93-044

YUKON MINING INCENTIVE PROGRAM 93-044
SUMMARY REPORT - 30 Dec 93

LOCATION The Bennett Range Project is located on NTS mapsheet 105D/02 just east of Monroe Lake on the West Arm of Bennett Lake. It ranges in altitude from 2100 feet to 5100 feet and includes most of the east slope of Finger Mountain. Three major fault structures were examined on the west side of Finger Mountain (AD, AB, and PP fault zones) but the east slope contained most of the mineralization. On the east slope of Finger Mountain 14 fault zones (IE, IF, HC, HB, GF, RA, RB, FC, FB, EB, EA, DC, CA, and BD fault zones) were examined and 181 samples were taken. In addition to the 14 fault zones on the east side of Finger Mountain is the ore zone that cuts the IE, HB, GF, RA, RB, FC and FB faults on strike (?) and at an azimuth of approximately 50 degrees.

ACCESS From a boat launch at the Carcross Airport (dirt runway just east of Carcross) we boated past the town of Carcross, under the highway bridge, under the narrow gage railroad bridge, and down Bennett Lake toward the Bennett Range. From Prejevaisky Point we went down the south side of the West Arm of Bennett Lake to camp YMIP (we named it camp YMIP and put up a flagpole and flag) located at the mouth of 007 creek (see map). From camp YMIP we worked DC, CA, BD, PP, AB and AD fault zones via Bennett Lake and by access trail via the west trail around 007 Lake to the other zones. The only other access would be by helicopter in that there are no roads or trails into the Finger Mountain area.

GEOLOGY The Bennett Range Project on Finger Mountain lies within the eastern margin of the Coast Plutonic Complex. The Coast Plutonic Complex consists of Cretaceous granites which intrude and lie under low grade metamorphic sediments and volcanics of the Mesozoic Whitehorse-Nechako Trough and quartzites, schists, and gneisses of the late Precambrian/Early Paleozoic Yukon Group. The upper most units of the Trough consist of conglomerates of the Jurassic to Cretaceous Tantalus Formation. These are overlain by subaerial intermediate volcanics of the Cretaceous Mt Nanson group. Approximately 10 km west of Finger Mountain is the Bennett Lake Caldera. It is a well developed ring fracture and dyke system with late stage rhyolite and andesite dykes that intrude into Finger Mountain area (?). Tertiary rhyolite and andesite dykes crosscut older rocks and are exposed in several of the east/west faults (IE, HB, GF, and FB fault zones). The volcanics are gray to green weathering and are found at the top of the talus slopes and form prominent cliffs. The Cretaceous granite is a medium grained K-feldspar megacrystic hornblende that weathers to a pink/gray outcropping rock. The conglomerate is a rusty and gray weathering outcrop and consists mostly of chert and quartz pebbles with some interbedded siltstones. The granite, conglomerates and volcanics are cut by east/west trending faults. The rhyolite dykes appear to strike with the east/west faults. The ore zone appears to strike approximately 50 degrees and is exposed by the east/west fault zones. The ore zone is approximately 20/30 meters wide and is formed in a wide alteration of silicification. It consists of fine

grained quartz, rusty pyrite, kaolinite and montmorillonite clay, epidote, sericite and chlorite. The ore zone has been traced for over a km by following the exposed rusty (limonite/hematite) gossans that are exposed by the east/west fault zones. Several anomalous Au assays were taken (see assays that were submitted with final submission form)

