1.0 SUMMARY

Hyland Gold is an advanced gold prospect consisting of 927 quartz mineral claims totaling 18,620 hectares located approximately 70 kilometres northeast of Watson Lake, in extreme Southeastern Yukon. The property is wholly owned by Banyan Gold Corp.

Work on and around the property has been ongoing since the late 1800's however most work prior to the early 1980's was focused on base metal mineralization. The potential for gold mineralization was first recognized by 1981 when anomalous arsenic-bismuth-gold soil geochemistry was discovered at the Main Zone and the CUZ anomaly areas. Ensuing exploration through the 1980's, 1990's and into the early 2000's consisted of extensive geochemical soil sampling, staged geophysical surveys (airborne and ground-based), diamond drilling, reverse circulation drilling and bulldozer trenching.

Historically, two areas, the Main Zone and the CUZ anomaly, have been the focus of most exploration to date. The Main Zone consists of a ~3.2 km long north trending zone of anomalous gold, arsenic and bismuth in soil. Diamond drilling has encountered gold mineralization in drill core in both an oxide and sulphide facies. The CUZ Anomaly is located 4 km south of the Main Zone and is defined by a 700 m by 400 m soil geochemical anomaly that has been tested by limited diamond drilling.

Sax and Carne (1990) reported that "the oxidized core of the Main Zone is estimated to contain a resource of about 3.2 million tonnes grading 1.1 g/t gold", and this estimate gives a general indication of the amount of oxidized mineralized material defined thus far in the Main Zone.

In 2012, and based on 2 seasons (2010-2011) of diamond drilling by Argus Metals Corp., a National Instrument ("NI") 43-101 compliant resource estimate was completed on the Main Zone of the Hyland Gold Property. Argus reported an Inferred Mineral Resource, at a 0.6 g/t gold equivalent ("AuEq") of 12,503,994 tonnes containing 361,692 ounces gold at 0.9 g/t and 2,248,948 ounces silver at 5.59 g/t. (Gray and Armitage, 2012).

In 2011, Argus Metals' diamond drilling program resulted in the first ever *in situ* gold mineralization discovery at the CUZ Zone. DDH HY-12-37 returned 4.5 m grading 1.93 g/t gold from 25.9 to 30.4 m and 4.5 m grading 0.65 g/t gold from 10.5 m to 15 m in the CUZ Zone discovery hole. Drillhole HY-11-36, 6 m grading 1.38 g/t gold from 9.0 to 15.0 m and 1.5 m grading 1.52 g/t gold from 25.50 m to 27.0 m located 80m northwest of discovery hole HY-11-36. Drillhole HY-11-38 with 3.6 m grading 1.12 g/t gold from 16.4 to 20.0 m, located 240m northwest of discovery hole HY-11-36. These three drill holed extend CUZ Zone mineralization over 240 of east-west strike in a previously defined as a soil anomaly.

Gold mineralization discovered at CUZ Zone during the 2011 drilling program has demonstrated mineralization continuity over 800m on a West-Northwest trend and remains open at both ends and down-dip. This gold mineralization has been interpreted to be distinct from the Main Zone Gold mineralization as there is a significantly lower silver component than the Main Zone. The CUZ Zone mineralization therefore is interpreted to represent a secondary (cross-cutting) structurally hosted mineralized component of the Hyland Property and re-affirms Banyan's interpretation that these secondary structures (and their intersections with the dominant north-south Quartz Lake Lineament) may offer important exploration targets for future work on the Property.

Coincident with Argus Metals 2011 Main Zone focused diamond drilling program, Argus Metals conducted a suite of ridge and spur soil geochemical sampling programs totaling 1,754 soil sample (and complementary watershed silt sediment sampling program – totaling 129 samples) on the recently staked (Fall-Winter 2010) Hyland Extension Claims. These Hyland Extension claims were staked to target gold mineralization targets distal to the Main Zone and related to cross-cutting (secondary) East-West structural intersections with the main North-South Quartz Lake Lineament as defined from a detailed regional geochemical stream sampling analysis (consisting of RGS + project proprietary silt sample data). These heavily under-explored portions of the claim package are prospective for discoveries of gold +/- silver mineralization, and following up on the defined ridge/spur and watershed gold/arsenic geochemical anomalies from the 2011 program was the main focus of Banyan's 2013-2015 exploration programs.

Banyan's 2013 geochemical exploration program consisted of four detailed soil grids, following up on defined ridge and spur anomalies, and two ridge and spur soil sampling runs designed to follow up on geochemically anomalous silt samples. Each of these grids and ridge and spur programs was successful in delineating and expanding historic gold-in-soils anomalies and has in particular, resulted in the discovery of an open and coincident gold/arsenic-in-soils anomaly designated as the Montrose Ridge Zone.

Banyan's 2014 geochemical sampling program was designed to extend the open 2013 Montrose Ridge soils anomaly in all directions as well as in-fill the areas between the Cuz South gold/arsenic-in-soils geochemical anomaly. The project also concentrated on rock sampling with the soils program. The program was successful in filling the unexplored areas between Montrose Ridge and Cuz South and moreover, extending and further defining the 2013 anomalous gold/arsenic-in-soils anomalies.

The 2015 Hyland Program represented the first ever heavy equipment supported exploration program Banyan has undertaken on the Project, and the first time since the early 1990's excavators and bulldozers were utilized on the Property. The successful March 2015 winter road mobilization of a D-6 Cat and PCS200 Excavator greatly enhanced the 2015 program by affording access construction (3.2 km) and targeted trench-based sampling (700m) of the Montrose Ridge Anomaly.

Preceding, and co-incident with, Montrose access construction, a systematic, XRF analysis soil sampling program (301 samples collected and analyzed) was conducted on the Montrose Ridge gold/arsenic-in-soils anomaly. This grid-based soil sampling program served to confirm XRF analyses effectiveness as well as in-fill and extend the 2013/14 Montrose Ridge anomaly. The 2015 XRF soils analytical work produced a strong 1.4 km long Bi/As in soils anomaly centred on the 2013/14 identified Au/As-in-soils anomaly at Montrose Ridge.

Subsequent to the completion and on-site analysis of the soil sample data from Montrose Ridge Zone, access construction and trench locations were determined and marked in the field; and finally excavated with the PCS200 Excavator. At the 2015 program conclusion, approximately 700m of trenches in 5 trenches were constructed along a 380 m strike length of the Montrose Ridge Soil anomaly (187 total chip and rock samples collected). The 2015 Montrose Ridge trenches were designed to cross-cut interpreted strike of the controlling structures as closely as possible. In all cases the trenches remain open in all directions with potential for hosting gold-mineralized structures.

Montrose Trench 2015 assay highlights include 6m of 4.4 g/t Au from 0-6m in Trench MT-15-01 including 2m of 13.1 g/t Au from 4-6m. Trench MT-15-01 also returned 24 m of 0.47 g/t Au from 18 to 42m, including 6m of 1.3 g/t Au from 36-42m. Trench MT-15-01 was 42 m long, however only 30m were sampled due to overburden conditions from 6m to 18m. Of the 187 samples collected and analyzed as part of the 2015 trench program, assays ranged from trace to 13.1 g/t Au and averaged 0.19 g/t Au. Selected chip and channel samples from the other trenches completed included 2.25 g/t Au, 1.35 g/t Au, 2.9 g/t Au and 1.3 g/t Au.

This, the first detailed rock sampling program at Montrose established a lack of a silver association with the Montrose Ridge gold mineralization. This is similar to the Cuz Zone, 2.5 km to the South of Montrose and fits with management's interpretation that both Cuz and Montrose represent a separate mineralized system from the Hyland Main Zone system, where an approximate 1:4 gold-silver ratio exits. This definition of repeated, multi-phased gold mineralization events on the Hyland Project further builds out the District-Scale gold system Banyan is working to demonstrate.

In 2016, a total seven trenches (two in the Camp Zone and five at Montrose Ridge) totaling 660 metres were excavated and sampled with 291 samples collected. Gold grades from these samples ranged from trace to 9.22 g/t Au and averaged 60 ppb Au. The gold mineralization identified in the Camp Zone trenches remains open in all directions. The 2016 trenching was successful in defining geometry and structure at Montrose Ridge and Camp Zones and positions the Company well for the 2017 exploration program.

This area of the Camp Zone had seen previous, but limited trench sample campaigns in the 1980's by Archer-Cathro, however these efforts did not produce long continuous gold mineralized results such as this year's trench CZ-16-01. It is postulated that the excavator utilized for this season's trench excavations afforded better depth penetration than historic trench efforts, and samples that are more representative have thus been collected and analyzed. Further trenches in the Camp Zone area are highly warranted.

Trench CZ-16-01 returned 96 metres of 0.64 g/t Au from 0 to 96 metres, including **56 metres of 1.03 g/t Au from 0 to 56 metres.** This trench was excavated in the Camp Zone and was designed to test a previously untested portion of a zone interpreted to host the mineralized north-south trending Quartz Lake Corridor, the >18km long structure that is believed to control gold mineralization on the Hyland Gold Project. Trench CZ-16-01 intersected a broad fault zone consisting of predominantly gouge and brecciated clastic units of the Hyland Formation within the mineralized interval.

Coincident with the trench and diamond drilling program at Hyland in 2016, a soils geochemical program focused on expanding the soil coverage around the Montrose Ridge zone was completed. In total, 592 soils samples were collected from these efforts, all of which were analyzed by XRF Instrumentation. The results continue to define strongly anomalous As+Bi trends and correspond well with the soil geochemical data Banyan has previously collected. These geochemically anomalous trends are interpreted to represent mineralized structures that can now be followed up with trenches and drill holes. XRF results for Bi ranged from trace to 626 ppm Bi and averaged 10 ppm Bi; As results ranged from trace to 541 ppm As and averaged 21 ppm As.

As previously demonstrated at the Hyland Project, soils geochemistry continues to be highly useful in delineating areas of potential gold mineralization, particularly with respect the As-in-soils element analysis. In specific, Montrose Ridge, which returned anomalous gold/arsenic-in-soils point data from a 2011 ridge and spur traverse was identified as highly anomalous in Gold and Arsenic from the 2013 program and further expanded from the 2014-2016 programs. This area represents a new, high priority target for follow-up exploration and more detailed mapping and sampling. This newly identified area is located ~6.5km south of the Main Zone and extends from CUZ Zone, with the most intriguing soils responses developing from ~2km south of the Cuz Zone.

Hyland Gold's regional potential, particularly along the Quartz Lake Lineament, has begun to be tested by the last three season's soil sampling programs. As (+/- Au) in soils have proven to be reliable indictors of potentially mineralized corridors and establishing vectors thereon. Results to date merit detailed follow-up exploration including access construction and targeted trenching of the CUZ South and Montrose Ridge zones. Additionally, continued soils collection is recommended to advance the Quartz Lake Lineament exploration through Hyland South. The litholigies known to outcrop in Hyland South are permissive of gold +/- silver mineralization and more exploration work to define this potential is warranted in any following mineral exploration programs.

2.0 INTRODUCTION

The 2016 Hyland Program continued where the 2015 program left off with utilizing the heavy equipment available on site as well as a parallel geochemical sampling program. The Montrose Ridge Zone was the focus of both trench and geochemical sampling efforts, and the Camp Zone was the focus of trench based sampling.

A 20 Day, YMEP supported mineral exploration program designed to follow-up on the 2015 Montrose Ridge trench discovery and extend the gold/arsenic-in-soils anomalies defined in the 2013-2015 in the Montrose Ridge Zone was conducted by Banyan Gold from September 2 through September 22, 2016.

The 2015 Hyland Program expanded upon the 2015 Montrose Ridge Trench discovery with the D-6 Cat and PCS200 Excavator that were mobilized to Hyland in 2015.

Preceding, and co-incident with, the Montrose Ridge trench campaign, a systematic, XRF analysis based geochemical soils sampling program was conducted over, and extended from, the Montrose Ridge gold/arsenic-in-soils anomaly. This grid-based soil sampling program was served to confirm XRF analyses effectiveness as well as in-fill and extend the 2013-15 Montrose Ridge gold-bismuth-in-soils anomaly. Additionally, the Eastern Ridge Zone was also the focus of a grid based soils sampling program.

In total, 592 soil samples were collected from the Montrose Ridge and Eastern Ridge Zones during the 2016 exploration program. All soil samples locations were determined by GPS and analyzed by XRF instrumentation. A tabulated summary of all soil samples data collected with their raw XRF analyses is presented in Appendix D of this report.

The XRF Soils results continue to define strongly anomalous As+Bi trends and correspond well with the soil geochemical data Banyan has previously collected. In 2015, XRF-Chemical analyses of soils samples in the Montrose Ridge zone established a strong correlation with a bismuth-gold relationship. These geochemically anomalous trends are interpreted to represent mineralized structures that can now be followed up with trenches and drill holes. XRF results for Bi ranged from trace to 626 ppm Bi and averaged 10 ppm Bi; As results ranged from trace to 541 ppm As and averaged 21 ppm As.

As demonstrated over the past two exploration seasons at the Hyland Project by Banyan, soils geochemistry continues to be highly useful in delineating areas of potential gold mineralization, particularly with respect the As/Bi-in-soils elemental analyses; moreover this season's XRF analysis of same was proven to be extremely effective in reproducing chemical analytical results and this offers a useful, "real-time" approach to mineral exploration on Hyland and Hyland South going forward. In specific, Montrose Ridge, which returned anomalous gold/arsenic-in-soils point data from a 2011 ridge and spur traverse was identified as highly anomalous in Gold and Arsenic from the 2013/2014 program and was ultimately defined as a trench discovery in 2015. This rapidly emerging mineralized zone area is located ~6.5km south of the Main Zone and extends from CUZ Zone, with the most intriguing soils responses developed from ~2km south of the Cuz Zone.

In addition to the soils geochemical programs, a targeted trench excavation and sampling exploration program was undertaken in 2016. All together seven (7) trenches, two (2) in the Camp Zone and five (5) at Montrose Ridge totaling 660 metres were excavated and sampled with 291 samples collected and sent for chemical analyses. Trench CZ-16-01 returned 96 metres of 0.64 g/t Au from 0 to 96 metres, including **56 metres of 1.03 g/t Au from 0 to 56 metres.** This trench was excavated in the Camp Zone, north of the 2015 diamond drill holes was designed to test a previously untested portion of a zone interpreted to host the mineralized north-south trending Quartz Lake Corridor, the >18km long structure that is believed to control gold mineralization on the Hyland Gold Project. Trench CZ-16-01 intersected a broad fault zone consisting of predominantly gouge and brecciated clastic units of the Hyland Formation within the mineralized interval.

Gold grades from these trench samples ranged from trace to 9.22 g/t Au and averaged 60 ppb Au. The gold mineralization identified in the Camp Zone trenches remains open in all directions. The 2016 trenching was successful in defining geometry and structure at Montrose Ridge and Camp Zones and positions the Company well for the 2017 exploration program.

This area of the Camp Zone had seen previous, but limited trench sample campaigns in the 1980's by Archer-Cathro, however these efforts did not produce long continuous gold mineralized results such as this year's trench CZ-16-01. It is postulated that the excavator utilized for this season's trench excavations afforded better depth penetration than historic trench efforts, and samples that are more representative have thus been collected and analyzed. Further trenches in the Camp Zone area are highly warranted.

Much like at the Cuz and Montrose Ridge Zones, this season's trench sampling established a lack of a silver association with the Camp Zone gold mineralization. This fits with management's interpretation that these zones represent separate mineralized systems from the Hyland Main Zone gold-silver system, where an approximate 1:4 gold-silver ratio exits. This continues to affirm the concept of repeated, multi-phased gold mineralization events at the Hyland Project is consistent with a District-Scale gold system.

Continued mineral exploration across the property is encouraged as there is high potential to discover additional mineralized zones and structures.

This report presents the 2016 YMEP supported assessment work on the Hyland South project and satisfies 2016 YMEP reporting requirements.

3.0 PROPERTY DESCRIPTION AND LOCATION

The Hyland property consists of 927 claims totaling 18,620 hectares, as detailed in Appendix C, and lies approximately 70 km northeast of the Town of Watson Lake within the Watson Lake Mining District (Figures 1 - 4). The property is centred at 60.501^{o} north latitude; 127.851^{o} west longitude, near Roy Lake and Hulse lake (also known as Quartz Lake) and covered by NTS map sheets 95D/5 and 95D/12.

The office of the Yukon Mining Recorder lists Banyan as owner of 100% of all claims. The Property is subject to a 1% and 0.25% NSR on all claims payable to Cash Minerals Ltd and Strategic Metals Ltd respectively. Additionally, there is a 1% NSR on 88 of the claims payable to Adrian Resources Ltd. that is capped at $1.5 million.

The location of quartz claims in the Yukon is determined by the position of initial and final posts on the ground along a straight location line not exceeding 1,500 feet. None of these claims have been surveyed. The quartz claims confer rights to mineral tenure, whereas surface rights are held by the Yukon Territory.

Two areas of interest, the Main Zone and the CUZ Zone, occur on the Property and have been the focus of the majority of mineral exploration on the Property to date. The Main Zone consists of a ~3.2 km long north trending area of anomalous gold, arsenic and bismuth in soil. The anomaly deflects from northwest trending to north northeast trending roughly half way along its length. This area has been the focus of numerous exploration programs including geophysical and geochemical surveys, bulldozer trenching diamond and reverse circulation drilling. Gold mineralization in drill core has been encountered in both an oxide and sulphide facies. The CUZ Zone is located 4 km south of the Main Zone and is defined by a 700 m by 400 m soil geochemical anomaly that has been tested by very limited diamond drilling.

More recently, Hyland South and its Cuz South and Montrose Ridge Zones have become a more active exploration focus for the Project with focused 2013-2016 geochemical and geological programs undertaken thereon, inclusive of this reporting year.

