GEOLOGICAL AND GEOCHEMICAL REPORT

IN SUPPORT OF

2016 Exploration Program funded under the Yukon Mineral Exploration Program

KELLI CLAIM GROUP

Whitehorse Mining Division

NTS: 115G/12 61°33′ N Lat., 139°37′ W Long.

Report by: G. Gutrath, Geologist, P.Eng.

Date: January 30, 2017

INTRODUCTION

This report is written on behalf of the claim owners listed in *Appendix F.*

The time spent on the property in 2016 and the cost of the program is outlined in *Appendix E.*

The writer carried out geological mapping and geochemical soil and silt sampling in 2011, 2013, 2014 and 2015. This report summarizes the general property information that is given in much greater detail in the 2012 Geological Report. This report is based on the geological mapping, sampling and geochemical soil and silt sampling field work carried out in 2016.

In 2016 the exploration was carried out under a Class 1 Mining Land Use Program.

ACKNOWLEDGEMENTS

The writer was assisted in the field by Mr. Fred Erler, one of the claim owners. Mr. Erler is a member of BC Search and Rescue, first aid qualified and a keen mountain climber.

Mr. Lorne Smith, a long-time resident of Haines Junction organized access to the claim group from Highway 1. He is an outstanding master mechanic, Argo and D8 bulldozer operator. In addition, he is very familiar with the history of the Kelli Claim Group as he worked on the claims with the late Larry Tremblay. He is the owner of the Quartz Claims on Swede Johnson Creek that is reported to have very similar geology to the Kelli Claim Group.

Mr. Dennis Dickson of Burwash Landing has been very helpful in providing the rental of his 8 wheel all terrain Argo for mobilization and demobilization to the Kelli Claim Group.

Mrs. Louise 'Toots' Bouvier is one of the claim owners and a long-time resident of Destruction Bay. She provides one of the ATVs used for the exploration program and stores it at her shop in Destruction Bay. In addition, she is the owner of the camp and the D8 bulldozer on the property.

In Whitehorse my good friends, Louise and Wayne Lerner, provide lodging for Fred Erler and the writer. All the exploration equipment, truck, trailers and ATV are stored and maintained by Wayne who is a master mechanic and has a large shop on Jasper Avenue. The Lerners have also donated substantial pieces of exploration and camp equipment for use at the Kelli Claim Group.

A special thanks to Doug Eaton, principal of Archer Cathro & Associates (1981) Ltd., for providing the Kelli Claim Group project with the complete airborne LIDAR Survey of the Vault Claim Group. The Vault Claims surround the south one-half of the Kelli Claim Group. This survey provides detailed topographic data that is very helpful in plotting the geochemical and geological data from the Upper Canyon to beyond the Forks (*Map 2*).

Kathie Jaworski Mapping and GIS took the LIDAR data and integrated it into the existing government topographic data to provide a comprehensive map on a scale of 1:20,000 of the Kelli Claim Group and adjoining area (*Map 4*). In addition, Ms. Jaworski prepared maps on scales of 1:2000 and 1:4000 and plotted the 2016 GPS Waypoints on these maps.

The Yukon Mineral Exploration Program has been very helpful in funding 50% of the exploration costs in 2014, 2015 and 2016. Many thanks to Mr. Derek Torgerson, Manager of the Yukon Mineral Exploration Program for his guidance and patience.

LOCATION

The Kelli Claim Group is located on the northwest facing slope of the Kluane Range and is within the Kluane Game Sanctuary. The centre of the Kelli Claim Group is approximately UTM Coordinate 682400 N 573000 E, Zone 7, NAD 83 located on NTS Map 115/12.

PHYSIOGRAPHY

The Kelli Claim Group is centered on a north-northwesterly flowing tributary of Reed Creek (Reed-Kelli Creek) that joins the westerly flowing Reed Creek proper on the south side of Shakwak Trench. The south boundary of the Kelli Claim Group is at an elevation of 4,500 feet (1,372 m) and the north boundary is at an elevation of 2,600 feet (792 m).

The primary focus of historic mineral exploration and placer gold mining has been within the steep 'V' walled canyon referred to as the Lower, Middle and Upper Canyon that extend over a distance of 1000 m and over an elevation interval of 150 m.

Vegetation is predominantly stunted black spruce in areas of muskeg (permafrost). Tall, large diameter spruce border the thawed outwash channel. The Canyon area of Reed-Kelli Creek is bordered by thick alder as well as the adjoining slopes to an elevation of 4,000 feet (1,220 m). At an elevation above 5,000 feet (1,524 m) open grassland and willow predominate representing an alpine environment.

CLIMATE

The Kelli Claim Group is located on the east flank of the St. Elias Mountains and in theory is protected from direct coastal weather. However, weather is funneled from the coast along the low valleys that follow the Denali Fault/Shakwak Trench. As a result, there is considerable yearly variation in summer rainfall. Both the summer of 2011 and starting in July, 2013 the rainfall was abnormally high. In 2014, during the August exploration program weather conditions were ideal. There were only a few rain showers and the creek levels were low.

The range of annual temperature in the Kluane Lake area is –20°C in December, the coldest month to +13°C in July, the warmest month of the year.

The average annual rainfall is 20 cm and snowfall is 18 cm. The Reed-Kelli Creek area is at a higher elevation and will have colder winter weather and greater accumulated snowfall and rain.

ACCESS

The turnoff from the Alaska Highway to the winter heavy equipment trail/summer ATV trail is at UTM coordinate 580651 E 6830392 N, 340 km west of Whitehorse or 170 km from Haines Junction. The trail crosses 10 km of the Shakwak Trench through continuous swamp, skirting small lakes and crossing three streams reaching the Reed-Kelli Creek gravel fan at approximately 3 km from the campsite.

Helicopter service is available from Haines Junction with a suitable staging area on the Alaska Highway at Mile 1118. There is a good helicopter pad at the campsite.

In 2016 access from the Alaska Highway was provided by an 8 wheel Argo off-road vehicle rented from Mr. Denis Dixon of Burwash Landing. Mr. Lloyd Smith operated the Argo, carrying approximately 300 kilos of supplies and navigating the Shakwak Swamp and the washed out road to the Kelli Camp with no problems. The road from the Reed-Kelli Creek fan to the camp was built in the 1990s and was in good condition in 2011. However, in 2013 the road was 90% destroyed by a flash flood making it very slow and difficult to gain access to the Kelli Camp. On site transportation was provided by two ATVs that followed the Argo into the property.

In 2016 the bridges built in 2015 and the upgraded ATV trail following the outwash fan to the camp were all in good condition. The access trail from Highway 1 to the Kelli Camp is shown on *Figure 3.*

HISTORY

The Reed-Kelli Creek has had a long history of placer gold mining starting in the early 1900s and again in the period 1935 to 1939. The more recent mining was carried out by Dublin Gulch Placers under the onsite direction of Darrel Duensing between1983 and 1988. Overall production from the creek gravels is very uncertain but is probably in the range of 3,000 to 5,000 oz. of gold.

Larry Tremblay, project manager and claim owner, carried out an extensive trenching program in the Lower and Middle Canyons. In 2004 Mr. Tremblay and associates drilled five BQ holes in the Lower Canyon.

