APPENDIX A – ROCK SAMPLE REPORT	13
APPENDIX B – CERTIFICATE OF ANALYSIS	15
APPENDIX C – FIELD NOTES	24

INTRODUCTION

This report prepared for Tanana Exploration Inc., summarizes prospective exploration funded under Grant # 01-013 of the Yukon Mineral Incentives Program (YMIP) and carried out during the 2001 exploration field season.

The writer assisted with some of the field work detailed in this report and has reviewed research materials, field notes and rock samples supplied by Mr. Carrell, the prospector whom the company grubstaked.

PROJECT AREA #1 – MT. CAMERON

PROJECT SUMMARY

Only preliminary reconnaissance and orientation work was completed on this project area during the 2001 field season. During the period of June 20th to 22nd some claim maintenance and assessment of environmental conditions in the area of the main showing was completed in anticipation of a property exam that was subsequently carried out by Noranda Exploration Inc. personnel.

Figure 1 – Cameron Main Showing (center foreground), looking west from the head of Alverson Gulch

On July 1, 2001 Noranda Inc. notified Tanana Exploration Inc that it had elected to exercise its option on the Cameron property and title was subsequently transferred to Noranda upon receipt of the first payment in accordance with the terms of the agreement.

During the first three weeks of August 2001, Noranda personnel carried out a limited drill program on the main Cameron showing to assess the structure and mineralization identified during previous drilling in 1974. A report detailing the results of this work is currently being prepared by Dave King, the Noranada geologist who oversaw the project.

PROJECT AREA #2 – RYE CREEK

PROJECT SUMMARY

No work was completed in this project area during the course of the 2001 exploration season. The target is still considered highly viable, but the current grassroots status of the area does not present a very positive risk/reward analysis given the industries current focus on more advanced ('drill ready targets') as result of the present market fundamentals.

PROJECT AREA #3 – WEASEL LAKE (SPICE PROPERTY)

PROJECT SUMMARY

A separate report detailing exploration activities in this project area has been submitted under separate cover. Please see the included report entitled, "Evaluation Report on the Spice Property".

PROJECT AREA #4 – DORSEY LAKE

PROJECT SUMMARY

Prospecting activities in this area were proposed as an amendment to the original application (correspondence dated June 4, 2001) to follow up research indicating potential for intrusive related gold and gemstones. A total of 65 man days (not including rain days and travel) were spent on prospecting and evaluating targets within the project area during the 2001 field season.

AREA LOCATION AND ACCESS

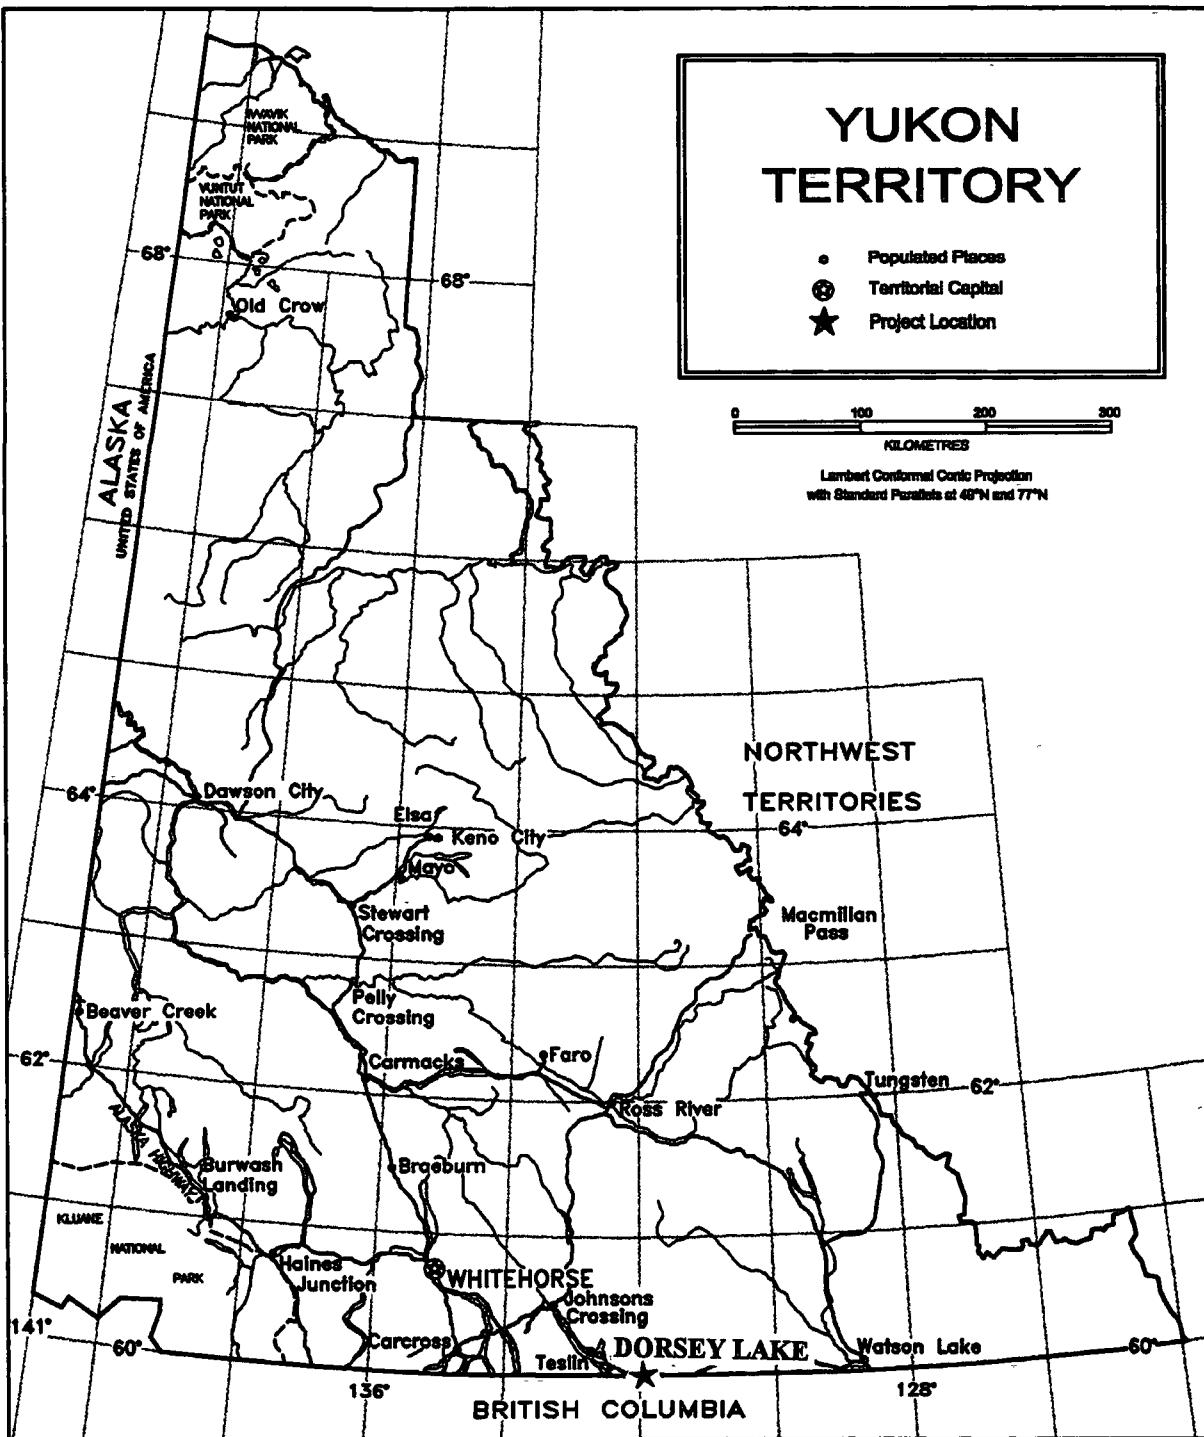

The project area is located in the Swift River region of the southern Yukon (see Figure 2) and is shown on the NTS 105B/4 map sheet. It covers a large area N and NW of Dorsey Lake which is found

YUKON TERRITORY

about 25 kilometers due east of Teslin in the Smart River system and roughly centered at 60° 12' N latitude and 131° 38' W Longitude. Access to the area is by float plane, generally from Whitehorse and an existing cabin at the NW end of Dorsey Lake was upgraded and used as a base camp from which exploration traverses were carried out. More detailed followup recommended will make use of a helicopter supported fly camp to cut down on the large hiking distances (10 to 15 km roundtrip) that were required during the 2001 field season.

