REPORT FOR APPLICATION #94-050

LOCATION, ACCESS AND LIST OF CLAIMS/LEASES

The Discovery Creek Property is located within the Mount Nansen Area, Whitehorse District. It lies approximately 120 miles northwest of Whitehorse, as shown on the property location map of Page 2

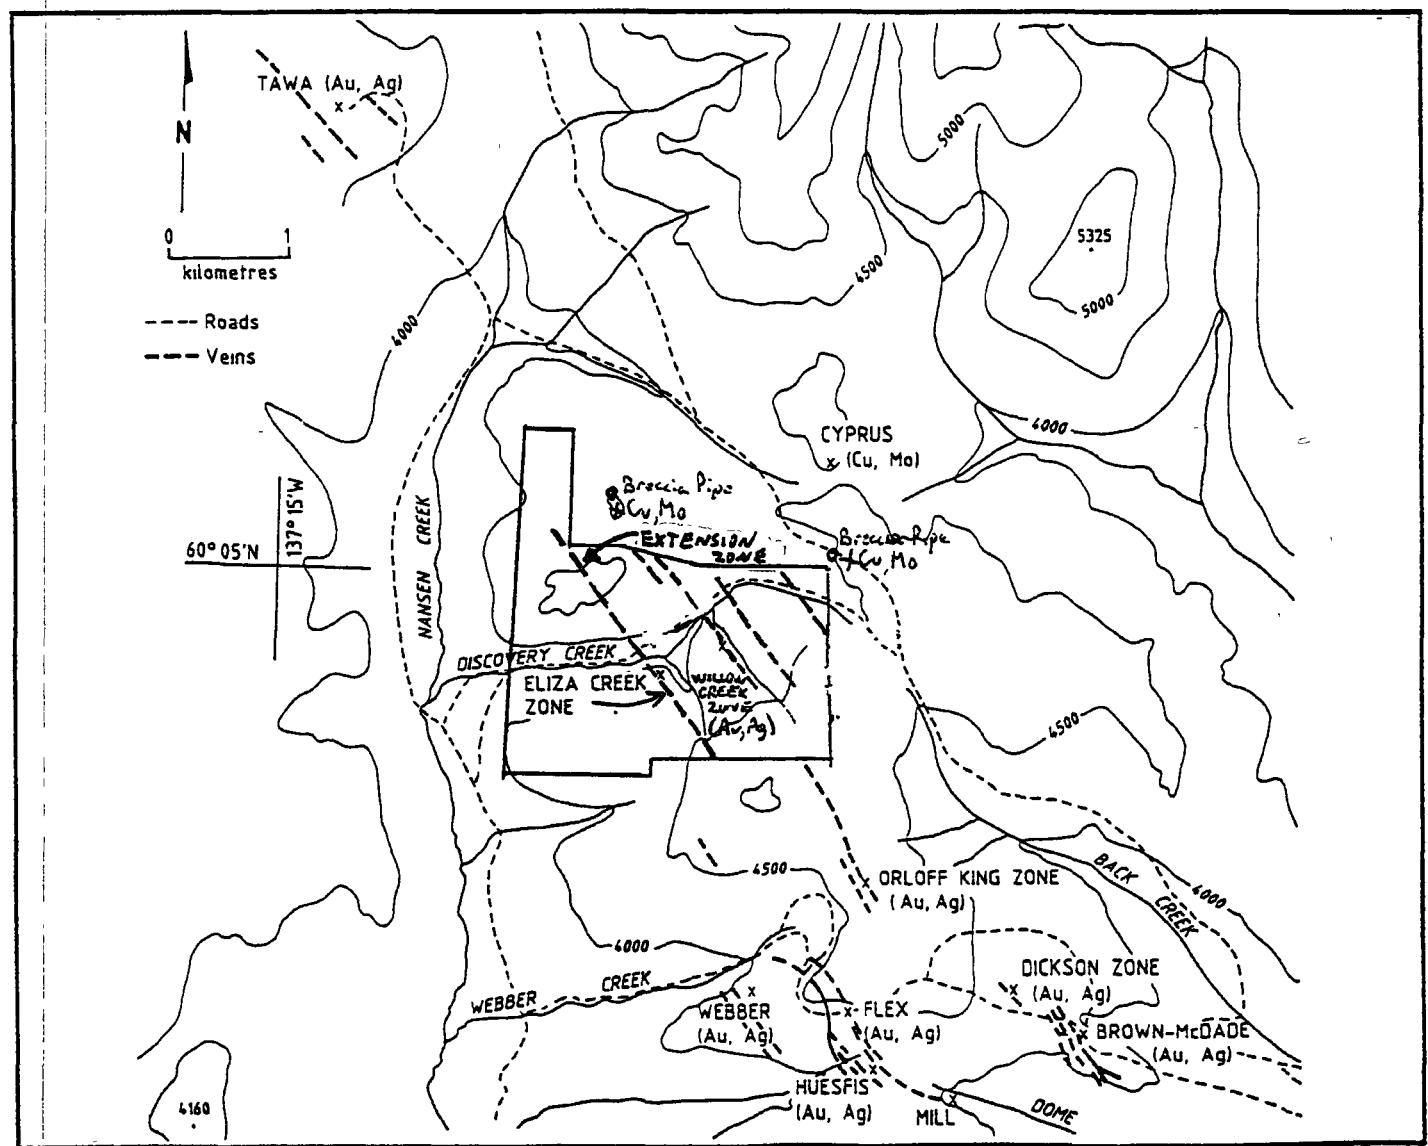

Access to the property is via the Klondike Highway from Whitehorse to Carmacks and then going west on the Mount Nansen Road. The Mount Nansen Road is a gravel/dirt road maintained by the Yukon Government as far as the Mount Nansen Mine site. Road access from here to the centre of the Discovery Creek Property is well established. The property in relation to the deposits of Mount Nansen Mines is shown on the Regional Location Map on Page 3.

The Discovery Creek Property consists of 32 full and fractional claims and 7 leases. The location of these are shown on the Yukon Government's Claim Map on Page 4. A list of the claims and leases follows this map

REGIONAL LOCATION MAP

Shows relative position of the epithermal veins of Mount Nansen to the S.E. and Tawa to the Northwest. (Note: Claim Property outline is shown including the Bullito 10 claims and the Lucky Star Lease owned by others.)

TOTAL: 32 FULL AND FRACTIONAL CLAIMS AND 7 LEASES.

NOTE: At the present time, it appears that the following claims are unlikely to hold any ground and may therefore be of no value; BIT 2, BIT 3, JBF 2, and JBF 3.

General Information on Report

This report summarizes the geology and exploration done for Application #94-050. This involves three reverse circulation drill holes in the "Extension Zone" of the property.