Some additional historical information was provided by Mr. Lorne Smith of Haines Junction, a long-time resident of the area. Mr. Smith has quartz claims on Swede Johnson Creek 4 km to the southwest of Reed-Kelli Creek. In 2003 – 2004 Mr. Smith carried out some bulk placer tests between the Lower Canyon and campsite and found areas of good placer gold values. In 2004 his equipment was used to move the drill. He was very helpful in confirming the location of the 2004 drill holes. In addition, he stated that when Larry Tremblay first located the property there were numerous old placer workings and possibly underground workings. Mr. Smith referred to the location of a ladder at WP66 573393 E 6824638 N on the east side of the creek that went up the edge of the large outcrop and led to underground mine workings 7 m to 10 m above the level of the creek gravels.

The History section pages 3, 4 and 5 in the writer's 2012 Report gives a more detailed description of the early work done on the Reed-Kelli Claim Group area.

REGIONAL GEOLOGY

The Kluane Range forms the northeast margin of the St. Elias Mountains that are predominantly underlain by a thick sequence of mainly layered Paleozoic strata that have been highly altered and deformed. The property is bordered to the north by the Denali Fault that occupies the Shakwak Trench. To the southwest of the Shakwak Trench in the Quill Creek – Donjak River area the strata has been intruded by granitic to ultramafic bodies. The Quill Creek ultramafic hosts a nickel-copper deposit with PGE values.

In the Kelli Claim Group area of the Kluane Range the predominant rocks are Permian Pennsylvanian andesites covered by shales and thin bedded limestone. These units are repeated by a complex series of faults. Oligocene dikes in the area have been sheared indicating that the faulting is Tertiary or younger (T. Bremner, 1990).

The Denali Fault has formed the northeast facing slope of the front range of the St. Elias Mountains in the Kelli Claim Group area and has influenced the emplacement of the sub-parallel intrusive bodies in the Lower to Upper Canyon of Reed-Kelli Creek. These intrusive bodies are related to a 'structural kink' in the stream drainage both to the west and east of Reed-Kelli Creek over a distance of 8 km and subparallels the trend of the Denali Fault. This "kink" is an important reference point for the start of placer gold deposits in these creeks.

PROPERTY GEOLOGY

General

The primary objective of the 2016 program was to continue the geological mapping on a scale of 1:500 through the Lower Canyon and sample prospective mineralized zones. The division of the geology into Statigraphy and Intrusive units was outlined in the 2012 and 2013 reports and supported by the work done by Dr. Gettsinger and Mr. Bremner.

Statigraphy

The layered rocks exposed from the camp area upstream to the Middle Canyon (Geology Map 1 1:1000, 2013) are divided into four units designated **pc** (phyllitic carbonate), **gs** (greenstone/meta volcanic), **gs (fp)** (subvolcanic greenstone and/or an intrusive feldspar porphyry), and **bgpl** (black graphitic phyllite with interbedded limestone). These units have been interpreted as being Pennsylvanian to Permian in age and part of the Skolai Group. The writer divided the **gs** unit into **gs** and **gs(fp)** to differentiate the marked contrast between the two units:

gs dark brown adesite often foliated to a chloritic schist, highly fractured with pyrite content from 1% to 10%, pyrrhotite trace to 1% and magnetite 1%. Widely spaced, flat pyritic quartz veins of variable width cut across the unit.

gs(fp) grey, possibly subvolcanic fine-grained to porphyritic andesite or intrusive with blocky, course fracturing with less than 1% pyrite.

The **bgpl** unit is the principal unit downstream from the Lower Canyon to the campsite.

Intrusive Rocks

The layered rocks are intruded by dikes and sills of Oligocene to Miocene age (date of 23 Ma, ref. Bremner, 1991). Both Getsinger and Bremner agree that this intrusive is a feldspar hornblende porphyry. The writer mapped the intrusives as two separate rock types.

dd light orange weathering dacite dike, fine grained to aphanitic with an absence of porphyritic texture. In the fresh, fine grained dacite crystalline hornblende "blades" make up 1% to 2% of the ground mass

fp light grey subhedral medium grained feldspar phenocrysts in an aphanitic to fine grained feldspar rich ground mass.

2016 Claim Staking

The silt sampling carried out in 2015 located a number of gold anomalous samples on the east side of the Kelli Claim Group near Reed-Allen Creek. One of the samples was just to the north of the Grace 7 claim on open ground and analyzed 592 ppb gold. There were also a number of other anomalous gold samples in the same general area. As a result of this sampling the Toots 1 to 12 claims were staked adjoining the north side of the Kelli Claim and the Vault Claim Groups. Silt samples were collected from a number of small streams draining the area to the north. The claims cover the projected extension of Structure1 from the Lower Canyon on Reed-Kelli Creek to the east through Toots Claim 10. They also cover the possible projected strike of the feldspar porphyry dike that outcrops in Reed-Allen Creek. Bill Allen is hand mining placer gold from the creek gravels at the base of this dike.

The Grace-Toots claims are plotted on *Map 3*, 1:4000 and have been included in the Kelli Claim Group listed under *Appendix F.*

2016 Placer Exploration Program

The placer exploration program sampled a short section of the bedrock gravel interface exposed in bulldozer trench 1 and 2. A small sluice box was used to process the samples on site. The results from the Right Limit were positive for potential placer gold reserves. It is recommended that the sampling program be continued in 2017.

The costs of the 2016 placer sampling were excluded from the overall costs of the 2016 hard rock exploration program.

PHOTO 2: sample 1767 (281 ppb gold) 1.5 m channel sample. Increase in pale yellow brown sericite schist. Thin oxidized quartz veining, pyrite 2-3%

PHOTO 3: sample 1768 (14 ppb gold) 0.25m channel sample, oxidized, crenulated thin quartz veins in graphitic schist interlayered with less than 5% sericite schist-oxidized but little or no pyrite

