YMIP Grant **10-069**

A Summary Technical Report on the Alberta-Rosebud Projects Of a Focussed Regional Module, Hard Rock Type

A Geochemical/Geological Report

Claims staked under this grant:
In the Alberta Creek Project Area
AC 1 to AC 98, AC 97A, AC 98A, AC99 to AC 126
Grant Numbers AD64152 to AD64280
Owner: Gordon Richards

Location
Alberta Creek Area: 115O/01 and 115J/16
Camp UTM 636,618/6,987,364 NAD83 Zone7, Elev 760 m
Rosebud Area: 115O/01
Camp UTM 642,478/7,009,737 NAD83 Zone 7, Elev 1143 m

Grant awarded to Gordon Richards
Work performed by Gordon Richards and Jeff Mieras

TABLE OF CONTENTS

SUMMARY

Work described in this report was conducted under a YMIP Focussed Regional Grant, Hardrock Type. YMIP No is 10-069.

The original proposed project areas were Alberta Creek Project Area (NTS 115O/01) and Clarke-Preacher Project Area (NTS 115O/02). On June 4, 2010 the applicant checked the areas for recent staking in the offices of the Dawson Mining Recorder. He found that the Clarke-Preacher Project Area had been recently staked and so substituted the Rosebud Project Area (NTS 115O/01) with approval by Danielle Heon and Mike Burke. The possibility of recent staking of one or both of the project areas had been considered by the applicant so the Rosebud Project Area had been reviewed in Whitehorse on June 3, 2010 with Danielle Heon and Mike Burke.

The applicant flew by helicopter June 5 to the Alberta Creek Area and began staking the area as the possibility of others staking this ground was considered high. A camp was established from which staking was completed followed by soil sampling at 100 m intervals along widely spaced lines. Geological information was collected from outcrops, float, and chips in soil pits. A “cat” trail estimated to be about 20 years old was seen passing through the camp area. Cat work was noticed at the pingo two km west of camp. A placer test cut that appeared not to have reached bedrock was seen two km northwest of camp along an east flowing creek. An old camp of the same age was seen near the present camp. The area lies in unglaciated terrane so float and soil chips are considered to be sourced locally.

On June 15 personnel and camp were moved by helicopter to a ridge top in the centre of the Rosebud Area. Similar soils and geological information were collected there. Here the ridge line is shown on government maps as unglaciated with lower slopes shown as having undergone pre Reid glaciations older than 200,000 years. On June 21 camp, personnel, samples and garbage were flown by helicopter back to Dawson where samples and gear were sorted and claims recorded ending the fieldwork portion of the grant.

Following is a description of the claims staked, geochemical survey, geological survey, results, and conclusions and recommendations for the two project areas. Detailed maps are appended.

ALBERTA CREEK PROJECT AREA

Claims:

128 Quartz Claims were staked June 5, 6, 8, 10, and 11 in an easterly direction along east-west UTM grid lines prior to collection of soil and rock samples. The claims are the AC 1 to AC 98, AC 97A, AC 98A, AC99 to AC 126. Grant Numbers are AD64152 to AD64280 respectively. All claims are held by Gordon Richards. The claims were optioned to Pacific Ridge Exploration after results were obtained.

Geochemical Survey:

202 soil samples were collected June 7, 9, 12, 13 and 14 by auger from C-horizon at depths of 50 to 100 cm. Loess was present at all sample sites at thicknesses of 10 to 30 cm starting near surface beneath a thin organic layer. Sampled material was placed into numbered gusseted kraft sample bags and filled the bags about three quarter full. Similarly numbered flagging was place on nearby vegetation. Sample location was recorded as a UTM co-ordinate, Zone 7 (NAD 83) on a handheld Garmin GPSmap 60Cx. Every tenth UTM co-ordinate was also recorded in notebooks as a backup in case of loss of the GPS unit or loss of data stored on the unit. No loss occurred. Soil colour and rock type when available was also recorded along with slope of sample site and dampness of sample. Samples were collected at 100 m intervals along widely spaced lines as shown on the accompanying detailed map. Sometimes 100 m interval was prevented by rocky soil. Such rocks were described in notebooks and that information placed on the map.

During the course of the above soil sampling, two stream sediment samples, A113 and A114, were collected from streams in the east part of the surveyed area. They are shown as soils on the accompanying map but are actually streams. They were collected by a plastic trowel from active sediment beneath water in the centre of the streams. These samples were placed into gusseted kraft sample bags and filled the bags completely.

Also collected were 11 rock chip samples of float as described below. These samples, weighing from 0.11 to 0.28 kg, were also placed into gusseted kraft sample bags.