PREVIOUS WORK AND EXPLORATION HISTORY

This area was extensively explored for tin associated skarn zones formed along the margins of the Seagull Batholith intrusions between 1977 and 1984. J.C. Stephens Exploration completed much of the early work, followed by a syndicate between Dome and Cominco and finally a large multi year project carried out by DuPont/Duval, known as the Klinkit Joint Venture, which included numerous properties in the Yukon and B.C. Mapping, geochemistry, geophysics, trenching and limited drilling was carried out during this time. The reader is referred to the Yukon Minfile (occurrences 105B 040, 070, 081, 084, 086 088) for specific details of these explorations.

Subsequent to this period, in 1993, YMIP funded prospecting by H. Kearns identified an area containing fragments of quartz veins hosting well developed beryl crystals located on a NE trending ridge in the central part of the region north of Dorsey Lake. This information together with previous mapping by Dupont which shows quartz-tourmaline veining and quartz stockworks, occasionally forming griesen zones is indicative of possible emerald potential in the area.

REGIONAL AND GENERAL GEOLOGY

The area is situated in the Dorsey Range in the south central Yukon on the flank of the Seagull Batholith. The batholith, consisting of monzonite and granodiorite, is mid-Cretaceous in age and intrudes Devonian and Mississippian rocks of the YTT, comprised of the Englishman Group of cherts, argillites, phyllites, quartzites and marbles. Well developed skarn formation is widespread throughout the area wherever limestone units of the group are present.

Contacts between the YTT units are very gradational and due to differential weathering can be identified in most cases simply by these differences.

The batholith overall shows pervasive jointing that is evident in the overlying rock, generally as north-south and east-west trending vertical fractures.

DESCRIPTION AND SUMMARY OF WORK

Prospecting of a large region, comprising approximately 20 sq km., identified four targets that were staked and subsequently followed up with more detailed sampling/trenching/prospecting. Three targets were staked for their gemstone potential (M.C , Eccles and Skarn) while the fourth was staked as possible tungsten play (J C.) when preliminary reconnaissance indicated the presence of scheelite and possibly wolframite.

Difficult travel conditions were improved with the upgrade of an existing access trail from Dorsey Lake into the high country to the NW. This helped to reduce travel times required for the 10+km. roundtrip hikes and improved safety during the often wet conditions.

Detailed prospecting and preliminary sampling precipitated the decision to stake a total of ten claims comprising 4 small blocks (see Figure 3) in mid July which was followed up as summarized below,

M.C #1 and M.C. #2 (60° 11' 37" N Latitude/131 37' 37" W Longitude)

These claims were staked to cover the previously mentioned beryl occurrence after its location was determined during reconnaissance prospecting. Trenching and more detailed prospecting were then completed to facilitate the evaluation of this occurrence. A total of approximately 25 cu. m. of residual cover and broken bedrock were excavated and screened to test for gemstone potential (see Figures 4 and 5).

Eccles #1 and Eccles #2 (60° 12' 56" N Latitude/131 36' 17" W Longitude)

This target was staked because of its similarities to the MC claims and was prospected briefly during the course of regional reconnaissance. No other work has been completed on this target at this time.

Skarn #1 and Skarn # 2 (60° 13' 15" N Latitude/131 35' 14" W Longitude)

As a result of detailed research of historical data this area was identified as prospective and was subsequently staked. Prospecting was then carried out and minor trenching was completed.

J.C. #1 to J.C. #4 (60° 11' 38" N Latitude/131 41' 10" W Longitude)

Reconnaissance prospecting precipitated the staking of this known Sn occurrence, with detailed prospecting and sampling being completed to assess its potential to host Au or W mineralization. A total of 9 samples were collected from old workings and outcrop in the area and submitted for multi-element ICP analysis

