behaviour are likely to result in reliable estimates of hydraulic conductivity using the method presented in Section 4.2.1. Moderate quality data will likely still result in reasonable estimates of hydraulic conductivity but should be used with some caution. Poor quality data with non-linear flow behaviour should be interpreted cautiously and may not result in representative estimates of hydraulic conductivity.

As shown in Tables 4A and 4B most packer tests yielded good to moderate quality data that are expected to provide reliable estimates of the bedrock hydraulic conductivity in the immediate vicinity of the test holes. The poor quality data may not satisfy the underlying assumptions of the analysis method presented in Section 4.2.1 and may not provide reliable estimates of bedrock hydraulic conductivity. These results are highlighted in Tables 3A and 3B, not included in Figure B, and should be used with caution.

Tables 3A to 3B (attached) presents the inferred hydraulic conductivities for each packer test. The inferred hydraulic conductivities range from about  $<1 \times 10^{-9}$  m/s to about  $1 \times 10^{-5}$  m/s which are typical values for fractured bedrock (e.g., Freeze and Cherry, 1979).

Equity Exploration Consultants also logged all drill core for some basic geotechnical parameters, including Recovery and Rock Quality Designation (RQD). Both Recovery and RQD are related to the degree of fracturing of the bedrock and therefore potentially to the permeability as well. Figures 6a and 6b (attached) shows the inferred hydraulic conductivities from packer tests along with the Recovery and RQD values. However, there is no clear correlation between the inferred hydraulic conductivities and Recovery or RQD.

Figure B shows the inferred hydraulic conductivities as a function of depth. Typically, hydraulic conductivities decrease with depth as a result of increased pressure due to the overlying rock mass and the associated closure of permeable features, such as joints and faults. A similar trend is apparent in Figure B with a decreasing trend in the inferred hydraulic conductivities with increasing depths.

**Figure B: Hydraulic conductivities inferred from packer tests vs. depth (blue – packer tests conducted by Tetra Tech EBA; red – packer tests conducted by Knight Piesold)**

### 5.3.2 Hydraulic Response Testing Results

Hydraulic response tests were conducted on all monitoring wells where artesian conditions were not present to infer the hydraulic conductivity of the bedrock and overburden aquifers. Multiple tests were conducted on each monitoring well to confirm the test results and reduce uncertainty if the recovery was sufficiently fast. Only one or two tests were conducted on monitoring wells that exhibited a very slow recovery. However, all hydraulic response tests conducted on slow recovery wells produced suitable response data and Tetra Tech EBA therefore deems the inferred hydraulic conductivities reliable.

Table L summarizes the hydraulic response test results for each individual monitoring well. The hydraulic response test data and detailed analysis are included in Appendix D.

The inferred hydraulic conductivities agree reasonably well with the results from the packer tests discussed in Section 5.3.1.

**Table L: Hydraulic Response Test Results**

| Well ID  | Number of Tests | Inferred Hydraulic Conductivity |
|----------|-----------------|---------------------------------|
|          |                 | Geometric Mean                  |
|          |                 | (m/s)                           |
| MW15-01  | 3               | 1.2E-06                         |
| MW15-03S | 4               | 8.5E-06                         |
| MW13-03D | 4               | 1.9E-06                         |

| MW15-11S | 2               | 3.6E-05                         |

### 5.3.3 Pumping Test Results

Pumping tests were conducted at WW15-01 and WW15-02 in order to estimate the bulk hydraulic conductivities of the permeable overburden and shallow fractured bedrock units.

#### 5.3.3.1 Pumping Test Results – WW15-01 (Overburden)

Water levels were recorded during the step-drawdown and constant rate tests at WW15-01 and observation well BH95G-23. Observed drawdown and recovery in both wells during the constant rate pumping test are shown in Figure E1 (Appendix E). Figure E1 shows the water level in WW15-01 continued to fall throughout the 12-hour pumping test and had not stabilised at the termination of the test.

Figure E2 presents a semi-log plot of time vs drawdown in WW15-01 and observation well BH95G-23. This figure shows a slowing in the rate of drawdown after approximately 5 hours, potentially indicating a recharge boundary had been encountered. Based on the surrounding setting, it is possible the recharge boundary may be associated with leakage from the pond, located approximately 40 m to the east of WW15-01.

Data recorded at BH95G-23, a small diameter (32 mm) well which is screened in the same aquifer as WW15-01 indicates a direct and rapid hydraulic connection between the two wells, with changes in pumping rates at WW15-01 during the step rate and constant rate tests observed almost immediately at BH95G-23.

Drawdown data at WW15-01 and BH95G-23 during the constant rate test were analyzed using the Cooper-Jacob Straight-Line Time-Drawdown and Theis recovery Methods (e.g., Fetter, 2001). Both interpretation methods were applied using the software AquiferTest Pro (by WHI, v2014.1), which was used to analyze the pumping test data (see Appendix E).

The results of the pumping test are presented in Table M. The observed hydraulic conductivity of about  $1 \times 10^{-4}$  m/s is typical for conductive sand and gravel deposits as encountered at WW15-01. However, this value is significantly higher than the geometric mean of the hydraulic conductivity of the overburden aquifer ( $4 \times 10^{-6}$  m/s) inferred from the hydraulic response tests (see Table 3A). It should be noted that the highest hydraulic conductivity inferred from the hydraulic response tests was also observed in the area of the ABM deposit (MW15-11S), which may indicate that the hydraulic conductivity of the overburden aquifer in the area of the proposed open pit is higher than the average of the study area.

Based on data collected from the observation well (BH95G-23) during the pumping test, the aquifer has a storativity value of  $6.5 \times 10^{-4}$ , which is in line with typical literature values for storativity values in confined aquifers (e.g., Fetter, 2001).

**Table M: Pumping Test Results WW15-01**

| Well                    | Method         | Transmissivity (T)  | Hydraulic Conductivity (K) <sup>1</sup> | Storativity (S) <sup>2</sup> |
|-------------------------|----------------|---------------------|---|------------------------------|
|                         |                | [m <sup>2</sup> /s] | [m/s]                                   | [unitless]                   |
| <b>Pumping Well</b>     |                |                     |   |                              |
| WW15-01                 | Cooper-Jacob   | 5.1E-04             | 1.2E-04                                 | -                            |
|                         | Theis Recovery | 3.8E-04             | 9.0E-05                                 | -                            |
|                         | Mean           | <b>4.5E-04</b>      | <b>1.1E-04</b>                          | -                            |
| <b>Observation Well</b> |                |                     |   |                              |
| BH95G-23                | Cooper-Jacob   | 5.1E-04             | 1.2E-04                                 | 6.5 E-04                     |
|                         | Theis Recovery | 4.0E-04             | 9.6E-05                                 | -                            |
|                         | Mean           | <b>4.6E-04</b>      | <b>1.1E-04</b>                          | -                            |

<sup>1</sup> Assumes an aquifer thickness of 4.2 m <sup>2</sup> Based on radial distance from the pumping well of 24 m.

### 5.3.3.2 Pumping Test Results – WW15-02 (Bedrock)

Water levels were recorded during the step-drawdown and constant rate tests at WW15-02. Observed drawdown and recovery in WW15-02 during the constant rate pumping test is shown in Appendix E. As shown in Figure E3, the water level continued to fall throughout the 24-hour pumping test, although the data shows there was very little change in water level during the last 12 hours of the test (< 0.1 m).

Dataloggers were installed in nearby groundwater wells BH95G-21 and BH95G-22 during the pumping test program. Both of these wells are small diameter (32 mm) monitoring wells. BH95G-21 is screened in bedrock from approximately 6 to 9 m bgs while BH95G-22 is screened across the overburden and bedrock aquifers. The data recorded from these two wells showed no response to the pumping of WW15-02 during the step-drawdown or constant rate tests. Readings were also obtained from VWPs in K15-200 over the course of the pumping test program. The VWPs in K15-200 measures piezometric levels at three intervals in the bedrock aquifer; 47 m, 117 m and 188 m bgs. Measurements from the VWPs at 47 m and 188 m bgs did not show a response to the pumping of

WW15-02, with elevations generally increasing over the course of the pumping test program. The VWP at 117 m bgs showed an approximate 0.23 m decline in elevation over 12 hr period in the middle period of the pumping test, before showing a 0.03 m increase in elevation over the last eight hours of the test. Tetra Tech EBA consider this response is unlikely to be related to the pumping test at WW15-02 and is more likely related to exploration drilling work that was being conducted in the general vicinity.

While the absence of clear response in observation well infers there may not be a hydraulic connection between the pumping and observation wells/ VWP's, the pumping rates and time intervals of the testing program, particularly the 24-hour constant rate test (3 USgpm) may not have been sufficient to induce a response in the observation wells.

The drawdown data during the pumping test were analyzed using the Cooper-Jacob Straight-Line Time-Drawdown and Theis recovery Methods (e.g., Fetter, 2001). Both interpretation methods were applied using the software AquiferTest Pro (by WHI, v3.5), which was used to analyze the pumping test data (see Appendix E).

The results of the WW15-02 pumping test are presented in Table N. The observed hydraulic conductivity of about  $1.7 \times 10^{-6}$  m/s is in the expected range for fractured rock aquifer, such as that encountered at WW15-02.

**Table N: Pumping Test Results WW15-02**

| Well    | Method         | Transmissivity (T)  | Hydraulic Conductivity (K) <sup>1</sup> |
|---------|----------------|---------------------|---|
|         |                | [m <sup>2</sup> /s] | [m/s]                                   |
| WW15-02 | Cooper-Jacob   | 7.6E-5              | 2.2E-6                                  |
|         | Theis Recovery | 3.9E-5              | 1.1E-6                                  |
|         | Mean           | <b>5.8E-5</b>       | <b>1.7E-6</b>                           |

<sup>1</sup> Assumes an aquifer thickness of 34.7 m

### 5.3.3.3 Well Capacity – WW15-01 and WW15-02

WW15-01 and WW15-02 were designed and constructed in recognition that they may be used during mining operations as dewatering/ extraction wells. Pumps used for dewatering/ extraction should be selected in recognition of the maximum theoretical yield that can be obtained from a well.

The maximum theoretical yield from a well is governed by multiple factors including maximum flow through the well screen (screen transmitting capacity) and maximum flow within the well casing/screen (to maintain laminar flow). When assessing the maximum pumping rate, it should be set at the smallest of the governing flow rates for the well.

#### WW15-01

Table O provides recommended maximum flow values for WW15-01, based on physical well details and assumes that the pump is placed within the screen to maximise its dewatering capability.

Table O shows that flow from WW15-01 will be constrained by the screen transmitting capacity value. In order to ensure laminar flow and maximise pump efficiency, the ideal pumping rate for WW15-01 is at or below 26 L/s (416 USgpm). If this well is to be used as a dewatering well, a pump should be selected in consideration of this constraining flow rate.

## WW15-02

Table P provides recommended maximum flow values for WW15-02 based on physical well details. These calculations are based on the 152 mm (6") PVC liner installed in the well.

Table P shows flow from WW15-02 will be constrained by the screen transmitting capacity. Therefore, in order to ensure laminar flow and maximise pump efficiency, based on the physical well details, the ideal pumping rate for WW15-02 is at or below 5.5 L/s (87 USgpm).

Tetra Tech EBA notes that in reality, flow from the well will be constrained by the yield from the aquifer. Based on the October 2015 pumping test program, pumping rates on the order of 0.7 L/s (11 USgpm) resulted in drawdown close to the base of the well. If this well is to be used as a dewatering well, the pump should be selected in consideration of this constraining flow rate, rather than the higher screen transmitting capacity value.

**Table O: Well Capacity - WW15-01**

| Flow Type   | Maximum Flow Value |       |
|---|--------------------|-------|
|   | L/s                | USgpm |
| Screen Transmitting Capacity <sup>1</sup>               | 26                 | 416   |
| Casing/Well Screen (0.176 m [7" diameter]) <sup>2</sup> | 39                 | 615   |

<sup>1</sup> Assumes screen is fully saturated <sup>2</sup>Based on screen internal diameter as pump likely to be placed within screen for dewatering

**Table P: Well Capacity - WW15-02**

| Flow Type   | Maximum Flow Value <sup>1</sup> |       |
|---|---------------------------------|-------|
|   | L/s                             | USgpm |
| Screen Transmitting Capacity  | 5.5                             | 87    |
| Casing/ Well Screen (0.133 m [5.2" internal diameter]) <sup>2</sup> | 31                              | 338   |

<sup>1</sup> Assumes 12.1 m screen is fully saturated <sup>2</sup>Based on screen inner diameter (ID) of 0.133 m

<sup>2</sup> Based on screen section internal diameter as pump likely to be placed within screen for dewatering

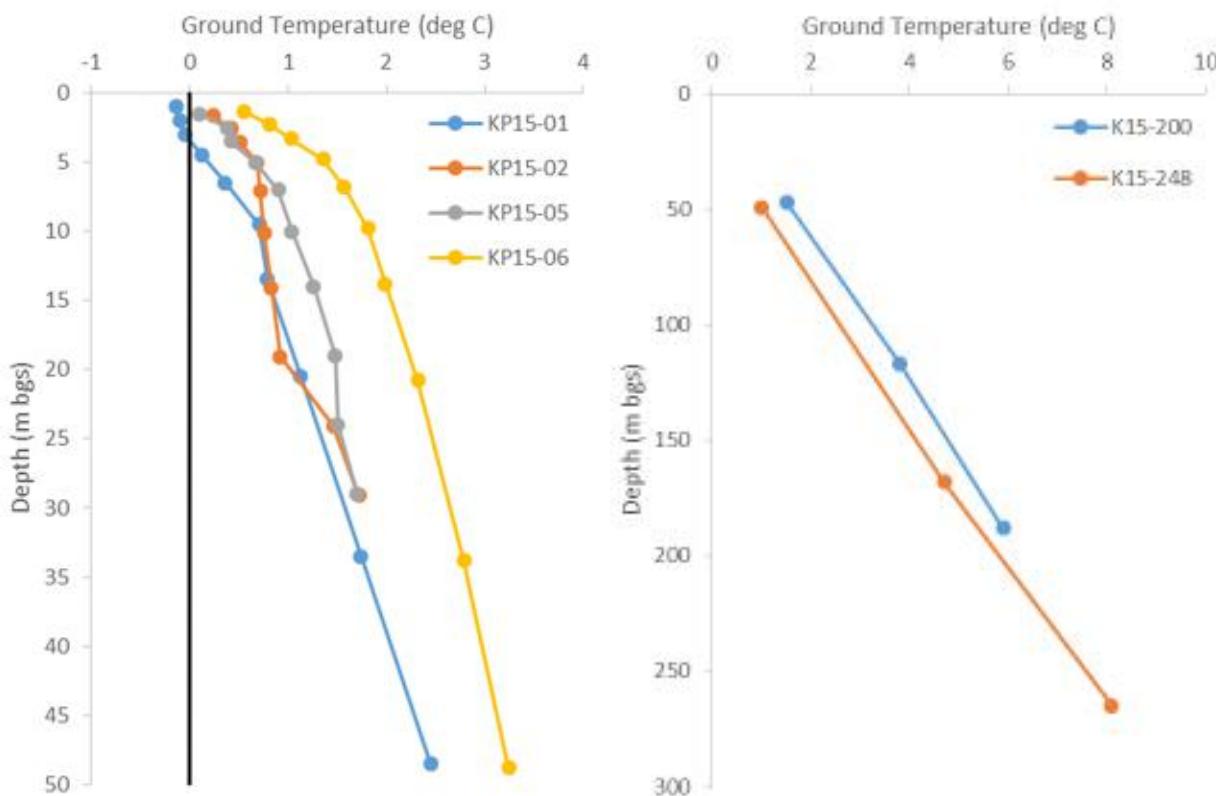

## 5.4 Ground Temperatures

Ground temperatures were measured using two observation wells with VWPs within the area of the ABM deposit and four ground temperature observation wells with thermistor cables located across the site. The VWPs were installed in August 2015 whereas the four ground temperature observation wells were installed in December 2015 with the thermistor cables deployed in February 2016. It is expected that drilling and well installation resulted in a disturbance of the ground temperature profile in the vicinity of the observation wells and that it would take several days to weeks for the ground temperatures to re-equilibrate. Ground temperatures were monitored in March 2016 about six weeks after the last disturbance caused by well completion. Data recorded twice a day for the ground temperature observation wells indicate that temperatures had re-equilibrated shortly after deployment of the

thermistor cables by consistent temperature readings below a depth of about 10 m bgs. Figure C shows the ground temperature profiles observed in the ground temperature observation wells and VWPs, respectively.

The ground temperature profiles presented in Figure C suggest that permafrost is absent at all six locations below a depth of about 50 m bgs, and completely absent (even at shallow depths) at the locations of the four ground temperature observations wells KP15-01, KP15-02, KP15-05, and KP15-06. The negative temperatures measured in KP15-01 near surface very likely represent seasonal frost rather than shallow permafrost.