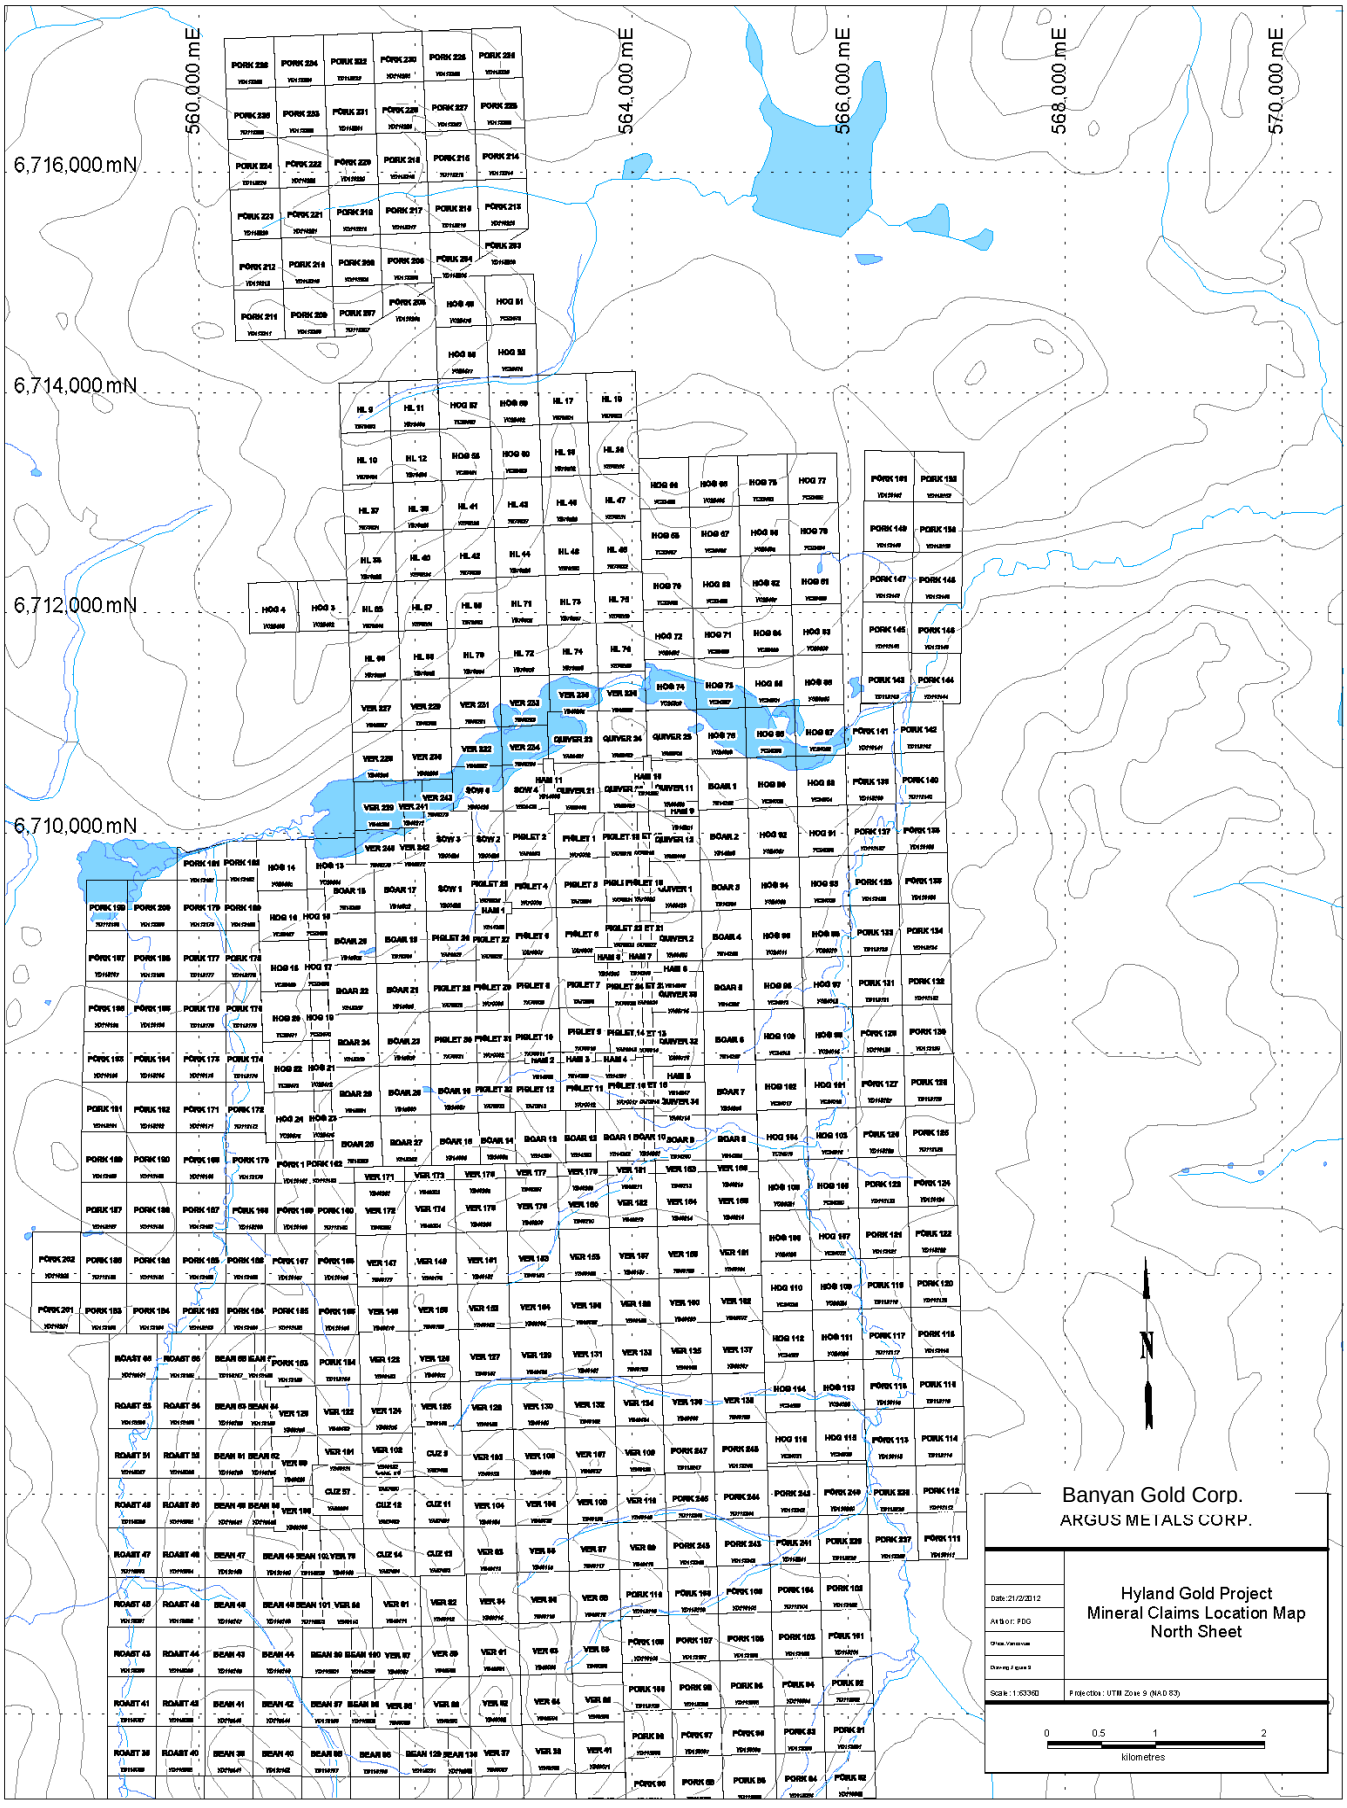

Figure 4: Tenure Map – South Sheet

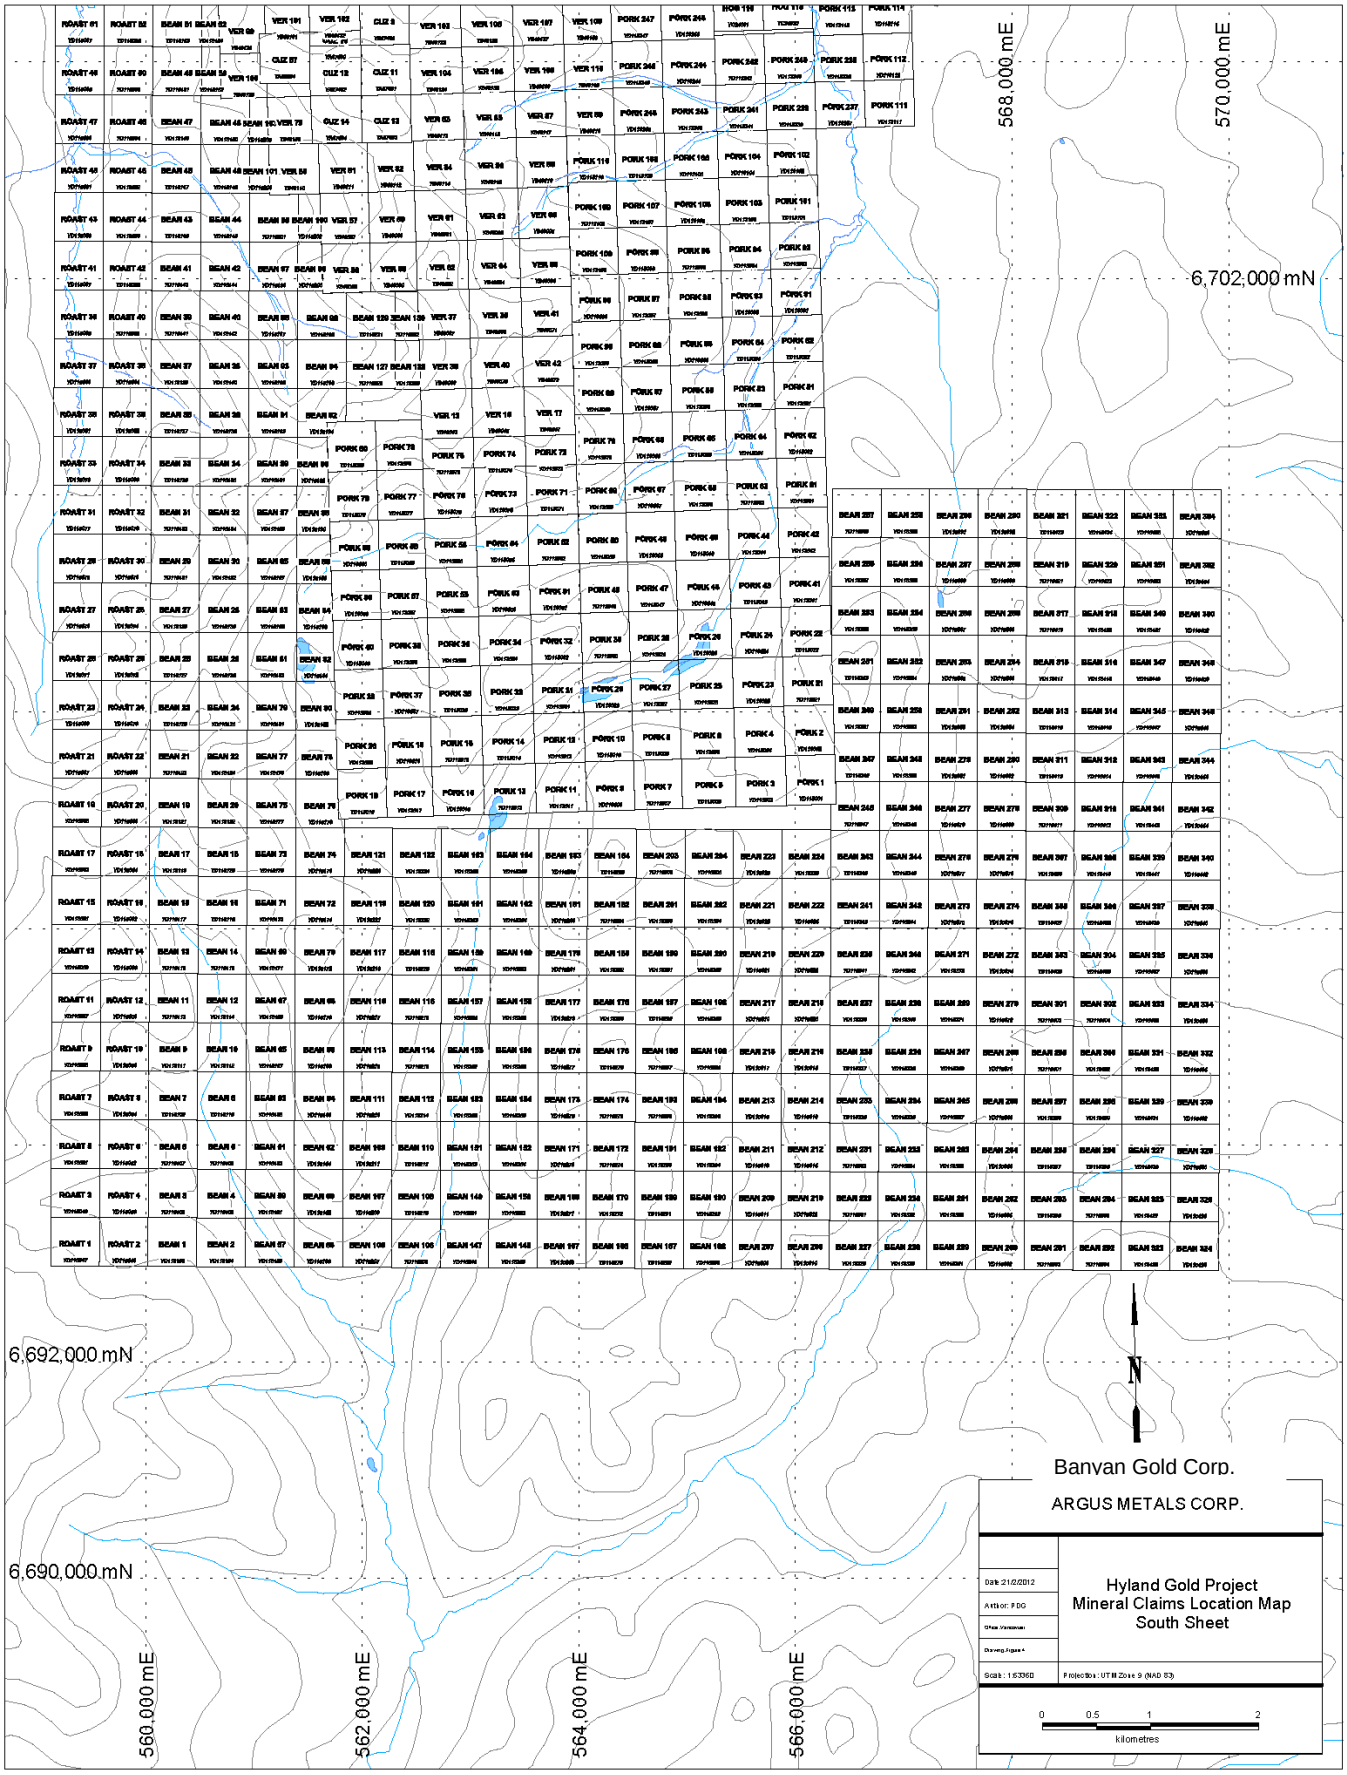

4.0 ACCESSIBILITY, CLIMATE, LOCAL RESOURCES, INFRASTRUCTURE, PHYSIOGRAPHY

The Hyland property is located in the southeast Yukon approximately 70 km northeast of Watson Lake on the Alaska Highway. The property is accessible by float plane from Watson Lake to Hulse Lake (Quartz Lake) or by helicopter from Watson Lake. A 40 km long winter trail built in 1989, and re-established in 2011, provides access to the property from the Coal River Road 35 km from the Alaska Highway. This access corridor is permitted for use under a Land Use Permit which was re-assessed and approved in 2015. Subsequent to the LUP Approval, the winter trail was utilized in March 2015 to mobilize the heavy equipment to support the 2015 Hyland Project Trench activities presented in this report. Both the Coal River Road and the winter road to the property are passable by 4x4 vehicles for most of the year except for a swampy section between kilometres 1 and 3 on the winter road. The winter trail connects to a network of drill roads over the Main Zone that leads down into the exploration camp on Hulse Lake. Vehicular access to the Cuz and Montrose Ridge Zones is available since trail construction in 2015 by Banyan.

A 35 man exploration camp is located on the south shore of Hulse Lake (Quartz Lake) and consisting of three, four man cabins and six, 4 man tent platforms. A Dry and Kitchen/dining facilities were constructed in 2011. Two storage sheds, a geology shack, a dedicated first aid building and core logging and cutting facilities complete the buildings on site. A compositing toilet and 16 kVA 220/110V generator round out physical infrastructure in the camp.

The Property covers moderately rugged terrain with elevations that range from 920 m on the shores of Hulse Lake to 1,830 m at the highest peak on the property. Treeline starts at approximately 1,450 m where alpine brush and vegetation give way to a mix of black spruce, alder, willow, pine, white spruce and moss depending on the moisture content and aspect of the slope. Subcrop is abundant above treeline with some outcrop below treeline however bedrock exposure is limited to small cliffs and creek cuts. The area underwent glaciation during the Pleistocene with ice movement from the north to the south. Till has been eroded from most steep north facing slopes but south and west facing hillsides display varying thicknesses of glacial debris. A prominent terrace of glaciofluvial material wraps around the hillsides at about 1,065 m elevation in the northern half of the Property.

The Hyland property is subject to a continental climate with long cold winters and warm dry summers. The average annual precipitation on the property is about 450 mm occurring mostly as rain in the warmer months. In the winter, the snowpack rarely exceeds 1 m in depth. Permafrost occurs irregularly across north facing slopes. The lakes are typically ice free and available to float planes by June and begin to freeze in early November.

5.0 HISTORY

Mineral Exploration in the area of the Hyland property was first spurred on in the late 1800's by the discovery of the Macmillan zinc-lead-silver deposit located 5 km west of the Hyland property. Since that time, the original 299 mineral claim package has been explored intermittently by several operators either simultaneously or sequentially. The area was first staked as the SN claims by Liard River Mining in 1954. The focus of their exploration was base metal mineralization similar to the nearby Macmillan deposit and to that end they employed a mix of geological mapping, hand trenching, soil sampling, an EM survey and diamond drilling (4 diamond drill holes). Results were not encouraging and the potential for gold mineralization was not investigated at the time thus the claims were allowed to lapse in 1955.

In July of 1973 the *Hyland Joint Venture,* composed of Marietta Resources International Ltd., Mitsubishi Metals Corp. and Messrs. Landon T. Clay and Harris Clay, re-staked a lead-zinc target near the Main Zone as the Porker 1-56 claims. Work completed by the joint venture over a three year period and ending in 1975 included prospecting, geological mapping, grid soil sampling, gravity surveys and diamond drilling (303 m in four drill holes). Results of this work outlined widespread arsenic anomalies with several high gold values. No further work was undertaken after 1976 and the claims were allowed to lapse in 1984.

In 1981, shortly before the Porker claims were set to expire, exploration in the area was beginning to focus on potential gold mineralization. Gold exploration on the property began in earnest with the staking of the Cuz and Quiver claims by Archer Cathro and Associates ("AC") on behalf of Kidd Creek Mines. These claims were staked to cover the gold-arsenic anomalies identified by the *Hyland Joint Venture* located south and east of the Porker claims. Kidd Creek Mines Inc. ("Kidd Creek") contracted AC to perform geological mapping and grid soil sampling the following year that defined a 450 m long Au-As-Bi geochemical anomaly on the Cuz property and scattered, weakly to moderately anomalous Au values on the quiver claims. No further work was done on the properties until Kidd Creek performed follow-up prospecting and rock sampling on the Cuz property in 1985. When a source for the anomalous gold-arsenic-bismuth geochemistry could not be located claim ownership was transferred to AC who had re-staked the expired Porker claims the previous year as the Piglet 1-32 claim group.

In 1986 AC acquired the Quiver claims north of the Piglet block and sold the entire property comprised of 88 claims to Silverquest Resources Ltd. ("Silverquest") who performed prospecting, soil sampling and hand trenching that same year. The following year the Hyland Gold Joint Venture (HGJV1), comprised of Silverquest, Novamin Resources Ltd. ("Novamin") and NDU Resources Ltd. ("NDU") carried out a program of soil geochemistry, bulldozer trenching and road construction. Novamin withdrew from the partnership in 1988 and was replaced by Adrian Resources Ltd. ("Adrian") as a joint venture partner. That year soil sampling and several ground geophysical surveys including magnetic, IP and EM were conducted with concurrent bulldozer trenching, diamond drilling (376 m in four holes) and road construction. The road construction continued into the early winter of 1989 culminating with the completion of a 40 km long winter road from the property to the Coal River Road. The winter road facilitated the mobilization of an RC drill rig in 1990 and completion of 3,656 m of RC drilling in 41 holes.

TRENCH PROGRAMS

All mechanized trenching on the property was carried out over the Main Zone in 1988 by E. Caron Diamond Drilling Ltd. of Whitehorse with a ripper-equipped Caterpillar D7E bulldozer. A total of 2,760 m of bedrock was exposed in 16 trenches, and 1,515 m of overburden was stripped from trenches that did not reach bedrock. Bulldozer trenches were cut across the Main Anomaly at approximately 100 m intervals over a 2,000 m strike length and across a few of the secondary anomalies.

All trenches that reached bedrock were continuously chip sampled along their floor or lower ribs. Samples were taken over 5 to 10 m intervals from all potentially mineralized exposures, except in particularly interesting areas where the intervals were shortened as required. Four hundred and thirty, 5 to 10 kg

samples were collected and sent to Chemex Labs Ltd. (now ALS –Chemex Laboratories Ltd.) where they were dried, crushed, ring pulverized, screened to -140 mesh and homogenized before a one assay ton split was taken and fire assayed for gold using a gravimetric finish. In addition to the rocks, 170 soil samples were collected along the bottom of trenches that did not reach bedrock in order to compare the geochemical response deep in the soil profile to that at surface. They were also sent to Chemex and analyzed for gold by the same geochemical technique outlined above for the 1986 surveys.

It should be noted that even within the Main Zone, many of the trenches did not reach bedrock along their entire lengths. Trenches cut through the Main Zone outlined a mineralized fault breccia complex approximately 1,000 m long by 200 m wide. The best trench exposure chip samples averaged **4.87 g/t gold over 30 m including 6.55 g/t over 20 m from trench P-36** near the centre of the complex. This particular interval coincides with a north – trending fault and consists of moderately graphitic gouge. True thickness of these mineralized intervals is difficult to determine as the sampling is across the core of an interpreted antiform and true thickness could vary from sample to sample.

Farther west in the same trench, seventeen chip samples taken over an 88 m width returned a weighted average of 0.81 g/t Au from an area cut by three large faults. To the east where overburden tended to be deeper, three chip samples averaged 1.84 g/t Au over 16 m.

Hemlo Gold Mines Inc. (“Hemlo”) optioned the property from Cash Resources Ltd. (“Cash”; a restructured and renamed Silverquest) in 1994 and in 1995 completed a geological mapping program followed by diamond drilling program of 439 m in three holes. The option expired without Hemlo earning an interest in the property. In 1998 Cash purchased United Keno Hill Mines interest in the property (having previously merged with NDU) and in 1999 further consolidated ownership of the Hyland Gold Property by purchasing Adrian’s portion.

In 1994, contemporaneous to Hemlo’s deal with Cash, Westmin Resources Ltd. (“Westmin”) became active in the area by staking 416 claims surrounding the Main and Cuz zones. Work by Westmin that year included an airborne geophysical survey, detailed geological mapping and soil sampling. Further airborne geophysical surveys (flown by Newmont for Westmin) and soil sampling was completed in 1995 that led to the staking of an additional 84 claims. The final exploration program completed by Westmin included geological mapping, rock sampling, reconnaissance soil sampling and power auger soil sampling. Expatriate Resources Ltd. (“Expatriate”) purchased Westmin’s interest in the spring of 1999 and conducted a small prospecting and sampling program that summer. (Tucker et al. 2003).

In March of 2000 a third joint venture was created to explore the Hyland Gold property with the following interests 55% Cash Minerals Ltd. (formerly Cash Resources), 31% Expatriate and 14% Strategic Metals. The following year the joint venture conducted a small exploration program consisting of re-mapping the bulldozer trenches, hand trenching and sampling of the geochemical anomalies identified by Westmin. By the end of January 2003 Expatriate had acquired 100% interest in the Hyland Gold Property and sold it in its entirety to Stratagold.

In 2003 Stratagold completed a program of diamond drilling totalling 2,416 m in 12 holes. The focus of the drilling was to intersect auriferous sulphides below the extensively explored oxide zone. Nine of the twelve holes encountered significant gold mineralization with the best results encountered in hole HY-03-002 returning 53.11 m of 1.38 g/t Au including 5.54 m of 4.24 g/t Au. In 2004 Stratagold completed 15.72 line kilometres of IP/Res surveying divided into six east-west trending lines over the main zone. Results of the geophysical survey were followed up with 1,800 m of diamond drilling in eight holes. Five of the holes drilled in 2004 intersected significant gold mineralization however the tenor of mineralization was lower grade than encountered the previous year with the best results encountered in hole HY-04-13 that returned 31.76 m of 0.633 g/t Au from a depth of 186.46 m. In 2005 Stratagold drilled four diamond drill holes for a total of 985 m focused on discovering new gold mineralization east of the Main zone and at the Cuz anomaly.

GEOCHEMISTRY

The Hyland Main Zone area has been covered by numerous soil and stream geochemical surveys from 1973 to 2011. All detailed soil sampling of the Main Zone was performed before there were any surface disturbances from road building, trenching or drilling. A brief history of the different surveys over the Main Zone follows.

The entire area of the original "Hyland Gold" core claims was sampled prior to 1986 by several generations of wide-spaced soil geochemical surveys. Arsenic analyses were carried out on soil samples collected in 1973-1975 from the -80 mesh fraction digested in nitric-perchloric acid and analyzed by Atomic Absorption Spectrometry (AAS). These samples were collected at wide-spaced grid intervals (60 by 245 m or 200 by 800 feet) and from regional-scale soil and stream sediment traverses across the entire property. Splits from these samples were reanalyzed for gold by Fire Assay pre-concentration for Neutron Activation Analysis (FA-NAA) during the spring of 1984. Soil sampling on the Quiver claims was carried out in 1982 at 30 m intervals along and in between the old 800 foot cut lines. These were analyzed for gold by FA-NAA on the –35 mesh fraction of the samples. Sample splits were later re-analyzed for arsenic, bismuth, lead, copper, tungsten and manganese by ICP (Induced Coupled Plasma) technique and for antimony using standard AAS techniques.

Soil samples collected on the Piglet claims in 1984 were screened to –35 mesh and pulverized to better than -100 mesh and analyzed by FA-NAA for gold. This procedure was used to minimize the anticipated effects of silica encapsulation of micro-sized gold in very fine detrital material. Rock samples were crushed and pulverized to better than -100 mesh and analyzed by the same method.

Detailed soil sampling carried out in 1986 covered a 3.3 km^2 area. Two thousand one hundred soil samples were collected at 30 m intervals on 60 m line spacings. Soil samples were screened to -35 mesh, pulverized to better than -100 mesh and analyzed for gold by FA-NAA. Every second sample also underwent a 30 element analysis by the ICP technique. All analyses from 1975 to 1986 were performed by Chemex Labs Ltd., North Vancouver, B.C. (now ALS – Chemex Laboratories Ltd.)

Results of geochemical surveys carried out in previous years on the Hyland Gold property have defined a 2 km long, northerly-trending zone (Main Anomaly) of strongly anomalous gold values, with coincident highly anomalous arsenic and bismuth soil geochemical response. This anomaly continues 1.2 km to the south east (Southeast Anomaly) with similar gold values but only weakly to moderately anomalous arsenic values. A broad zone of moderately anomalous gold and weakly anomalous arsenic spans the east part of the Main Zone (East Anomaly).

Geochemical background, threshold and maximum values for important chemical elements in the Hyland mineralizing system are tabulated below (Table 1).

Note, geochemical patterns and associations between bismuth, antimony, silver, lead, zinc, and manganese rely on observations made from historical data in map and report form not included in this document.

Table 1 Background and threshold values for important geochemical elements in the Hyland Property mineralizing system.

Element		**Background**		**Threshold**		**Maximum**
Gold		5 ppb		25 ppb		1,950 ppb
Arsenic		50 ppm		200 ppm		>1%
Bismuth		<2 ppm		4 ppm		546 ppm
Copper		15 ppm		50 ppm		309 ppm
Lead		35 ppm		50 ppm		380 ppm
Zinc		50 ppm		100 ppm		600 ppm
Barium		150 ppm		300 ppm		1,160 ppm

Antimony		<10 ppm		10 ppm		310 ppm
Manganese		200 ppm		600 ppm		>1%

Main Anomaly

Gold values in soils range from a threshold value of 25 to a maximum of 1,950 ppb. Arsenic values exceed 1% from a threshold of 200 ppm and bismuth values range up to 546 ppm with a threshold value of 4 ppm. The anomalous zone is terminated on the north by an area of deep glacial overburden. Bismuth anomalies closely follow gold anomalies with the strongest and most continuous values occurring along the Quartz Lake Lineament. Arsenic response follows the same trends as gold and bismuth, although the anomalies tend to be more widespread.

Antimony values are generally less than the 10 ppm lower detection limit of the ICP analytical technique used. Anomalous values (>10 ppm) cluster in isolated patches along the length of the Main anomaly with peak values to 310 ppm Sb. Silver response is weak and erratic with only localized anomalies present with individual values reaching 32.4 ppm Ag. Lead, zinc and manganese show a good inter-correlation with anomalous values clustering west of, and peripheral to, the elongate gold-bismuth-arsenic-antimony-silver Main anomaly. This pattern in the soil geochemistry is evidence of metal zoning from precious metal core to base metal periphery.

Southeast Anomaly

The Southeast Anomaly was not completely delineated by the 1986 grid sampling program. Gold and bismuth outline a 1.2 km long, 300 m wide southeast trending anomalous zone that is not associated with any obvious topographic feature but closely matches a northwest - southeast feature evident in the Newmont airborne magnetics survey. Arsenic values in soils from the Southeast Anomaly are not as strong as those from the northern part of the anomalous trend. Peak values in soils along the South Anomaly exceed 100 ppb Au, 250 ppm As and 10 ppm Bi.

Antimony values are generally less than the 10 ppm lower analytical limit of the ICP analytical technique used. Scattered clusters of soil samples containing 10 ppm Sb are associated with the broader gold-bismuth anomaly although no strongly anomalous values were detected. Silver response is generally low with large areas of weakly anomalous values to 20 ppm Ag. Lead, zinc and manganese response varies from threshold to moderately anomalous values. Unlike the North Anomaly, however, the distribution of lead, zinc and manganese anomalies generally follows that of the gold-bismuth-arsenic suite.

East Anomaly

The East Anomaly was not re-sampled during the 1986 survey so sample density is lower in this area and consequently the data was not contoured. Broad, discontinuous areas of moderate gold, arsenic, lead, zinc and manganese response resulting from the 1982 sampling program are not related to any known geological feature. Broad areas exceed the 25 ppb Au threshold with several spot values above 100 ppb Au.

Effective soil sampling in the Main Zone area is hampered by pockets of deep overburden in north – south trending gullies immediately east of the Main Anomaly and a thick glaciofluvial terrace that flanks the topographic high that the Main Zone soil anomalies are located on. To test for extensions of the Main Anomaly to the north, south and east would require power auger sampling to penetrate this cover. Similarly, increasing overburden depth on the East anomaly may, in part, be responsible for the decreased magnitude of the geochemical signature and power auger sampling would be an effective tool to test this.

The location of the Main Anomaly closely follows the main axis of the anticline along the Quartz Lake Lineament and is closely associated with the Lower Phyllite unit exposed in the core of this structure. Outcrop in the East Anomaly area is very sparse, and it is possible that the anomaly signature is lower in this area due to stratigraphic position within less favourable host rocks.

Similarly, testing the southern extension of the Main and Southeast Anomalies may be complicated by changes in stratigraphic position. Mapping suggests that as topography descends to the south, Lower Limestone units are exposed. It is well understood that these units form barriers to hydrothermal fluids in the Hyland system, but that significant mineralization in phyllites or quartzites beneath limestones is possible.

Additionally, several iterations of Property wide stream sediment sampling have been conducted on the Hyland Property.

DRILLING

Drilling on the Hyland property has focused primarily on the Main Zone and immediate area. Seven distinct drilling campaigns have tested the Main Zone area, specifically in 1988, 1990, 1995, 2003, 2005, 2010 and 2011. The 1988 program consisted of diamond drilling over the core of the Main Zone deposit. The 1990 program consisted of reverse circulation drilling over the core of the Main Zone deposit and to the north of it. The 1995 program consisted of diamond drilling to the north of the Main Zone deposit and off axis to the west of the Quartz Lake Lineament. The 2003 and 2005 core drilling programs focused on Main Zone targets as well as the Quartz Lake structural trend, north and south of the main Zone deposit. 2010 and 2011 core drilling campaigns targeted Main Zone mineralization as well as Au-As and Au-Bi soil anomalies to the east and south of the Main Zone deposit.

1988 Diamond Drilling

Four diamond drill holes totalling 375.8 m were drilled in 1988 by E. Caron Diamond Drilling Ltd. of Whitehorse. A unitized Longyear 38 drill was used and all holes were completed with either HQ or NQ equipment. Results from this program were severely hampered by recovery problems.

Core recovery was a severe problem, particularly in strongly oxidized breccia and gouge zones that contain extremely hard, quartzite fragments in a soft limonite or clay matrix. Recovery in the top 40 to 70 m of the holes was often as low as 1 or 2% and averaged about 20%. Most of the core that was recovered consisted of barren quartzite "marbles" without any of the mineralized matrix. Heavy mud mixtures were used in all holes in an attempt to improve core recovery and build up the walls of the holes. Unfortunately, the clays and limonite that made up the mineralized matrix were suspended in the mud and would not settle out in sludge samples.

The core was logged and mineralized intervals were split and sent to Chemex where they were dried, crushed, ring pulverized, screened to -140 mesh and homogenized before a one assay ton split was taken and fire assayed for gold using a gravimetric finish. Several of the most promising intervals were not sampled because recovery was less than five percent. The remaining core was stored on the property.

All holes were located within the fault-breccia complex and tested beneath some of the better trench intersections and are briefly described below.

Hole 88-1 tested downdip from a fault zone in Trench P-25 that assayed 2.25 g/t Au over 22.7 m. The hole cut a mixture of quartzites and phyllites that are well fractured and in places strongly sheared and brecciated. Recovery ranged from 0 to 100% but was generally less than 10% in sheared or brecciated intervals. The rocks are well oxidized to 45 m. The best assay was 2.19 g/t Au over 3.0 m from a highly pyritic horizon near the bottom of the hole.

Holes 88-2 and 88-3 were drilled in opposite directions from the same collar and explored beneath well mineralized intervals in Trench P-23. The upper half of Hole 88-2 cut a series of broad faults while the bottom half intersected fairly massive phyllite, siderite and limestone. The top half is totally oxidized but recovery averaged only about 10%. Most of the material recovered consists of rounded, barren quartzite

fragments. The best intersection from the hole was 3 m of 0.96 g/t Au compared 1.93 g/t Au over 45 m in the overlying trench.

Hole 88-3 appears to have been drilled downdip. Recovery was generally better than that obtained in Hole 88-2 but in two, 12m intervals no core was recovered. The rocks are a mixture of phyllites and quartzites and the base of oxidation is at 64 m. None of the assays from this hole exceeded 0.70 g/t Au even though the trench directly above it averaged 1.50 g/t Au over 52.3 m.

Hole 88-4 was drilled beneath Trench P-25 at the north end of the fault-breccia complex. The highest assay (1.17 g/t Au over 3 m) came from a quartz and pyrite rich band located 65 m downdip from a 5 m interval in the trench that assayed 2.23 g/t Au. The apparent dip of this zone is about 80^{o} toward the west.

