SUMMARY

The Hit property is located in the central Yukon Territory, 27 kilometers N.N.E. of MacMillan Pass, just west of the Yukon/NWT border. The closest access is by helicopter from MacMillan Pass, a distance of 20 kilometers. Topography varies from moderate to extreme, with several areas impassable due to cliffs and frequent rock and/or snow avalanches.

The Hit Project is located within the Selwyn Basin, a large sedimentary depocenter active from the Precambrian to the Mississippian. The mid-late Cretaceous Tombstone Suite (90-92 Ma), consisting of stocks, sills and dykes of granitic composition has been emplaced within these sediments. Tombstone Suite intrusives are commonly associated with bulk-tonnage gold targets within an east-southeast trending belt which extends from east-central Alaska to the Yukon/NWT border, a total distance of almost 600 kilometres. Significant Yukon targets hosted by, or associated with, the Tombstone Suite include: Brewery Creek, Dublin Gulch, McQuesten/Wayne and Scheelite Dome, while Alaskan discoveries include Pogo, Fort Knox and True North.

The 2009 exploration program on the Hit property consisted of geologic mapping, prospecting and geochemical sampling between August 1-4, 2009. The crew consisted of two geologists and two field technicians. The crew was mobilized by helicopter and set up a temporary fly camp beside the lake on the property, where traverses were completed from here daily. At the end of the program, the crew mobilized out by helicopter to the Canol Road and drove from there back to Ross River and subsequently Whitehorse.

The focus for the geological mapping was to follow and map out the intrusive contact as well as note and document any important and/or mineralizing structures encountered during the time in the field. Along the southern contact zone, it is more difficult to follow due to the extensive talus cover. The contact in the southern zone was only noted at station AHHTG004, where it correlates very closely with the historic mapping. The contact in the northern zone of the property was easier to follow but is also much more irregular. Nevertheless the contact between the intrusive unit and the sediments was better delineated. No major structures were located during the project and only small shear planes were noted, sometimes associated with minor skarn mineralization.

During the 2009 exploration program, 10 soil samples and 11 rock samples were taken over the 2 days in the field. Of the rock samples taken, the best results was from sample AHHTR005. This sample was taken at a skarn zone close to the contact with a granodiorite dyke. This grab sample returned 3.85 g/t Au, 17.7 g/t Ag and 901 ppm Cu. Grab sample AHHTR003, taken at the Ridge Zone occurrence, returned 0.41 g/t Au, 0.7 g/t Ag and 674 ppm Cu.

One soil line was run parallel to previous line to test for continuity of the results. The only sample with an anomalous value for Au was NTHTD001, which returned 57.6 ppb Au, 1.4 ppm Ag and 197 ppm Cu. The few samples taken in very close proximity to a previous sample that returned 1455 ppb Au did not replicate this result. The sample quality however was quite poor due to little to no soil development and the samples consisted mostly of talus fines.

The Hit property remains an intriguing and prospective Au target. The main economic potential on the property is found associated with mineralization of a probable replacement style within calcareous siltstone along the northeast edge of the Hit pluton. Sediments in this area strike parallel to, and dip steeply towards, the intrusive contact. There is also potential in skarned units in close proximity to the intrusive unit, whether that be the main body or related proximal dykes. Much of the mineralization on the north side of the intrusive contact appears to be structurally controlled but no major structures have been identified and cataloged to date that would be contributing factors. Further work is recommended.

Total expenditures for the 2009 exploration program were \$21,037.72

INTRODUCTION

Property Description and Location

The property is located in the central Yukon Territory, 27 kilometers N.N.E. of MacMillan Pass, just west of the Yukon/NWT border. The Mactung tungsten skarn deposit is situated approximately 23 kilometers to the south. The closest access is by helicopter from MacMillan Pass, a distance of 20 kilometers. Topography varies from moderate to extreme, with several areas impassable due to cliffs and frequent rock and/or snow avalanches.

There are, to the best knowledge of the writers, no liens or encumbrances on the claims. The title was researched using the Yukon Government on - line database.

History

The majority of previous work in this area was directed towards assessing a copper-tungsten skarn located just inside the NWT border. This showing was initially worked by a subsidiary of Cyprus Mining Corp. during 1970-71. It was re-staked in 1982 by a joint venture between Amax Mining and Canada Tungsten, who continued exploration until the end of 1984. The Amax/Cantung work resulted in the staking of six claims in the Yukon, over what is now the Hit claims main zone area. Documentation of the historical work is not in the public domain.