The geothermal gradient inferred from the ground temperature measurements below about 15 m depth (i.e., below the depth of seasonal ground temperature fluctuations) is about 3°C per 100 m for wells KP15-05, KP15-06, K15-200 (VWP) and K15-248 (VWP) which is an average geothermal gradient for continental crust. However, ground temperatures recorded in KP15-01 and KP15-02 suggest a much larger geothermal gradient of about 50°C per km which would be an anomalously high geothermal gradient. It should be noted that KP15-01 and KP15-02 are only about 50 m and 30 m deep, respectively, and that the VWPs in K15-200 and K15-248 span a much larger depth range of about 150 m and 200 m, respectively; and hence, are likely to provide a more reliable estimate of the regional geothermal gradient. One possible explanation of the higher geothermal gradient observed in KP15-01 and KP15-02 is that the shallow ground temperatures at these locations are affected by upwelling of warmer groundwater from greater depth which would be in line with the observed upward vertical hydraulic gradients at most locations throughout the site (see Section 6.2).

**Figure C: Ground temperatures observed across the KZK project site. (A) Ground temperatures measured in ground temperature observation wells. (B) Ground temperatures measured by VWPs in the area of the ABM deposit.**

## 5.5 Groundwater Quality

The following sections present a characterization of the baseline groundwater quality at the site based on data collected to date.

### 5.5.1 Summary of Historical Groundwater Quality Data

In September 1995, groundwater samples were collected from select piezometers and exploration holes to characterize the quality of groundwater providing baseflow to Geona Creek and South Creek (Cominco, 1996; Table Q). One piezometer below the proposed tailings dam (BH95G-13D), and two in the area of the proposed open pit (BH95G-26 and BH95G-29) were sampled, and analyzed for a range of non-metal "general parameters" as well as total and dissolved metals. The general parameters included pH, conductivity, suspended solids, dissolved solids, hardness, alkalinity, nitrogen species, phosphorous and sulphate. Three other piezometers, located on the north and south sides of the open pit (BH95G-21 and BH95G-23), and west of the proposed Class C Storage Area (95G-31) were also sampled. These samples were analyzed for total and dissolved metals only. Flowing exploration boreholes were sampled including one each on the north and south sides of the open pit (T94-23 and T94-49). These samples were analyzed for general parameters and total and dissolved metals. Three other borehole samples (T94-14, T94-26 and T94-30) were analyzed for total and dissolved metals only. All of the exploration boreholes were cased through the overburden, and are open for the remaining length of the borehole in bedrock.

Analytical results showed that groundwater chemistry was similar to surface water chemistry (Table R). The groundwater pH was similar to that of surface water. Alkalinity, total dissolved solids and hardness were slightly higher in groundwater than in surface water. Sulphate concentrations were variable, with two wells (one shallow, one deep) having sulphate concentrations more than double the concentrations in surface water and the remaining three having similar concentration to surface water. Concentrations of nitrate, nitrite and ammonia were generally low except for a moderate level of nitrate-N (0.13 mg/L) in shallow well BH95G-26. The two shallow overburden wells (BH95G-26 and BH95G-29) had phosphorus concentrations an order of magnitude or more above those measured in surface water. Metal concentrations in both shallow and deep groundwater were low. In particular, copper and lead concentrations in all groundwater samples were equal to or lower than the concentrations in surface water. Exceptions to the pattern of low metals were elevated concentrations of arsenic and iron in the three deep bedrock wells within the orebody (T94-49, T94-30 and T94-13) and elevated arsenic, iron, cadmium and zinc in one overburden well.

The deep well (T94-49) with the highest arsenic and iron concentrations (170 µg/L and 4300 µg/L, respectively) also had elevated sulphate (71.4 mg/L) and the lowest pH and alkalinites of any of the wells measured. Zinc was also somewhat elevated (160 µg/L). Sulphate, pH and alkalinity were not measured in the shallow well that had elevated arsenic, iron, cadmium and zinc (BH95G-26).

**Table Q: Summary of Wells with Historical Groundwater Quality Data (Cominco, 1996)**

| Borehole  | Location        | Well Screen (mbgs) | Flowing | Analyses           |             | Field Measurements |              |           |           |
|-----------|-----------------|--------------------|---------|--------------------|-------------|--------------------|--------------|-----------|-----------|
|           |                 |                    |         | General Parameters | Metals Only | pH                 | Cond (µS/cm) | Temp (°C) | DO (mg/L) |
| BH95G-13D | Tailings Dam    | 39.4-50.3          | Y       | X                  |             | 8.2                | 202          | 3.0       | 4.2       |
| BH95G-26  | Open Pit        | 10.0-14.3          | N       | X                  |             | 7.9                | 330          | 2.5       | 3.5       |

## 5.5.2 Current Baseline Groundwater Quality

The following sections present the results of the groundwater monitoring events conducted in May, August/September, and November 2015, and March 2016. The laboratory analytical results of the monitoring events are summarized in Tables 5A to 5E (attached). Laboratory reports are included in Appendix G.

### 5.5.2.1 Quality Assurance and Quality Control (QA/QC)

A summary of the QA/QC procedures implemented for the groundwater monitoring program to ensure the validity of the data set is provided in Table S. Sample duplicate results and relative percent differences (RPD) are presented in Table 6 (attached).

**Table S: Groundwater monitoring QA/QC**

| QA/QC Aspect                   | Evidence and Evaluation   |
|--------------------------------|---|
| Sample Integrity               | All samples were collected in new sample bottles provided by the laboratory (Maxxam Analytics, located in Burnaby BC). All preservatives were also provided by the laboratory. The samples were shipped on ice with a Laboratory Request Form/ Chain of Custody as soon as feasibly possible following the completion of the fieldwork.<br><br>Tetra Tech EBA notes that given the remote location of the property and the intermittent courier service that operated between the camp and Whitehorse, samples often arrived at the Burnaby laboratory several days after sample collection. Tetra Tech EBA ensured that samples were placed on ice, packed in insulation and shipped in insulated coolers; however, the long transit times meant that on occasion samples arrived at the laboratory above the preferred temperature (4°C). |
| Holding Times                  | All samples were received by the laboratory within appropriate holding times with the following exceptions: <ul style="list-style-type: none"><li>▪ pH: holding time of 15 min was exceeded; however, pH was also measured in the field</li><li>▪ Nitrate/nitrite: holding time of 3 days was exceeded for separate analysis of nitrate and nitrite. However, nitrate + nitrite were also analyzed as a combined parameter within the appropriate holding time of 28 days.</li></ul>  |
| Field Procedures               | Monitoring wells were sampled using Waterra inertial pumps. Field parameters were monitored while purging and samples were taken when field parameters were stabilized to ensure a representative sample was obtained.  |
| Calibration of Field Equipment | The following calibration of field equipment was undertaken regularly during fieldwork and documented on standard field forms. <ul style="list-style-type: none"><li>▪ pH: three-point calibration with pH4, pH7 and pH10 calibration solutions</li><li>▪ Electrical conductivity: one-point calibration with a 1,413 µS/cm standard</li><li>▪ Dissolved oxygen: air calibration</li></ul> Calibration solutions were pre-made by Hanna Instruments and were within expiration dates. Calibration data indicated that field equipment was operating within suitable precision and accuracy ranges during field programs.  |
| Ion Balance                    | To evaluate the quality of the analysis, the ion balance for each sample was calculated, i.e., the balance between sum of anion and cation equivalent charges. Usually, an ion balance of within (0±10)% is considered satisfactory. The calculated ion balances vary from 0.31% to 6.1% (see Tables 5A to 5E), i.e., the ion balance for all samples is within (0±10)%. This suggests that analytical errors are within acceptable limits and all major cations and anions were included in the analyses.  |
| Blind Duplicates               | A blind duplicate is a coded duplicate sample submitted to the primary laboratory for analysis as an individual sample without any indication to the laboratory that it has been duplicated. Blind duplicates allow comparison of parameters that are analysed using identical analytical techniques to ascertain the   |

| QA/QC Aspect | Evidence and Evaluation  |
|--------------|--|
|              | <p>method precision. Blind duplicate pairs were collected simultaneously, with each container filled with approximately 10% of the total sample volume at a time until both containers are filled. Eight blind duplicate samples were collected during the 2015/16 groundwater monitoring program which equates to a frequency of one duplicate to every nine samples collected.</p> <p>Relative percent difference (RPD) calculations for duplicate samples are shown in Table 6. Most duplicate results showed an acceptable relative percent difference (RPD) of less than 30% when compared to concentrations measured in the respective sample from the same monitoring well for all concentrations greater than five times the method detection limit (MDL).</p> <ul style="list-style-type: none"> <li>▪ Acceptance Criteria: RPD &lt; 30%</li> <li>▪ Groundwater Samples Analysed: 82</li> <li>▪ Blind Replicate Samples Analysed: 8</li> <li>▪ Blind Replicate Analyte Pairs: 503</li> <li>▪ Number of Analyte Pairs Exceeding Criteria: 22</li> <li>▪ Percentage of Analyte Pairs Exceeding Criteria: 4.4%</li> </ul> <p>Total metals and total phosphate RPDs were not calculated given the high turbidity of many samples potentially resulting in erroneous concentrations and high RPDs. This does not affect the validity of the results given that total metals and total phosphorus concentrations are generally not representative of mobile (<i>in situ</i>) concentrations in groundwater and are not compared against guideline values.</p> <p>As shown above and in Table 6, a number of duplicates fell outside the typically acceptable 30% RPD range. Of the elevated RPDs, a number of exceedances are noted where concentrations are within 10 times the laboratory detection limit (LDL). Tetra Tech EBA notes that while the RPD value can appear exaggerated where concentrations are close to the detection limit, there can be a comparatively low difference in concentrations between samples. Therefore, a reasonable level of confidence can still be obtained from results within 10 times the LDL when RPD values are over 30%.</p> <p>A number of duplicate pairs with concentrations above 10 times the LDL displayed RPD values in excess of the acceptable 30% range. Where these exceedances were observed, results were checked and confirmed by the laboratory.</p> <p>There is no firm understanding as to the reason for these discrepancies, with various parameters displaying exceedances across the course of the monitoring program. Sampling field sheets indicated that wells were generally purged to stabilization of physicochemical parameters measured in the field and field personnel collected duplicate samples using appropriate procedures (splitting sample between primary and duplicate samples to collect representative and homogeneous samples). Discrepancies may be due to a number of factors including the high turbidity/ sediment content noted in some samples (potentially resulting in variability in dissolved metals concentrations after filtering), the long transit time to the lab (potentially allowing sample chemistry to alter) or laboratory analytical error.</p> <p>Tetra Tech EBA notes that where these duplicates exceeded the 30% RPD range, they were generally within the variability of results displayed across the monitoring program and within the range displayed across the study area. <u>Where a duplicate pair exceeded the 30% RPD range, in all samples the maximum primary and duplicate concentrations were below the maximum site concentration and below all applicable water quality guideline values.</u></p> <p>Tetra Tech EBA consider that for the purpose of this hydrogeological assessment, primary and blind duplicate results and the dataset as a whole are considered acceptable to characterize groundwater chemistry across the study area.</p> |
| Trip Blanks  | Trip blanks are analyte-free reagent water that are sent from the laboratory to the field, and are later returned along with samples. Containers remain unopened in the field and in storage transit. Trip blanks are useful to determine contamination that might arise from sample containers, preservatives, handling, transport and storage conditions.  |

| QA/QC Aspect               | Evidence and Evaluation   |
|----------------------------|---|
|                            | <p>Three trip blanks, consisting of samples of laboratory supplied de-ionised water, were submitted for analysis during the May 2015, September 2015 and March 2016 monitoring programs. Samples were analyzed for the same parameters as groundwater samples. A fourth trip blank was submitted to the laboratory with the November samples on November 8, 2015 and accidentally placed on hold. Analysis was requested on 16 December 2015, however the laboratory advised us that the sample had been disposed of. All three trip blank samples showed trace concentrations of bicarbonate alkalinity. Trace concentrations of total aluminum and total iron were detected in May 2015, along with trace concentrations of lithium in September 2015 and manganese in March 2016. Orthophosphate was detected in the September 2015 and March 2015 samples. Ammonia was detected in the September 2015 sample. Where detected, concentrations in trip blanks were between 1 and 2.3 times the MDL. Sample containers remained closed while in the possession of Tetra Tech EBA and in sealed coolers under Chain of Custody when in transit. Tetra Tech EBA considers it is extremely unlikely that contamination of the trip blanks occurred in transit or storage on Site as contamination through screw caps or leaching through plastic bottles would only be considered possible by highly volatile compounds. We consider that it is far more likely that the parameters detected were either present in the reagent water prior to filling bottles, were contaminated in the laboratory during analysis preparation or are erroneous detections.</p> <p>Tetra Tech EBA understands that based on detections of these parameters in trip blank samples there is the potential that groundwater samples may be reported at erroneously high concentrations. However, as detections in blanks were reported at concentrations typically well below those detected in groundwater, at concentrations only just above the MDL and at concentrations between 8 and 250 times lower than the relevant guideline criteria, any impact to groundwater samples would have been minor and would not be considered to effect the overall conclusions and recommendations of this hydrogeological assessment report.</p> |
| Laboratory Internal QA/QC  | Laboratory internal QA/QC is detailed within the laboratory reports (Appendix G). The laboratory showed acceptable testing frequency and results for method blanks, laboratory duplicates and matrix spikes.  |
| Laboratory Detection Limit | Laboratory reports indicate that the MDL's were lower than the respective assessment criteria for all parameters.   |
| Other                      | Tetra Tech EBA notes that dissolved metals concentrations (in particular lead) reported for WW15-01 in October 2015 are potentially erroneous given that several dissolved concentrations are higher than the total concentrations, as well as one result (lead) being substantially higher than the concentration reported from the same well in the previous monitoring round. The analytical laboratory was called and confirmed analytical results reported were correct. While the cause of the variance cannot be confirmed, it is considered possible that during filtration a break in the filter has potentially allowed sediment into the dissolved sample, resulting in elevated concentrations.   |
| Validity of Data Set       | The data quality review indicates no significant systematic errors in the data collection or analysis process for groundwater and therefore, the data set used as the basis for the groundwater assessment is considered valid and complete.  |

### 5.5.2.2 Discussion of Groundwater Chemistry

#### General Site Wide Groundwater Chemistry

In general, the chemical composition of groundwater depends on the local and upgradient aquifer lithologies. As groundwater flows through an aquifer it assumes and continuously evolves a characteristic chemical composition due to interaction with the aquifer matrix. As such a groundwater sample represents the local and upstream aquifer conditions, and its composition is a function of aquifer lithology, solution kinetics, water residence time, mixing, and groundwater flow patterns.

Given the extent of the site (over 5 km north to south), the various groundwater flow systems and recharge sources (east and west of Geona Creek) and the potential for differing chemistry in the vicinity of the ABM deposit, the study area was divided into five zones for the purpose of assessing and comparing groundwater chemistry. Each zone generally represents either an assumed separate flow system, where potential differences in groundwater quality may exist (i.e. ABM deposit location) or areas of future potential contaminant sources (e.g., Class A, B and C storage areas). Table T details the five areas and the extent of each area is shown in Figure 7.

**Table T: Zones for Groundwater Chemistry Interpretation**

| Area    | Number of Wells              | Rationale and Notes   |
|---------|------------------------------|---|
| Zone 1  | 9 (4 overburden, 5 bedrock)  | <ul style="list-style-type: none"> <li>▪ Spans east and west of Geona Creek</li> <li>▪ Includes the mill site, tailing management facility, water management pond and polishing pond</li> </ul> |
| Zone 2  | 9 (4 overburden, 5 bedrock)  | <ul style="list-style-type: none"> <li>▪ East side of Geona Creek</li> <li>▪ Includes the Class C Storage Facility and Seepage Collection Pond, overburden stockpile.</li> </ul>                |
| Zone 3  | 5 (1 overburden, 4 bedrock)  | <ul style="list-style-type: none"> <li>▪ West side of Geona Creek</li> <li>▪ Includes the Class B Storage Facility and Seepage Collection Pond</li> </ul>                                       |
| Zone 4a | 10 (2 overburden, 8 bedrock) | <ul style="list-style-type: none"> <li>▪ West side of Geona Creek</li> <li>▪ Includes ABM deposit</li> </ul>  |
| Zone 4b | 6 (3 overburden, 3 bedrock)  | <ul style="list-style-type: none"> <li>▪ East side of Geona Creek</li> <li>▪ Includes ABM deposit</li> </ul>  |

Groundwater analytical chemistry results from the 2015/16 monitoring program at KZK Property are provided in Tables 5A through 5E.

A summary of maximum, minimum and average results of key parameters from each of the five zones as well as the entire study area is provided in Table U. pH, total dissolved solids, dissolved hardness were selected as key parameters as they are generally representative of overall general water quality and can be used for broad scale comparison and assessment of water types and potential groundwater regimes. Sulphate was selected as a key parameter as concentrations are expected to be elevated in areas downgradient of where groundwater contacts the deposit (due to the oxidation of sulfide to sulfate).