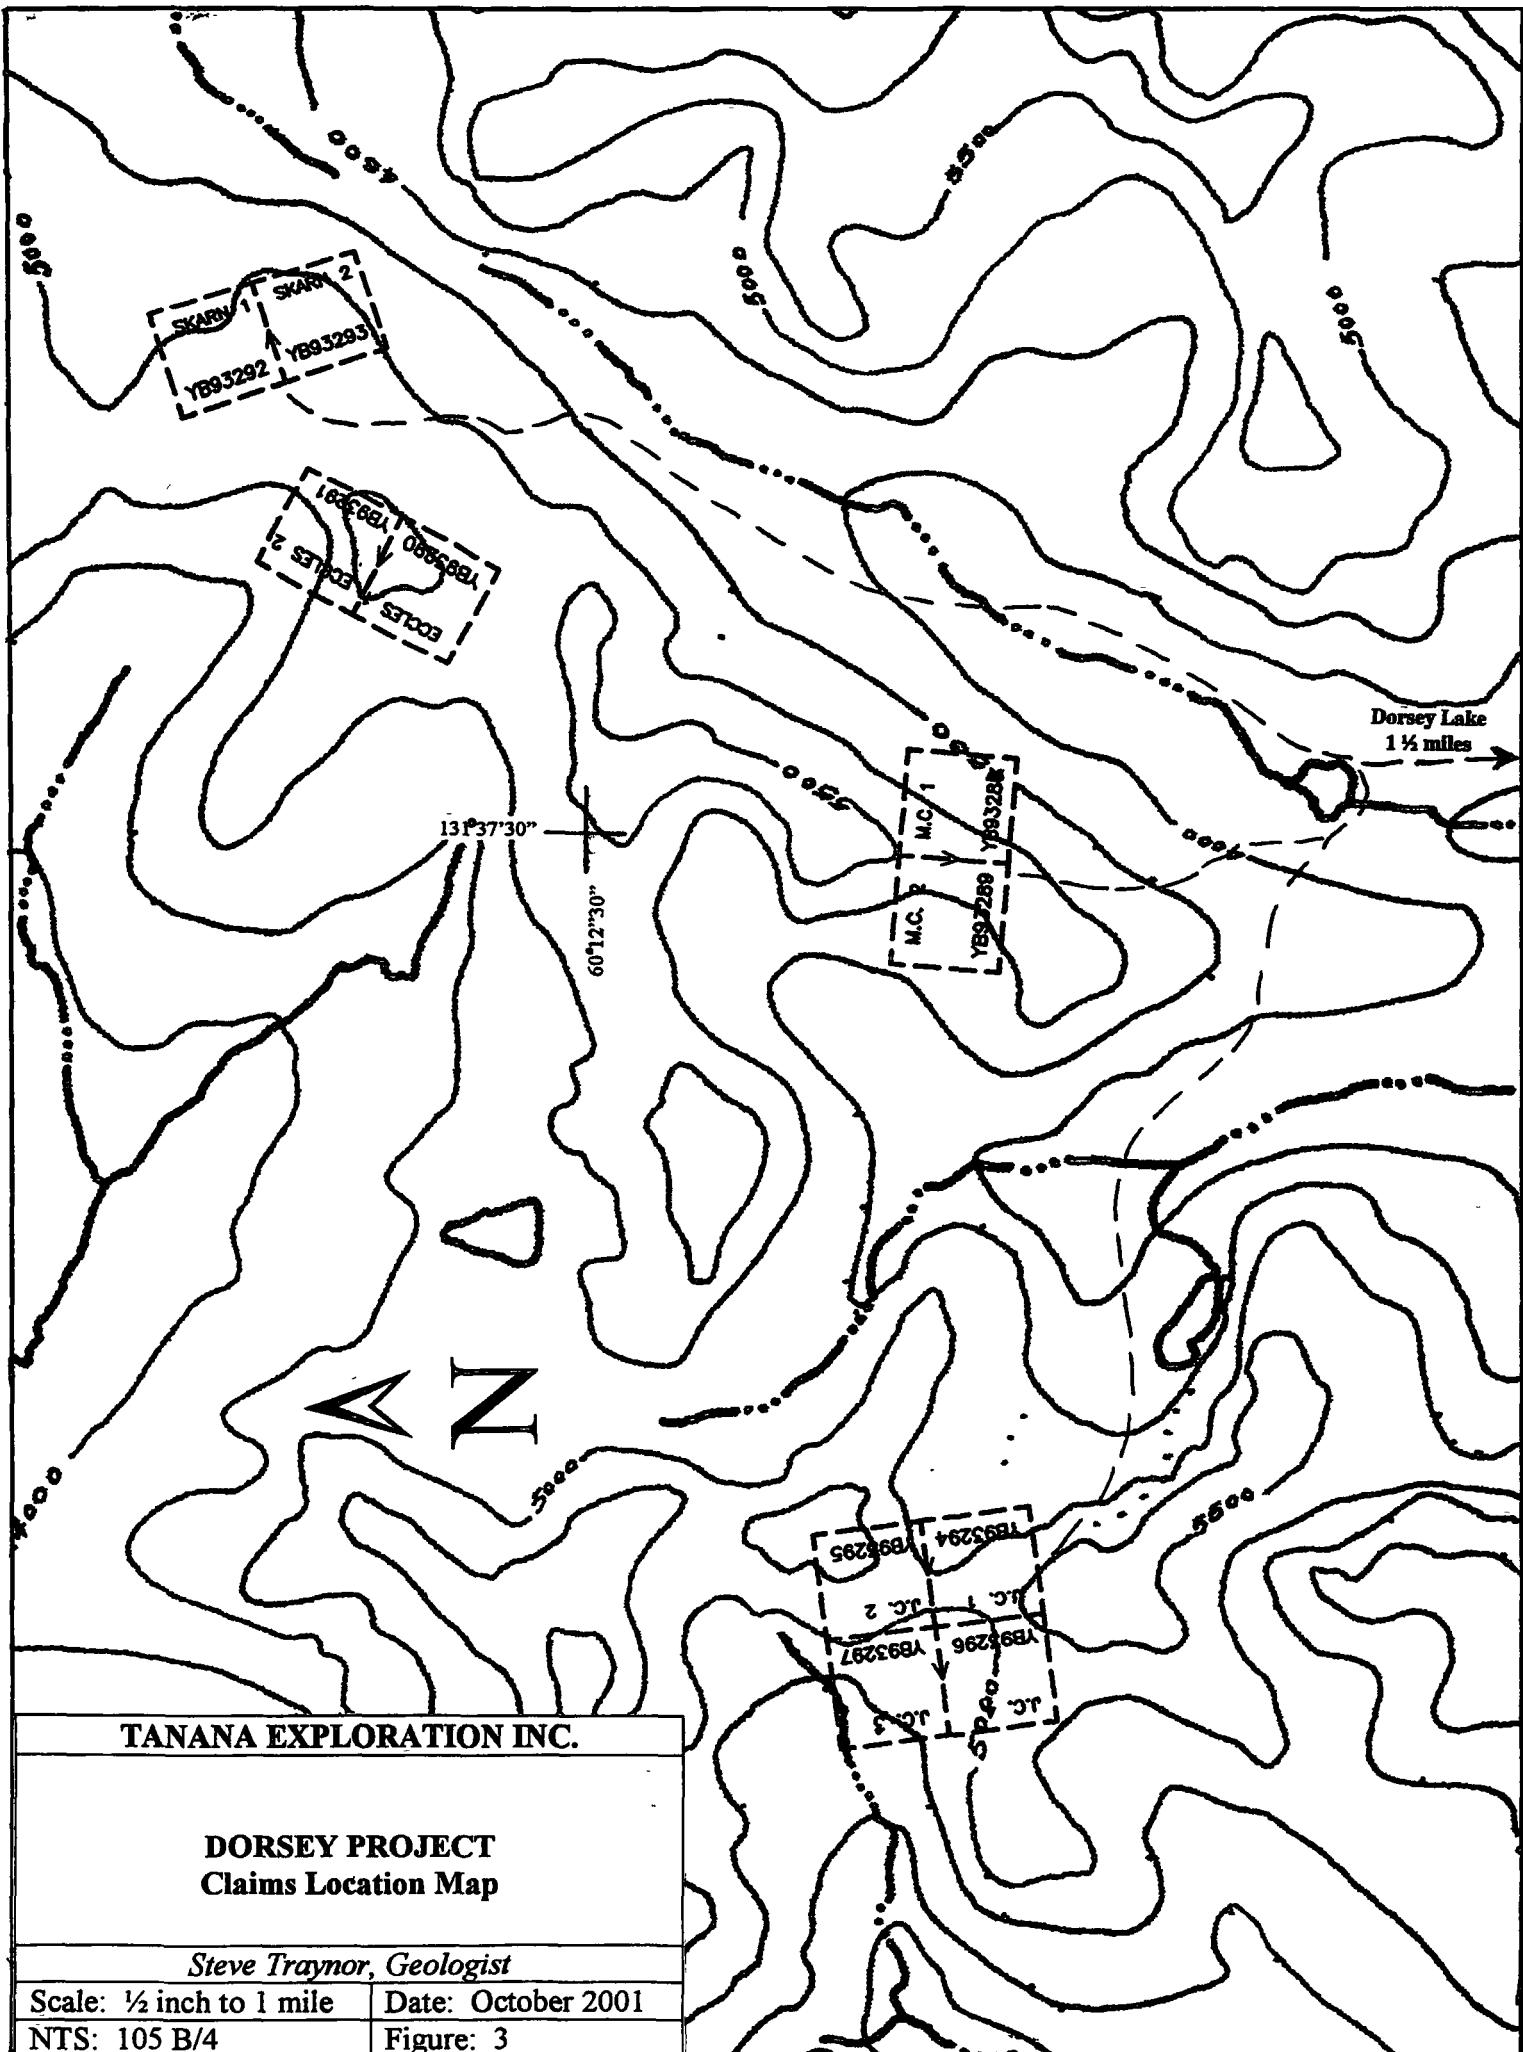

Figure 4 – Main trench, M.C. claims

Figure 5 – Excavated material being sorted and screened

ANALYSIS AND RESULTS

M.C. #1 and M.C. #2 (60° 11' 37" N Latitude/131° 37' 37" W Longitude)

A east-west trending structure located on the main ridge in this area was found to containing a large vein or dike. Composed primarily of massive white quartz as well as clusters of beryl crystals ranging in color from white to pale green (see Figure 6) this vertical feature yield a number of well formed, but fractured beryl crystals that were up to 10 cm long. The material was mostly opaque, with only a few small pieces approaching a semi-transparent character.