In 1998, Bernie Kreft spent 8 days in the project area following up on an RGS Au stream sediment anomaly. Concurrent with this work, 8 Quartz claims were staked over the most promising area by Mr. Kreft on behalf of Eagle Plains Resources.

A two phase program was carried out on the property in 1999. Phase 1 consisted of prospecting in conjunction with rock, silt and soil sampling. This work was designed to cover the favorable calcareous siltstone horizon along the northeast edge of the pluton, where the sediments dip towards the contact. Time was also spent at the Gully Zone to try and further define the existing mineralization. Based on the results from Phase 1 and from historic work on the property a two hole diamond drilling program was completed in late August, 1999.

Drill testing of the Gully Zone consisted of a one set-up, two hole program designed to test the showing at depth, approximately 30 meters along strike to the northwest. Although the favorable calcareous horizon was intersected, results were disappointing, with a maximum value of 2566 ppb Au over a 0.9 meter interval of brecciated and pyrrhotite mineralized limestone (highly calcareous siltstone?) cut by carbonate veins.

GEOLOGY

Regional Geology

The Hit Project is located within the Selwyn Basin, a large sedimentary depocenter active from the Precambrian to the Mississippian. The mid-late Cretaceous Tombstone Suite (90-92 Ma), consisting of stocks, sills and dykes of granitic composition has been emplaced within these sediments. Tombstone Suite intrusives are commonly associated with bulk-tonnage gold targets within an east-southeast trending belt which extends from east-central Alaska to the Yukon/NWT border, a total distance of almost 600 kilometres. Significant Yukon targets hosted by, or associated with, the Tombstone Suite include: Brewery Creek, Dublin Gulch, McQuesten/Wayne and Scheelite Dome, while emerging Alaskan discoveries include Pogo, Fort Knox and True North. The granitic intrusion located at the Hit property likely belongs to the Tombstone Suite; age dating is currently in progress and should provide a definitive answer.

Property Geology

Strata underlying the claims consist of Cambrian aged black shale, argillaceous limestone, calcareous siltstone, green silty slate and rare quartzite, belonging to the Road River Formation. The Hit pluton has extensively hornfelsed these sediments, resulting in the development of widespread skarn and calc-silicate minerals/effects as well as numerous gossans.

Faulting is common in the area of the Hit Claims. The main structural features are NW-trending normal faults and joint sets, the development of which likely occurred during the emplacement of the Hit Pluton. Post-dating the NW-trending set are several NE-trending cross-faults. These faults usually exhibit weak epithermal characteristics, and often contain anomalous gold values. A third set of faults consists of small-scale, flat-lying structures. This type is best recognized in the area of the main showing and has caused several slight displacements of the auriferous beds.

The Hit pluton contains several phases, which vary from a fine-grained granodiorite border to a coarse porphyritic core. Weak porphyry-style molybdenum mineralization has been noted within the core area. Alteration is limited to bleaching and the development of trace sericite along vein margins and adjacent to fractures. Contacts with the surrounding sediments are steep where exposed.

Alteration, Mineralization and Structure

Highly anomalous gold values have been returned from several mineralized showings located within the pluton and its hornfels aureole. Highly anomalous gold values within silt and talus/soil samples suggest additional mineralized showings and strike extensions to the existing occurrences.

Best values to date have been returned from replacement type mineralization within interbedded, hornfelsed, calcareous siltstone and green silty slate. Five consecutive channel samples taken across the main showing (Gully Zone) by Miner River/Eagle Plains in 1998 returned a weighted average of 7.85 g/t Au over 7.0 metres, while subsequent sampling of the same interval by Placer Dome returned 6.93 g/t Au over 7.0 metres. Chip samples taken on either side of the zone returned only traces of gold. Potential for a parallel zone exists within the overburden covered footwall of the showing. Anomalous elements in relative order of abundance are: calcium, arsenic, antimony and tungsten. A stream

sediment sample taken approximately 80 metres downstream from this zone returned 606 ppb Au; re-sampling of this site later in the season returned 511 ppb Au. A high value of 10834 ppb Au in silt was returned from a tributary stream approximately 150 metres east of the main showing. This high value is likely a result of strike extensions of the main showing.