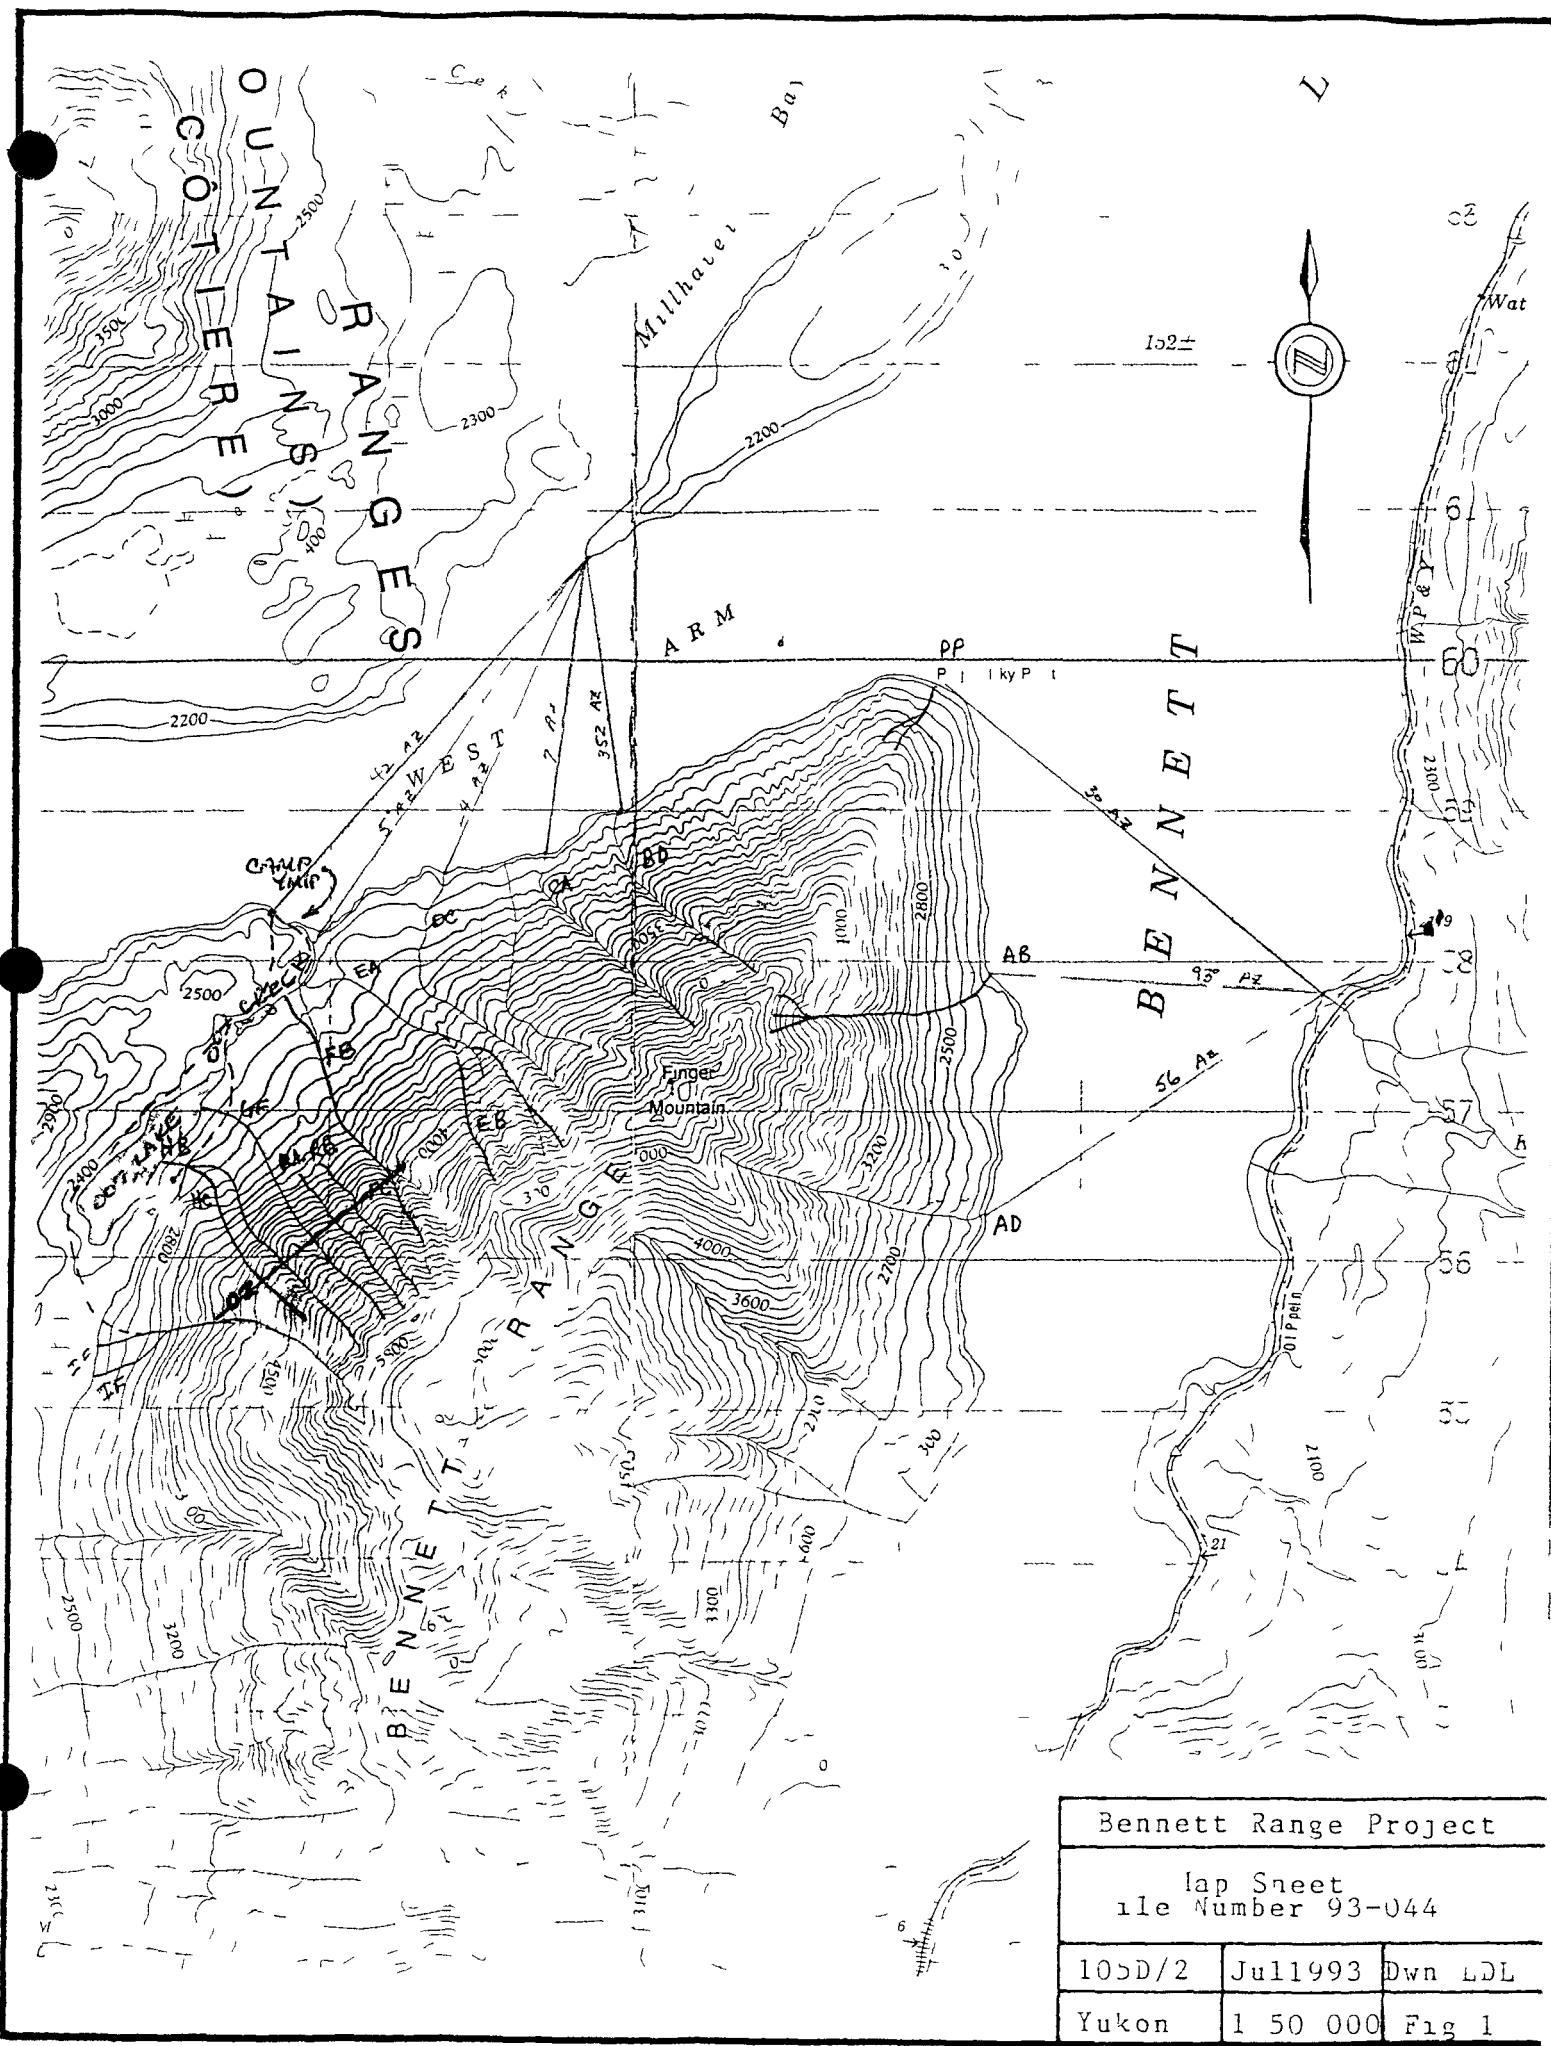

WORK DONE A detailed traverse up 17 fault zones, as outlined in the accompanying map, with 181 samples taken and 100 samples assayed. The project started on the 22nd of June and ran until the 4th of August 1993. It covered over 20 square kilometers and outlined an ore zone that strikes for over a kilometre. During the course of the exploration program we staked 10 claims (the Goldfinger 1-10) to cover the ore zone and filed these claims with the Whitehorse Mining Records Office on the 12th of July 1993.

RESULTS An ore zone striking for over a kilometre and assay values as follows

| | | | |
|----|----------|-------|--------|
| 1 | OZ-LL-13 | 485 | ppb Au |
| 2 | OZ-LL-16 | 1 43 | g/t Au |
| 3 | OZ-LL-22 | 160 | ppb Au |
| 4 | OZ-LL-23 | 255 | ppb Au |
| 5 | IF-LL-4 | 380 | ppb Au |
| 6 | IE-LL-4 | 115 | ppb Au |
| 7 | HC-LL-7 | 95 | ppb Au |
| 8 | HC-LL-8 | 13 73 | g/t Au |
| 9 | HC-LL-9 | 130 | ppb Au |
| 10 | HC-LL-10 | 9 34 | g/t Au |
| 11 | HC-LL-11 | 5 61 | g/t Au |
| 12 | HB-LL-12 | 120 | ppb Au |
| 13 | GF-LL-6 | 640 | ppb Au |
| 14 | RA-LL-4 | 730 | ppb Au |
| 15 | RB-LL-1 | 180 | ppb Au |
| 16 | FC-LL-4 | 18 47 | g/t Au |
| 17 | FC-LL-5 | 4 61 | g/t Au |
| 18 | FC-LL-6 | 1 01 | g/t Au |
| 19 | FC-LL-7 | 375 | ppb Au |
| 20 | EB-LL-8 | 125 | ppb Au |

The anomalous gold values to 18 47 g/t Au are most encouraging and definitely identify a prospect warranting further exploration.