GEOLOGY

Previous Exploration

Previous to 1993, exploration on the property could be summarized as follows

- (1) picketed grid on most of the property;
- (2) a magnetics survey,
- (3) an I.P./Resistivity Survey
- (4) a soil geochem survey;
- (5) geological mapping;
- (6) follow-up trenching with mapping/sampling;
- (7) preliminary reverse circulation drill program.

This exploration displayed a property with large and significant anomalies. A relatively complex geological model was created of a central porphyry complex surrounded by a late epithermal system encroaching upon the central system. Significant anomalies were defined as to mineral type, style and potential, as they related to their position within the two mineralizing systems. Areas of common characteristics as to alteration, mineralization, style, etc., were grouped together if anomalous to form "Mineral Zones" within the property. These are briefly described later.

An important component recognized in the geological model and in the formation of "Mineral Zones" was structure. Three main fault structures of N330°, N20° and N95° appear not only to control and define "Mineral Zones", but also create local structural conditions for enhanced mineralization within a zone.

Upon review, Aurchem located within the property, two areas deemed to have prime potential that to date were unexplored. Therefore in 1993 Aurchem expanded the grid to cover these areas and applied the previous exploration techniques that had been established. Additional I.P./Resistivity surveys (Realsection) were also conducted over other "Mineral Zones" to help define targets.

One of these new target areas was termed the "Extension Zone", where the drill holes of this report are located. A major N.W. fault system striking into this area previously had been partially explored. It held a combination of the "Eliza Creek South" and "Eliza Creek North" Mineral Zones covering a strike length of about 6000 feet. The "Extension Zone" is the northwest continuation or extension of the Eliza Creek Zones, (i.e. Eliza Creek Extension Zone). The results of the 1993 geochemical/geophysical surveys confirmed this "new target area" as a prime location for further exploration.

Regional Geology

The regional geology map on Page 10 shows the Discovery Creek Property on the southwest flank of a Porphyry Complex.