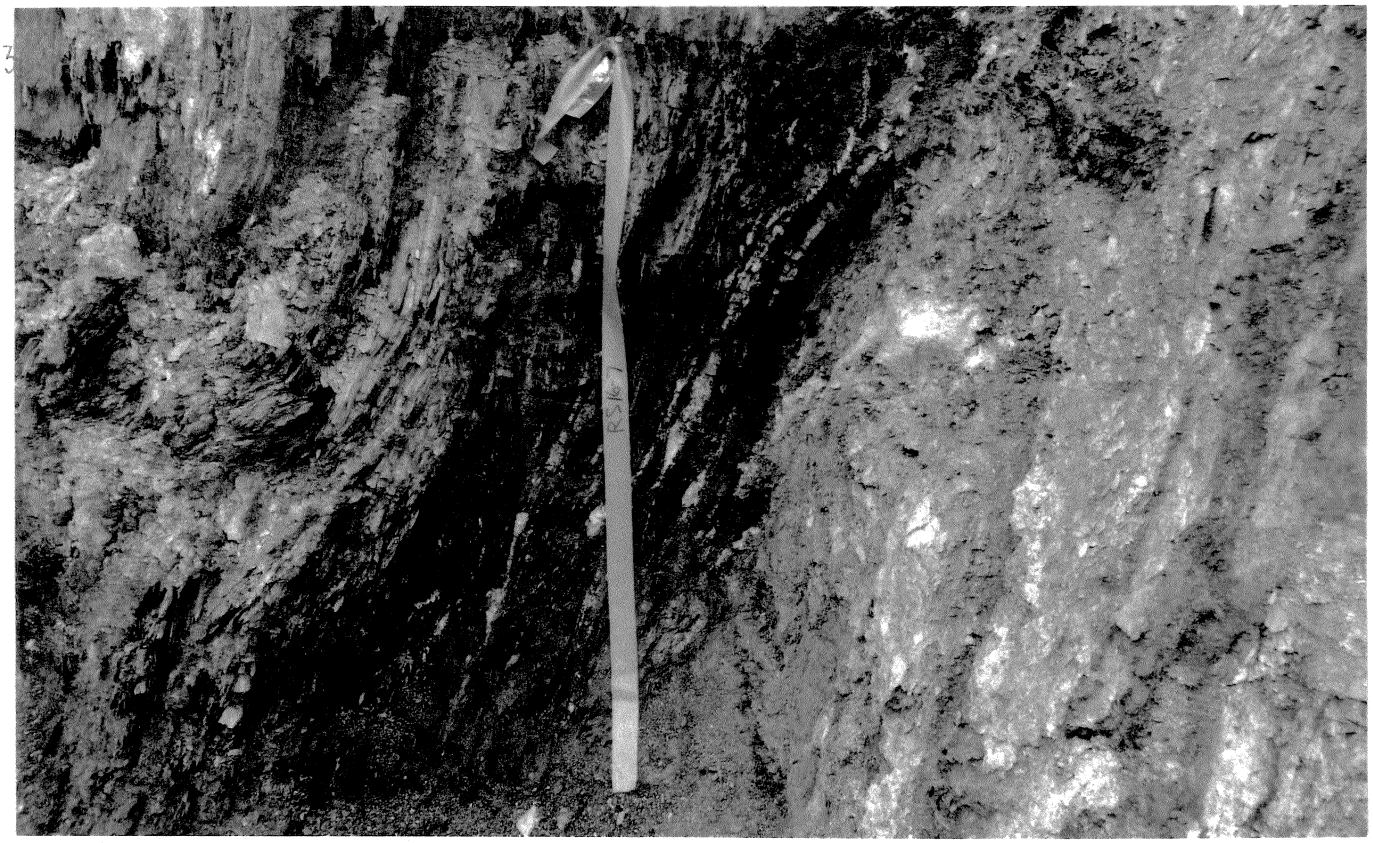

PHOTO 4: sample 1773 (71 ppb gold) 30% thin discontinuous quartz veins in black graphitic schist. Fold structure in limey altered sediments on left side and oxidized-grey gouge on right

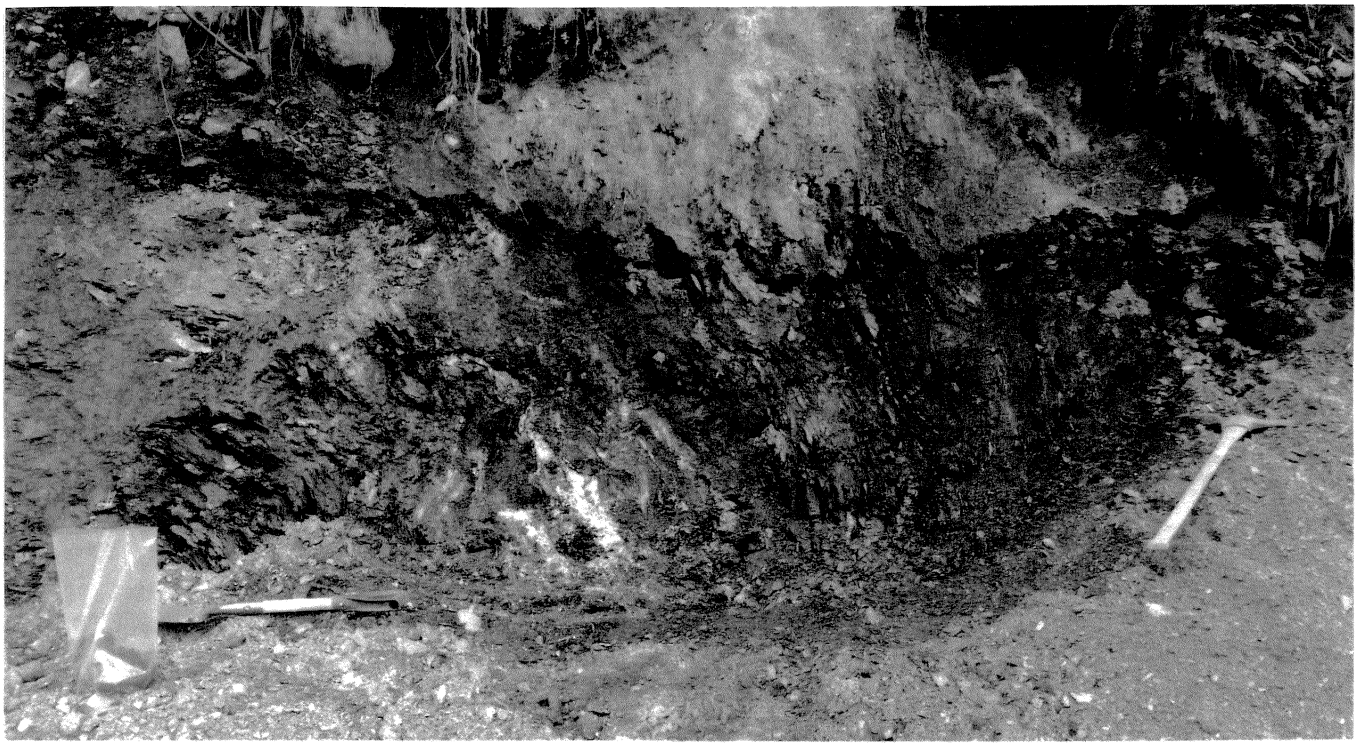

PHOTO 5: sample 1775 (295 ppb gold), 1772 (87ppb gold), 1771 (65ppb gold), 1773(71 ppb gold), 1774(22 ppb gold) highly crenulated graphitic schist with irregular clots of white clay gouge, oxidized central fine bedded/foliated sericite schist interlayered with quartz veinlets.

PHOTO 6: bulldozer reclaiming trenched material along the road near the north end of the 2016 trench.

2016 Analytical Procedure

The analytical work prior to 2016 was done by Bureau Veritas with samples being prepared in Whitehorse and shipped to Vancouver for analysis. The analysis was for 36 elements including gold and provides a very valuable data base for elements associated with gold mineralization. In 2016 all the samples were taken by the writer on the return road trip to Vancouver and delivered to ALS Laboratories. They provide a single element trace level gold analysis. Since the associated elements are well known from the previous four years of multi-element analytical work the focus in 2016 was on gold, the only element of economic interest. This new procedure was done largely as a cost saving measure. However, the writer prefers the multi-element analysis and this will be considered for the 2017 sample analysis.