Figure 6 – Massive quartz with white and green beryl.

While more extensive excavations may yield some nice specimen quality beryl crystals, there does not appear to be any material with enough transparency or proper color to be considered gem quality. Cleaning and evaluation of a number of specimens is ongoing and a later decision will be made with regard to future exploration plans for this ground during the off season.

Eccles #1 and Eccles #2 (60° 12' 56" N Latitude/131° 36' 17" W Longitude)

While alteration in this area originally suggested a similar setting to the MC area, further investigation failed to detect any significant amount of quartz veining or beryl formation in this area. No other followup was completed or is proposed for these claims, which will likely be dropped.

Skarn #1 and Skarn # 2 (60° 13' 15" N Latitude/131° 35' 14" W Longitude)

One of the features of the skarning throughout this region, identified through research and detected during prospecting, was that the calc-silicate rich skarns are found to contain abundant garnets often as bedded garnetite (see Figure 7). While previous investigations in the area did not focus on garnet formation, except as an indication of skarn stages, many of the occurrences were mapped.

Figure 7 – Bedded garnetite in skarnified marble

One such occurrence indicated in the area covered by the Skarn #1 and #2 was located and investigated towards the end of the 2001 field season. It contained abundant well formed brown to greenish garnets up to 1 ½ cm in diameter. These first garnets though were mostly opaque and of little value as gemstones. Further investigation of the target and delineation of the garnetite beds did provide evidence that the area was also host to more transparent specimens. In scree below the original occurrence the author located 3 micro garnets in the .1mm to .2mm size range that showed good transparency and excellent yellow-green to green coloration indicating that larger gem quality stones will likely be found in place with further evaluation of this promising occurrence that is being proposed for the 2002 field season.

J.C. #1 to J.C. #4 (60° 11' 38" N Latitude/131° 41' 10" W Longitude)

Sampling of this known occurrence, see Figure 8, produced some interesting base metal anomalies (up to 4.43 % Zn and 4.50 % Cu), but gold and tungsten values were very disappointing. The base metal mineralization detected is not considered significant as it is found to be very poddy within the more abundant magnetite rich skarn. Subsequent discussion with Grant Abbott of DIAND about the mineralization associated with Cretaceous aged intrusions throughout the Yukon points to a growing realization that these systems are either gold, tin or tungsten rich and that invariably the enrichment of one results in the exclusion of the others. No clear indication of why this occurs is available yet, but the pattern is certainly evident from the sampling completed on this property which showed only minor tin enrichment.