Note that average values may be skewed by wells that were sampled multiple times during the 2015-16 program whereas other wells in the same zone may only have been sampled once.

**Table U: Key Analytical Results, Zone 1 to Zone 4b, 2015/16 Groundwater Monitoring Program**

| Zone       | Number of Samples <sup>1</sup> | Temperature (°C) | Field pH (units)     | Total Dissolved Solids (mg/L) | Dissolved Hardness (mg/L) | Sulfate (mg/L)      |
|------------|--------------------------------|------------------|----------------------|-------------------------------|---------------------------|---------------------|
| Zone 1     | 17                             | 0.0 - 3.3        | 5.68 - 7.71<br>(7.0) | 176 - 1,960<br>(593)          | 136 - 2,108<br>(575)      | 1.0 - 52<br>(29)    |
| Zone 2     | 19 - 24                        | 0.0 - 1.7        | 6.06 - 8.1<br>(7.6)  | 136 - 266<br>(208)            | 78.9 - 212<br>(158)       | 10 - 42.2<br>(22)   |
| Zone 3     | 12 - 13                        | 0.1 - 2.4        | 6.59 - 8.5<br>(7.5)  | 206 - 370<br>(282)            | 181 - 296<br>(229)        | 33.3 - 138<br>(59)  |
| Zone 4a    | 20 - 25                        | 0.1 - 4.3        | 5.98 - 8.6<br>(7.3)  | 180 - 832<br>(353)            | 112 - 415<br>(207)        | 37.2 - 273<br>(102) |
| Zone 4b    | 12 - 14                        | 0.1 - 4.3        | 7.13 - 7.79<br>(7.4) | 258 - 772<br>(575)            | 204 - 683<br>(483)        | 44 - 222<br>(164)   |
| Study Area | 80 - 93                        | 0 - 4.3          | 5.68 - 8.6<br>(7.4)  | 136 - 1,960<br>(379)          | 78.9 - 2,108<br>(396)     | 1.01 - 273<br>(68)  |

xx - xx maximum and minimum range from all wells (includes duplicates), 1995 & 2015/16 groundwater monitoring program

(in brackets) - average concentration from all wells (includes duplicates), 1995 & 2015/16 groundwater monitoring program

<sup>1</sup>Range provided where there is variability in the suite of analytes between 1995 and 2015/16 and due to field parameters not being reported on duplicates.

The following key points are noted in regards to general groundwater chemistry within the study area over the 2015/2016 groundwater monitoring program:

- Field pH values ranged from 5.68 to 8.6 units and averaged a slightly alkaline 7.4 in both overburden and bedrock aquifers across the whole study area.
- Groundwater has an average total dissolved solids (TDS) concentration of 379 mg/L across the study area. TDS averaged 406 mg/L in bedrock wells and 306 mg/L in overburden wells. Zone 1 and Zone 4b exhibited the highest average TDS concentrations, indicating groundwater is more mineralised in these zones. The highest TDS concentration (1,960 mg/L in Zone 1) was more than twice the highest TDS in any of the other four zones.
- Dissolved hardness concentrations are variable across the site, ranging from 78.9 to 2,108 mg/L. The maximum concentration reported in Zone 1 was over three times higher than the next highest maximum concentration (in Zone 4b). Average and maximum concentrations were typically higher in bedrock wells than overburden wells in each zone and appear to increase in concentration with depth within the bedrock aquifer.
- Sulfate concentrations averaged 68 mg/L across the study area, with an average of 67 mg/L in overburden wells and 69 mg/L in bedrock wells. Sulphate concentrations were highest in Zones 4a and 4b and showed a general trend of increasing concentration with depth in these two zones.
- Groundwater temperatures ranged from 0.0 to 4.3°C.
- Many monitoring wells showed considerable variability in analytical results over the course of the monitoring program suggesting there may be a strong seasonal influence on groundwater chemistry. Ongoing groundwater monitoring scheduled in 2016/2017 will provide additional data to characterize seasonal changes in groundwater quality and quantity.

## Metals

A site wide summary of the range and average concentration of key metals potentially associated with a massive sulphide ore deposit is provided in Table V. Zinc, lead and copper were selected as key parameters as these metals may be elevated in areas hydraulically downgradient of where groundwater contacts the deposit. Arsenic, cadmium and iron were selected as key parameters as these metals have been detected at concentrations above guidelines in multiple wells across the site over the monitoring program.

Note that all results presented and discussion is in reference to dissolved metals. Total metal concentrations have not been discussed as these concentrations are often dependent on well completion, well development and sampling method and are typically less representative of in situ groundwater quality and mobile dissolved phase concentrations.

The following points are noted in relation to key metals concentrations across the site from the 1995 and 2015/16 groundwater monitoring programs:

- Zinc concentrations were considerably higher in Zones 4a and 4b than any of the other three zones as expected due to the ABM deposit.
- Lead concentrations were considerably higher at Zone 4a than any of the other zones as expected due to the ABM deposit.
- Copper concentrations were relatively similar across the study area, but slightly higher at the ABM deposit.
- Iron concentrations are considerably higher in Zones 1, 4a and 4b than the other two zones.
- Across the study area copper and iron concentrations were similar in both bedrock and overburden monitoring wells.
- Average arsenic concentrations ranged between 0.31 and 43 µg/L. The average and maximum concentrations in Zone 4a were approximately ten times higher than the next highest zone, Zone 4b.
- Average and maximum selenium concentrations were higher in Zones 1, 2 and 3 than concentrations reported in the deposit vicinity (Zones 4a and b).
- Cadmium concentrations were highest in Zone 4a, with the maximum concentration almost ten times higher than the next highest zone, Zone 4b.
- On average, lead concentrations were higher in overburden wells than bedrock wells (7.8 µg/L and 0.46 µg/L respectively).
- On average, zinc concentrations were higher in overburden wells than bedrock wells (841 µg/L and 136 µg/L respectively).

Further discussion of major ion chemistry and metals concentrations within individual zones is provided in the following sections.

**Table V: Key Dissolved Metals Results, 2015/16 Groundwater Monitoring Program**

| Zone              | Number of Samples | Zinc ( $\mu\text{g/L}$ ) | Lead ( $\mu\text{g/L}$ )  | Copper ( $\mu\text{g/L}$ ) | Iron ( $\mu\text{g/L}$ ) | Arsenic ( $\mu\text{g/L}$ ) | Selenium ( $\mu\text{g/L}$ ) | Cadmium ( $\mu\text{g/L}$ ) |
|-------------------|-------------------|--------------------------|---------------------------|----------------------------|--------------------------|-----------------------------|------------------------------|-----------------------------|
| <b>Zone 1</b>     | 17                | 0.87 - 24.9 (9.7)        | 0.01 - 1.36 (0.21)        | <0.05 - 3.09 (0.45)        | 2.2 - 36,600 (6,705)     | 0.66 - 11.7 (2.5)           | <0.04 - 6.2 (1.3)            | <0.005 - 1.57 (0.39)        |

| <b>Zone 3</b>     | 13                | 0.25 - 5.03 (1.6)        | <0.005 - 0.141 (0.042)    | 0.062 - 0.613 (0.29)       | <1 - 129 (39)            | 0.098 - 0.88 (0.31)         | 0.326 - 6.27 (2.1)           | <0.005 - 0.13 (0.034)       |
| <b>Zone 4a</b>    | 26                | 0.21 - 5,080 (951)       | <0.005 - 122 <sup>1</sup> | <0.05 - 6.44 (0.56)        | 2.4 - 10,400 (2,800)     | 0.024 - 181 (43)            | <0.04 - 0.804 (0.15)         | <0.005 - 31.6 (2.6)         |
| <b>Zone 4b</b>    | 14                | 0.5 - 845 (65)           | <0.005 - 4.06 (0.86)      | <0.05 - 3.7 (0.54)         | 114 - 7,620 (2464)       | 0.407 - 10.3 (4.9)          | <0.04 - 1.35 (0.12)          | <0.005 - 3.75 (0.29)        |
| <b>Study Area</b> | 94                | 0.21 - 5,080 (206)       | <0.005 - 122 <sup>1</sup> | <0.05 - 6.44 (0.47)        | <1 - 36,600 (2442)       | 0.024 - 181 (10.3)          | <0.04 - 6.2 (0.87)           | <0.005 - 31.6 (0.67)        |

< – less than MDL

XX - XX – minimum and maximum range from all wells, 1995 & 2015/2016 groundwater monitoring program

(in brackets) – average concentration from all wells (concentrations less than MDL were conservatively assumed to be equal to the MDL), 1995 & 2015/2016 groundwater monitoring program

<sup>1</sup> value of 122  $\mu\text{g/L}$  is potentially erroneous. Average Zone 4a lead concentration is 0.55  $\mu\text{g/L}$  and average site lead concentration is 0.28  $\mu\text{g/L}$  when value of 122  $\mu\text{g/L}$  not included in calculation.

### 5.5.2.3 Discussion of Groundwater Chemistry, Zone 1 to Zone 4b

The following sections provide a more detailed discussion of major ion chemistry and metals concentrations in each of the five zones.

Major ion chemistry is determined through a review of groundwater samples chemical composition, taking into account all major anions and cations exceeding 10 meq-%<sup>1</sup>. The water type or hydrochemical facies is determined by listing the ions with concentrations greater than 10 meq-% in decreasing order (cations are listed first). Figures 8a through 8e show trilinear Piper Plots illustrating the major ion chemistry and hydrochemical facies for all groundwater samples collected during the September 2015 (or closest corresponding date) groundwater monitoring event. The September event was selected for Piper plots because it was the most complete round of monitoring (most wells sampled) during the 2015/16 program.

<sup>1</sup> The unit meq-% represents the percentage of cations and anions calculated from their milliequivalents per litre (meq/L). The unit meq/L is the molar concentration multiplied by the charge of the ions.

## Zones 1 to 3 (North of ABM Deposit)

### Zone 1

- In general, groundwater in Zone 1 can be described as calcium-magnesium-bicarbonate-sulphate type water (see Figure 8a). While there are no clear differences in major ion chemistry between the overburden and bedrock aquifers, the following points are noted:
  - BH95G-2, a shallow bedrock monitoring well (19.8 m bgs) which is the furthest north in the monitoring network, has a slightly higher proportion of magnesium and lower proportion of calcium than the other eight wells in this zone.
  - MW15-09D and MW15-10D have a lower proportion of sulphate than the other monitoring wells.
- Zone 1 reported the highest site wide TDS concentration at bedrock monitoring well MW15-10D. MW15-10D is a 31.5 m deep well and consistently reported TDS results over two times higher than any other well on site. There is insufficient information to determine the mechanism behind the high TDS at this location, although it is considered likely to be associated with groundwater having a comparatively long residence time in the bedrock aquifer, allowing the dissolution of more mineral species along its flow path.
- The average pH in Zone 1 was 0.3 units lower than the next highest zone. Of the nine wells in this area, three wells (two shallow bedrock [ $<50$  m deep] and one overburden) reported slightly acidic water quality, with pH ranging from 6.17 to 5.68 units, which is over 1.2 units below the site wide pH average.
- In general, metals concentrations in the bedrock aquifer are approximately equal to or higher than metals concentrations in the overburden aquifer.
- Average nitrate concentrations are higher in the bedrock aquifer than the overburden aquifer.
- Gas was observed to emanate from MW15-10D. A gas sample was collected by Tetra Tech EBA using appropriate safety equipment including a portable gas detector and self-contained breathing apparatus, assuming the gas could potentially be hazardous. The results of the gas sample indicate that the gas contained mostly carbon dioxide (782,000 ppmV) and nitrogen (100,000 ppmV) with small amounts of methane (15.3 ppmV) and hydrogen sulfide below the detection limit ( $<2,500$  µg/L). The laboratory certificate is included in Appendix G. Based on the results above, there does not seem to be an immediate hazard associate with the chemical composition of the gas emanating from MW15-10. However, as a precautionary measure we recommend that any person accessing this monitoring well wear a portable gas detector. A second person should be present at the site and stand back while the other person opens the well cap and measures the gas concentrations using the portable gas detector. Well sampling should only proceed if the gas composition has been deemed safe based on the readings from the portable gas detector.

### Zone 2

- The dominating cations in the groundwater were found to be calcium and magnesium, although the samples obtained from monitoring wells MW15-03S and MW15-05D contained significant amounts of sodium and lesser amounts of calcium (see Figure 8b). The dominating anions within the groundwater were found to be bicarbonate and sulphate. In general, the major ion chemistry is relatively similar for the samples collected from both overburden and bedrock wells and do not show any clear differences between the two aquifers.
- Zinc, lead and iron concentrations were all below the site wide averages and well below the site wide maximum concentrations.

- In general, metals concentrations in the bedrock aquifer are higher than concentrations in the overburden aquifer.
- Average nitrate and nitrite concentrations are higher in the bedrock aquifer than the overburden aquifer.

### Zone 3

- Groundwater quality was only obtained from wells screened in the shallow (<50 m deep) bedrock aquifer as there was insufficient water in the single overburden well in this zone to obtain a sample in the September 2015 monitoring round and the well was dry in the subsequent November 2015 and March 2016 monitoring rounds.
- In general, the major ion chemistry is relatively similar for all samples collected with the dominating cations calcium and magnesium and the dominating anions bicarbonate and sulphate (see Figure 8c).
- Zinc, lead and iron concentrations were all below the site wide averages and well below the site wide maximum concentrations.

### Zone 4a and 4b (ABM Deposit)

Tetra Tech EBA understands that the proposed mine design will require the excavation of an open pit. During pit excavation and mine operation, overburden and bedrock will be dewatered (through dewatering wells, trenches and/or sumps) to enable excavation and keep the pit from flooding.

Under the site's existing water licence (Yukon Territory Water Board Type A Water Use Licence Number QZ97-026 (Exp. September 28, 2018), Section E – Effluent Quality Standards [the Licence]), 14 analytical parameters are required to be monitored and are required to meet effluent quality criteria at two points of compliance. While Tetra Tech EBA understands that the current Licence is likely to be superseded, an updated licence would be expected to contain similar requirements to meet effluent discharge criteria.

Given the large volumes of groundwater expected to require disposal during initial dewatering and ongoing operation of the mine, groundwater would be expected to be a key contributor of water to be discharged under the Licence and may require treatment prior to discharge to ensure that effluent meets the discharge requirements. As the open pit is excavated to depth and moves from overburden to shallow bedrock and then deep bedrock, there is a possibility that the water quality may vary and treatment requirements may differ.

For the purpose of assisting in understanding groundwater chemistry at various depths and to assist in future water management and treatment design options, Tables 5A to 5E provides statistical calculations (minimum, maximum, median, mean, standard deviation and 90th percentile) for groundwater in Zone 4a and Zone 4b in overburden, shallow bedrock (<50 m depth) and deep bedrock (>50 m depth). Tetra Tech EBA notes that these values may be skewed by wells that were sampled multiple times during the 2015/16 program whereas other wells in the same zone may only have been sampled once. Additional statistical analysis is recommended following the incorporation of 2016/17 field monitoring program data.

The following points are noted in regards to the general groundwater quality in the pit area:

- Dissolved metals and dissolved phosphorus concentrations are considered to be representative of dissolved phase and mobile groundwater quality in the pit area.
- Total metals and total phosphorus concentrations are considered to have been strongly influenced by the presence of suspended solids introduced during the sampling process that have resulted in concentrations higher than those actually present and mobile in groundwater. Properly designed, constructed and developed

dewatering wells should minimise suspended solids and associated elevated metals and phosphorus concentrations.

- If groundwater pumped from dewatering wells (or sumps) exhibits high sediment concentrations, total metals and phosphorus concentrations shown in Tables 5A to 5E may be more representative of groundwater quality pumped from the pit area during dewatering. However, suspended solids would be removed from the water as a first step in water treatment if required.

Further discussion of water quality in Zone 4a and Zone 4b is provided in the following sections:

### Zone 4a

- The dominating cations in the groundwater are calcium and magnesium and the dominating anions are either sulphate or bicarbonate (see Figure 8d). Both overburden wells in Zone 4a (BH95G-23 and WW15-01) recorded proportionally high sulphate and low bicarbonate, while bedrock wells reported a wide spread of sulphate and bicarbonate proportions. There does not appear to be a clear correlation between groundwater chemistry, aquifer type or sample depth.
- Average pH is slightly more alkaline moving from overburden (7.02 units) through to deep bedrock (7.49 units).
- Sulphate concentrations are higher in Zones 4a than the other four zones, which is considered due to oxidation of sulphide in the mineral ore body within these zones. Sulphate concentrations are variable with depth, with both the maximum and minimum concentrations reported in the deep bedrock aquifer.
- Lead concentrations are higher in Zone 4a than the other zones, most likely due to dissolution into groundwater that contacts the ore deposit. There is no clear correlation of concentration with depth, with the highest lead concentration reported at overburden well WW15-01 at the completion of the 24 hr pumping test. The concentration was over 50 times higher than the next highest concentration, reported from a deep (125 m bgs) bedrock well. Lead concentrations increase approximately one order of magnitude from the shallow bedrock to the deep bedrock aquifer.