All the 2016 reject rock samples and geochemical soil and silt sample fractions have been saved and can be processed if additional analytical work is warranted.

2016 Geological Mapping, Geochemical Sampling Program

The exploration results from the 2015 program recommended additional work on four areas within the Kelli Claim Group. This report will review the 2016 exploration program as it relates to these four areas.

1 a) Lower Canyon (Map 1, 2014, 2105 and 2016, 1:500)

(a) The bulldozer trench was extended 80 m from the end of the Pautler 01–6 Trench that was panel sampled in 2015. The 2016 geology, sample location and analytical results are detailed in the following table and sample locations are outlined on *Map 1*. Channel samples were taken from geological sections that were considered favourable for gold mineralization.

Sample Number		Description	ppb gold
	(470)	3419 / 4685 = 0 on tape	
1767	(471)	3418 / 4690 = 0 + 3.5 to 4 m (0.5 m channel sample) crenulated chlorite schist interlayered with tan sericite schist (20%). Thin irregular oxidized, drag-folded quartz veining, fine pyrite 2-3%	**281**
1768	(473)	3430 / 4693 = 13.5 (473) + 18.3 m – 19.7 m) 0.25 m wide oxidized crenulated, thin quartz vein system, highly oxidized vein selvages. No pyrite noted.	**14**
1769	(473)	+ 22.1 m to 22.6 m 22.1 m to 22.6 m, tan sericite schist, minor quartz veining, thin highly oxidized layers, carbonate hanging wall	**46**

Sample Number		Description	ppb gold
1770	(476)	3434 / 4715 0.3 m wide sample, interlayered graphitic schist and thin quartz veins, highly oxidized	**35**
1771	(478)	3451 / 4735 = (471 + 24 m) 20 cm by 30 cm clot of quartz in intensely sheared sericite, quartz graphitic schist (faults–shear zone–seepage)	**65**
1772	(476)	+ 19.3 to 20.3 m black graphitic schist to 19.5 m and then into a black–cream gouge–clay fault alteration zone, orange oxidation	**87**
1773	(476)	+ 27.7 m to 28.3 m 30% thin discontinuous quartz veins in black graphitic oxidized schist (280° / 80° SE)	**71**
1774	(476)	+ 18.8 m to 29.5 m approximate 1 m wide sample, 25% thin irregular quartz veinlets in graphitic schist, highly oxidized	**222**
1775	(481)	2.5 m sample Channel sample, black gouge, 15% white quartz clasts, fine discontinuous quartz veinlets, 10% sericite schist, 20% graphite schist	**295**

Comment

The analytical results indicate anomalous but sub-economic gold values in this highly altered, sheared mylonized section of the south margin of the Denali Fault zone. There is outcrop exposed to the north along the continuation of the 1980s placer mining cut but additional bulldozer trenching is not possible because of the close proximity to the creek. In addition within a short distance to the north deep bulldozed placer tailings cover the original west edge (Left Limit) of the placer mined area.

1 b) Lower Canyon

In addition to the mapping and sampling of the 80 m trench a traverse was made starting on the road at WP 29 (3306 / 4618) and going up the very steep talus filled gully to the west. This gully–fault–contact zone is the south contact of the zone of structural deformation. To the south is a 6 m to 7 m thick grey feldspar porphyry dike that strikes 285° and dips steeply south. This dike possibly intersects the much more prominent north-south trending grey feldspar porphyry dike. The footwall contact of the major north-south dike can be traced but the dikes continuation to the north is uncertain. It is possible the dike is faulted off as the prominent westerly trending ridge is more likely the continuation of the dacite dike complex. The intruded formation is much more a thick section of thin bedded impure limestone than andesite / chlorite schist. Soil samples collected immediately above the outcrop area (canyon) gave

very low gold values. At WP 398 following the outcrop area to the east is a prominent 'pinnacle' of thin bedded tan-cream limestone that forms the northerly edge of the outcrop area. This silty–limestone outcrops along the west edge of the road at the start of the bulldozer trenching and 2015 sampling.

Comment

This mapping has confirmed that the major east-west trending dike that is in the order of 20 m thick and dips to the west at –60° to –80° continues over a distance of at least 300 m to 350 m. The continuation to the north is uncertain but it does cross Reed-Kelli Creek to the east before it is obscured by overburden, muskeg and thick alders. The prominent formation on the west side of the Lower Canyon is thin bedded limestone cut by the steep dipping dacite dike swarm that crosses Reed-Kelli Creek at 115°/295°. Soil and silt sampling in this section of the Lower Canyon has produced only gold background results.

2) Middle Canyon

The 2015 rock sampling in the Middle Canyon located one highly anomalous gold sample of 1,014 ppb (WP 213 Sample #17). A soil sample in close proximity to the rock sample that analyzed 493 ppb gold. In the field the outcrop sampled was described as a dark green, oxidized sheared footwall of a massive chlorite schist. Pyrite, fine to medium grained 10% is disseminated in the schist with up to 5% irregular thin quartz veins. Hand Specimen #35, was taken of the chlorite schist, strongly magnetic, moderately effervescent in dilute HCl, with 10% fine grained pyrite.

ALS Metallurgy / Mineralogy

In order to get a more complete analysis of this sample the reject was taken to ALS Metallurgy-Mineralogy. Services in Kamloops. The report is under *Appendix C*. The analysis lists 15 specific minerals in descending order: quartz 7%, feldspar 23%, chlorite 18%, muscovite 8%, carbonates 7%, iron oxides 4%, pyrite 3%, amphibole 3% and titanium minerals 1.6%. Copper minerals are very low <0.1%. The distribution of sulphur bearing minerals is 99.5% pyrite which represents 3.4% by weight.

Vancouver Petrographics Ltd.

Hand Specimen #35 was given to Vancouver Petrographics Ltd. to prepare a thin section for a petrographic evaluation. The entire report is under *Appendix D*. The following is an excerpt from the report.

Petrographic Description

Sample 1: 213(35)

Chlorite schist

Inequigranular fragments of quartz and albite are wrapped by discontinuous cleavage domains of fine-grained chlorite. Subordinate calcite, pyrite and magnetite crystals are dispersed within the schistose microstructure.

Mineral	*Modal %*	*Size Range (mm)*	*Distinguishing Features*
quartz	31 – 33	up to 0.5 long	low relief, birefringence up to first order white
albite	*29 – 31*	*up to 0.4*	low relief, first order grey birefringence, albite twinnings
Fe-chlorite	20 – 22	up to 0.15	moderate relief, weak pleochroism with green tints, straigth extinction, low and anomalous birefringence, positive elongation
calcite	6 – 7	up to 0.1	high relief, extreme birefringence, brisk reaction to cold dilute (10%) HCl
white mica	5 – 6	up to 0.05	moderate relief, birefringence up to third order blue, straight extinction
pyrite	3 – 3.5	up to 0.25, rare up to 1.2 long	high reflectance, creamy white, isotropic
magnetite	2 – 3		low reflectance, dark grey, isotropic
rutile/leucoxene	1 – 1.2	up to 0.02 long	
tremolite/actinolite	0.5 – 1	up to 0.05	moderate relief, colourless, oblique extinction up to 15°, up to second order birefringence
chalcopyrite	tr	up to 0.04	high reflectance, yellow

Quartz forms inequigranular and xenoblastic crystal fragments intergrown with slightly less abundant xenoblastic to subidioblastic fragments of **albite**. The quartz tends to form elongate microlithons, which are oriented sub-parallel to the main schistosity. In some cases the quartz-albite aggregates form porphyroblastic aggregates, which are wrapped by the chlorite-

Comment

The ALS mineral composition and Vancouver Petrographic mineral distribution are very similar. However, in neither study was gold noted in any form. Considering the sample analysis of 1,014 ppb gold it is surprising that gold did not appear somewhere in the overall evaluation of the reject sample or in the polished section.