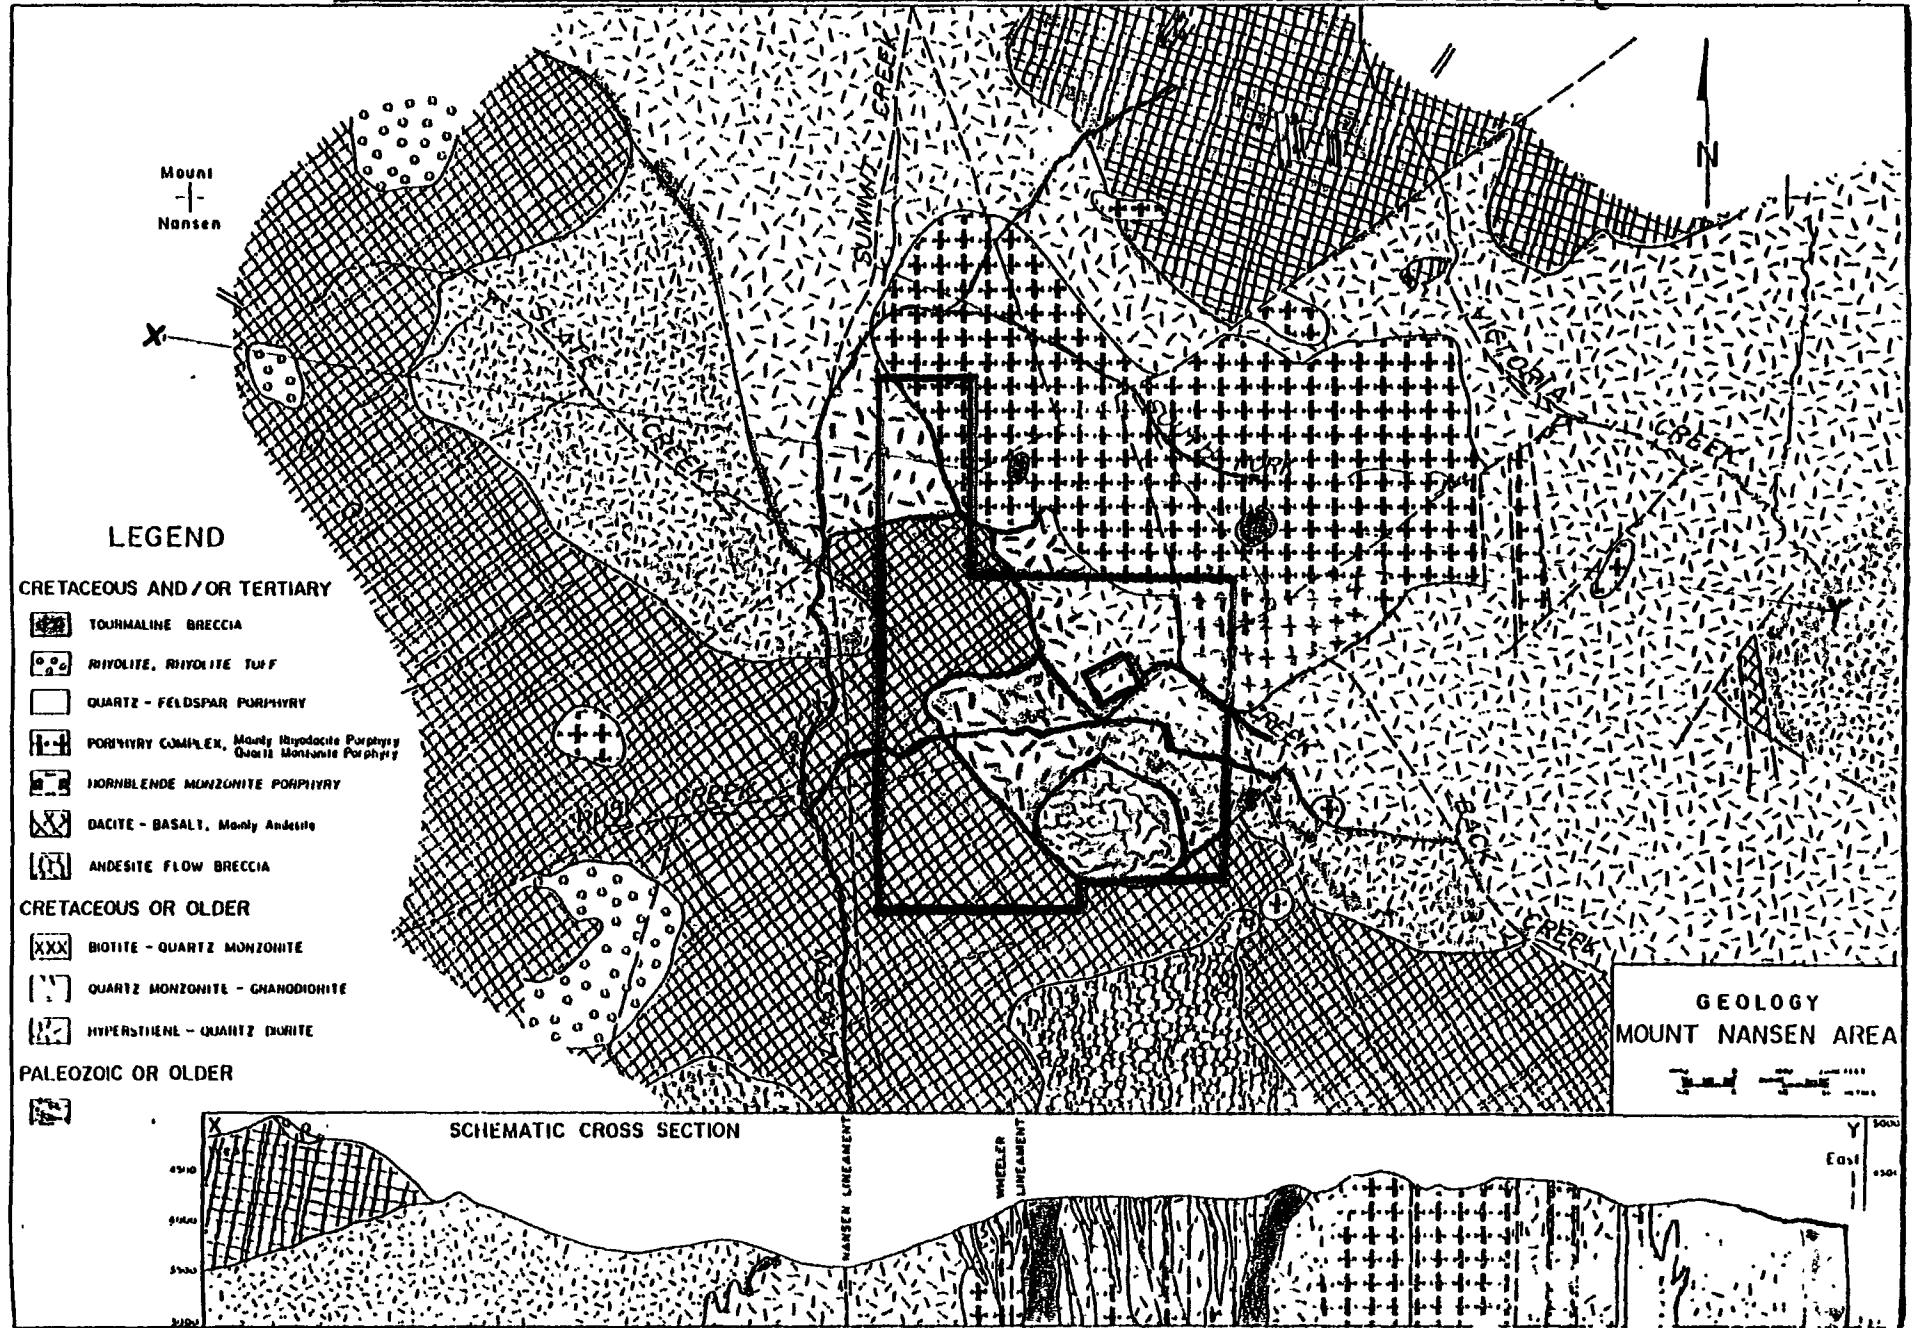

The Porphyry Complex is centred on a major N95° fault on intersection with northwest faults. Local features of dykes, stocks, mineralization, etc., within the Porphyry Complex appear to be dominantly controlled by the northwest structures within an overall east-west area. The central area of the Porphyry Complex has been shown to host disseminated copper/molybdenum mineralization typical of a copper porphyry. An outer perimeter area displays precious metals associated with pyrite veins and stockworks with minor copper-silver associated.

The Porphyry Complex is defined by Porphyry related dykes, stocks and breccias within earlier host lithologies of phyllitic or potassic alteration. Surrounding the Complex are halos of argillic and propylitic alteration. The Porphyry Complex appears to dip at a relatively shallow angle under the Discovery Creek Property.

The precise boundary of the Porphyry Complex is indistinct as a "transitional" area exists. In this transitional setting, Porphyry Complex dykes, sills, breccias and phyllitic altered host rocks exist, but are not dominant enough to be defined as Porphyry Complex. It is within these "transitional" settings that epithermal mineralization appears to cut earlier porphyry derived mineralization and lithologies, and the best potential for the discovery of mineable orebodies may exist. The "Extension Zone" lies within this transitional setting of porphyry/epithermal nature.

Epithermal mineralization is structurally controlled dominantly in steeply west dipping and northwest striking faults. This vein system is cut by a later minor vein system with a N E strike.

MOUNT NANSEN AREA REGIONAL GEOLOGY - DISCOVERY CREEK PROPERTY (Perimeter outline)