Numerous NE-trending, steeply dipping faults occur across the property. They often exhibit epithermal characteristics such as weakly developed, banded chalcedonic quartz and minor vuggy veining, and are best developed within granite. A chip sample from the Ridge Zone returned 1298 ppb Au over 6.0m, while selected grab samples of what was thought to be the best mineralized samples returned only traces of gold. A single soil sample line across the zone 100 metres along strike to the SW of the showing returned values up to 383 ppb Au. Soil data as well as an increasing abundance of fault zone material suggests a widening of the structure in this direction.

Skarn type mineralization is widespread throughout the claim area. Most occurrences are restricted in size except for the zones which occur just inside the NWT, and within an area along the NW edge of the pluton. The NWT showings (TWN) consist of at least four pyrrhotite mineralized horizons 1.0 to 8.0 metres wide and traceable for at least 100 metres, occurring within a 100 metre stratigraphic interval. High copper and tungsten values are likely attainable, unfortunately, gold values are only slightly anomalous with a peak of 168 ppb Au over 3.0 metres. Along the NW edge of the pluton are several heavily mineralized skarn pods/horizons within a large area of pyrrhotite mineralized (2%) hornfelsed sediments (Discovery Zone). Samples of skarn returned up to 3482 ppb Au from a representative grab sample, and up to 854 ppb Au over a 2.0 metre width. A line of talus fine samples taken at 50 metre spacings along the base of the slope below the showings returned 12 consecutive samples with values from 129 ppb to 1097 ppb Au. Further anomalies to 904 ppb Au occur along the line, and suggest additional mineralized occurrences.

The intrusion is host to several styles of mineralization, all of which would be expected within a Fort Knox type system. Grades of up to 22.8 g/t Au have been returned from several 2.0 to 6.0 centimetre wide quartz-sulphide (arsenopyrite dominant) veins. The distribution and extent of the known veins suggests they are currently of mineralogical interest only. Sheeted veining and highly fractured areas with associated anomalous gold values were found in two main locations within the pluton.

Mineralization is weak and consists of pyrite-pyrrhotite and occasionally molybdenum within veins and fractures, and as wallrock disseminations. Alteration is also weak, and consists of trace sericite with some minor bleaching of wallrock adjacent to veins and fractures. Values up to 719 ppb Au were returned from a 2.0 metre chip of fractured granite, while a representative grab sample of a 1.0cm qtz-py-mo vein returned 793 ppb Au. Other anomalous elements include bismuth and occasional copper. Some clustering of anomalous intrusive hosted gold values is noted along the NW edge of the stock in the vicinity of the Discovery Zone skarn horizons.

Although drill testing of the Gully Zone in 1999 intersected the favorable calcareous horizon, results were disappointing, with a maximum value of 2566 ppb Au over a 0.9 meter interval of brecciated and pyrrhotite mineralized limestone (highly calcareous siltstone?) cut by carbonate veins.

2009 EXPLORATION PROGRAM

The 2009 exploration program on the Hit property consisted of geologic mapping, prospecting and geochemical sampling between August 1-4, 2009. The crew consisted of two geologists and two field technicians. The crew was mobilized by helicopter from their previous location located at the Itsi pluton just south of the Canol Road. The crew set up a temporary fly camp beside the lake on the property, where traverses were completed from here daily. At the end of the program, the crew mobilized out by helicopter to the Canol Road and drove from there back to Ross River and subsequently Whitehorse.

2009 EXPLORATION PROGRAM RESULTS

Over the four day program, 2 days were spent in the field mapping, prospecting and geochemical sampling and resulted in the collection of 10 soil and 11 rock samples. These samples were collected in the field using a digital palm interface and entered into a database. The soils were prepped by sieving the sample to gain a homogeneous fine sample and placed in a labeled Ziploc bag for XRF analysis. The rocks were sent to the laboratory to be pulverized so that they could be placed in a labeled ziploc bag and analyzed using the XRF analyzer. The rock and soil samples that were deemed to have the potential to host gold mineralization were then sent to Eco Tech Laboratories for 28 element ICPMS in the case of the soils and Ag and Au assays in the case of the rocks. The samples sent to the lab were identified and singled out using gold associated elements such as As, Cu, Mo and Ag that were identified by XRF as pathfinders elements.