RECOMMENDATIONS A detailed geochemical and geophysical survey over an established grid and baseline. A 1.5 kilometre baseline with gridlines every 100 meters and station intervals every 20 meters. The baseline would follow the ore zone (50 degree azimuth) and gridlines would run east and west off of the baseline. A VLF/EM survey and a magnetometer survey would be run in conjunction with a soil sampling of the B-horizon. The geophysical surveys would outline the continuous strike of the ore zone and delineate the structural geology and the geochemical survey would define the economic potential of the deposit. I will be forwarding a detailed proposal for the 1994 Yukon Mining Incentive Program.

LARRY D. LUTJEN * FILE: 93-044

YMIP - DAILY DIARY (1993)

22-23 JUNE 1993 mobilized
survey and drove the
Yellowhead Highway to Tazewell
Lake, Yukon and camped
at the Tazewell Lake public
access just north of
Tazewell Lake, you turn
left at the cemetery
on the Carcross road
and follow the boat
ramp signs for about
2-3 kilometers. There
is a paved parking
area and a boat
launching area and
campsite.

(1) + (2)

(3)

24 JUNE 1993 partly cloudy
this morning, looks like
it might cloud over this
afternoon. Drove to Cairns
from Tagish Lake and
attempted to locate the
pipeline road for access
into Bennett Lake area
as shown on NTS map
1050/02, as it runs
parallel to the narrow
gauge railroad. Located
the pipeline road but
overgrown and impassable,
but we were able to
park the truck and
launch the boat. Boated
down Bennett Lake to
Prijevalsky Point, thence
down Bennett Lake
locating drainage and
looking for a campsite.
Found an excellent
I named Camp Y.M.F.
Returned to campsite
at Tagish Lake!