Tetra Tech EBA notes that the dissolved lead concentration at WW15-01 in October 2015 (122 µg/L) is potentially erroneous given that the dissolved concentration is higher than the total lead concentration and the result is over 100 times higher than that reported at the same well in August 2015. It is considered possible that during filtration a break in the filter has potentially allowed sediment into the dissolved sample, resulting in the elevated result. If the result of 122 µg/L is discounted, the average lead concentration in the overburden aquifer is similar to that of the deep bedrock aquifer.

- Average zinc concentrations are higher in Zone 4a than the other zones, most likely due to its dissolution into groundwater during contact with the ore deposit. Average and maximum zinc concentrations are highest in the overburden aquifer, with concentrations in the deep bedrock slightly lower. Concentrations in the shallow bedrock are approximately over two orders of magnitude lower than those in the overburden and deep bedrock aquifer.
- In general, variances in groundwater quality within Zone 4a are likely due to individual well locations in relation to the mineralized zones within the ABM deposit and groundwater flow direction. Wells with high concentrations are located close to or downgradient of the main mineralized zones, while wells with lower concentrations are screened either above or up/ cross-gradient of the ore zones. The number of samples per well and the time of year they were sampled are also likely to affect the variances in observed water quality with variable recharge rates between seasons (greatly increased over fall and early summer) potentially effecting shallow groundwater quality and flow direction in both the overburden and shallow bedrock aquifers.

- While the shallow bedrock wells appear to display different chemistry to the overburden and deep bedrock aquifers, particularly in respect to metals concentrations, this may be a function of well location, with these wells located close to the northern extent of the mineralized zone. Groundwater in the shallow bedrock aquifer further to the south and closer to the centre of the ore deposit may exhibit groundwater chemistry comparable to the overburden and deep bedrock aquifers.
- Dissolved hardness and dissolved metals results reported from the 1995 monitoring program from BH95G-21 and BH95G-23, were compared against 2015/16 results. RPD calculations indicated many 2015/16 concentration were comparable to those reported in 1995, although a number of analytes showed considerable difference, with RPD's of over 60%. While some of this variability may be attributed to seasonal variation, it may also be a function of numerous other variables including; sample sampling, storage, preservation and analysis methods. Flowing boreholes over the past 20 years also may have altered groundwater conditions, resulting in some of the variation in groundwater chemistry observed.

## Zone 4b

- The dominating cations in the groundwater in Zone 4b were found to be calcium and magnesium although the sample obtained from monitoring well MW15-11S contained significant amounts of sodium (see Figure 8e). The dominating anions within the groundwater were found to be bicarbonate and sulphate. There does not appear to be a clear correlation between groundwater chemistry, aquifer type or sample depth.
- Average and median sulphate concentrations are comparable in the shallow and deep bedrock aquifers and slightly higher than concentrations in the overburden aquifer.
- Average and median TDS concentrations increase with depth, almost doubling between the overburden and deep bedrock aquifers. Higher TDS concentrations (i.e. more dissolved minerals) of samples from the deep bedrock is likely associated with longer groundwater residence time and increased mineralisation of groundwater along the flow path with increasing depth.
- Zinc and lead concentrations in Zone 4b are lower than those in Zone 4a, however are still noticeably higher than each of the other zones. Zinc concentrations are highest in the shallow bedrock aquifer, almost two orders of magnitude higher than in the overburden or deep bedrock aquifers. However, zinc concentrations display variance even within the shallow bedrock aquifer, with over two orders of magnitude difference between the minimum and maximum values in this aquifer alone.
- Average lead concentrations are comparable in the shallow and deep bedrock aquifer and slightly higher than the overburden aquifer.
- The maximum nitrate concentration was reported from the overburden aquifer, and was almost an order of magnitude higher than the maximum concentration in the shallow bedrock aquifer. While maximum nitrate concentrations in each aquifer decreased with depth, each aquifer also reported concentrations below the LDL, indicating variability within each aquifer depth interval.
- pH, electrical conductivity, total dissolved solids, dissolved hardness, alkalinity, sulphate, ammonia, nitrate, nitrite, phosphorus and dissolved metals results reported from the 1995 monitoring program from BH95G-29 were compared against 2015/16 analytical results. Inorganic analyte results from 1995 correlated well with 2015 results with only phosphorus showing an RPD outside of  $\pm 30\%$ . Dissolved metals results were more variable with five of seven results showing RPD's greater than 50%. While some of this variability may be attributed to seasonal variation, it may also be a function of numerous other variables including; sampling, storage, preservation and analysis methods. Flowing boreholes over the past 20 years also may have altered groundwater conditions, resulting in some of the variation in groundwater chemistry observed.

#### 5.5.2.4 Comparison with Applicable Regulatory Water Quality Guidelines

Groundwater quality results were compared with the following regulatory guidelines and standards:

- Yukon CSR Schedule 3, Generic Numerical Water Quality Standards for Aquatic Life (CSR-AW) (Yukon Environment Act, Contaminated Sites Regulation, 2002).
- Federal Interim Groundwater (FIG) Quality Guidelines for Commercial and Industrial Land Uses and Protection of Freshwater Aquatic Life (FIG) (Environment Canada, 2012).
- Canadian Council of Ministers of the Environment (CCME) Canadian Water Quality Guidelines for the Protection of Freshwater Aquatic Life (CCME-AW) (CCME, 1999).
- Yukon Territory Water Board Type A Water Use Licence Number QZ97-026 (Exp. September 28, 2018), Section E - Effluent Quality Standards (the Site Water Licence).

The Yukon CSR AW standards and FIG guidelines apply to dissolved metals rather than total metals. This is also in accordance with general industry practice of using dissolved rather than total metals to characterize groundwater quality. Total metal concentrations are often dependent on well completion, well development and sampling method and are typically less representative of in situ groundwater quality and mobile dissolved phase concentrations that discharge to surface. Dissolved metals were therefore used for comparison with the applicable regulatory water quality standards and guidelines. Similarly, for the reasons outlined above, only dissolved phosphorus results were compared against regulatory water quality standards and guidelines.

Results have also been compared against the Site Water Licence to provide an indication of which parameters exceed the licence maximum allowable discharge limits and may require treatment options to be implemented in order to meet licence requirements.

All exceedances of the aforementioned water quality standards and guidelines are shown in Tables 5A through 5E and maximum guideline exceedances from the 2015/16 monitoring program are detailed in Tables 7A through 7E. Tetra Tech EBA understands that the current Water Use Licence will expire during the permitting process and a new water licence will be applied for and that the parameter list and maximum allowable discharge limit may change from those shown in the attached tables.

The following key points are noted in regards to guideline exceedances:

- There are no obvious overall spatial trends or difference between aquifers with respect to exceedances of water quality guidelines.
- Groundwater collected from every well at KZK over the 2015/16 monitoring program reported at least one parameter that exceeded one or more FIG or CCME-AW guideline values.
- Field pH exceeded the lower range of the FIG and Site Water Licence in wells located in Zones 1, 2 and 4a indicating spatial variability in pH range across the site.
- Fluoride exceeded the FIG and CCME-AW guidelines in overburden and bedrock aquifers within Zone 1, 2, 4a and 4b. All fluoride results were below the CSR-AW guideline value.
- Sulphate concentrations exceeded the FIG in overburden and bedrock wells in Zones 3, 4a and 4b. All results were below the CSR-AW guideline value. There were proportionally more guideline exceedances in Zone 4b (6 of 7 wells exceeded) than Zone 4a (2 of 10 wells) and Zone 3 (1 of 4 wells). Higher sulphate concentrations in Zones 4a and 4b are considered due to contact of groundwater with the massive sulphide deposit, although

the single elevated concentration in Zone 3 (at MW15-01) indicates concentrations above guideline criteria are present outside of the area considered to be influenced by the ABM deposit.

- Ammonia exceeded the FIG and CCME-AW guideline criteria in a single well in Zone 4a (ART-4). ART-4 is believed to be a deep bedrock well (depth unknown) located at the northern extent of the proposed open pit.
- Cadmium exceedances of the FIG and CCME-AW guidelines were widespread across the site. The cadmium CSR guideline value was exceeded by one well in each of Zones 1 and 4b and two wells in Zone 4a. Exceedances of all guidelines were seen in both bedrock and overburden wells. There was a single exceedance of the Site Water Licence guideline, at WW15-01 (Zone 4a).
- Zinc exceeded the FIG guideline in at least one well in each of Zones 1, 2, 4a and 4b. Concentrations were substantially higher in Zones 4a and 4b where the Site Water Licence guideline was exceeded in multiple wells. There was no obvious correlation of exceedances with aquifer type. Higher concentrations in Zones 4a and 4b are considered due to the contact of groundwater with the zinc rich ABM deposit.
- Iron exceeded the FIG and CCME-AW guidelines in at least one well in each of Zones 1, 2, 4a and 4b.
- Chromium exceedances of the CCME-AW were only observed in two bedrock wells within Zone 1.
- Aluminum exceeded the FIG and CCME-AW in three wells in Zone 1 and one well in Zone 2. Exceedances were observed in both bedrock and overburden aquifers.
- Lead in one well WW15-01 (Zone 4a) exceeded the FIG, CCME-AW, CSR-AW and Site Water Licence guidelines. As discussed in previous sections, this result is potentially erroneous and more representative of the total lead concentration. When the lead result from the August 2015 sample round from WW15-01 is alternatively assessed, it falls below all guideline values.
- Copper in a single well in Zone 4a (BH95-22) exceeded the FIG and CCME-AW guideline values.
- Uranium exceeded the FIG and CCME-AW guideline values at a single well, BH95-131 in Zone 4b. This well is a deep bedrock well (approximately 126 m bgs) and is located close to the centre of the proposed open pit.
- Total suspended solids exceeded the Site Water Licence maximum allowable limit at least once in 32 of the 36 analysed wells. As previously discussed, elevated total suspended solids concentrations are considered to be a consequence of the sampling process rather than mobile concentrations in groundwater. Properly constructed and developed dewatering wells would be expected to at least partially mitigate elevated suspended solids concentrations.
- Selenium concentrations exceeded the FIG and CCME-AW guideline values in wells in Zones 1, 2, 3 and 4b. There were no exceedances in Zone 4a and only a single exceedance of both values in Zone 4b. Almost half the wells in Zones 1, 2 and 3 exceeded both guidelines. There were no clear trends in regards to exceedances in bedrock and overburden aquifers.
- Concentrations of arsenic exceeded the FIG and the CCME-AW in multiple wells within Zones 1, 4a and 4b. Concentrations were substantially higher in several wells in Zone 4a, where four of the ten wells sampled also exceeded the Site Water Licence maximum allowable limit guidelines.
- Phosphorus concentrations exceeded the CCME-AW guidelines for ultra-oligotrophic aquatic systems in wells in each of the five zones. Across the site, 30 of 37 wells sampled reported concentrations above the CCME-AW guideline. However, it should be noted that the phosphorus guideline is applied through a framework for the management of freshwater systems and does not apply to groundwater. The guideline value depends on

the trophic status of the aquatic system with the above referenced guideline for ultra-oligotrophic systems being the most stringent.

Tetra Tech EBA notes that while there are multiple exceedances of the applicable regulatory water quality guidelines, the concentrations of exceedances are considered to be representative of natural background conditions. Assessment against the guidelines presented above are for preliminary assessment and comparison purposes only at this baseline assessment stage. In due course and with sufficient data, site specific guideline values can be formulated that are representative of the actual groundwater quality across the study area.

## 6.0 CONCEPTUAL HYDROGEOLOGICAL MODEL

The conceptual hydrogeological model is intended to conceptually describe the existing local hydrogeological conditions in the area of the ABM deposit and conceptual open pits, storage areas, tailings management area, water management pond and polishing pond at KZK with respect to groundwater flow and groundwater quality. The conceptual model is based upon information gathered during the 1995 and 2015 hydrogeological field programs, along with other pertinent geological information available related to the KZK Project.

### 6.1 Hydrostratigraphy

The local hydrogeological system within the study area consists of a bedrock aquifer overlain across valley floors by an overburden aquifer. The overburden aquifer is inferred to be confined to semi-confined, at least in the area of the ABM deposit.

Based on the current level of subsurface information for the site, for the purpose of this baseline hydrogeology assessment, it is assumed that the bedrock aquifer consists of one aquifer. Even though this assumption is simplistic, it is supported by the fact that the bedrock aquifer consists of a similar lithology throughout the site. Hydraulic conductivities inferred from packer tests show a slight correlation with depth but do not suggest stratification of the aquifer based on a sudden change in hydraulic conductivity with depth, at least not within a depth of about 200 m bgs. Furthermore, interpolation of the observed groundwater elevations indicates a groundwater flow regime that agrees with anticipated groundwater flow directions based on the topography and therefore also supports the hypothesis of one hydraulically connected bedrock aquifer.

From first principles, groundwater flows from areas of higher piezometric elevations to lower piezometric elevations. Groundwater recharge occurs at higher elevations on mountain slopes where overburden is thin or absent ultimately discharging to the receiving water bodies at lower elevations in the valley (i.e., ponds, and Geona Creek). This flow pattern is confirmed by groundwater elevations in nested wells along the valley floor, with an upwards hydraulic gradient present from the bedrock aquifer to the overburden aquifer indicating discharge of groundwater to surface at the base of the valley.

#### 6.1.1 Overburden Aquifer

Overburden in the study area is primarily composed of till and glacial deposits ranging in thickness from a thin veneer on valley flanks, to more than 20 m near the centreline of the valley. Previous investigations have typically logged overburden deposits as an upper compact to dense brown sand with varying amounts of silt, gravel or cobble overlying a basal dense to very dense sand and gravel. An overburden aquifer over 10 m thick is present within the sediments along the valley floor. The thickness of the overburden deposits generally decreases with increasing elevation. Above about 1,500 m elevation, the surficial deposits consist of a layer of organic material less than 0.5 m thick, overlying colluvium. The latter originates from frost loosening of bedrock.

In the region of the ABM deposit, groundwater in the basal sand and gravel unit is believed to be confined to semi-confined by the overlying compact to dense sand. This was evidenced during the drilling of WW15-01 where the upper compact to dense sand layer was logged as damp, then saturated conditions were encountered immediately upon intercepting the underlying sand and gravel layer. At the completion of drilling and installation of the screen in the sand and gravel unit (see well log in Appendix B2), the water level rose approximately 6 m above the top of the sand and gravel and above the top of the inferred confining dense sand layer (Appendix B2), indicating a confining layer is present. The inference of a confining overburden unit is supported by the rapid response in the observation well during the pumping test at WW15-01, a reaction generally indicative of a confined aquifer.

Recharge to the overburden aquifer is expected to be through discharge from the underlying bedrock aquifer and infiltration of precipitation and snowmelt through surficial soils on valley flanks. Recharge through surface water infiltration may be limited due to the expected upwards hydraulic gradient in the overburden aquifer across much of the valley floor. At higher elevations where overburden thins, perched water may sit on top of the bedrock contact and migrate through higher permeability overburden in the direction of the surface dip. Towards the centre of the valley, groundwater is expected to move through the upper compact to dense sand layer and discharge to Geona Creek and low lying surface water bodies that line the valley floor.

Based on single-well response tests, Golder estimated the hydraulic conductivity of the overburden material ranges from about  $1 \times 10^{-6}$  m/s to about  $1 \times 10^{-5}$  m/s. However, Golder noted that most of these tests were conducted in material with a "significant fine-grained component" (likely the upper dense sand unit) and the bulk hydraulic conductivity of the overburden (including relatively "clean" sands and gravels in the basal unit) is likely higher, more likely in the range of  $1 \times 10^{-5}$  m/s to  $1 \times 10^{-4}$  m/s.

To better estimate the bulk hydraulic conductivity of the basal sand and gravel unit, Tetra Tech EBA conducted a long term (12 hr) pumping test at WW15-01 during the 2015 hydrogeological investigation. This test indicated that the hydraulic conductivity of the sand and gravel unit in the vicinity of the deposit to be approximately  $1.1 \times 10^{-4}$  m/s, which generally concurs with the hypothesis that the basal sand and gravel unit has a higher hydraulic conductivity.

Based on data collected from an observation well (BH95G-23) during the pumping test, the overburden aquifer has a storativity value of  $5.7 \times 10^{-4}$ , which is in line with typical literature values for storativity values in confined aquifers (e.g., Fetter, 2001). Tetra Tech EBA notes that during the pumping test conducted at WW15-01, water levels in BH95G-23 were observed to respond almost instantaneously to the pumping of WW15-01 and decreased a similar magnitude as in the pumping well (Figure E1). This response indicates both wells are screened in the same confined aquifer and that there is a direct hydraulic connection between the two wells. In areas where the overburden aquifer is unconfined or semi-confined, i.e., where the upper dense sand unit contains less fine sediments or where this unit is absent, the storativity of the overburden aquifer would be expected to be higher and more similar to the specific yield which can be estimated to be in the range of about 0.15-0.25 for a sand and gravel aquifer (e.g., Freeze and Cherry, 1979).