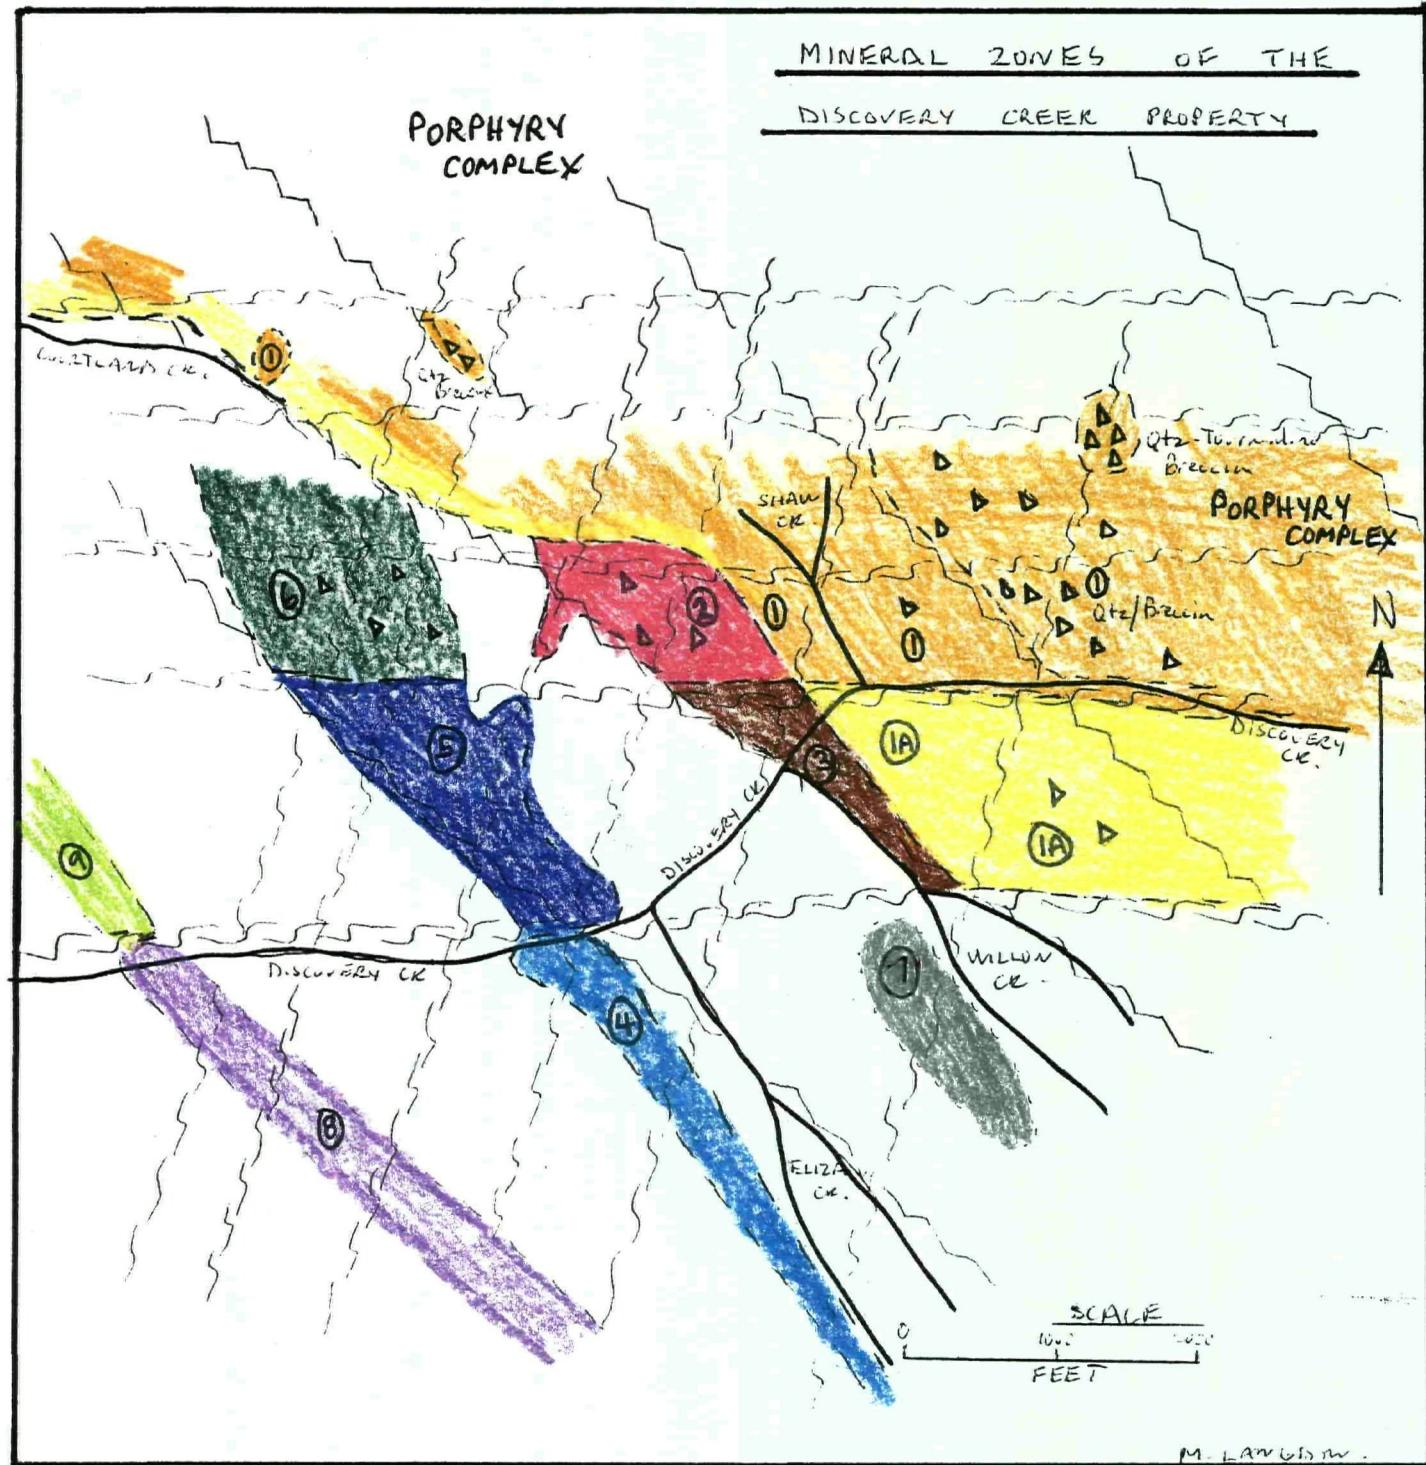

- MAP TAKEN FROM "MOUNT NANSEN" BY J.P.B. SAWYER AND R.A. DICKINSON, VANC. B.C.
PAPER 34 RIM SPECIAL VOLUME NJ 15

Property Geology and Mineralization

The property lithologies are as listed below .

- (1,2) Yukon Metamorphic Group - a mixed group of Metamorphic basement lithologies of schists, gneisses, quartzites, amphibolites, etc. A broad distinction of Group 1 being dominantly metasedimentary lithologies and Group 2 being metavolcanic/plutonic/volcanoclastic in origin can be seen. These lithologies are Paleozoic to Pre-Cambrian in age.
- (4) Quartz Diorite - of Jurassic age, this hypabyssal plutonic is of local origin and small size
- (5) Casino Granodiorite, The Cretaceous aged biotite-hornblende granodiorite is a major regional lithology in the area
- (7) Mount Nansen Volcanics; The volcanic group is of late-Cretaceous age. I have grouped them into three broad categories.
 - (7c) - on the south end of the property are basaltic andesite to latite flows and dykes with a distinct heterogeneous nature,
 - (7a) - in the west and northern portions of the property, these andesitic flows and minor lapilli tuffs and pyroclastics are generally a homogeneous group with almost none-existent flow boundaries;
 - (7b) - just north of the property is a large dome of late group 7 volcanics of rhyolite/dacite/latite lapilli tuffs, vitric lapilli tuffs and minor pyroclastics
- (9) Mount Nansen Suite Porphyries; The Paleocene aged lithologies are associated with the Porphyry Complex and are the heat source for both the porphyry and epithermal mineralization systems:
 - (9a) - Quartz-Feldspar Porphyry Dykes are a general classification of porphyry dykes found outside the Porphyry Complex. They are strongly associated with the epithermal mineralization;
 - (9b) - Hypabyssal Dacite Porphyry; generally found within the Porphyry Complex as northwest trending dykes and sills; the siliceous content forms domes and ridges as erosion resistant topography;
 - (9c) - Hypabyssal Latite Porphyry; generally indistinguishable from above, but displays an association with copper mineralization, potassic alteration and a low quartz content;
 - (9d) - Quartz-Monzonite Porphyry; a much coarser grained lithology from (9a) to (9c), with porphyritic feldspars centimetres in length: Easily confused with argillic to phyllitic altered granodiorite of group 5;
 - (9-QB)
 - (9-QTB) - Quartz-Breccia and Quartz-Tourmaline-Breccia are very common, both within the Porphyry Complex and within the outer transitional setting. The quartz-breccia displays multi-stage brecciation while the Quartz-Tourmaline appears to be a single late/final stage of the Porphyry system. Weak gold-silver mineralization is found associated within the breccias, but more commonly along contacts of breccias displaying northwest trends. Within the Porphyry Complex large oval shaped breccia pipes occur. To date Aurchem has found gold on the pipe perimeters, but not within the pipe itself