3) 2016 Middle Canyon Geological Mapping and Sampling

a) East side of Reed-Kelli Creek in area of 2015 Sample 17

The entire outcrop area over a distance of 100 m was remapped on a scale of 1:500 centered on the location of Sample 17 (WP 213: 3219 E / 4314 N). A number of the soil samples are anomalous. The highest is 349 ppb gold from the hanging wall zone related to Sample 17. This is a massive dark fine grained andesite(?) , blocky jointing, magnetite 1% – 3%, sample of the hanging wall and footwall analyzed 7 ppb gold and 67 ppb gold. Both soil and rock samples were taken from the outcrop area below Tremblay's screen. Soils are often anomalous but no rock samples were anomalous even though highly altered with quartz veining and pyritic. There is a high component of carbonate mineral in these rocks even though they appear to be andesite and more often chlorite schist. Magnetite is much more erratic but it is significant in the area of Sample 17. Grey feldspar porphyry dikes with random orientation are common and occur adjacent to Sample 17.

The sampling has not produced anything like the grade of Sample 17. It is possible that a random placer gold particle was included in the sample but the location is not favourable for placer gold and no other particles were located in the reject by the ALS analysis.

The data cannot be properly plotted on a scale of 1:500 and should be replotted on a scale of 1:200.

b) West side of Reed-Kelli Creek

This section deals with the west side of Reed-Kelli Creek starting where the major feldspar porphyry dike outcrops on the road. Mapping on the east side of the creek located numerous outcrops of this dike indicating that the intrusive crosses the north-south trending, probable fault structure, that forms Reed-Kelli Creek and enveloping canyons without any offset. This dike has two subparallel dikes on its south hanging wall side that are in the order of 3 m – 4 m thick and dips 60° south. A soil/rock chip sample (SSo 15) from the highly sheared chloritic hanging wall returned a value of 192 ppb gold. Fifteen metres to the south is the start of massive dark orange brown weathering chloritic andesite cut by thick, 0.2 m to 0.5 m crenulated/faulted quartz veins that make up 10% to 20% of the outcrop mass. This quartz vein system can be traced along the west canyon wall for 200 m and over a width of 15 m to 20 m and may be thicker but the very steep canyon wall makes it difficult to evaluate. The quartz veins have variable amounts of pyrite as disseminations and clots in the order of 2% to 10%. However, numerous samples of these quartz veins in place and selected samples from float have little or no associated gold.

In 2015 a sample of highly oxidized gouge and orange weathering soil at the base of the quartz vein system (WP 142, Soil Sample 8) analyzed 3,750 ppb gold. Rock samples in the immediate quartz vein gave very low gold

values. In 2016 Sample 3, WP 347 was taken from the highly oxidized selvage of the same quartz vein and it analyzed 439 ppb gold. Sample 4, WP 348 was taken from a vertical oxidized structure 0.25 m thick composed of gouge and a drag-folded quartz vein and analyzed 199 ppb gold. In the same area in 2015 Soil Sample 11, WP 201 composed of orange-oxidized soil analyzed 987 ppb gold.

Over a distance of 250 m to 300 m along the west side of the Middle Canyon there are numerous gold anomalous soil samples. The soil samples are largely from the edge of talus slopes that originate from the major quartz vein system. A great many rock samples have been taken from float that looks very promising for gold mineralization but the gold content is uniformly low.

Comment

The 2016 program continued to locate soil samples with highly anomalous gold values related to the quartz vein–oxidized chloritic schist that forms the west wall of the Middle Canyon. The source of the gold is not from the quartz veins but from the selvage of the veins and cross cutting fault structures. These structures are normally thin and discontinuous. The 1:500 scale map of the Upper Canyon is still a work in progress.

4) 2016 Exploration Area 2

This area was 'circled' on the 2015, 1:3000 scale map (*Map 3*) and covered a section on the east side of Reed-Kelli Creek between the south end of the Upper Canyon and the Forks. Three silt samples collected from small tributary streams on the east side of the valley were gold anomalous ranging from 88 ppb gold to 604 ppb gold. The samples extended over a distance of 250 m along the east side of the valley.

The lower elevations of the valley adjacent to the creek have irregular low bench development that is uniformly covered by alders. The small tributary streams often disappear in the bench areas and the alders make it very difficult to see the stream channels on the hillside. This resulted in a stream not being sampled that flows on the north side of the slide area.

The 2016 field work was plotted on the base Map 2, scale 1:1000 developed from the LIDAR airborne topographic survey. The waypoints locating the silt samples plotted very accurately on the stream channels.

The 2016 stream silt sampling program began at WP 441 (572773 E / 6823534 N) and went up a small stream. Six silt samples have been collected from this stream with the lowest value being 118 ppb gold and the highest being 746 ppb gold. All six samples are gold anomalous. The sampling continued in the next stream to the south but at a higher elevation of 1,210 m. At this elevation the alder have been replaced by open muskeg, willows and buck brush. The first two samples at WP 448 and WP 449 were gold anomalous at 182 ppb gold and 1,610 ppb gold. Three other samples were collected going downstream and these were anomalous ranging from 55 ppb gold to 148 ppb gold.

There are a few small outcrops in the creeks and rock specimens 7 to 11 were collected from these outcrops. Outside of one feldspathic dike all the rocks are chloritic schists with a significant carbonate component (effervesces moderate to high in dilute HCl). Fine grained disseminated pyrite from 2% to 5% is often associated with thin quartz veining but with low to nil magnetite. One large block of white quartz float occurs in the creek at WP 449.

The sampling continued up Reed-Kelli Creek and at WP 329 at the base of the organic slide the sample was threshold anomalous at 88 ppb gold. On the south side of the slide a large stream was originally dammed by the slide but has eroded a new channel. Upstream from WP 462 it is blocked by a maze of criss-crossed stunted black spruce trees. The silt at WP 462 was threshold anomalous at 54 ppb gold. A secondary tributary was sampled at WP 463 with a value of 304 ppb gold. There is a small outcrop of massive blocky altered andesite cut by a feldspar porphyry dike at WP 463.

Continuing to the south up Reed-Kelli Creek there is a large outcrop area on the east side of the creek-bar. It is massive andesite, 10 m vertical and cut by a feldspar porphyry dike. A silt sample from a small 'trickle' of water at the end of the outcrop area at WP 468, Silt Sample #40 had a very low value of 7 ppb gold.