## 6.1.2 Bedrock Aquifer

The primary bedrock aquifer in the vicinity of the mineralized zones mainly consists of schistose felsic volcanics intersected with thick felsic tuff and sill/flow complexes that host the ore deposit.

Groundwater flow in bedrock aquifers predominantly occurs in secondary pore space (fractures and fault zones) as primary porosity is usually very small, or essentially non-existent as in the case of volcanic and metamorphic rocks like those encountered at KZK. Bedrock aquifers therefore typically act like confined aquifers. In general, groundwater flow in fractured rocks is complex and can vary greatly in direction and rate, depending on the local hydrogeological and structural geological conditions. Transmissivity values can change over several orders of magnitude within the same rock mass over short distances (scale of metres), and groundwater flow may be largely controlled by a few conductive fractures or other rock mass discontinuities.

Recharge to the bedrock aquifer will occur primarily through infiltration of precipitation and snow melt on valley peaks and flanks, where bedrock outcrops or overburden is thin. Within the study area, discharge occurs to the overlying overburden along the valley floor, and eventually to Geona Creek and/or its tributaries.

Results of packer tests conducted by Golder (1995) and Tetra Tech EBA (2015) vary over several orders of magnitude, ranging from between  $1 \times 10^{-6}$  m/s to  $1 \times 10^{-5}$  m/s in upper weathered and more fractured bedrock to  $1 \times 10^{-8}$  m/s to  $1 \times 10^{-7}$  m/s in deeper and relatively massive bedrock. Packer test results are only representative for

the short discrete test intervals and the immediate vicinity of the wellbore. Single features like fractures, faults, or shear zones can significantly affect and dominate the hydraulic conductivity of the test interval, which explains the variability of inferred hydraulic conductivities observed on site.

To better gauge the bulk hydraulic conductivity in the vicinity of the ABM deposit, a single long-term (24 hr) pumping test was conducted at bedrock well WW15-02 during the 2015 hydrogeological investigation program. WW15-02 is a 38.10 m deep open hole well, targeted to intercept the upper and more fractured bedrock zone. Testing at this location indicated the bedrock has a hydraulic conductivity of about  $2 \times 10^{-6}$  m/s. The geometric mean of  $5 \times 10^{-7}$  m/s for all packer tests and hydraulic response tests conducted in shallow bedrock (<50 m deep) agrees reasonably well with the results of the pumping test and provides a reasonable average hydraulic conductivity for the bedrock aquifer at KZK to depths of about 50 m bgs (see also Figure B).

Golder (1996) reported the volcanic rock assemblages which contain the ore zone as generally competent, and strong to very strong while the ore materials are massive and very strong, with little or no structure. The hydraulic conductivity of these rocks would be expected to be at the lower end of the primary bedrock unit (in the order of  $1 \times 10^{-8}$  or lower).

Several northeast to southwest trending faults are mapped as intersecting the deposit area, including the East Fault, Northwest Fault and Fault Creek Fault. Grain size analyses of fault gouge associated with these fault zones indicate that the gouge is comprised primarily of sand and gravel-sized material with a minor fine grained fraction (Golder, 1996). As the aforementioned three major faults within the area of the ABM deposit were only discovered and delineated during the 2015 exploration program, packer tests have not targeted these specific fault zones. However, based on the geological description of the gouge material, the fault zones would be expected to have a higher hydraulic conductivity than the adjacent bedrock (potentially in the order of 2 or more orders of magnitude) and may provide preferential groundwater flow paths.

## 6.2 Groundwater Flow Regime

The groundwater flow regime in the study area can generally be inferred from observed piezometric elevations as groundwater typically flows from areas with higher piezometric elevations to areas with lower piezometric elevations. Figures 9 and 10 (attached) show the inferred piezometric elevation contours for both the overburden and bedrock aquifers based on the September 2015 monitoring event. Based on the mountainous terrain that dominates the study area, it can be assumed that the groundwater flow is mainly controlled by the area's topographic features. As shown in these figures, groundwater flow mimics topography with groundwater flow from the topographically high mountain tops and slopes on either side of the valley toward discharge zones on the valley floors. At the base of the valley, the water table is at or very near the ground surface, while beneath the mountains it may be greater than 200 m below ground surface.

Recharge to the bedrock aquifer in the mountains would be expected to migrate into deep local flow paths, moving towards the valley through fractures and faults prior to discharging to the overburden aquifer. Groundwater then moves through the overburden aquifer prior to discharging to surface water features on the valley floor. On valley flanks, the water table is generally located within the competent bedrock. However, during periods of snow melt, it is expected that a perched or temporary water table develops within the fractured bedrock and overlying overburden.

Figure 11 shows a hydrogeological cross section through the ABM deposit and approximately perpendicular to the Geona valley axis. Given that the study area with the proposed mine infrastructure is restricted to the Geona valley and that groundwater flow is generally from the west and east valley walls toward Geona Creek, the cross section in Figure 11 would also be representative for other locations within the study area.

The flow regime is generally supported by hydraulic gradient data collected from nested monitoring wells and VWP across the study area. Table W presents data from nine nested wells located across the study area and Figure D shows piezometric elevations from two VWP, located in the vicinity of the ABM deposit.

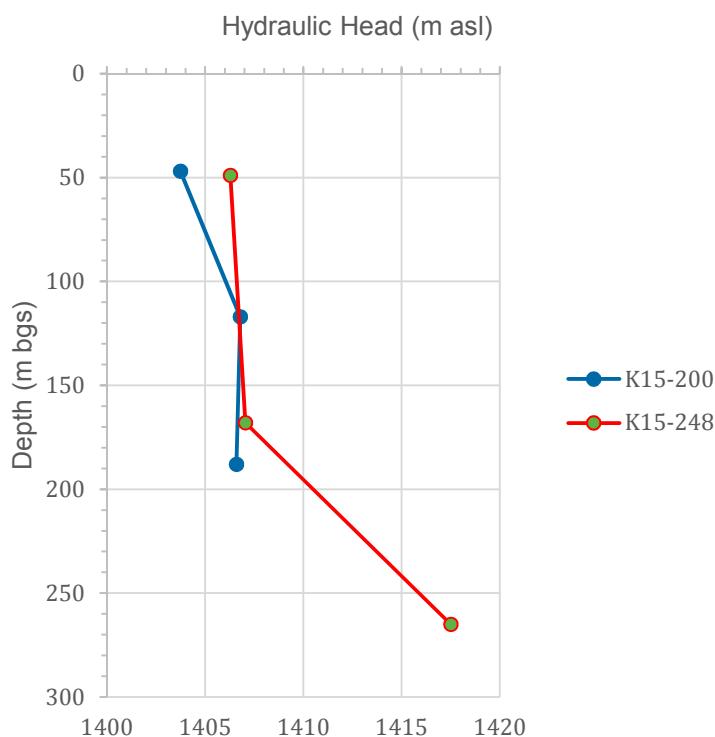

**Table W: Vertical Hydraulic Gradients at Nested Well Locations (September 2015)**

| Monitoring Well Location | Groundwater Elevation, September 22/23, 2015 (m asl) |                      | Vertical Hydraulic Gradient | Hydraulic Gradient Direction |
|--------------------------|--|----------------------|-----------------------------|------------------------------|
|                          | Shallow/Overburden                                   | Deep/Bedrock         |                             |                              |
| MW15-03                  | 1461.85  | 1463.41              | -0.209                      | Upwards                      |
| MW15-04                  | 1444.85  | 1444.87              | -0.001                      | Upwards                      |

| MW15-10 <sup>2</sup>     | 1318.86  | 1318.89 <sup>1</sup> | -0.001                      | Upwards                      |
| MW15-11 <sup>3</sup>     | 1385.01  | 1387.07              | -0.092                      | Upwards                      |
| BH95G-25                 | 1385.54  | 1382.52              | 0.325                       | Downwards                    |
| BH95G-33                 | 1384.18  | 1384.65              | -0.075                      | Upwards                      |

<sup>1</sup> Well flowing over casing on date of gauging. Groundwater elevation is assumed to be the top of the casing.

<sup>2</sup> No data available on Sept. 22/23, 2015, data from September 4, 2015.

<sup>3</sup> No data available on Sept. 22/23, 2015, data from November 7, 2015.

**Figure D: Piezometric elevations (hydraulic heads) inferred from pore pressure measurements using VWPs at K15-200 and K15-248 (September 23, 2015)**

The data in Table W and Figure D shows a general upwards hydraulic gradient from deeper bedrock towards shallow overburden throughout the lower valley area. This data, along with the observation of multiple flowing boreholes across the site (in the range of 4 L/min up to 45 L/min) demonstrates the topographically controlled flow regime (driving head from higher elevations), with the discharge of groundwater from the bedrock aquifer to the overburden aquifer then to surface along the valley floor. The compact to dense sand layer noted to overlie the basal sand and gravel layer may act as a confining layer, limiting discharge where present or concentrating discharge in areas where the confining layer is thinner or absent (i.e. incised creeks, deep water bodies).

Tetra Tech EBA notes that downward hydraulic gradients are present at MW15-08 and BH95G-25. MW15-08S was flowing when monitored in August and September, 2015 (and frozen when visited in November 2015 and March 2016). While the reason for reversed gradient at these locations is unclear, it may be associated with localised confined/semi-confined overburden aquifers on the valley slopes, sourced from surface water infiltration or seepage from the bedrock aquifer at higher elevations up the slopes. Overall, areas along the lower valley where a downward hydraulic gradient is present would be considered to be limited and isolated, with the bulk movement of groundwater towards and discharging to surface on the valley floor.

Fault zones that have been observed to have permeable gouge material (sand and gravel), may offer preferential paths for groundwater flow. This is particularly noted for the Fault Creek Fault which extends several km to the southwest of the deposit area. As noted by Golder (1996) the water table is potentially deeper beneath the eastern valley flank than the western flank (although it is difficult to confirm given the limited number of wells at higher elevations), which may be due to the presence of permafrost on west-facing slopes. The permafrost would act as a confining or semi-confining layer depending on the spatial extent and thickness, thereby limiting recharge to the aquifer in this area which causes the groundwater table to be located at greater depth when compared to the east facing slopes where permafrost is believed to be mostly absent.

Table X presents approximate horizontal hydraulic gradients of the overburden and bedrock across the site based on the August/September groundwater elevation data.

**Table X: Groundwater Horizontal Hydraulic Gradients and Velocity**

| Zone       | Zone Features                                    | Hydraulic Gradient (m/m) |         | Groundwater Velocity (m/day) <sup>1</sup> |          |
|------------|--|--------------------------|---------|---|----------|
|            |  | Overburden               | Bedrock | Overburden                                | Bedrock  |
| Zone 1 (1) | Class A Storage Facility, Water Management Ponds | 0.16                     | 0.16    | 8 to 38                                   | 14 to 35 |
| Zone 1 (2) | Mill and Polishing Pond                          | 0.20                     | 0.12    | 10 to 47                                  | 10 to 26 |
| Zone 2 (1) | Overburden stockpile                             | 0.21                     | 0.25    | 11 to 50                                  | 22 to 55 |
| Zone 2 (2) | Class C Storage Facility                         | 0.31                     | 0.27    | 16 to 74                                  | 23 to 59 |
| Zone 3     | Class B Storage Facility                         | 0.12                     | 0.15    | 6 to 29                                   | 13 to 33 |
| Zone 4a    | Open Pit   | 0.12                     | 0.19    | 6 to 28                                   | 16 to 41 |
| Zone 4b    | Open Pit   | 0.29                     | 0.06    | 15 to 69                                  | 5 to 13  |

<sup>1</sup> Porosity assumed to be 20% in overburden and 1% in bedrock.

The inferred horizontal hydraulic gradient based on groundwater elevations measured in August/September 2015 ranges from approximately 0.12 to 0.31 m/m in overburden and 0.06 to 0.27 m/m in the bedrock aquifer, measured in the direction of groundwater flow toward Geona Creek. Gradients are generally reflective of topography, being comparatively steeper in areas of steeper topography.

Tetra Tech EBA notes that the calculated horizontal hydraulic gradients are estimates based on extrapolation of inferred groundwater elevation contours in some areas where there is a sparse data set. This is particularly evident in area 4b where a hydraulic gradient of 0.06 m/m was calculated. This gradient was determined based data from a bedrock monitoring well located close to the valley floor (BH95-131) and a single inferred groundwater elevation contour (Figure 10). To the east of BH95-131 the surficial topography increases sharply and it would be expected that the groundwater elevation and hence gradient would reflect this increase. Tetra Tech EBA considers the hydraulic gradient through the east side of Zone 4b would likely be similar to the gradient in Zone 2, in the region of 0.2 to 0.3 m/m.

The average horizontal linear groundwater flow velocity in each zone can be estimated using a modification of Darcy's Law:

$$v = K \cdot i \cdot n^{-1}$$

where  $v$  is the groundwater flow velocity (m/s),  $K$  is the hydraulic conductivity of the aquifer (m/s),  $i$  is the hydraulic gradient (m/m), and  $n$  is the effective porosity of the aquifer material (–).

Using the maximum and minimum bulk hydraulic conductivities of the overburden and bedrock aquifers (determined from the 2016 packer tests, hydraulic response tests and pumping tests) and assuming an overburden porosity of 20% and a shallow fractured bedrock equivalent porosity of 1% (e.g., Freeze and Cherry, 1979), the maximum and minimum overburden and bedrock linear groundwater flow velocities were calculated. Estimated flow velocities are detailed in Table X.

As detailed in Table X, calculated groundwater velocities in the overburden range from between 8 and 74 m/day. Lower velocities would be expected in the upper dense sand unit, which has been estimated to have a hydraulic conductivity one to two orders of magnitude lower than the underlying basal sand and gravel unit. Groundwater velocity in the bedrock aquifer ranges from 5 to 59 m/day. Lower velocities would be expected in the deep bedrock, where lower hydraulic conductivities are seen.

It should be noted that local groundwater flow velocities can be much larger or smaller based on the local aquifer hydraulic conductivity and hydraulic gradient. For example, permeable faults can form preferential flow paths for groundwater with significantly higher flow velocities than the estimate above.

### 6.3 Permafrost

The permafrost (where present) acts as a confining or semi-confining layer depending on the spatial extent and thickness, thereby limiting recharge to the aquifer in this area which causes the groundwater table to be located at greater depth when compared to the east facing slopes where permafrost is believed to be mostly absent.

The KZK Project is located in an area with discontinuous permafrost. Cominco (1996) noted that permafrost is present on north and west facing slopes, especially above 1,400 m elevation, although permafrost had been observed as low as 1,250 m elevation. Geotechnical site investigations in the 1990s encountered permafrost in the northern portion of the proposed Class C storage facility and in some areas, especially the east valley slopes, along the Geona Creek valley. Permafrost was found to be mostly absent on the western valley walls as well as in the area of the proposed open pit, except for some localized ice lenses. Where permafrost is present it is believed to be warm permafrost with ground temperatures just below 0°C and therefore susceptible to disturbance.

Permafrost was not observed by Tetra Tech EBA during any of the 2015/16 monitoring program work, although it is noted that it was not in the scope of work to assess permafrost and drilling methods overseen by Tetra Tech EBA were not conducive to observing permafrost. All four ground temperature observation wells installed by Knight

Piesold as part of the preliminary geotechnical site investigations (see Sections 4.6 and 5.4) did not encounter any permafrost.

## 6.4 Groundwater – Surface Water Interaction

Groundwater flow at KZK is generally controlled by topography and groundwater divides are assumed by Tetra Tech EBA to coincide with surface water divides. Groundwater is being recharged at higher elevations on the mountain slopes and generally flows down-valley mimicking the local topography. The groundwater eventually discharges to the receiving streams along the valley bottoms, mainly Geona Creek. Groundwater originating from the area of the proposed Class C storage facility likely discharges to the tributary of Geona Creek in the valley where the storage facility is located and/or to Geona Creek directly.

Geona Creek is the main groundwater discharge feature within the study area encompassing the KZK project with most facilities at lower elevation being located in discharge areas indicated by a vertical upward hydraulic gradient. The amount of baseflow, i.e., groundwater seepage into the creeks, depends on the hydraulic gradient and hydraulic conductivity of the shallow aquifer in the vicinity of the receiving stream. In general, the fraction of baseflow in the creek will be much larger in the winter when there is little or no surface runoff or shallow subsurface runoff (also referred to as interflow). The (late) winter creek discharge usually provides a good estimate of the baseflow as it amounts to nearly 100% of the total discharge observed during this time of the year.