Geology

The focus for the geological mapping was to follow and map out the intrusive contact as well as note and document any important and/or mineralizing structures encountered during the time in the field. The intrusive contact was followed along where it could be. Along the southern contact zone, it is more difficult to follow due to the extensive talus cover. The contact in the southern zone was only noted at station AHHTG004, where it correlates very closely with the historic mapping. The contact in the northern zone of the property was easier to follow but is also much more irregular. Nevertheless the contact between the intrusive unit and the sediments was better delineated. No major structures were located during the project and only small shear planes were noted, sometimes associated with minor skarn mineralization. The updated geology is shown in figure 4.

Geochemistry

During the 2009 exploration program, 10 soil samples and 11 rock samples were taken over the 2 days in the field. Of the rock samples taken, the best results was from sample AHHTR005. This sample was taken at a skarn zone close to the contact with a granodiorite dyke. This grab sample returned 3.85 g/t Au, 17.7 g/t Ag and 901 ppm Cu. Grab sample AHHTR003, taken at the Ridge Zone occurrence, returned 0.41 g/t Au, 0.7 g/t Ag and 674 ppm Cu. One float sample of a small molybdenite bearing quartz vein (AHHTR002) did return 909 ppm Mo, within the intrusive granodiorite but the source was not located. A grab sample from the Gulley Zone occurrence (LJHTR001), returned 0.35% Cu but only 2.4 g/t Ag and 0.08 g/t Au.

One soil line was run parallel to previous line to test for continuity of the results. The only sample with an anomalous value for Au was NTHTD001, which returned 57.6 ppb Au, 1.4 ppm Ag and 197 ppm Cu. The few samples taken in very close proximity to a previous sample that returned 1455 ppb Au did not replicate this result. The sample quality however was quite poor due to little to no soil development and the samples consisted mostly of talus fines.

When comparing the small dataset of XRF vs ICP lab results the copper values correlate very well in both the soils and the rocks. The lead in the soil samples also correlated well. The good gold value correlates strongly with high bismuth which is picked up in the XRF as well quite strongly.

The results of the geochemical program are shown in figures 5a-b.

Legend

- Minifile
- Rock Sample (Cu - ppm, Mo - ppm)
- Soil Sample (Cu - ppm, Mo - ppm)
- No Sample
- Index Contour
- Contour
- Moraine
- KGR - Cretaceous Granitic Intrusion
- Perninant Snow
- Tenure Boundary

CONCLUSIONS

The Hit property remains an intriguing and prospective Au target. The main economic potential on the property is found associated with mineralization of a probable replacement style within calcareous siltstone along the northeast edge of the Hit pluton. Sediments in this area strike parallel to, and dip steeply towards, the intrusive contact. There is also potential in skarned units in close proximity to the intrusive unit, whether that be the main body or related proximal dykes. Much of the mineralization on the north side of the intrusive contact appears to be structurally controlled but no major structures have been identified and cataloged to date that would be contributing factors.

RECOMMENDATIONS

For the 2010 season, the following recommendations are made and would consist of a 25 day field program:

- extend soil geochemical coverage to cover all intrusive / sediment contact zones; in some areas a more specialized geochemical sampling method such as deep sampling with soil augers or possibly Mobile Metal Ion methods may accurately detect Au mineralization under areas of thicker overburden cover.
- some effort should be made to better understand the controlling structures on the property and their relationship with mineralization; surface mapping is somewhat limited due to a lack of outcrop, but it is possible that a geophysical VLF survey could be used to better define subsurface structures;
- based on the results from the above work, a short airborne diamond drill program should be completed to test the best target area; some thought should be given to using a modified grid to drill short holes along the intrusive / sediment contact.

The recommended budget for the 2010 program is as follows:

Table 2 – 2010 Recommended Budget

| Category | Amount |
|------------------------------|--------------|
| Wages | \$50,000.00 |
| Analytical | \$10,000.00 |
| Equipment Rental | \$10,000.00 |
| Diamond Drilling | \$187,500.00 |
| Helicopter | \$225,000.00 |
| Camp Supplies, Food and Fuel | \$10,000.00 |
| Shipping | \$2,000.00 |
| Report Writing | \$5,000.00 |
| Subtotal | \$297,000.00 |
| 10% Contingency | \$29,700.00 |
| Total | \$326,700.00 |

Appendix I – Statement of Qualifications

AARON A. HIGGS, B. Sc.