1990 Reverse Circulation (RC) Percussion Drilling

A total of 3,656.0 m in 41 holes were drilled during the 1990 field season. 35 holes were drilled on 100 m sections over the core of the Main Zone, while 6 second phase holes were wide spaced step-outs drilled to the north of the Main Zone testing the continuity of mineralization. All work was carried out by E. Caron Diamond Drilling Ltd. of Whitehorse using a truck-mounted rotary percussion drill. Reverse circulation (RC) with a down-hole hammer was most often used; however conventional circulation was used to aid recovery in badly broken ground. Select drill intersections from the Main Zone deposit included 2.65 g/t gold over 16.7 m in PDH90-09 and 1.19 g/t gold over 129.7 m in PDH90-41. Select intersections from step out drilling to the north averaged 1.0 g/t gold over 13.7 m in PDH90-34 and 0.9 g/t gold over 33.6 m in PDH90-34.

2003, 2005 Core drilling Programs

During the summer of 2003 StrataGold conducted two phases of diamond drilling totaling 2,416 meters, to better understand and define the extension of the main north-south linear/fault structure known as the Quartz Lake Lineament. This structural feature appears to trend for at least 13 km and contains a 3.2 km long area of anomalous gold, arsenic and bismuth from soil geochemical surveys. A 2004 exploration program included a 15.72 line kilometer Induced Polarization/Resistivity (IP/res) Survey divided into 6 west-east trending lines and eight diamond drill holes totaling 1,800 meters. In 2005, exploration work consisted of four diamond drillholes totaling 985 meters, one which followed up on an IP/res geophysical target defined in 2004 and located east of the Main Zone, as well as targeting geochemical soil anomalies in the CUZ Anomaly Zone that are coincident with apparent structural features 4 km south of the Main Zone.

2010 and 2011 Drill programs

20 drill holes (3,953 metres, 5,591 assays) completed in 2010 and 2011 by Argus Metals Corp. In 2010 four diamond drilling holes were drilled in the Main Zone and north extension for a total of 765 m drilled in four holes from three sites. Apex diamond drilling of Smithers, BC ably performed the recovery of HQ and NQ sized drill core using a heli-supported drill rig. Significant results included HY-10-25 with 9.13m of 2.08 g/t Au and 13.51 g/t Ag and Hole HY-10-26 with 34.74 m of 1.1 g/t Au and 3.79 g/t Ag extending the main Zone mineralization to the east.

In 2011, 16 core recovery drill holes were drilled for a total of 3,218m of NQ and HQ drilling targeted the Main Zone deposit, and soil anomalies to the south and east of the Main Zone and one Vein hosted target south of the CUZ Zone. Candrill Global Ltd. of Tisdale Saskatchewan executed the program with a “A5” skid mounted drill rig. As in previous drill programs, recovery was difficult in the upper oxide zone, however through effective control of drill torque and water pressure, as well as reduced core increased core retrieval cycles there was a noticeable increase in recovery and competence of core material.

Significant results included HY-11-29, 39.4 metres of 0.80 g/t gold and 3.28 g/t silver from 71.6 metres to 111.0 metres depth, HY-11-31, 42.2 metres of 0.78 g/t gold and 2.38 g/t silver from 143.8 metres to 186.0 metres depth including 9.2 metres of 1.79 g/t gold and 0.36 g/t silver from 143.8 metres to 153.0 metres

depth and HY-11-30, 1.5 metres of 1.56 g/t gold from 75.0 to 76.5 metres (a zone of no recovery of 7.5 metres and then 3 metres of 0.33g/t gold and 11g/t silver

HY-11-41, 25.9 m grading 2.03 g/t gold and 6.42 g/t silver from 122.9 to 148.8 m within 144.3 m grading 0.54 g/t gold and 2.84 g/t silver from 3.0 to 148.8 m including 1.5 m of 11.7 g/t gold and 20.1 g/t silver at 131.2 m which extends Main Zone mineralization to depth and to the east. HY-11-40, 17.7 m grading 1.0 g/t gold and 8.0 g/t silver from 99.3 to 117 m which extends Main Zone mineralization to the east. HY-11-42, 21.0 m grading 1.1 g/t gold and 15.0 g/t silver from 48 to 69 m within 45 m of 0.65 g/t gold and 7.8 g/t silver from 24 to 69 m which extends Main Zone mineralization to the east.

DDH HY-11-37 for 4.5 m grading 1.93 g/t gold from 25.9 to 30.4 m and 4.5 m grading 0.65 g/t gold from 10.5 m to 15 m in the CUZ Zone discovery hole. Drillhole HY-11-36, 6 m grading 1.38 g/t gold from 9.0 to 15.0 m and 1.5 m grading 1.52 g/t gold from 25.50 m to 27.0 m located 80m northwest of discovery hole HY-11-36. Drillhole HY-11-38 with 3.6 m grading 1.12 g/t gold from 16.4 to 20.0 m , located 240m northwest of discovery hole HY-11-36. These three drill holed extend CUZ Zone mineralization over 240 of east-west strike in a previously defined as a soil anomaly.

GEOPHYSICS

Ground geophysical surveys were executed in 1988 over a 2,500 x 2,900m area in the northern part of the property along E-W oriented lines ~125m apart. Induced Polarization/Resistivity (IP/Res), Magnetic (GMag) and VLF-EM data were collected. Not all lines were surveyed with IP/Res; that part of the ground surveys covers only the northern part of the Main Zone and the area further to the north. All data is available in profile and contour form. No actual data points are shown on the original maps; station intervals are therefore unknown.

A 542 line kilometer Dighem-V survey was executed in June 1994. Lines were flown in an E-W direction at 200m intervals. The survey covers an area of 14 x 7km and is centered just north of the Cuz Zone. The full Dighem report, maps and digital data are available including the Calculated Resistivity for the 7200Hz coplanar coil set.

An airborne magnetic and radiometric survey was flown with the Newmont airborne system in June 1995. An area of ~1,800 square kilometers was covered with E-W oriented lines at 250m interval, the aircraft – including the 1,024 cu in spectrometer- flying at 90m above ground level, the magnetometer was towed 30m below the aircraft. The data is available in map and digital format and a report by the Newmont staff.

The IP/Res survey used a single separation Schlumberger array (transmitter dipole AB=240m, receiver dipole MN=40m). The VLF-EM employed the Seattle station transmitting at 24.8kHz. The direction towards that station means that ~N-S oriented conductors and resistivity contrasts are emphasized over those oriented ~E-W.

The data available is of good quality. The IP contours were digitized in 2003 using the NAD83 base and then converted to NAD27. The main anomalous axes of the other ground data sets were traced on to the NAD27 base map. There will be no doubt some discrepancies in this process so care has to be taken when cross correlating different data sets in detail or when deciding on the actual location of anomalies.

The Aeromagnetic (“AMag”) results show a large (~2,000 x 1,500m) smooth magnetic low (<56,800nT) roughly centered near the Main Zone. This type of broad, smooth magnetic low can be caused by a deep-zoned intrusive or by pervasive alteration over a large area destroying primary magnetite. The latter is the more likely source of this magnetic low. Directly north of the Main Zone are short-waved (=shallow sourced) N-S trending AMag and GMag highs and lows visible; they are superimposed on this broad low. They most likely reflect local pockets of pyrrhotite (but magnetite cannot be excluded) emplaced by mineralizing fluids. Pyrrhotite was detected in DDH HY-03-04 supporting this interpretation. It has to be emphasized that these shallow magnetic features are not seen over the Main Zone.

The ground geophysical results can be divided in to two parts. Only the northern portion of the Main Zone is covered with IP/Res. The IP data over the Main Zone shows surprisingly low values: <20msec. This value means that chargeable material (sulphides, graphite etc.) is present in low quantity (~1%). The general background for the whole grid is ~25msec. Res values are also non-anomalous in the 500 – 1500 ohm range. There are no VLF-EM or AEM conductors mapped over the Main Zone. The Res values calculated from the 7200Hz AEM data are over the Main Zone in the 400 – 500ohmm range. The GRes and ARes values show different ranges for they are calculated differently; they have to be compared within their individual data sets. It has to be concluded that the Main Zone does not show an (obvious) anomalous geophysical signature.

The area directly to the north of the Main Zone shows a complete different geophysical character. Narrow somewhat en-echelon IP highs with amplitudes of >50msec coincide or are en-echelon with VLF-EM conductors and short-waved magnetic responses. This zone contains also the best AEM conductor from the Dighem survey. The Ternary Radiometric map shows also a weak change compared with the areas immediately to the west and east. Holes DDH HY-03-04 to 07 were drilled in this area. These holes most likely intersected higher concentrations of sulphides than the holes in the Main Zone. These are most likely semi-massive to massive (py + po) bands assuming they intersected the conductors.

It has to be noted that the axis of the geophysical anomalies in the North Zone are oriented ~N5ºW. These axes do not project though the Main Zone. It is therefore possible or most likely that the Main Zone and North Zone represent two separate mineralizing events possibly originating from the same deep source. The two zones appear slightly offset along an ~NW – SE structure roughly coinciding with the 500ohmm GRes contour visible directly north of DDH HY-03-03. It should be pointed out that the large area of GRes low (<500ohmm) extends to the west of the North Zone and correlates with a large portion of the center of the large Mag low. It is important to note that the trend of the geophysical anomalies cuts obliquely across the geology as seen on detailed maps, (Lusting et al., 2003).

The main fault zone indicated on the various maps and bifurcating through and along the east side of the Main Zone, cuts the geophysical anomalies of the North Zone obliquely by ~15º. There is no obvious geophysical expression of this structural zone in this area. A fault several hundred meters to the east and in part coincident with a gulley coincides with a weak narrow GRes low. There is no VLF-EM conductor correlating with it but its northern part shows a weak IP high. Further to the east is a block of <500 ohm rock present. The VLF-EM conductors along its edges are typical resistivity contrast anomalies not those caused by true conductors.

The ARes map shows a low (<100 ohm) correlating with the large GRes low directly west of the North Zone. The Main zone, as mentioned already, displays elevated ARes values. A structural zone is mapped along its east side (=contrast in Res values) it can be followed southward to ~6,706,000N and possibly along the east side of the Cuz Zone and further south. The Cuz Zone does not show any conductive responses (=AEM) rather it displays high ARes values of ~6,000ohmm. The assumed fault offset near the CUZ Zone is not visible in the 7,200Hz Res or AMag data.

The AMag data is also presented in Vertical Gradient (VG) and Analytic Signal (AS) format. The VG image shows the North Zone clearly. A N70ºE break or contact is present directly to the north of DDH HY-03-07 (blue line). This image shows N150-160ºE trends and a possible N170ºE break separating a magnetic more active area in the east from a more subdued area in the west (marked Z). The Cuz Zone is located in a quiet region: the structure close to it as shown on the ARes image is not visible on the VG map. The AS image supports these and other breaks or contacts (dark green lines). A Ternary Radiometric map was made to complement the individual ones (K40, Th and U3O8) made by the Newmont staff. The ratio of the three radioactive elements is different for the Main and North Zones. The responses over the Cuz Zone are very similar to those over the surrounding rocks.

An area in the SE part of the IP/Res grid (~6,708,500N – ~564,000E) shows elevated values up to 50msec; it is open to the south. A VLF-EM conductor projects in to it together with a weak N-S trending AEM conductor. The northern tip of a strong linear Mag high coincides with the SE-most peak of the high IP zone. Main Quartzite (MQ), a brittle unit that shows open fractures and dilatant zones, underlies it. The IP values further to the north over the same unit are not as high. Au-geochemical values over it are 25ppb or less but directly to the south, where there is no IP/Res coverage, are numerous high Au values recorded. This area is

of interest for it is possible that the IP high reflects hydrothermal sulphides and Au further to the south rather than graphite or primary sulphides. (Klein, 2004).

From October 3rd - 15th 2010 Frontier Geosciences carried out a Transient Electromagnetic (TEM) survey. The purpose of the survey was to trace massive to semi-massive sulphide mineralization at depth beneath and to the north of the main zone. The survey consisted of a single ~1,000 m by 500 m loop surveyed from five 1km long traverses with readings taken every 25m. Results of the survey indicate that there are no shallow conductors beneath the Main Zone of the Hyland property, possibly reflecting the depth of oxidation and/or lack of interconnectivity of the sulphides. The geophysical survey indicates that a steep, shallowly dipping conductive plate strikes ~009° and is buried 150 m below the surface. The data set was not conducive to modeling the thickness or conductivity.

From July 19 – July 30, 2011 Abitibi Geophysics carried out a **TDEM** (Time Domain ElectroMagnetics) Survey. The purpose of the survey was to trace massive to semi-massive sulphide mineralization at depth beneath and to the south of the Main Zone. The survey consisted of a ~1,800 m by 1,600 m loop surveyed from eight 1.5 km long traverses with readings taken every 25 and 50m, and "In-Loop survey 1,000 x 1,000 In-Loop surveyed from four 1 km long traverses with readings taken every with 25m and 50m. TEM anomalies were detected over the TEM survey grid at the South end of the Main Zone. These anomalies are considered as moderate conductors and their response is typical of disseminated sulphide type mineralization. Two anomalies are identified at the southern end of the TEM Survey and remain open to expansion in the southern dimension. The Authors of the Geophysical report recommended an IP survey to help detect sulphide mineralization associated with gold. (Dubois, 2011)

Historical Resource Estimates

Sax and Carne (1990) reported that "the oxidized core of the Main Zone is estimated to contain a resource of about 3.2 million tonnes grading 1.1 g/t gold". This estimate gives a general indication of the amount of oxidized mineralized material defined in the Main Zone.

In 2012 a National Instrument ("NI") 43-101 compliant resource estimate was completed on the Main Zone of the Hyland Gold Property. The resource report was commissioned by Argus Metals and completed by GeoVector. Argus reported an Inferred Mineral Resource, at a 0.6 g/t gold equivalent ("AuEq") of 12,503,994 tonnes containing 361,692 ounces gold at 0.9 g/t and 2,248,948 ounces silver at 5.59 g/t. (Gray and Armitage, 2012).

The Inferred Mineral Resource was estimated by Allan Armitage, Ph.D., P. Geol, of GeoVector Management Inc. Armitage is an independent Qualified Persons as defined by NI 43-101. Practices consistent with CIM (2005) were applied to the generation of the resource estimate. There are no mineral reserves estimated for the Property at this time. Inverse distance squared interpolation restricted to a single mineralized domain was used to estimate gold and silver grades into the block model.

Table 2 2012 Resource Estimate for the Main Zone

Cut-off Grade (AuEq* g/t)	Tonnes	Au (g/t)		Ag (g/t)		AuEq* (g/t)	
		Grade	Ozs	Grade	Ozs	Grade	OZS
<0.1 g/t	20,560,309	0.69	456,475	4.3	2,820,087	0.76	500,069
0.1 g/t	20,466,502	0.69	456,324	4.3	2,818,954	0.76	499,903
0.2 g/t	19,972,613	0.71	454,078	4.4	2,804,570	0.77	497,443
0.3 g/t	18,629,311	0.74	443,813	4.6	2,740,244	0.81	486,193
0.4 g/t	16,820,094	0.79	425,424	4.8	2,619,911	0.86	465,946
0.5 g/t	14,734,230	0.84	397,785	5.2	2,453,560	0.92	435,738
0.6 g/t	**12,503,994**	**0.90**	**361,692**	**5.6**	**2,248,948**	**0.99**	**396,468**
0.7 g/t	9,678,679	0.99	307,098	6.4	1,988,733	1.09	337,824
0.8 g/t	7,038,666	1.10	248,349	7.3	1,654,686	1.21	273,942

* *"Gold equivalent" or "AuEq" is based on silver metal content valued at 0.016 gold value using a $1016 US Au price and a $15.82US Ag price, which approximates the average prices for these metals over the last three years.*

6.0 REGIONAL GEOLOGY AND MINERALIZATION

Regional Geology

The Hyland project is located in the southeastern Selwyn Basin, a Late Precambrian to Middle Devonian tectonic element characterized by underlying marine and deep water derived clastic rocks. Deposition of sediments into the basin was restricted by the Cassiar platform to the southwest and the Mackenzie shelf to the east. It is considered part of Ancestral North America and records several episodes of pericratonic rifting with subsequent subsidence. Generally, the basin fill comprises shale, limestone, chert and grit that have been subdivided across the basin into many formations and distinct facies that may or may not be time-equivalent. Recent regional scale geological mapping of the area (Pigage et al., 2011) provides a framework for the regional and property-scale descriptions below.

On a regional scale the Hyland property is located in an area of the Selwyn basin underlain by Precambrian (Yusezyu, Narchilla and Vampire formations), Lower-Middle Cambrian (Sekwi Formation), Cambrian-Ordovician (Otter Creek and Rabbitkettle formations), Ordovician (Sunblood Formation), Silurian-Devonian (Road River Group and undivided Nonda-Muncho-McConnell-Stone-Dunedin formations) and locally Eocene (Rock River basin) sequences (Figure 5). The sedimentary rocks were subsequently intruded by Cretaceous granite, quartz monzonite and granodiorite plugs assigned to the Selwyn Plutonic Suite. Collectively, they record a quiescent, subsiding continental margin punctuated by transgressive and regressive cycles, rifting, a receptacle for orogenic detritus from the north, collision of allochthonous terranes, mountain building and magmatism (Gordey and Anderson, 1993).

The lower Hyland Group (Yusezyu Formation, **Py**) comprises quartz-rich sandstones ranging from medium grained sand to pebble conglomerate sized clasts. Distinct, opalescent blue spherical quartz grains are common. The bottom of the formation is not exposed in the basin but the formation is estimated to be greater than 3 km thick (Gordey and Anderson, 1993). At the top of the Yusezyu Formation, a crystalline limestone or calcareous sandstone unit (**PCvn-l**) is generally present. This unit marks the transition from Yusezyu Formation sandstones to finer grained clastic rocks of the Narchilla Formation (**PCvn-m**). In the Coal River area the Narchilla and Vampire formations are undivided with the former representing the basinal facies and the latter the basin to shelf transitional facies. The Narchilla Formation consists of maroon and green phyllite, silty phyllite and minor quartzose sandstone to pebble conglomerate. The limestone and Narchilla mudstones are locally interfingered. The Vampire Formation (**PCvn**) consists of green phyllite, silty phyllite, minor quartzose sandstone to pebble conglomerate, and bedded limestone.

Lower Cambrian rocks interpreted to be correlative to the Sekwi Formation (**Cs**) conformably overlie the Narchilla-Vampire sequences. They consist of green to tan brown weathering phyllite, siltstone and arkose. The finer grained lithologies are locally calcareous and/or fossiliferous. Locally, a mafic volcanic sequence of tuff, flows and pillowed lavas (**Cv**) occurs near the top(?) of the Vampire-Narchilla formations

The Lower Cambrian rocks are unconformably overlain by Cambrian to Ordovician rocks including the Otter Creek formation (**COoc**) comprising resistant light grey limestone and buff coloured dolostone. Overlying theses rocks is the Rabbitkettle formation (**CO$_R$**) divided into; a volcanic facies (**CO$_{R-v}$**) comprised of mafic tuff, breccias and amygdaloidal pillowed flows; a west facies (**CO$_{R-lp}$**) including platy phyllitic limestone, calcareous phyllite and light grey, yellow weathering silty limestone; and an east facies (**CO$_{R-n}$**) that is more calcareous comprised of wavy banded, nodular silty limestone and pale grey bedded limestone.

The Ordovician is represented by the Sunblood formation comprised of two members a mafic volcanic member comprised of basaltic tuff, breccia and amygdaloidal pillowed flows (**OSu-v**) and a laminated and/or bioturbated buff to orange weathering dolostone or limestone (**OSu**). Conformably overlying the Sunblood formation is the Silurian to Devonian Road River Group (**SD$_{RR}$**) comprised of dark grey to black calcareous or dolomitic locally graptolitic recessive shale, siltstone and bedded chert. The laterally equivalent carbonate dominated Siluro-Devonian unit **SDc** (undivided Nonda-Muncho-McConnell-Stone-Dunedin formations) is present to the south and comprises grey thick-bedded dolostone, and black thick-bedded limestone.

Devonian to Mississippian extension resulted in subvertical normal faults of varying orientation juxtaposing deeper basinal rocks against younger lithologies. This geometry effectively preserved Ordovician to Silurian rocks locally and resulted in unconformable relationships between the Hyland and Earn group rocks elsewhere. The occurrence of abundant debris flows containing car sized clasts of underlying lithologies are a product of this block faulting (Gordey, 2008).

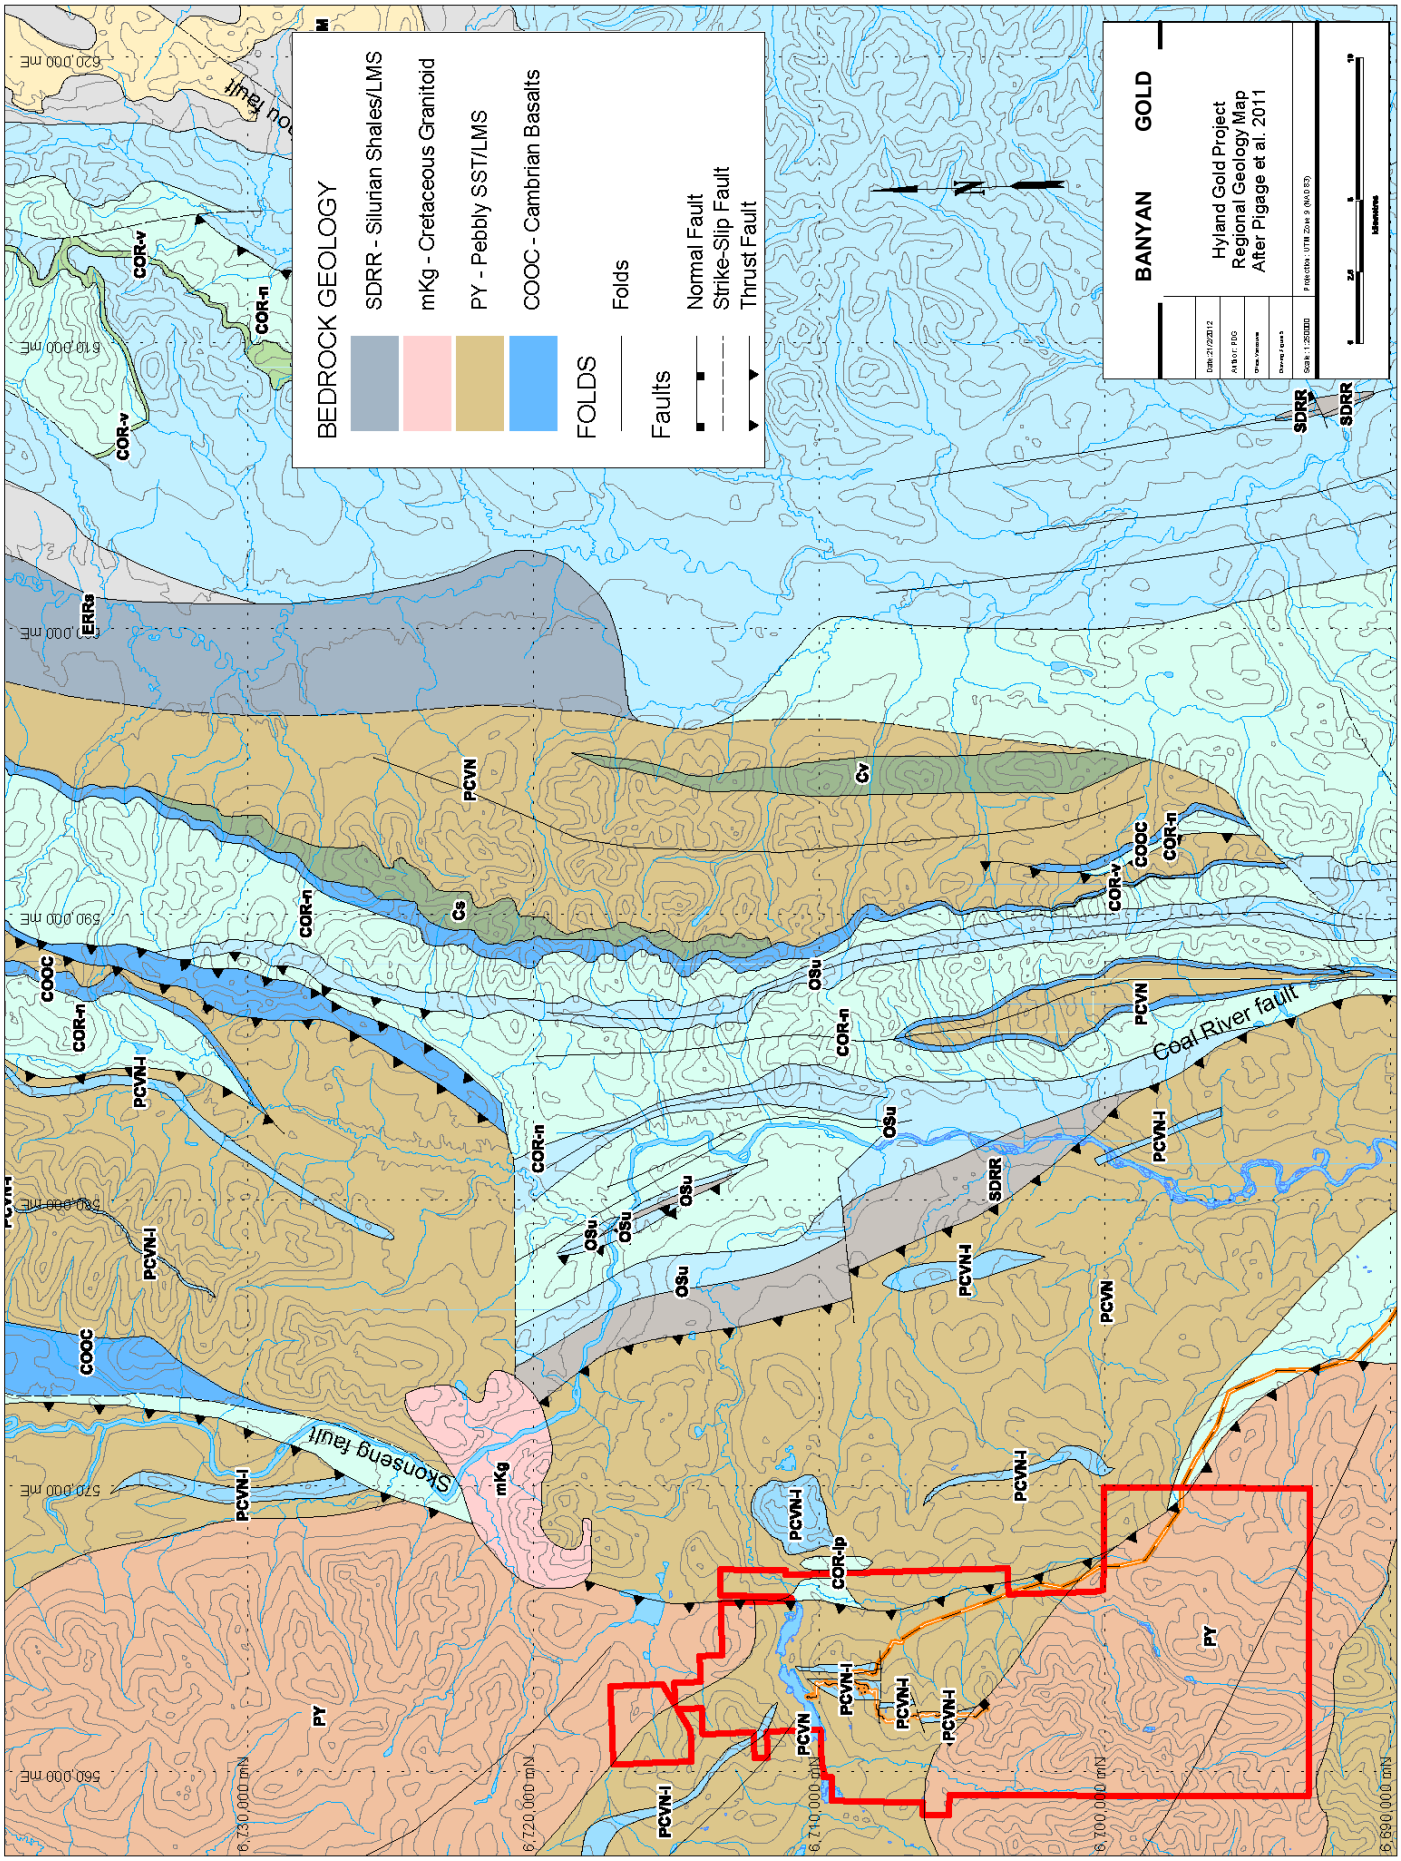
Mesozoic docking of allocthonous terranes to the southwest of the Selwyn Basin resulted in thin-skinned thrusting and folding with eastward displacements upwards of 200 km (Gabrielse, 1991). Related deformation in the Selwyn Basin is dominated by the interplay of less competent quartz-poor and competent quartz-rich layered rocks. Large-scale structures consist of thrust-faults, open to tight folds, locally intense small scale folds and zones of closely spaced imbricate thrust sheets. These structures are attributed to Early Cretaceous northeast directed compression pre-dating the extensive plutonism in the basin. Typically a well-developed phyllitic to slatey cleavage is present and is most prevalent in mudstone and siltstone. The dominant fabric in the basin trends northwest and generally dips steeply to the northeast but in places may be shallowly south-dipping. Locally, however, structural trends vary and commonly parallel the arcuate Paleozoic shale-carbonate boundary within the Mackenzie Mountains to the east. This results in structural trends that may vary from east-northeast to east-west with northerly, easterly, or westerly vergence of major structures (Gabrielse, 1991).