The Discovery Creek Property hosts a number of "Mineralized Zones" as previously discussed. The map on Page 12 shows these "Mineral Zones". Porphyry Zones (1) and (1A) represent Porphyry Complex domains. These two zones are separated by a major E-W fault which also separates zones (2) and (3) and zones (5) and (6). This fault appears to represent a major vertical movement with the north side being a much greater paleodepth relative to the Porphyry Complex. Significant differences in alteration and mineralization occur across this fault. Zone (1A) represents a strong potential with pyrite-gold-silver veins and stockworks. Mineral Zones (3), (2) and (6) are transitional settings of porphyry/epithermal and likely hold the greatest potential for epithermal style deposits. Zones (4) and (7) are purely epithermal vein plays, as would be (8) and (9) at depth. Zone (5) is unique with local structural and geological features for enhanced epithermal veins.

M. LANGRISH

Eliza Creek Extension Zone Geology: Work Done and Results

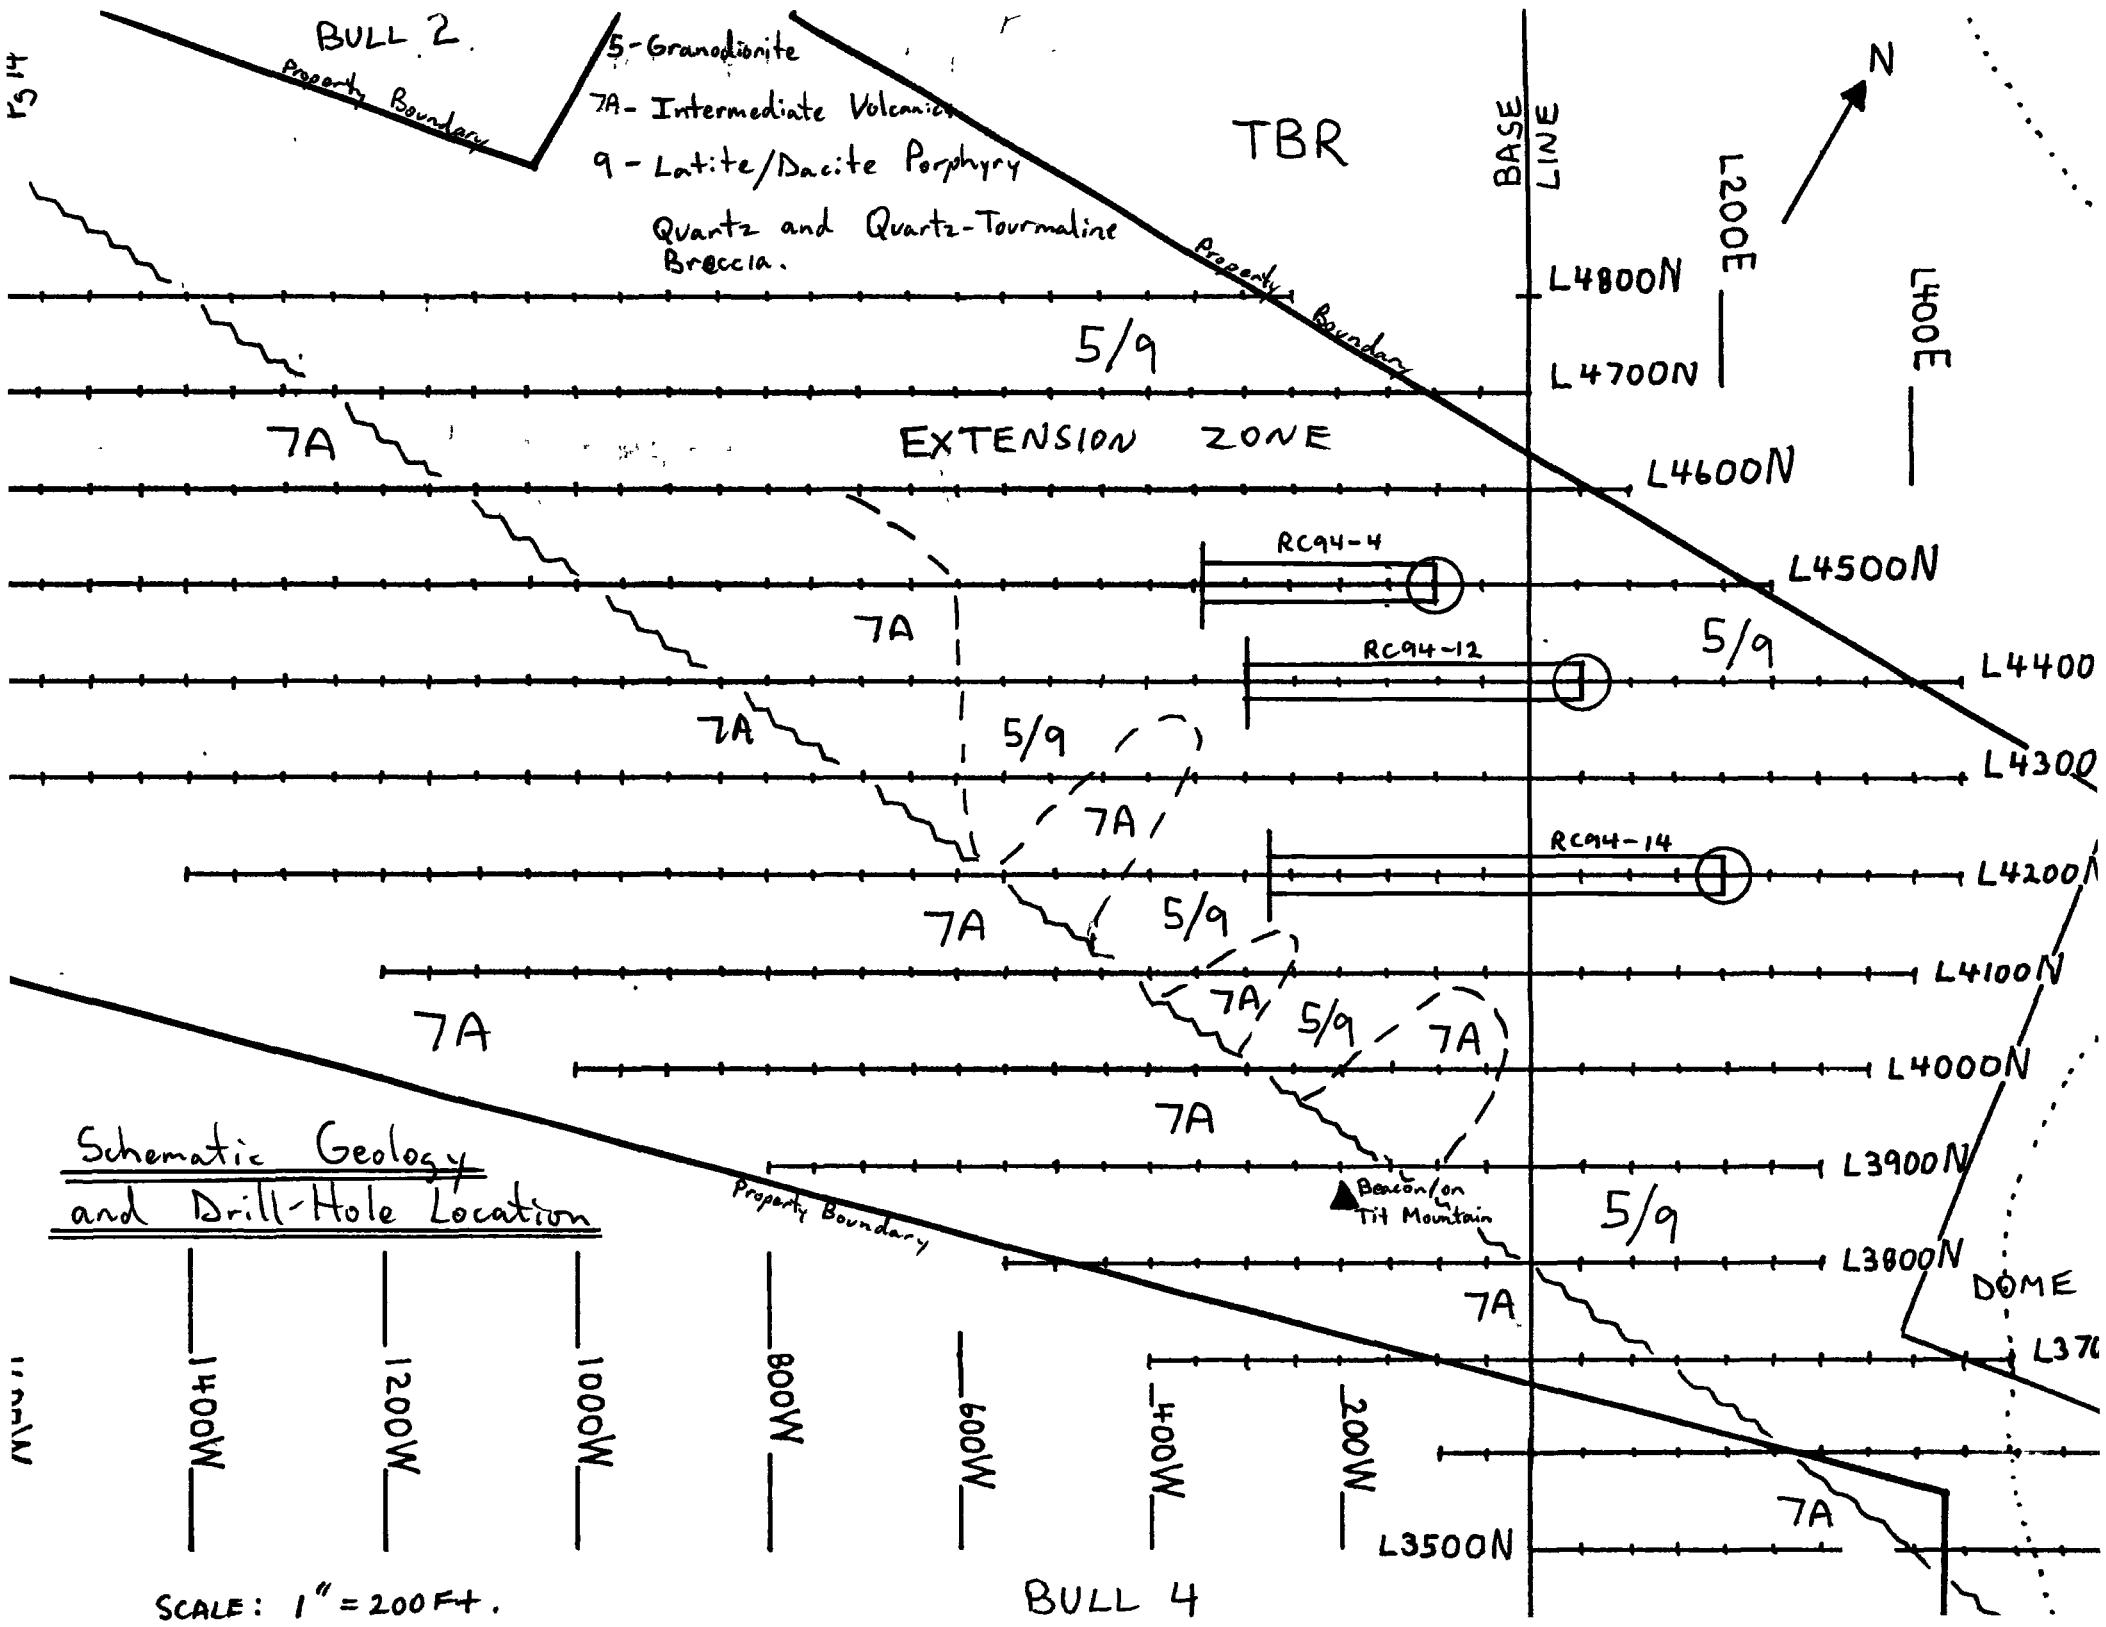

The Mineral Zones Map (Page 12), shows the location of the Extension Zone (6). Zone (6) is clearly a continuation of the Northwest trending Eliza Creek Zone of (4), (5). In crossing the fault from Zone (5), we enter a transitional setting lying on the flank of the Porphyry Complex. South of the E-W fault within Zone (5), we find Mount Nansen Andesitic Volcanics (7A). Epithermal veins show up on the ridge as northwest trending topographic lows with a rusty/gravelly surface. North of the E-W fault within Zone (6) a significant lithology change takes place. The dominant lithology is granodiorite (5). Dykes and small sills of Andesitic Volcanics trending N20° cut the granodiorite being most prominent within 200-300 feet of the E-W fault. Cutting through this are multiple NW and NE trending dykes of Hypabyssal Dacite Porphyry (9B), Quartz Breccia and Quartz-Tourmaline Breccia. Epithermal veins then cut all lithologies with N330° and N20° strikes, (dip steeply west).