I, Aaron Ashwell Higgs, B.Sc. do hereby certify that:

I am currently employed as a Senior Geologist by Bootleg Exploration Inc., with business location of Suite 200, 16-11th Ave S., Cranbrook, BC, V1C 2P1 (Telephone: 250-426-0749, email: aah@eagleplains.com)

I graduated with a B.Sc. degree in Geology from the University of British Columbia in 2005.

I have worked as a Geologist in Western Canada for 4 years since my graduation from university.

I am responsible for the preparation of this report entitled "Geological and Geochemical Report for the Hit Property, February 4, 2010".

Dated at Cranbrook, British Columbia, Canada this 4th day of February, 2010.

Respectfully submitted

Aaron A. Higgs, B.Sc. (Geol)

| TOTAL EXPENSES | | \$21,037.72 |

Appendix III – Geochemical Protocol

3.1 Field Sampling Techniques

3.2 Analytical Techniques

APPENDIX 3.1 FIELD SAMPLING TECHNIQUES

All 2009 samples were collected by Bootleg Exploration Inc. employees. The sampling process is standardized and continually monitored for quality assurance and quality control. Two types of samples were collected during this program, soil and rock samples. All samples are described in a digital form on a Palm Pilot in the field at the time of collection and also have a GPS location recorded at the site. Sample data was also recorded in field books and locations plotted on field maps as a backup to the digital forms. Upon return to town, the digital forms are uploaded to a relational database where quality control is conducted to assure all pertinent attribute information has been recorded and the spatial coordinates of each sample is correct.

Rock Samples

Rock samples were collected on sampling and mapping traverses where mineralization was noted. Transported rock materials were sampled as Float, Talus or Subcrop rock sample types, depending on the perceived distance the rock had travelled from its source. Rocks were collected from outcrops as fist sized Grab samples, or as Channel samples. In each case rock samples are recorded on the digital forms with a spatial location and a variety of attributes which include: map unit, major rock type, minor rock type, colour fresh, colour weathered, texture, grain size, mineralization major and mineralization minor. All samples were shipped in plastic rice bags.

Soil Samples

Soil samples were collected from pits dug with geo-tools to an average depth of 10-20 cm. Where possible the soil sample was collected from the B-Horizon of the soil profile. Attribute data collected for each soil sample included: sample size, quality, depth, slope of sample site, soil horizon, colour and other notes. Sample size is rated from 1-5 with one being much too small sample size and 5 being the perfect sample size, filling roughly $\frac{3}{4}$ of the sample bag. Quality of the sample rated from 1-5 with 1 being very poor quality and 5 being excellent quality. Factors that include: sample size, soil development and quality (the lack of organics), and depth of sample all contribute to the overall quality attribute.

Analytical Procedure Assessment Report

Eco Tech Laboratory Ltd. is registered for ISO 9001:2008 by QMI Quality registrars for the "provision of assay, geochemical and environmental analytical services". Eco Tech also Participates in The Canadian Certified Reference Materials Project (CCRMP) testing program annually.

SAMPLE PREPARATION

Samples (minimum sample size 250g) are catalogued and logged into the sample-tracking database. During the logging in process, samples are checked for spillage and general sample integrity. It is verified that samples match the sample shipment requisition provided by the clients. The samples are transferred into a drying oven and dried.

Soils are prepared by sieving through an 80-mesh screen to obtain a minus 80-mesh fraction. Samples unable to produce adequate minus 80-mesh material are screened at a coarser fraction. These samples are flagged with the relevant mesh.

Rock samples are crushed on a Terminator jaw crusher to -10 mesh ensuring that 70% passes through a Tyler 10 mesh screen.

Every 35 samples a re-split is taken using a riffle splitter to be tested to ensure the homogeneity of the crushed material.

A 250 gram sub sample of the crushed material is pulverized on a ring mill pulverizer ensuring that 95% passes through a -150 mesh screen. The sub sample is rolled, homogenized and bagged in a pre-numbered bag.

