**INTRODUCTION**

New geochemical data from re-analysis of archived stream sediment samples have been assessed using weighted sums modeling and catchment basin analysis as described in the methodology report that accompanies this map (Mackie et al., 2015). Both commodity and pathfinder element abundances are evaluated to highlight areas that show geochemical responses consistent with a variety of base and precious-metal mineral deposit types. The results of modeling, completed using two approaches, are presented as a series of catchment maps and associated data files. This release is part of a regional assessment of stream sediment geochemistry that covers a large part of Yukon.

**SAMPLING AND ANALYSIS PROGRAMS**

Stream sediment and water samples from the Stevenson Ridge Area (NTS 115J and part of 115K) were collected at a reconnaissance scale in 1986 as part of the Canada-Yukon Mineral Development Agreement (Geological Survey of Canada, 1987). Field descriptions and initial geochemical data for 1305 sites were released in Geological Survey of Canada (GSC) Open File 1363. New geochemical data from the re-analysis of archive sample material were released in Yukon Geological Survey (YGS) Open File 2011-28 (Jackman, 2011). The reader is referred to these reports for detailed descriptions of sampling techniques, analytical procedures and quality control measures.

**MINERAL OCCURRENCES**

A variety of types of base and precious-metal mineralization has been identified in the Stevenson Ridge area as listed in Table 1 (Yukon MINFILE, 2015). The most significant deposits are classed as Cu-Mo porphyry (Casino deposit), Orogenic Au (Supremo deposit; Mascot and Boulevard prospects) and polymetallic Ag-Pb-Zn (Bomber deposit). Other deposit types within the area include Cu skarn (Nutzotin) and magmatic Ni-Cu-PGE (Snag showing). The Golden Saddle orogenic Au and Toulary Cu-Ag-Zn volcanogenic massive sulphide deposits occur in the adjacent map area to the north and the Wellgreen Ni-Cu-PGE deposit occurs in the adjacent map area to the south supporting the prospectivity of the region for these deposit types.

**WEIGHTED SUMS MODELING**

As described in the methodology report (Mackie et al., 2015), two approaches have been used to subdue the influence of background lithological variation and secondary absorption on the composition of stream sediments. One uses data levelled by the dominant geology mapped within each catchment, while the other uses residuals calculated from regression against selected principal components. Weighted sums models (WSM) have been generated using the processed data.

The importance rankings used in WSMs are summarized in Table 2. Each model is optimized for a target deposit type however other deposit types may be represented in a given model due to similarities in elemental abundances and associations.

Exploratory data analysis using both raw element data and principal components indicate that lithological variation and secondary scavenging influence the distribution of many commodity and pathfinder elements. However, much of the variability in the data for this map area can be linked to mineralization. The first principal component accounts for ~30% of the total geochemical variation and shows high positive loadings for Ca, loss-on-ignition, Sr, Mn, Hg, Cu, Co, As, Fe and Zn. Given a spatial relationship with a topographically subdued region in the southwestern part of the map area it is interpreted that this principal component reflects scavenging of metals by organic material and/or Fe-Mn oxides/hydroxides. High negative loadings for Th, Sn, La, Rb, Li, and Ce are clearly linked to regions mapped as felsic-intermediate intrusions. The second principal component shows high positive loadings for Mo, Cd, Ag, U, Bi and Ti. Spatially, this principal component can be linked to known occurrences suggesting it represents a mineralization signal. Similarly, the third principal component with high loadings in Cu, Ag and Pb is also spatially related to areas of mineralization.

Regression analysis of selected metals against the relevant principal component(s) effectively filters the scavenging and lithological controls while preserving responses related to known occurrences. Leveling by mapped geology has a more subdued effect on filtering the interpreted lithological control on the distribution of certain pathfinder elements. In order to reduce the impact this has on the WSM using this approach, certain elements were given low importance rankings or, in some cases, were omitted for certain deposit types. Negative weightings were assigned to Sn for several models in order to reduce contributions from alaskite composition intrusions with high background Ag and Zn values.

The effectiveness of historical sampling coverage has been assessed empirically using graphs of WSMs plotted against catchment surface area to determine the ideal maximum catchment size (16 km<sup>2</sup>). Catchments that cover larger areas (shown on the map with bold outlines) are interpreted to have been under-sampled and thus require further sampling to properly evaluate the area for geochemical anomalies. Given the likelihood that a mineralization signal would be progressively diluted with increasing catchment size, marginally high WSM scores in large catchments may also be of interest.

**Table 2: Importance rankings for weighted sums models using data levelled by mapped geology.**

Target Deposit Type <sup>a</sup>	Other Deposit Type <sup>b</sup>	Mn	Fe	Co	Ni	Pb <sup>c</sup>	Cu <sup>c</sup>	Mo	Zn <sup>c</sup>	Pb	Ag	Au <sup>c</sup>	As <sup>c</sup>	Ba	Cd	Sn <sup>c</sup>	Sb	Te	Hg <sup>c</sup>	Tl	Bi	W	
Porphyry Cu-Mo	Cu skarn; Porphyry Mo; VMS (Cu-rich)				-2	4	3			1	1	1					2				1		
Polymetallic Ag-Pb-Zn	VMS; SEDEX; Pb-Zn skarn									2	4	3	2		1	-2							
Epithermal Au-Ag	Polymetallic Ag-Pb-Zn									4	3	-2					1			2		-2	
Orogenic Au	Intrusion-related Au; Epithermal Au-Ag					-2				-1	4	3						1	1				
Magmatic Ni-Cu-PGE	Cu skarn		3	4	2		3	-2															
Hydrothermal Anomaly													1										

<sup>a</sup>Polymetallic Ag-Pb-Zn type includes vein and matrix styles; SEDEX = sedimentary exhalative; VMS = volcanic-hosted massive sulphide deposits  
<sup>b</sup>For elements that appear to be influenced by scavenging by organic material, clays and/or secondary Fe-Mn oxides, residuals are used following regression against loss-on-ignition, Fe and/or Mn.  
<sup>c</sup>For heavily censored elements and those not strongly controlled by geology as interpreted from principal component analysis, raw data are used following a log<sub>10</sub> transformation.