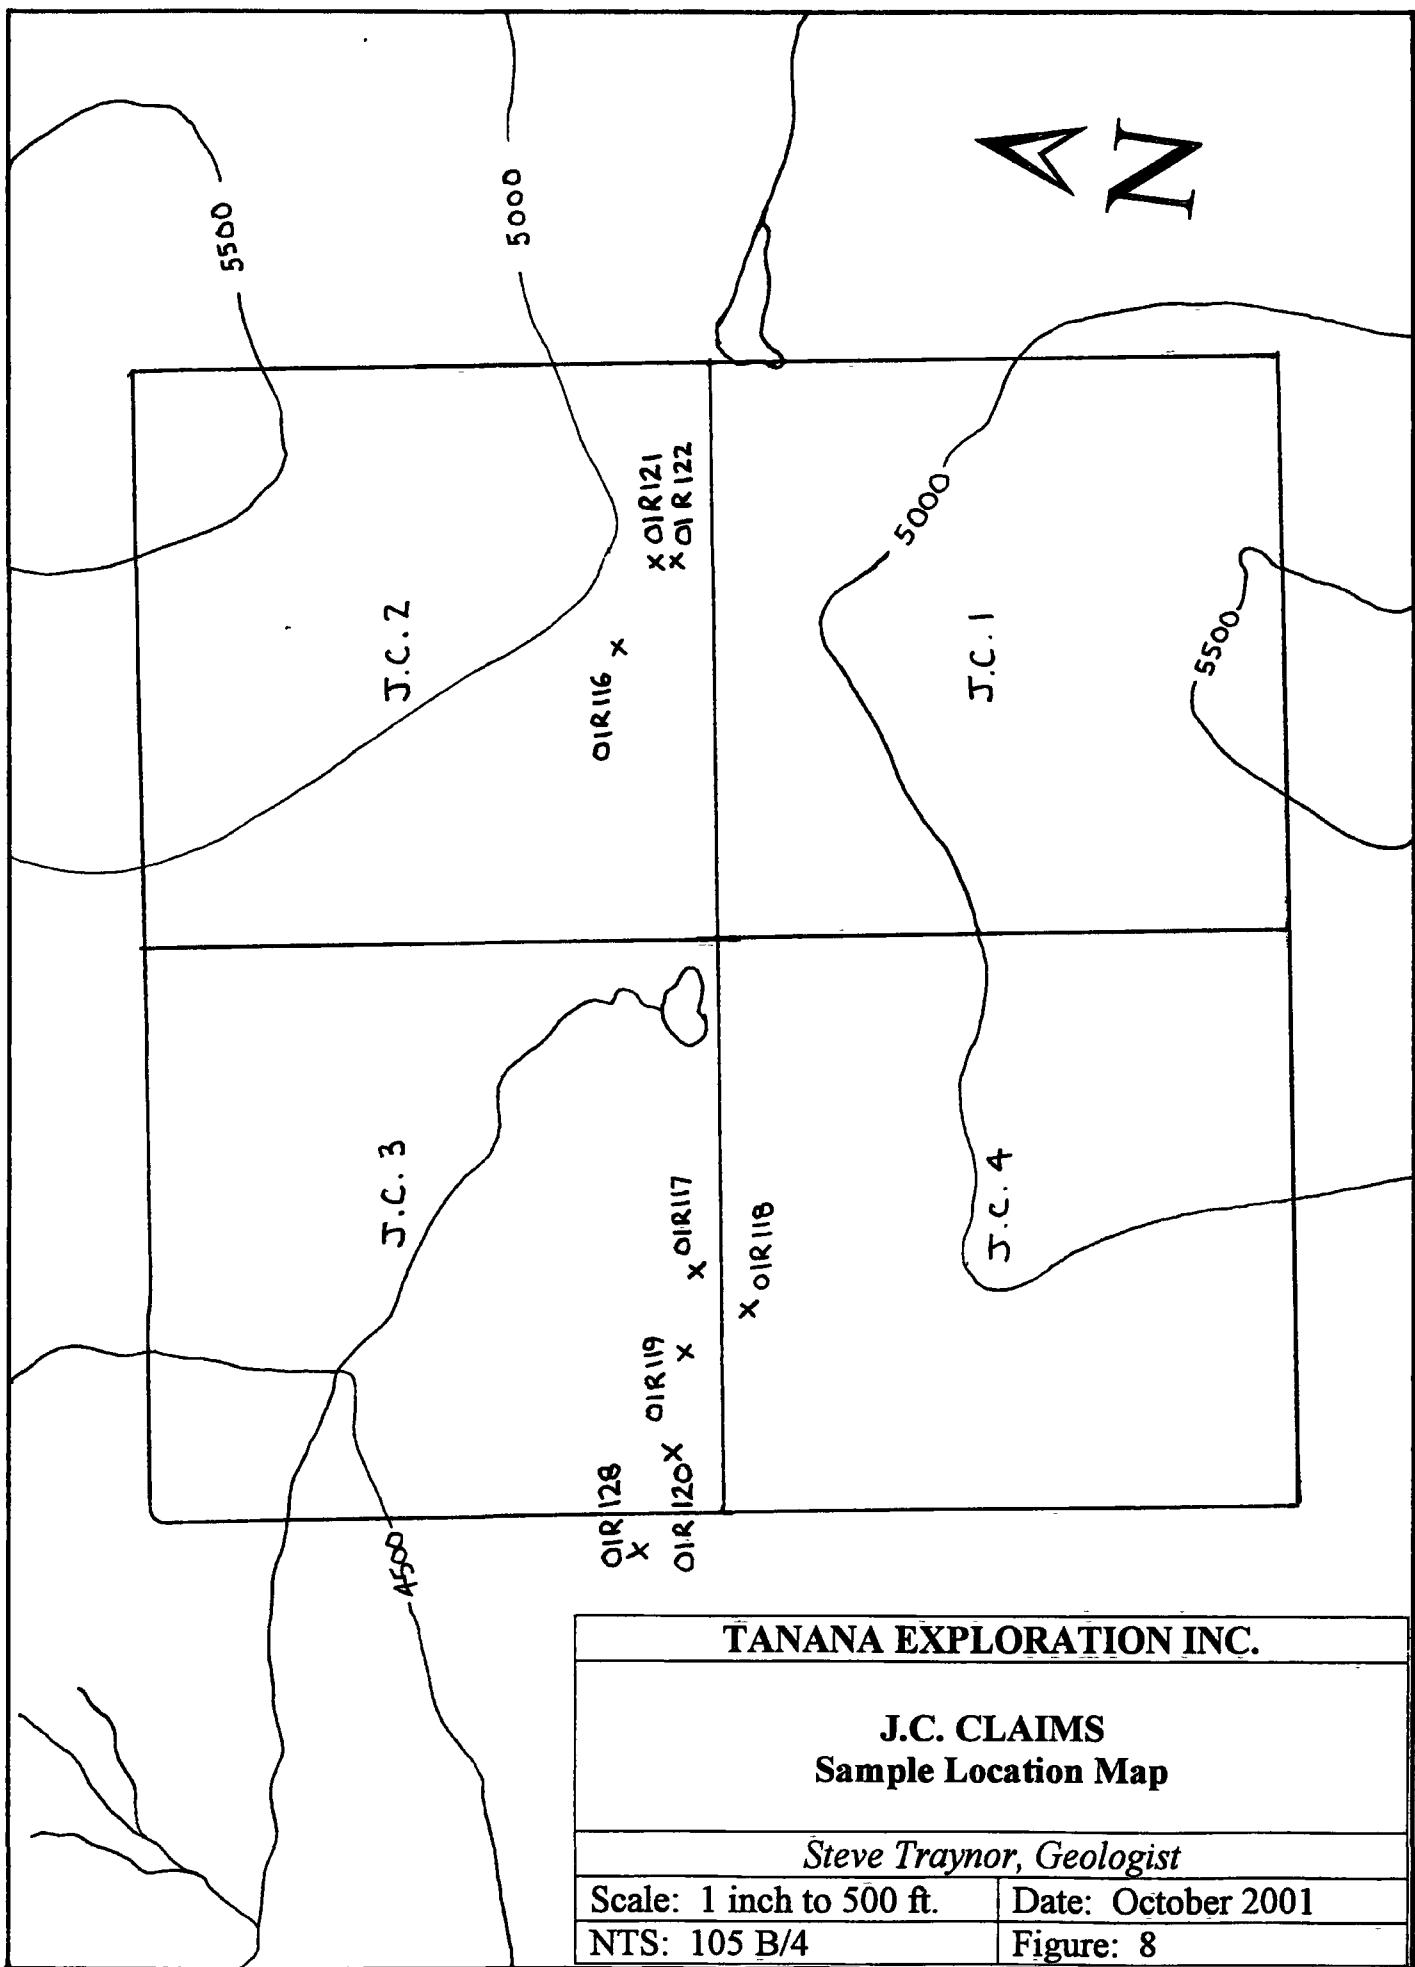

No further work will be carried out on this property.

CONCLUSIONS AND RECOMMENDATIONS

The discovery of an occurrence of apparently gem quality garnets on the Skarn claims was the result of research driven prospective exploration. Despite time constraints imposed by the late season discovery and extended travel times required to work the showing, a significant area with high potential for further discovery was ultimately identified.

Garnets have been prized as gems for at least 5000 years and even a small deposit of gem garnets could prove significant when one considers that good-quality one carat tsavorite (vanadium rich grossular) garnets are retailed for \$1,500 to \$3,000 (Walton, 1996).

It is recommended that an extensive program of sampling and recovery of garnets be carried out on this very promising target during the 2002 field season to evaluate the gem potential of these claims. The experience of this season indicates the necessity of moving a camp into the vicinity of the claims, now that a principal target has been identified. This will eliminate the need to spend large portions of the day travelling and will focus exploration efforts on the area of interest. Reconnaissance of the area completed this season indicated a suitable camp site with water available. Proposed work for next season will include setting up a helicopter fly camp on the edge of the claim block, detailed prospecting and excavation of trenches to further delineate the source of the micro garnets discovered at the end of the 2001 field season and recovery of potential gem quality specimens for further identification and gemological testing.

APPENDIX C

FIELD NOTES

No

Date

SPICE

JUNE 14, 2001 Page 02

IUAN, ELASH & I SET OUT
ON SPICE CLAIM AT 8:30 AM

CAMP LOCATED & SET UP
ON RIDGE SOUTH OF COMMON
LINE ON SPICE #3.

IUAN & I LOCATED & TAGGED
THE CLAIM POSTS IN THE
AFTERNOON.

WE CLEARED A HELI PAD
20 METERS WEST OF CAMP

WE FRIGHTENED OFF A
3 OR 4 YEAR OLD CINNAMON
BEAR IN THE EVENING.

No

Date

SPICE

JUNE 15, 2001 Page 03

IUAN ELASH & I TRAVESED
THE RIDGE NORTH EAST OF
CAMP.

NO OUTCROPS FOUND. HOWEVER
LARGE, 3 METER BOULDERS OF
DIORITE AT VARIOUS PLACES
ALONG THE RIDGE.

TOOK SAMPLE #01R-102
FROM QUARTZITE OUTCROP
NORTH OF CAMP. THIS
AREA WILL BE DESIGNATED
(OUTCROP #1) & LOCATED
WHEN THE SOIL LINES ARE
CHAINED IN TOMORROW.

CINNAMON BEAR RAIDED
OUR MEAT COOLER IN OUR
ABSENCE. JUDGING BY
THE BITE MARKS ON THE
COOLER LID, THERE IS A
SMALL CUB WITH HER.

APPENDIX A – ROCK SAMPLE REPORT	14
APPENDIX B – CERTIFICATES OF ANALYSIS	16

INTRODUCTION

This report details exploration activities carried out during the 2001 field season on the Spice property. Detailed soil geochemical sampling, prospecting and followup sampling facilitated by hand trenching was carried out as detailed investigation of highly anomalous results obtained by Jeff Bond of the Yukon Geology Program (see Bond, 2000) subsequent to ground acquisition in February 2001. The program successfully expanded the area of anomalous response, but failed to delineate a bedrock source.

PROPERTY LOCATION AND ACCESS

The Spice claims are located 28 kilometers east of Ross River, Yukon (see Figure 1), in the Watson Lake Mining District as shown on Claim Map Sheet 105 G 13. The property is located on the Pelly Plateau northeast of the Tintuna Trench between the Ross and Pelly Rivers.