Following crustal thickening numerous calc-alkaline plutons were emplaced into the sedimentary package described above. Cretaceous plutonism in the Selywn basin progressed from the southeast to the northwest beginning with the emplacement of the Anvil and Tay River suites and culminating with the emplacement of the Tungsten and Tombstone suites ca. 90 – 93 Ma (Anderson 1983, 1987, 1993). Previously the nearest known intrusion to the Hyland property was a 15 km diameter stock located 22 km to the west. Recent mapping of Pigage et al. (2011) however, has identified a 7 km x 3 km body granitic body that returned a U-Pb zircon age of 97.8 Ma (Pigage et al., 2011). This body is the southernmost exposure of cretaceous granitic rocks along a northeast trending belt of higher metamorphic grade (locally up to garnet-staurolite grade) and cretaceous magmatism that parallels the Skonseng fault.

Structure

Regionally, the Hyland property is located in the hanging wall of an east-verging imbricate thrust system controlled by the Coal River fault. Indeed, the surface trace of westernmost fault of this system is located within the eastern margin of the Property. Within the hanging wall the structural grain is largely northwest trending and lineations plunge both to the northwest and to the southwest. The dominantly Precambriam sedimentary rocks of the hanging wall are folded into a series of anticline-syncline pairs that expose the Yusezyu at the core of northwest trending anticlines.

Figure 5: Regional Geology Map



East of the imbricate thrust system Cambrian to Devonian rocks with a carbonate shelf affinity contain a north trending structural fabric. Mapped folds are typically tighter with more closely spaced axial planes and east-verging. Lineations plunge north and south likely controlled by their proximity to second-order east-west trending strike slip faults related to the larger thrust faults. Locally, the strike-slip faulting has up to 3 km of throw. (Gray and Armitage, 2012).

The regionally significant north striking Rock River normal fault separates an elongate belt of Precambrian rocks from Silurian to Devonian shelf rocks and was likely the boundary fault to the Eocene Rock River basin host to Lignite coal occurrences deposited the eastern side of the fault. The Rock River fault cuts the Coal River thrust fault but it is unclear from the regional mapping the timing relationship between the two. (Black, 2010).

Regional Mineralization and Metallogeny

The Selwyn basin is most well-known for its endowment of SEDEX Zn-Pb-Ag occurrences including twelve deposits with proven reserves three of those were past producers. The SEDEX deposits can be divided into three categories based on their age of formation; Late Cambrian (e.g. Faro; 57.6 Mt @ 5.7 % Zn adn 3.4 % Pb), Early Silurian (e.g. Howards Pass; 115.4 Mt @ 5.38 % Zn and 2.08 % Pb) and Late Devonian (e.g. Tom; 15.7 Mt @ 7.0 % Zn, 4.6 % Pb and 49.1 g/t Ag). In addition to the SEDEX deposits the basin also contains MVT and stratiform barite deposits. (Gray and Armitage, 2012).

The Hyland project is located in a second regionally significant metallogenic province referred to as the Tintina gold belt, comprised of several gold rich districts extending from western Alaska to southern Yukon. The belt includes notable gold deposits such as Donlin Creek, Fort Knocks and Pogo in Alaska and the Dawson Gold district, Brewery Creek, Mt Nansen, Ketza River and the Newley discovered Nadaleen trend in Yukon. The Tintina Gold Belt is roughly constrained by the Tintina fault to the north and east and the Denali fault to the south and west. It is coincident with extensive mid cretaceous plutonism and deposit types are typically associated with these intrusions in some fashion. The compositions of the intrusive rocks are typically granodiorite, granite and syenite. They are predominantly metaluminous, calk-alkaline to locally alkallic, have low primary oxidation states and typically contain significant crustal contamination (Black, 2010).

The most significant mineral occurrence near the Hyland property is the McMillan Ag-Pb-Zn deposit 5 km to the west. A historical resource of 1.1 million tonnes grading 8.3% zinc, 4.1% lead and 62 g/t silver in strata concordant and discordant mineralization. It is hosted in late Precambrian rocks of the Hyland formation. The deposit has been alternately described as syngenetic and post depositional replacement style mineralization.

7.0 PROPERTY GEOLOGY AND MINERALIZATION

Geology

The Hyland Property is comprised of an interbedded sequence of quartzites, limestones, and phylites. Individual beds vary from less than one meter to tens of meters in thickness. Several units are mixed, with phylitic dirty limestones, calcareous quartzites and so on. This stratigraphic complexity coupled with structural features (folding and faulting), and a lack of sufficient outcrop exposure produces a complex geologic area which is difficult to map stratigraphically (Black, 2010).

In general, a mixed unit of quartzites, phylites, and limestones appears to be folded about a north-south trending anticline with its axis lying in the Main Zone. Flanking the mixed unit to the east and west is a relatively clean, massive limestone unit. A north-south structural corridor referred to as the Quartz Lake Lineament trends through the Main Zone and is thought to be a major control of mineralization. Late east-west brittle faults are known to occur in the Yukon and Selwyn Basin and are likely to occur on the property although none have been identified on surface to date.

Previous workers have developed property stratigraphy that is interpreted to comprise one continuous conformable sequence. The following description is in stratigraphic order and taken from Lustig et al. (2003).

Upper Quartzite (Q2)

The upper quartzite unit consists of blocky weathering, tan, grey and pale green lithic quartzite, orthoquartzite, calcareous quartzite and minor sandstone with phylittic siltstone and phyllite.

Upper Limestone (L1)

The Upper Limestone unit is a dark shaly and gritty fissile limestone with common phyllitic partings. Bedding ranges from 1 – 100 m thick. A horizon of phyllite and interbedded quartzite occurs near the base of this unit. 3

Upper Phyllite (P2)

The Upper Phyllite consists of thinly laminated silver-grey, green and black, locally graphitic or calcareous phyllite. This unit contains quartzite horizons upto 5 m thick.

Main Quartzite (Q1)

The Main Quartzite is an orthoquartzite greater than 20 m thick. Phyllite becomes more prevalent towards the top of the unit with individual phyllite horizons up to 10 cm thick.

Lower Limestone (L2)

The Lower Limestone is a black to grey, platy, silty limestone that is typically weakly recrystalized.

Lower Phyllite (P3)

The Lower Phyllite consists of interbedded siltstone, sandstone, greywacke, and quartz-lithic granule conglomerate. Locally, this unit may resemble a quartzite where strong quartz flooding or alteration occurs.

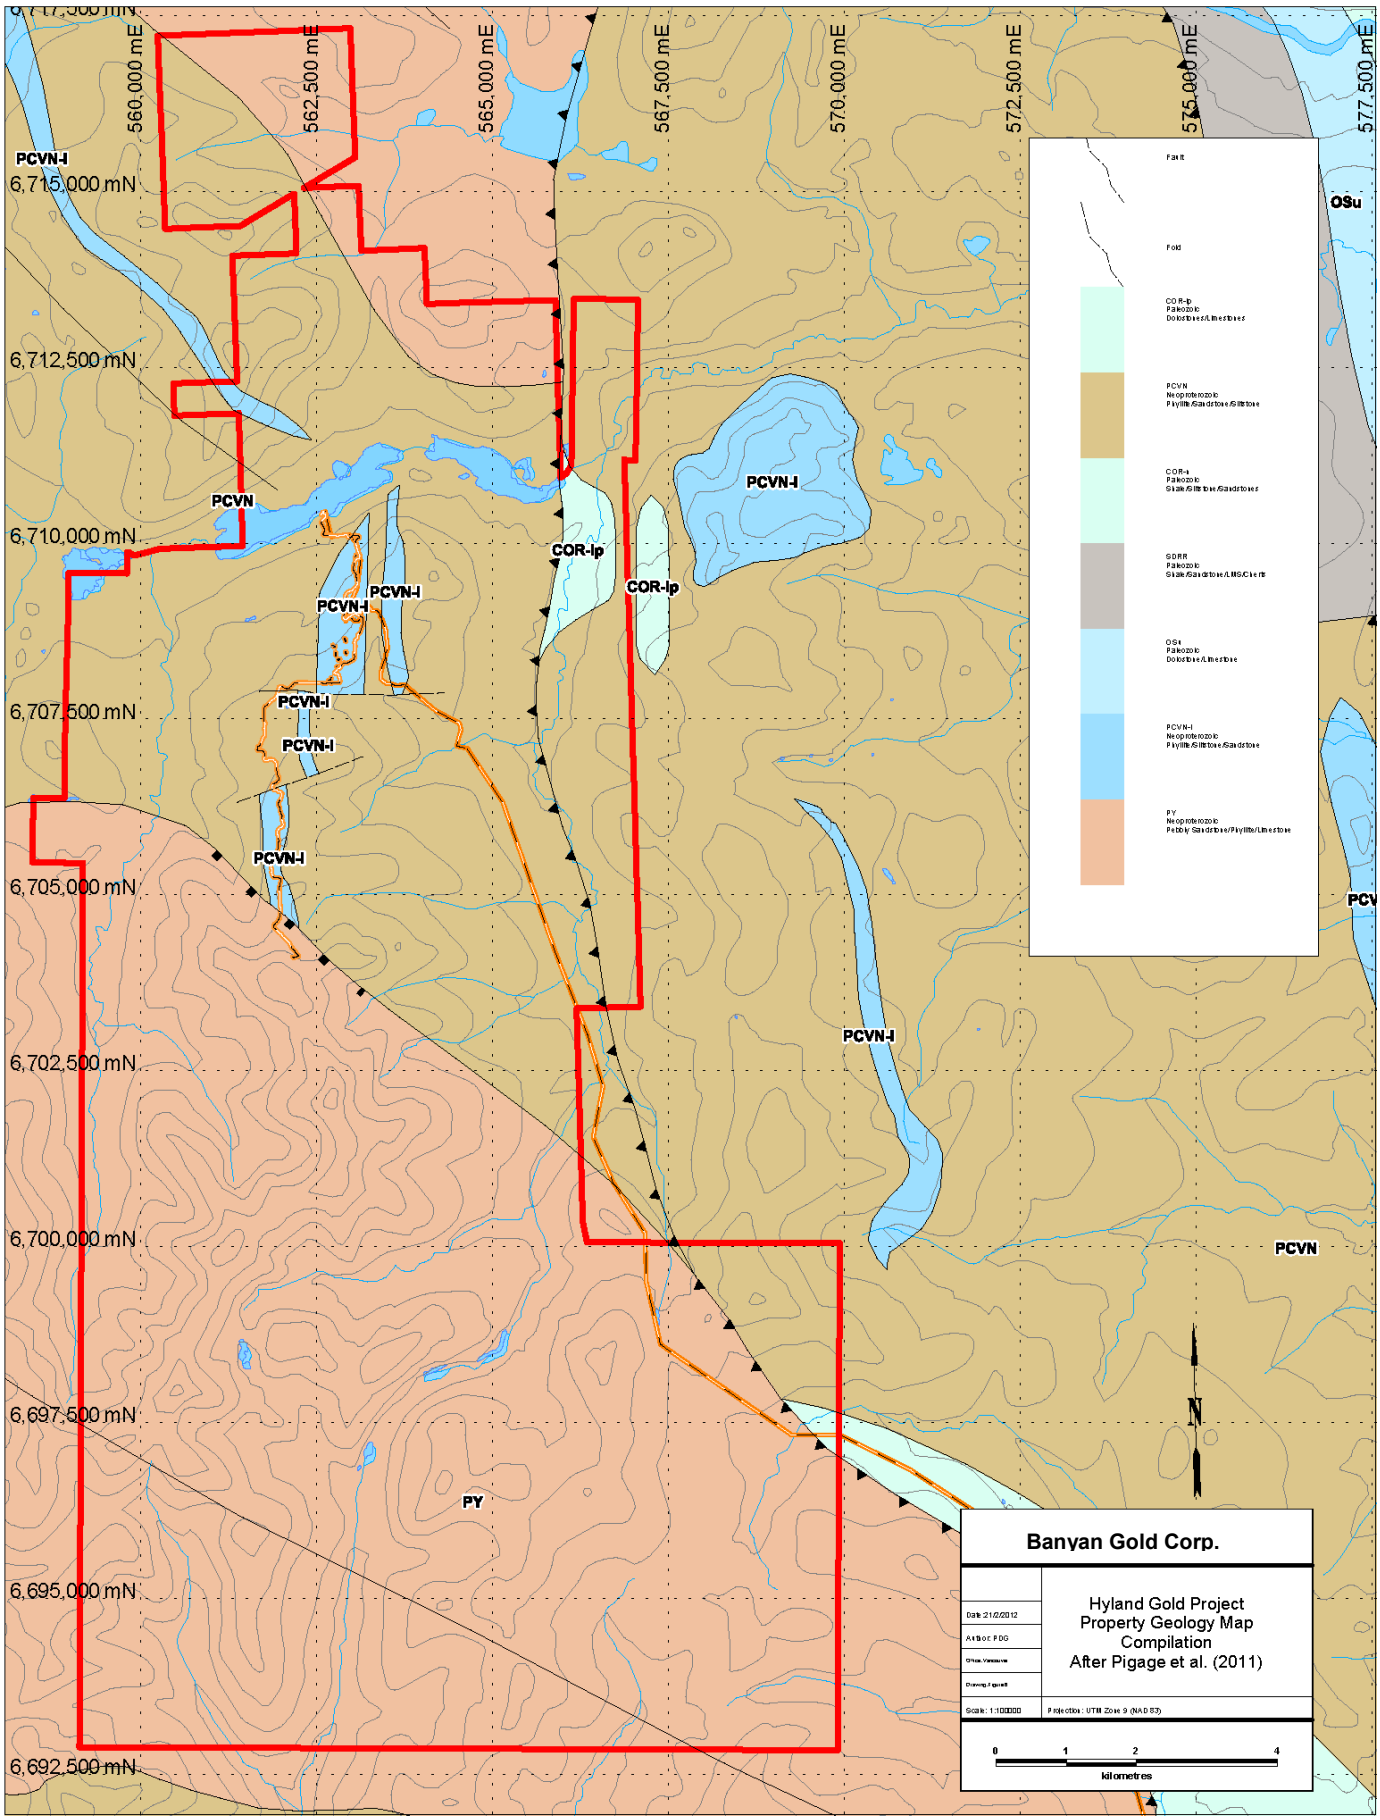
A 25 cm wide mafic dyke is reported to have been encountered in an unnamed bulldozer trench.

Alteration

Two styles of alteration occur on the Hyland property. Tourmaline+/-arsenopyrite-pyrite-silica alteration is ubiquitous in mineralized intervals. The alteration locally eradicates primary sedimentary features and imparts a light greyish brown colour on all lithologies. White quartz veins cut this alteration and adjacent, less altered, intervals but are interpreted to be part of the same alteration assemblage. Sulphide minerals occur as anhedral fine to medium grained aggregates disseminated throughout the altered intervals and in dismembered irregular veins. Tourmaline is visible only in thin section and consists of very fine grained anhedral to euhedral crystals occurring in aggregates or disseminated throughout the groundmass. Notably, the eradication of sedimentary structures in strongly altered zones can give the false impression that the original rock type is a quartzite. They primary distinction is the lack of strain in the secondary silica (Black, 2010).

Patchy to pervasive, very fine grained iron carbonate alteration was not examined in thin section but observed in drill core. The iron carbonate alteration imparts a light beige wash across the drill core and appears antithetic to sulphide as well as overprinting the silica alteration. Furthermore, titanite-quartz-carbonate veins, thought to be contemporaneous to the iron carbonate alteration, cross cut quartz and quartz + sulphide veins. For these reasons the pervasive iron carbonate alteration is interpreted to be sulphide destructive and later than the earlier tourmaline+/-arsenopyrite-pyrite-silica alteration (Black, 2010).

Figure 6: Property Geology Map



Mineralization

Iron oxide units which contain semi-massive to massive sulphide (mostly pyrite with lesser arsenopyrite) are observed throughout the property. These units were previously believed to be limestone replacement beds occurring sporadically at the base of limestone units. In 2010 these iron oxide zones were found to be continuous and mapable following a trend similar to the Quartz Lake Lineament. The resulting interpretation is that this iron oxide unit is structurally rather than stratigraphically controlled and represents a good (untested) drill target north of the Main Zone (Black, 2010).

On surface the iron oxide occurs in two horizons that strike north and take a chicane like bend to the east before returning to a northward trend approximately 300 m further on. The western horizon appears to be thicker (~10 m) with more intense alteration and mineralization. Both contain moderate to intense secondary iron oxide mineralization (limonite, goethite, and locally earthy hematite) and moderate to intense manganese oxides. Unoxidized, podiform semi-massive to massive sulphides (pyrite with lesser arsenopyrite) remain unaltered locally.

Sulphide mineralization and cross-cutting relationships among sulphide bearing veins are complex. There are at least three generations of veining present in the samples sent for petrographic analyses that have been divided into types I, II and III. These veins overprint disseminated stratabound diagenetic(?) pyrite mineralization that occurs as aggregates of anhedral pyrite disseminated along bedding planes in less altered, layered metasedimentary rocks. The diagenetic mineralization has been cut by type I veins consisting of ill defined or discontinuous aggregates of fine to medium grained, intergrown, anhedral pyrite and arsenopyrite that in turn are dismembered by type II veins consisting of quartz + fine grained sulphides (pyrite +/- arsenopyrite +/- chalcopyrite +/- bismuthinite) +/- tetrahedrite +/- native gold. The type III veins consist of Quartz +/- Fe-carbonate +/- pyrite +/- titanite that cross cut all other vein types and mineralization.

The gold typically occurs at pyrite-arsenopyrite grain boundaries or less commonly as inclusions within pyrite and are interpreted to be genetically related to the pyrite. Gold shows a strong geochemical correlation with bismuth, a moderate correlation with arsenic, copper and silver. Bismuthinite was identified in two petrographic samples that returned 4 g/t and 2 g/t Au and arsenopyrite is a common constituent in the quartz + sulphide stockwork associated with the Main zone mineralisation. High levels of bismuth and the presence of bismuthinite is often used as evidence for a magmatic origin for gold mineralization. Arsenic, on the other hand can occur in a variety of environments (Black, 2010).

8.0 2016 EXPLORATION PROGRAM

Summary

A 20 Day, YMEP supported mineral exploration program designed to follow-up on the 2015 Montrose Ridge trench discovery and extend the gold/arsenic-in-soils anomalies defined in the 2013-2015 in the Montrose Ridge Zone was conducted by Banyan Gold from September 2 through September 22, 2016.

The 2016 Hyland Program expanded upon the 2015 Montrose Ridge Trench discovery with the D-6 Cat and PCS200 Excavator that were mobilized to Hyland in 2015.

Pre-ceding and co-incident with, the Montrose Ridge trench campaign, a systematic, XRF analysis based geochemical soils sampling program was conducted over, and extended from, the Montrose Ridge gold/arsenic-in-soils anomaly. This grid-based soil sampling program was served to confirm XRF analysis effectiveness as well as in-fill and extend the 2013-15 Montrose Ridge gold-bismuth-in-soils anomaly. Additionally, the Southern Ridge Zone was also the focus of a grid based soils sampling program.

In total, 592 soil samples were collected from the Montrose Ridge, Southern Ridge and three lines south east of the Main Zone during the 2016 exploration program (See Figure 7). All soil samples locations were determined by GPS and analyzed by XRF instrumentation. A tabulated summary of all soil samples data collected with their raw XRF analyses is presented in Appendix D of this report.

As demonstrated over the past two exploration seasons at the Hyland Project by Banyan, soils geochemistry continues to be highly useful in delineating areas of potential gold mineralization, particularly with respect the As/Bi-in-soils elemental analysis; moreover this season XRF analysis of same was proven to be extremely effective in reproducing chemical analytical results and this offers a useful, “real-time” approach to mineral exploration on Hyland and Hyland South going forward. In specific, Montrose Ridge, which returned anomalous gold/arsenic-in-soils point data from a 2011 ridge and spur traverse was identified as highly anomalous in Gold and Arsenic from the 2013/2014 program and was ultimately defined as a trench discovery in 2015. This rapidly emerging mineralized zone area is located ~6.5km south of the Main Zone and extends from CUZ Zone, with the most intriguing soils responses developed from ~2km south of the Cuz Zone.

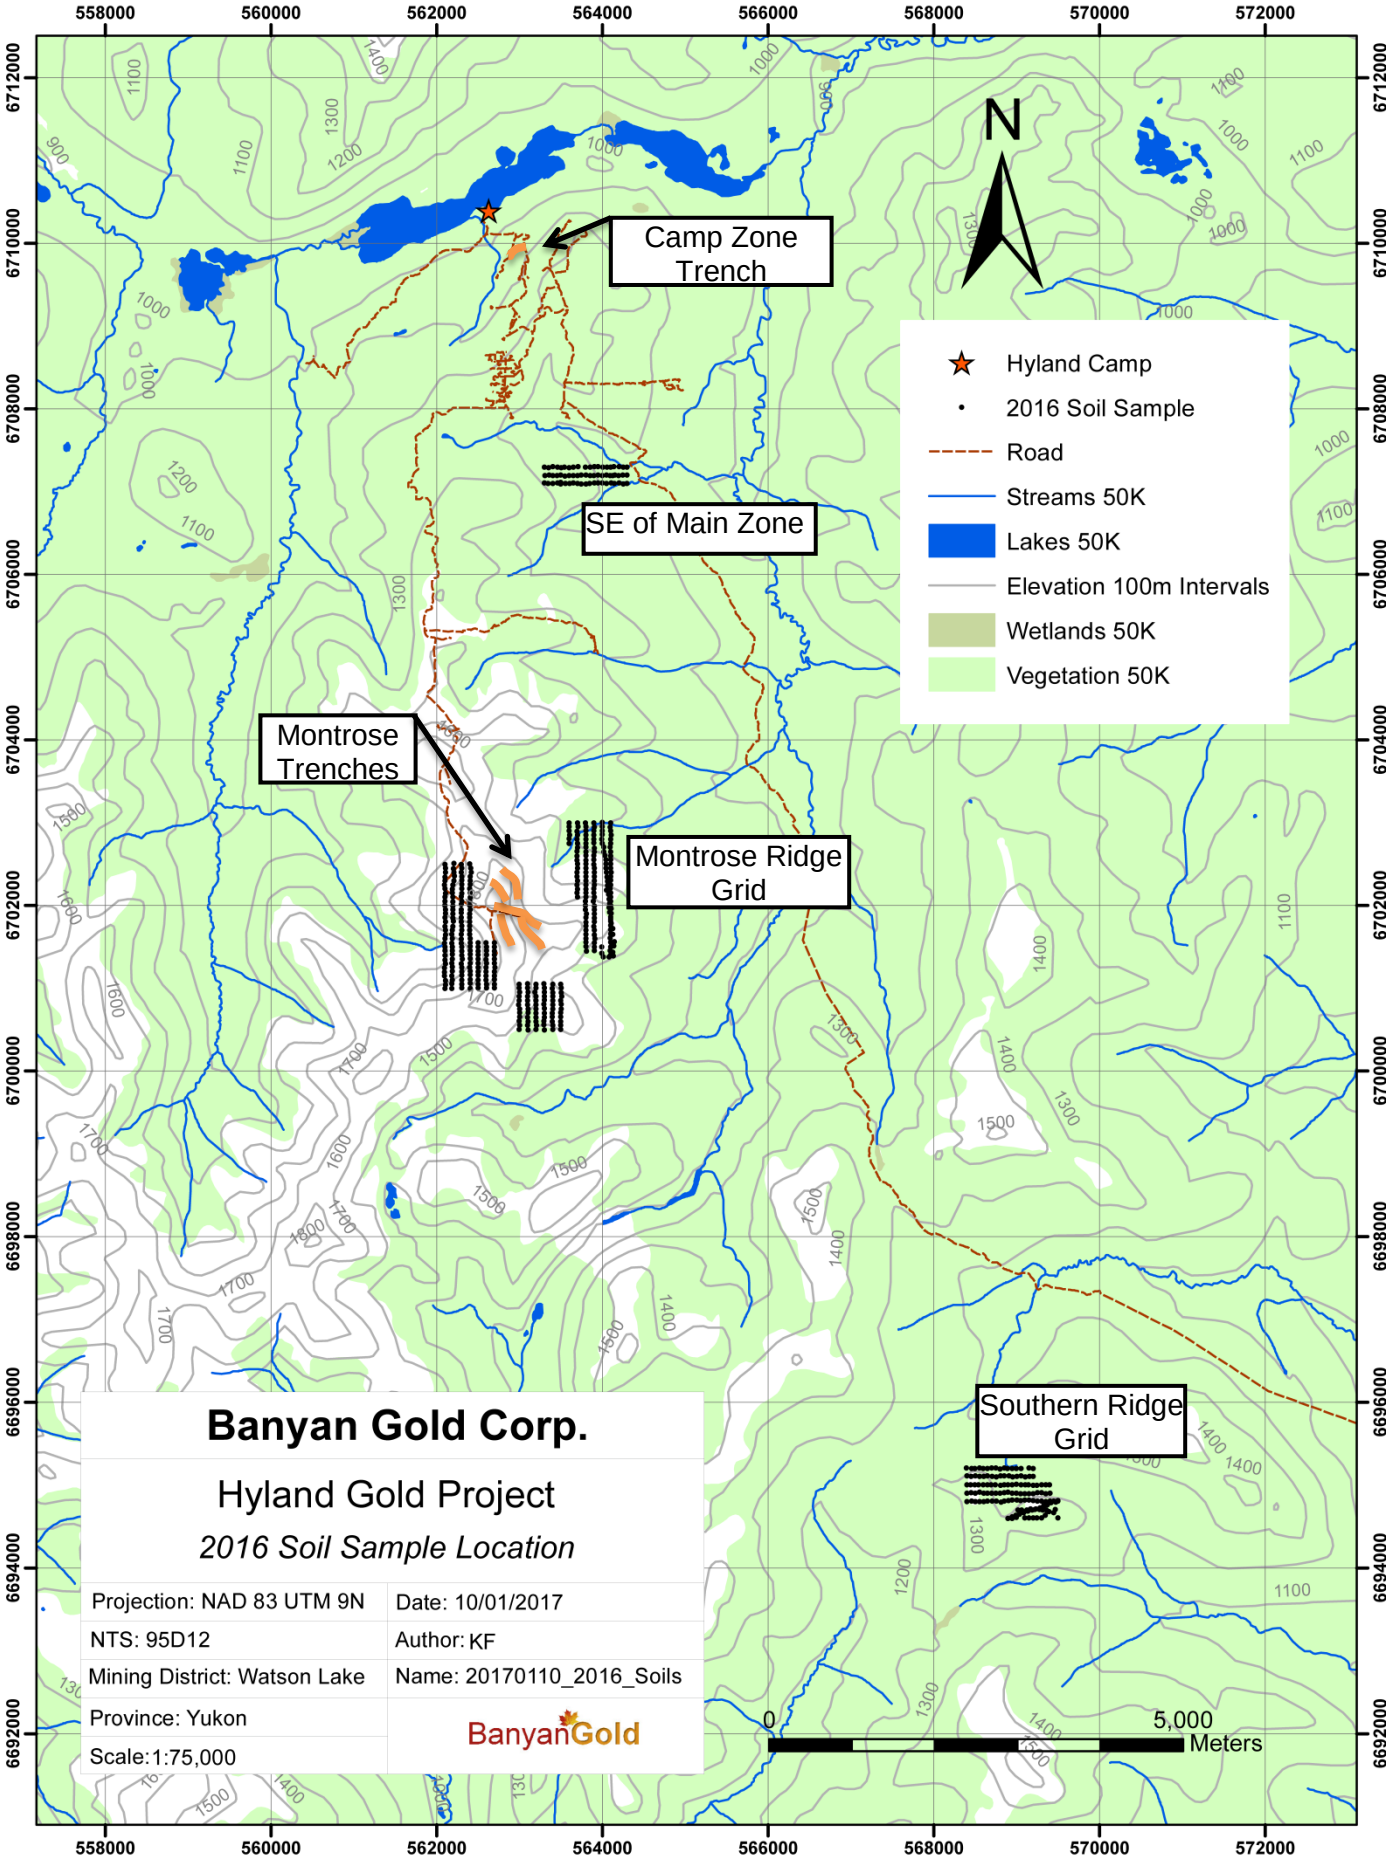
In addition to the soils geochemical programs, a targeted trench excavation and sampling exploration program was undertaken in 2016. All together seven (7) trenches, two (2) in the Camp Zone and five (5) at Montrose Ridge totaling 660 metres were excavated and sampled with 291 samples collected and sent for chemical analyses. Trench CZ-16-01 returned 96 metres of 0.64 g/t Au from 0 to 96 metres, including **56 metres of 1.03 g/t Au from 0 to 56 metres.** This trench was excavated in the Camp Zone, north of the 2015 diamond drill holes was designed to test a previously untested portion of a zone interpreted to host the mineralized north-south trending Quartz Lake Corridor, the >18km long structure that is believed to control gold mineralization on the Hyland Gold Project. Trench CZ-16-01 intersected a broad fault zone consisting of predominantly gouge and brecciated clastic units of the Hyland Formation within the mineralized interval.