(4)

25 JUNE 1993 It did cloud over yesterday and is raining today, not too hard but persistent. Returned to Carcross from Jacques Lake and landed the boat at the pipeline access southwest of the town of Carcross. Boated down Bennett Lake to Camp Ympf, located on the south shore of the West Arm of Bennett Lake, opposite Millhaver Bay (42 degrees from the tip of the Millhaver Bay peninsula) on a no name stream that drains from a no name lake just east (1-2 km) of Monroe Lake. It's a beautiful campsite with an excellent beach to land and launch the boat. Boated back to Prejevalsky Point and traversed and flaged up PP creek, which I was dry, at the time and contained mostly granite to granodiorite float boulders and cobbles.

Some greenstone andesite
cobbles were encountered
but no bedrock occurrence
were located. No mineralogists
was found. It appears
that this drainage, which
forks at the 2700 foot
level is mainly arosanche
in origin. Returned to
Camp Ymp.

24 JUNE 1993 The rain
has stopped and it
partly cloudy today. Looks
like we might get some
sunshine and dry things
out. Boated back to
Prejevalsky Point, thence
to the first cove south
of Prejevalsky Point on
Bennett Lake (94 degree
azimuth from the confluence
of Knob Creek and Bennett
Lake) where we traversed
and flagged up AB creek
through heavy vegetation
of willow, alder, spruce,
Lodgepole pine, and fir. Two
bedrock occurrences were
encountered up to the 3000
foot level, but alpine
can be seen at the
3200 to 3300 foot level
with what appears to be
bedrock exposures. We
will attempt to reach
tomorrow. Returned to
Camp YMF.

27 JUNE 1993 Partly cloudy
again today but doesn't
look like it will rain.

It seems to be calm
in the morning, then
windy in the afternoon.

Reached the 3200 foot level
from just over and traversed
into a deep seated fault
striking 268 degrees and
dipping 80-90 degrees to the
north, with several good
bedrock exposures at the
3500 to 3600 foot level of
hornblende/biotite granite
and/or granodiorite with
some phenocrysts of potassium
feldspar up to 8 mm. No
visible mineralization was
encountered, but several
bedrock samples were
taken (AB-LL-1-93 to AB-LL-
4-93) and these locations
flagged. The fault appears
to fork at approximately
the 4500 foot level into
three minor splays off
of the main east/west
fault, but we were

- OVER -

unable to traverse to that level. Returned to the English Lake campsite, will go to Whitehorse tomorrow for supplies, maps, geological reports, and check-in with ~~the~~ Karen Pelletier at GMLP.

28 JUNE 1993 partly cloudy
this morning, might
get some sunny breaks.
It's warmed up these
last 2 days and the
wind calms down in the
evening. Checked in with
YMMT at the Shoppers
Drug Mart but Karen
Pelletier wasn't in this
morning. I was told to
continue my work in the
field. Purchased food,
gas, oil, geological
reports, and maps. Purchased
C. Hart and J. Radloff's
open file 1990-4 and found
murchison occurrence 1104
in my area. Purchased
Yukon Exploration 1987 for
report on murchison occurrence
pages 114-116 and am very
excited at the results. I
knew about the 853-459
ppb gold results from
the C.S.C. open file 1218,
but had no idea that
an ore zone had been
located. - OVER -

Returned to camp Ympf
on the west arm of
Bennett Lake. I logged
trail into no name
creek which flows
from no name lake
and will be used
for access into the
east arm of Finger
Mountain. (Bennett Camp)
and the 104 gold
occurrence. Returned to
Camp Ympf.

29 JUNE 1993 sprinkling
this morning, look
like a wet day today.
Continued the trail into
no name lake, crossing
over at the beaver dam
between no name lake
and the swamp lake
directly down stream
from no name lake,
then south along the
east side of no name
lake. Once reaching
the east side of no
name lake the going
got extremely difficult
because of avalanche
debris of willow, spruce,
alder, pine and fir stacked
like cordwood. We were
trying to reach the
south end of no name
lake but terminated our
efforts shortly after
crossing HB creek. Tomorrow
we will stay on the west
side of no name lake
and stay in the
lodgepole pine forest

where the going was
much easier. Returned
to Camp Y.M.P.

30 JUNE 1993. The rain has let up and the clouds have lifted. We might get some sunshine and dry out. Continued trail into the west side of no name lake and crossed over to the east side of the Finger Mountains and located IE creek. I think this was the creek that the G.S.C. sampled in their open file 1218 report, but we couldn't locate the sample site. I took several samples (IE-LL-1-93 to IE-LL-5-93) and flagged these locations. The drainage of the creek at the 2500 foot level was striking at an azimuth of 81 degrees. The vegetation on the west side of no name lake was predominantly lodgepole pine and spruce, but changed

-OVER-

quickly to popular birds
willow, alder, spruce
and fir on the east side
of Fanger Mountain. Returned
to Camp Y.M.P.

1 JULY 1993 traversed the west-side trail around no name lake to IE creek. IE creek is an east/west trending fault striking 89 degrees at the 3000 foot level and dipping nearly vertical. Quite large float boulders of granite / granodiorite were located but bedrock samples weren't located until the 3000 foot level. At the 3200 foot level it gets very steep with slope often exceeding 100%. The fault above the 3200 foot level has cut a deep crevasse in the talus slope on IE creek. Just above the 3900 foot level we came across the ore zone whose alteration has imprinted a huge gossan across IE creek fault. The exposed ore zone is 10-20 meters in width and 80-90 meters in length striking at a 50 degree azimuth and dipping 80-90 degrees to the south. Vegetation is low

level bush and alpine
flowers with the occasional
stand of falsewax fir and
spruce. I took several
samples (I.E.-LL-6-93 to
I.E.-LL-15-93) and flagged
these locations. Returned
to Camp Y.M.T.