The final upstream Silt Sample #41, WP 469 taken from the start of a significant stream has a value of 582 ppb gold.

Because the silt samples were only analyzed for gold three samples were sent to Acme Analytical Laboratories Ltd. for AQ200, 36 element analyses to see if there were associated elements. Copper ranged from 77 ppm to 170 ppm, arsenic from 7 ppm to 73 ppm, iron 3% to 8% and calcium 3% to 8%. These results do not indicate any significant element association with the high gold values.

Sampling on the west side of Reed-Kelli Creek is very limited. There are three anomalous silt samples near the outlet of the stream at the ATV trail crossing on the north side of Map 2. In 2015 six silt samples were collected from shallow stream/springs at an elevation of 1,180 m between WP 112 and WP 118. The samples were uniformly low, less than 10 ppb gold. However, the only soil sample collected on the west side of Reed-Kelli Creek opposite the gold anomalous creeks on the east side is a 2015 Soil Sample #4. It is described as being taken from a depth of 0.25 m from thawed soil, no volcanic ash, next to a very large round granite boulder. It returned a value of 390 ppb gold.

There are two other samples, one a soil sample taken by Placer dome in the 1980s and a rock sample taken by Jean Pautler in 2011. The Placer Dome sample is shown on Map 2 and is extrapolated as being taken at an elevation of 1,280 m to the southeast of the start of the organic slide. This was the only anomalous (785 ppb gold) soil sample from a long series of soils taken from the Forks to the outlet of Reed-Kelli Creek. The balance of the soils were in the 20 ppb gold to 30 ppb gold range.

The Jean Pautler sample was taken over a 1 m width of quartz stringer and averaged 1.5 g gold per ton. The sample is from or near the large outcrop area on the east side of the valley (WP 335).

Comment

The 2015 and 2016 silt sampling has outlined a significant area of gold anomalous silt sample values on the east side of Reek-Kelli Creek. The anomalous values extend over 400 m of valley bottom and an elevation interval of 80 m.

5) 2016 Exploration Area 1 – Reed-Allen Creek

This area was 'circled' as an exploration target on the 2015 Map 3, 1:3000. Within this area there are a number of gold anomalous silt samples. The entire area is downslope from Structure 1 that is projected from the Lower Canyon on Reed-Kelli Creek. In addition, Bill Allen is hand mining placer gold from gravels in Reed-Allen Creek at the base of a feldspar porphyry dike on the east side of the creek.

One of the silt samples that analyzed 592 ppb gold was on open ground not covered by the Kelli Claim Group. As a result twelve additional claims were staked to the north and east. The Toots Claims 1 to 12 are outlined on Map 3, 1:4000. This map shows the possible projection of the feldspar porphyry dike to the southeast as well as the projected Structure 1 from Reed-Kelli Creek. The assumed feldspar porphyry dike extension marked by a distinct ridge with a gentle slope to the south but a very steep face to the north. Silt samples were collected from a number of small stream/springs that drain from the ridge to the north. Of the 11 silt samples collected only one was gold threshold anomalous at 59 ppb gold. The majority were in the range of 2 ppb gold to 5 ppb gold. The 59 ppb gold silt sample was from the north-south tributary that crosses the Toots 7 and 9 claims. Six silt samples taken on the north side of Toots 4 claim from 3 small streams that are within the south margin of the Shakwak trench/Denali Fault. One of the streams had two samples of 47 ppb gold and 106 ppb gold.

Comment

The silt sampling program on the Toots Claims was a very early stage exploration program and produced only one gold anomalous value. However, the projected geology is of great interest and deserves detailed evaluation.

CONCLUSION AND RECOMMENDATIONS

1) The results of the 2016 exploration program continue to advance the project and prioritize exploration targets.

a) The sampling in 2015 and 2016 of the mylonized graphitic sericite chlorite schist formation at the outlet of the Lower Canyon of Reed-Kelli Creek (*Map 1, 1:500*) has outlined a gold anomalous zone over a width of 140 m. The results are not economic but there is a concern that the full potential of this section has not been evaluated. In 1989 (INAC, 1990) T. Bremner reported free gold being panned from a "black quartz-carbonate graphite material containing up to 50% white quartz veinlets... Panning the black altered material from the excavation yielded about 14 gr of coarse gold from one out of 10 4.5 kg samples". A gravity gold recovery program is being developed to process the 2015 reject panel samples that are stored in Whitehorse.

b) The exploration of the Middle Canyon can only be viewed as a work in progress. Exceptional gold values have been found but often in narrow discontinuous zones. The work to date continues to advance the understanding of the overall geology and distribution of gold values. The detailed mapping in 2016 and previous data based should be plotted on a scale of 1:200. On the west side of the Reed-Kelli Creek the shattered quartz vein swarm cuts highly altered andesite-chlorite schist over a strike length of 200 m and a width of 20 m to 30 m. Soil samples along the entire length of this zone indicate it is gold anomalous.

It is recommended that ongoing mapping sampling be continued to better define this potential drill target.

c) The 2015 and 2016 silt sampling program on the east side of Reed-Allen Creek between Structure 2 and the Forks has produced a series of exceptional gold values over a large area. This area plus the west side of Reek-Kelli Creek warrant an expanded geochemical sampling and geological mapping program. This area is considered the highest priority exploration target for 2017.

d) The Reed-Allen Creek area within the Grace and newly staked Toots Claims is an early stage exploration target. Both the placer gold production in the area, significant silt sample results and general geology demonstrates that the area warrants ongoing exploration.

Respectfully submitted,

G. Gutrath, BSc, PEng geologist

STATEMENT OF QUALIFICATIONS

ENGINEER'S CERTIFICATE

I, GORDON GUTRATH, of 702 – 181 Athlete's Way in the city of Vancouver in the Province of British Columbia, DO HEREBY CERTIFY:-

1. That I am a geologist with a business address of 702 – 181 Athlete's Way, Vancouver BC V5Y 0E5

2. That I am a graduate of the University of British Columbia where I obtained by B.Sc., in geological science in 1960.

3. That I am a Registered Professional Engineer in the Geological Section of the Association of Professional Engineers in the Province of British Columbia

4. That I have practiced my profession as a geologist for the past fifty-seven years.

DATED at the city of Vancouver, Province of British Columbia, this 30th day of January, 2017.

Gordon G. Gutrath, B.Sc., P.Eng.