Gold grades from these trench samples ranged from trace to 9.22 g/t Au and averaged 60 ppb Au. The gold mineralization identified in the Camp Zone trenches remains open in all directions. The 2016 trenching was successful in defining geometry and structure at Montrose Ridge and Camp Zones and positions the Company well for the 2017 exploration program.

This area of the Camp Zone had seen previous, but limited trench sample campaigns in the 1980’s by Archer-Cathro, however these efforts did not produce long continuous gold mineralized results such as this year’s trench CZ-16-01. It is postulated that the excavator utilized for this season’s trench excavations afforded better depth penetration than historic trench efforts, and samples that are more representative have thus been collected and analyzed. Further trenches in the Camp Zone area are highly warranted.

Much like at the Cuz and Montrose Ridge Zones, this season’s trench sampling established a lack of a silver association with the Camp Zone gold mineralization. This fits with management’s interpretation that these zones represent separate mineralized systems from the Hyland Main Zone gold-silver system, where an approximate 1:4 gold-silver ratio exits. This continues to affirm the concept of repeated, multi-phased gold mineralization events at the Hyland Project is consistent with a District-Scale gold system.

Figure 7: 2016 Work Areas Location Map



Soils

All 2016 soil samples were collected by Banyan employees utilizing shovel, hand-held soil sampling auger and -10 sieve where applicable. Samples were collected at regular intervals from the B or C horizon wherever possible at depths that varied from 10 and 60 cm. Sample forms were filled out at each site containing germane information on all samples collected including GPS coordinates and soil sample descriptions. Samples collected in the field were sealed at the sample point with sample numbers written on the Kraft Sample Bags and 1 part of a 3-part tag inserted into Sample bag at sample site.

All samples were analyzed using a portable XRF (Olympus Innov-X Delta Premium XRF) unit. Soil samples were dried and transferred into a thin plastic bag ('Glad' Sandwich Bag) and placed into the XRF work station, and subsequently analyzed under a 3 beam SOIL setting of 30:30:30. Soil locations, sample information and compiled XRF results can be found in Appendix D.

Sample preparation, analyses and security for sampling on the Hyland Gold Project were supervised by Paul D. Gray, P.Geo. for the duration of the 2016 program. The author has determined and is confident that adequate sample preparation, analyses and security procedures for soil sampling on the Hyland Gold Project were all performed in accordance with industry standards.

Results

Grid 1: Montrose Ridge

This 2016 Montrose grid was designed to confirm infill and expand upon the 2013-2015 Montrose Ridge soils grids (and their resultant anomalies) and was emplaced irregularly on nineteen N-S lines separated by 100m. These N-S lines varied from 1,600m to 205 m in length (dependant on in-fill and grid expansion requirements) and were sampled on nominal 50m centres. In total, 389 soil samples were collected from this irregularly shaped grid and all samples were XRF analyzed. XFR analyses resulted in gold grades from trace to 2.7 ppm Au and averaged 0.1 ppm Au; arsenic values from trace to 133 ppm As with an average of 16.5 ppm As and bisumuth from trace to 626 ppm Bi with an average of 12.34 ppm Bi. XRF Results indicate a through-going As+Bi-in-soils anomaly with a general NE-SW trend. These data are interpreted to be highlighting a possible NE-SW Striking mineralized structure that is controlling the mineralization at Montrose Ridge. The Montrose grid anomaly remains open in all directions, particularly to the north, northeast and southwest.

Results from the 2016 XRF Soils program are presented in Figures 8 - 10 (Gold, Bismuth and Arsenic-in-soils, respectively) and detailed compilations of XRF Results are found in Appendix D of this Report.

The 2016 XRF soils analytical work produced a ~1,000m extension to the strong 1.4 km long Bi/As in soils defined in 2013-2015 identified Au/As-in-soils anomaly at Montrose Ridge. The Bi+As-in-soils anomaly forms a broadly East-West trending zone with a possible 110° main strike, which is interpreted to represent a possible secondary mineralized structure akin to the control of gold mineralization previously identified by drilling in the Cuz Zone to the north.