## 7.0 SUITABILITY OF MONITORING WELL NETWORK

At the direction of BMC, the groundwater monitoring network was designed based on Cominco's (1996) mine design. The network was designed to fill data gaps in the historical monitoring well network and data set with the objective to assess baseline conditions across the site, with wells located generally hydraulically up and down gradient of, or near potential sources of groundwater impact (e.g. Class A, B, and C storage facilities, mill site). Monitoring wells were installed by Tetra Tech EBA during the 2015 field program in addition to historic monitoring wells that were upgraded and re-developed.

Following the installation of the network in 2015, the mine design has been amended, with locations of the Class A, B, and C storage facilities, as well as the mill moved and the open pit extended. Subsequently, in several locations where groundwater monitoring wells had previously been located upgradient of potential impact sources these wells are now within the source footprint and other potential impact sources have no up/down gradient monitoring locations. Tetra Tech EBA understands that additional monitoring wells have been installed by others during the summer 2016 field program. However, these additional monitoring wells will be reported under separate cover and have not been included in this report.

In light of the amended mine design, the following sections present a review and discussion of the adequacy of the groundwater monitoring network in relation to the current mine design (as of September 20, 2016) and the networks ability to adequately characterise baseline groundwater conditions.

### Class A Storage Facility

The area of the Class A Storage Facility has one nested groundwater monitoring well (MW15-07S and MW15-07D) located hydraulically downgradient of the southern edge of the proposed location. Tetra Tech EBA understands that two additional monitoring wells were installed in 2016, one upgradient of the Class A storage facility and one downgradient of the facility and associated seepage collection pond.

### Mill Site

The proposed mill site has been relocated to the south between the Class A and B storage facilities. There are currently no monitoring wells immediately up- or downgradient of this new proposed mill location. However, monitoring wells MW15-01 and the new upgradient monitoring well of the Class A storage facility provide data on the general upgradient area of the mill site. Monitoring well MW15-07 is located near the downgradient area of the mill and likely representative of the general groundwater conditions downgradient of the new mill location.

### Class B Storage Facility

The Class B storage facility area has two groundwater monitoring wells that are considered to be downgradient of the footprint of the Class B storage area, BH95G-32 and nested well pair BH95G-33S and BH95G-33D. There are two wells within the proposed footprint of the area (MW15-01 and MW15-02) and no upgradient monitoring locations.

Given the proximity of MW15-01 to the western extent of the Class B storage facility footprint and the fact that the site is undeveloped and groundwater is presently un-impacted by mining operations it can be considered to be representative of current upgradient baseline conditions and suitable to characterise baseline conditions within this area. Tetra Tech EBA notes that following the commencement of mine operations and deposition of waste rock in this area, this well may not be suitable for the assessment of background conditions.

Tetra Tech EBA understands that an additional monitoring well was installed downgradient of the seepage collection pond downgradient of the Class B storage facility during the 2016 field program.

## **Class C Storage Facility**

The Class C storage facility area has at least one well that is considered to be downgradient of the area footprint (BH95G-31) and two wells that are potentially downgradient (BH95G-30 and MW15-06). Two nested wells are located within the proposed footprint of the area (MW15-03S/ MW15-03D and MW15-04S/ MW15-04D). There are no wells upgradient of this area.

However, while nested well pair MW15-03S/ MW15-03D is located within the storage area footprint, Tetra Tech EBA consider that as the site is undeveloped and groundwater is presently un-impacted, groundwater conditions at this location would be generally representative of upgradient groundwater conditions and can be used to characterise baseline conditions within this area. Tetra Tech EBA notes that following the commencement of mine operations and deposition of waste rock in this area, this well will have to be decommissioned and will no longer be available for ongoing monitoring.

## **Overburden Stockpile**

There are no groundwater monitoring wells directly up or down gradient of the overburden stockpile. However, nested monitoring well pair MW15-05S/ MW15-05D, located on the southern extent of the areas footprint, is located cross gradient of the stockpile footprint and can be considered in a suitable location to characterise present upgradient groundwater conditions. Tetra Tech EBA understands that an additional monitoring well was installed downgradient of the overburden stockpile and the associated seepage collection pond during the 2016 field program.

## **ABM Open Pit**

The monitoring network within the proposed open pit is intended to assess overburden and bedrock baseline groundwater conditions in the footprint of the excavation area. There are considered to be sufficient wells within the northern pit area extent to adequately characterise baseline conditions. To the south where the proposed pit extent has been expanded to encompass the Krakatoa zone, Tetra Tech EBA understands that an additional monitoring well has been installed during the summer 2016 field program to further characterise conditions in the southern most section of the pit area.

There is a single well (BH95G-29) located to the south of the proposed open pit extent. This well could be used as a general offsite/upgradient monitoring well to assess baseline conditions in the upper valley outside of the general operational mine area.

Based on Tetra Tech EBA's understanding of existing groundwater conditions (see discussion in Section 6), the current groundwater monitoring network, in conjunction with additional monitoring wells installed during the summer 2016 field program, provides reasonable coverage in order to characterise baseline groundwater conditions.

## 8.0 SUMMARY AND CONCLUSIONS

Based on the results of the monitoring well drilling and completion, and the baseline hydrogeological assessment presented in this report, Tetra Tech EBA arrived at the following conclusions:

- A monitoring well network was successfully installed at KZK consisting of 11 new monitoring wells (eight of which are nested with shallow overburden and deeper bedrock piezometers) in addition to 14 historic monitoring wells that were re-developed and upgraded with standpipe extensions and protective casings.
- All monitoring wells were completed with 32 mm (1.25") diameter PVC standpipes.
- In addition to the monitoring wells, two observations wells were installed with VWPs to monitor pore pressures at three different depths in each of the observation wells. The VWP observations wells were installed within the ABM deposit and proposed open pit. K15-200 is located west of Geona Creek whereas K15-248 is located on the east side of Geona Creek.
- Ground temperatures and permafrost conditions were assessed using subsurface temperature data from the VWPs and four ground temperature observation wells installed by Knight Piesold.
- Permafrost appears to be discontinuous and mostly restricted to north and west facing slopes at elevations above 1,400 m asl. No permafrost was encountered in any of the monitoring wells or ground temperature observation wells.
- The local groundwater regime consists of a bedrock aquifer overlain across valley floors by an overburden aquifer. The overburden aquifer is inferred to be confined to semi-confined, at least in the area of the ABM deposit.
- The overburden aquifer consists of till, glaciofluvial, and alluvial deposits with a coarse basal sand and gravel unit overlain by silty sand and gravel till. The overburden aquifer is typically between about 10 to 20 m thick along the valley bottom and thins out with increasing elevations.
- The primary bedrock aquifer in the vicinity of the ABM deposit mainly consists of schistose felsic volcanics intersected with thick felsic tuff and sill/flow complexes that host the ore deposit.
- The groundwater flow regime at the site is controlled by the steep terrain with groundwater flow from areas at higher elevations on the mountain slopes toward the valley bottoms with the groundwater flow generally mimicking the local topography and eventually discharging to Geona Creek.
- Hydraulic conductivities of the overburden aquifer were inferred from hydraulic response tests across the study area and one pumping test conducted in the area of the ABM deposit. The inferred hydraulic conductivities ranged from about  $1 \times 10^{-6}$  m/s to about  $1 \times 10^{-4}$  m/s with the highest values measured in the area of the ABM deposit (i.e., WW15-01 and MW15-11S).
- Hydraulic conductivities of the bedrock aquifer were inferred from packer tests conducted in select exploration drill holes in the area of the ABM deposit as well as select monitoring wells. In addition, hydraulic response tests and one pumping test in shallow bedrock were conducted. Inferred hydraulic conductivities ranged over several orders of magnitude from about  $3 \times 10^{-9}$  m/s to about  $4 \times 10^{-6}$  m/s. Hydraulic conductivity in bedrock is inferred to be largely controlled by fracture density and permeability. In general, the bedrock hydraulic conductivity tends to decrease with depth with the higher values found in shallow, weathered bedrock less than about 50 m deep, and smaller values ( $< 1 \times 10^{-7}$  m/s) in deeper, more competent bedrock at depth of more than about 50 m.

- Groundwater samples were collected from monitoring wells across the site during May, August/September, and November 2015 as well as March 2016. Seasonal groundwater monitoring is currently ongoing to further characterize baseline groundwater quality and seasonality.
- Groundwater quality was found to be variable across the site with individual areas discussed in detail in Section 5.5.
- Most groundwater samples showed a near neutral or slightly basic pH (between 7 and 8), with few samples, primarily in the northern part of the study area (Zone 1) showing slightly acidic pH values of less than 7.
- Groundwater samples had an average total dissolved solids concentration of 379 mg/L across the study area, suggesting moderately mineralized groundwater, with some samples from the northern part of the study area (Zone 1) and from the area of the ABM deposit (Zone 4) having significantly higher TDS concentrations.
- Hardness concentrations are variable across the site, ranging from about 80 to 2,100 mg/L. Maximum concentrations reported in Zones 1 and 2 were over two times higher than maximum concentrations in each of the other three zones. Average and maximum concentrations were typically higher in bedrock wells than overburden wells in each zone.
- Sulfate concentrations averaged 68 mg/L across the study area, with an average of 67 mg/L in overburden wells and 69 mg/L in bedrock wells. Sulphate concentrations were highest in Zones 4a and 4b and showed a general trend of increasing concentration with depth in the two zones.
- Various dissolved metals were found to exceed the FIG and CCME-AW water quality guidelines as well as the Water Use Licence (QZ97-026) Effluent Quality Criteria. Observed dissolved metals exceedances primarily include arsenic, cadmium, iron, lead, selenium, and zinc.
- Many monitoring wells showed considerable variability in analytical results over the course of the monitoring program suggesting there may be a strong seasonal influence on groundwater chemistry. Ongoing groundwater monitoring scheduled in 2016/2017 will provide additional data to characterize seasonal changes in groundwater quality and quantity.

## 9.0 CLOSURE

We trust this report meets your present requirements. If you have any questions or comments, please contact the undersigned.

**Notes:**

"Functional" means that representative groundwater elevation or sample can be obtained from the well.

'mag' - meters above ground

'mbtopvc' - meters below top of PVC casing

'mbg' - meters below ground

**Table 2: Summary of Groundwater Elevations**

**Notes:**

<sup>1</sup> Environment Canada (Revised March 2014). Guidance Document on Federal Interim Groundwater Quality Guidelines (FIGGG) for Federal Contaminated Sites, Tier 1 guidelines for fine and coarse grained soil under Commercial/Industrial land use

<sup>2</sup> Canadian Council of Ministers of the Environment (CCME) (Updated 2014). Canadian Water Quality Guidelines for the Protection of Aquatic Life (Freshwater)

<sup>3</sup> Environment Act. Contaminated Sites Regulation (CSR) (2002). Schedule 3, Generic Numerical Water Standards for Aquatic Life (AW)

<sup>4</sup> Maximum increase of 25 mg/L from background levels

<sup>5</sup> Standard varies with pH and temperature. Values shown based on field pH range of 5.68 to 7.71 and temperature range of -2.7 °C to 3.3 °C

<sup>6</sup> Guideline varies with pH. Values shown based on field pH range of 5.68 to 7.71

<sup>7</sup> Guideline varies with chloride. Values shown based on chloride range of <0.50 mg/L to 3.8 mg/L

<sup>8</sup> Guideline applies is for ultra-oligotrophic

<sup>9</sup> Guideline varies with hardness. Value shown based on hardness range of 200 mg/L to 2120 mg/L for total metals, and 136 mg/L to 2180 mg/L for dissolved metals

<sup>10</sup> Guideline is for Chromium VI

... No applicable standard or not analyzed

Shaded - Greater than Federal Interim Guideline

**BOLD** - Greater than CCME AW Guideline

Underlined - Greater than Yukon CSR Guideline

**RED** - Greater than current Site Water Licence QZ97-026

**Notes:**

<sup>1</sup> Environment Canada (Revised March 2014). Guidance Document on Federal Interim Groundwater Quality Guidelines (FIGGG) for Federal Contaminated Sites, Tier 1 guidelines for fine and coarse grained soil under Commercial/Industrial land use

<sup>2</sup> Canadian Council of Ministers of the Environment (CCME) (Updated 2014). Canadian Water Quality Guidelines for the Protection of Aquatic Life (Freshwater)

<sup>3</sup> Environment Act. Contaminated Sites Regulation (CSR) (2002). Schedule 3, Generic Numerical Water Standards for Aquatic Life (AW)

<sup>4</sup> Maximum increase of 25 mg/L from background levels

<sup>5</sup> Standard varies with pH and temperature. Values shown based on field pH range of 5.68 to 7.71 and temperature range of -2.7 °C to 3.3 °C

<sup>6</sup> Guideline varies with pH. Values shown based on field pH range of 5.68 to 7.71

<sup>7</sup> Guideline varies with chloride. Values shown based on chloride range of <0.50 mg/L to 3.8 mg/L

<sup>8</sup> Guideline applied is for ultra-oligotrophic

<sup>9</sup> Guideline varies with hardness. Value shown based on hardness range of 200 mg/L to 2120 mg/L for total metals, and 136 mg/L to 2180 mg/L for dissolved metals

<sup>10</sup> Guideline is for Chromium VI

"." No applicable standard or not analyzed

Shaded - Greater than Federal Interim Guideline

**BOLD** - Greater than CCME AW Guideline

Underlined - Greater than Yukon CSR Guideline

**RED** - Greater

**Notes:**

<sup>1</sup> Environment Canada (Revised March 2014). Guidance Document on Federal Interim Groundwater Quality Guidelines (FIGQQ) for Federal Contaminated Sites, Tier 1 guidelines for fine and coarse grained soil under Commercial/Industrial land use

<sup>2</sup> Canadian Council of Ministers of the Environment (CCME) (Updated 2014). Canadian Water Quality Guidelines for the Protection of Aquatic Life (Freshwater)

<sup>3</sup> Environment Act. Contaminated Sites Regulation (CSR) (2002). Schedule 3, Generic Numerical Water Standards for Aquatic Life (AW)

<sup>4</sup> Maximum increase of 25 mg/L from background levels

<sup>5</sup> Standard varies with pH and temperature. Values shown based on field pH range of 5.68 to 7.71 and temperature range of -2.7 °C to 3.3 °C

<sup>6</sup> Guideline varies with pH. Values shown based on field pH range of 5.68 to 7.71

<sup>7</sup> Guideline varies with chloride. Values shown based on chloride range of <0.50 mg/L to 3.8 mg/L

**Notes:**

<sup>1</sup> Environment Canada (Revised March 2014). Guidance Document on Federal Interim Groundwater Quality Guidelines (FIGGG) for Federal Contaminated Sites, Tier 1 guidelines for fine and coarse grained soil under Commercial/Industrial land use

<sup>2</sup> Canadian Council of Ministers of the Environment (CCME) (Updated 2014). Canadian Water Quality Guidelines for the Protection of Aquatic Life (Freshwater)

<sup>3</sup> Environment Act. Contaminated Sites Regulation (CSR) (2002). Schedule 3, Generic Numerical Water Standards for Aquatic Life (AW)

<sup>4</sup> Maximum increase of 25 mg/L from background levels

<sup>5</sup> Standard varies with pH and temperature. Values shown based on field pH range of 5.68 to 7.71 and temperature range of -2.7 °C to 3.3 °C

<sup>6</sup> Guideline varies with pH. Values shown based on field pH range of 5.68 to 7.71

<sup>7</sup> Guideline varies with chloride. Values shown based on chloride range of <0.50 mg/L to 3.8 mg/L

<sup>8</sup> Guideline applied is for ultra-oligotrophic

<sup>9</sup> Guideline varies with hardness. Value shown based on hardness range of 200 mg/L to 2120 mg/L for total metals, and 136 mg/L to 2180 mg/L for dissolved metals

<sup>10</sup> Guideline is for Chromium VI

... No applicable standard or not analyzed

Shaded - Greater than Federal Interim Guideline

BOLD - Greater than CCME AW Guideline

Underlined - Greater than Yukon CSR Guideline

RED - Greater than current Site Water Licence QZ97-026

**Notes:**

<sup>1</sup> Environment Canada (Revised March 2014). Guidance Document on Federal Interim Groundwater Quality Guidelines (FIGGG) for Federal Contaminated Sites, Tier 1 guidelines for fine and coarse grained soil under Commercial/Industrial land use

<sup>2</sup> Canadian Council of Ministers of the Environment (CCME) (Updated 2014). Canadian Water Quality Guidelines for the Protection of Aquatic Life (Freshwater)

<sup>3</sup> Environment Act. Contaminated Sites Regulation (CSR) (2002). Schedule 3, Generic Numerical Water Standards for Aquatic Life (AW)

<sup>4</sup> Maximum increase of 25 mg/L from background levels

<sup>5</sup> Standard varies with pH and temperature. Values shown based on field pH range of 5.68 to 7.71 and temperature range of -2.7 °C to 3.3 °C