The property is accessible via a short flight from Ross River by helicopter, which is the preferred method of access due to the lack of availability of float equipped aircraft in the area.

PROPERTY DESCRIPTION

The property consists of 10 contiguous quartz mineral claims, as shown in Figure 2 and listed in the table below. The Spice 1 – 10 claims were staked in February 2001, the author has inspected and supervised the maintenance of the claim posts and claim lines, which are all in good order. Tanana Exploration Inc. of Whitehorse, Yukon currently holds a 2/3 interest in the property.

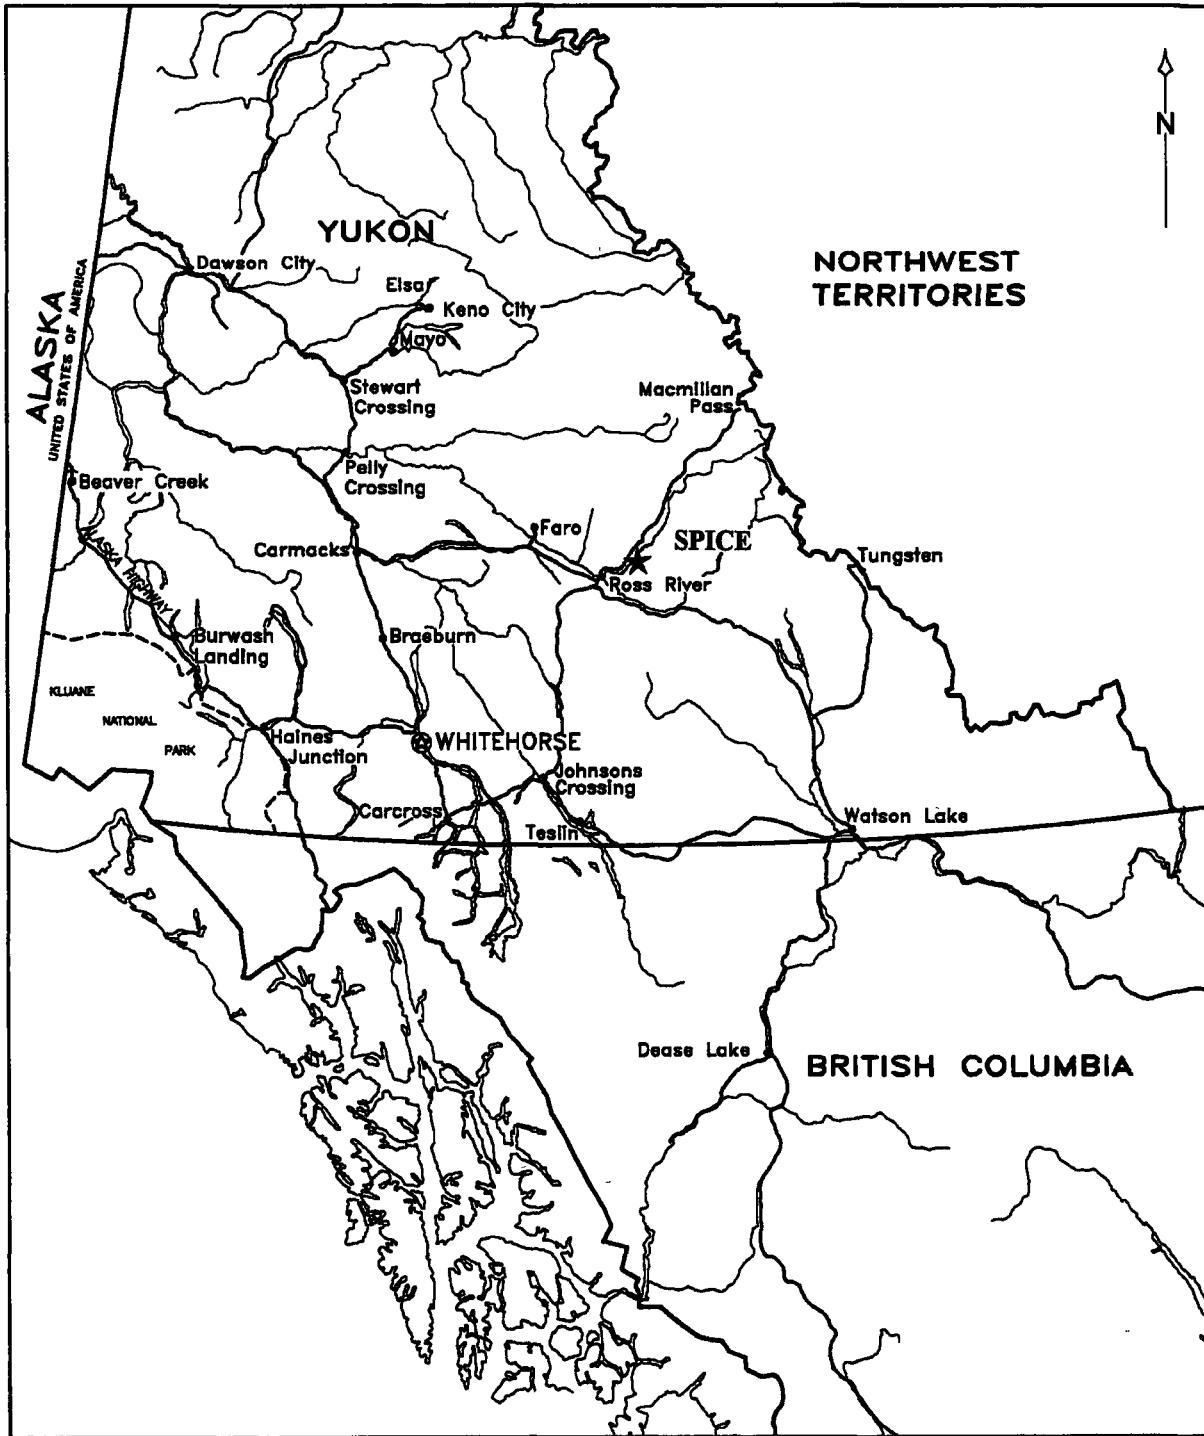

Claim Data

<u>Claim Name</u>	<u>Grant Number</u>	<u>Expiry Date (*in process)</u>
SPICE 1 - 10	YB93156 – YB93165	Dec. 31, 2005*

The claims are located in an area of subdued topography predominated by widespread glaciofluvial deposits of sand and silt. Situated on and to the west of a small unnamed lake in the area the claims lie between 2500 and 2600 feet. Alders, willows and aspen predominate the area with an occasional stand of small spruce interspersed.

PREVIOUS WORK AND EXPLORATION

Originally identified from a highly anomalous sample collected by Bond (2000) during the course of a regional till sampling program during the 2000 field season the area has apparently seen

limited to no exploration activity as reported by the Yukon Minfile due to the widespread Quaternary cover that predominates the region. An area to the north of the property was explored by airborne surveying in the late 1970's with limited ground followup. Cominco explored to the east in 1994 following up a number of conductors identified during a regional airborne geophysical survey, but after limited ground followup they concluded that the conductors likely reflected slices of carbonaceous sediments in an area that lacked any indication of felsic volcanic rock (MacRobbie (1995)).

Bond completed surficial mapping and till geochemistry across the region in 2000 collecting and analysing 175 till samples, of which sample JB00-155 collected in an area now covered by the Spice #4 claim returned the highest values for Au (28.9 ppb), As (484.5 ppm), Sb (151.37 ppm), Hg (21,020 ppm), Tl (1 ppm) and Ag (1,374 ppm). The elements that form the anomaly at this sample site are considered pathfinders for epithermal gold mineralization in which As, Sb, Hg and Tl surround and overlie a Au ore-bearing zone. Bond (personal communication) suggests that the source of the anomaly is "either from a small valley that drains into the lake from the west, or possibly at depth beneath the peninsula.