All samples were stored in 28 cm by 50 cm by 3 mm thick plastic bags for handling. After removal from the project areas, they were stored in a truck owned by the applicant and eventually driven to Acme Analytical Laboratories Ltd, 1020 Cordova St East, Vancouver, B.C., V6A 4A3 for analyses. Soil and silt samples were dried at 60 degree C, sieved up to 100 g to minus 80 mesh. Rock samples were crushed to 80% passing a 10 mesh screen, from which 500 g is split (all, in this case because of the small sample size) and pulverized to 85% passing a 200 mesh screen.

Analytical method was Acme's 1DX on a requested 15 g sample size. In this method sample splits of 15 g are leached in hot (95degree C) Aqua Regia and analyzed by ICP-MS. Results are reported for 41 elements in ppb, ppm or % depending on the element in question as shown on the Certificate of Analyses provided by Acme Labs. An attached Appendix provides results in original format and also attached to GPS co-ordinates of all sample sites as described above.

Geological Survey:

Outcrops, float and soil rock chips were used to build a geological map as shown on the attached detailed sample location map. The limit of a marble unit was determined using calcium values from soil samples in excess of one percent calcium.

Metamorphic rocks include gneiss, schist and marble. Float of gneiss is often quartz-feldspar-hornblende±biotite gneiss with a colour index of 10-20 and a strong foliation. More mafic gneisses are not uncommon. Garnet is present in some samples. Micaceous samples have also been noticed. Quartz rich gneisses including quartzite were noted on the hillside sampled by C92 to C97. Intrusive float was also noted at a few sites as noted on the sample location map. Gneissic units of like compositional type have not been mapped in any detail. The gneiss that lies east of the quartz monzonite intrusion described below are much finer grained and much more mafic and uniform in their composition and colour that the gneisses to the west. They are dark green and well foliated. They may be part

of an ultramafic package of rocks that have a pronounced magnetic high on the government aeromagnetic map. The contact with the quartz monzonite stock may be a fault. The marble unit shown on the map is probably not a uniform marble unit but made up of lenses and layers of marble within the unit shown. Where seen the marble is fine-grained and clean. Limits of the unit were based on using the 1% calcium limit of soil sample results. The unit is from 200 to 600 m wide and has been traced over a four km length. It appears to be truncated by the quartz monzonite stock.

The metamorphic rocks have been intruded by an unmetamorphosed potassium feldspar phyric biotite-hornblende quartz monzonite possibly of the Early Jurassic Aishihik Suite or the Middle Cretaceous Whitehorse Suite as mapped and described by Colpron and Ryan to the east on Geoscience Map 7. It lies in the eastern third of the project area as shown on the map. It contains pink and white feldspars, quartz and hornblende (up to ten percent), lesser biotite and less than one percent potassium feldspars to three cm long. Foliation is not common but present. All exposures and float are unaltered.

Quartz-eye rhyolite outcrop and float occurs over two large areas, one in the extreme northeast of the area and the other in the southernmost part of the area. It is characterized by generally small (<1mm) quartz eyes in an aphanitic very pale creamy-tan coloured groundmass. Following are rock descriptions from the northeast occurrence.

A91 quartz eye rhyolite boulder.

A92 bedded(?) siliceous hematitic rhyolite.

A93 Mn stained siliceous quartz eye rhylolite

A118 Very siliceous bedded(?) rhyolite wuth minor fracture limonite.

A119 Siliceous rhyolite tuff(?). Hematite stained. At hanging wall contact of quartz-eye rhyolite.

A120 Siliceous breccias with 2% leached sulphide(?) At hanging wall contact of quartz-eye rhyolite.

A121 Rhyolite with 2 mm quartz veinlets. Some vuggy quartz. Low limonite-hematite. From centre of rhyolite exposures.

A122 Fragmental textured rhyolite with low limonite fractures.

A123 Quartz-eye rhyolite with 5% 1mm to much smaller quartz eyes. Some quartz eyes appear to be shards. Very minor feldspar phenocrysts.

The exposure in the northeast near A90 is particularly siliceous and glassy looking with a hematitic banded hanging wall over the one metre wide exposure here. Sulphide content is everywhere low to absent. The exposure in the south downslope from A117 contains at least one dykelet about 20 to 50 cm wide of feldspar porphyritic dacite to rhyolite. This rock unit is fresh and unaltered everywhere it has been seen. It is believed to belong to the Upper Cretaceous Carmacks Group known to be widespread in the Dawson Range.

Results:

The soil geochemical results provide strong encouragement for finding significant gold mineralization. The results can be divided into two groups: one with anomalous gold with support of other elements and a second group with no anomalous gold but strong multi-element anomalous values that could be fringing gold mineralization lying beyond the sample line. The following is a brief description of the selected anomalous geochemical targets starting with those that contain anomalous gold. Also one of two sulphur anomalies, this one without any anomalous pathfinder elements, occurs within the marble unit from samples A13 to A18.