A barren gravel blank is prepared before each job in the sample prep to be analyzed for trace contamination along with the processed samples.

ASSAY GOLD ANALYSIS (BAUFA-32)

A 30 g sample size is fire assayed along with certified reference materials using appropriate fluxes. The flux used is pre-mixed, purchased from Anachemia which contains Cookson Granular Litharge. (Silver and Gold Free). The ratios are 66% Litharge, 24% Sodium Carbonate, 2.7% Borax, 7.3% Silica. (These charges may be adjusted with borax or silica based on the sample). Flux weight per fusion is 120g. Purified Silver Nitrate is used for inquartation. The resultant dore bead is parted and then digested with nitric and hydrochloric acid solutions and then analyzed on an atomic absorption instrument (Perkin Elmer/Thermo S-Series AA instrument). Gold detection limit on AA is 0.03-100 g/t. Any gold samples over 100g/t will be run using a gravimetric analysis protocol.

Appropriate certified reference material and repeat/re-split samples (Quality Control Components) accompany the samples on the data sheet for quality control assessment.

GEOCHEM GOLD ANALYSIS (BAUFG-11)

A 15 g sample size is fire assayed along with certified reference materials using appropriate fluxes. The flux used is pre-mixed, purchased from Anachemia which contains Cookson Granular Litharge. (Silver and Gold Free). The ratios are 66% Litharge, 24% Sodium Carbonate, 2.7% Borax, 7.3% Silica. (These charges may be adjusted with borax or silica based on the sample). Flux weight per fusion is 120g. Purified Silver Nitrate is used for inquartation. The resultant dore bead is parted and then digested with nitric and hydrochloric acid solutions and then analyzed on an atomic absorption instrument (Perkin Elmer/Thermo S-Series AA instrument).

Over-range geochem values (Detection limit 5-1000ppb) for rocks are re-analyzed using gold assay methods (see below).

Appropriate certified reference material and repeat/re-split samples (Quality Control Components) accompany the samples on the data sheet for quality control assessment.

TRACE ICP-MS ANALYSIS (BMS-11)

Samples are digested in an aqua regia solution for 45 minutes. They are bulked with de-ionized water, and an aliquot of this is taken for analysis a Thermo Scientific X series II ICP-MS unit. All synthetic standards are purchased and verified by 3 independent analysts and are used for instrument calibration before each and every ICP-MS run.

A 2-3 point standardization curve is used to check the linearity (high and low). Certified reference material is used to check the performance of the machine and to ensure that proper digestion occurred in the wet lab. QC samples are run along with the client samples to ensure no machine drift or instrumentation issues occurred during the analysis of the sample(s). Repeat samples (every 10 or less) and re-splits (every 35 or less) are also run to ensure proper weighing and digestion occurred.

Results are collated by computer and are printed along with accompanying quality control data (re-splits and standards). Results are printed on a laser printer and are faxed and or mailed to the client.

Appendix VII – XRF

7.1 XRF Techniques

7.2 Rock XRF Geochemical Results

7.3 Soil XRF Geochemical Results

Appendix 7.1 – XRF Techniques

Sample Preparation

The soil samples collected at the Hit property were first completely dried while in the original soil bags. The samples were then sieved to a less than 250µm size; a minimum of 1 teaspoon of this fine fraction was placed in a labeled thin plastic bag (e.g. Ziplock bag). Rock samples were sent to the prep lab in whitehorse to be crushed and pulverized. A 30 g portion of the pulp was then placed in a Ziplock bag for XRF analysis.

XRF Analysis

Samples were analyzed using an Niton XL3t handheld x-ray fluorescence (XRF) analyzer. The ziplock bags were shaken to compact the sample in a bottom corner of the bag and this was then positioned under the XRF analyzer window. Samples were analyzed for a total of 90 seconds using 3 filters for 30 seconds each. Results were downloaded to the Bootleg database at the end of each day and quality assurance and quality control procedures were conducted.

Quality Control Quality Assurance

The integrity of the XRF analyzer was tested daily by verifying calibration of the analyzer, analyses of blank samples and standards. As an internal QAQC function, the Niton XL3t will not function if the calibration of the fails. Blanks and standards are compared to assure they are within the accepted range of values provided by the standard supplier. Duplicate samples were analyzed approximately every 25 samples and results were compared nightly.