The Extension Zone with preliminary geology showing the E-W fault, the grid and property boundary is shown on the Map of Page 14. The three reverse circulation drill holes (RC94-4, RC94-12 and RC94-14), are also shown. The base line of the grid strikes N330°, the same direction as the most prominent epithermal veins, and the Porphyry related dykes and breccias. The volcanics (7A) are shown to possibly only reach a couple of hundred feet at N20° into the zone. To depth and to the north, the andesite becomes much more intensely altered. Phylllic altered andesite is indistinguishable from phylllic dacite and even phylllic granodiorite to some degree. Therefore, some dykes identified as dacite porphyry may actually be phylllic altered andesite. The fact that the porphyry group (9) is actually a late phase of the volcanics (7) makes this confusing. The two groups though appear to be distinct phases, possibly separated by time and show different textures on a microscopic scale.

Epithermal mineralization in of the Eliza Creek Zones is represented as a wide zone of multiple epithermal veins. In the Extension Zone the zone of veining appears to go from about 400 East to 1000 West on the grid. About five to eight sub-parallel epithermal veins are suspected within this 1400 foot width. The three drill-holes shown were designed to test the "baseline vein" running from about 100 west on L4600N to 150 west on L4300N. A number of other minor parallel veins also exist. RC94-4 was collared too far to the west.

Appendix I gives the drill logs with assay results of the three holes. Significant amounts of Breccia are reported in RC94-14. Assays generally show anomalies proximal to these breccias with weak Au/Ag within them.

Oxidation within the Extension Zone is generally quite extensive, but variable. Strongly oxidized veins have been encountered at depths greater than 400 feet, while some veins right at surface are only partially oxidized. Ground water was not encountered in any drill holes within the Extension Zone. Alteration was highly variable from weakly propylitic to phylllic suspected as northwest trending bands. The Porphyry Complex appears to dip under this area and a general sense of increased alteration with depth was found. This was more prominent in closer proximity to the main E-W fault.

Recommendations

The "base line" vein should be explored inbetween RC94-14, and the E-W fault both at surface and to depths of at least 400 feet vertically. Very strong soil geochem anomalies cover the grid area east of the drill holes. This area has not been drill tested at all. Numerous veins to the west of the drill holes also require drilling. The grid should be extended to cover the area southeast of Bull 2 and geochemical soils should be taken as an initial investigation.

| Location L4204N/200E | | | | | | | | | | | | | |
| Bearing/Dip N240 I-45 | | | | | | | | | | | | | |
| Hole Length 671ft | | | | | | | | | | | | | |
| 0' to 10' (10') | | | | | | | | | | | | | |
| OVERBURDEN | | | | | | | | | | | | | |
| - where overburden ended/ any bedrock began was not determined | | | | | | | | | | | | | |
| - suggested 28' in field notes based on oxidized versus non-oxidized return | | | | | | | | | | | | | |
| 10' to 28' | | | | | | | | | | | | | |
| PHYLLIC ANDESITE (7A-3) AND PROPYLITIC GRANODIORITE (5-5), OXIDIZED | | | | | | | | | | | | | |
| WITH QUARTZ-BRECCIA (QB) | | | | | | | | | | | | | |
| - unusual mixture of alterations, 40/60 granodiorite to andesite, gd is generally light green colour with propylitic alteration, andesite is 50/50 argillic to phyllitic, and is light orange oxide in colour, pyrite stringers and disseminations are rusty coated, 1-2% magnetite, overall orange colour, minor breccia | (ox)4 0% | 0134 | 10-15 | 0.08 | -0.50 | 19 | 33 | 117 | 6 | 13 | <1 | 0.09 | |
| - same as above, but 60% quartz breccia of phyllitic andesite, 25% gd and 15% phyllitic andesite, orange colour, a number of clasts suggest that some of the andesite may be phyllitic dacite porphyry | (ox)3 0% | 0135 | 15-20 | 0.11 | 1.50 | 46 | 46 | 451 | 7 | 58 | <1 | 0.13 | |
| - as in 10'-15', with rare breccia | (ox)0 5% | 0136 | 20-25 | 0.10 | 0.70 | 73 | 28 | 353 | 4 | 34 | 4 | 0.11 | |
| - no assay sample for 25' to 30' (sample lost) | 0137 | 25-30 | MISS | | | NO ASSAYS | | | | | | | |
| 28' to 41' (13') | | | | | | | | | | | | | |
| ARGILLIC/PROPYLITIC GRANODIORITE (5-4,5), WITH ARGILLIC ANDESITE (7A-4) AND MINOR QUARTZ BRECCIA | | | | | | | | | | | | | |
| - differs from above because overall colour is a light/medium greenish-grey, 75% clasts are weakly argillic granodiorite with the remaining 25% being argillic to phyllitic andesite with lesser quartz breccia, 1-2% magnetite | 2.0% | 0138 | 30-35 | 0.09 | 0.50 | 40 | 21 | 223 | 4 | 21 | 1 | 0.10 | |
| | 2.0% | 0139 | 35-40 | 0.02 | -0.50 | 12 | 13 | 105 | 4 | 23 | <1 | 0.03 | |
| 41' to 48' (7') | | | | | | | | | | | | | |
| QUARTZ BRECCIA OF PHYLLIC GRANODIORITE (QB, 5-3), PORPHYRY DACITE STRINGERS, OXIDIZED | | | | | | | | | | | | | |
| - bright orange coloured clasts that are brecciated, both quartz and quartz-sericite, unknown if clasts are granodiorite or dacite porphyry, some possible quartz-tourmaline also, 2% magnetite | (ox)1 0% | 0140 | 40-45 | 0.07 | 0.70 | 56 | 21 | 314 | 4 | <10 | 2 | 0.08 | |
| | (ox)0 5% | 0141 | 45-50 | 0.07 | -0.50 | 49 | 26 | 497 | 5 | 26 | 1 | 0.08 | |
| 48' to 64' (16') | | | | | | | | | | | | | |
| ARGILLIC GRANODIORITE (5-4) WITH MINOR QUARTZ-BRECCIA (QB) | | | | | | | | | | | | | |
| - appears to be 90% gd/10% quartz breccia of granodiorite, partial oxidation to orangy-grey/green colour, 25% of clasts are phyllitic and orange gd, 25% propylitic gd, rare breccia clasts identifiable, possible minor dacite and/or andesite stringers, 1-2% magnetite, slightly calcareous, almost looks like it could still be overburden or part of a wide fault zone | 0.75% | 0142 | 50-55 | 0.10 | 0.80 | 48 | 16 | 762 | 6 | 36 | 1 | 0.11 | |
| | 0.5% | 0143 | 55-60 | 0.09 | 0.70 | 43 | 17 | 1026 | 4 | 22 | <1 | 0.10 | |
| - same but no breccia | 1.0% | 0144 | 60-65 | 0.08 | -0.50 | 65 | 18 | 1739 | 5 | 21 | <1 | 0.09 | |
| 64' to 75' (11') | | | | | | | | | | | | | |
| FAULT ZONE - ARGILLIC GRANODIORITE (5-4) | | | | | | | | | | | | | |
| - light brownish-green colour, strong carbonate, many sheared surfaces, really a sheared propylitic gd, minor hematite staining, all pyrite is partially oxidized, 1% magnetite | 1.0% | 0145 | 65-70 | 0.07 | -0.50 | 25 | 15 | 763 | 5 | <10 | 1 | 0.08 | |
| - same but 50% oxidized fractures | 0.75% | 0146 | 70-75 | 0.03 | -0.50 | 61 | 20 | 2750 | 4 | 12 | 2 | 0.04 | |
| 75' to 80' (5') | | | | | | | | | | | | | |
| PHYLLIC GRANODIORITE (5-3) AND ARGILLIC DACITE PORPHYRY (9B-4), OXIDIZED | | | | | | | | | | | | | |
| - dark orange colour, oxidized phyllitic gd with stringers of oxidized dacite, rare sericite, possibly 50/50 gd to dacite, 1% gypsum, minor quartz/pyrite stringers | (ox)2 0% | 0147 | 75-80 | 0.11 | 2.50 | 75 | 101 | 1277 | 5 | 77 | 1 | 0.15 | |
| 80' to 85' (5') | | | | | | | | | | | | | |
| ARGILLIC GRANODIORITE (5-4) WITH MINOR PYRITE STRINGERS | | | | | | | | | | | | | |
| - brownish-green colour, argillic gd with minor pyrite stringers, some | 3.0% | 0148 | 80-85 | 0.06 | 0.50 | 48 | 21 | 2010 | 5 | <10 | 2 | 0.07 | |