2 JULY 1993 warm and partly cloudy today but will probably get an afternoon squall as we have gotten several this last week. Traversed the westside trail to IE creek, thence up IE creek to the ore zone. Sampled along ore zone from IE creek at an azimuth of 50 degrees for approximately 100 meters. The slope is very steep and talused, but where the ore zone crops out it is bedrock exposure. The hanging wall and footwall alterations are phylite, sericite and chlorite with clay alteration of kaolinite and montmorillonite. The ore zone itself is a highly silicified precip of sugar quartz, chalcedony, quartz, pyrite, gold(?), silver(?), and lead(?). The granite / granodiorite host rock is also highly silicified for 20-30 meters ^{to over}

on either side of the footwall
and hanging wall with
silica fracture filling
most likely related to the
brecciation events. There
is virtually no vegetation
in this area as bedrock
outcrops and talus slopes
are all that remain.

Several samples were taken
(OZ-LL-1-93 to OZ-LL-16-93)
and these locations flagged.
Returned to Camp YMU.

3 JULY 1993 partly cloudy today and cooler, afternoon shower quite probable. Traversed the west side trail to IE creek, then up the creek to the ore zone. Traversed along strike at an azimuth of 230 degrees from IE creek for about 100 meters in an attempt to locate the ore zone to the south, heavily talusd over. Several samples were taken (02-4-17-93 to 02-4-30-93) and their locations flagged. The ore zone appears to splay just above IE creek with some exposure of ore, horseshoing off of the 230 degree back azimuth of the ore zone. Stringers off of the main ore zone strike as much as 130-140 degrees and dip almost vertically. Vegetation above the exposure and to the south is basically low bush and alpine flowers with patches of spruce and ~~over~~

balsam fir. Despite the fact that continuation of the ore zone to the south lacks exposure, aerial photos of Frigg Mountain A 25291-128 and A 25291-129 show a fault trace at 230 degree back azimuth. Returned to Camp GMP.

4 JUL 1993 still cool today
and partly cloudy. It seems
that everyday we get a
squall in the afternoon with
windy gusts. Today we
traversed the west side trail
up IE creek to the ore zone.
Fixed the strike at 50 degrees
and followed for over a
kilometer. Limited bedrock
exposure due to talused
slopes over grown with low
level alpine brush. The talus
boulders and cobbles are
predominantly K-feldspar
hornblende / biotite
granodiorite that weathers
gray to greenish gray. Where
east / west faults cut the talus
slopes the ore zone is exposed
and strikes consistently
at 50 degrees. Where the
ore zone is exposed on HB
creek there is a huge zone
and samples there contain
arsenite, hematite and pyrite,
plus gold (?), silver (?) and
lead (?). Several samples were
taken (OZ-11-31-93 to OZ-11-40-93)

and the sample sites flagged.
We are quite excited by
the prospect in that the
structural integrity of the
ore zone has mesothermal
possibilities. Returned to
camp O.M.T.

5 JULY 1993 Clouding over this morning, looking like it might rain this afternoon. Traveled back to the ore zone and attempted to extend strike south from IE creek at a back azimuth of 230 degrees.

Structurally we are up on a bench that appears to be a down dip block fault striking 230 degrees but the talus slopes obscure any bedrock exposures. The vegetation is low level alpine bush and wild flowers, with the occasional patch of spruce and balsam fir. It appears that the IE creek fault (striking 90 degrees) has sheared the ore zone fault (50 degrees) at or near the creek bottom and played the ore zone into a series of horsetails that strike off as much as 120-130 degrees. Several samples were taken (OZ-LL-41-99 to OZ-LL-48-93)

and these locations stayed.
Returned to Camp M.T.

6 JULY 1993 it's raining
and wet today. Low level
clouds have set in so
it will probably rain
all day. Returned to ore
zone via TE creek and
cut posts and built
monuments in preparation
to stake 10 claims that
will be called the Goldfinger
claim 10. The claims will
be staked on the ore
zone (50 degree azimuth) with
one claim 1500 feet to the
right of the ore zone and
the other claim 1500 feet
to the left of the ore zone. The
ore zone on TE creek will
be approximately on the
Goldfinger 1, 2, 3, and 4.
Traversing is not too
difficult except when you
come to an east/west fault
structure, then you have to
climb several hundred
feet up slope to cross
the crevasse and then
climb back down to the
other side. ^{sometimes it}
-ATE-

takes an hour or more
to go 20-80 meters across
the crevasse to the
other side. We have done
most of the prep work
and tomorrow we will
stake the Goldfinger 1-10
claims. Returned to Camp
Y.M.T.

2 JULY 1993 much colder
Today and still raining
looks like it won't let up
Traversed to the initial
post of the Goldfinger 1 and
2, then to the final
post and initial post
of the Goldfinger 4, 2, 3
and 4. Continued stepping
on an azimuth of 50
degrees to the final
post of the Goldfinger
9 and 10. Returned to
Camp Grant.