<sup>6</sup> Guideline varies with pH. Values shown based on field pH range of 5.68 to 7.71

<sup>7</sup> Guideline varies with chloride. Values shown based on chloride range of <0.50 mg/L to 3.8 mg/L

<sup>8</sup> Guideline applied is for ultra-oligotrophic

<sup>9</sup> Guideline varies with hardness. Value shown based on hardness range of 200 mg/L to 2120 mg/L for total metals, and 136 mg/L to 2180 mg/L for dissolved metals

<sup>10</sup> Guideline is for Chromium VI

.. No applicable standard or not analyzed

Shaded - Greater than Federal Interim Guideline

**BOLD** - Greater than CCME AW Guideline

Underlined - Greater than Yukon CSR Guideline

**RED** - Greater than current Site Water Licence QZ97-026

**Notes:**

- <sup>1</sup> Environment Canada (Revised March 2014). Guidance Document on Federal Interim Groundwater Quality Guidelines (FIGQQ) for Federal Contaminated Sites, Tier 1 guidelines for fine and coarse grained soil under Commercial/Industrial land use
- <sup>2</sup> Canadian Council of Ministers of the Environment (CCME) (Updated 2014). Canadian Water Quality Guidelines for the Protection of Aquatic Life (Freshwater)
- <sup>3</sup> Environment Act. Contaminated Sites Regulation (CSR) (2002). Schedule 3, Generic Numerical Water Standards for Aquatic Life (AW)
- <sup>4</sup> Maximum increase of 25 mg/L from background levels
- <sup>5</sup> Standard varies with pH and temperature. Values shown based on field pH range of 6.06 to 8.10 and temperature range of -1 °C to 3.2 °C
- <sup>6</sup> Guideline varies with pH. Values shown based on field pH range of 6.06 to 8.10
- <sup>7</sup> Guideline varies with chloride. Values shown based on chloride range of <0.50 mg/L to 3.2 mg/L
- <sup>8</sup> Guideline applied is for ultra-oligotrophic
- <sup>9</sup> Guideline varies with hardness. Value shown based on hardness range of 1

**Notes:**

- <sup>1</sup> Environment Canada (Revised March 2014). Guidance Document on Federal Interim Groundwater Quality Guidelines (FIGQQ) for Federal Contaminated Sites, Tier 1 guidelines for fine and coarse grained soil under Commercial/Industrial land use
- <sup>2</sup> Canadian Council of Ministers of the Environment (CCME) (Updated 2014). Canadian Water Quality Guidelines for the Protection of Aquatic Life (Freshwater)
- <sup>3</sup> Environment Act. Contaminated Sites Regulation (CSR) (2002). Schedule 3, Generic Numerical Water Standards for Aquatic Life (AW)
- <sup>4</sup> Maximum increase of 25 mg/L from background levels
- <sup>5</sup> Standard varies with pH and temperature. Values shown based on field pH range of 6.06 to 8.10 and temperature range of -1 °C to 3.2 °C
- <sup>6</sup> Guideline varies with pH. Values shown based on field pH range of 6.06 to 8.10
- <sup>7</sup> Guideline varies with chloride. Values shown based on chloride range of <0.50 mg/L to 3.2 mg/L
- <sup>8</sup> Guideline applied is for ultra-oligotrophic
- <sup>9</sup> Guideline varies with hardness. Value shown based on hardness range of 147 mg/L to 2530 mg/L for total metals, and 78.9 mg/L to 212 mg/L for dissolved metals
- <sup>10</sup> Guideline is for Chromium VI
- <sup>11</sup> No applicable standard or not analyzed
- Shaded - Greater than Federal Interim Guideline
- BOLD** - Greater than CCME AW Guideline
- Underlined - Greater than Yukon CSR Guideline
- RED** - Greater than current Site Water Licence QZ97-026

## Notes:

<sup>1</sup> Environment Canada (Revised March 2014). Guidance Document on Federal Interim Groundwater Quality Guidelines (FIGQQ) for Federally Contaminated Sites, Tier 1 guidelines for fine and coarse grained soil under Commercial/Industrial land use

<sup>2</sup> Canadian Council of Ministers of the Environment (CCME) (Updated 2014). Canadian Water Quality Guidelines for the Protection of Aquatic Life (Freshwater).

<sup>3</sup> Environment Act. Contaminated Sites Regulation (CSR) (2002). Schedule 3. Generic Numerical Water Standards for Aquatic Life (

<sup>4</sup> Maximum increase of 25 mg/L from background level.

<sup>5</sup> Standard varies with pH and temperature. Values shown based on field pH range of 6.06 to 8.10 and temperature range of -1 °C to 32 °C.

<sup>6</sup> Guideline varies with pH. Values shown based on field pH range of 6.06 to 8.1.

Guideline varies with pH. Values shown based on field pH range  
7. Guideline varies with chloride. Values shown based on chloride range

<sup>a</sup> Guideline values with chloride. Values shown based on chloride range of <0.50 mg/L to 3.2 mg/L

◦ Guideline applied is for ultra-oligotrophic

<sup>9</sup> Guideline varies with hardness. Value shown based on hardness range of 147 m

<sup>10</sup> Guideline is for Chromium VI

"—" No applicable standard or not an

**Notes:**

<sup>1</sup> Environment Canada (Revised March 2014). Guidance Document on Federal Interim Groundwater Quality Guidelines (FIGQQ) for Federal Contaminated Sites, Tier 1 guidelines for fine and coarse grained soil under Commercial/Industrial land use

<sup>2</sup> Canadian Council of Ministers of the Environment (CCME) (Updated 2014). Canadian Water Quality Guidelines for the Protection of Aquatic Life (Freshwater)

<sup>3</sup> Environment Act. Contaminated Sites Regulation (CSR) (2002). Schedule 3, Generic Numerical Water Standards for Aquatic Life (AW)

<sup>4</sup> Maximum increase of 25 mg/L from background levels

<sup>5</sup> Standard varies with pH and temperature. Values shown based on field pH range of 6.59 to 8.50 and temperature range of -2.4 °C to 2.4 °C

<sup>6</sup> Guideline varies with pH. Values shown based on field pH range of 6.59 to 8.50

<sup>7</sup> Guideline varies with chloride. Values shown based on chloride range of <0.50 mg/L to 1.4 mg/L

<sup>8</sup> Guideline applied is for ultra-oligotrophic

<sup>9</sup> Guideline varies with hardness. Value shown based on hardness range of 215 mg/L to 1010 mg/L for total metals, and 181 mg/L to 296 mg/L for dissolved metals

<sup>10</sup> Guideline is for Chromium VI

**Notes:**

<sup>1</sup> Environment Canada (Revised March 2014). Guidance Document on Federal Interim Groundwater Quality Guidelines (FIGGG) for Federal Contaminated Sites, Tier 1 guidelines for fine and coarse grained soil under Commercial/Industrial land use

<sup>2</sup> Canadian Council of Ministers of the Environment (CCME) (Updated 2014). Canadian Water Quality Guidelines for the Protection of Aquatic Life (Freshwater)

<sup>3</sup> Environment Act. Contaminated Sites Regulation (CSR) (2002). Schedule 3, Generic Numerical Water Standards for Aquatic Life (AW)

<sup>4</sup> Maximum increase of 25 mg/L from background levels

<sup>5</sup> Standard varies with pH and temperature. Values shown based on field pH range of 6.59 to 8.50 and temperature range of -2.4 °C to 2.4 °C

<sup>6</sup> Guideline varies with pH. Values shown based on field pH range of 6.59 to 8.50

<sup>7</sup> Guideline varies with chloride. Values shown based on chloride range of <0.50 mg/L to 1.4 mg/L

<sup>8</sup> Guideline applied is for ultra-oligotrophic

<sup>9</sup> Guideline varies with hardness. Value shown based on hardness range of 215 mg/L to 1010 mg/L for total metals, and 181 mg/L to 296 mg/L for dissolved metals

<sup>10</sup> Guideline is for Chromium VI

“.” No applicable standard or not analyzed

**Notes:**

<sup>1</sup> Environment Canada (Revised March 2014). Guidance Document on Federal Interim Groundwater Quality Guidelines (FIGQG) for Federal Contaminated Sites, Tier 1 guidelines for fine and coarse grained soil under Commercial/Industrial land use

<sup>2</sup> Canadian Council of Ministers of the Environment (CCME) (Updated 2014). Canadian Water Quality Guidelines for the Protection of Aquatic Life (Freshwater)

<sup>3</sup> Environment Act. Contaminated Sites Regulation (CSR) (2002). Schedule 3, Generic Numerical Water Standards for Aquatic Life (AW)

<sup>4</sup> Maximum increase of 25 mg/L from background levels

<sup>5</sup> Standard varies with pH and temperature. Values shown based on field pH range of 6.59 to 8.50 and temperature range of -2.4 °C to 2.4 °C

<sup>6</sup> Guideline varies with pH. Values shown based on field pH range of 6.59 to 8.50

<sup>7</sup> Guideline varies with chloride. Values shown based on chloride range of <0.50 mg/L to 1.4 mg/L

<sup>8</sup> Guideline applied is for ultra-oligotrophic

<sup>9</sup> Guideline varies with hardness. Value shown based on hardness range of 215 mg/L to 1010 mg/L for total metals, and 181 mg/L to 296 mg/L for dissolved metals

<sup>10</sup> Guideline is for Chromium VI

" No applicable standard or not analyzed

Shaded - Greater than Federal Interim Guideline

**BOLD** - Greater than CCME AW Guideline

Underlined - Greater than Yukon CSR Guideline

**RED** - Greater than current Site Water Licence QZ97-026

**Notes:**

<sup>1</sup> Environment Canada (Revised March 2014). Guidance Document on Federal Interim Groundwater Quality Guidelines (FIGQQ) for Federal Contaminated Sites, Tier 1 guidelines for fine and coarse grained soil under Commercial/Industrial land use

<sup>2</sup> Canadian Council of Ministers of the Environment (CCME) (Updated 2014). Canadian Water Quality Guidelines for the Protection of Aquatic Life (Freshwater)

<sup>3</sup> Environment Act. Contaminated Sites Regulation (CSR) (2002). Schedule 3, Generic Numerical Water Standards for Aquatic Life (AW)

<sup>4</sup> Maximum increase of 25 mg/L from background levels

<sup>5</sup> Standard varies with pH and temperature. Values shown based on field pH range of 5.98 to 8.60 and temperature range of -2.4 °C to 4.3 °C

<sup>6</sup> Guideline varies with pH. Values shown based on field pH range of 5.98 to 8.60

<sup>7</sup> Guideline varies with chloride. Values shown based on chloride range of <0.50 mg/L to 2.5 mg/L

<sup>8</sup> Guideline applied is for ultra-oligotrophic

<sup>9</sup> Guideline varies with hardness. Value shown based on hardness range of 125 mg/L to 773 mg/L for total metals, and 112 mg/L to 683 mg/L for

<sup>10</sup> Guideline is for Chromium VI

... No applicable standard or not analyzed

Shaded - Greater than Federal Interim Guideline

BOLD - Greater than CCME AW Guideline

Underlined - Greater than Yukon CSR Guideline

RED - Greater than current Site Water Licence QZ97-026

**Notes**

<sup>1</sup> Environment Canada (Revised March 2014). Guidance Document on Federal Interim Groundwater Quality Guidelines (FIGQQ) for Federal Contaminated Sites, Tier 1 guidelines for fine and coarse grained soil under Commercial/Industrial land use

Canadian Council of Ministers of the Environment (CCME) (Updated 2014). Canadian Water Quality Guidelines for the Protection of Aquatic Life (Freshwater).

<sup>3</sup> Environment Act, Contaminated Sites Regulation (CSR) (2002), Schedule 3, Generic Numerical Water Standards for Aquatic Life (AWN) (2002).

<sup>4</sup> Maximum increase of 25 mg/L from background level.

<sup>5</sup> Standard varies with pH and temperature. \*

<sup>6</sup> Guideline varies with pH. Values shown based on field pH range of 5.98 to 8.60.

<sup>7</sup> Guideline varies with chloride. Values shown based on chloride range of <0.50 mg/L to 2.5 mg/L.

<sup>7</sup> Guideline varies with chloride. Values shown based on chloride range of <0.50  
<sup>8</sup> Guideline applied is for ultra-oligotrophic.

<sup>8</sup> Guideline applied is for ultra-oligotrophic  
<sup>9</sup> Guideline varies with hardness. Value shown based on hardness range of 125

<sup>9</sup> Guideline varies with hardness. Value shown is for 300 Brinell.

<sup>10</sup> Guideline is for Chromium VI  
--- No applicable standard or not analyzed

**Notes:**

<sup>1</sup> Environment Canada (Revised March 2014). Guidance Document on Federal Interim Groundwater Quality Guidelines (FIGGG) for Federal Contaminated Sites, Tier 1 guidelines for fine and coarse grained soil under Commercial/Industrial land use

<sup>2</sup> Canadian Council of Ministers of the Environment (CCME) (Updated 2014). Canadian Water Quality Guidelines for the Protection of Aquatic Life (Freshwater)

<sup>3</sup> Environment Act. Contaminated Sites Regulation (CSR) (2002). Schedule 3, Generic Numerical Water Standards for Aquatic Life (AW)

<sup>4</sup> Maximum increase of 25 mg/L from background levels

<sup>5</sup> Standard varies with pH and temperature. Values shown based on field pH range of 7.13 to 7.79 and temperature range of -0.1 °C to 4.3 °C

<sup>6</sup> Guideline varies with pH. Values shown based on field pH range of 7.13 to 7.79

<sup>7</sup> Guideline varies with chloride. Values shown based on chloride range of 0.51 mg/L to 24 mg/L

<sup>8</sup> Guideline applied is for ultra-oligotrophic

<sup>9</sup> Guideline varies with hardness. Value shown based on hardness range of 218 mg/L to 775 mg/L for total metals, and 217 mg/L to 593 mg/L for dissolved metals

<sup>10</sup> Guideline is for Chromium VI

<sup>11</sup> No applicable standard or not analyzed

**Notes:**

RDL - Reportable detection limit

RPD - Relative percent difference calculated as  $(\text{abs}(\text{C1}-\text{C2})/\text{average}(\text{C1}+\text{C2})) * 100$

N/A - Not applicable

"." Indicates RPD not calculated. RPD cannot be calculated if one or more of the analytical results are less than detection limits or within 5 times the detection limits.

**BOLD** - RPD value greater than 30%

**Table 6: Quality Assurance / Quality Control**

**Notes:**

RDL - Reportable detection limit

RPD - Relative percent difference calculated as  $(\text{abs}(C1-C2)/\text{average}(C1+C2)) * 100$

N/A - Not applicable

"-" Indicates RPD not calculated. RPD cannot be calculated if one or more of the analytical results are less than detection limits or within 5 times the detection limits.

**BOLD** - RPD value greater than 30%

**Notes:**

RDL - Reportable detection limit

RPD - Relative percent difference calculated as  $(\text{abs}(\text{C1}-\text{C2})/\text{average}(\text{C1}+\text{C2})) \times 100$

N/A - Not applicable

"." Indicates RPD not calculated. RPD cannot be calculated if one or more of the analytical results are less than detection limits or within 5 times the detection limits.

**BOLD** - RPD value greater than 30%

**Notes:**

RDL - Reportable detection limit

RPD - Relative percent difference calculated as  $(\text{abs}(\text{C1}-\text{C2})/\text{average}(\text{C1}+\text{C2})) \times 100$

N/A - Not applicable

"-" Indicates RPD not calculated. RPD cannot be calculated if one or more of the analytical results are less than detection limits or within 5 times the detection limits.