APPENDIX B

HAND SPECIMENS

Specimen Number	Waypoint Location		Description
	East	North	
1	573256	6824631	**Impure graphitic limestone/marble** Dark greenish-black, fine grained uniform, foliated, crystalline groundmass cut by thin calcite veinlets subparallel and cross-cutting the foliation. Mag – 0, Ca (HCl)+++ both groundmass and veinlets. >1% fine pyrite
2	575658	6823035	**Quartz mica schist** Light grey-green, fine grained, highly foliated quartz-mica lesser chlorite schist. Mag++, probable pyrrhotite (very fine grained and in short-thin veinlets). Fracture subparallel foliation orange iron oxides. Pyrite/pyrrhotite 1%, Ca(HCl) – 0.
3	575596	6823072	**Chlorite schist** Dark blackish-green groundmass, foliated with black, very soft, thin plates of chlorite(?), fine grained crystalline with 1% fine grained pyrite, oxidized fractures. Highly magnetic+++, Ca(HCl)+++ numerous carbonate fractures and fine clots with pyrite 5%. Groundmass is Ca(HCl) – 0.
4	573216	6824307	**Foliated andesite** Fine grained, dark grey-green, with fine grained light grey feldspar (30%) in dark, soft foliated plates chloritic groundmass. <5% fine grained quartz. Pyrite, fine grained 1%, <5% calcite carbonate clots HCL+++, Mag – 0
5	573207	6824312	**Impure limestone/marble** Fine grained dark grey-green groundmass, weak foliation, impure marble as fine grained calcite is HCl++. Fine grained pyrite 2% - 4% disseminated in groundmass, highly magnetic, Mag+++
6	573221	6824284	**Chlorite schist** Fine grained dark grey-green, moderate foliation, interstitial calcite clots, calcite high to moderate effervescence HCl++. No magnetite, Mag – 0, Pyrite, very fine grained 1%.
7	572818	6823471	**Chlorite schist** Dark grey-green, fine to medium grained, highly foliated, chloritic matrix with fine grained calcite in dark green chlorite groundmass, cross-cutting calcite veinlets. Highly effervescent in HC1+++. Highly magnetic. Fine disseminated pyrite 2% - 3%. Specimens8 4, 5, 6 and 7 are very similar in appearance but vary in magnetite content.
8	572841	6823433	**Feldspathic dike** Light coloured greyish-green, fine grained with weak foliation, HCl–, Mag – 0, less than 10% quartz, >1% very fine grained pyrite.

Specimen Number	Waypoint Location		Description
	East	North	
9	572827	6823424	**Quartz carbonate** Light coloured orange oxide weathering, light grey groundmass, irregular quartz veinlets with 3% - 4% fine grained pyrite, possibly lesser chalcopyrite, numerous inclusions of calcite – moderately effervescent HCl++, Mag – 0.
10	572824	6823435	**Chlorite, quartz-carbonate schist** Light grey-green, this platy intense foliation, thin calcite layers 15% HCl++, very finely disseminated pyrite 1%.
11	572803	6823451	**Chloritic carbonate schist** Dark grey-green, crystalline appearance, highly foliated, calcite 10% - 15% fine grained highly effervescent HCl++, Mag – 0, finely disseminated pyrite 5%
12	572681	6823354	**Chloritic carbonate schist** Light greenish-grey coloured siliceous(?) groundmass with thin (1 mm) black, 3 mm – 5 mm spaced layers, bordering siliceous feldspathized breccias with irregular thin veining with finely disseminated pyrite 3%. Numerous thin carbonate inclusions – veinlets 5% highly effervescent HCl++.
13	572672	6823368	**Pyritic quartz vein** Dark yellow-orange gossanous coating on pyritic quartz vein. Open space filling with some oxidized rugs having associated calcite (effervescent). Pyrite in clots and disseminations.
14	573278	6824499	**Andesite (fine grained quartz diorite dike?)** Uniformly fine grained light grey quartz and feldspar 40% and black 55% hornblende(?) weak foliation. Highly magnetic Mag+++, cut by thin 2 mm quartz veins with associated minor calcite (HCl+). No calcite in groundmass HCl–. Less than 1% finely disseminated pyrite.
15	572972	6824159	**Foliated / limestone (marble)** White with pale orange weathering on fracture. Highly foliated, thin interbedded fine bands/beds alternating with white to light tan colour. Scattered areas of disseminated black mineral, soft subrounded of uncertain composition. HCl+++, no pyrite, Mag – 0.
16	573245	6824332	**Impure limestone** Massive, dark grey-green, fine to medium grained weak laminations, cut by 3 cm – 6 cm white, irregular calcite veinlet. Fine grained calcite throughout a dark green platy chlorite(?). Highly effervescent HCl+++ and Mag+++. Finely disseminated pyrite 2% - 4%, possible chalcopyrite.

Specimen Number	Waypoint Location		Description
	East	North	
17	573253	6824325	**Impure limestone** Massive, dark grey-green, similar to Specimen 16. Weak laminations, irregular subparallel calcite veinlets 5%, orange oxidization (carbonate) on fractures highly effervescent in HCl+++, Magnetite++. Pyrite disseminated 4% - 6% fine grained green patches epidote with minor chalcophrite, pyrrhotite(?).
18	573258 (WP 546)	6824318	**andesite** Massive dark grey-green, more competent than Specimen 17, fine grained. Minor calcite veinlets. Ca minor, HCl – 0. Highly magnetic, Mag+++, green chlorite on fractures, fine pyrite 1%.

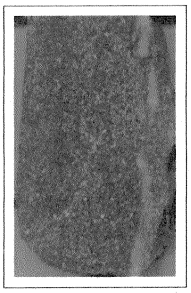
Petrographic Report on One Rock Sample for Atleb Exploration Management Ltd.

Fabrizio Colombo, Ph.D., P.Geo.
fab.petrologic@gmail.com

Petrographic Description

Sample 1: 213(35)



Chlorite schist

Inequigranular fragments of quartz and albite are wrapped by discontinuous cleavage domains of fine-grained chlorite. Subordinate calcite, pyrite and magnetite crystals are dispersed within the schistose microstructure.

Mineral	*Modal %*	*Size Range (mm)*	*Distinguishing Features*
quartz	31 – 33	up to 0.5 long	low relief, birefringence up to first order white
albite	29 – 31	up to 0.4	low relief, first order grey birefringence, albite twinnings
Fe-chlorite	20 – 22	up to 0.15	moderate relief, weak pleochroism with green tints, straigth extinction, low and anomalous birefringence, positive elongation
calcite	6 – 7	up to 0.1	high relief, extreme birefringence, brisk reaction to cold dilute (10%) HCl
white mica	5 – 6	up to 0.05	moderate relief, birefringence up to third order blue, straight extinction
pyrite	3 – 3.5	up to 0.25, rare up to 1.2 long	high reflectance, creamy white, isotropic
magnetite	2 – 3		low reflectance, dark grey, isotropic
rutile/leucoxene	1 – 1.2	up to 0.02 long	
tremolite/actinolite	0.5 – 1	up to 0.05	moderate relief, colourless, oblique extinction up to 15°, up to second order birefringence
chalcopyrite	tr	up to 0.04	high reflectance, yellow

Quartz forms inequigranular and xenoblastic crystal fragments intergrown with slightly less abundant xenoblastic to subidioblastic fragments of **albite**. The quartz tends to form elongate microlithons, which are oriented sub-parallel to the main schistosity. In some cases the quartz-albite aggregates form porphyroblastic aggregates, which are wrapped by the chlorite-

rich cleavage domains.