8. JULY 1993 warming up today and only patchy rain, it might clear up this afternoon (?) so we can dry out. Followed the west side trail to IE creek and sampled the creek from the 3900 foot level to the 4400 foot level. Were in a huge fault basin with steep sloping sides. The host rock is granodiorite and/or granite with silicification of fracture filling dominant on either side of the ore zone for at least 50 to 60 meters. The granite/granodiorite is a K-feldspar plus hornblende and biotite in a medium grain matrix. There is no vegetation in this area which consists of a granite/granodiorite talus of boulders, cobbles and pebbles. Several samples were taken (IE-LL-16-93 to IE-LL-23-93) and locations

Stayed. Returned to
Camp yours

9 JULY 1993 partly cloudy
and finally drying out.
Traversed the west side
trail past no name lake
(with the Goldfinger claims
I named the no name
lake 007 lake and the
creek 007-creek and the
swamp lake 007 swamp
lake for future references)
to IF creek. The creek
is striking 82 degrees at
the 2700 foot level with
some limited avalanche
debris. The vegetation is
willow, alder, birch, poplar,
spruce and fir with
dense growths at lower
elevations. There are no
bedrock exposures and samples
were taken from float that
appeared to have come
from the hornfelsed contact
of the ore zone above. Several
samples were taken (IF-LL-
1-93 to IF-LL-6-93) and
these locations flagged.
Returned to Camp Y.M.T.

10 JULY 1993 partly cloudy
this morning, looks like
a good day. Traversed
across the beaver dam
between 007 lake and
007 swamp lake to
H13 creek then up HC
creek to the 3100 foot
level. There was considerable
avalanche debris and the
going was difficult. Larger
areas of willow, alder,
birch, spruce, and fir
are stacked like cordwood.
No bedrock exposures were
found and samples were
taken from float that
appeared to be altered
granite and/or gneiss.
The HC creek fault strikes
156 degrees at the 3000
foot level and appears
to dip almost vertically.
There is snowpack in
the creek bed from the
avalanche at the 2900
foot level up, which
makes it easier going.
Samples were taken
-over-

(HC-LL-1-93 to HC-LL-6-93)
and flagged. Bedrock
exposures can be seen
at higher elevations and
we will attempt to
reach tomorrow. Return
to Camp YMT

11 JULY 1993 it seems to be
warming up a bit, no
rain but partly cloudy
with some sunny breaks.
Traversed the eastside trail
to HB creek then up the
HC creek fault to the 4100
foot level which strikes
136 degrees and dips almost
vertically. Crossed the ore
zone with its prominent geom.
Host rock is granite/granodiorite
with hornfelsed alteration
for 20 to 30 meters on
either side of the ore zone.
There is no vegetation at this
altitude in the fault crevasse
which consists of granite/
granodiorite talus. Several
samples were taken (HC-LL-
7-93 to HC-LL-17-93) and
these locations flagged. Will
be going to Whitehorse
tomorrow for supplies
and to file the Goldfinger
1-10 claims. Returned to
Camp YMP.

12 JULY 1993 another good day, very little wind only partly cloudy with sunny breaks. Went to Whitebox and filed the goldfinger 1-10 claims. Purchased food, gas, oil, and returned to Camp Y.M.U. Boated to Mouse creek and took three samples (MC-LL-1-93 to MC-LL-3-93) and flagged these locations. The host rock at Mouse creek is the K-feldspar megacrystic hornblende granodiorite that has been dated at 220 ma. The vegetation is willow, poplar, birch, spruce and fir. Returned to Camp Y.M.U.

13 JULY 1993 warm again
with sunny breaks. Traversed
the trail east of 007 lake
to HB creek then up the
north slope to bypass the
avalanche debris. It was
easier going in the forest
that hasn't been levelled.
Reached the 3600 foot level
which is striking 126 degrees
and dipping almost vertically.
Are mostly in the alpine
now with spotty clusters of
small spruce and balsam
fir. Took several samples
(HB-LL-1-93 to HB-LL-5-93)
and flagged these locations.
Above us is the ore zone
which we hope to reach
tomorrow. Returned to
Camp Y.M.T.

14 JULY 1993 warm again today but clouds are building up, maybe afternoon shower (3). Returned to HB creek and traversed to the 4600 foot level. Crossed the ore zone gossan with its characteristic yellow/orange iron staining. The host rock is still the granite/granodiorite and has quartz-filled fractures in the hornfels contact around the ore zone. The strike of the HB creek fault at the 4600 foot level is 133 degrees and is dipping almost vertically. Sampled several locations (HB-LL-6-93 to HB-LL-12-93) and flagged. Returned to Camp G.M.P.

15 JULY 1993 warm and
shower, no sun today (?).
Traversed the beaver dam
trail to GF creek, then
around the debris flow on
the north side of the
creek in the forested area
of poplar, alder, spruce,
birch and fir to the 3450
foot level. The GF creek
fault is striking 132
degrees at the 3400 foot
level and dips 80-90 degrees
to the northwest. The host
rock is granite/granodiorite
with no bedrock exposures.
We sampled several
locations of altered granite/
granodiorite float (GF-LL-
1-93 to GF-LL-4-93) and
flagged. Returned to Camp
YMP.

16 July 1993 partly cloudy
today with some sunbursts,
will dry out today. Returned
to GF Crak and traversed
to the 4600 foot level having
crossed the ore zone. Samples
alteration on either side
of the ore zone showing high
degrees of silicification.
Sericite alteration grades
into the quartz breccia
zone and mineralization
is hematite, limonite,
pyrite, gold (?), silver (?),
and lead (?). Several
samples were taken (GF-
LL-15-93 to GF-LL-11-93)
and these locations flagged.
Returned to Camp CHM.

17 JULY 1993 showers again today, it just cleared up yesterday, then more rain. Traveled back to GF creek via the beaver dam trail to the 3000 foot level on the north side of the creek, then east for several hundred meters until we reached the RA fault which is a ravine cut out by avalanches and talus flows. The fault is striking 135 degrees at the 3600 foot level and is comprised of talus flows of granite / granodiorite boulders, cobbles, and pebbles. It appears to dip vertically and the going was most dangerous. We never made it to the ore zone but took several samples (RA-LL-1-93 to RA-LL-4-93) and flagged their location. Returned to camp Y.M.T.