REGIONAL AND PROPERTY GEOLOGY

Rocks underlying this part of the Yukon have been assigned to the Yukon-Tanana and the Slide Mountain Terranes. Outcrop in the area is severely limited with moderate to deep Quaternary cover obscuring most of the area. In the immediate vicinity of the property the upper sequence of the YTT rocks are exposed to the SW and comprise mostly Pennsylvanian black shales with minor quartzites, these rocks are apparently overlain by an overlap sequence of laterally extensive conglomeritic unit of Triassic to Permian age (D. Murphy, personnal communication). This overlap sequence was likely formed along a subduction zone that is expressed in a subhorizontal to moderately N to NE penetrative ductile deformation fabric. All rocks in the area show signs of the affects of later thrust faulting during the formation of the Finlayson Lake Thrust Fault Zone which parallels the earlier formed Tintuna Trench.

High level porphyritic felsic volcanics were detected along the southern boundary of the property and these may be associated with the Permian basalts that are reported to occur to the E-SE of the area and may have provided the heat source needed to drive the inferred epithermal system in the area..

The brittle host provided by the previously mentioned conglomerate unit shows the type of structural preparation necessary for the formation of this deposit type The unit has been strongly

silicified and contains moderate amounts of disseminated sulfides including pyrite, arsenopyrite (?) and stibnite.

DESCRIPTION AND SUMMARY OF WORK

During the 2001 season a total of 16 man days were spent sampling and prospecting the Spice property. From June 14 to June 17, Wade Carrell and Ivan Elash completed soil sampling and prospecting and were joined during this time by Jeff Bond and Don Murphy of the Yukon Geology program who also completed sampling (as followup to the 2000 season, Bond) and geological mapping (continuation of ongoing regional work, Murphy). Followup of the sampling completed by Tanana personnel was carried out from August 11 to August 13 and included hand pitting, trenching and sampling of areas of anomalous response identified during earlier efforts described above. Limited prospecting of the western end of the claim block was also completed at this time. Wade Carrell, Steve Traynor and Ivan Elash were involved in this phase of the exploration and development of the property.