Figure 8: Montrose Ridge Soil Sample Au Results

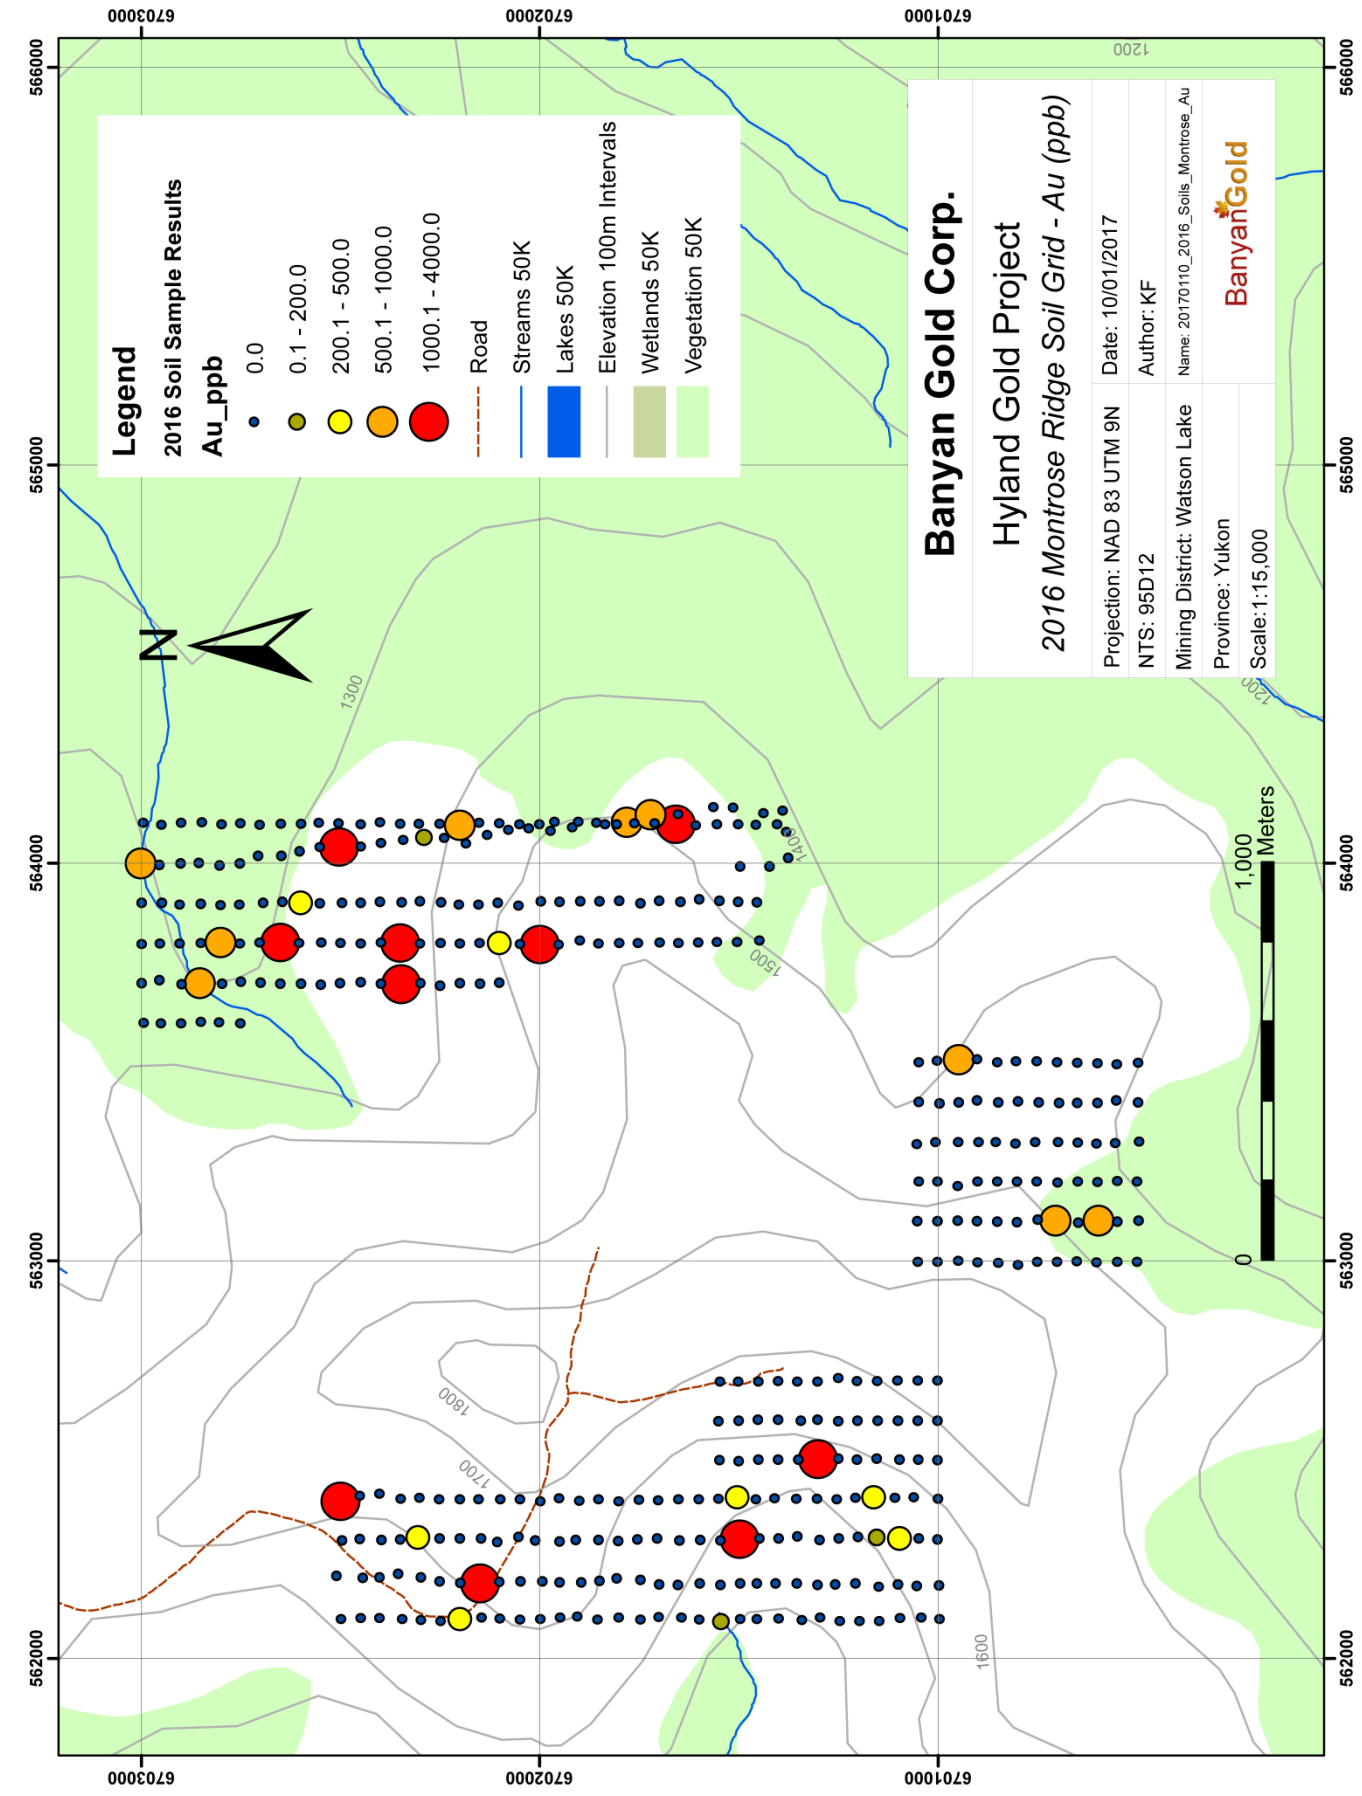


Figure 9: Montrose Ridge Soil Sample Bi Results

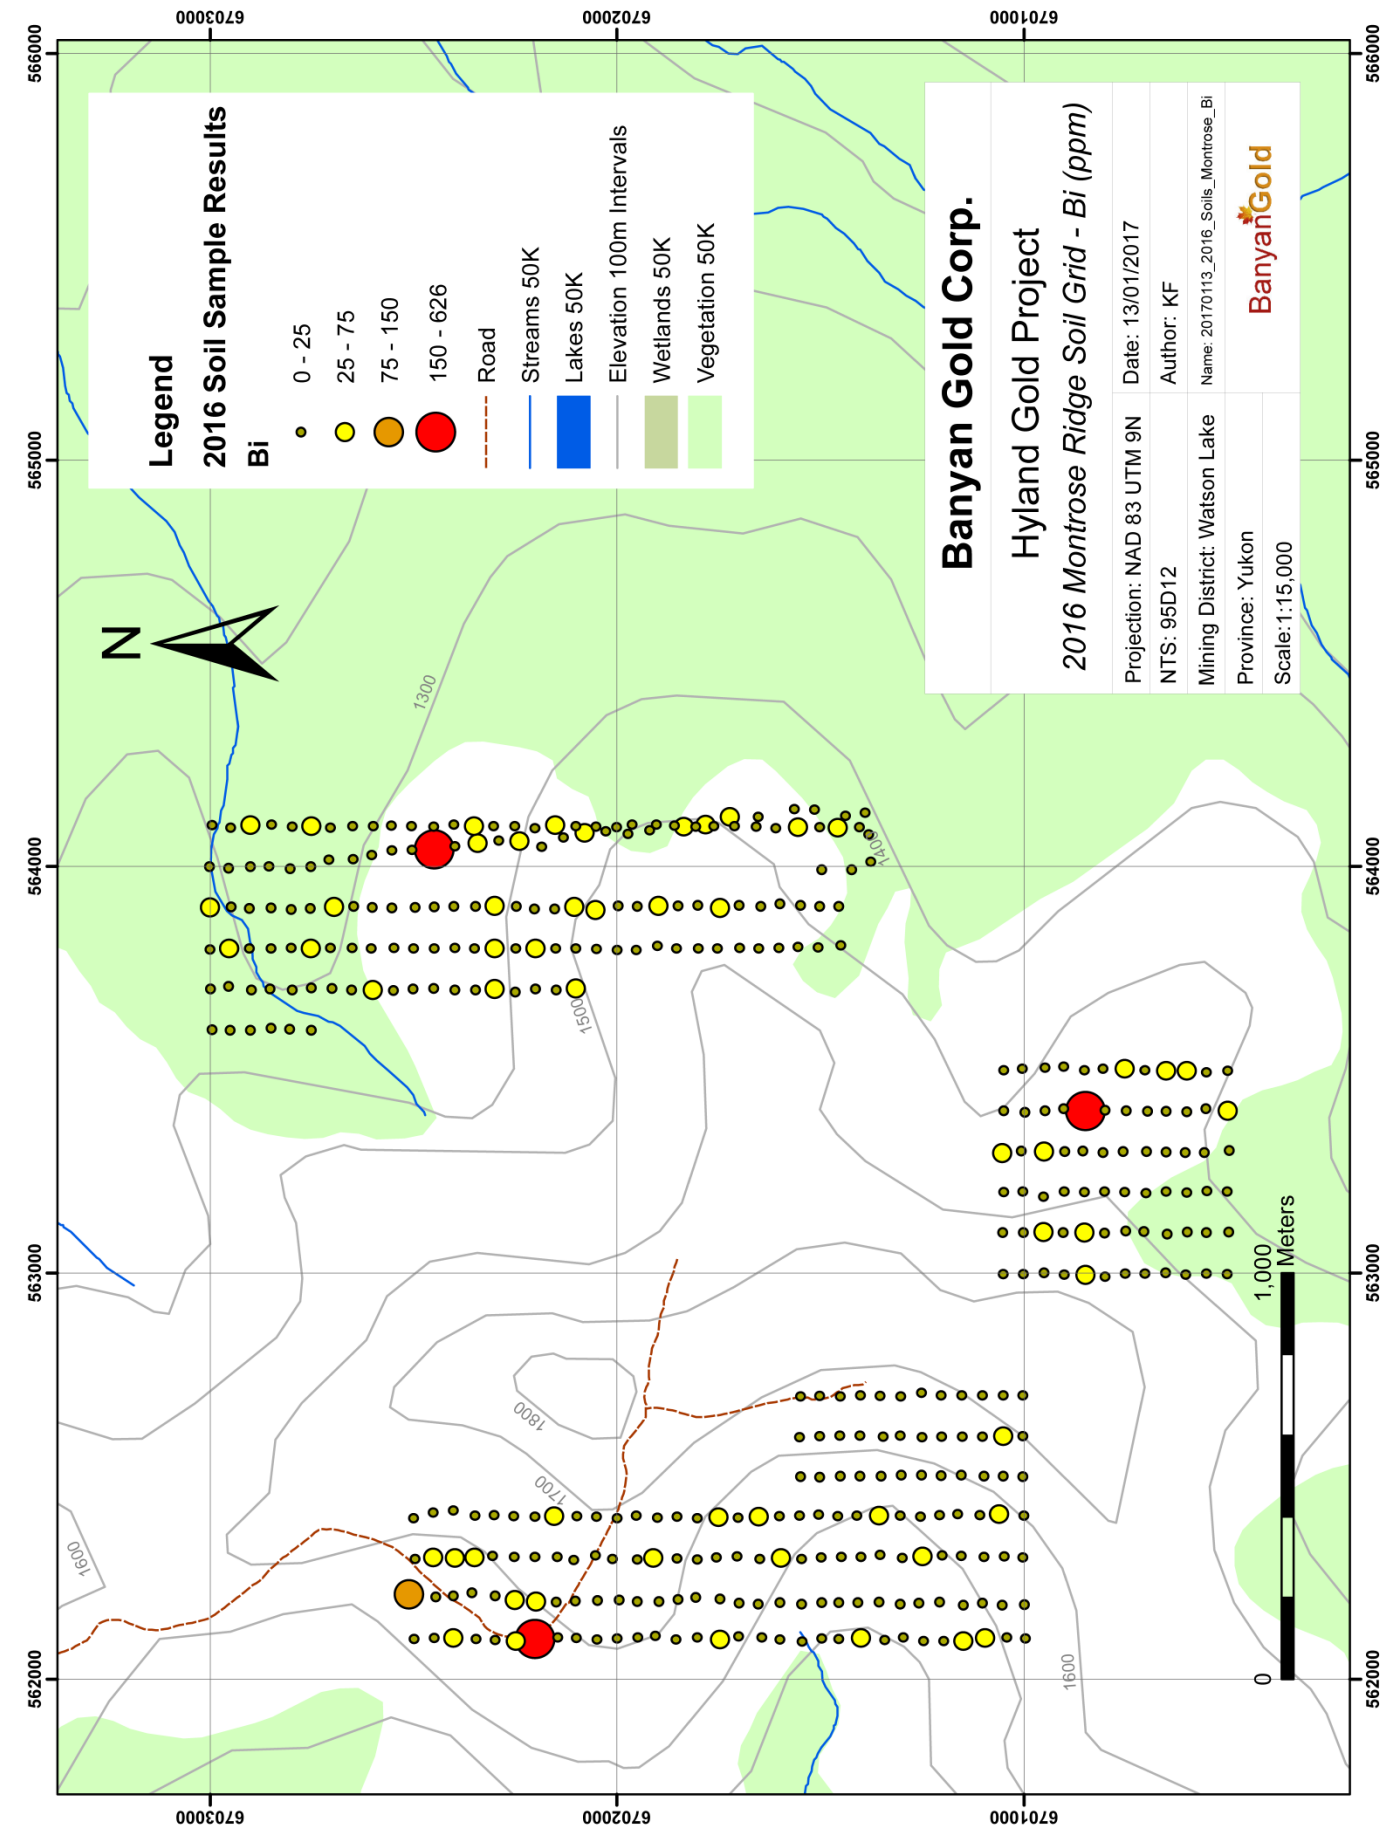

Figure 10: Montrose Ridge Soil Sample As Results

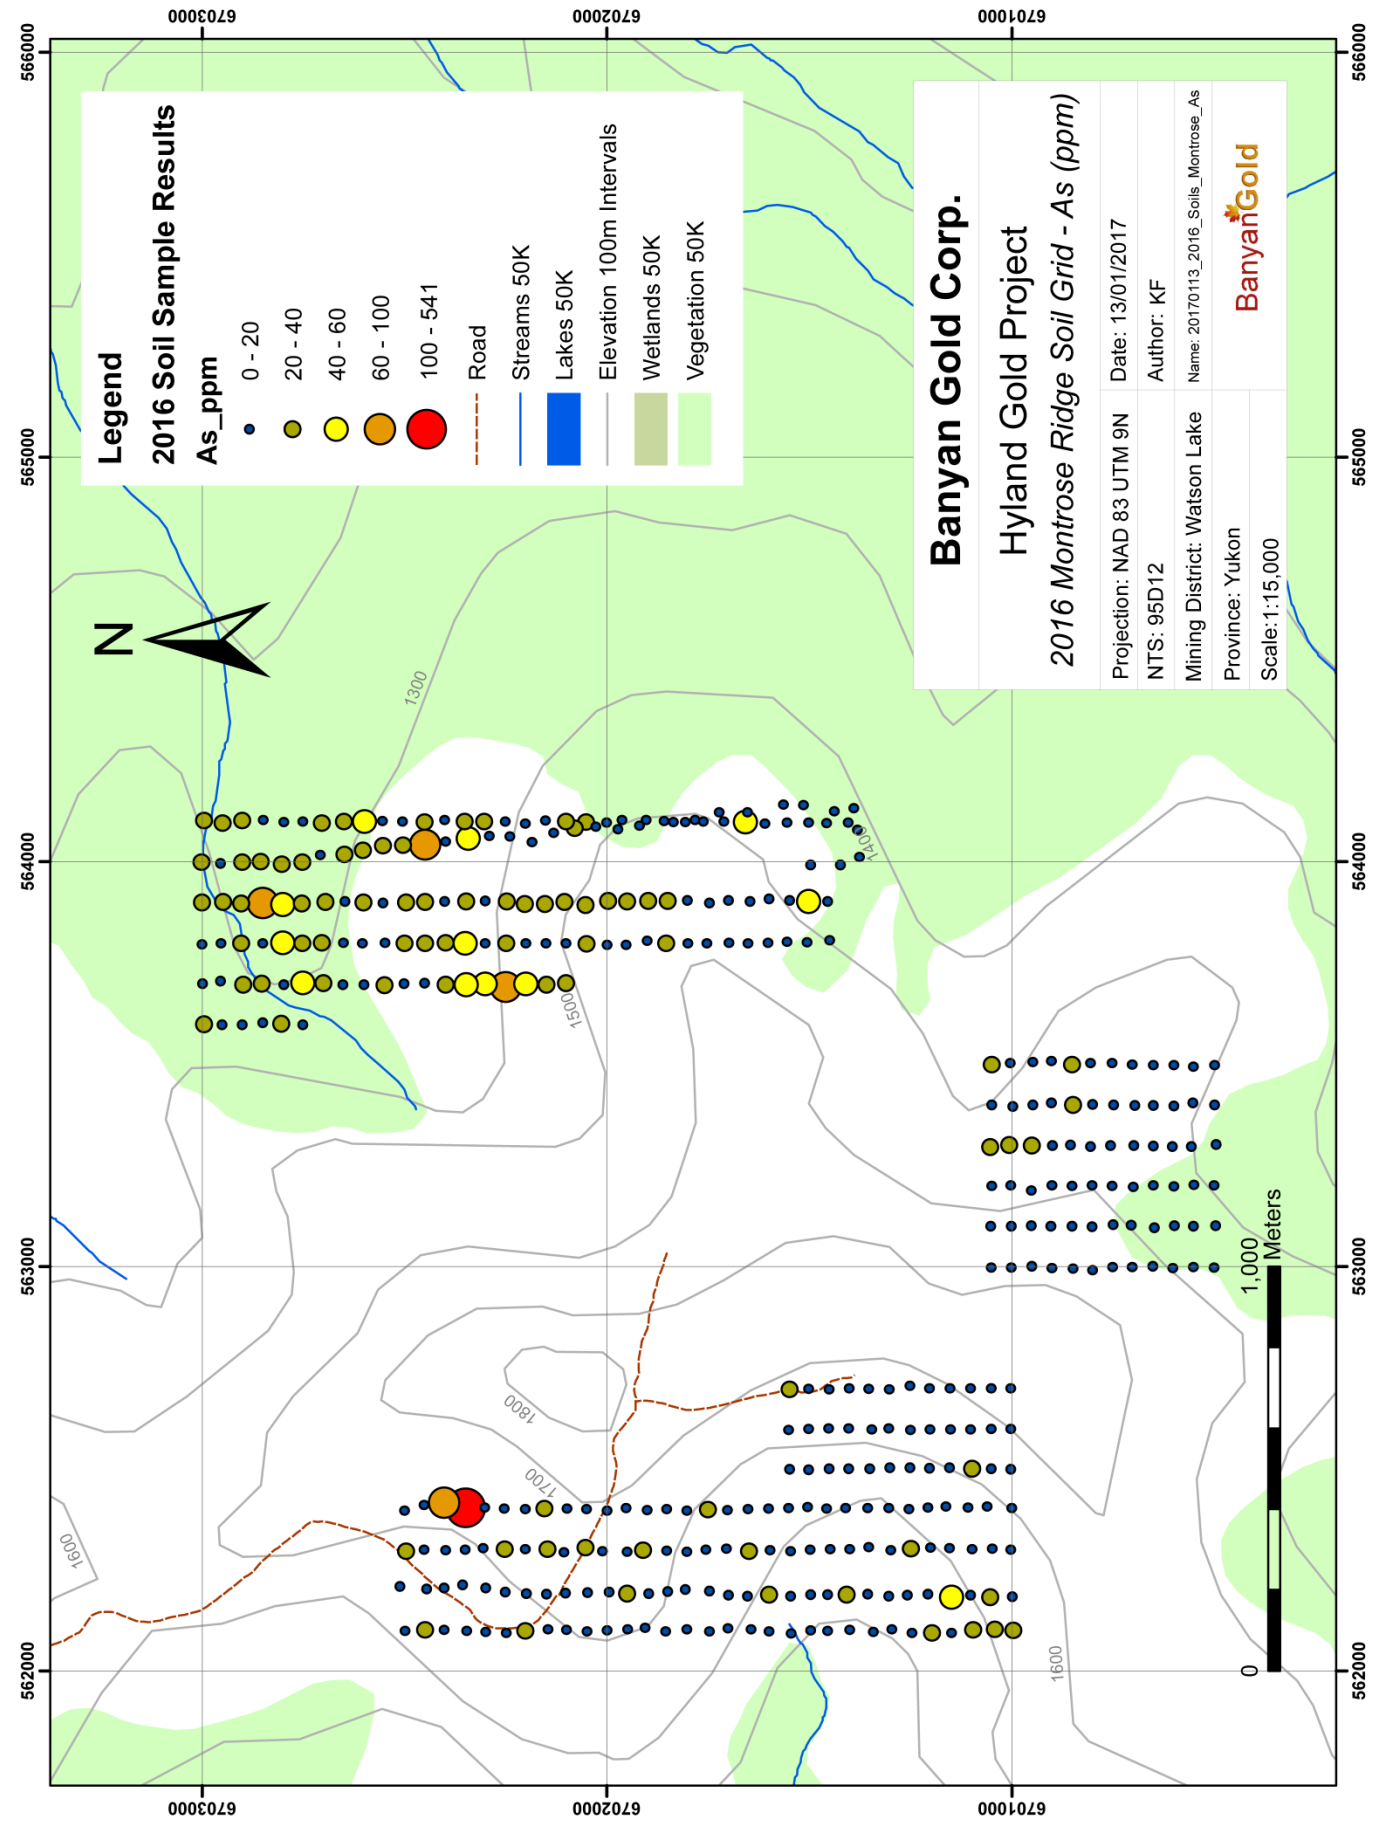

Grid 2: Southern Ridge

This 2016 grid was designed to confirm infill and expand upon the 2013 Southern Ridge and Spur soil sampling program conducted by Banyan in 2013. That 2013 ridge and spur sampling program was designed to follow-up on an historic set of stream sediment samples from the immediate downslope drainage that returned values up 25.3ppb Au. Southern Ridge soils grids (and their resultant anomalies) and was emplaced irregularly on seven E-W lines separated by 100m. These E-W lines varied from 1,000m to 500 m in length (dependant on in-fill and grid expansion requirements) and were sampled on nominal 50m centres. In total, 132 soil samples were collected from this irregularly shaped grid and all samples were XRF analyzed. XRF analysis reported gold grades from trace to 2.2 ppm Au with an average of 0.09ppm Au and arsenic values from trace to 42.4 ppm As with an average of 11.34 ppm As.

Arsenic does not appear to be an important pathfinder element in this area, as there is no correlation with gold. A review of Bi, Pb, Zn, Hg and Cu show only modest elemental increases in all elements with the exception of copper and bismuth, which appear as coincident anomalies. These results are interpreted as a sign of a different lithological package than within the Main Zone and Montrose areas, and a detailed geological mapping project over the Southern Ridge is recommended to further evaluate the elevated gold responses. Further, the soil samples from this area should be sent for chemical analysis to determine XRF vs. chemical assay correlation.

Results from the 2016 XRF Soils program are presented in Figures 11 - 12 (Gold and Arsenic-in-soils, respectively) and detailed compilations of XRF Results are found in Appendix D of this Report.

Figure 11: Southern Ridge Soil Sample Au Results

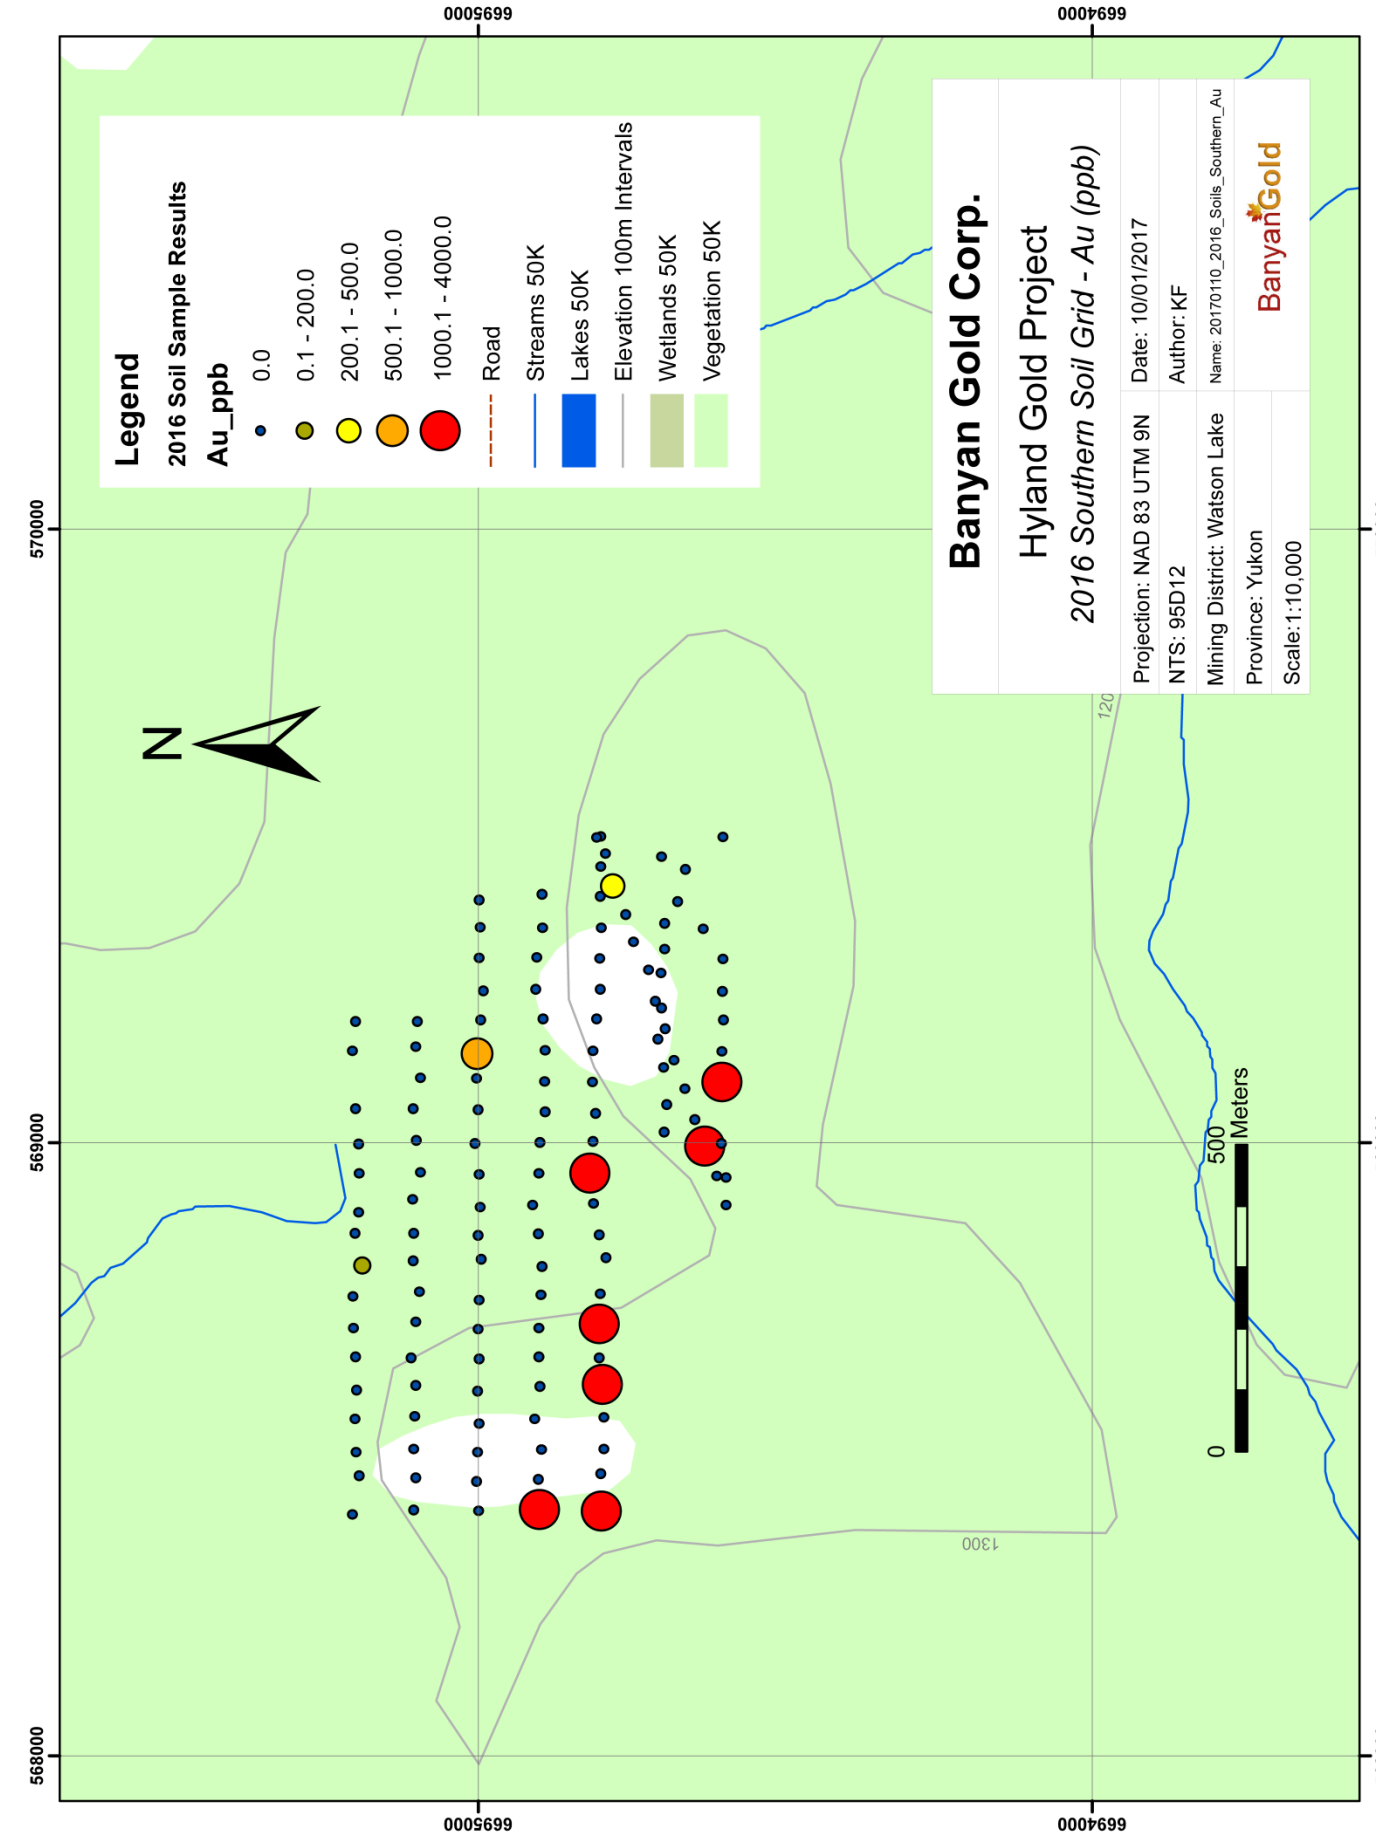

Figure 12: Southern Ridge Soil Sample As Results

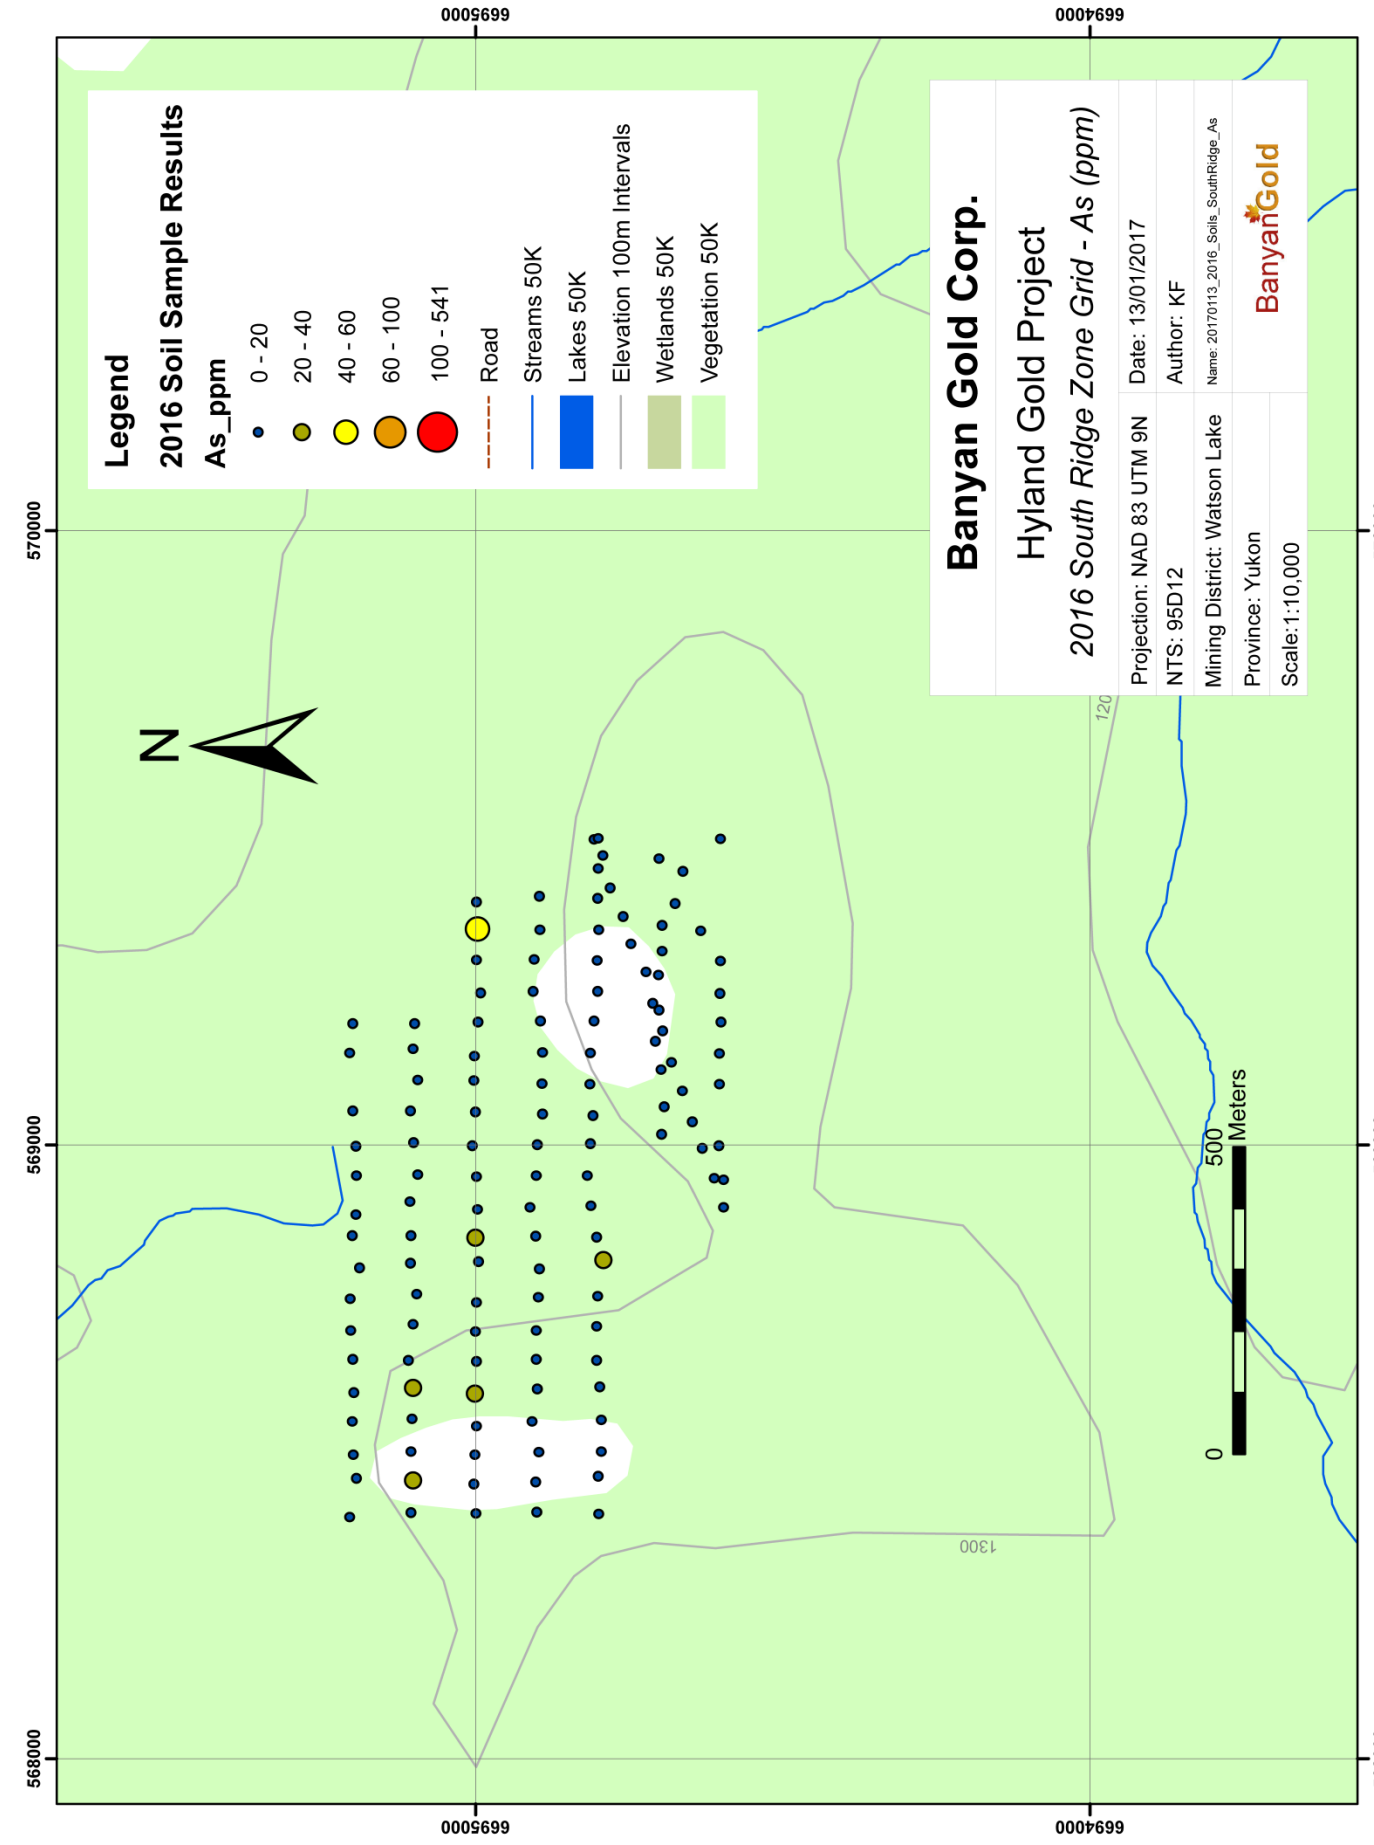

Grid 3: South East of Main Zone

This 2016 grid was designed to expand upon historic soil grid lines emplaced by Archer-Cathro in the 1980s. Several arsenic highs were reported in the extreme southern portion of these grids, and had never been followed up upon.

These three soils lines were emplaced on three, 1,000 metre E-W lines separated by 100m. In total, 64 soil samples were collected from this irregularly shaped grid and all samples were XRF analyzed. XRF analyses reported gold grades from trace to 4 ppm Au with an average of 0.43 ppm Au and arsenic values from trace to 541 ppm As with an average of 66.3 ppm As. A clear arsenic+gold-in-soils geochemical anomaly exists in this area, and additional lines should be added to this area to more accurately define this anomalous zone.

These three lines reported a significant above average response to all elements reviewed (Au, As, Cu, Hg, Pb and Bi) and a high priority should be given to expanding the soils coverage in this area, inclusive in-fill lines on tighter line spacing (50m) and 25m sample centres.

Results from the 2016 XRF Soils program are presented in Figures 13 - 14 (Gold and Arsenic-in-soils, respectively) and detailed compilations of XRF Results are found in Appendix D of this Report.