1. A45 to A52 are anomalous for Au (4-78 ppb) with support from Mo, Pb, As and Sb over a 700m length. A rock chip from sample A52 contained a medium grained diorite with leached fracture sulphide. Nearest sample line is 600 m south where a single sample, A22, is anomalous for Au (61 ppb) with no support from other elements.
2. C65 and C66, 36 and 18 ppb Au, have anomalous Mo, Sb, and Se with modest As and Ag support. These samples lie along the south side of the marble unit.
3. C76 and C77, 26 and 14 ppb Au, have modestly anomalous Sb and one sample anomalous for Bi.

4. C7 and C8, 28 and 134 ppb Au, have no support from other elements and lie within the quartz monzonite stock. These values could be associated with a gold mineralized structure lying beneath the small gulley lying between the two samples.
5. A31 to A34, and C50, 57, 8, 16, 11, and 12 ppb Au have modest partial support from Sb and W.
6. C51 and C52, 126 and 15 ppb Au, have some Sb and modest Se and W support. The samples are well removed from other samples. They are located near the quartz monzonite contact with mafic gneiss.
7. A113, 24 ppb Au, is a single stream sediment with only modest W support lying at the south end of sampling collected in a creek with abundant quartz-eye rhyolite.

Two areas with no anomalous gold could be fringing gold mineralization beyond the limits of sampling.

8. C27 to C32 are unique in having anomalous S with values of 0.07 to 0.28 %S above a persistent background of <0.05 %S. The samples are also partially anomalous for Mo, Pb, Se, As, Sb, and Bi.
9. A76 to A98 are partially anomalous for Mo, Cu, Pb, Ag, Sb, As, Bi, and Se. Cr is anomalous in many of these samples and Ni values are elevated. Anomalous Cr and Ni are probably related to the underlying mafic to ultramafic gneiss seen in some soil chips and the few available outcrops of this rock type. Outcrops of very siliceous rhyolite were sampled by rock chips A091 to A099 and A118 to A123. See descriptions above. Results of these rock chips were anomalous for the same elements as the soils thereby explaining a probable source. Whether or not this area leads into gold-bearing mineralization further east and or north remains a possibility.

Conclusions:

Amphibolite grade metamorphic rocks including a 200 to 600 m wide marble unit trend northwest across the project area. These rocks are intruded by

an Early Jurassic or Middle Cretaceous locally foliated potassium feldspar phyric hornblende quartz monzonite and by an Upper Cretaceous quartz-eye rhyolite.

Soil samples collected at 100 m intervals along widely spaced lines and one stream sediment sample define 7 zones of anomalous gold with variably anomalous pathfinder elements that include Mo, Pb, As, Sb, Bi, W, and Se. Two other zones of the same variably anomalous elements and also S could lead into areas of anomalous gold with underlying gold mineralization.

The area is unglaciated so that the source of the anomalous metals is believed to be very local.

Recommendations:

Additional soil sampling is recommended over and around the zones of anomalous gold in soils defined above. Additional soil sampling is also recommended adjacent to the two zones of anomalous pathfinder elements that lack anomalous gold. Geological information should be collected wherever possible.

ROSEBUD PROJECT AREA

Geochemical Survey:

131 soil samples were collected June 16 to 21 by auger from C-horizon at depths of 50 to 100 cm. Loess was present at all sample sites at thicknesses of 10 to 30 cm starting near surface beneath a thin organic layer. Method of collection, storage, shipment and analyses was as described above under Alberta Creek Project Area.

Also collected were 5 rock chip samples of float as described below. These samples, weighing from 0.11 to 0.33 kg, were also placed into gusseted kraft sample bags.

Geological Survey:

Outcrops, float and soil rock chips were used to build a geological map as shown on the attached detailed sample location map.

Float and outcrop seen along ridgeline soil surveys were primarily gneisses with minor intrusive exposures. The resistant gneisses were comprised of variable amounts of feldspar, hornblende, biotite, and quartz with minor garnet. Soil pits found considerable muscovite in some areas as indicated on the accompanying sample location map.

A potassium feldspar porphyritic “granite” with 5 to 15 percent potassium feldspar phenocrysts occurs in two areas. The groundmass is chlorite rich and foliated and the Kspar phenocrysts are augen-like. Kspar lamellae are also present in the groundmass of some samples. These bodies do not appear to be extensive judging from the angular gneissic float commonly encountered on the survey lines.

Results:

Geochemical results of the soil and rock samples were disappointingly low for all elements. It is difficult to glean any interesting results from the analyses.

Conclusions:

The area is underlain by gneisses and schists similar to rocks encountered on the Alberta Creek Project Area except that no marble or mafic-ultramafic gneisses were encountered.

Soil samples collected at 100 m intervals along ridge lines did not return any anomalous metal values.

Recommendations:

No further exploration is warranted in the immediate vicinity of the project area.