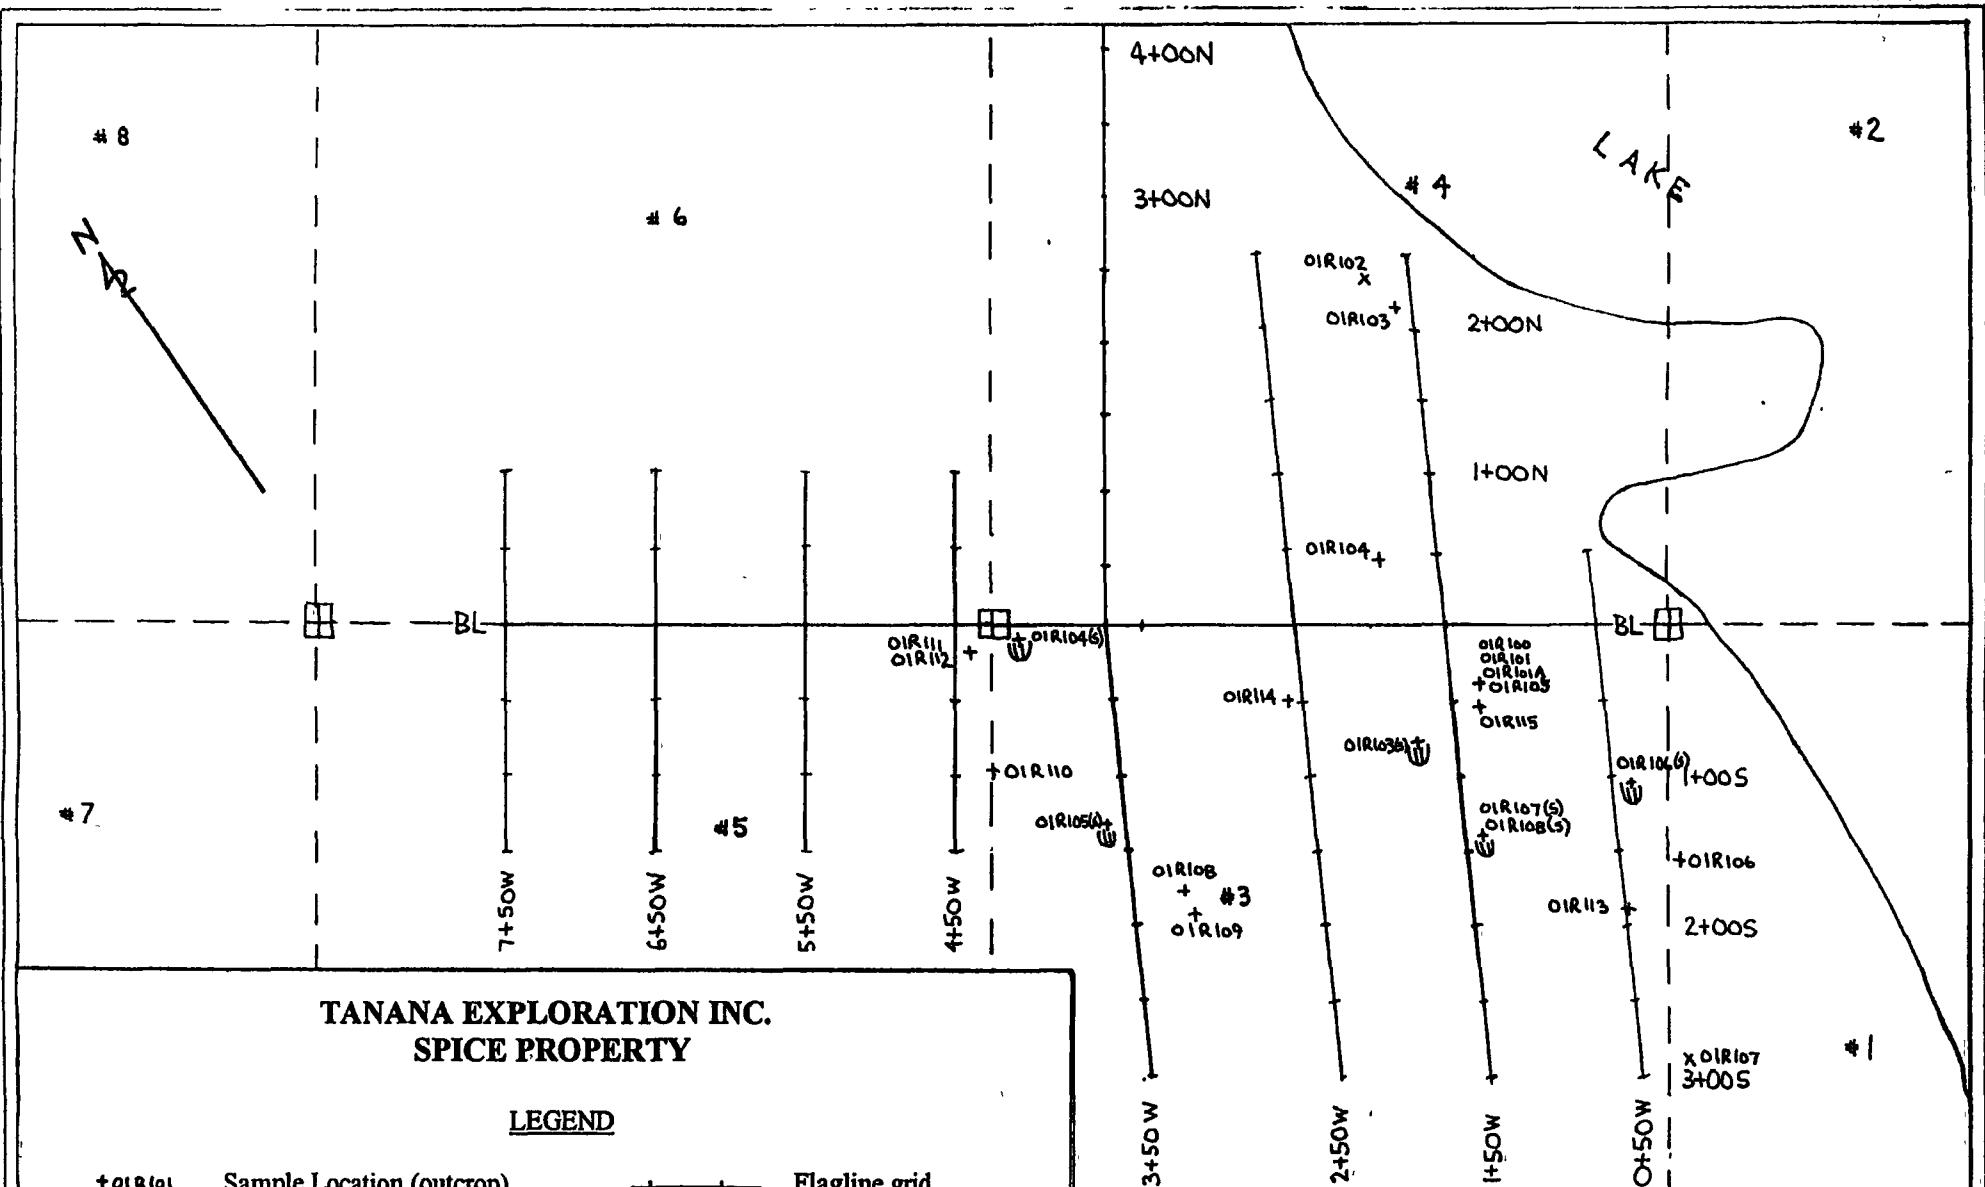

ANALYSIS AND RESULTS

A total of 24 rock samples and 33 soil/silt samples were collected during the course of this seasons exploration efforts. Data for the rock samples is presented in Figure 3 and in Appendices 1 and 2, while data for the soil/silt samples is presented in Figures 4, 5, 6, 7 and Appendix 2.

Rock samples were analyzed for Ag, Cu, Pb, Zn, Mo, Ni, Co, Cd, Bi, As, Sb, Hg, Fe, Mn, Te, Ba, Cr, V, Sn, W, La, Al, Mg, Ca, Na, K, Sr, Y, Ga, Li, Nb, Sc, Ta, Ti, Zr and S by ICP and Au by Fire Assay/AA at Bondar Clegg in Vancouver, B.C.

Soil samples, consisting of 1g of -80mesh, were analyzed for Mo, Cu, Pb, Zn, Ag, Ni, Co, Mn, Fe, As, U, Au, Th, Sr, Cd, Sb, Bi, V, Ca, P, La, Cr, Mg, Ba, Ti, B, Al, Na, K, W, Sc, Tl, S, Hg, Se, Te, Ga, by ICP/ES & MS at Acme Analytical Laboratories in Vancouver, B.C.

Statistical analysis of the soil results and plotting of the resulting data indicates a strongly anomalous linear trend between 1+00S and 1+00N that apparently parallels the baseline established in the area. Anomalous samples are those determined to be in the 80th percentile or above of the data set. The elements choosen for plotting include gold (Au), arsenic (As), antimony (Sb) and mercury (Hg). These elements are seen to show coincident anomalies in most cases. Of note though is the fact that data obtained

ARSENIC SOIL GEOCHEMISTRY

Arsenic in ppm

during the collection of the samples shows that the anomalous results are all from samples that had a high clay content, suggesting that clay in the area may be concentrating the anomalies. It was not immediately evident whether the clay was a weathering product or is of Quaternary origin

Analysis of the rock samples obtained during the followup phase from hand pits and trenches returned values that were disappointingly low and did little to explain the anomalies indicated during the soil sampling phase of the program. In fact, except for mercury the rock results were barely above the expected background for the area.

CONCLUSIONS AND RECOMMENDATIONS

Soil geochemical sampling resulted in the identification of a number of promising anomalies that subsequent followup failed to locate a bedrock source for. It is possible that further independant analysis of additional data collected by Jeff Bond, which will include analysis of different size fractions, sample sizes and sample compositions may provide additional insight into the source of these anomalies and/or indicate another course of followup for the area.

At the present time, the lack of positive response from bedrock sampling combined with the difficulties in obtaining addtional bedrock samples due to the depth and extent of the Quaternary cover in the area, precludes any further work on the property. The property will be held in inventory until such time that another course of followup is indicated and/or until gold prices increase to a level necessary to provide for a more positive risk/reward analysis.

ROCK SAMPLE REPORT

TANANA EXPLORATION INC. – Rock Sample Report

Property SPICE Location 105 G 13

SAMPLE NUMBER	SAMPLE LOCATION	SAMPLE DESCRIPTION
01R100	130W/045S	Highly silicified brecciated conglomerate showing minor sericite alteration and possibly fine grained arsenopyrite.
01R101	130W/045S	Highly silicified, greyish black sandstone with up to 15% fine grained fragments of other volcanic and sed. lithologies
01R101A	130W/045S	Fine grained, silicified sandstone(?)
01R102	177W/240N	Float of sheared and silicified conglomerate.
01R103	160W/220N	Sheared conglomerate containing large clasts of micaceous quartzite and pure quartz.
01R104	187W/050N	Same as 103, but less matrix and more clasts.
01R105	130W/045S	Same as 103.
01R106	043W/154S	Whitish grey, silicified almost pure quartzite
01R107	015W/300S	Float of carbonaceous argillite.
01R108	316W/176S	Same as 106, except shows signs of shearing.
01R109	310W/190S	Greyish, heavily silicified quartzite with grey-brown sulfides shot throughout
01R110	425W/092S	Greyish, fractured quartzite that is heavily silicified and contains abundant very fine grained pyrite.
01R111	~440W/15S	Same as 103.
01R112	~440W/15S	Same as 103, except larger clasts and more silicified/sheared
01R113	050W/184S	Same as 106, very limonitically stained.
01R114	258W/047S	Sheared blackish quartzite that has been hornfelsed Shows very brittle deformation.
01R115	~135W/050S	Same as 107.
<i>01R103(S)</i>	173W/066S	Black, heavily sheared, fine grained micaceous quartzite that appears to highly carbonaceous.
<i>01R104(S)</i>	418.5W/021S	Greyish quartz-mica schist showing formation of abundant sericite
<i>01R105(S)</i>	360W/130S	Quartzite with minor sulfides.
<i>01R106(S)</i>	038W/100S	Black shaly quartzite.
<i>01R107(S)</i>	140W/135S	Silicified and fractured quartzite, abundantly fractured with with blackish filling on fractures
<i>01R108(S)</i>	140W/135S	Silicified and fractured quartzite, abundantly fractured with with blackish filling on fractures

*Sample numbering sequence was duplicated in error and will be differentiated from previous samples by the addition of (S) to the sample number. Analytical result numbering has been amended to correspond.