18 JULY 1993 partly cloudy
and clearing, things well
dry and today. Returned to
Cf creek and traversed to
the 3000 foot level then past
the RA fault ravine to the
RB fault ravine. The RB
fault is striking 132 degrees
at the 3000 foot level and
is dipping 80-90 degrees
to the northeast. Both the
RA and RB faults are
very dangerous, for there
is no way out of the
ravine. If an avalanche
occurs your a sitting
duck for the sidewalls are
too steep to climb out
of. Once again we never
made it to the ore zone
but made it to the 4000
foot level. Mostly talus
flows of granite gneiss
with the occasional bedrock
exposure. Took several
samples (RB-LL-1-93 to
RB-LL-5-93) and flagged
these locations. Returned to
Camp Y.M.M.

19 JULY 1993 warm and partly cloudy today. Boated out to Carcross and unloaded samples in 4x4. Shopped for supplies and boated back to Camp YMT. Sample 007 creek (1007-LL-1-93 to 007-LL-4-93) and flagged the locations. Returned to camp YMT.

20 JULY 1993 cooler today
and starting to cloud over,
looks like rain (?). Traversed
the 007 creek trail to FB
creek which enters 007 creek
closer to 007 swamp lake,
then on the topographical
map NTS 1050/02. Then
around the debris on the
north side of the creek to
the 2800 foot level. The
vegetation is lodgepole pine,
birch, alder, spruce and
fir with heavier growth
at lower elevations. The
FB fault is striking 167
degrees at the 2800 foot
level and dipping 80-90
degrees to the north. We
made it to the 3600 foot
level but only talus boulders
and cobbles of granite/
granofelsic were exposed
in the creek bed. At the
3600 foot level we are
in a steep gorge which
strikes 128 degrees and
dips almost vertically.
Several float samples
-OVER-

were taken (FB-LL-1-93 to
FB-LL-4-93) and flaged.
Returned to Camp [unclear]

21 July 1993 showers today and looks like were soaked in, the clouds are hanging low in the valley. Returned to FB creek via the north side access to the 3700 foot level where the creek forks into FB creek to the north and FC creek to the south. The host rock is granite and/or granodiorite plus hornblende biotite and K-feldspar. We traversed up FC creek fault to the 4300 foot level and crossed the ore zone gossan, which runs down the Goldfinger claim line. The creek is striking 158 degrees and dipping almost vertically. There is no vegetation in the fault crevasse, only steep talus slopes. These young east/west faults must be active to keep moving talus over the alpine vegetation. Took several samples (FC-U-1-93 to FC-U-8-93) and

-OVER-

slagged there, locations.
At these altitude the
fault crevasses become
exceedingly difficult to
traverse and the most
dangerous from the
standpoint of avalanches.
Returned to Camp Y.M.T.

22 JULY 1993 showers again
this morning and cold.

Returned to FB creek and
traversed to the 4400 foot
level. This fault appears
to have offset the ore
zone gossan, in that
very little limonite /
hematite alteration and
silicification were found
on the north side of the
ore zone. The FB Creek
fault is striking 132
degrees and dipping
vertically. There is no
vegetation in these fault
crevasses, only talus
rocks. The host rock
is granite / granodiorite
which weathers gray to
gray / green. Several samples
were taken (FB-LL-5-93
to FB-LL-12-93) and
flagged. Returned to
Camp Y.M.F.

23 July 1993 - again
this morning. We went
to the 007 creek trail to
EA creek, then up the
creek to the 2700 foot
level. We have traversed
through lodgepole pine,
birch, alder, spruce
and fir with very
little asplandue debris.
The strike of the EA creek
fault is 135 degrees at the
2900 foot level and dipping
almost vertical. Took
several samples (EA-11-
1-93 to EA-11-3-93) and
flagged. Reached the
3100 foot level and the
EA creek forks into the
EB creek to the south
and the EA creek to
the north. Continued up
EB creek to the 3400
foot level and sampled
the float (EB-11-1-93
to EB-11-4-93) and
flagged these locations.
EB creek fault strikes
178 degrees at the

3400 foot level and
dip vertically. Returned
to Camp Y.M.S.P.

24 JULY 1993 showers once
again but clouds are
breaking up, might
get some sunshine
this afternoon (?). Returned
to EA creek via 007
creek trail and traversed
to the 4300 foot level
of EB creek. EB creek
fault is striking 154
degrees and dipping 80-90
degrees to the north. No
ore zone alteration was
crossed, it was probably
cut-off by the EB creek
fault. The host rock
is granite/granodiorite
plus K-feldspar phenocrysts.
Several float and bedrock
samples were taken (EB-
11-5-93 to EB-11-10-93)
and these locations flagged.
Returned to Camp YMP.

25 JULY 1993 rain finally
let up, partly cloudy today
and warmer, hopefully
will dry thing out. Returned
to EA creek and traversed
to the 4500 foot level of EA
creek. It is striking 134
degrees and dipping 80-90
degrees to the north. The
host rock is the same
granite, weathering gray to
tanish gray. EA creek
appears to fork again at
approximately the 4500 foot
level but we never reached
that level. It is very steep
in the fault scarp
with virtually no vegetation.
Everything is extremely loose,
sometimes you take a step
up and then avalanche
5 steps back. Samples
taken and flagged were
(EA-LL-40-93 & EA-LL-8-93).
Returned to Camp Ympf.