Figure 13: Southeast of Main Zone Soil Sample Au Results

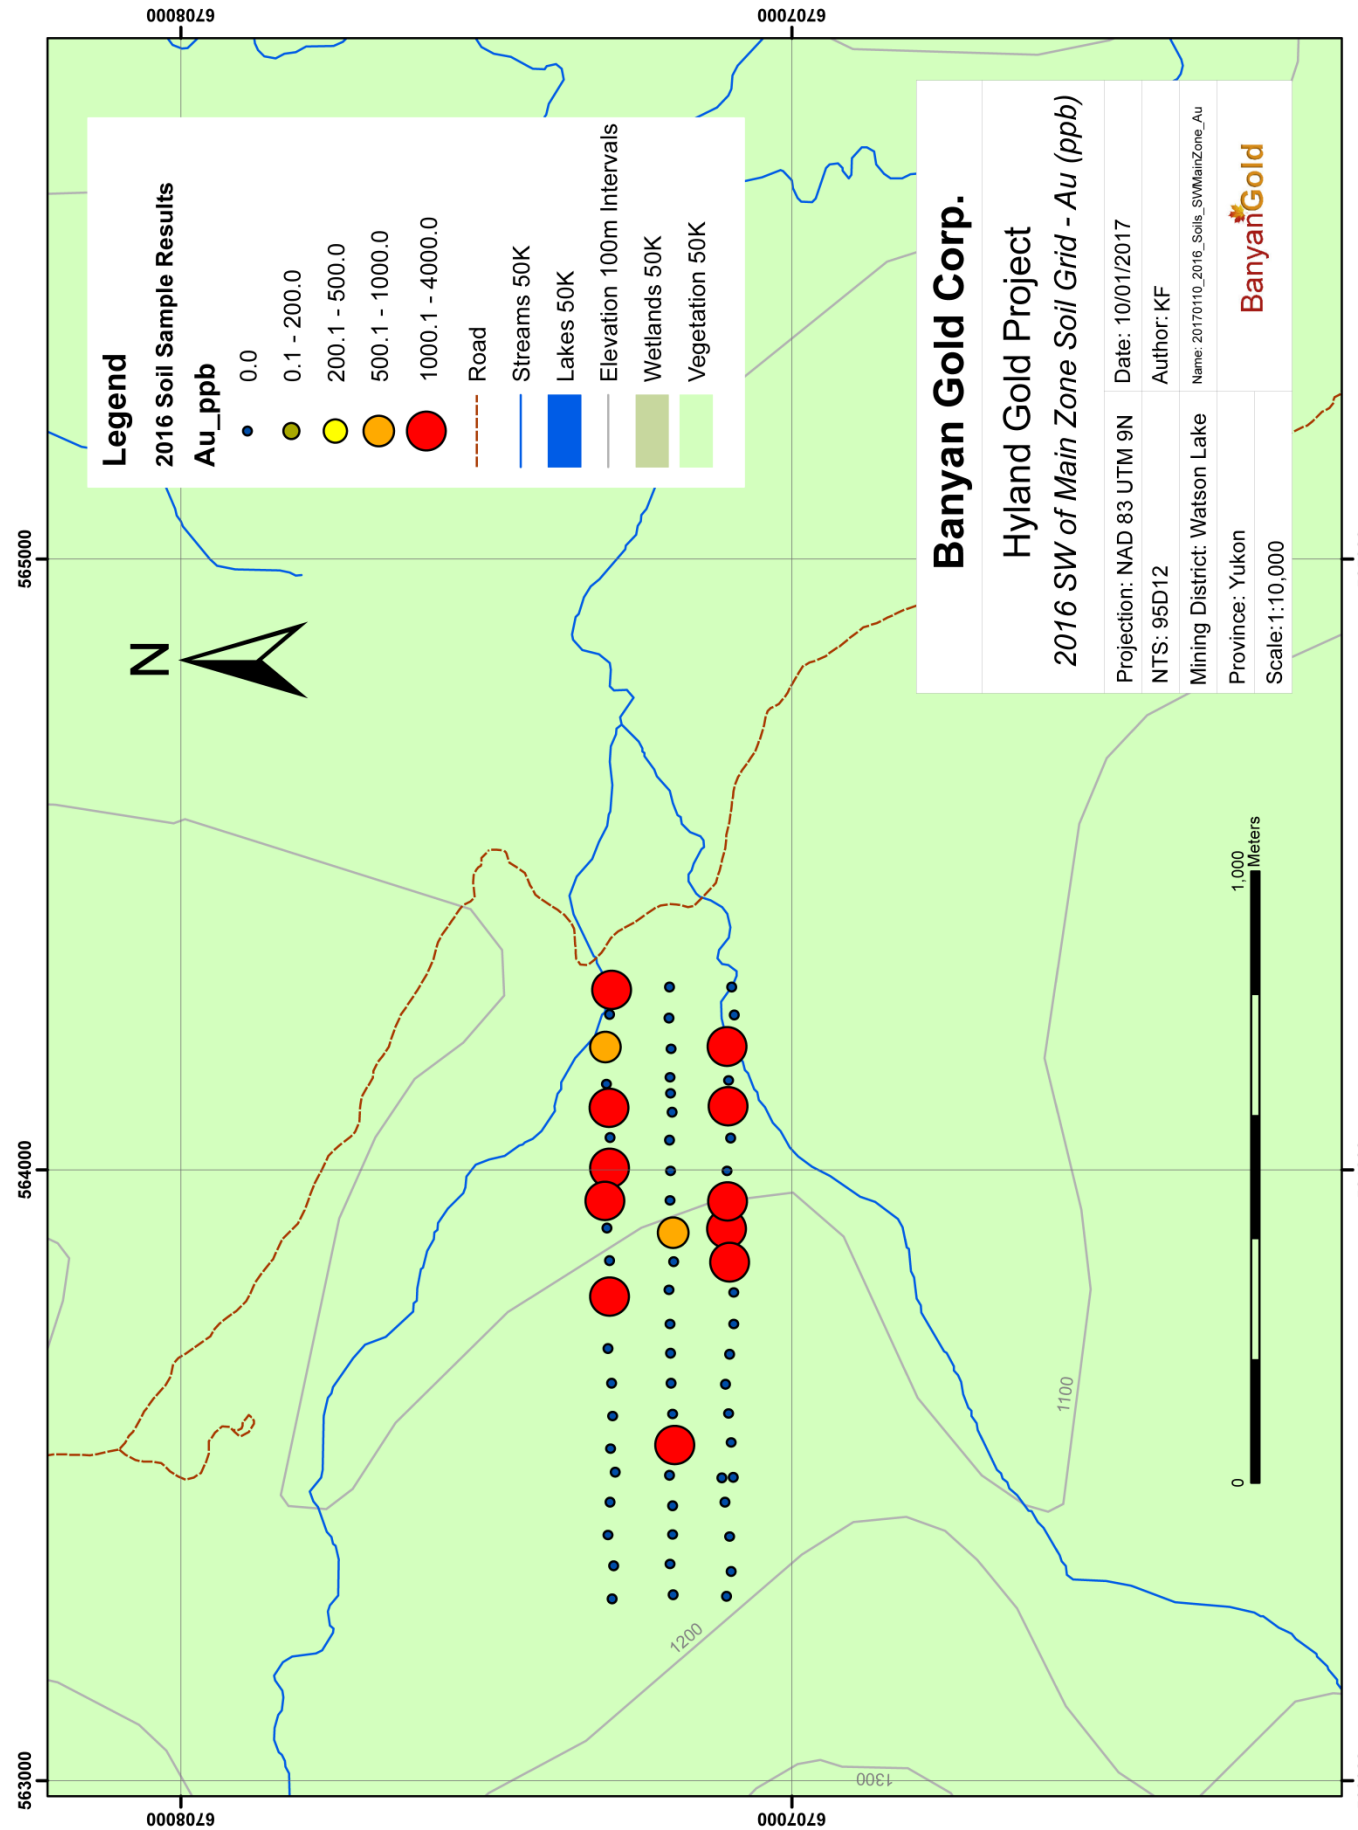

Figure 14: Southeast of Main Zone Soil Sample As Results

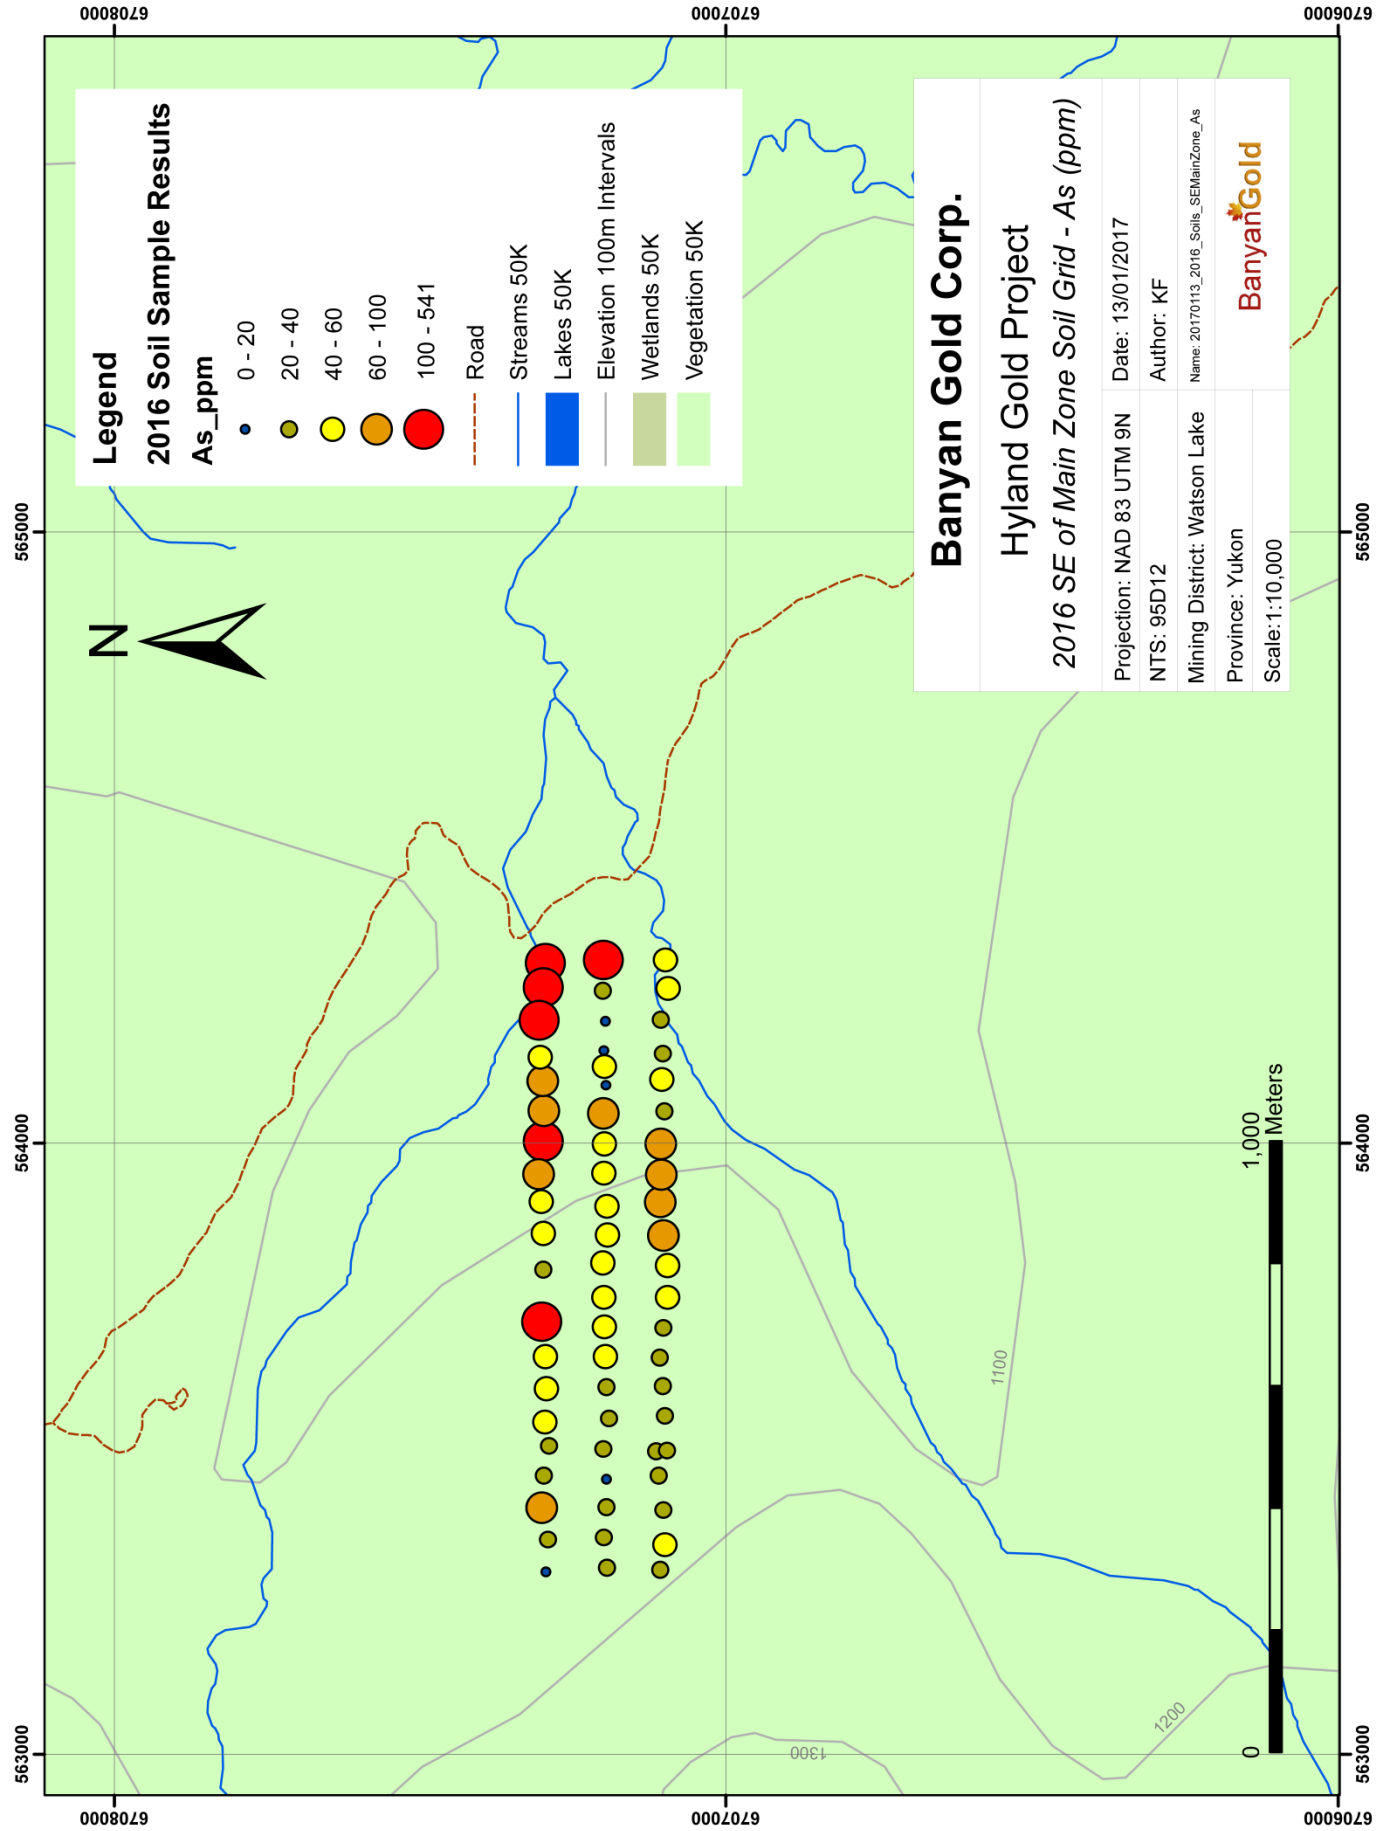

Trenches

Montrose Ridge and Camp Zones were the targets of all 2016 Hyland Project trench excavation and sample activities. Trench locations at Montrose Ridge were designed to test the area west and upslope of the 2015 trench discovery; 6m of 4.4 g/t Au from 0-6m in Trench MT-15-01. The saddle along the main Montrose Ridge and the competent bluff exposures surrounding the saddle represented the main focus of the 2016 the trench and chip sampling at Montrose.

Start and end points for each trench were marked in the field; and then excavated with the PCS200 Excavator to the limit of excavatable cover; after that 2m wide chip samples were utilized to sample the exposed lithologies of the competent rock. After trenches were excavated, Banyan geologists measured, surveyed the full lengths of the trenches and marked each trench in 2m intervals utilizing a 100m tape. During these trench surveys, all sampleable intervals within the trench were noted and GPS marked. Then Banyan geologists entered the trenches and bagged samples over the pre-determined two metre widths. All rock samples (channel or chip, and rock type with descriptions) were noted in sample forms and subsequently sealed in marked Rice bags with 1 part of a 3-part laboratory tag inserted into each bag.

Results from the trench sampling program are presented in Figures 15 - 16 (Au in ppm from Montrose and Camp Zones, respectively) and detailed compilations of all sample results are found in Appendix D of this Report.

In total seven trenches (two in the Camp Zone and five at Montrose Ridge) totaling 660 metres were excavated and sampled with 291 samples collected. Gold grades from these samples ranged from trace to 9.22 g/t Au and averaged 60 ppb Au.

All exploration trench samples collected from the Hyland 2016 program were analyzed at SGS Canada Inc. of Burnaby, B.C. utilizing the GE-ARM133, 48-element ICP analytical package with GE-FAA515 50-gram Fire Assay with Gravimetric finish for gold on selected samples. All trench samples collected from the Hyland Gold Project in 2016 were bagged and tagged at the trench face, with samples subsequently organized for final shipment at the Company's Quartz Lake Exploration camp. From there, samples were shipped to SGS Canada Inc.'s Burnaby laboratory where they were sorted and crushed to appropriate particle size (coarse crush) and representatively split to a smaller size.

The Montrose Ridge trenches concentrated on the saddle of the ridge and did not locate the mineralized control for the interpreted Montrose Ridge structure. Well altered (red to orange) oxidized coarse pebble conglomerates of the Yusezyu Formation were the only lithology sampled within these trenches. Drusy quartz and common brecciation of quartz veining was common, and an overall stockwork style of quartz veining was noted in the trench mapping. In short, the rocks appeared to be extremely anomalous compared to the surrounding unaltered lithologies of the phyllites to the south. The low grades returned from chemical analyses prompted the author to re-assay 25% of the collected material from these trenches with a 50gram FA to ensure the grades as reported were accurate. Results of the re-assay initiative confirmed the orginal assays.

Follow-up trenches in 2017 should concentrate at lower elevations and begin sampling from the 6m of 4.4 g/t Au from 0-6m returned from Trench MT-15-01 in 2015.

In the Camp zone, Trench CZ-16-01 returned 96 metres of 0.64 g/t Au from 0 to 96 metres, including **56 metres of 1.03 g/t Au from 0 to 56 metres.** This trench was excavated in the Camp Zone, north of the 2015 diamond drill holes and was designed to test a previously untested portion of a zone interpreted to host the mineralized north-south trending Quartz Lake Corridor, the >18km long structure that is believed to control gold mineralization on the Hyland Gold Project. Trench CZ-16-01 intersected a broad fault zone consisting of predominantly gouge and brecciated clastic units of the Hyland Formation within the mineralized interval.

This area of the Camp Zone had seen previous, but limited trench sample campaigns in the 1980's by Archer-Cathro, however these efforts did not produce long continuous gold mineralized results such as this year's trench CZ-16-01. It is postulated that the excavator utilized for this season's trench excavations afforded better depth penetration than historic trench efforts (which were conducted with a small dozer), and samples that are more representative of the underlying lithologies and grade have thus been collected and analyzed during the 2016 activities. Further trenches in the Camp Zone area are highly warranted. The gold mineralization identified in the Camp Zone trenches remains open in all directions.

Much like at the Cuz and Montrose Ridge Zones, this season's trench sampling established a lack of a silver association with the Camp Zone gold mineralization. This fits with management's interpretation that these zones represent separate mineralized systems from the Hyland Main Zone gold-silver system, where an approximate 1:4 gold-silver ratio exits. This continues to affirm the concept of repeated, multi-phased gold mineralization events at the Hyland Project is consistent with a District-Scale gold system.