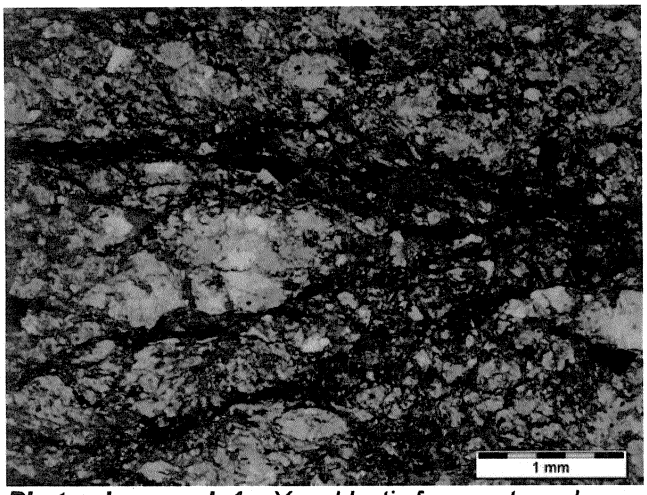
Fe-chlorite is fine-grained and it is concentrated within anastomosing cleavage domains, which are discontinuous, irregular, and sub-parallel, thus defining a weak schistosity in this sample. The chlorite-rich cleavage domains are intergrown with subordinate and fine-grained flakes of white mica.

Pyrite forms xenoblastic crystals, which are homogeneously dispersed within the schistosity. Some of the crystals hosts very fine-grained inclusions of magnetite, rutile(?) and unresolved nonreflectant minerals.

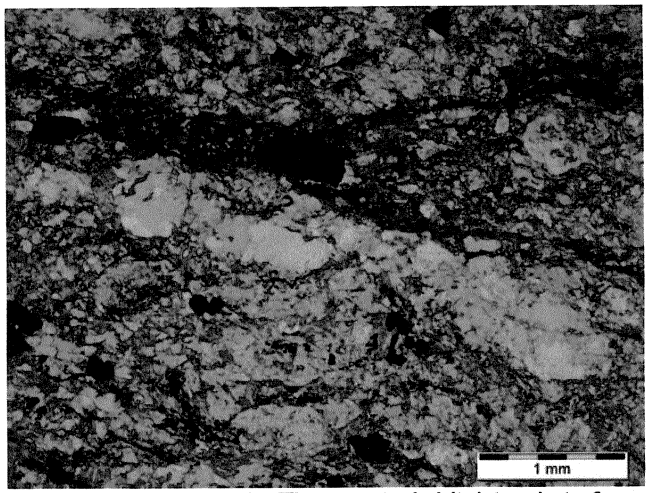
Calcite is dispersed as xenoblastic crystals within the schistosity, and it is distinguished by its brisky reaction to cold dilute (10%) HCl.

Magnetite is very fine-grained and is prefentially dispersed within the chlorite-rich aggregate. The occurrence of magnetite is confirmed by the relatively high magnetic susceptibility ($SI \cdot 10^{-3}=2.29$). The inclusion of the magnetite within some of the pyrite crystals indicates that the magnetite crystallization pre-dated the crystallization of the pyrite.

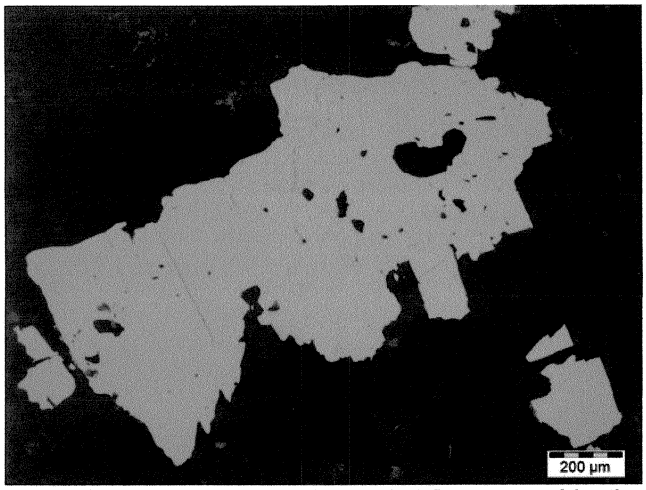
Very fine-grained xenoblastic crystals of probable **rutile/leucoxene** are spatially associated with the chlorite-rich aggregates.



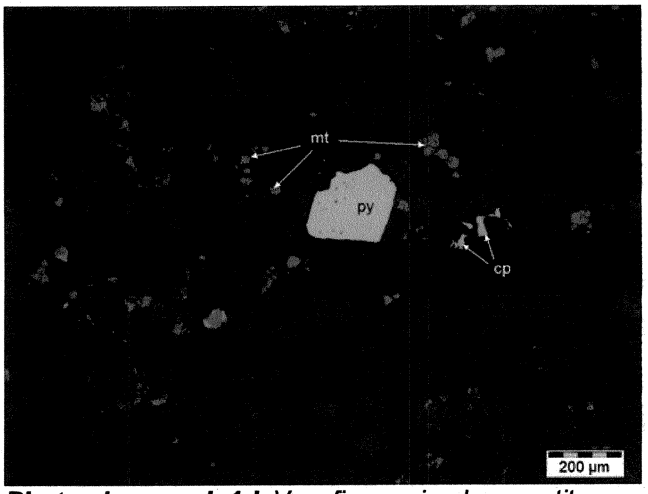
***Photomicrograph 1a**: Xenoblastic fragments and crystal aggregates of quartz and albite (white) are wrapped by anastomosing cleavage domains of chlorite (green). Plane-polarized transmitted light.*



***Photomicrograph 1b**: The quartz (white) tends to form elongate microlithons sub-parallel to the schistosity, which is defined by the chlorite-rich cleavage domains (green). Plane-polarized transmitted light.*



***Photomicrograph 1c**: Pyrite (white) forms xenoblastic crystals, which host very fine- to fine-grained mineral inclusions. Plane-polarized reflected light.*



***Photomicrograph 1d**: Very fine-grained magnetite (mt) and very rare chalcopyrite (cp) are dispersed within the schistose sample. Plane-polarized reflected light.*

This is to certify that an affidavit setting out a detailed statement of work done on the above claim(s) since the 20 day of July 2015 has this day been filed in my office; and in pursuance to the provisions of the Quartz Mining Act, I do now issue this certificate of work in respect of the above claim(s) to:

Kelli J. Tremblay	33.33 %
Fred Erler	50.00 %
Sandra Erler	33.33 %
Kluane Martin	50.00 %
Sulo Poystila	25.00 %
Kelli J. Tremblay	37.00 %
Louise Bouvier	50.00 %
Kelli J. Tremblay	50.00 %
Kluane Martin	19.00 %
Louise Bouvier	19.00 %
Kristy Roberts	33.34 %
Fred Erler	100.00 %

CERTIFICATE VA16154052

This report is for 25 Rock samples submitted to our lab in Vancouver, BC, Canada on 12- SEP- 2016.

The following have access to data associated with this certificate:

G. GUTRATH

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI- 21	Received Sample Weight
CRU- QC	Crushing QC Test
PUL- QC	Pulverizing QC Test
LOG- 22	Sample login - Rcd w/o BarCode
CRU- 31	Fine crushing - 70% < 2mm
SPL- 21	Split sample - riffle splitter
PUL- 31	Pulverize split to 85% < 75 um

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
Au- AA24	Au 50g FA AA finish	AAS

To: ATLED EXPLORATION MANAGEMENT LTD
ATTN: G. GUTRATH