**BOLD** - RPD value greater than 30%

**Notes:**

- Result does not exceed guideline value

<sup>1</sup> Environment Canada (Revised March 2014). Guidance Document on Federal Interim Groundwater Quality Guidelines (FIGGG) for Federal Contaminated Sites, Tier 1 guidelines for fine and coarse grained soil under Commercial/Industrial land use

<sup>2</sup> Canadian Council of Ministers of the Environment (CCME) (Updated 2014). Canadian Water Quality Guidelines for the Protection of Aquatic Life (Freshwater)

<sup>3</sup> Environment Act. Contaminated Sites Regulation (CSR) (2002). Schedule 3, Generic Numerical Water Standards for Aquatic Life (AW)

<sup>4</sup> Maximum increase of 25 mg/L from background levels

<sup>5</sup> Standard varies with pH and temperature. Values shown based on field pH range of 7.13 to 7.79 and temperature range of -0.1 °C to 4.3 °C

<sup>6</sup> Guideline varies with pH. Values shown based on field pH range of 7.13 to 7.79

<sup>7</sup> Guideline varies with chloride. Values shown based on chloride range of 0.51 mg/L to 24 mg/L

<sup>8</sup> Guideline applied is for ultra-oligotrophic

<sup>9</sup> Guideline varies with hardness. Value shown based on hardness range of 218 mg/L to 775 mg/L for total metals, and 217 mg/L to 593 mg/L for dissolved metals

<sup>10</sup> Guideline is for Chromium VI

"-" No applicable standard or not analyzed

Shaded - Greater than Federal Interim Guideline

**BOLD** - Greater than CCME AW Guideline

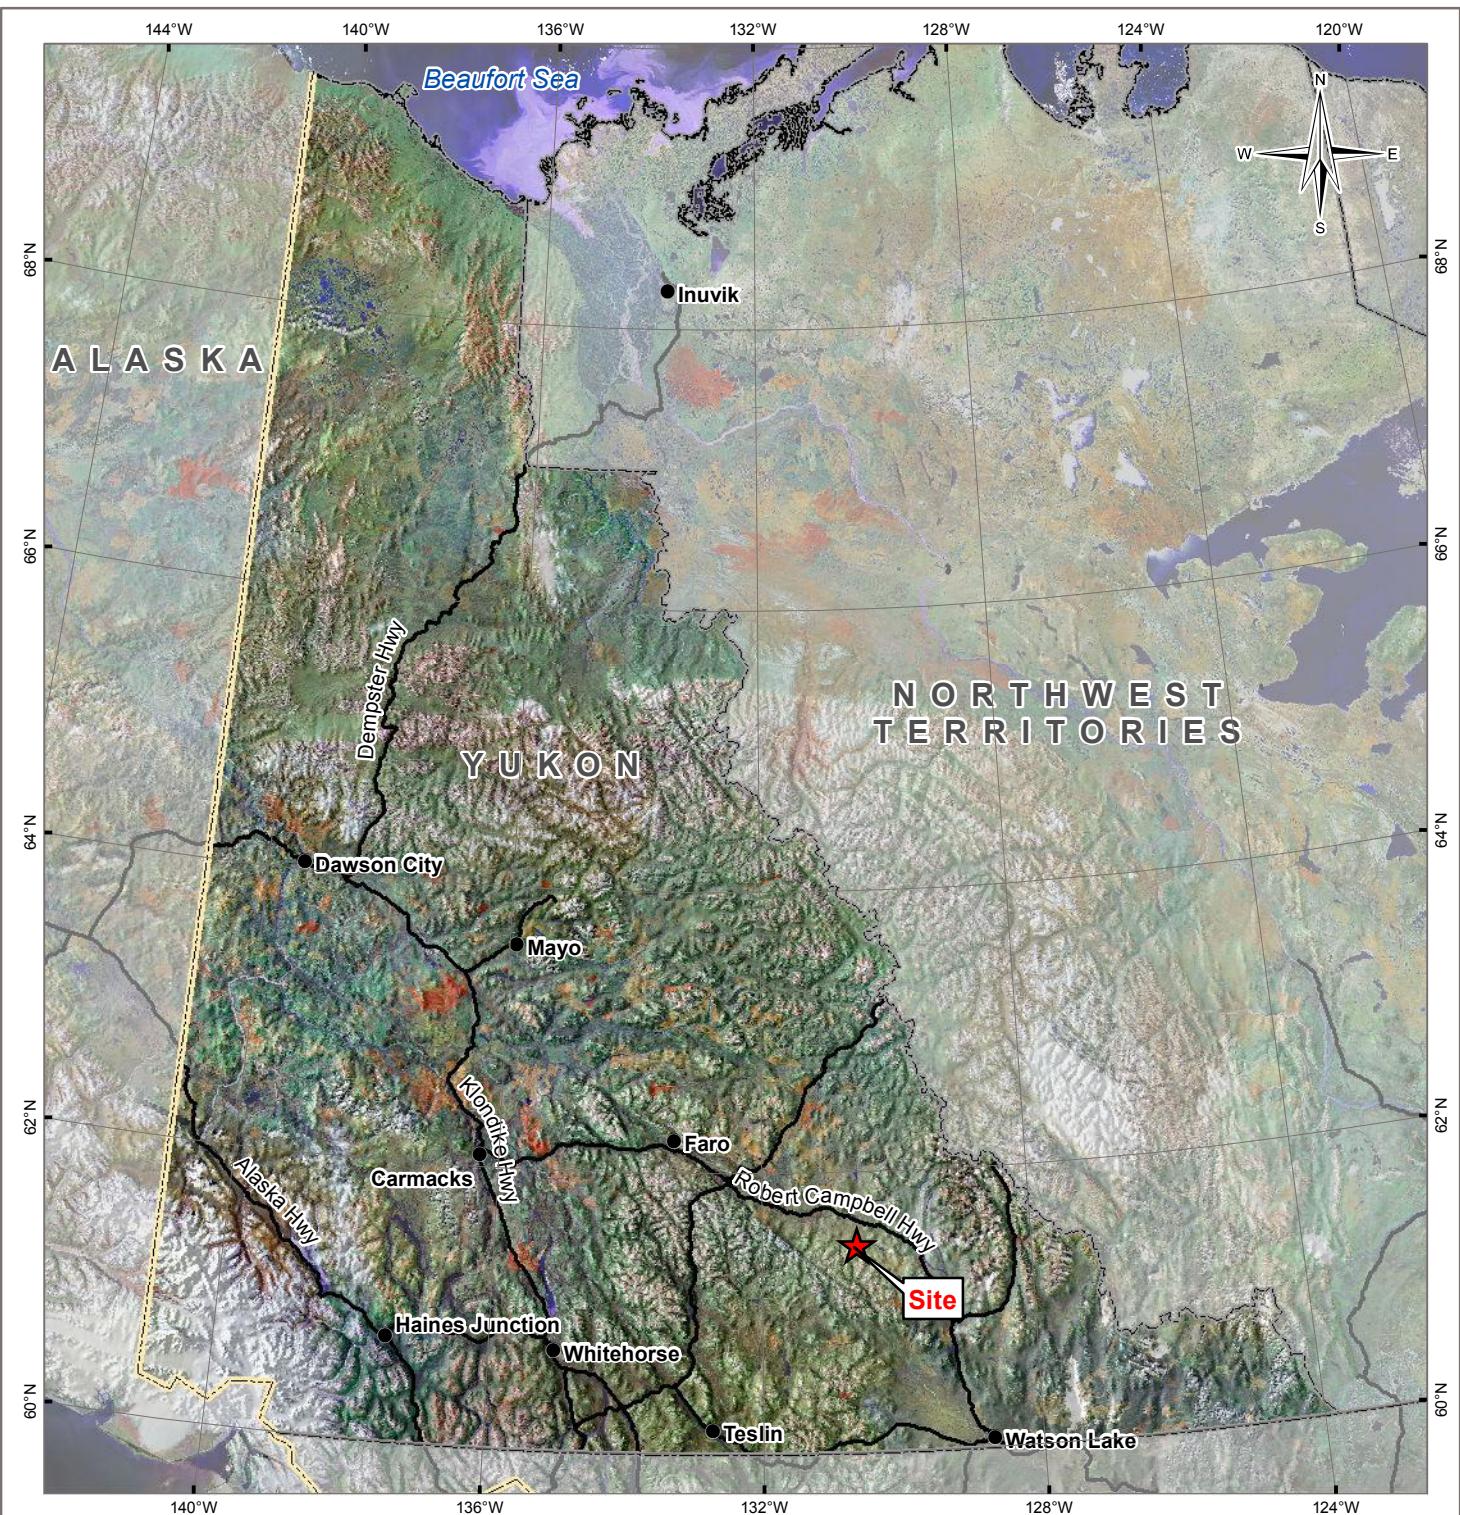

Underlined - Greater than Yukon CSR Guideline

**RED** - Greater than current Site Water Licence QZ97-026

## TETRA TECH'S GENERAL CONDITIONS

---

# GENERAL CONDITIONS

## GEOENVIRONMENTAL REPORT

This report incorporates and is subject to these "General Conditions".

### 1.1 USE OF REPORT AND OWNERSHIP

This report pertains to a specific site, a specific development, and a specific scope of work. It is not applicable to any other sites, nor should it be relied upon for types of development other than those to which it refers. Any variation from the site or proposed development would necessitate a supplementary investigation and assessment.

This report and the assessments and recommendations contained in it are intended for the sole use of TETRA TECH's client. TETRA TECH does not accept any responsibility for the accuracy of any of the data, the analysis or the recommendations contained or referenced in the report when the report is used or relied upon by any party other than TETRA TECH's Client unless otherwise authorized in writing by TETRA TECH. Any unauthorized use of the report is at the sole risk of the user.

This report is subject to copyright and shall not be reproduced either wholly or in part without the prior, written permission of TETRA TECH. Additional copies of the report, if required, may be obtained upon request.

### 1.2 ALTERNATE REPORT FORMAT

Where TETRA TECH submits both electronic file and hard copy versions of reports, drawings and other project-related documents and deliverables (collectively termed TETRA TECH's instruments of professional service); only the signed and/or sealed versions shall be considered final and legally binding. The original signed and/or sealed version archived by TETRA TECH shall be deemed to be the original for the Project.

Both electronic file and hard copy versions of TETRA TECH's instruments of professional service shall not, under any circumstances, no matter who owns or uses them, be altered by any party except TETRA TECH. The Client warrants that TETRA TECH's instruments of professional service will be used only and exactly as submitted by TETRA TECH.

Electronic files submitted by TETRA TECH have been prepared and submitted using specific software and hardware systems. TETRA TECH makes no representation about the compatibility of these files with the Client's current or future software and hardware systems.

### 1.3 NOTIFICATION OF AUTHORITIES

In certain instances, the discovery of hazardous substances or conditions and materials may require that regulatory agencies and other persons be informed and the client agrees that notification to such bodies or persons as required may be done by TETRA TECH in its reasonably exercised discretion.

### 1.4 INFORMATION PROVIDED TO TETRA TECH BY OTHERS

During the performance of the work and the preparation of the report, TETRA TECH may rely on information provided by persons other than the Client. While TETRA TECH endeavours to verify the accuracy of such information when instructed to do so by the Client, TETRA TECH accepts no responsibility for the accuracy or the reliability of such information which may affect the report.

## PARTICLE SIZE ANALYSIS REPORT

ASTM D422, C136 & C117

Project: Kudz Ze Kyah Sample No.: 2  
 Project No.: ENVMIN07071 Material Type:  
 Site: Kudz Ze Kyah Sample Loc.: WW15-01  
 Client: BMC Sample Depth: 14 m (46 ft) bg  
 Client Rep.: Sampling Method: Drilled with air rotary, from  
 Date Tested: August 1, 2015 By: AJS Date sampled: August 1, 2015  
 Soil Description<sup>2</sup>: SAND (med to coarse) and GRAVEL, tra Sampled By: Name REDACTED  
 USC Classification: Cu: 28.5  
 Moisture Content: -100.0% Cc: 3.6

Notes: <sup>1</sup> The upper clay size of 2 um, per the Canadian Foundation Engineering Manual

<sup>2</sup> The description is visually based & subject to EBA description protocols

<sup>3</sup> If cobbles are present, sampling procedure may not meet ASTM C702 & D75

Specification: \_\_\_\_\_

Remarks: \_\_\_\_\_

Reviewed By: SK \_\_\_\_\_

|             | 9:55  | 163                         | 250  | 40750  | 154255                                     | 0.2  |   |
|             | 9:57  | 165                         | 250  | 41250  | 156148                                     | -  | Halted development - sump was almost full and in danger of overflowing.   |

Notes: Did not surge during development as driller worried about pressure blowing water to surface outside of the casing.

The geological log plot displays various parameters against depth. The y-axis represents depth from 260 to 280 meters. A vertical black line marks the borehole wall. Data points are plotted at specific depths, connected by horizontal lines. Green triangles represent RQD values (40, 60, 80, 100). Red squares represent recovery percentages (40, 60, 80, 100). Black circles represent fracture frequencies (2, 4, 6, 8). Vertical dotted lines indicate joints. A horizontal dashed line is drawn at 278.5 meters, labeled as the end of the borehole. Specific labels include 'Run 88 - 39 Joints' through 'Run 93 - 36 Joints'. The x-axis on the right shows elevation in meters, ranging from 1676 to 1694.

Linear Calibration Factor: C.F. = 0.00082740 MPa/B unit  
 Regression Zero: At Calibration = 8824.2 B unit  
 Temperature Correction Factor: Tk = 0.0006503 MPa/°C rise

Polynomial Gage Factors (MPa)

A: -3.8493E-09

B: -0.00077349

C: 7.1183

Pressure is calculated with the following equations:

Linear:  $P(\text{MPa}) = \text{C.F.}(\text{L}_i - \text{L}_c) - [\text{Tk}(\text{T}_i - \text{T}_c)] + [0.00010(\text{B}_i - \text{B}_c)]$

Polynomial:  $P(\text{MPa}) = \text{A}(\text{L}_c)^2 + \text{B}\text{L}_c + \text{C} + \text{Tk}(\text{T}_c - \text{T}_i) - [0.00010(\text{B}_c - \text{B}_i)]$

Linear:  $P(\text{MPa}) = \text{C.F.}(\text{Li}-\text{Lc}) - [\text{Tk}(\text{Ti}-\text{Tc})] + [0.00010(\text{Bi}-\text{Bc})]$

Polynomial:  $P(\text{MPa}) = \text{A}(\text{Lc})^2 + \text{BLc} + \text{C} + \text{Tk}(\text{Tc}-\text{Ti}) - [0.00010(\text{Bc}-\text{Bt})]$

| Date (dd/mm/yy) | VW Readout Pos. B (Li) | Temp °C (Ti) | Baro (Bi) |
|-----------------|------------------------|--------------|-----------|
|-----------------|------------------------|--------------|-----------|

Shipped Zero Readings: 6-Jul-15 8833 23.2 1014.8

Li, Lc = initial ( at installation) and current readings

Ti, Tc = initial ( at installation) and current temperature, in °C

Bi, Bc = initial ( at installation) and current barometric pressure readings, in millibars

B units = B scale output of VW 2102, VW 2104, VW 2106 and DT 2011 readouts

B units = Hz<sup>2</sup> / 1000 ie: 1700Hz = 2890 B units

Name REDACTED  
 Technician: \_\_\_\_\_ Date: 6-Jul-15

This instrument has been calibrated using standards traceable to the NIST in compliance with ANSI Z540-1

Document Number: ELL0143H

## APPENDIX D

### HYDRAULIC RESPONSE TEST DATA ANALYSIS

---

## Field Procedure and Interpretation of Hydraulic Response Test Data

The following field procedure was followed for all hydraulic response tests:

- The static water level was measured prior to initiating the hydraulic response test;
- A pressure transducer/datalogger was installed in the well to record total pressure and water temperature during the test at a recording frequency of 1 s to 10 s, depending on the rate of recovery;
- Falling head test:
  - A solid slug consisting of a 1 m or 2 m long solid 1-inch diameter PVC pipe filled with sand (slug volume of 0.9 L or 1.8 L, respectively) was lowered quickly into the well and fully submerged to create a quasi-instantaneous rise in water level;
  - The water level recovery was recorded by the pressure transducer/datalogger.
- Rising head test:
  - After the water level had fully recovered, the slug was quickly withdrawn from the well to cause a quasi-instantaneous drop in water level;
  - Alternatively, a bailer was used to remove a slug of water (volume of 1 L) to cause a quasi-instantaneous drop in water level;
  - The water level recovery was recorded by the pressure transducer/datalogger.
- At the end of the testing sequence, the pressure/transducer datalogger was retrieved from the well and the data were downloaded onto a field laptop.

The hydraulic conductivity  $K$  of the aquifer in the vicinity of the monitoring well was inferred from the recovery data using the Bouwer and Rice (1976) method. The hydraulic conductivity is inferred from the test data as follows:

$$K = \frac{r^2 \ln\left(\frac{R_{cont}}{R}\right)}{2L} \cdot \frac{1}{t} \cdot \ln\left(\frac{h_0}{h_t}\right)$$

where

$r$  – casing radius

$R$  – radius measured from centre of well to undisturbed aquifer material (borehole radius)

$R_{cont}$  – contributing radial distance over which the difference in head,  $h_0$ , is dissipated in the aquifer

$L$  – the length of the screen

$b$  – length from bottom of well screen to top of the aquifer

$h_t$  – displacement as a function of time ( $h_t/h_0$  must always be less than one, i.e. water level must always approach the static water level as time increases)

$h_0$  – initial displacement

Slug test models including the Bouwer and Rice (1976) method neglect storage in the formation and therefore predict that the logarithm of water level change should be a linear function of time. In reality, all formations are compressible to some extent and have some storage capacity. Storage in the formation is manifested by curvature in the data in semilog space. This introduces complications in the interpretation of some of the data sets collected at the site where the curvature in the recovery data makes it difficult to identify an unambiguous straight line fit. For the Bouwer and Rice analysis, Butler (1998) recommends that the straight line be fitted to the interval  $\Delta H/\Delta H_0 = 0.2$  to  $\Delta H/\Delta H_0 = 0.3$  which is judged to be the most representative portion of the response.