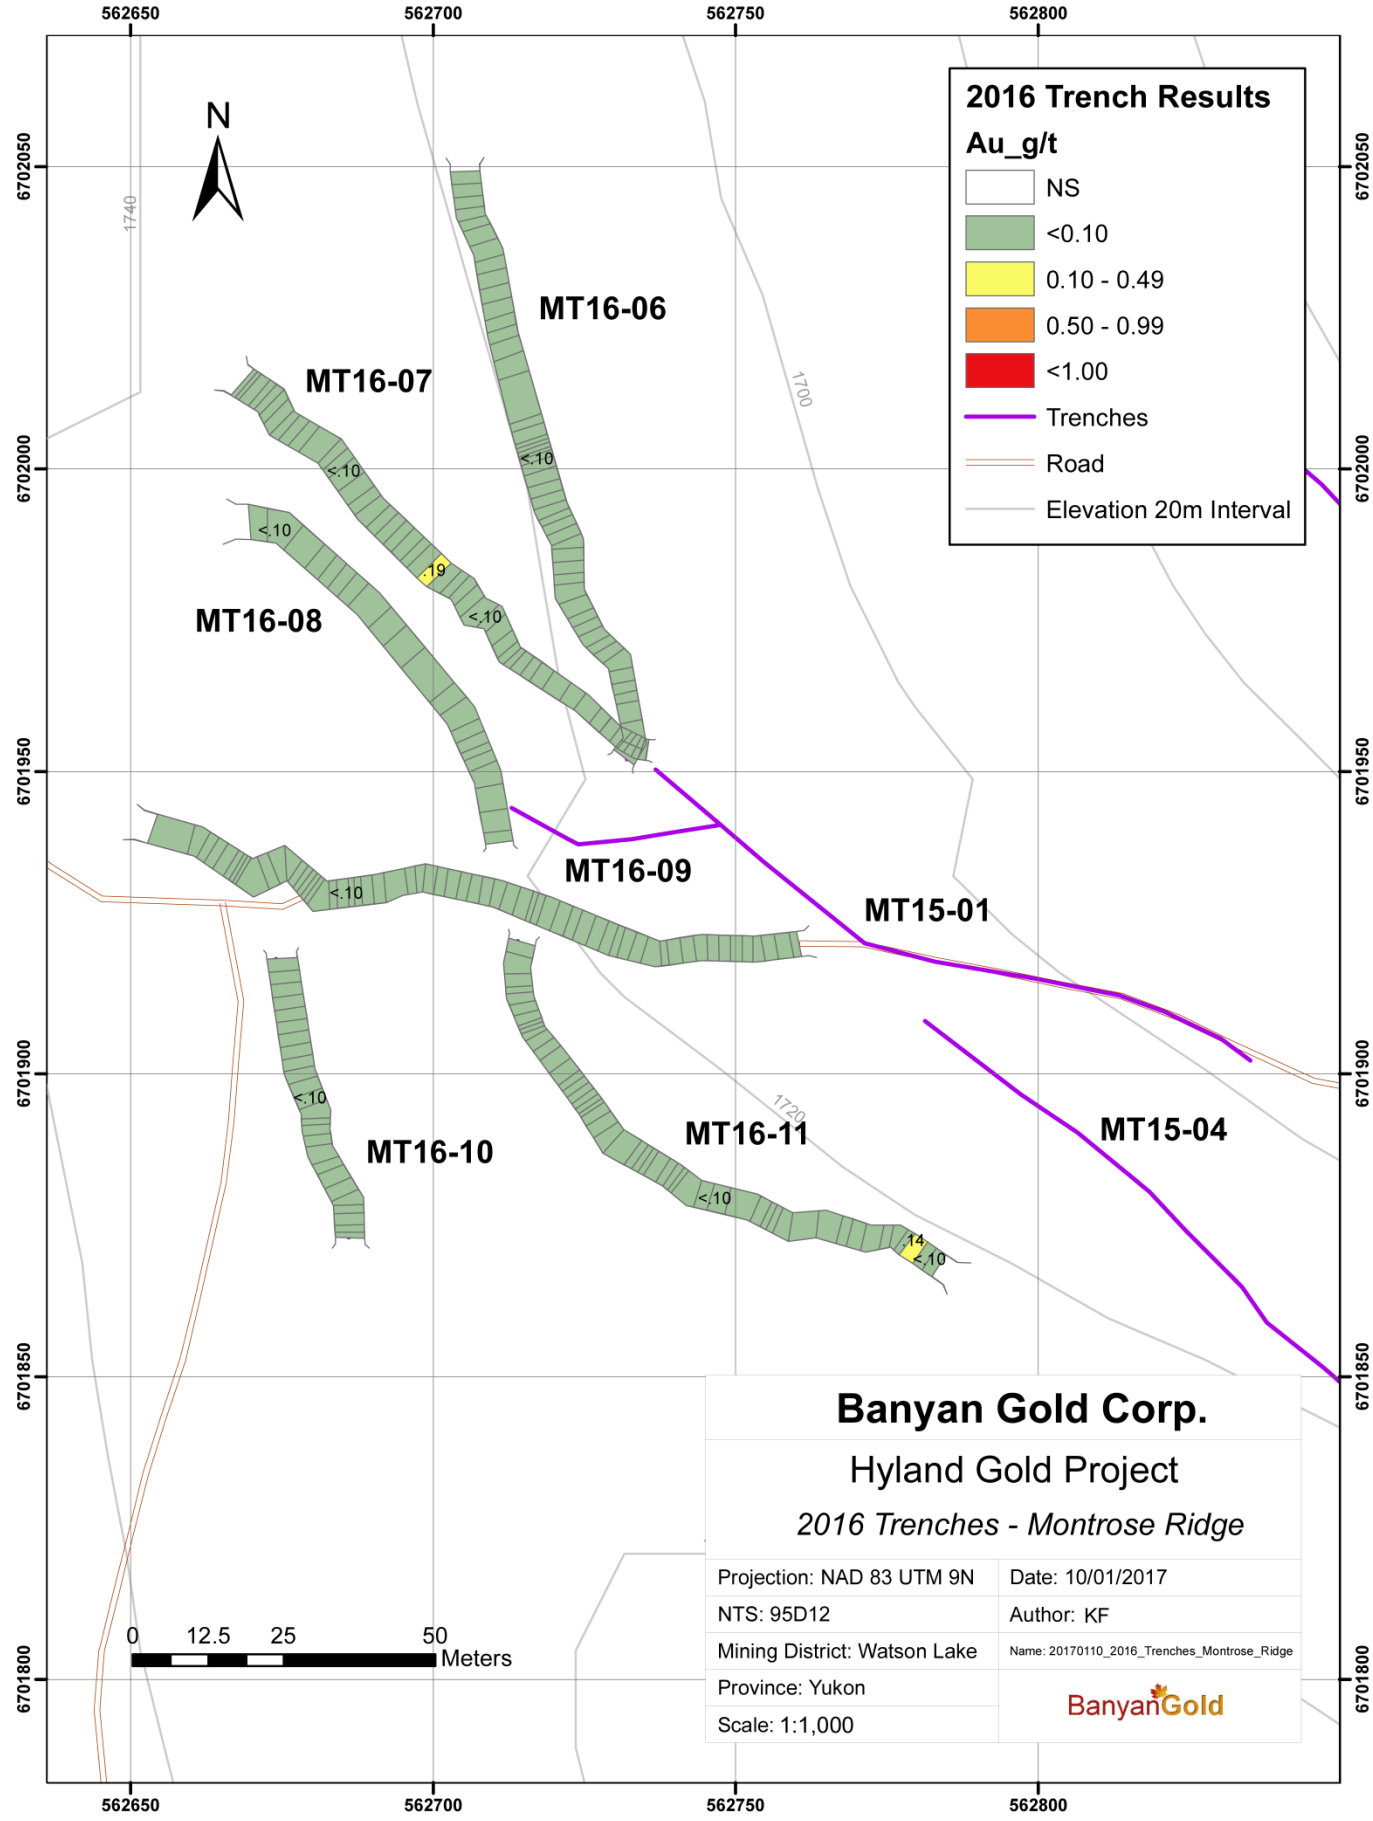

Figure 16: 2016 Camp Zone Trench Locations and Results – Au

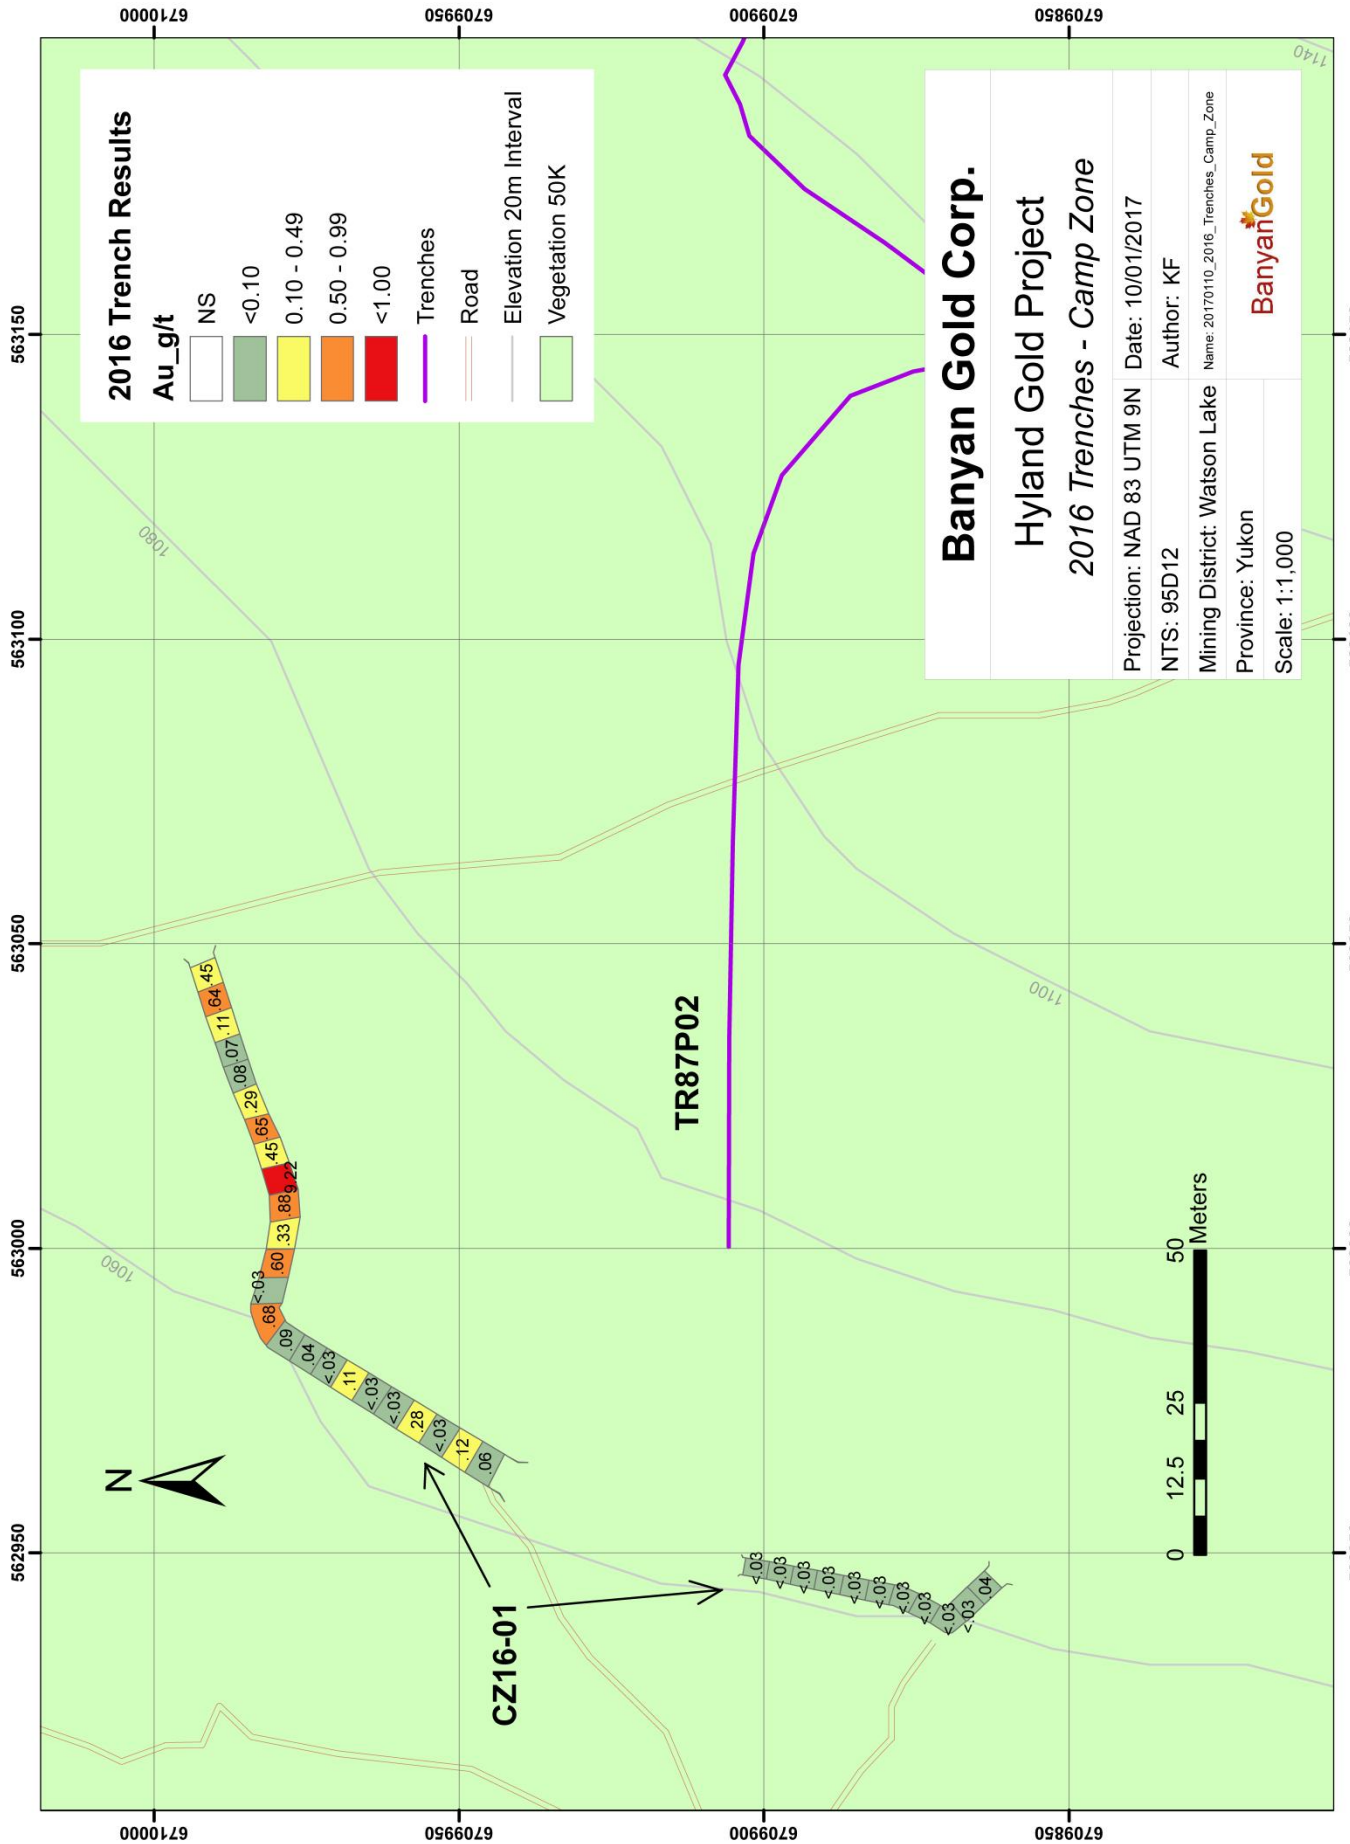


Analytical Method

All exploration trench samples collected from the Hyland 2016 program were analyzed at SGS Canada Inc. of Burnaby, B.C. utilizing the GE-ARM133, 48-element ICP analytical package with GE-FAA515 50-gram Fire Assay with Gravimetric finish for gold on selected samples. All trench samples collected from the Hyland Gold Project in 2016 were bagged and tagged at the trench face, with samples subsequently organized for final shipment at the Company's Quartz Lake Exploration camp. From there, samples were shipped to SGS Canada Inc.'s Burnaby laboratory where they were sorted and crushed to appropriate particle size (coarse crush) and representatively split to a smaller size.

9.0 DISCUSSION AND CONCLUSIONS

The Hyland Project has been explored for gold and silver intermittently since the 1970's. Mineral exploration work has included large scale to focused prospecting, hand and mechanized trenching, extensive soil sampling, regional and Property wide stream sediment sampling, multiple geophysical surveys (airborne and ground based), with numerous reverse circulation and diamond drilling campaigns. This work has resulted in the discovery of the Main Zone Gold Deposit as well as a series of additional mineralized zones which are interpreted to be related to a dominant north-trending shear (Quartz Lake Lineament) and cross cutting secondary east-west structures.

More recent exploration programs conducted by Argus Metals Corp. (2010 and 2011) concentrated on re-evaluating the geological controls on the known mineralization and have resulted in the expansion of the Main Zone gold deposit as well as the discovery of additional zones of gold mineralization (e.g. the CUZ zone). Additionally, the project extents have been significantly expanded through the staking of additional claims to the south, North, East and West of the original Hyland Gold Project. This staking was done in conjunction with the Property wide re-assessment of the mineralization potential of the Property and was designed to ensure coverage of interpreted secondary east-west structures. A concentrated effort on prospecting, geological mapping, stream sediment sampling and ridge-spur soil traverses were run by Argus on these newly staked claims in 2011 and have helped guide all on-going mineral exploration campaigns.

The Main Zone at the Hyland Project has been calculated to host a gold inferred resource, at a 0.6 g/t gold equivalent ("AuEq") at 12,503,994 tonnes containing 361,692 ounces gold at 0.9 g/t and 2,248,948 ounces silver at 5.59 g/t. The results of diamond drilling to date show that the Main Zone is open in all directions. Historic exploration on the Main Zone was primarily focused on the near-surface oxide gold resource, Banyan' drilling campaigns concentrated on delineating the deposit to depth (within the sulphide zone) as well as to the east.

Gold mineralization discovered from at CUZ Zone from the 2011 drilling program has demonstrated mineralization continuity over 800m on a West-Northwest trend and is open at both ends and down-dip. This gold mineralization has been interpreted to be distinct from the Main Zone Gold mineralization as there is a significantly lower silver component than the Main Zone. The CUZ Zone mineralization therefore may represent a secondary (cross-cutting) structurally hosted mineralized component of the Hyland Property and re-affirms Banyan' interpretation that these secondary structures (and their intersections with the dominant north-south Quartz Lake Lineament) may offer important exploration targets for future work on the Property.

A compilation of the historic and 2011 soil sampling surveys conducted on the Property have resulted in a suite of gold(+As)-in-soils geochemical anomalies which require follow-up exploration including trenching and geological mapping to define the underlying source of the gold.

In 2013 Banyan Gold became the 100% owner of the Hyland project and immediately recognized and focused on the regional mineralization potential of the Hyland Project. The exploration concept being the pronounced N-S Quartz Lake Lineament provides a known corridor of structurally controlled mineralization, as demonstrated by the Main Zone and later Cuz Zone discoveries. The Cuz Zone is interpreted to be controlled by a secondary (E-W) structure with a limited Ag association, and the main target of exploration at the CUZ Zone is to locate the structural intersection(s) of these E-W structures with the Quartz Lake Lineament (as the Main Zone), as these areas have the potential to provide adequate open space and structural control(s) to allow a mineral deposition.

To that end, The 2013 Hyland Regional Program targeted six of these 2011 defined geochemically anomalous areas with detailed grid based soil sampling programs over identified Au +/- As in soils anomalies and successfully identified targets for follow-up on 5 out of the six areas. In specific, the Montrose Ridge grid returned a large, >1.6km^2 Au+As-in-soils anomaly that was the focus of the 2014 mineral exploration program by Banyan.

The 2014 program was successful in joining the defined CUZ South zone soil coverage with the 2013 Montrose Ridge soils grid. The anomalous gold-arsenic in soils zone was extended by virtue of this program and a more defined structural vector determined in the process. These results indicate a broad (500m by 1,000m) east-west trending gold-in-soils anomaly (>20ppb Au) focused around the Montrose Ridge Zone.

Additionally, a parallel soils anomaly (As +/- Au) is located near the CUZ South anomaly, and together these 2 anomalies define a >2km long cohesive arsenic-in-soils NE trend. The Montrose Ridge and CUZ Extension grid anomalies remain open, particularly to the east and north.

The 2015 Hyland Program represented the first ever heavy equipment supported exploration program Banyan has undertaken on the Project, and the first time since the early 1990's excavators and bulldozers were utilized on the property. The successful March 2015 winter road mobilization of a D-6 Cat and PCS200 Excavator greatly enhanced the 2015 program by affording access construction (3.2 km) and targeted trench-based sampling (700m) of the Montrose Ridge Anomaly.

Proceeding, and co-incident with, Montrose access construction, a systematic, XRF analysis soil sampling program was conducted on the Montrose Ridge gold/arsenic-in-soils anomaly. This grid-based soil sampling program was served to confirm XRF analyses effectiveness as well as in-fill and extend the 2013/14 Montrose Ridge anomaly. It was quickly determined that the XRF analysis of Montrose soil samples reported comparable As-in-soils results as 2013/14 chemical analysis; and additionally that Bi was a highly applicable pathfinder element for the Montrose Ridge Gold-In-soils anomaly.

The 2016 Hyland Exploration program continued where the 2015 campaign left off and extended the soils coverage around Montrose Ridge as well as to the south on the Southeast Ridge Zone. Importantly, a trench program was conducted in 2016 with over 660m of trench samples collected from the Montrose and Camp Zones. The Camp Zone trench returned the most interesting results of the program and extending trench coverage in this area are highly warranted. Additional trench sampling is also required at the Montrose Ridge Zone to follow-up on the 2015 Montrose Ridge Trench discovery.

As demonstrated over the past four exploration seasons at the Hyland Project by Banyan, soils geochemistry continues to be highly useful in delineating areas of potential gold mineralization, particularly with respect the As/Bi-in-soils elemental analysis; moreover this season XRF analysis of same was proven to be extremely effective in reproducing chemical analytical results and this offers an exciting, "real-time" approach to mineral exploration on Hyland and Hyland South going forward. In specific, Montrose Ridge, which returned anomalous gold/arsenic-in-soils point data from a 2011 ridge and spur traverse was identified as highly anomalous in Gold and Arsenic from the 2013/2014 program was defined as a trench discovery in 2015. This rapidly emerging mineralized zone area is located ~6.5km south of the Main Zone and extends from CUZ Zone, with the most intriguing soils responses developed from ~2km south of the Cuz Zone.

Continued, targeted follow-up exploration work by systematic soils and rock sampling programs involving access construction, extended and in-fill soil sampling, trenching (of the CUZ South and Montrose Ridge zones) is warranted. Detailed analysis of glacial transport direction in and around the Montrose and Cuz South grid areas should be a priority for any trenching and soil profile programs. Based on results from such programs, diamond drilling targeting source of mineralization may be considered.

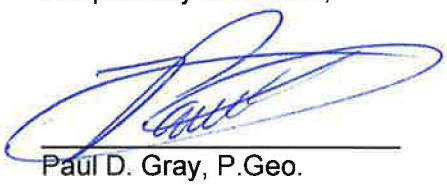
Further, the point sample Au anomalies located within the more southern grids should be revisited and step out soil sampling conducted in conjunction with geological mapping programs. Interestingly, the southern grids have a low background As component in comparison to the CUZ and Montrose Ridge grids. This could be a function of primary mineralizing event and/or host rock (lithological) differences. More work (mapping and sampling) will be required to more adequately qualify this discrepancy, and should concentrate on determining if a separate domain of As background should be utilized in all future exploration programs in these areas.

Continued mineral exploration across the property is encouraged as there is high potential to discover additional mineralized zones and structures.

10.0 RECOMMENDATIONS

- A follow-up and expansion program of systematic trenches to extend the Montrose Ridge 2015 trench sample anomalies to the East and North
- Continue to extend Montrose Ridge Zone geochemical coverage with a focus on bismuth as a primary vector to Au mineralization along with As from XRF
- Analyze by Gold Fire Assay all soils samples collected from the South Ridge and South East Zones in 2016, towards establishment of anomalous gold-in-soils
- Detailed review of glacial transport directions on Montrose/Cuz South targets areas
- Property Wide Terrain Suitability Analysis (with historic soils compilation analysis)
- Reinterpretation of structures from the 1995 Airborne Magnetics and 2003 EM data
- Access construction from the Montrose Ridge Zones to the South along Ridges to extend accessibility to Hyland South geochemical targets
- Diamond drilling in the CUZ and Montrose Ridge Zones

Respectfully submitted,



Paul D. Gray, P.Geo.

Appendix E: Certificates of Analysis

Certificate of Analysis
Work Order : VC163138
[Report File No.: 0000019505]

Date: October 21, 2016

To: **Paul Gray**
COD SGS ASSAYERS
Banyan Gold Corp
166 Cougarstone Cresent SW
Calgary
AB T3H 4Z5

P.O. No.: Banyan Gold 11101-133
Project No.: -
Samples: 33
Received: Oct 3, 2016
Pages: Page 1 to 8
(Inclusive of Cover Sheet)

Methods Summary

No. Of Samples	Method Code	Description
33	G_LOG02	Pre-preparation processing, sorting, logging, boxing
33	G_PRP89	Weigh, dry,(up to3.0 kg) crush to 75% passing 2 mm, split 250 g, pulverize to
33	G_WGH79	Weighing of samples and reporting of weights
33	GE_ARM133_VA	Aqua Regia Digest 25g-300ml, ICPMS (Vancouver)

Storage: Pulp & Reject

REJECT STORAGE	:	DISCARD
PULP STORAGE	:	RETURN

Certified By :
John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the @ symbol (e.g. @Cu) denote assays performed using accredited test methods

Final : VC163138 Order: Banyan Gold 11101-133

Date: October 21, 2016

To: **Paul Gray**
COD SGS ASSAYERS
Banyan Gold Corp
166 Cougarstone Cresent SW
Calgary
AB T3H 4Z5

P.O. No.: Banyan Gold 11134-166
Project No.: -
Samples: 33
Received: Oct 3, 2016
Pages: Page 1 to 8
(Inclusive of Cover Sheet)

Methods Summary

No. Of Samples	Method Code	Description
33	G_LOG02	Pre-preparation processing, sorting, logging, boxing
33	G_PRP89	Weigh, dry,(up to3.0 kg) crush to 75% passing 2 mm, split 250 g, pulverize to
33	G_WGH79	Weighing of samples and reporting of weights
33	GE_ARM133_VA	Aqua Regia Digest 25g-300ml, ICPMS (Vancouver)

Storage: Pulp & Reject

REJECT STORAGE	:	DISCARD
PULP STORAGE	:	RETURN

Certified By :

John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the @ symbol (e.g. @Cu) denote assays performed using accredited test methods

Date: October 21, 2016

To: **Paul Gray**
COD SGS ASSAYERS
Banyan Gold Corp
166 Cougarstone Cresent SW
Calgary
AB T3H 4Z5

P.O. No.: Banyan Gold 11167-199
Project No.: -
Samples: 33
Received: Oct 3, 2016
Pages: Page 1 to 8
(Inclusive of Cover Sheet)

Methods Summary

No. Of Samples	Method Code	Description
33	G_LOG02	Pre-preparation processing, sorting, logging, boxing
33	G_PRP89	Weigh, dry,(up to3.0 kg) crush to 75% passing 2 mm, split 250 g, pulverize to
33	G_WGH79	Weighing of samples and reporting of weights
33	GE_ARM133_VA	Aqua Regia Digest 25g-300ml, ICPMS (Vancouver)

Storage: Pulp & Reject

REJECT STORAGE : DISCARD
PULP STORAGE : RETURN

Certified By :
John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:
L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result
*INF = Composition of this sample makes detection impossible by this method
M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion
Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the @ symbol (e.g. @Cu) denote assays performed using accredited test methods

Date: October 21, 2016

To: **Paul Gray**
COD SGS ASSAYERS
Banyan Gold Corp
166 Cougarstone Cresent SW
Calgary
AB T3H 4Z5

P.O. No.: Banyan Gold 11200-232
Project No.: -
Samples: 33
Received: Oct 3, 2016
Pages: Page 1 to 8
(Inclusive of Cover Sheet)

Methods Summary

No. Of Samples	Method Code	Description
33	G_LOG02	Pre-preparation processing, sorting, logging, boxing
33	G_PRP89	Weigh, dry,(up to3.0 kg) crush to 75% passing 2 mm, split 250 g, pulverize to
33	G_WGH79	Weighing of samples and reporting of weights
33	GE_ARM133_VA	Aqua Regia Digest 25g-300ml, ICPMS (Vancouver)

Storage: Pulp & Reject

REJECT STORAGE	:	DISCARD
PULP STORAGE	:	RETURN

Certified By :
John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R.	= Listed not received	I.S.	= Insufficient Sample
n.a.	= Not applicable	--	= No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted

Elements marked with the @ symbol (e.g. @Cu) denote assays performed using accredited test methods

Certificate of Analysis
Work Order : VC163142
[Report File No.: 0000019509]

Date: October 21, 2016

To: **Paul Gray**
COD SGS ASSAYERS
Banyan Gold Corp
166 Cougarstone Cresent SW
Calgary
AB T3H 4Z5

P.O. No.: Banyan Gold 11233-265
Project No.: -
Samples: 33
Received: Oct 3, 2016
Pages: Page 1 to 8
(Inclusive of Cover Sheet)

Methods Summary

No. Of Samples	Method Code	Description
33	G_LOG02	Pre-preparation processing, sorting, logging, boxing
33	G_PRP89	Weigh, dry,(up to3.0 kg) crush to 75% passing 2 mm, split 250 g, pulverize to
33	G_WGH79	Weighing of samples and reporting of weights
33	GE_ARM133_VA	Aqua Regia Digest 25g-300ml, ICPMS (Vancouver)

Storage: Pulp & Reject

REJECT STORAGE	:	DISCARD
PULP STORAGE	:	RETURN

Certified By :
John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R.	= Listed not received	I.S.	= Insufficient Sample
n.a.	= Not applicable	--	= No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted

Elements marked with the @ symbol (e.g. @Cu) denote assays performed using accredited test methods

Final : VC163142 Order: Banyan Gold 11233-265

Date: October 21, 2016

To: **Paul Gray**
COD SGS ASSAYERS
Banyan Gold Corp
166 Cougarstone Cresent SW
Calgary
AB T3H 4Z5

P.O. No.: Banyan Gold 11266-275, 301-323
Project No.: -
Samples: 33
Received: Oct 3, 2016
Pages: Page 1 to 8
(Inclusive of Cover Sheet)

Methods Summary

No. Of Samples	Method Code	Description
33	G_LOG02	Pre-preparation processing, sorting, logging, boxing
33	G_PRP89	Weigh, dry,(up to3.0 kg) crush to 75% passing 2 mm, split 250 g, pulverize to
33	G_WGH79	Weighing of samples and reporting of weights
33	GE_ARM133_VA	Aqua Regia Digest 25g-300ml, ICPMS (Vancouver)

Storage: Pulp & Reject

REJECT STORAGE	:	DISCARD
PULP STORAGE	:	RETURN

Certified By :
John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R.	= Listed not received	I.S.	= Insufficient Sample
n.a.	= Not applicable	--	= No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted

Elements marked with the @ symbol (e.g. @Cu) denote assays performed using accredited test methods

[Report File No.: 0000019519]

Date: October 21, 2016

To: **Paul Gray**
COD SGS ASSAYERS
Banyan Gold Corp
166 Cougarstone Cresent SW
Calgary
AB T3H 4Z5

P.O. No.: Banyan Gold 11324-356
Project No.: -
Samples: 33
Received: Oct 3, 2016
Pages: Page 1 to 8
(Inclusive of Cover Sheet)

Methods Summary

No. Of Samples	Method Code	Description
33	G_LOG02	Pre-preparation processing, sorting, logging, boxing
33	G_PRP89	Weigh, dry,(up to3.0 kg) crush to 75% passing 2 mm, split 250 g, pulverize to
33	G_WGH79	Weighing of samples and reporting of weights
33	GE_ARM133_VA	Aqua Regia Digest 25g-300ml, ICPMS (Vancouver)

Storage: Pulp & Reject

REJECT STORAGE	:	DISCARD
PULP STORAGE	:	RETURN

Certified By :
John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R.	= Listed not received	I.S.	= Insufficient Sample
n.a.	= Not applicable	--	= No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted

Elements marked with the @ symbol (e.g. @Cu) denote assays performed using accredited test methods

Date: October 21, 2016

To: **Paul Gray**
COD SGS ASSAYERS
Banyan Gold Corp
166 Cougarstone Cresent SW
Calgary
AB T3H 4Z5

P.O. No.: Banyan Gold 11357-370, 426-444
Project No.: -
Samples: 33
Received: Oct 3, 2016
Pages: Page 1 to 8
(Inclusive of Cover Sheet)

Methods Summary

No. Of Samples	Method Code	Description
33	G_LOG02	Pre-preparation processing, sorting, logging, boxing
33	G_PRP89	Weigh, dry,(up to3.0 kg) crush to 75% passing 2 mm, split 250 g, pulverize to
33	G_WGH79	Weighing of samples and reporting of weights
33	GE_ARM133_VA	Aqua Regia Digest 25g-300ml, ICPMS (Vancouver)

Storage: Pulp & Reject

REJECT STORAGE	:	DISCARD
PULP STORAGE	:	RETURN AFTER 90 DAYS

Certified By :
John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:

L.N.R.	= Listed not received	I.S.	= Insufficient Sample
n.a.	= Not applicable	--	= No result

*INF = Composition of this sample makes detection impossible by this method

M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion

Methods marked with an asterisk (e.g. *NAA08V) were subcontracted

Elements marked with the @ symbol (e.g. @Cu) denote assays performed using accredited test methods

Final : VC163145 Order: Banyan Gold 11357-370, 426-444

Certificate of Analysis
Work Order : VC163146
[Report File No.: 0000019522]

Date: October 21, 2016

To: **Paul Gray**
COD SGS ASSAYERS
Banyan Gold Corp
166 Cougarstone Cresent SW
Calgary
AB T3H 4Z5

P.O. No.: Banyan Gold 11445-450, 476-496
Project No.: -
Samples: 27
Received: Oct 3, 2016
Pages: Page 1 to 8
(Inclusive of Cover Sheet)

Methods Summary

No. Of Samples	Method Code	Description
27	G_LOG02	Pre-preparation processing, sorting, logging, boxing
27	G_PRP89	Weigh, dry,(up to3.0 kg) crush to 75% passing 2 mm, split 250 g, pulverize to
27	G_WGH79	Weighing of samples and reporting of weights
27	GE_ARM133_VA	Aqua Regia Digest 25g-300ml, ICPMS (Vancouver)

Storage: Pulp & Reject

REJECT STORAGE : DISCARD
PULP STORAGE : RETURN AFTER 90 DAYS

Certified By :
John Chiang
QC Chemist

SGS Minerals Services Geochemistry Vancouver conforms to the requirements of ISO/IEC 17025 for specific tests as listed on their scope of accreditation which can be found at http://www.scc.ca/en/search/palcan/sgs

Report Footer:
L.N.R. = Listed not received
n.a. = Not applicable
I.S. = Insufficient Sample
-- = No result
*INF = Composition of this sample makes detection impossible by this method
M after a result denotes ppb to ppm conversion, % denotes ppm to % conversion
Methods marked with an asterisk (e.g. *NAA08V) were subcontracted
Elements marked with the @ symbol (e.g. @Cu) denote assays performed using accredited test methods

Appendix F: Geologist's Certificate

GEOLOGISTS CERTIFICATE

I, Paul D. Gray, P. Geo., do hereby certify:

THAT I am a Professional Geoscientist with offices at Suite 250 - 2237 2nd Avenue, Whitehorse, YT Y1A 0K7

THAT I am an author of the Technical Report entitled “2016 Trench and Geochemical Report on the Hyland Project” and dated January 30, 2017, relating to the Hyland property (the “Assessment Report”). I personally oversaw the entirety of the Hyland 2016 Program in the field.

THAT I am a member in good standing (#29833) of the Association of Professional Engineers and Geoscientists of British Columbia.

THAT I am a graduate of Dalhousie University, Halifax, in the Province of Nova Scotia, with a Bachelor of Science degree (Honours) in Earth Sciences

THAT I have practised my profession as an exploration geologist in the mineral exploration industry continuously since 1997. I have worked on base, precious and industrial metals exploration projects as a geologist in Canada, the United States of America, Asia, and South and Central America.

THAT I am employed as Vice President, Exploration with Banyan Gold Corp.

THAT I have read the definition of "qualified person" set out in National Instrument 43-101 ("NI 43-101") and certify that by reason of my education, affiliation with a professional association (as defined in NI 43-101) and past relevant work experience, I fulfill the requirements to be a "qualified person" for the purposes of NI 43-101.

Dated at Vancouver, British Columbia, this 30th day of January, 2017.

_____

Paul D. Gray, P. Geo.