26 JULY 1993 partly cloudy this morning with some sunny breaks. Boated back to Prejovally Point, then past first cove to second cove (56 degree azimuth from the confluence of Knob creek and Bennett lake), then up Ad creek to the 2800 foot level where the going was most difficult due to avalanche conditions that existed this spring and left massive areas of debris. The vegetation once again consists of willow, alder, spruce, lodgepole pine, birch and fir. I counted 20 rings on a spruce tree that was snapped off five feet above the ground, which must have made this last winter snow-pack above normal or the melt came all at once. Overburden conditions combined with avalanche debris left no bedrock exposures, but tomorrow

- OVER -

we will get a better
start for we found a
better access on our
way out. Returned to
Camp Gray.

27 JULY 1993 cloudy again
but warmer than
yesterday. Boated back to
second cove and traversed
up AD creek to the 3600 foot
level, this is a deeper
seated fault than AB creek
and is striking 290 degrees
and dipping 80-90 degrees
to the north. Encountered
several bedrock occurrences
of hornblende (biotite
granite and one leucocratic
granite showing. Took
several bedrock samples
(AD-11-1-93 to AD-11-13-93)
and flagged these locations.
No mineralization was
encountered. We will, we
will work the east side
of Inga Mountain towards
looking for more
mineralization and (or
epithermal alterations. Returned
to Camp YMW?

28 JULY 1993 warm and partly
cloudy, with some sunny
breaks and wind in the
afternoon. Boated to BS creek
and once again access is
very difficult in that
colluvial debris is extensive.
Several flagged trails had
to be abandoned, but access
was obtained by going up
the streambed. Vegetation is
alder, willow, spruce, lodgepole
pine, birch and fir. The
main fault is striking
at an azimuth of 186 degrees
and dipping 80-90 degrees
to the west. The east wall
at the 2900 foot level is
propylitized and is
striking at an azimuth
of 122 degrees and dipping
70-80 degrees to the north. At
the 3100 foot level both
sides of the fault are quartz
felled fractured propylitized
andesite. Some quartz shear
veining occurs at a 20-30
degree azimuth with a
60-70 degree dip to the
-OVER-

northeast. Mineralization was
spotty, mostly pyrite,
hematite, and limonite in
quartz filled fractures and
shear zones. Took several
bedrock samples (BO-LL-1
-93 to BO-LL-14-93) and
flagged these locations.
Returned to Camp YMT.

29 July 1993 warm but
clouding over heavily, no
sun today (?). Boated
back to BO creek and
traversed to the 4200 foot
level. The strike was 125
degrees and the dip was
80-90 degrees to the northwest.
The host rock is a
granite/granodiorite plus
hornblende/biotite and
K-feldspar. Several float
and bedrock samples
were taken (BO-11-5-93 to
BO-11-10-93) and these
locations flagged. Most
of the BO creek fault
crevasse is still compacted
with snow about 2.5
meter thick. You can
hear the water running
under the snow. Mineralization
is once again spotty.
There is virtually no
vegetation in the BO creek
fault, only talused boulders
and cobbles. Return to
Camp YMP.

30 JULY 1993 Showers this morning and looks soaked in (?). Boated to CA creek and once again access was difficult due to avalanche debris. Access was gained this time by going around the avalanche debris up the adjoining treeline. The strike of the fault at the 2600 foot level is 130 degrees and dips 70-80 degrees to the north. The rock type changes dramatically to a granite/gneiss with phenocrysts of potassium feldspar. There is a deep gorge at the 2900 foot level that continues to the top of Finger Mountain, with a gash at the 3000 foot level that strikes 132 degrees and dips 80-90 degrees to the north. Mineralogy is prominent in the area, mostly hematite, limonite, and pyrite. Several bedrock samples were taken at the

- OVER -

2900 to 3100 foot level
(CA-LL-1-93 to CA-LL-5-93)
and other locations of layer
Returned to Camp Yuma

31 JULY 1993 still raining
but occasional, hope
it stops this afternoon(?)
Boated back to CA creek
and traversed to the 400
foot level. The CA creek
fault is striking 132 degrees
and is dipping nearly
vertical. This is a very
deep fault and is most
difficult to traverse up the
sides. The host rock is a
K-feldspar megacrystic
hornblende granite / granodiorite
weathering gray to greenish
gray. Vegetation is nonexistent
on the heavily talused
CA creek fault. The fault
crevasse is very dangerous
at this level because there
is no way out except
down. Several bedrock and
float samples were
taken (CA-11-6-93 to CA-11-
10-93) and flagged. Mineralogy
is mostly quartzite and
amorphous. Returned to
Camp Yuma.

1 AUGUST 1993 rain didn't stop, showers again today, but breaking up (?). Boated to OC creek which has very little avalanche debris, mostly due to the slope. The OC creek fault strike at 175 degrees to the 2700 foot level then turns vertically to 130 degrees with a dip of 80-90 degrees to the south.

Vegetation consists of willow, pine, alder, poplar, birch, spruce and fir. Considerable overburden exists with float boulders of granite/gneiss until you reach the 3000 foot level where bedrock samples were taken and flagged (OC-LL-1-93 to OC-LL-5-93). Once again mineralization was hematite and limonite. Several quartz veins were encountered striking 120 degrees and dipping 70-80 degrees northward.

but were very hungry.
Returned to Camp ~~Y.M.A.~~

2 AUGUST 1993 cloudy today,
we might deposit (2).

Collected samples, broke
camp and boated down
Bennett Lake to boat
landing on the pipeline
right-of-way. Loaded
samples, boat, and camp
gear and drove to the
Taylor's Lake camp for
the night.

3-4 AUGUST cloudy but dry. Demobilized the survey and drove the Yellowhead Highway back to Sturtevant Lakes, British Columbia! A most memorable excursion into the magnificent Bennett Range.

In closing I would like to thank all of the folks of the Yukon Mining Incentive Program and in particular Karen Pelletier for all of her personal help and advice. Thanks again and am looking forward to returning to the Yukon.

Randy D. Suter
Prospector