| - same, but minor hematite and 8% carbonate | 0.5% | 0221 | 440-445 | -0.02 | -0.50 | 22 | 14 | 64 | 3 | <10 | <1 | 0.03 | |
| - hematite stronger | 0.3% | 0222 | 445-450 | 0.12 | 0.80 | 38 | 18 | 89 | 3 | 37 | 1 | 0.13 | |
| - as above, medium green, calcareous | 0.2% | 0223 | 450-455 | 0.04 | 0.50 | 24 | 23 | 103 | 3 | 15 | <1 | 0.05 | |
| - same | 1.25% | 0224 | 455-460 | 0.07 | -0.50 | 13 | 53 | 128 | 3 | 24 | <1 | 0.08 | |
| - same, chloritic biotite | 1.0% | 0225 | 460-465 | 0.03 | -0.50 | 32 | 31 | 122 | 2 | 22 | <1 | 0.04 | |
| 467' to 470' (3') | | | | | | | | | | | | | |
| ARGILLIC GRANODIORITE (5-4) | | | | | | | | | | | | | |
| - light green/grey colour, strong carbonate, most biotite completely replaced | 1.5% | 0226 | 465-470 | 0.08 | 0.50 | 70 | 32 | 111 | 2 | 26 | 3 | 0.09 | |
| 470' to 475' (5') | | | | | | | | | | | | | |
| PHYLLIC GRANODIORITE (5-3) WITH MINOR QUARTZ/TOURMALINE STRINGERS | | | | | | | | | | | | | |
| - light grey colour, quartz rich, about 1% black tourmalines, one clast of breccia seen | 6.0% | 0227 | 470-475 | 0.18 | 1.00 | 49 | 39 | 126 | 6 | 39 | 2 | 0.19 | |
| 475' to 482' (7') | | | | | | | | | | | | | |
| ARGILLIC GRANODIORITE (5-4) | | | | | | | | | | | | | |
| - medium grey green colour, pervasive carbonate | 1.5% | 0228 | 475-480 | 0.04 | 0.50 | 17 | 27 | 93 | 2 | 10 | 3 | 0.05 | |
| 482' to 499' (17') | | | | | | | | | | | | | |
| PROPYLITIC GRANODIORITE (5-5) | | | | | | | | | | | | | |
| - medium green/grey propy gd, 5% biotite, 70/30 propy to argillitic, 2% magnetite | 1.5% | 0229 | 480-485 | 0.04 | -0.50 | 24 | 20 | 106 | 2 | 14 | <1 | 0.05 | |
| - 50/50 propy to argillitic gd | 1.0% | 0230 | 485-490 | 0.08 | -0.50 | 70 | 35 | 140 | 2 | 19 | <1 | 0.09 | |
| - propy gd with strongly chloritic biotite, calcareous | 0.5% | 0231 | 490-495 | 0.03 | -0.50 | 27 | 66 | 406 | 2 | <10 | 1 | 0.04 | |
| - as above to 499' and then phyllitic gd to qtz/sulphide vein | 3.0% | 0232 | 495-500 | 0.05 | 1.20 | 20 | 97 | 688 | 2 | 66 | 1 | 0.07 | |
| 499' to 506' (7') | | | | | | | | | | | | | |
| QUARTZ/SULPHIDE VEIN | | | | | | | | | | | | | |
| - whitish grey quartz with sulphides, some hydrofracturing of quartz clasts, appears to be all pyrite, minor oxidized clasts, general dark grey colour, no Pb or Zn seen | 60.0% | 0233 | 500-505 | 0.73 | 15.80 | 54 | 542 | 4570 | 3 | 815 | 4 | 0.95 | |
| 506' to 520' (14') | | | | | | | | | | | | | |
| QUARTZ/TOURMALINE BRECCIA OF PHYLLIC GRANODIORITE (5-3, QTB, QB) | | | | | | | | | | | | | |
| - medium green/grey phyllitic gd clasts with quartz/pyrite stringers, appears to be a number of quartz/tourmaline clasts showing some breccia, also some quartz/breccia | 10.0% | 0234 | 505-510 | 1.37 | 9.60 | 52 | 233 | 1138 | 2 | 293 | 4 | 1.50 | |
| - same but greenish grey/buff colour, quartz/tourmaline rare, 30% argillitic | 3.0% | 0235 | 510-515 | 0.09 | 1.00 | 55 | 51 | 184 | 2 | 18 | <1 | 0.10 | |
| - same but greenish grey/buff colour, quartz/tourmaline rare, 30% argillitic | 3.0% | 0236 | 515-520 | 0.11 | 1.00 | 49 | 31 | 122 | 2 | 20 | 1 | 0.12 | |
| 520' to 552' (32') | | | | | | | | | | | | | |
| ARGILLIC GRANODIORITE (5-4), HORNFELS(??) | | | | | | | | | | | | | |
| - medium to dark green colour clasts within a pale green/buff background, appears to be a mixture of argillitic and propylitic gd, strongly chloritic clasts and chlorite replaced biotite flakes, samples have that "cooked" appearance | 3.0% | 0237 | 520-525 | 0.06 | 0.50 | 30 | 24 | 131 | 2 | 15 | <1 | 0.07 | |
| - same but greenish grey/buff colour, quartz/tourmaline rare, 30% argillitic | 2.0% | 0238 | 525-530 | 0.10 | 1.50 | 53 | 29 | 125 | 2 | 23 | <1 | 0.12 | |
